producing a specific gravity, which increases as the quantity of acid is greater, but does not exceed 2·687, which is that of the glacial acid. 2. It produces heat when mixed with water, though not very considerable. 3. It has no smell when pure, and its taste is sour, but not corrosive. 4. When perfectly dry, it sublimes in close vessels; but loses this property by the addition of water; in which circumstance it greatly differs from the boracic acid, which is fixed when dry, but rises by the help of water. 5. When considerably diluted with water, and evaporated, the aqueous vapour carries up a small portion of the acid. 6. With charcoal or inflammable matter, in a strong heat, it loses its oxygen, and becomes converted into phosphorus.

Phosphoric acid crystallises with difficulty.

Though the phosphoric acid is scarcely corrosive, yet, when concentrated, it acts upon oils, which it discolours, and at length blackens, producing heat, and a strong smell like that of æther and oil of turpentine; but does not form a true acid soap. It has most effect on essential oils, less on drying oils, and least of all on fat oils. — *Ure.*

It would appear from recent observations that two distinct acids have been confounded under the name of phosphoric, namely, the *phosphoric* and the *pyrophosphoric*. When phosphorus is burned in a dry vessel containing air or oxygen gas, an anhydrous pyrophosphoric acid is obtained in the form of white flakes. It absorbs moisture rapidly on exposure to the air, and when kept for a few days is converted into phosphoric acid. These two acids, the phosphoric and pyrophosphoric appear to be entirely isomeric, and, according to Dulong and Berzelius, consist of 15·7 parts, or one equivalent of phosphorus, and twenty parts, or two equivalents and a half of oxygen. In their properties they present the following differences. Phosphoric acid forms a yellow salt with oxide of silver, pyrophosphoric acid a white salt. Phosphoric acid has no effect on a solution of albumen, pyrophosphoric acid causes a precipitate. At a red heat phosphoric acid is converted into pyrophosphoric, and pyrophosphoric acid is converted into phosphoric by exposure, or to the action of cold water, for a few days; the same conversion is effected rapidly by hot water or acids. The *phosphates* or salts of phosphoric acid become pyrophosphates when exposed to a red heat, while the *pyrophosphates*, or salts of pyrophosphoric acid are converted into phosphates by boiling in water, acidulated with any of the strong acids.

PHO'SPHOROUS ACID. *Acidum phosphorosum.* When phosphorus and corrosive sublimate act on each other at an elevated temperature, a liquid called *protochloride of phosphorus* is formed. Water, added to this, resolves into muriatic and phosphorous acids. A moderate heat suffices to expel the former, and the latter remains associated with water. It has a very sour taste, reddens vegetable blues, and neutralises bases.

PHO'SPHORUS. (*us, i.* m.; from φως, light, and φερω, to bear.) A substance which is regarded as simple, having never yet been decomposed.

If phosphoric acid be mixed with a fourth of its weight of powdered charcoal, and distilled at a moderate red heat, in a coated earthen retort, the beak of which is partially immersed in a basin of water, drops of a reddish waxy-looking substance will pass over. This is phosphorus in an impure state. It must be purified, by straining it through a piece of chamois leather, under warm water. It is then yellow and semi-transparent; as soft as wax, but more cohesive and ductile. Its sp. gr. is 1·77. It melts at 90° F. and boils at 550°. In the atmosphere, at common temperatures, it emits a white smoke, which, in the dark, appears luminous. This smoke is acidulous, and results from the slow oxygenation of the phosphorus. In air perfectly dry, however, phosphorus does not smoke, because the acid which is formed is solid, and, closely incasing the combustible, screens it from the action of the air.

When phosphorus is heated in atmospheric air to about 148°, it inflames and burns with a brilliant white light, and a copious dense smoke. If the combustion take place within a large glass receiver, the smoke is condensed in the form of white flakes, which consist of *phosphoric acid.*

When phosphorus is inflamed in oxygen, the light and heat are much more intense; the former dazzling the eye, and the latter cracking a glass vessel. *Solid phosphoric acid* results, consisting of 1·5 phosphorus + 2·0 oxygen. See *Phosphoric acid.*

When phosphorus is heated in highly rarefied air, three products are formed from it: one is phosphoric acid; one is a volatile white powder; and the third is a red solid, of comparative fixity, requiring a heat above that of boiling water for its fusion. The volatile substance is soluble in water, imparting acid properties to it. It seems to be phosphorous acid. The red substance is probably an oxide of phosphorus, since for its conversion into phosphoric acid it requires less oxygen than phosphorus does. The nature of this substance, however, has not yet been perfectly ascertained.

Phosphorus and *chlorine* combine in two proportions. See *Chlorine.*

The compounds of iodine and phosphorus have been examined by Sir H. Davy and Gay Lussac.

Phosphorus unites with *iodine* in three proportions. When one part of phosphorus is fused with about twelve of iodine, a reddish brown and very fusible compound is obtained, which is considered as a sesquioxide. When one part of phosphorus is fused with about forty parts of iodine, the compound formed is black and less fusible. It is a periodide. The formation of these compounds is attended with the evolution of much heat, but no light. Both the iodides of phosphorus are decomposed by water, the sesquioxide being resolved into hydriodic and phosphorous acids, and the periodide into hydriodic and phosphorous acids.

With *hydrogen* phosphorus combines in several proportions, of which the best ascertained are two. 1. *Phosphuretted hydrogen, or hydroguret of phosphorus.* Phosphorus may be heated, and

even sublimed, in hydrogen gas, without the formation of any definite compound, although, under such circumstances, the gas retains a portion of the vapour of phosphorus, acquiring its peculiar odour, and becoming luminous in the dark when mixed with atmospheric air. When phosphorus is presented to *nascent* hydrogen, two gaseous compounds result. The one inflames spontaneously upon the contact of the atmosphere. This may be procured by heating phosphorus in a solution of caustic potassa, or by acting upon *phosphuret of lime* by dilute muriatic acid. In the former case about a quarter of an ounce of phosphorus should be introduced into a small retort, capable of holding about four ounces of water; it should then be completely filled with a moderately strong solution of potassa, and the beak being placed under the shelf of the pneumatic apparatus, the heat of an argand lamp carefully applied till it boils: gas will gradually be generated, so as to expel a portion of the alkaline solution, and ultimately to bubble up through the water. Upon coming into contact with the air, the bubbles inflame with a slight explosion; and if the atmosphere is still, each as it bursts produces a beautifully expanding ring of smoke, in consequence of the sudden formation of phosphoric acid and water. If the retort, in which the gas is generated, contain common air, the first bubbles burn within the vessel, and the retort is frequently broken by the percussion, or by the rush of cold water from the trough, caused by the sudden expansion and subsequent contraction of the air within, an accident prevented by filling the retort with the liquid.

For obtaining this gas by the second process, Dr. Thomson gives the following directions: — Fill a small retort with water, acidulated by muriatic acid, and then throw into it a quantity of phosphuret of lime in lumps. Plunge the beak of the retort under water, and place over it an inverted jar filled with that liquid. Phosphuretted hydrogen gas is extricated in considerable quantity, and soon fills the glass jar. Half an ounce of phosphuret of lime yields about seventy cubic inches of this gas.

This gas was discovered by Gengenbre in 1783; it is colourless, has a nauseous odour like onions, a very bitter taste, and inflames when mixed with air, a property which it loses by being kept over water: water takes up about two *per cent.* of this gas, and acquires a bitter taste, and the smell of onions; but the solution has no acid properties like that of sulphuretted hydrogen. When the gas is retained in dry vessels, or over mercury, and carefully excluded from light, it may be kept some time without alteration; but, in the contact of water, and exposed to light, it soon deposits a red film of phosphorus without changing its volume, and loses the property of spontaneous inflammability. It has been asserted, that in this case the gas deposits half of its phosphorus, and that a definite *subphosphuretted hydrogen* remains; but this statement requires further proof. Houton Labilladière has remarked that bubbles of phosphuretted hydrogen sent up into a portion of common air standing over mercury, do not inflame when the air is compressed, or when the mercury is at the same level within and without the vessel; but that explosion immediately ensues when the confined air is rarefied by lifting up the jar, so that the column of mercury within may be above that without. When bubbles of phosphuretted hydrogen are sent up into a jar of oxygen, they burn with greatly increased splendour; in chlorine, too, they burn with a beautiful pale blue light, forming muriatic acid and perchloride of phosphorus. In a narrow tube it may be mixed with oxygen, without exploding, in which case it is deprived of its phosphorus. It burns when thrown up into nitrous oxide.

The specific gravity of this gas, according to Dumas, is 1·761: according to Thomson, it is 1·77. When heated with corrosive sublimate, muriatic acid gas is formed, equal to three times the volume of the phosphuretted hydrogen decomposed, whence it appears to contain in the 100 measures, 150 measures of hydrogen; Dumas states the weight of the phosphorus to that of the hydrogen as 15·9 to 1, numbers which closely approximate to 16 and 1, or one equivalent of each of its components.

2. *Sesquihydroguret of phosphorus, or hydrophosphoric gas.* This compound of phosphorus and hydrogen was discovered by Sir H. Davy, in 1812. It is procured by heating the solid *hydrate of phosphorous acid* or *hydrophosphorous acid* in a small retort. The gas must be collected over mercury, for water absorbs one-eighth its volume. It is not spontaneously inflammable, but explodes when heated with oxygen. It inflames spontaneously in chlorine. Its smell is less disagreeable than the former.

Both this and the former gas frequently contain free hydrogen, the relative proportion of which may be ascertained by agitation with a cold saturated solution of persulphate of copper, which absorbs the phosphuretted hydrogen, and leaves the pure hydrogen. Dumas infers, from the action of perchloride of mercury on this gas that 100 measures yield 150 of hydrogen. Dr Turner, on the authority of Dumas and of Buff, considers 100 measures of this variety of phosphuretted hydrogen as constituted of 150 of hydrogen gas, and 25 of the vapour of phosphorus, and hence as

		Grains
150 cubic inches of	hydrogen weigh	3·197
25	phosphorous vapour	33·542
100	phosphuretted hydrogen gas should weigh	36·740

The calculated density of a gas so constituted should be 1·1853.

The chemistry of the combinations of phosphorus and hydrogen is still involved in considerable intricacy, and indeed the study of all the compounds of this substance is rendered theoretically difficult by the peculiarities of their atomic relations.

Grotthus has described a liquid compound of phosphorus and hydrogen, analogous probably to the corresponding combination of sulphur, and, if so, a *biphosphuret of hydrogen*, obtained by boiling phosphorus in alkoholic solution

potassa. The phosphorus liquefies and remains fluid when cold: if boiled in water, phosphuretted hydrogen is evolved, but no phosphoric acid is formed, nor is the water decomposed; and phosphorus, which concretes as usual, remains behind.

Common phosphorus always yields a trace of hydrogen or of phosphuretted hydrogen, which it evolves when in the act of combining with some of the metals, and Davy found that by acting on fused phosphorus by the voltaic spark, small portions of hydrogen were given off. — *Brande.*

Phosphorus and *sulphur* are capable of combining. They may be united by melting them together in a tube exhausted of air, or under water. In this last case, they must be used in small quantities; as, at the moment of their action, water is decomposed, sometimes with explosions. They unite in several proportions forming substances, of which little is yet known.

Phosphorus is soluble in *oils*, and communicates to them the property of appearing luminous in the dark. It is also dissolved in alkohol and ether, but more sparingly.

The earliest account we have concerning the medicinal use of phosphorus, is in the seventh volume of Haller's Collection of Theses relating to the history and cure of diseases. The original dissertation is entitled, *De Phosphori Loco Medicamenti adsumpti virtute medica, aliquot casibus singularibus confirmata Auctore J. Gabr. Mentz.* There are three cases of singular cures performed by means of phosphorus, narrated in this thesis. The first instance is of a man who laboured under a putrid fever. The second is that of a man who laboured under a bilious fever. The third case is entitled a malignant catarrhal fever, with petechiæ. Many experiments have since been made with phosphorus, the result of which is, that it is a very violent poison and can be safely administered as a medicine, only in extremely minute doses and with the utmost possible caution. It stimulates the nervous system generally, and appears to act especially on the generative organs.

At first, not more than $\frac{1}{8}$ of a grain should be given daily. This may be gradually increased to a grain. It should be administered in the form of emulsion.

PHO'SPHURET. *Phosphuretum.* A combination of phosphorus, with a combustible or metallic oxide.

Phosphuretted hydrogen. See *Phosphorus.*

PHOTO'METER. (From φως, light, and μετρον, a measure.) An instrument for measuring the intensity of light. Several photometers have been invented. Those of Count Rumford and Sir C. Leslie are the most used.

PHOTOPHO'BIA. (*a*, *æ.* f.; from φως, light, and φοβεω, to dread.) Such an intolerance of light, that the eye, or rather the retina, can scarcely bear its irritating rays. Such patients generally wink or close their eyes in light, which they cannot bear without exquisite pain, or confused vision. The proximate cause is too great a sensibility in the retina. It is a particular symptom of the internal opthalmia. It is caused also from the disuse of light, which happens to persons long confined in dark places or prisons, on the coming out of which into light the pupil contracts, and the persons cannot bear light. The depression of the cataract occasions this symptom, which appears as though fire and lightning entered the eye, not being able to bear the strong rays of light.

An increased sensibility of the nervous expansion and optic nerve also produces it; as does likewise too great light, as looking at the sun, or at the strong light of modern lamps. When a symptom of any disease, it requires the treatment of that disease; and when a mere nervous affection, cold bathing, cold applications to the eyes, and tonics are proper.

PHOTO'PSIA. (*a*, *æ.* f.; from φως, light, and οψις, vision.) Lucid vision. An affection of the eye in which the patient perceives luminous rays, ignited lines, or coruscations.

PHRAGMI'TES. (*es*, *æ.* m.; from φραγμος, a hedge or fence, because it is used in hedges or fences.) The specific name of a species of reed, the *Arundo phragmites.*

PHRA'GMUS. (Φραγμος, a fence; from φρασσω, to enclose.) The rows of teeth; so called because they are set round like a fence.

PHRE'NES. (From φρην, the mind: because the ancients imagined that the mind was seated there.) The præcordia, and, according to some writers, the diaphragm.

Phrenesis. See *Cephalitis.*

Phrenetiasis. See *Cephalitis.*

PHRE'NIC. (*Phrenicus*; φρενικος, belonging to the *mind* or to the *diaphragm.* It is now used only in the latter sense.

Phrenic arteries. See *Diaphragmatic arteries.*

PHRENIC NERVE. Diaphragmatic nerve. It arises from an union of the branches of the third, fourth, and fifth cervical pairs, on each side, passes between the clavicle and subclavian artery, and thence descends by the pericardium to the diaphragm.

Phrenic veins. See *Diaphragmatic veins.*

PHRENI'TIS. (*is*, *idis.* f. Φρενιτις; from φρην, the mind.) Phrensy. Inflammation of the brain. A very faulty term. See *Encephalitis.*

PHRENO'LOGY. (*Phrenologia æ*, f.; from φρην, the mind, and λογος, a discourse.) This term signifies the doctrine of the mind, and is therefore synonymous with mental philosophy. It is usually restricted however to that particular view of the constitution of the mind entertained by Drs. Gall and Spurzheim. The doctrine of phrenology owes its origin to some observations made by Gall at a very early age. While at school he remarked that those boys who had prominent eyes excelled in the memory of words, and this led to the observation of certain peculiarities in the shape of the head in connexion with varieties of mental power and moral disposition. These investigations, pursued with great ardour by Gall in after life, gave rise to a system, according to which, all the faculties, sentiments, and propensities are localised in some particular region of the brain, and indicated by a corresponding size and shape of the cranium. In this study Dr. Spurzheim became his associate, and subsequently gave to the new

science the name which it now bears. Gall began to deliver lectures at Vienna in 1796, and some years after an elaborate work was commenced at Paris, and came out in successive volumes, the first of which was published in the joint names of Gall and Spurzheim, but the rest in that of Gall alone, a misunderstanding and separation having occurred between Gall and his disciple.

The "Physiognomical system" of Dr. Spurzheim was published in English in 1815, and is principally an abstract of the large French work.

Phrenology began soon after to attract general attention, and was supported by Spurzheim, Combe, Sir George Mackenzie, and a number of other authors. Its opponents at first treated it as a mere piece of German quackery; but they soon found out that they had fallen into a great mistake, and that the authors of the phrenological system were men of no ordinary ability and learning.

A great variety of objections have been raised against phrenology as absurd in a metaphysical point of view — tending to materialism — and opposed to morals and religion. If, however, the facts be as they are stated, metaphysics cannot prevail against them, and if phrenology be true in natural science, it cannot possibly be opposed to any correct views of morals or religion. The right way to take the matter up, therefore, is simply to inquire whether the facts really be as they are stated, or, in other words, *whether there be an actual correspondence between the characters of men and the size and shape of their brains as indicated by a phrenological examination of their skulls.*

The observations of physiologists in general are unfavourable to the admission of such a correspondence; and hence phrenology, as it now stands, is not admitted into the circle of the true sciences: at the same time all candid inquirers will be ready to admit that there may be truth in its general principles — that the subject is worthy of further investigation — and that great credit is due to Gall for the ingenuity and originality of his ideas; and both to Gall and Spurzheim for their minute and careful examination of the structure of the brain, and their industrious accumulation of facts which, although they may not yet have led to any satisfactory conclusions, may nevertheless conduce eventually to the establishment of important truths.

Those portions of the encephalos which minister to the different faculties, propensities, or sentiments, are called respectively the *organs* of those faculties, propensities, or sentiments.

The following enumeration of the organs by M. Vimont, an eminent French writer on the subject, comprises all those recognised by Dr. Spurzheim and himself.

1. Conservation.
2. Alimentation.
3. Destruction.
4. Cunning.
5. Courage.
6. Choice of places.
7. Concentration.
8. Attachment for life, or marriage.
9. Attachment.
10. Reproduction.
11. Attachment to the produce of conception.
12. Property.
13. Circumspection.
14. Perception of substance or objects.
15. Configuration.
16. Size.
17. Distance.
18. Geometrical sense.
19. Resistance.
20. Localities.
21. Numbers.
22. Order.
23. Time.
24. Language.
25. Colouring.
26. Eventuality.
27. Talent for construction.
28. Musical talent.
29. Talent for imitation.
30. Comparison.
31. Causality.
32. Discrimination.
33. Vanity.
34. Self esteem.
35. Firmness, perseverance.
36. Conscience.
37. Veneration.
38. Hope.
39. Benevolence.
40. Sentiment of the marvellous.
41. Poetical sentiment.
42. Sentiment of the beautiful in arts.

It is but justice to the phrenologists to state that some of the organs are considered much better established than others, and that several are allowed to be little more than conjectural.

Phrensy. See *Phrenitis.*

Phtheiriasis. See *Phthiriasis.*

Phtheirium. See *Delphinium.*

PHTHEIRO'CTANUM. (From φθειρ, a louse, and κτεινω, to kill: because it destroys lice.) See *Delphinium staphisagria.*

PHTHIRI'ASIS. (*is, is.* vel *eos.* f.; from φθειρ, a louse.) *Morbus pediculosus. Pediculatio. Phtheiriasis.* A disease in which several parts of the body generate lice, which often puncture the skin, and produce little sordid ulcers.

PHTHI'SIS. (*is, is.* or *eos.* f.; φθισις, from φθιω to consume.) Wasting of the frame from whatever cause; but in the medical language of the present day the term is restricted to the disease commonly called *pulmonary consumption.*

The causes which predispose to this disease are very numerous. The following are, however, the most general: — Hereditary disposition; particular formation of body, obvious by a long neck, prominent shoulders, and narrow chest; scrofulous diathesis, indicated by a fine clear skin, fair hair, delicate rosy complexion, large veins, thick upper lip, a weak voice, and great sensibility; certain diseases, such as syphilis, scrofula, the small-pox, and measles; particular employments exposing artificers to dust, as in the case of needle-pointers, stone-cutters, millers, &c., or to the fumes of metals or minerals under a confined

and unwholesome air; violent passions, exertions, or affections of the mind, as grief, disappointment, anxiety, or close application to study, without using proper exercise; frequent and excessive debaucheries, late watching, and drinking freely of strong liquors; great evacuations, as diarrhœa, diabetes, excessive venery, fluor albus, immoderate discharge of the menstrual flux, and the continuing to suckle too long under a debilitated state; and, lastly, the application of cold, either by too sudden a change of apparel, keeping on wet clothes, lying in damp beds, or exposing the body too suddenly to cool air, when heated by exercise; in short, by any thing that gives a considerable check to the perspiration. The more immediate or occasional causes of pthisis are, hæmoptysis, pneumonic inflammation proceeding to suppuration, catarrh, asthma, and tubercles, the last of which is by far the most general. Dr. James Clarke, in his able work on pulmonary consumption, has entered very minutely into the characteristics of that state of constitution, which usually precedes the development of tubercles in the lungs or other organs, and has described in particular a primary affection of the digestive organs, in which the *tuberculous cachexia*, as he names it, has its origin. "The dyspepsia of the tuberculous constitution, says Dr. Clarke, has peculiar characters by which it may generally be known. These have been fully and accurately described by Dr. Todd, under the name of *Strumous Dyspepsia;* a condition of the digestive organs which is not only present in the hereditary strumous constitution, but is capable, I believe, of generating this constitution, and of leading ultimately to tuberculous cachexia. In Dr. Todd's opinion, 'it presents a more characteristic feature of this habit of body than any physiognomical portrait which has yet been drawn of it. In this respect it is more to be depended on than either the fine skin, the clear, delicate complexion, the light hair, large blue eyes, and dull sclerotica of one variety; or the foul, dull, swarthy-coloured skin, the sallow complexion and swollen countenance, the dark hair and tumid lip of the other. It betokens, indeed, little familiarity with scrofula to connect it with any particular temperament, for it belongs to all temperaments — to the sanguine as well as the phlegmatic, to the nervous as well as the melancholic, and to all their varieties and combinations. But upon whatever temperament the disordered habit, which we call scrofula, may engraft itself, we venture to say that this form of dyspepsia will also there be found; and, therefore, being constantly present with it, preceding and accompanying the various symptoms which issue from it, it would be contrary to all reason to refuse to it an important share in the development of this disordered habit, and in the production of the local affections which have hitherto too much engrossed the attention, to the exclusion of a proper consideration of the constitutional disease.' I have great pleasure and satisfaction in citing Dr. Todd's observations, because they are in accordance with my own, and because they cannot, in my opinion, be too strongly pressed upon the consideration of the profession; so much importance do I attach to this disordered state of the digestive organs as a source of tuberculous disease.

"I shall now notice the leading symptoms by which this affection of the digestive organs is characterised — more especially in children, in whom it is so important to attend to it. The tongue is redder than natural, especially towards the extremity and along the margins; the anterior part is thickly spotted with small red points of a still brighter colour, the central portion being more or less furred, in general, according to the duration of the disorder; sometimes the tongue is covered with a dirty whitish fur, through which the red papillæ project; in which case the central part of the tongue is often dry, and of a brownish colour in the morning. There is generally some thirst; the appetite is variable, more frequently craving than deficient, seldom natural; and the breath is fetid. The bowels are generally confined, though occasionally they are too loose; the evacuations are always unnatural, generally of a pale greyish colour, of the consistence and appearance of moist clay: and they are often mixed with mucous and partially digested food. The urine is often turbid, sometimes high-coloured, and at other times too abundant and pale. The skin is generally harsh and dry, or subject to cold perspirations, particularly the hands and feet, which are habitually cold; copious partial nightsweats are common. The sleep is seldom sound — the child is restless, and talks in his sleep, or grinds his teeth.

"When this disordered state has continued for some time, the complexion loses its natural colour, and the face has a pasty, faded aspect; the child is languid, disinclined for exercise or play, and generally fretful; a train of secondary disorders also soon appears, as a consequence of the irritation of the digestive organs. The internal fauces become full and red, inflammatory sore throats are common, and the tonsils often become permanently enlarged. The nose is generally dry, or discharges thick mucus in large quantity; and epistaxis occasionally occurs. The eye-lids are subject to chronic inflammation; and eruptions behind the ears and on the scalp, or other parts, are very frequent. Copious discharges of mucus, sometimes mixed with blood, take place from the bowels, and from the bronchial membrane; and are indeed common from all the mucous surfaces. The brain and spinal marrow frequently become the seat of secondary irritation, and hydrocephalus, epilepsy, and chorea, or paralysis may be the consequence; but the most frequent and most important of all the consequences of this disordered state of the digestive organs is tuberculous cachexia."

The incipient symptoms of phthisis usually vary with the cause of the disease; but when it arises from tubercles, it is usually thus marked: it begins with a short dry cough, that at length becomes habitual, but from which nothing is spit up for some time, except a frothy mucus, that seems to proceed from the fauces. The breathing is at the same time somewhat impeded, and upon the least bodily motion is much

hurried; a sense of straitness, with oppression at the chest, is experienced; the body becomes gradually leaner, and great langour, with indolence, dejection of spirits, and loss of appetite, prevail. In this state the patient frequently continues a considerable length of time, during which, he is, however, more readily affected than usual by slight colds, and upon one or other of these occasions the cough becomes more troublesome and severe, particularly by night, and it is at length attended with an expectoration, which towards morning is more free and copious. By degrees the matter which is expectorated becomes more viscid and opake, and now assumes a greenish colour and purulent appearance, being on many occasions streaked with blood. In some cases, a more severe degree of hæmoptysis attends, and the patient spits up a considerable quantity of florid, frothy blood. The breathing at length becomes more difficult, and the emaciation and weakness go on increasing. With these, the person begins to be sensible of pain in some part of the thorax, which, however, is usually felt at first under the sternum, particularly on coughing. At a more advanced period of the disease, a pain is sometimes felt on one side, and at times prevails in so high a degree as to prevent the person from lying easily on that side; but it more frequently happens, that it is felt only on making a full inspiration, or coughing. Even where no pain is felt, it often happens that those who labour under phthisis cannot easily lie on one or other of their sides, without a fit of coughing being excited, or the difficulty of breathing being much increased. At the first commencement of the disease, the pulse is often natural, or perhaps is soft, small, and a little quicker than usual; but when the symptoms which have been enumerated have subsisted for any length of time, it then becomes full, hard, and frequent. At the same time the face flushes, particularly after eating, the palms of the hands and soles of the feet are affected with burning heat; the respiration is difficult and laborious; evening exacerbations become obvious, and, by degrees, the fever assumes the hectic form. This species of fever is evidently of the remittent kind, and has exacerbations twice every day. The first occurs usually about noon, and a slight remission ensues about five in the afternoon. This last is, however, soon succeeded by another exacerbation, which increases gradually until after midnight; but about two o'clock in the morning a remission takes place, and this becomes more apparent as the morning advances. During the exacerbations the patient is very sensible to any coolness of the air, and often complains of a sense of cold when his skin is, at the same time, preternaturally warm. Of these exacerbations, that in the evening is by far the most considerable. From the first appearance of the hectic symptoms, the urine is high coloured, and deposits a copious branny red sediment. The appetite, however, is not greatly impaired, the tongue appears clean, the mouth is usually moist, and the thirst is inconsiderable. As the disease advances the fauces put on rather an inflamed appearance, and are beset with aphthæ, and the red vessels of the tunica adnata become of a pearly white. During the exacerbations, a florid circumscribed redness appears on each cheek; but at other times the face is pale, and the countenance somewhat dejected. At the commencement of hectic fever, the belly is usually costive; but in the more advanced stages of it, a diarrhœa often comes on, and this continues to recur frequently during the remainder of the disease; colliquative sweats likewise break out, and these alternate with each other, and induce vast debility. In the last stage of the disease, the emaciation is so great, that the patient has the appearance of a walking skeleton: his countenance is altered, his cheeks are prominent, his eyes look hollow and languid, his hair falls off, his nails are of a livid colour and much incurvated, and his feet are affected with œdematous swellings. To the end of the disease the senses remain entire, and it is a singular and happy circumstance attendant on phthisis, that those who labour under it are frequently quite unconscious of their dangerous state, and keep in excellent spirits throughout the disease: it is indeed no uncommon occurrence to meet with persons labouring under its most advanced stage, flattering themselves with a speedy recovery, and forming distant projects under that vain hope. Some days before death the extremities become cold. In some cases a delirium precedes that event, and continues until life is extinguished. The ordinary duration of phthisis is from eight or nine months to a year and a half; but this varies greatly according to circumstances.

The diagnosis of pulmonary consumption, in its ordinary forms, is not generally difficult. The only disease which simulates it very closely is chronic bronchitis; and, doubtless, there are instances in which, without the aid of the stethoscope, it would be next to impossible to discriminate between the two. (See *Bronchitis*.) It used to be thought of great importance to determine whether the matter expectorated were mucus or pus, and several criteria were invented for this purpose. (See *Pus*.) But this is now little depended upon as a ground of diagnosis, because it is well ascertained that a copious secretion of pus may take place from the surface of the bronchial membrane without any solution of its continuity, or disease of the substance of the lungs. The use of auscultation and percussion have, however, tended greatly to remove the ambiguity from the diagnosis of phthisis. The presence of tubercles in an early stage is not detected by percussion, and if the surrounding portions of lung be emphysemetous, the sound on percussion instead of being dull, will be clearer than natural. Tubercles in the advanced stage when clustered together are always surrounded by hepatisation of the lung; the sound on percussion is dull, the respiratory murmur absent, and the bronchial respiration preternaturally distinct. When tubercles have been resolved, vomicæ formed, and the matter discharged by ulceration into the bronchial tubes, the phenomenon called pectoriloquy (see *Pectoriloquy*) takes place; and, when distinct, and supported by the symptoms, and corroborated

the signs derived from percussion, may be considered as conclusive as to the nature of the case.

All the signs indicative of the presence of tubercles, more frequently present themselves in the subclavicular regions than elsewhere, because the upper part of the lung is the most frequent seat of tubercles: they may occur, however, in any part of the chest.

The phenomena of phthisis occasionally vary considerably from the general description given above. There is a rapidly fatal form, vulgarly called a *galloping consumption*, in which the patient is soon worn out by the extent of the suppuration and the violence of the hectic and other symptoms. This generally runs its course within three months, and sometimes in one. Consumption is sometimes as rapidly fatal under a very different aspect; the symptoms are by no means acute, but the constitution is too feeble to offer much resistance, and the patient sinks. On the other hand, tubercles will sometimes make a very slow progress, the patient being troubled with cough, debility, and emaciation, in winter and spring, and recovering his health in a great measure in summer; but constantly presenting indications of pulmonary disease, and subject to dyspnœa on slight exercise. Such a case may go on for years, and is generally at length terminated by an attack of inflammation from cold or any other cause, which occasions a more rapid development of the tubercles, and establishes the symptoms of confirmed phthisis.

There is a particular form of consumption, first described by Dr. Wilson Philip, under the name of *dyspeptic phthisis*. This, however, is merely an insidious case of tubercular phthisis combined with dyspepsia, and marked at its commencement by the predominance of dyspeptic symptoms.

Consumption, at a very early period of life, differs in its symptoms from the same disease in adults. The cough is of a different character, and often comes on in paroxysms resembling those of hooping-cough; the expectoration comes on later in the disease, and the hectic fever is less perfectly formed. In children, the bronchial glands are often tuberculated as well as the lungs; the disease frequently commences in the bronchial glands, the lungs being afterwards affected; occasionally, though rarely, the disease remains confined to the bronchial glands, and in this case the diagnosis is very obscure, nor can we derive any aid from auscultation.

Pulmonary consumption is in every case to be considered as attended with much danger; but it is more so when it proceeds from tubercles, than when it arises in consequence either of hæmoptysis, or pneumonic suppuration. In the last instance, the risk will be greater where the abscess breaks inwardly, and gives rise to empyema, than when its contents are discharged by the mouth. Even cases of this nature have, however, been known to terminate in immediate death. The impending danger is generally to be judged of by the hectic symptoms; but more particularly by the nature of the expectoration, the degree of emaciation and debility, the colliquative sweats, and the diarrhœa. The disease has, in many cases, been found to be considerably retarded in its progress by pregnancy; and in a few has been alleviated by an attack of mania. It may in general be said with truth, that tubercular phthisis is an incurable disease. The researches of Laennec and other pathologists have indeed proved that a few tubercles may be developed, undergo the softening process, discharge their contents, and leave a cavity which fills up and cicatrises, and, that the patient may survive this process; but there is not an instance on record of extensive tuberculous affection of the lungs from which the patient has recovered: and who ever has seen the lungs of a person who has died of phthisis, must be convinced that it would have been as easy to make a new pair as to restore them to a healthy state.

The morbid appearance most frequently to be met with on the dissection of those who die of phthisis, is the existence of tubercles in the cellular substance of the lungs. These are small tumours which have the appearance of indurated glands, are of different sizes, and are often found in clusters. Their firmness is usually in proportion to their size; and when laid open in this state they are of a white colour, and of a consistence nearly approaching to cartilage. Although indolent at first, they at length become inflamed, and lastly form little abscesses or *vomicæ*, which breaking and pouring their contents into the bronchia, give rise to a purulent expectoration, and to the symptoms of confirmed phthisis. Such tubercles or vomicæ are most usually situated at the upper and back part of the lungs; but in some instances they occupy the outer part, and then adhesions to the pleura are often formed. For a fuller description of tubercles, see the article *Tubercle*.

When the disease is partial, only about a fourth of the upper and posterior part of the lungs is usually found diseased; but in some cases life has been protracted till not one twentieth part of them appeared, on dissection, fit for performing their function. It is singular that the left lung is much more frequently affected with tubercles than the right.

The treatment of tubercular phthisis is directed to one of three ends. 1. To prevent the development of tubercles, or in other words to obviate the tubercular diathesis. 2. To allay the inflammatory state with which the formation of phthisis commences. 3. To palliate symptoms and support the strength of the patient in the advanced stage.

The treatment of the tubercular diathesis. — This depends much more on the regulation of diet and regimen than on the administration of medicines. The diet should be nourishing, but not stimulating, and consist chiefly of plain animal food with or without a moderate allowance of wine or fermented liquors according to circumstances. The clothing should be carefully adapted to the seasons, and all sudden vicissitudes of temperature avoided. The patient should take moderate exercise, and avoid too long an addiction to any sedentary occupation,

and above all any which occasions a bent position of the thorax. He should live in the country, in a mild and salubrious atmosphere; but allowance must be made, in this respect, for the general habit of the patient, since there are many persons of a lax fibre, in whom too mild an atmosphere produces a constant state of relaxation, very unfavourable to the general health: when such individuals, therefore, are the subjects of the tubercular diathesis, a more bracing, though by no means a bleak air will be preferable. It is in this dormant state of tubercular disease that change of climate is so eminently useful. Many a person dies of consumption in this country who, if he had emigrated when young to New South Wales or Madeira, would have had excellent health and lived to a good old age. Unfortunately change of climate is too often resorted to when, instead of being beneficial, it is in the highest degree injurious, namely, in the advanced stages of the disease; and many an exhausted patient is sent to incur the fatigues and discomforts of a long journey, and to die in a foreign country some months sooner than he would have done if he had stayed at home. The mode of living of patients predisposed to consumption, should be very regular, and late hours are destruction. It is needless to say that the bowels must be carefully attended to, and all the sources of dyspepsia sedulously avoided.

The treatment of the inflammatory stage of phthisis. — The development of pulmonary tubercles is attended with chronic inflammation of the surrounding pulmonary tissue, and frequently with attacks of pleurisy of a more or less active character. Such states are to be combated by the remedies applicable to inflammation in general; but these are to be cautiously employed, and with due reference to the symptomatic character of the inflammation, and the chronic and wasting nature of the disease which it accompanies. In young and plethoric subjects bleeding from the arm, to a small extent, may sometimes be required; but leeches are generally to be preferred. It will be found in most cases that the application of a very few leeches, as two or three, repeated every other day while the inflammatory symptoms continue, will be more effectual than a larger number applied at more distant intervals. The frequent use of blisters is very beneficial, and digitalis is useful both in diminishing the force of the pulse and allaying irritation of the air passages. The specific effects of digitalis, so much vaunted some years ago, are now acknowledged to be entirely imaginary.

In the suppurative stage of phthisis it is impossible, except under very particular circumstances, either to arrest or cure the disease; our attention must therefore be directed to supporting the patient's strength, allaying irritation and distress, and obviating urgent symptoms. The first indication is best fulfilled by a nourishing diet; although the vegetable and mineral tonics are useful where they do not aggravate febrile excitement — an effect which however precludes their use in a great many cases. Irritation is best allayed by opiates, particularly the acetate of morphia; and, where they produce a soothing effect, we need not hesitate to use them freely, and increase the dose as occasion may require. The cough may be allayed by demulcents, the night sweats diminished by the administration of the diluted sulphuric acid, and the colliquative diarrhœa restrained by the cretaceous mixture, with catechu, and the occasional use of mild doses of rhubarb with potash.

Phthisis dorsalis. See *Tabes dorsalis.*

Phthisis laryngea. The wasting and hectic occasioned by ulceration of the larynx.

Phthisis mesenterica. See *Tabes mesenterica.*

Phthoe. *Φθοη.* The same as *Phthisis.*

PHTHORE. (From *φθορα*, corruption.) A name given by some chemists to fluorine, on account of the corroding properties of the acid which it generates with hydrogen. See *Fluorine*, and *Hydro-fluoric acid.*

Phtho'rius. (*Φθοριος*; from *φθορα*, an abortion.) Promotive of abortion.

Phu. (n. indeclinable; from *phua*, Arabic.) The name of a plant. See *Valeriana phu.*

PHYGE'THLON. (*Φυγεθλον*; from *φυω*, to grow.) Inflammation of the subcutaneous lymphatic glands.

PHYLACTE'RIUM. (*um, i.* n.; *Φυλακτηριον*; from *φυλασσω*, to preserve.) An amulet or preservative against infection or disease.

PHYLLA'NTHUS. (*us, i.* f.; from *φυλλον*, a leaf, and *ανθος*, a flower: because the flowers in one of the original species, now a *Hylophylla*, grow out of the leaves.) The name of a genus of plants. Class, *Monœcia;* Order, *Monadelphia.*

Phyllanthus e'mblica. The systematic name of the Indian tree, from which the emblic myrobalan is obtained.

Phylli'tis. (From *φυλλον*, a leaf: so called because the leaves only appear.) See *Scolopendrium vulgare.*

PHY'MA. (*a, atis.* n.; from *φυω*, to produce. It appears that this term was used by the Greek and Roman physicians with great latitude and want of precision: sometimes, as by Hippocrates and Paulus Ægineta, being applied to scrofula, and other imperfectly suppurative tumours; sometimes, as by Celsus and Galen, to tumours perfectly and rapidly suppurative; and sometimes by other writers, as Celsus also informs us, to fleshy excrescences or warts on the glans penis.) 1. A tubercle or any external part of the body.

2. A genus of a cuticular disease in Dr. Willan's arrangement, in which he includes *terminthus, epynictis, furunculus,* and *anthrax.*

PHY'SALIS. (*is, is.* f.; from *φυσαω*, to inflate: so called because its seed is contained in a bladder.) The name of a genus of plants. Class, *Pentandria;* Order, *Monogynia.*

Physalis alkekengi. The systematic name of the winter-cherry, or *Alkekengi:* called also *Halicacabum.* This plant, *Physalis — foliis geminis integris acutis caule herbaceo, infernè subramosa,* of Linnæus, is cultivated in our gardens. The berries are recommended as a diuretic in dropsical and calculous diseases. They were once in great repute, and supposed to produce speedy relief in the removal of strangury. It certainly possesses sedative and diuretic prope

ties, without heating or irritating, and seems to be worthy of further trial. As a sedative, Hoffmann employed it in hæmoptysis; and as a diuretic, it has been still more generally made use of in dropsy. About five or six cherries, or an ounce of the juice, forms a dose; the pericarp is bitter; yet the fruit within possesses little of this property, and has an acidulous and not unpleasant taste.

PHYSCO'NIA. (*a*, *æ*. f.; from *φυσκων*, a big-bellied fellow.) Enlargement of the abdomen: known by a tumour occupying chiefly one part of the abdomen, increasing slowly, and neither sonorous nor fluctuating.

The diseased conditions of the several viscera of the abdomen, which produce such an enlargement or protuberance as to come under this genus, are described by Dr. Good by the name of *Parabysma*, a term which he thinks more appropriate. The several species are denominated from the viscus in which the enlargement takes place.

1. *Physconia hepatica.* This may be produced from a variety of causes.

α. One very common cause is a morbid turgescence of the biliary ducts, from a want of due action in the vessels themselves, or from a torpid motion of the absorbents, from both of which causes a commorant motion of the bile results. Children are frequently subjects of this disease, and those adults who indulge in malt liquors and the luxuries of the table. It is attended with symptoms of dyspepsy and hypochondriacism. In children, it is relieved by those means which invigorate the system, with occasional mercurial purges; and, in adults, by small doses of the oxides of mercury, and aperients, and especially the purging waters of Cheltenham and Leamington. The cold bath, where it can be resorted to, is an excellent adjuvant.

β. Another cause of an enlargement of the liver is the acephalo-cyst, or headless bladder-worm: but, before it can produce a physconia, it must have acquired a great size. It is only to be known by a fluctuating tumour in the region of the liver, not preceded by inflammation, and not interfering with the health, except by its mere mechanical pressure. The fasciola hepatica, or fluke, so commonly found in the bile-ducts of sheep, is said to produce it; but this is very doubtful. There is no cure for this species of physconia, but by tapping, which lets out the fluid and kills the animal, and gives the person a chance of recovery. Dr. Douglas, now of Kelso, when practising at Reading, saw a case of this kind, and gave it as his opinion that the immense tumour of the hypochondrium was caused by hydatids. Mr. Bully, the surgeon, tapped, by his desire, in his presence, and a fluid with hydatids, escaped: the opening was enlarged, an immense number discharged, and the patient got well. Electricity will kill this animal; but it is a dangerous application, for the fluid will act as an extraneous body, as well as the cysts, and create much serious mischief.

γ. Scrofula in children produces an enlargement of the liver. The child is pot-bellied, and the liver is felt large and hard. It is accompanied mostly by rickets, or scrofula in other parts, and is removed by a steady course of chalybeates and aperients, with pure air, and sea-bathing.

δ. Another cause of physconia hepatica, is all morbid growths of that organ: these are various; as the deposition of fat in the liver, cephalomatous and other tumours, &c. Of the cure of these we are in ignorance.

2. *Physconia peritonei.* The only instance of this that I ever witnessed was from the acephalocyst, or headless bladder-worm. The subject was a female, about twenty-two, who had been supposed to be pregnant for more than two years. On opening her body, the cavity of the abdomen was occupied by an immense mass of hydatids, of various sizes, but most of them the size of pot oranges, and generally oval, though of various shapes. Every part of the abdomen was occupied by them, adhering to the peritonæum of the mesentery, intestines, omentum, and uterus: as much as filled an ordinary pail was removed before the viscera could be seen.

There is no cure for this disease.

3. *Physconia splenica.* The spleen becomes enlarged, occasionally to so great an extent as to cause an obvious increase of the size of the belly.

α. The most frequent cause is intermittent fever or ague, when the tumour is termed the ague cake. It is known by a large and hard swelling in the region of the spleen, verging towards the spine. The enlargement produced from this cause consists in a deposition of a morbid secretion into the parenchyma of the spleen, either from a morbid action of its secreting arteries, or a deficient action of the absorbents, but most probably the former, because the deposition is a morbid one. This disease gives way to tonics, such as cure the ague, in combination with mild mercurial alteratives, good pure air, and nourishing diet.

β. Another cause is, morbid growths, — as chondromatous, cephalomatous, and other tumours. These are beyond the reach of medicines.

4. *Physconia omentalis.* There are many morbid conditions of the omentum which cause the belly to become physconical, and these are morbid growths or depositions in the cellular tissue, which have accumulated so as to weigh from five to twenty pounds. They are lypomatous, cephalomatous, cartilaginous, bony, or other tumours. Dr. Hooper has in his collection an omentum that contains some thousands of soft tumours, which caused a physconia for near three years. The cure of these diseased conditions of the omentum is never effected, even if the disease were known.

5. *Physconia renalis.* When any enlargement of the kidney produces a swelling of the belly, it is from a growth of a morbid material. Dr. Hooper removed a kidney from the body of an officer, which, when put into a very large wash-hand basin so over-filled it, that it was with difficulty held in it. The disease was fungus hæmatodes.

6. *Physconia uterina.* This is, perhaps, the most frequent cause of physconia. The uterus itself, and its appendages, are often diseased,

and so enlarged as to cause a great swelling of the belly, and often at a period and under circumstances to favour the opinion of the female being pregnant. The swelling may be caused by coacervated menses, from obstruction in the vagina; by other secretions into the uterus, or its appendages; by depositions of morbid substances, either cartilaginous, cephalomatous, or of other natures; by many diseased states of the ovaria, by ovarial, tubal, or extra-uterine fœtation, &c.

Medicines are of little avail against these morbid states.

7. *Physconia mesenterica.* Many cases are recorded of glandular enlargements of the mesentery causing this disease, but they are rare.

Children have protuberant bellies when labouring under mesenteric obstruction, but with such obstruction the abdomen is seldom much swollen. Mercurial alteratives, aperients, mild tonics, and especially chalybeates, are the best remedies, and with pure air and regulated diet, they mostly effect a cure. Tumours of a scrofulous, hæmatomatous, cephalomatous, and other natures, are now and then found to produce an enlargement of the belly.

Should the nature of the swelling be known, a cure for it could not be effected when caused by one of the just-mentioned diseases.

8. *Physconia intestinalis.* A laxity of the intestinal canal produces an enlargement of the belly, which is cured by tonics, dry diet, and exercise. Morbid growths of the intestines also occasionally cause physconia.

PHYSE'MA. (*a, atis.* n.; from φυσαω, to inflate.) *Physesis.* A windy tumour.

PHYSE'TER (*er, eris.* m.; from φυσαω, to blow: so named from its action of blowing and discharging water from its nostrils.) The name of a genus of whale-fish in the Linnæan system.

PHYSETER MACROCE'PHALUS. The spermaceti whale. Spermaceti, called in the pharmacopœia, *Cetaceum*, is an oily, concrete, crystalline, semi-transparent matter, obtained from the cavity of the cranium of several species of whales, but principally from the *Physeter macrocephalus*, or spermaceti whale. It was formerly very highly esteemed, and many virtues were attributed to it; but it is now chiefly employed in affections of the lungs, primæ viæ, kidneys, &c. as a softening remedy, mixed with mucilages. It is also employed by surgeons as an emollient, in form of cerates, ointments, &c. See also *Ambergris.*

PHYSIC. (Φυσικη from φυσις, nature.) A term originally signifying natural philosophy, but in modern language restricted to that branch of medicine which forms the province of the physician, as opposed to that of the surgeon. It is vain to attempt a definition of physic in this point of view, because, although an arbitrary division is useful in practice, physic and surgery are, as a science, inseparable, and the study of both is essential to the knowledge of either.

PHYSIO'GNOMY. (*Physiognomia, æ.* f.; φυσιογνωμονια; from φυσιογνωμονεω, to judge of the disposition by the countenance; from φυσις, nature, and γινωσκω, to know.) The art of judging of the characters of individuals by their countenances, gestures, and other external peculiarities. What is called *expression* in the countenance exists in man in a much higher degree than in any other animal, and there are several muscles in the human face which are not found in brutes, and the sole use of which appears to be to convey the mute language of expression: such are the *corrugator supercilii;* the anterior portion of the *occipito-frontalis;* the *triangularis oris;* the *depressor alæ nasi;* the *nasalis labii superioris.* For many original and interesting observations on this subject, see Sir Charles Bell's *Anatomy and Philosophy of Expression.* The expression of the eye in men and animals depends on the direction given to the ball by the muscles which act upon it, and the degree of tension caused by the muscles which retract the eyelids. Physiognomy, therefore, when properly pursued, is a real science, founded on the observation of nature, and a study of no small utility in our intercourse with mankind. There is, however, a spurious kind of physiognomy with which the term is frequently associated. This consists in the attempt to trace a correspondence between the size and contour of particular parts of the head and face, and the disposition of the individual. Such is the physiognomy of Lavater — a fanciful system in which there is little truth, and that little probably residing in the predominance of certain casts of feature in individuals of a certain temperament. There is a kind of physiognomy which is of great importance in the practice of medicine, and which embraces the expression of the countenance as affected by certain diseased states — the complexion of the face and of the whole surface of the body — the attitude of the patient, and his manner of speaking and moving. The practitioner, who has a discerning and experienced eye in medical physiognomy, will attain, in many cases, to a readiness of diagnosis, and a certainty of prognosis, which will astonish those who have neglected this study. The reader will find many accurate remarks on the physiognomy of disease in Dr. Marshall Hall's admirable work on *Diagnosis.*

PHYSIO'LOGY. (*Physiologia, æ.* f.; φυσιολογια; from φυσις, nature, and λογος, a discourse.) This term, in its original meaning is synonymous with natural philosophy, and in this sense it was used by the Greeks. It is now restricted, however, to that branch of natural knowledge which relates to the laws of life and the functions of living beings. Physiology is divided into *general* and *special*, the former having for its object the general laws of life, the latter the functions of particular organs. It is also divided, like anatomy, into *human*, which relates to man, and *comparative*, which relates to the inferior animals and to vegetables.

PHY'SIS. (Φυσις, nature.) A term applied by Hippocrates to the instinctive power of the living body. See *Life.*

PHYSOCE'LE. (*e, es.* f.; from φυσα, wind, and κηλη, a tumour.) The same as *Pneumatocele.*

PHYSOCE'PHALUS. (*us, i.* m.; from φυσα, wind, and κεφαλη, the head.) Emphysema of the head.

PHYSOME'TRA. (*a, æ.* f.; from φυσαω, to inflate, and μητρα, the womb.) *Hysterophyse.* A windy swelling of the uterus. A tympany of the womb, characterised by a permanent elastic swelling of the hypogastrium, from flatulent distension of the womb. It is a rare disease, and seldom admits of a cure.

PHYTE'LEPHAS. (From φυτον, a plant, and ελεφας, an elephant: so called because its fruit is of great size, and contains a milk which hardens into a substance resembling ivory.) A genus of plants inhabiting America. The Tagua plant. *Caleza de Negro.* Buttons are made of the hardened albumen of the fruit.

PHYTEU'MA. (*a, atis.* n.; from φυτευω, to plant or sow: so called from its great increase and growth.) The name of a genus of plants. Class, *Pentandria;* Order, *Monogynia.*

PHYTEUMA ORBICULARE. *Rapunculus corniculatus.* Horned rampions. By some supposed efficacious in the cure of syphilis.

PHYTOLA'CCA. (*a, æ.* f.; from φυτον, a plant, and λακκα, gum-lac: so called because it is of the colour of lacca.) The name of a genus of plants. Class, *Decandria;* Order, *Decagynia.*

PHYTOLACCA DECANDRIA. The systematic name of the Pork-physic; called also, Pork-weed, Poke-weed, Red-weed of Virginia, Red nightshade, and American nightshade. *Solanum racemosum Americanum. Solanum magnum Virginianum rubrum.* In Virginia and other parts of America, the inhabitants boil the leaves, and eat them in the manner of spinach. They are said to have an anodyne quality, and the juice of the root is violently cathartic. The Portuguese had formerly a trick of mixing the juice of the berries with their red wines, in order to give them a deeper colour; but it was found to debase the flavour. This was represented to the king of Portugal, who ordered all the stems to be cut down yearly before they produced flowers, thereby to prevent any further adulteration. This plant has been used as a cure for cancers, but to no purpose.

PHYTO'LOGY. (*Phytologia, æ.* f.; from φυτον, an herb, and λογος, a discourse.) That part of natural history which treats of plants. Botany.

PI'A MA'TER. *Localis membrana. Meninx tenuis.* A thin membrane, almost wholly vascular, that is firmly accreted to the convolutions of the cerebrum, cerebellum, medulla oblongata, and medulla spinalis. Its use appears to be, to distribute the vessels to, and contain the substance of, the cerebrum.

PI'CA. (*a, æ.* f.; the magpie: so named because it is said the magpie is subject to this affection.) Depraved appetite, with strong desire for unnatural food. It is very common as a symptom of disease in pregnancy, dyspepsy, and chlorosis.

In infants it occurs from improper management and direction, for nothing is more tractable in infancy than the organ of taste; and hence it is that different nations of the world are brought by early habit to prefer such kinds of food as their respective climates produce in greatest abundance: thus the Hindoos live almost entirely on grain; the Tonguses, on berries, and the refuse lichen found undigested in the stomach of the reindeer; the Californians on snakes, rats, lizards, &c.

It also exists in an idiopathic affection or disease, being brought on occasionally by a desire to improve the beauty of the person, or giving graceful slenderness to the form, or a fairness to the skin, from which the Greek physicians called it μαλακια, softness, or effeminacy. When this morbid propensity has once taken place, the substances for which it excites a desire are often not only of the most indigestible, but disgusting quality, as dirt, cinders, ordure, rank tallow, chalk, wood, hair, paper, stones, glass, &c.

Emetics and purgatives are useful in removing this morbid action of the stomach, Rhubarb, in combination with bark and steel, generally destroy it. The *Cachexia Africana*, called also, *Mal d'estomac*, which is the desire of dirt-eating amongst the negroes generally, depends on glandular disease and dropsy, and requires their remedies.

Picatio. See *Pica.*

PI'CEA. (*a, æ.* f. Πευκη, the pitch-tree.) The common or red fir or pitch-tree is so named. The cones, branches, and every part of the tree, afford the common resin called frankincense. See *Pinus abies.*

PICHU'RIM. See *Pechurim.*

PI'CRIS. (*is, idis.* f.: from πικρος, bitter.) The name of a genus of plants. Class, *Syngenesia;* Order, *Polygamia æquales.*

PICRIS ECHOIDES. The name of the common ox-tongue. The leaves are frequently used as a pot-herb by the country people, who esteem them good to relax the bowels.

PI'CROMEL. (*el, ellis.* n.; from πικρος, bitter, and μελι, honey: so called from its taste.) The bitter principle of bile. See *Bilis.*

PICROTO'XIA. (*a, æ.* f.) Picrotoxine. The poisonous principle of the cocculus indicus. It is obtained in the following way:—"To the filtered decoction of these berries add acetate of lead, while any precipitate falls. Filter and evaporate the liquid cautiously, to the consistence of an extract. Dissolve in alkohol of 0·817, and evaporate the solution to dryness. By repeating the solutions and evaporations, we at last obtain a substance equally soluble in water and alkohol. The colouring matter may be removed by agitating it with a little water. Crystals of pure picrotoxia now fall, which may be washed with a little alkohol.

It acts as an intoxicating poison. The sulphate, nitrate, acetate, &c. have been formed, but not yet applied to any medicinal use.

Piedmont truffle. See *Lycoperdon tuber.*

PIE'STRUM. (From πιεζω, to compress.) An instrument to compress the head of a dead fœtus, for its more easy extraction from the womb.

PIG-NUT. The bulbous root of the *Bunium bulbocastanum*, of Linnæus: so called because pigs are very fond of them, and will dig with their snouts to some depth for them. See *Bunium bulbocastanum.*

PIGME'NTUM. (*um, i.* n.; from *pingo*, to paint.) A pigment. This name is given by anatomists to a mucous substance found in the

eye, which is, 1. The *pigment of the iris*, which covers the posterior surface of the iris, and is called also *uvea* from the resemblance of its colour to that of the grape. 2. *The pigment of the choroid membrane*, a black or brownish mucus, which covers the anterior surface of the choroid membrane, and is called *pigmentum nigrum*. The depth of its shade varies with the colour of the hair and skin.

Pike. See *Esox lucius.*

PI'LA HY'STRICIS. The bezoar hystricis.

PI'LA MARI'NA. A globular mass composed of the fibres of marine plants, and principally of the *Zostera marina*. It abounds on the shores of the Mediterranean. It was formerly esteemed in scrofula and as an anthelmintic; but is not now in use.

Pilchard. See *Clupea pilchardus.*

PILES. *Hæmorrhoides.* The seat of this disease is the extremity of the great gut or rectum, upon the side of it, around the anus or fundament. The rectum, like the other intestines, is composed of several membranes connected to each other by an intervening cellular substance; and as the muscular fibres of this intestine always tend, by their contraction, to lessen its cavity, the internal membrane, which is very lax, forms itself into several rugæ, or folds. In this construction nature respects the use of the part, which occasionally gives passage to or allows the retention of the excrements, the hardness and bulk of which might produce considerable lacerations, if this intestine were not capable of dilatation. The arteries and veins subservient to this part, are called hæmorrhoidal, and the blood that returns from it is carried to the meseraic veins. The rectum is particularly subject to the piles, from its situation, structure, and use; for whilst the course of the blood is assisted in almost all the other veins of the body, by the distension of the adjacent muscles, and the pressure of the neighbouring parts, the blood in the hæmorrhoidal veins, which is to ascend against the natural tendency of its own weight, is not only destitute of these assistances, but is impeded in its passage: for, first, the large excrements which lodge in this intestine dilate its sides, and the different resistances which they form there are so many impediments obstructing the return of the blood; not in the large veins, for they are placed along the external surface of the intestine, but in all the capillaries which enter into its composition. Secondly, as often as these large excrements, protruded by others, approached near the anus, their successive pressure upon the internal coats of the intestine, which they dilate, drives back the blood into the veins, and for so long suspends its course; the necessary consequence of which is, a distension of the veins in proportion to the quantity of blood that fills them. Thirdly, in every effort we make, either in going to stool, or upon any other occasion, the contraction of the abdominal muscles, and the diaphragm pressing the contents of the abdomen downwards, and these pressing upon the parts contained in the pelvis, another obstruction is thereby opposed to the return of the blood, not only in the large veins, but also in the capillaries, which, being of too weak a texture to resist the impulse of the blood that always tends to dilate them, may hereby become varicose.

The dilatation of all these vessels is the *primary cause* of the piles; for the internal coat of the intestine, and the cellular membrane which connects that to the muscular coat, are enlarged in proportion to the distension of the vessels of which they are composed. This distension, not being equal in every part, produces separate tumours in the gut, or at the verge of the anus, which increases according as the venal blood is obstructed in them, or circulates there more slowly.

Whatever, then, is capable of retarding the course of the blood in the hæmorrhoidal veins, may occasion this disease. Thus, persons that are generally costive, who are accustomed to sit long at stool, and strain hard; pregnant women, or such as have had difficult labours; and likewise persons who have an obstruction in their liver, are for the most part afflicted with the piles; yet every one has not the hæmorrhoids, the different causes which are mentioned above being not common to all, or at least not having in all the same effects. When the piles are once formed, they seldom disappear entirely; and we may judge of those within the rectum by those which, being at the verge of the anus, are plainly to be seen. A small pile, that has been painful for some days, may cease to be so, and dry up; but the skin does not afterwards retain its former firmness, being more lax and wrinkled, like the empty skin of a grape. If this external pile swells and sinks again several times, we may perceive, after each return, the remains of each pile, though shrivelled and decayed, yet still left larger than before. The case is the same with those that are situated within the rectum: they may happen, indeed, never to return again, if the cause that produced them is removed; but it is probable that the excrements, in passing out, occasion a return of the swelling, to which the external ones are less liable: for the internal piles make a sort of knots or tumours in the intestine, which, straitening the passage, the excrements, in passing out, occasion irritations there that are more or less painful in proportion to the efforts which the person makes in going to stool; and it is thus these tumours become gradually larger. The piles are subject to many variations: they may become inflamed from the above irritations to which they are exposed; and this inflammation cannot always be removed by art. In some, the inflammation terminates in an abscess, which arises in the middle of the tumour, and degenerates into a fistula. These piles are very painful till the abscess is formed. In others, the inflammation terminates by induration of the pile. These never lessen, but often grow larger. These hardened piles sometimes ulcerate, and continually discharge sanies, which the patient perceives by stains on his shirt, and by its occasioning a very troublesome itching about the verge of the anus. There are some, and those of different sizes, which are covered with so fine a skin as frequently to admit blood to pass through. This fine skin is only the internal coat of the rectum, greatly a

tenuated by the varicose distension of its vessels. The hæmorrhage may proceed from two causes; namely, either from an excoriation produced by the hardness of the excrements, or from the rupture of the tumefied vessels, which break by their too great distension. In some of these, the patient voids blood almost every time he goes to stool; in others not so constantly. We sometimes meet with men who have a periodical bleeding by the piles, not unlike the menses in women; and as this evacuation, if moderate, does not weaken the constitution, we may infer that it supplies some other evacuation which nature either ceases to carry on, or does not furnish in due quantity; and hence, also, we may explain why the suppression of this discharge, to which nature had been accustomed, is frequently attended with dangerous diseases. The piles are sometimes distended to that degree as to fill the rectum, so that if the excrements are at all hard they cannot pass. In this case the excrements force the piles out of the anus to procure a free passage: consequently the internal coat of the rectum, to which they are connected, yields to extension; and upon examining these patients immediately after having been at stool, a part of the internal coat of that gut is perceived. A difficulty will occur in the return of these, in proportion to their size, and as the verge of the anus is more or less contracted. If the piles come out in the same manner upon going to stool, it is then they void most blood, because the verge of the anus forms a kind of ligature above them.

The most common arrangement of piles, is into,—

1. The *blind piles;* as they exist in their simplest state, consisting of nothing more than a varicose state of the veins, with more or less of thickening of the internal membrane of the bowel.

2. The *mucous piles;* in which the varicose veins or tumours and the mucous follicles are excoriated, and pour out a quantity of mucus, which mixes with some pus or sanies, and is constantly discharged by the anus.

3. The *bleeding piles;* which are attended with bleeding.

4. The *excrescential;* in which there are fleshy excrescences about the verge of the anus, or within the gut. These are mostly large, loose, and flabby within the bowel, and of great size; and externally they are of various shapes, resembling, as it was supposed, figs, on which account they have been denominated *fici, condylomata,* &c.

The treatment of this complaint will vary much, according to circumstances. When the loss of blood is considerable, we should endeavour to stop it by applying cold water, or ice; or some astringent, as a solution of alum, or sulphate of zinc: but a more certain way is, making continued pressure on the part. At the same time, internal astringents may be given, joined with opium, if much pain or irritation attend. Care must be taken, however, to avoid constipation: and in all cases patients find benefit from the steady use of some mild cathartic, procuring regular loose motions. Sulphur is mostly resorted to for this purpose; and, especially in combination with supertartrate of potash, tamarinds, &c. in the form of electuary, usually answers very well; likewise castor oil is an excellent remedy in these cases. Should the parts be much inflamed, leeches may be applied near the anus, and cold saturine lotions used; sometimes, however, fomenting with the decoction of poppy will give more relief: where symptomatic fever attends, the antiphlogistic regimen must be strictly observed, and, besides clearing the bowels, antimonials may be given to promote diaphoresis. Where the tumours are considerable and flaccid, without inflammation, powerful astringent or even stimulant applications will be proper, together with similar internal medicines; and the part should be supported by a compress kept on by a proper bandage. An ointment of galls is often very useful, with opium, to relieve pain; and some of the liquor plumbi acetatis may be farther added, if there be a tendency to inflammation. In these cases of relaxed piles of some standing, the copaiba frequently does much good, both applied locally and taken internally, usually keeping the bowels regular; also the celebrated Ward's Paste, a medicine of which the active ingredient is black pepper. When a portion of the internal membrane of the rectum is constantly protruded, and when tumours and excrescences form, which from their shape have been called *fici, condylomata,* &c., &c., their removal is alone to be effected by ligature or the knife.

PI'LEUS. A hat. The cap, or that part of a gymnosperm fungus or mushroom, which forms the upper round part or head; as in *Boletus,* and *Agaricus.*

Pilewort. See *Ranunculus ficaria.*

Pill. See *Pilula.*

Pill, aloëtic, with myrrh. See *Pilulæ aloës cum myrrha.*

Pill, compound aloëtic. See *Pilulæ aloës compositæ.*

Pill, compound calomel. See *Pilulæ hydrargyri chloridi compositæ.*

Pill, compound galbanum. See *Pilulæ galbani compositæ.*

Pill, compound gamboge. See *Pilulæ cambogiæ compositæ.*

Pill, compound squill. See *Pilulæ scillæ compositæ.*

Pill of iron with myrrh. See *Pilulæ ferri compositæ.*

Pill, mercurial. See *Pilulæ hydrargyri.*

Pill, soap, with opium. See *Pilulæ saponis cum opio.*

PILOSE'LLA. (*a. æ.* f.; from *pilus,* because its leaves are hairy.) See *Hieracium.*

Pilosella major. See *Hypochæris.*

PILO'SUS. (From *pilus,* hair.) Hairy. Applied very generally in *Natural History,* &c. to the stems, leaves, and receptacles of plants, as that of the *Cerastium alpinum;* to the nectary of the *Parnassus palustris,* which is in form of five hairy fascicules at the base of the stamina; and to the receptacle of the *Carthamus tinctorius.*

Pilous. See *Pilosus.*

PI'LULA. (*a*, *æ*. f.; diminutive of *pila*, a ball.) καταποτιον, and σφαιριον, of the Greeks. A pill. A medicine in the shape of a small globe, the size of a pea, which can be swallowed whole, so as to cover the taste of bitter or ungrateful ingredients: hence the proverb, — *Pilulæ et injuriæ non masticandæ, sed deglutiendæ sunt.* The consistence of pills is best preserved by keeping the mass in bladders, and occasionally moistening it. In the formation of masses to be thus divided, the proper consistence is to be looked for at first, as well as its preservation afterwards; for if the mass then become hard and dry, it is unfit for that division for which it was originally intended; and this is, in many instances, such an objection to the form, that it is doubtful whether, for the purposes of the pharmacopœia, the greater number of articles had not better be kept in powder, and their application to the formation of pills left to extemporaneous direction.

Pilulæ alepha'nginæ. *Pilulæ aloephanginæ.* Pills composed of aloes and aromatics. The name *alephanginæ* is Arabic, according to Lemery, and signifies odorous.

Pilulæ aloes compositæ. Compound aloëtic pills. Take of aloes powdered, an ounce; extract of gentian, half an ounce; oil of caraway, forty minims; simple syrup, as much as is sufficient. Beat them together, until they form an uniform mass. From fifteen to twenty-five grains prove moderately purgative and stomachic.

Pilulæ aloes cum myrrha. Aloëtic pills with myrrh. Take of aloes, two ounces; saffron, myrrh, of each an ounce; simple syrup, as much as is sufficient. Powder the aloes and myrrh separately; then beat them all together until they form an uniform mass. From ten grains to a scruple of this pill, which is a substitute for the *pilula Rufi*, prove stomachic and laxative, and are calculated for delicate females, especially where there is uterine obstruction.

Pilulæ cambogiæ compositæ. Compound gamboge pills. Take of gamboge, powdered, a drachm; aloes, powdered, a drachm and a half; ginger, powdered, half a drachm; soap, two drachms. Mix the powders together: then having added the soap, beat the whole together until they are thoroughly incorporated. These pills were introduced into the London Pharmacopœia, as forming a more active purgative pill than the pill aloes cum myrrhâ, and in this way supplying an article very commonly necessary in practice. The dose is from ten grains to one scruple.

Pilulæ de caccio'nde. Astringent pills containing catechu.

Pilulæ ferri compositæ. Compound iron pills. Pills of iron and myrrh. Take of myrrh, powdered, two drachms; carbonate of soda, sulphate of iron, treacle, of each a drachm. Rub the myrrh with the carbonate of soda; add the sulphate of iron, and rub them again; then beat the whole together until they are thoroughly incorporated. These pills answer the same purpose as the mistura ferri composita. The dose is from ten grains to one scruple.

Plulæ ga'lbani compositæ. Compound galbanum pills; formerly called *pilulæ gummosæ*. Take of galbanum, an ounce; myrrh, sagapenum, of each an ounce and a half; assafœtida, half an ounce; simple syrup, as much as may be sufficient. Beat them together, until they form an uniform mass. A stimulating antispasmodic and emmenagogue. From half a scruple to half a drachm may be given three times a day in nervous disorders of the stomach and intestines, in hysterical affections and hypochondriasis.

Pilulæ hydrargyri. Mercurial pills. Often, from its colour, called the blue pill. Take of mercury, two drachms; confection of red roses, three drachms; liquorice-root, powdered, a drachm. Rub the mercury with the confection, until the globules disappear; then add the liquorice-root, and beat the whole together until they are thoroughly imcorporated. An alterative and anti-venereal pill, which mostly acts on the bowels if given in sufficient quantity to attempt the removal of the venereal disease, and therefore requires the addition of opium. The dose is from five grains to a scruple. Three grains of the mass contain one of mercury. Joined with the squill pill, it forms an excellent expectorant and alterative in asthmas attended with visceral obstruction, and an efficacious diuretic in dropsy.

Pilulæ hydrargyri chloridi compositæ. Compound pills of chloride of mercury. Take of chloride of mercury, oxy-sulphuret of antimony, of each two drachms; guaiacum resin, powdered, half an ounce; treacle, two drachms. Rub the chloride of mercury, first with the oxy-sulphuret of antimony, and then with the guaiacum resin and treacle, until they are incorporated. This is intended as a substitute for the famed Plummer's pill. It is exhibited as an alterative in a variety of diseases, especially cutaneous eruptions, pains of the venereal or rheumatic kind, cancerous and scirrhous affections, and chronic ophthalmia. The dose is from five to ten grains. In about five grains of the mass there is one grain of the submuriate of mercury.

Pilulæ hydrargyri iodidi. Pills of iodide of mercury. Take of iodide of mercury a drachm; confection of dog-roses, three drachms; powdered ginger, a drachm. Beat them together till they are incorporated. The dose is from five grains to ten. For the virtues. See *Hydrargyri iodidum*.

Pilulæ ipecacuanhæ compositæ. Compound pills of ipecacuanha. Take of compound powder of ipecacuanha three drachms; squill fresh-dried, ammoniacum, each a drachm; mixture of acacia as much as may be sufficient. Beat them together until incorporated. These pills are anodyne, diaphoretic, and expectorant. The dose is from five to ten grains.

Pilulæ rhei compositæ. Compound pills of rhubarb. Take of rhubarb, powdered, an ounce; aloes, powdered, six drachms; myrrh powdered, half an ounce; soap a drachm; oil of carraway half a fluid drachm; syrup as much as may be sufficient; mix the powders together, then beat the whole together until incorporated. These pills form a good stomachic laxative. Dose, gr. x. to gr. xx.

PILULÆ SAGAPE'NI COMPOSITÆ. Compound pills of sagapenum. Take of sagapenum an ounce; aloes half a drachm; syrup of ginger as much as may be sufficient. Beat them together until incorporated. These are laxative and antispasmodic. Dose, five to ten grains.

PILULÆ SAPONIS CUM OPIO. Pills of soap and opium; formerly called *pilulæ saponaceæ*. Take of hard opium, powdered, half an ounce; hard soap, two ounces. Beat them together until they are thoroughly incorporated. The dose is from three to ten grains. Five grains of the mass contain one of opium.

PILULÆ SCILLÆ COMPOSITÆ. Compound squill pills. Take of squill-root, fresh dried and powdered, a drachm; ginger-root, powdered, ammoniacum powdered, of each two drachms; syrup as much as may be sufficient. Mix the powders together, then beat them with the soap, and add the syrup, so as to give a proper consistence. An expectorant and diuretic pill, mostly administered in the cure of asthma and dropsy. The dose is from ten grains to a scruple.

PILULÆ STYRACIS COMPOSITÆ. Compound pills of storax. *Pilulæ e Styrace.* Take of purified storax three drachms; hard opium, powdered, saffron, each a drachm. Beat them together until incorporated. These pills are balsamic, stimulant, and slightly expectorant. They are used in chronic pulmonary affections. Dose from gr. iii. to gr. x.

PI'LUS. (Πιλος, wool carded.)

I. In *Anatomy*, the short hair which is found all over the body. The hair of the head, eyebrows, and eyelids, are termed *pili congeniti*, because they grow *in utero*; and that which grows from the surface of the body after birth, *pili postgeniti*. See *Capillus*.

II. In *Botany*, a hair: which, according to Linnæus, is an excretory duct of a bristle-like form. They are fine, slender, cylindrical, flexible bodies, found on the surface of the herbaceous parts of plants. Some of them are the excretory ducts of glands, but many of them are not; and it is not easy to conceive any satisfactory opinion of their use to the plant. When placed under the microscope they appear to be membraneous tubes, articulated in the majority of instances, often punctured, and in some plants, as the *Borago laxiflora*, covered with warts. They are either *simple* or undivided, *compound* or branched.

1. *Pili simplices.* The most common form of the simple hair is that of a jointed thread, generally too flexible to support itself, and thus most commonly found bent and waved. According to its degree of firmness, its quantity, and the mode of its application to the surfaces of stems and leaves, it constitutes the characteristic of surfaces: thus the surface is termed *pilosus*, or hairy, when the hairs are few and scattered, but conspicuous, as in *Hieracium pilosella*; — *lanatus*, woolly, when they are complicated, but nevertheless the single hairs are distinguishable, as in *Verbascum*; — *tomentosus*, shaggy, when they are so thickly matted that the individual hairs cannot be distinguished, and when the position of the hair is nearly parallel with the disk, being at the same time straight, or very slightly curved, and thick, although unmatted: it constitutes the *silky* surface, as is seen on the leaves of *Potentilla anserina*, and *Achemilla alpina*. In some instances the simple hair is firm enough to support itself erect; in which case it is usually awl-shaped, and the articulations are shorter towards the base, as in *Bryonia alba*. It does not always, however, terminate in a point, but sometimes in a small knob, as in the newly-evolved succulent shoots of ligneous plants, *Belladonna*, &c. In some instances also, as on the under disk of the leaves of the *Symphytum officinale*, the simple hair is hooked towards its apex, which occasions the velvety feeling when the finger is passed over the surface of these leaves, the convex part of the curve of the hair being that only which comes in contact with the finger. Another variety of the simple hair is that which has given rise to the term *glanduloso-ciliata*: it is a slender hollow thread, supporting a small, cup-shaped, glandular body, and is rather to be regarded as a stipate gland.

2. *Pili compositi* are either *plumosus*, feathery, which is a simple hair with other hairs attached to it laterally, as in *Hieracium undulatum*; or it is *ramosus*, branched, that is lateral hairs are given off from common stalks, as on the petiole of the gooseberry leaf, or it consists of an erect firm stem, from the summit of which smaller hairs diverge in every direction, as in *Marrubium peregrinum*; or it is *stellatus*, star-like, being composed of a number of simple diverging awl-shaped hairs, springing from a common centre, which is a small knob sunk in the cutis, as on the leaves of marsh mallow. Some authors have applied the term *ramenta* to small, flat, or strop-like hairs which are found on the leaves of some of the genus *Begonia*. — *Thomson*. See *Pubescence*.

PIME'NTA. (*a*, *æ*. f.; from *pimienta*, the Spanish for pepper.) See *Myrtus pimenta*.

PIME'NTO. See *Myrtus pimenta*.

Pimpernel. See *Anagallis arvensis*.

Pimpernel, water. See *Veronica beccabunga*.

PIMPINE'LLA. (*a*, *æ*. f.; *quasi bipinella*, or *bipenula*, from the double pennate order of its leaves.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia*. Pimpinella.

2. The pharmacopœial name of the *Pimpinella alba* and *magna*.

PIMPINELLA ALBA. A variety of the *pimpinella magna*, the root of which is indifferently used with that of the greater pimpinella. The *pimpinella saxifraga* was also so called.

PIMPINELLA ANI'SUM. The systematic name of the anise plant; called in the pharmacopœias, *Anisum*, and *Anisum vulgare*. *Pimpinella — foliis radicalibus trifidis incisis*, of Linnæus. A native of Egypt. Anise-seeds have an aromatic smell, and a pleasant, warm, and sweetish taste. An essential oil and distilled water are prepared from them, which are employed in flatulencies and gripes, to which children are more especially subject: also in weakness of the stomach, diarrhœas, and loss of tone in the primæ viæ.

Pimpinella italica. See *Sanguisorbæ*.

PIMPINELLA MAGNA. The systematic name of the greater pimpinella; called also *Pimpi-*

nella nigra. The root has been extolled by some in the cure of erysipelatous ulcerations, tinea capitis, rheumatism, and other diseases.

Pimpinella nigra. See *Pimpinella magna.*

Pimpinella saxifraga. The systematic name of the Burnet saxifrage: formerly called *Tragoselinum.* Several species of pimpinella were formerly used officinally; but the roots which obtain a place in the Materia Medica of the Edinburgh Pharmacopœia, are those of this species of saxifrage, the *Pimpinella — foliis pinnatis, foliolis radicalibus subrotundis, summis linearibus,* of Linnæus. They have an unpleasant smell, and a hot, pungent, bitterish, taste: they are recommended by several writers as a stomachic: in the way of gargle, they have been employed for dissolving viscid mucus, and to stimulate the tongue, when that organ becomes paralytic.

Pin and web. An old English vernacular name for an opacity of the cornea.

"The tunicle called *cornea* sometimes loseth its colour and brightness, sometimes it grows thick by dryness, as in old men, and is incurable; sometimes gross humours are fastened to it by reason of inflammation, sometimes by resolving medicines, the thinner humours are dissolved, and the thicker remain; or, by the use of cold medicines, the humours are thickened and a white humour is contracted, which is called by some *Leucoma,* by others *Albugo,* commonly a Pin and Web." — *Tanner's Hidden Treasures of the Art of Physick.*

Pinaste'llum. (From *pinus,* the pine-tree: so called, because its leaves resemble those of the pine-tree.) See *Peucedanum silaus.*

Pine. See *Pinus.*

Pine-apple. See *Bromelia ananas.*

Pine-thistle. See *Atractylis gummifera.*

Pinea. See *Pinus pinea.*

PI'NEAL. (*Pinealis;* from *pinea,* a pine-apple: from its supposed resemblance to that fruit.) Formed like the fruit of the pine.

Pineal gland. *Glandula pinealis. Conarium.* A small heart-shaped boor, about the size of a pea, situated immediately over the corpora quadrigemina in the brain. See *Encephalos.* It was whimsically imagined by Descartes to be the seat of the soul.

Pineus purgans. See *Jatropha curcas.*

PINGUE'DINOUS. (*Pinguedinosus;* from *pinguis,* fat.) Fatty; greasy.

Pingue'do. (*o, onis.* f.; from *pinguis,* fat.) See *Fat.*

PINGUI'CULA. (*a, æ.* f.: from *pinguis,* fat: so called because its leaves are fat to the touch.) 1. The name of a genus of plants. Class, *Diandria;* Order *Monogynia.*

2. The name of a form of pterygium. See *Pterygium.*

Pinguicula vulgaris. *Sanicula montana. Sanicula eboracensis. Viola palustris. Liparis. Cucullata. Dodecatheon Plinii.* Butterwort, or Yorkshire sanicle. The remarkable unctuosity of this plant has caused it to be applied to chaps, and as a pomatum to the hair. Decoctions of the leaves in broths are used by the common people in Wales as a cathartic.

Pinhones indici. See *Jatropa curcas.*

PI'NIC. (*Pinicus;* from *pinus,* the fir.) Appertaining to the fir.

Pinic acid. *Acidum pinicum.* In the colophony of France, or resin, which is obtained in all probability from the *Pinaster* or *Pinus maritima,* Mons. Baup has found a substance which crystallises in triangular plates, soluble in about four parts of alkohol, but insoluble in water. It reacts like an acid, and neutralises alkaline matter.

Pink, Indian. See *Spigelia.*

PI'NNA. (*a, æ.* f. Πινν*α*, a wing.) 1. The name of the latter and inferior part of the nose, and the broad part of the ear.

2. The leaflet of a pinnate leaf. See *Leaf.*

Pinna'culum. (Dim. of *pinna,* a wing.) A pinnacle: applied formerly to the uvula, from its shape.

PINNATI'FID. *Pinnatifidus.* Leaves which are cut transversely into several oblong parallel segments; as in *Ipomosis,* and *Myriophyllum verticillatum.*

PINNA'TUS. Pinnate. Applied to a leaf which has several leaflets proceeding laterally from one stalk. It refers especially to the leaf; whereas *alatus* relates to the stem or leaf-stalk. There are several kinds: —

1. *Folium pinnatum cum impari,* with an odd or terminal leaflet; as in roses.

2. *Cirrosum,* with a tendril, when furnished with a tendril instead of the odd leaflet; as in the pea and vetch tribe.

3. *Abruptè pinnatum,* abruptly, without either a terminal leaflet or a tendril; as in the genus *Mimosa.*

4. *Oppositè pinnatum,* oppositely, when the leaflets are opposite or in pairs; as in saintfoin, roses, and *Sium angustifolium.*

5. *Alternatim pinnatum,* alternately, when they are alternate; as in *Amorpha fruticosa.*

6. *Interruptè pinnatum,* interruptedly, when the principal leaflets are ranged alternately with an intermediate series of smaller ones; as in *Spiræa filipendula,* and *ulmaria.*

7. *Articulatè pinnatum,* jointedly, with apparent joints in the common foot-stalk; as in *Weinmannia pinnata.*

8. *Decursivè pinnatum,* decurrently, when the leaflets are decurrent; as in *Eryngium campestre.*

9. *Lyrato-pinnatum,* in a lyrate manner having the terminal leaflet largest, and the rest gradually smaller as they approach the base, as in *Erysimum præcox;* and with intermediate smaller leaflets, as in *Geum rivale,* and the common turnip.

10. *Verticillato-pinnatum,* in a whorled manner, the leaflets cut into five divaricated segments, embracing the footstalk; as in *Sium verticillatum.*

PI'NNULA. (*a, æ.* f.) The leaflet of bipinnate and tripinnate leaves.

PINNULA'TUS. Pinnulate: applied to the leaflet of a winged leaf when it is again subdivided.

PI'NUS. (*us, i.* and *ûs.* f.) The name of a genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Monadelphia.* The pine tree.

Pinus abies. The fir, called formerly *El*

theleia. The Norway spruce fir, which affords the Burgundy pitch and common frankincense.

1. *Pix burgundica*, from the place it was made at. *Pix arida*. The prepared resin of the *Pinus abies — foliis solitariis, subtetragonis acutiusculis distichis, ramis infra nudis conis cylindraceis*, of Linnæus. It is obtained by incision through the bark. The different portions are collected, fused in boiling water, and cleansed by pressing through canvass cloths. When genuine it has a very peculiar odour; and, although brittle in cold weather, it assumes a tenacious viscidity when gently heated or kneaded in the warm hand. It therefore forms an excellent adhesive and gently stimulating plaster, exciting some degree of irritation, and often a slight serous exudation from the parts to which it is applied. It will remain adherent to the cuticle for a long time; and is beneficially applied to the thorax in catarrhal affections, and to the loins in rheumatism and lumbago. These plasters, independently of the irritation of the skin which they excite, are useful merely as keeping the part warm and supported. It is customary with apothecaries to keep Burgundy pitch in a small ladle, or old saucepan, and to remelt the same portion repeatedly, by which it loses its characteristic adhesiveness and irritating quality, and is little more active than common resin. It should always be applied fresh, and spread upon the leather with the aid of as little heat as possible. Upon some skins, a Burgundy pitch plaster, or any similar application, creates incessant itching, and excites a pimply eruption, attended by almost intolerable irritation, so that it is frequently necessary to remove it within a few hours after its application: in these instances, however, it often does great service, especially in chronic rheumatism, where it may thus prove almost as effectual as a blister.

2. *Abietis resina*: called also, *Thus*. Common frankincense. This is a spontaneous exudation, and is brought in small masses or tears, chiefly from Germany, but partly and purest from France. It is applicable to the same purposes as Burgundy pitch.

Pinus balsamea. The systematic name of the balsam of Gilead fir-tree, which affords the Canada balsam. The Canada balsam is one of the purest turpentines. For its properties, see *Turpentine*.

Pinus cedrus. The wood of this species, cedar wood, is very odorous, more fragrant than that of the fir, and it possesses similar virtues.

Pinus cembra. This affords the Carpathian balsam, and Briançon turpentine, and the shoots the Riga balsam, by distillation. This balsam, called *Oleum germanis*, and *Oleum carpathicum*, is obtained both by wounding the young branches of the *Pinus — foliis quinis, levibus*, of Linnæus, and by boiling them. It is mostly diluted with turpentine, and comes to us in a very liquid and pellucid state, rather white.

Pinus larix. The tree which gives us the agaric and Venice turpentine. The larch tree. *Larix. Pinus — foliis fasciculatis mollibus obtusiusculis bracteis extra squamas strobilorum extantibus*. Hort. Kew. The Venice turpentine issues spontaneously through the bark. It is usually thinner than any of the other sorts; of a clear whitish or pale yellowish colour; a hot, pungent, bitterish, disagreeable taste; and a strong smell, without any thing of the aromatic flavour of the Chian kind. Orenburgh gum, and Briançon manna, exude from the bark of this tree. See *Turpentine*.

Pinus picea. The systematic name of the silver fir, or common fir. From it is obtained the Strasburgh turpentine, by puncturing the small vesicles of the bark in which it is contained, and common turpentine by larger incisions.

Pinus pinea. The systematic name of the stone pine-tree. The young and fresh fruit of this plant are eaten in some countries in the same manner as almonds are here, either alone or with sugar. They are nutritive, aperient, and diuretic.

Pinus pumi'lio. Mountain pine. Mugho pine. The turpentine called Hungarian balsam exudes from this tree, and it is also procured by pressing the cones.

Pinus sylvestris. The systematic name of the Scotch fir. *Pinus — foliis germinis rigidis, conis ovato-conicis longitudine foliorum subgeminis basi rotundatis*, of Linnæus, which affords the following officinals: —

1. *Common turpentine* is the juice which flows out on the tree being wounded in hot weather. See *Turpentine*.

2. An oil is obtained from this tree by distillation, mostly with water, in which case yellow resin is left; but if without addition, the residuum is common resin, or colophony. The oil is ordered to be purified in the pharmacopœia. See *Oleum terebinthinæ rectificatum*.

3. When the cold begins to check the exudation of the juice from the tree, a part concretes in the wounds; which is collected and termed *galipot*, in Provence, *barras* in Guienne, sometimes also *white resin*, when thoroughly hardened by long exposure to the air. See *Resina flava* and *alba*.

4. The *Pix liquida*, or tar, is produced by cutting the wood into pieces, which are enclosed in a large oven constructed for the purpose. It is well known for its economical uses. Tar-water, or water impregnated with the more soluble parts of tar, was some time ago a very fashionable remedy in a variety of complaints, but in the present practice it is not much used.

5. Common pitch is tar inspissated; it is now termed in the pharmacopœia, *Pix nigra*.

PI'PER. (*er, eris*. n. Πεπερι; from πεπτω, to concoct: because by its heat it assists digestion.) Pepper. The name of a genus of plants in the Linnæan system. Class, *Diandria*; Order, *Trigynia*.

Piper album. See *Piper nigrum*.

Piper brasilianum. See *Capsicum*.

Piper caleuticum. See *Capsicum*.

Piper caryophyllatum. See *Myrtus*.

Piper caudatum, See *Piper cubeba*.

Piper cube'ba. The plant, the berries of which are called cubebs. *Piper caudatum. Cumamus. Piper — foliis oblique ovatis, seu oblongis venosis acutis, spica solitaria pedunculata oppositifolia, fructibus pedicellatis*, of Linnæus.

The dried berries are of an ash-brown colour, generally wrinkled, and resembling pepper, but furnished each with a slender stalk. They are a warm spice, of a pleasant smell, and moderately pungent taste, imported from Java, and may be exhibited in all cases where warm spicy medicines are indicated, but they are inferior to pepper. Of late they have been successfully given internally in the cure of the common gleet and clap. Mr. Crawford informs us that they are the common remedy in Bengal and Java, where it yields very soon to their use. Well pounded, about half a drachm, or a dessert spoonful, is given three times a day; during which time, all heating aliments are to be abstained from.

Piper decorticatum. White pepper.

PIPER FAVASCI. The clove berry tree.

Piper Guineense. See *Capsicum.*

Piper Hispanicum. See *Capsicum.*

Piper Indicum. See *Capsicum annuum.*

Piper Jamaicense. See *Myrtus pimenta.*

PIPER LONGUM. *Macropiper. Acapatli. Catu tripali. Pimpilim.* Long pepper. *Piper — foliis cordatis petiolatis sessilibusque*, of Linnæus. The berries or grains of this plant are gathered while green, and dried in the heat of the sun, when they change to a blackish or dark grey colour. They possess precisely the same qualities as the Cayenne pepper, only in a weaker degree.

Piper Lusitanicum. See *Capsicum.*

Piper murale. See *Sedum acre.*

PIPER NIGRUM. *Melanopiper. Molagocodi. Lada. Piper aromaticum.* Black pepper. This species of pepper is obtained in the East Indies from the *Piper — foliis ovatis septemnerviis glabris, petiolis simplicissimis*, of Linnæus. Its virtues are similar to those of the other peppers. The black and white pepper are both obtained from the same tree, the difference depending on their preparation and degrees of maturity. Pelletier has extracted a new vegetable principle from black pepper, in which the active part of the grain resides, to which the name of *piperine* is given. To obtain it, black pepper was digested repeatedly in alkohol, and the solution evaporated until a fatty resinous matter was left. This, on being washed in warm water, became of a good green colour. It had a hot and burning taste; dissolved readily in alkohol, less so in ether. Concentrated sulphuric acid gave it a fine scarlet colour. The alkoholic solution after some days deposited crystals, which were purified by repeated crystallisation in alkohol and ether. They then formed colourless four-sided prisms, with single inclined terminations. They have scarcely any taste. Boiling water dissolves a small portion; but not cold water. They are soluble in acetic acid, from which combination feather-formed crystals are obtained. This substance fuses at 212° F. The fatty matter left after extracting the piperine, is solid at a temperature near 32°, but liquefies at a slight heat. It has an extremely bitter and acrid taste, is very slightly volatile, tending rather to decompose than to rise in vapour. It may be considered as composed of two oils, one volatile and balsamic, the other more fixed, and containing the acrimony of the pepper.

PIPERINE. The active principle of pepper. See *Piper nigrum.*

PIPERI'TIS. (*is, idis.* f.; from *piper*, pepper: so called because its leaves and roots are biting like pepper to the taste.) The herb dittany, also lepidium and peppermint.

PIPERI'TUS. (From *piper*, pepper.) Peppered.

PIPERITÆ. The name of an order of plants in Linnæus's Fragments of a natural Method, consisting of the *Piper*, and such as, like it, have flowers in a thick spike.

PI'SIFORM. (*Pisiformis*; from *pisum*, a pea, and *forma*, likeness.) Pea-like.

PISIFO'RME OS. The fourth bone of the first row of the carpus.

Pismire. See *Formica rufa.*

Pis-a-bed. See *Leontodon taraxacum.*

PISSASPHA'LTUS. (From πισσα, pitch, and ασφαλτος, bitumen.) The thicker kind of rock-oil.

PISTA'CIA. (*a, æ.* f. Πιστακια, supposed to be a Syrian word.) The name of a genus of plants in the Linnæan system. Class, *Diœcia*; Order, *Pentandria.*

PISTACIA LENTISCUS. The systematic name of the tree which affords the mastich. *Mastiche. Mastix. Pistacia — foliis abruptè pinnatis, foliolis lanceolatis*, of Linnæus. A native of the south of Europe. In the island of Chio, the officinal mastich is obtained most abundantly; and, according to Tournefort, by making transverse incisions in the bark of the tree, from whence the mastich exudes in drops, which are suffered to run down to the ground, when, after sufficient time is allowed for their concretion, they are collected for use. Mastich is brought to us in small, yellowish, transparent, brittle tears, or grains: it has a light agreeable smell, especially when rubbed or heated; on being chewed, it first crumbles, soon after sticks together, and becomes soft and white, like wax, without impressing any considerable taste. No volatile oil is obtained from this substance when distilled with water. Pure alkohol and oil of turpentine dissolve it; water scarcely acts upon it; though by mastication it becomes soft and tough, like wax. When chewed a little while, however, it is white, opake, and brittle, so as not to be softened again by chewing. The part insoluble in alkohol much resembles in its properties caoutchouc. It is considered to be a mild corroborant and astringent; and as possessing a balsamic power; it has been recommended in hæmoptysis, proceeding from ulceration, leucorrhœa, debility of the stomach, and in diarrhœas and internal ulcerations. Chewing this drug has likewise been said to have been of use in pains of the teeth and gums, and in some catarrhal complaints: it is, however, in the present day, seldom used either externally or internally. The wood abounds with the resinous principle; and a tincture may be obtained from it, which is esteemed in some countries in the cure of hæmorrhages, dysenteries, and gout.

Pistacia nux. See *Pistacia vera.*

Pistacia terebinthus. The systematic name of the tree which gives out the Cyprus, Chio, or Chian turpentine. *Terebinthina de Chio.* This substance is classed among the resins. It is procured by wounding the bark of the trunk of the tree. The best Chio turpentine is about the consistence of honey, very tenacious, clear, and almost transparent; of a white colour, inclining to yellow, and a fragrant smell, moderately warm to the taste, but free from acrimony and bitterness. Its medicinal qualities are similar to those of the other turpentines. See *Turpentine.*

Pistacia vera. The systematic name of a large tree, which affords the pistachio nut. *Pistacia vera — foliis impari pinnatis — foliolis subovatis recurvis,* of Linnæus. An oblong pointed nut, about the size and shape of a filbert, including a kernel of a pale greenish colour, covered with a yellow or greenish skin. Pistachio nuts have a sweetish unctuous taste, resembling that of sweet almonds, and, like the latter, afford an oil, and may be formed into an emulsion.

Pistachio nut. See *Pistacia vera.*

Pistil. See *Pistillum.*

PISTILLI'FEROUS. (*Pistilliferus*; from *pistillum*, a pistil, and *fero*, to bear.) Pistil-bearing: applied to flowers or florets which contain one or more pistils, but no stamens.

PISTI'LLUM. (*um, i.* n.; a pestle, from its likeness.) A pistil or pointal: the female genital organ of a flower, which, being no less essential than the male, stands within them in the centre of the flower. Linnæus believed the pistil to originate from the pith, and the stamens from the wood; and hence constructed an ingenious hypothesis relative to the propagation of vegetables, which is not destitute of observations and analogies to support it, but not countenanced by the anatomy and physiology of the parts:

A pistil consists of three parts: —

1. The *germen*, or rudiment of the young fruit and seed, which of course is essential.

2. The *stylus*, or style, various in length and thickness, sometimes wanting, and, when present, serving merely to elevate the third part.

3. The *stigma*, which is indispensable. The *Nicotiana tabacum* has these organs well displayed.

Pistolo'chia. (From πιστος, faithful, and λοχεια, parturition: so called, because it was thought to promote delivery.) Birthwort. See *Aristolochia.*

PI'SUM. (*um, i.* n.; Πισον.) The name of a genus of plants. Class, *Diadelphia*; Order, *Decandria.* The pea.

Pisum sativum. The common pea. A very nutritious, but somewhat flatulent article of food, of which there are very many varieties.

Pitch. See *Pinus sylvestris.*

Pitch, Burgundy. See *Pinus abies.*

Pitch, Jews'. See *Bitumen judaicum.*

Pitch-tree. See *Pinus abies.*

Pitcher-shaped. *Urceolatus.* See *Ascidiatus.*

Pitta'cium. (Πιττακιον; from πιττα, pitch.) A pitch plaster.

Pitto'ta. (Πιττωτα; from πιττα, pitch.) Medicines in which pitch was the principal ingredient.

PITUI'TA. (*a, æ.* f.) Phlegm; that is, viscid mucus.

PITU'ITARY. *Pituitarius.* Of or belonging to phlegm.

Pituitary body. See *Pituitary gland.*

Pituitary gland. *Glandula pituitaria. Corpus pituitarium.* A process of the brain situated in a duplicature of the dura mater, in the sella turcica of the sphenoid bone. See *Encephalos.*

Pituitary membrane. *Membrana pituitaria.* Schneiderian membrane. The mucous membrane that lines the nostrils, and sinuses communicating with the nose, is so called, because it secretes the mucus of those parts, to which the ancients assigned the name of *pituita.*

PITYRI'ASIS. (*is, is.* f.; from πιτυρον, bran: so named from its branny-like appearance.) A genus in the second order, or scaly diseases, of Dr. Willan's cutaneous diseases. The pityriasis consists of irregular patches of small thin scales, which repeatedly form and separate, but never collect into crusts, nor are attended with redness or inflammation, as in the lepra and scaly tetter. Dr. Willan distinguishes pityriasis from the porrigo of the Latins, which has a more extensive signification, and comprehends a disease of the scalp, terminating in ulceration; whereas the former is, by the best Greek authors, represented as always dry and scaly. Thus, according to Alexander and Paulus, pityriasis is characterised by "the separation of slight furfuraceous substances from the surface of the head, or other parts of the body, without ulceration." Their account of this appearance is conformable to experience; and the two varieties of it which they have pointed out may be denominated, *Pityriasis capitis,* and *Pityriasis versicolor.*

1. *Pityriasis capitis,* when it affects very young infants, is termed by nurses the dandriff. It appears at the upper edge of the forehead and temples, as a slight whitish scurf set in the form of a horse-shoe; on other parts of the head there are large scales, at a distance from each other, flat, and semipellucid. Sometimes, however, they nearly cover the whole of the hairy scalp, being close together and imbricated. A similar appearance may take place in adults; but it is usually the effect of lepra, scaly tetter, or some general disease of the skin.

Elderly persons have the pityriasis capitis in nearly the same form as infants; the only difference is that this complaint in old people occasions larger exfoliations of the cuticle. The remedies are, a regular ablution of the scalp with soap and water, or an alkaline or weak spirituous lotion, for which purpose the hair must be removed if not thin.

2. The *Pityriasis rubra* occurs most frequently in advanced life, and is the result of a slight inflammation of the portions of the skin affected, somewhat resembling in this respect the psoriasis diffusa. The cuticle is at first only red and rough, but soon becomes mealy or scurfy, and exfoliates, leaving a similar red cuticle underneath, which undergoes the like process;

the scaliness becoming greater as the exfoliation is repeated. This complaint is attended with a dry and unperspiring surface, a troublesome itching, and a feeling of stiffness. There is also a general langour and restlessness. When the redness and scales disappear, the patches are left of a yellowish or a sallow hue. But the whole process is liable to be repeated at short intervals, and the disease to be thus greatly prolonged.

This form of the disease is removed by a combination of antimonials with the decoction of woods, and the warm sea-water bath. It is also materially relieved by small doses of the tinctura veratri. Where the irritability of the skin is not very great, a gently restringent lotion or ointment, containing a portion of borax or alum, and super-acetate of lead, may be applied to the parts affected with advantage.

3. The *Pityriasis versicolor* chiefly affects the arms, breast, and abdomen. It is diffused very irregularly; and being of a different colour from the usual skin colour, it exhibits a singular chequered appearance. These irregular patches, which are at first small, and of a brown or yellow hue, appear at the scrobiculus cordis, about the mammæ, clavicles, &c. Enlarging gradually, they assume a tesselated form; in other cases they are branched, so as to resemble the foliaceous lichens growing on the bark of trees; and sometimes, when the discolouration is not continuous, they suggest the idea of a map being distributed on the skin like islands, continents, peninsulas, &c. All the discoloured parts are slightly rough, with minute scales, which soon fall off, but are constantly replaced by others. This scurf, or scaliness, is most conspicuous on the sides and epigastric region. The cuticular lines are somewhat deeper in the patches than on the contiguous parts; but there is no elevated border, or distinguishing boundary between the discoloured part of the skin, and that which retains its natural colour. The discolouration rarely extends over the whole body. It is strongest and fullest round the umbilicus, on the breasts, and sides; it seldom appears in the skin over the sternum, or along the spine of the back. Interstices of proper skin colour, are more numerous, and largest at the lower part of the abdomen and back, where the scales are often small, distinct, and a little depressed. The face, nates, and lower extremities are least affected; the patches are found upon the arms, but mostly on the inside, where they are distinct and of different sizes. The pityriasis versicolor is not a cuticular disease; for when the cuticle is abraded from any of the patches, the sallow colour remains as before in the skin or rete mucosum. This singular appearance is not attended with any internal disorder, nor with any troublesome symptom, except a little itching or irritation felt on getting into bed, and after strong exercise, or drinking warm liquors. There is in some cases a slight exanthema, partially distributed among the discoloured patches; and sometimes an appearance like the lichen pilaris; but eruptions of this kind are not permanent, neither do they produce any change in the original form of the complaint. The duration of the pityriasis versicolor is always considerable. Dr. Willan has observed its continuance in some persons for four, five, or six years. It is not limited to any age or sex. Its causes are not pointed out with certainty. Several patients have referred it to fruit taken in too great quantities; some have thought it was produced by eating mushrooms, others by exposure to sudden alternations of cold and heat. In some individuals, who had an irritable skin, and occasionally used violent exercise, the complaint has been produced, or at least much aggravated, by wearing flannel next to the skin. It is likewise often observed in persons who have resided for a length of time in a tropical climate.

PIX. (*ix, icis.* f.; from πισσα.) Pitch. See *Pinus sylvestris.*

Pix arida. See *Pinus abies.*

PIX ERU'TIA. A thick and resinous kind of pitch used by the ancients.

Pix Burgundica. See *Pinus abies.*

Pix liquida. See *Pinus sylvestris.*

PLACE'BO. (I will please.) An epithet given to any medicine adapted rather to please than benefit the patient.

PLACE'NTA. (*a, æ.* f.; a cake; from πλακους, a cake.) The afterbirth. The afterbirth is so called from its resemblance in shape to a cake. The membranes of the ovum have usually been mentioned as two, the amnion and the chorion; and the latter has again been divided into the true and the false. The third membrane (which, from its appearance, has likewise been called the villous or spongy, and from the consideration of it as the inner lamina of the uterus, cast off like the exuviæ of some animals, the decidua,) has been described by Harvey, not as one of the membranes of the ovum, but as a production of the uterus. The following is the order of the membranes of the ovum, at the full period of gestation:—1st, There is the outer or connecting, which is flocculent, spongy, and extremely vascular, completely investing the whole ovum, and lining the uterus. 2dly, The middle membrane, which is nearly pellucid, with a very few small blood-vessels scattered over it, and which forms a covering to the placenta and funis, but does not pass between the placenta and uterus. 3dly, The inner membrane, which is transparent, of a firmer texture than the others, and lines the whole ovum, making, like the middle membrane, a covering for the placenta and funis with the two last. The ovum is clothed when it passes from the ovarium into the uterus, where the first is provided for its reception.

These membranes, in the advanced state of pregnancy, cohere slightly to each other, though in some ova, there is a considerable quantity of fluid collected between them, which, being discharged when one of the outer membranes is broken, forms one of the circumstances which have been distinguished by the name of false waters.

Between the middle and inner membrane upon or near the funis, there is a small, flat and oblong body, which, in the early part of pregnancy, seems to be a vesicle containing milk or lymph, which afterwards becomes of a firm, ar

apparently fatty texture. This is called the *vesicula umbilicalis;* but its use is not known.

The placenta is a circular, flat, vascular, and apparently fleshy substance, different in its diameter in different subjects, but usually extending about six inches, or upwards, over about one fourth part of the outside of the ovum in pregnant women. It is more than one inch in thickness in the middle, and becomes gradually thinner towards the circumference, from which the membranes are continued. The placenta is the principal medium by which the communication between the parent and child is preserved; but though all have allowed the importance of the office which it performs, there has been a variety of opinions on the nature of that office, and of the manner in which it is executed.

The surface of the placenta, which is attached to the uterus by the intervention of the connecting membrane, is lobulated and convex; but the other, which is covered with the amnion and chorion, is concave and smooth, except the little eminence made by the blood-vessels. It is seldom found attached to the same part of the uterus in two successive births; and, though it most frequently adheres to the anterior part, it is occasionally fixed to any other, even to the os uteri, in which state it becomes a cause of a dangerous hæmorrhage at the time of parturition. The placenta is composed of arteries and veins, with a mixture of pulpy or cellular substance. Of these vessels there are two orders, very curiously interwoven with each other. The first is a continuation of those from the funis, which ramify on the internal surface of the placenta, the arteries running over the veins, which is a circumstance peculiar to the placenta; and then, sinking into its substance, anastomose and divide into innumerable small branches. The second order proceeds from the uterus; and these ramify in a similar manner with those from the funis, as appears when a placenta is injected from those of the parent. The veins, in their ramifications, accompany the arteries as in other parts. There have been many different opinions with respect to the manner in which the blood circulates between the parent and child, during its continuance in the uterus. For a long time it was believed that the intercourse between them was uninterrupted, and that the blood, propelled by the powers of the parent, pervaded, by a continuance of the same force, the vascular system of the fœtus; but repeated attempts having been made, without success, to inject the whole placenta, funis, and fœtus, from the vessels of the parent, or any part of the uterus, from the vessels of the funis, it is now generally allowed, that the two systems of vessels in the placenta, one of which may be called maternal, the other fœtal, are distinct. It is also admitted, that the blood of the fœtus is, with regard to its formation, increase, and circulation, unconnected with and totally independent of the parent; except that the matter by which the blood of the fœtus is formed must be derived from the parent. It is thought that which has probably undergone some preparatory changes in its passage through the uterus, is conducted by the uterine or maternal arteries of the placenta to some cells or small cavities, in which it is deposited; and that some part of it, or something secreted from it, is absorbed by the fœtal veins of the placenta, and by them conveyed to the fœtus for its nutriment. When the blood which circulates in the fœtus requires any alteration in its qualities, or when it has gone through the course of the circulation, it is carried by the arteries of the funis to the placenta, in the cells of which it is deposited, and then absorbed by the maternal veins of the placenta, and conducted to the uterus, whence it may enter the common circulation of the parent. Thus it appears, according to the opinion of Harvey, that the placenta performs the office of a gland, conveying air, or secreting the nutritious juices from the blood brought from the parent by the arteries of the uterus, and carried to the fœtus by the veins of the funis, in a manner probably not unlike to that in which milk is secreted and absorbed from the breasts. The veins in the placenta are mentioned as the absorbents, because no lymphatic vessels have yet been found in the placenta or funis; nor are there any nerves in these parts; so that the only communication hitherto discovered between the parent and child, is by the sanguineous system. The proofs of the manner in which the blood circulates between the parent and child are chiefly drawn from observations made upon the funis. When it was supposed that the child was supplied with blood in a direct stream from the parent, it was asserted that, on the division of the funis, if that part next to the placenta was not secured by a ligature, the parent would be brought into extreme danger by the hæmorrhage which must necessarily follow. But this opinion, which laid the foundation of several peculiarities in the management of the funis and placenta, is proved not to be true: for, if the funis be compressed immmediately after the birth of the child, and whilst the circulation in it is going on, the arteries between the part compressed and the child throb violently, but those between the compression and the placenta have no pulsation; but the vein between the part compressed and the placenta swells, and that part next to the fœtus becomes flaccid; but if, under the same circumstances, the funis be divided, and that part next the child be not secured, the child would be in danger of losing its life by the hæmorrhage; yet the mother would suffer no inconvenience if the other part was neglected. It is, moreover, proved, that a woman may die of an hæmorrhage occasioned by a separation of the placenta, and the child be nevertheless born, after her death, in perfect health. But if the placenta be injured, without separation, either by a rupture of the vessels which pass upon its inner surface, or in any other way, the child being deprived of its proper blood, would perish, yet the parent might escape without injury.

II. The receptacle of the fructification of plants has been called placenta. See *Receptaculum.*

Placenta febrilis. The ague cake. See *Ague.*

Plada'rotes. (Πλαδαροτης; from πλαδαρος, moist, flaccid.) A soft discoloured tumour within the eyelid.

Plague. See *Pestis.*

Plague, black. See *Pestis nigra*, in the Supplement.

Plaice. See *Pleuronectes platessa.*

Plaited. See *Plicatus.*

PLANT. (*Planta, æ.* f.) An organised body belonging to the vegetable kingdom. See *Body*, and *Vegetable.*

PLA'NTA. 1. A plant.

2. The lower part or sole of the foot, comprehended between the tarsus and toes.

PLANTA'GO. (*o, inis.* f.; from *planta*, the sole of the foot: so called from the shape of its leaves, or because its leaves lie upon the ground and are trodden upon.) 1. The name of a genus of plants in the Linnæan system. Class, *Tetrandria;* Order, *Monogynia.* The plantain.

2. The pharmacopœial name of the *Plantago major.*

Plantago coro'nopus. The systematic name of the buck's-horn plantain. *Coronopodium. Cornu cervinum. Stella terræ. Herba stella.* Its medicinal virtues are the same as those of the other plantains.

Plantago latifolia. See *Plantago major.*

Plantago major. The systematic name of the broad-leaved plaintain; called also, *Centinervia, Heptapleurum, Polyneuron*, and *Plantago latifolia. Plantago — foliis ovatis glabris, scapo tereti, spica flosculis imbricatis*, of Linnæus. This plant was retained until of late years in the materia medica of the Edinburgh College, in which the leaves are mentioned as the pharmaceutical part of the plant: they have a weak herbaceous smell; an austere, bitterish, subsaline taste; and their qualities are said to be refrigerant, attenuating, astringent, and diuretic.

Plantago psy'llium. The systematic name of the branching plantain, or flea-wort. *Psyllium, Pulicaris herba, Crystallion*, and *Cynomoia* of Oribasius. The seeds of this plant, *Plantago — caule ramoso herbaceo, foliis subdentatis, recurvatis; capitulis aphyllis*, of Linnæus, have a nauseous mucilaginous taste, and no remarkable smell. The decoction of the seeds is recommended in hoarseness and asperity of the fauces.

Plantain. See *Plantago.*

Plantain-tree. See *Musa.*

Plantain, water. See *Alisma plantago.*

PLA'NTAR. *Plantaris.* Appertaining to the sole of the foot.

Plantar aponeurosis. The strong tendinous expansion which lies under the integuments in the sole of the foot.

Plantar arteries. Two branches of the posterior tibial.

PLANTA'RIS. (From *planta*, the sole of the foot.) *Tibialis gracilis*, vulgo *plantaris*, of Winslow. *Extensor tarsi minor*, vulgo *plantaris*, of Douglas. A muscle of the foot, situated on the leg, that assists the soleus, and pulls the capsular ligament of the knee from between the bones. It is sometimes, though seldom, found wanting on both sides. This long and slender muscle, which is situated under the gastrocnemius externus, arises, by a thin fleshy origin, from the upper and back part of the outer condyle of the os femoris. It adheres to the capsular ligament of the joint; and after running obliquely downwards and outwards, for the space of three or four inches, along the second origin of the gastrocnemius internus, and under the gastrocnemius externus, terminates in a long thin and slender tendon, which adheres to the inside of the tendo Achillis, and is inserted into the inside of the posterior part of the os calcis. This tendon sometimes sends off an aponeurosis that loses itself in the capsular ligament, but it does not at all contribute to form the aponeurosis that is spread over the sole of the foot, as was formerly supposed, and as its name would seem to imply. Its use is to assist the gastrocnemii in extending the foot. It likewise serves to prevent the capsular ligament of the knee from being pinched.

PLANTI'GRADA. (From *planta*, the sole of the foot, and *gradior*, to walk.) Plantigrade animals. A tribe of mammiferous animals, which walk on the sole of the foot, as opposed to the *Digitigrada*, or those which walk on the extremities of the toes.

Plants, sexual system of. See *Vegetable kingdom.*

Planum os. The orbitary plate of the ethmoid bone is so called from its plane surface.

PLA'NUS. Flat; smooth. Applied to parts of animals, as *os planum*; and to the receptacle of the fruit of plants, as that of the *Helianthus annuus.*

Plaster. See *Emplastrum.*

Plaster of Paris. See *Gypsum.*

Pla'ta. (From πλατυς, broad.) The shoulder-blade.

PLATI'NUM. (*um, i.* n.; the name given to this metal by the Spaniards, from the word *plata*, which signifies silver in their language, by way of comparison with that metal, whose colour it imitates; or from the river *Plata*, near which it is found.) *Platina.* A metal which exists in nature only in a metallic state. Its ore has recently been found to contain, likewise, four new metals, *palladium, iridium, osmium* and *rhodium*, besides iron and chrome. The largest mass of which we have heard, is one of the size of a pigeon's egg, in the possession of the Royal Society of Bergara.

The crude platinum is to be dissolved in nitro-muriatic acid, precipitated by muriate of ammonia, and exposed to a very violent heat. Then the acid and alkali are expelled, and the metal reduced in an agglutinated state, which is rendered more compact by pressure while red hot.

Pure or refined platinum is by much the heaviest body in nature. Its sp. gr. is 21·. It is very malleable, though considerably harder than either gold or silver; and it hardens much under the hammer. Its colour on the touch stone is not distinguishable from that of silver. Pure platinum requires a very strong heat to melt it; and, when urged by a white heat, its parts will adhere together by hammering.

Platinum is not altered by exposure to air; neither is it acted upon by the most concentrated simple acids, even when boiling or distilled

from it. Its only solvent is chlorine, which acts on it with more difficulty than on gold.

Platinum is now hammered in Paris into leaves of extreme thinness. By enclosing a wire of it in a little tube of silver, and drawing this through a steel plate in the usual way, Dr. Wollaston succeeded in producing platinum wire not exceeding 1-3000th of an inch in diameter.

There are only two *oxides* of platinum distinctly known, though four are supposed to exist.

1. When 100 parts of the protochloride, or muriate of platinum, are calcined, they leave 73·3 of metal; 26·7 of chlorine escape. Hence the prime equivalent of the metal would seem to be 12·3. When the above protochloride is treated with caustic potash, it is resolved into a *black oxide* of platinum and chloride of potassium. This oxide should consist of 12·3 metal + 1 oxygen.

2. The *peroxide* appears to contain three prime proportions. Berzelius obtained it by treating the muriate of platinum with sulphuric acid, at a distilling heat, and decomposing the sulphate by aqueous potash. The precipitated oxide is a yellowish brown powder, easily reducible by a red heat to the metallic state. None of its compounds are used in medicine.

Ammonia forms a detonating compound with the oxide of platinum, analogous to fulminating gold and silver.

PLATYCO'RIA. (*a*, *æ*. f.; from πλατυς, broad, and κορη, the pupil of the eye.) An enlarged pupil.

PLATYOPHTHA'LMUM. (From πλατυς, broad, and οφθαλμος, the eye: so called because it is used by eastern women to make the eye look large and bright.) Antimony.

PLATY'SMA-MYOI'DES. (From πλατυς, broad, μυς, a muscle, and ειδος, resemblance.) *Musculus cutaneus*, of Winslow. *Quadratus genæ vel latissimus colli*, of Douglas. *Latissimus colli*, of Albinus. *Quadratus genæ, seu tetragonus*, of Winslow. A thin muscle on the side of the neck, immediately under the skin, that assists in drawing the skin of the cheek downwards; and when the mouth is shut, it draws all that part of the skin to which it is connected below the lower jaw upwards.

PLE'CTANÆ. (From πλεκω, to fold.) The horns of the uterus.

PLE'CTRUM. (Πληκτρον, a bow for striking on the strings of a musical instrument. So named from some fancied resemblance.) The styloid process of the temporal bone; also the uvula.

PLE'RES ARCHO'NTICUM. (Πληρες αχοντικον, full of power or efficacy.) The name of an old cephalic powder mentioned by Lemery.

Plero'sis. See *Plethora.*

Ple'smone. See *Plethora.*

PLETHO'RA. (*a*, *æ*. f. Πληθωρα; from πληθω, to fill.) *Plerosis. Plesmone.* An excessive fulness of the blood-vessels. This may be conceived to arise from an increased quantity of blood, or a diminished capacity of the vessels. In the former case it is called *plethora ad molem*; in the latter *plethora ad spatium.* When the quantity of blood is too great for the strength of the vessels, it is called *plethora ad vires.* Plethora may arise from a highly entonic state of the arterial system, and a thick crasis of the blood; and it is then called *sanguine plethora*; or it may arise from a lax and weak state of the arterial system with a redundance of serum in the blood; in which case it is called *serous plethora* or *atonic plethora.*

Pleumonia. See *Pneumonitis.*

PLEU'RA. (*a*, *æ*. f. Πλευρα.) The Greek word for a rib, or the side of the thorax formed by the ribs, but now applied by anatomists to the membrane which lines the internal surface of the thorax, and covers its viscera. It forms a great process, the mediastinum, which divides the thorax into two cavities. Its use is to render the surface of the thorax moist by the vapour it exhales. The cavity of the thorax is every where lined by this smooth and glistening membrane, which in reality consists of two distinct portions or bags, which, by being applied to each other laterally, form the septum called mediastinum: this divides the cavity into two parts, and is attached posteriorly to the vertebræ of the back, and anteriorly to the sternum. But the two laminæ of which this septum is formed, do not every where adhere to each other: for at the lower part of the thorax they are separated, to afford a lodgment to the heart; and at the upper part of the cavity they receive between them the thymus gland. The pleura is plentifully supplied with arteries and veins from the internal mammary, and the intercostals. Its nerves, which are very inconsiderable, are derived chiefly from the dorsal and intercostal nerves. The surface of the pleura, like that of the peritonæum and other membranes lining cavities, is constantly bedewed with a serous moisture, which prevents adhesions of the viscera. The mediastinum, by dividing the chest into two cavities, obviates many inconveniences to which we should otherwise be liable. It prevents the right and left lungs from compressing each other when we lie on one side, and consequently contributes to the freedom of respiration, which is disturbed by the least pressure on the lungs. If the point of a sword penetrates between the ribs into the cavity of the thorax, the lung on that side ceases to perform its office, because the air being admitted through the wound, prevents the dilatation of that lung; while the other lung, which is separated from it by the mediastinum, remains unhurt, and continues to perform its functions as usual.

PLEURA'LGIA. (*a*, *æ*. f.; from πλευρα, and αλγος, pain.) The same as pleurodynia.

PLEURI'TIS. (*is*, *idis*. f.; from πλευρα, the pleura.) Pleurisy or inflammation of the membrane which lines the cavity of the chest, and is reflected over the lungs. It assumes an *acute* and a *chronic* form.

1. *Acute pleurisy.* — In some instances the inflammation is partial, or affects one place in particular, which is commonly on the right side; but, in general, the morbid action is communicated throughout its whole extent. The disease is occasioned by exposure to cold, and by all the causes which usually give rise to other inflam-

matory complaints; and it attacks chiefly those of a vigorous constitution and plethoric habit. In consequence of the previous inflammation, it is apt, at its departure, to leave behind a thickening of the pleura, or adhesions to the ribs and intercostal muscles, which either lay the foundation of future pneumonic complaints or render the patient more susceptible of the changes of the atmosphere than before.

It comes on with an acute pain in the side, which is much increased by making a full inspiration, and is accompanied by flushing in the face, increased heat over the whole body, rigors, difficulty of lying on the side affected, together with a cough and nausea, and the pulse is hard, strong, and frequent, and vibrates under the finger when pressed upon, not unlike the tense string of a musical instrument. If blood is drawn and allowed to stand for a short time, it will exhibit a thick sizy or buffy coat on its surface. If the disease be neglected at its onset, and the inflammation proceeds with great violence and rapidity, the lungs themselves become affected, the passage of the blood through them is stopped, and the patient is suffocated; or, the inflammation goes on to suppuration, and an abscess is formed. When the substance of the lungs as well as the pleura is affected, the case is called *pleuro-peripneumony*. The prognosis in pleurisy must be drawn from the severity of the symptoms. If the fever and inflammation have run high, and the pain should cease suddenly, with a change of countenance, and a sinking of the pulse, great danger may be apprehended; but if the heat and other febrile symptoms abate gradually, if respiration is performed with greater ease and less pain, and a free and copious expectoration ensues, a speedy recovery may be expected. If the case come early under treatment, and vigorous practice be used, the prognosis in pleurisy may almost always be favourable, as it is more under the control of the lancet than any other case of inflammation.

If pleurisy be not checked, it may terminate in the effusion of lymph and the formation of adhesions between the pulmonary and costal pleura. These adhesions often exist during life, causing no other inconvenience than an occasional pain or sense of dragging. Another termination is by the effusion of serum, of pus, or a mixture of the two. In the latter event the patient generally sinks rapidly, but occasionally the case becomes chronic, and is then to be considered one of *hydrothorax* or *empyema*. (See these titles.)

The treatment of pleurisy consists in large bleeding from the arm, repeated if necessary, with the application of leeches or cupping-glasses; purgatives, diaphoretics, blisters, and a strict antiphlogistic regimen.

2. *Chronic pleurisy.* — This is principally a disease of advanced life, and seems most frequent in those addicted to the use of ardent spirits. It is very obscure in its symptoms, and is generally fatal, bronchitis supervening towards the termination. Chronic inflammation of the pleura gives rise to the thickening of the membrane, extensive adhesions, hydrothorax, and empyema. Occasional leeching and counter irritation by blisters, form the only treatment likely to do any good.

PLEUROCOLLE'SIS. (*is, is.* f.; from πλευρα, the pleura, and κολλαω, to glue.) An adhesion of the pleura to the lungs, or some neighbouring part.

PLEURODY'NIA. (*a, æ.* f.; from πλευρα, and οδυνη, pain.) A pain in the side, from whatever cause; but generally applied to those pains not arising from inflammation.

PLEURONE'CTES. (From πλευρα, the side, and νεω to swim, because they swim on their side.) The name of a genus of thoracic fishes.

PLEURONECTES HIPPOGLOSSUS. The holibut or holybut. This is not only one of the largest of the flat fish, but the largest of fishes properly so called, having been found of the weight of 300 or 400 pounds.

PLEURONECTES LIMANDA. The dab. Very like to the sole, but not so fine in flavour.

PLEURONECTES MAXIMUS. The turbot. By many this is esteemed the best of all fishes. It is a finely flavoured fish when in season, and inhabits the European and Mediterranean seas, and grows sometimes to thirty pounds weight. The flesh is firm, and easy of digestion.

PLEURONECTES PLATESSA. The plaice. A large flat fish, found in considerable quantity about our own and the Dutch coasts. The flesh is good, especially when large, but more watery than the sole. It is of easy digestion.

PLEURONECTES PLESSUS. The flounder. Extremely common about our coasts, and found in the rivers at a considerable distance from the salt water. It is a much esteemed fish, being easy of digestion, and proper for weak stomachs.

PLEURONECTES ROSEUS. The rose-coloured flounder. This is frequently found in the river Thames, and is considered as the finest of all flounders.

PLEURONECTES SOLEA. The sole. More frequently eaten than any of the flat fish, and perhaps inferior to none in delicacy and flavour. It is in season the greater part of the year.

PLEURONECTES ZEBRA. An elegant flat fish rather larger than our sole, a native of the Indian seas, and much esteemed as a wholesome and good fish.

PLEU'RO-PNEUMO'NIA. (*a, æ.* f.; from πλευρα and πνευμων, the lung.) The same as *pleuro-peripneumonia*.

PLEU'ROPERIPNEUMO'NIA. (From πλευρα, and περιπνευμονια, inflammation of the lungs.) An inflammation of the pleura and substance of the lungs.

PLEURORTHOPNÆ'A. (*a, æ.* f.; from πλευρα, the pleura, ορθος, upright, and πνεω, breathe.) A pleurisy in which the patient can not breathe without keeping his body upright.

PLEUROSTHO'TONOS. Improperly written for *pleurothotonos*.

PLEUROTHO'TONOS. (From πλευρ- θεν, to one side, and τεινω, to bend.) The form of tetanus in which the body is bent to one side.

PLEXI'METER. (From πληξις, percussion, and μετρον, a measure.) The name given

by M. Piorry to the ivory plate which he uses in mediate percussion. The word ought to be *plexeometer*.

PLEX'US. (*us, ûs.* m.; from *plecto*, to twine or knit.) A network: applied to blood-vessels, absorbents, and nerves, when many are near together, the branches crossing and intertwining in the form of a net.

PLEXUS CARDI'ACUS. The cardiac plexus of nerves which is formed by the union of the eighth pair of nerves and great sympathetic.

PLEXUS CHOROI'DES. Choroid plexus. A plexus of vessels situated in the lateral ventricle of the brain. See *Encephalos*.

PLEXUS PAMPINIFO'RMIS. The plexus of blood-vessels about the spermatic chord.

PLEXUS PULMO'NICUS. The pulmonic plexus of nerves which is formed by the union of the eighth pair of nerves with the great sympathetic.

PLEXUS RETICULA'RIS. The network of vessels under the fornix of the brain.

PLI'CA. (*a, æ.* f.; from *plico*, to entangle.) *Helotis. Kolto. Rhopalosis. Trichiasis. Trichoma. Plica Polonica.* Plaited hair. A disease of the hairs, in which they become long and coarse, and matted and glued into inextricable tangles. It is peculiar to Poland, Lithuania, and Tartary, and generally appears during the autumnal season. It has been asserted that the hair is acutely sensible, and cannot be cut off without danger. But this appears to be a fable.

PLICA'RIA. (*a, æ.* f.; from *plico*, to entangle: so called because its leaves are entangled together in one mass.) Wolf's-claw, or club moss. See *Lycopodium*.

PLICA'TUS. Plaited; folded. Applied to leaves when the disk, especially towards the margin, is acutely folded up and down; as in *Malva crispa*.

PLIN'THIUS. Πλινθιος. The fourfold bandage.

Plum. See *Prunus*.

Plum, Malabar. See *Eugenia jambos*.

PLUMBA'GIN. A principle detected by Dulong in the root of the *plumbago europæa*.

PLUMBA'GO. (*o, inis.* f.; from *plumbum*, lead.) 1. The name of a genus of plants so called from their being covered with lead-coloured spots. Class, *Pentandria*; Order, *Monogynia*.

2. Lead-wort. See *Polygonum persicaria*.

3. Black-lead. An iron ore of a shining blue-black colour, a greasy feel, and tuberculated when fractured. It is a pretty abundant mineral, and is called *graphite*. It may also be artificially prepared by exposing iron with an excess of charcoal to an intense and long continued heat. Graphite has generally passed for a carburet of iron, but according to Dr. Karsten, of Berlin, it is only a mechanical mixture of charcoal and iron, while the artificial black lead is a real carburet.

PLUMBAGO EUROPÆA. The systematic name of the tooth-wort. *Dentaria. Dentillaria.* This plant is to be distinguished from the pellitory of Spain, which is also called dentaria. It is the *Plumbago — foliis amplexicaulibus, lanceolatis, scabris*, of Linnæus. The root was formerly esteemed, prepared in a variety of ways, as a cure for the toothach, arising from caries.

PLUMBI ACE'TAS. *Cerussa acetata. Saccharum saturni.* Sugar of lead: so called from its sweet taste. It possesses sedative and astringent qualities in a very high degree. It is constantly used in lotions, and is perhaps the most powerful internal medicine in profuse hæmorrhages, especially combined with opium: but its use is not entirely without hazard, as it has sometimes produced violent colic and palsy; wherefore it is better not to continue it unnecessarily. The dose may be from one to three grains. It has been also recommended to check the expectoration and colliquative discharges in phthisis, but will probably be only of temporary service. According to Dr. A. T. Thompson it is poisonous only when it is decomposed and deposits the carbonate, which latter is the only deleterious salt of lead.

PLUMBI DIACETATIS LIQUOR. *Plumbi acetatis liquor.* Solution of diacetate of lead; formerly called *aqua lithargyri acetati*. Goulard's extract. Take of acetate of lead, two pounds and three ounces: oxide of lead, powdered, a pound and four ounces; water, six pints. Boil for half an hour, agitating frequently, and when the liquor is cool, add as much distilled water as will make it up to six pints, and strain. This has long been a celebrated refrigerant application in cases of local inflammation. It is to be mixed with distilled water in the proportion of from one to two drachms to a pint of water.

PLUMBI DIACETATIS LIQUOR DILUTUS. *Liquor plumbi acetatis dilutus. Aqua vegeto mineralis.* Diluted solution of diacetate of lead. *Aqua lithargyri acetati composita.* Take of solution of diacetate of lead, a fluid drachm and a half; distilled water, a pint; weak spirit, two fluid drachms. Mix. This is an unnecessary formula, as every surgeon dilutes the Goulard's extract with water, according to his own discretion.

PLUMBI CHLO'RIDUM. Chloride of lead. Take of acetate of lead nineteen ounces, boiling distilled water, three pints: chloride of sodium, six ounces. Dissolve the acetate of lead and chloride of sodium separately, the former in three pints of distilled water, and the latter in one pint. The liquors being then mixed together, wash the precipitate, when cold, with distilled water, and dry it. It is only used for preparing the hydrochlorate of morphia.

PLUMBI IODI'DUM. Iodide of lead. Take of acetate of lead, nine ounces; iodide of potassium, seven ounces; distilled water, a gallon. Dissolve the acetate of lead in six pints of the water, and filter. Add to the solution, the iodide of potassium dissolved in two pints of the water, wash the precipitate and dry it. The iodide of lead, as obtained by the above process, is a bright yellow powder, little soluble in cold water, but readily so in boiling water, from which, it is again deposited on cooling, in the form of crystalline scales.

This medicine has been found very effectual in resolving scrofulous tumours, and in the hands of M. Velpeau, has succeeded when iodine and its other compounds have failed. The dose

is from half a grain to four grains. An officinal ointment is now prepared from it. See *Unguentum plumbi iodidi.*

PLUMBI OXYDUM HYDRA'TUM. Hydrated oxide of lead. Take of solution of diacetate of lead, six pints; distilled water, three gallons; solution of potash, six pints; or as much as may be sufficient to precipitate the oxide. Mix. Wash the precipitate with water until nothing alkaline remains. This is used for preparing the disulphate of quinine.

Plumbi oxidum semivitreum. See *Lithargyrum.*

PLUMBI CARBO'NAS. *Plumbi subcarbonas.* Subcarbonate of lead; commonly called cerusse, or white-lead. This article is made in the large way in white-lead manufactories, by exposing thin sheets of lead to the vapour of vinegar. The lead is curled up and put into pots of earthenware, in which the vinegar is, in such a way as to rest just above the vinegar. Hundreds of these are arranged together, and surrounded with dung, the heat from which volatilises the acetic acid, which is decomposed by the lead, and an imperfect carbonate of lead is formed, which is of a white colour. This preparation is seldom used in medicine or surgery but for the purpose of making other preparations, as the acetate. It is sometimes employed medicinally in form of powder and ointment, to children whose skin is fretted. It should, however, be cautiously used, as there is great reason to believe that complaints of the bowels of children originate from its absorption.

Plumbi subcarbonas. See *Plumbi carbonas.*

PLU'MBUM. (*um, i.* n.) See *Lead.*

PLUMBUM CANDIDUM. Tin.

PLUMBUM CINEREUM. Bismuth.

PLUMBUM NIGRUM. Black-lead.

PLUMBUM RUBEUM. The philosopher's stone is so called in some old books.

PLUMBUM USTUM. Burnt lead.

PLUMME'RI PILULÆ. Plummer's pills. See *Pilulæ hydrargyri chloridi compositæ.*

PLUMO'SUS. (From *pluma*, a feather.) Plumose: feathered. In general use in *Natural History;* and applied, in *Botany*, to the down of seeds, which sometimes consists of fine, simple, or undivided hairs; in others it sends out lateral hairs, and then it is said to be feathered.

PLU'MULA. (*a, æ.* f.; a diminutive of *pluma*, a feather.) A little feather. The expanding embryo or germ of a plant within the seed, resembling a little feather. It soon becomes a tuft of young leaves, with which the young stem, if there be any, ascends. See *Corculum*, and *Cotyledon.*

PLUNKET'S CANCER REMEDY.—Take crow's foot, which grows in low grounds, one handful; dog's fennel, three sprigs, both well pounded; crude brimstone, in powder, three middling thimbles-full; white arsenic, the same quantity: incorporated all in a mortar, and made into small balls the size of a nutmeg, and dried in the sun. These balls must be powdered and mixed with the yolk of an egg, and laid over the sore or cancer upon a piece of pig's bladder, or stripping of a calf when dropped, which must be cut to the size of the sore, and smeared with the yolk of an egg. This must be applied cautiously to the lips or nose, lest any part of it get down; nor is to be laid on too broad on the face, or too near the heart, nor to exceed the breadth of half-a-crown; but elsewhere as far as the sore goes. The plaster must not be stirred until it drops off of itself, which will be in a week. Clean bandages are often to be put on.

PNEUMA'TIC. (*Pneumaticus;* from πνευμα, wind, relating to air.) Of or belonging to air or gas.

Pneumatic apparatus. See *Apparatus, pneumatic.*

Pneumatic trough. See *Apparatus, pneumatic.*

PNEUMATOCE'LE. (*e, es.* f.; πνευμα, wind, and κηλη, a tumour.) A tumour distended with gas. It has been applied especially to a distension of the scrotum with gas, which may happen when there is a scrotal hernia, and the intestine is distended with gas, or when the scrotum is emphysematous.

PNEUMATO'METER. (*Pneumatometrum, i.* n.; from πνευμα, air, and μετρον, a measure.) A graduated gasometer, by which the quantity of inspired air can be meausused.

PNEUMATO'MPHALUS. (From πνευμα, wind, and ομφαλος, the navel.) A hernia distended with gas.

PNEUMATO'SIS. (From πνευματοω, to inflate.) *Emphysema.* Windy swelling. A genus of disease in the Class *Cachexiæ*, and Order *Intumescentiæ*, of Cullen.

His species are,—

1. *Pneumatosis spontanea*, without any manifest cause.
2. *Pneumatosis traumatica*, from a wound.
3. *Pneumatosis venenata*, from poisons.
4. *Pneumatosis hysterica*, with hysteria.

Pneumatosis is known by a collection of air in the cellular texture under the skin, rendering it tense, elastic, and crepitating. Air in the cellular membrane is confined to one place, but, in a few cases, it spreads universally over the body, and occasions a considerable degree of swelling. It sometimes arises spontaneously, which is however, a very rare occurrence, or comes on immediately after child-birth, in consequence of rupture of the lungs; but it is most generally induced by some wound or injury done to the thorax, and which affects the lungs; in which case the air passes from these, through the wound, into a surrounding cellular membrane and from thence spreads over the whole body.

Pneumatosis is attended with an evident crackling noise, and elasticity upon pressure, and sometimes with much difficulty of breathing, oppression, and anxiety.

We are to consider it as a disease by no means unattended with danger; but more probably from the causes which give rise to it, than any hazard from the complaint itself. In every species the air may be let out by very small punctures with a lancet; and a bandage applied where it can be used. The poisonous species requires the internal administration of the antidote for the particular poison; and the

other species is cured by anti-hysterical remedies.

PNEUMOGA'STRIC NERVE. (Πνευμων, the lung, and γαστηρ, the belly, so named from its distribution.) *Nervus vagus. Par vagum.* A nerve which arises on each side by many filaments, from the lateral part of the medulla oblongata, immediately below the origin of the glosso-pharyngeal nerve. It passes out of the cranium along with the glosso-pharyngeal nerve, through the foramen lacerum posterius. Immediately after quitting the cranium, it is slightly enlarged for about an inch of its course, forming what is called its *ganglionic* enlargement. It descends in the neck at the outer and back part of the common carotid artery, in the cellular sheath of which it is included. In the neck it gives off the *pharyngeal* branch, the *superior laryngeal*, and twigs which contribute to form the *cardiac plexus*. It passes into the chest between the subclavian artery and vein, giving off the *inferior laryngeal* or *recurrent nerve* which twines round the subclavian artery on the right side, and the aorta on the left. In the chest it sends twigs contributing to the formation of the *pulmonary* and *œsophageal plexuses*. Lastly, entering the abdomen, it is finally dispersed on the stomach, sending twigs to the omentum and to the neighbouring abdominal plexuses.

PNEU'MO-HÆMORRHA'GIA. The name given by Andral to hæmorrhage from the lungs, as opposed to *broncho-hæmorrhagia*, or hæmorrhage from the bronchia.

PNEUMO'NIA. (*a, æ.* f.; from πνευμων, a lung.) See *Pneumonitis.*

PNEUMONI'TIS. (*is, idis.* f.; from πνευμων, the lung, and *itis*, inflammation.) Inflammation of the lung. This disease has also been called *Pneumonia*, *Peripneumonia*, and *Peripneumonia vera*. It is characterised by fever, difficulty of breathing, cough, and a sense of weight and pain in the thorax. It is mostly produced by the application of cold to the body, which gives a check to the perspiration, and determines a great flow of blood to the lungs. It attacks principally those of a robust constitution and plethoric habit, and occurs most frequently in the winter season and spring of the year; but it may arise in either of the other seasons, when there are sudden vicissitudes from heat to cold.

Other causes, such as violent exertions in singing, speaking, or playing on wind instruments, by producing an increased action of the lungs, have been known to occasion peripneumony. Those who have laboured under a former attack of this complaint, are much predisposed to returns of it.

The true peripneumony comes on with an obtuse pain in the chest or side, great difficulty of breathing (particularly in a recumbent position, or when lying on the side affected), together with a cough, dryness of the skin, heat, anxiety, and thirst. At the commencement of the disease the pulse is usually full, strong, hard, and frequent; but in a more advanced stage it is commonly weak, soft, and often irregular. In the beginning, the cough is frequently dry and without expectoration; but in some cases it is moist, even from the first, and the matter spit up is various both in colour and consistence, and is often streaked with blood.

If relief is not afforded in time, and the inflammation proceeds with such violence as to endanger suffocation, the vessels of the neck will become turgid and swelled; the face will alter to a purple colour; an effusion of blood will take place into the cellular substance of the lungs, so as to impede the circulation through that organ, and the patient will soon be deprived of life.

If these violent symptoms do not arise, and the proper means for carrying off the inflammation have either been neglected, or have proved ineffectual, although adopted at an early period of the disease, a suppuration may ensue, which event is to be known by frequent slight shiverings, and an abatement of the pain and sense of fulness in the part, and by the patient being able to lie on the side which was effected, without experiencing great uneasiness.

When peripneumony is not resolved, an effusion of blood takes place into the pulmonary substance, which becomes dark coloured, ceases to crepitate, and emits a bloody serum when cut into, which is the *engoument du poumon* of the French pathologists: or coagulable lymph, is thrown out, and the lung becomes solid and of the appearance of liver; whence this state is called *hepatisation:* or lastly, inflammation of the lung may terminate in abscess more or less extensive. From the first of these three states, that of *engoument*, the affected part may recover so as to resume its former functions; but a hepatised portion of lung never recovers its natural texture. Large portions of the lung, however, may be hepatised, and yet the remaining healthy portions may be sufficient to carry on respiration; and the patient may live, though the breathing can never be free. An abscess of the lungs may break into the bronchial tubes; the matter may be expectorated, and the patient may recover. Where pneumonia is very intense, the whole substance of the lungs becomes infiltrated with purulent matter, a state which is necessarily and speedily fatal. Gangrene of the lungs is not common, but sometimes occurs, and chiefly in exhausted constitutions. It is indicated by the peculiar fœtor of the expectoration. Portions of the lungs have sloughed away, and yet the patient has recovered; but this is very uncommon. Generally speaking, when acute inflammation of the lungs produces the state of engoument, hepatisation, or abscess, to any extent, the case is fatal.

When it goes off by resolution, some very evident evacuation almost always attends it; such as a great flow of urine, with a copious sediment, diarrhœa, a sweat diffused over the whole body, or a hæmorrhage from the nose; but the evacuation which most frequently terminates the complaint, and which does it with the greatest effect, is a free and copious expectoration of thick white or yellow matter, slightly streaked with blood; and by this the disease is carried off generally in the course of ten or twelve days.

Our opinion as to the event is to be drawn from the symptoms which are present. A high degree of fever, attended with delirium, great difficulty of breathing, acute pain, and dry cough, denote great danger; on the contrary, an abatement of the febrile symptoms, and of the difficulty of breathing, and pain, taking place on the coming on of a free expectoration, or the occurrence of any other critical evacuation, promise fair for the recovery of the patient.

In the early period of this disease we may hope, by active measures, to bring about immediate resolution; but when it is more advanced, we must look for a discharge by expectoration, as the means of restoring the part to a healthy state. We should begin by large and free bleeding, not deterred by the obscure pulse sometimes found in peripneumony; carrying this evacuation to faintness, or to the manifest relief of the breathing. In the subsequent use of this measure, we must be guided by the violence of the disease on the one hand, and the strength of the patient on the other: the scrofulous, in particular, cannot bear it to any extent; and it is more especially in the early part of the complaint, that it produces a full and decisive effect. Under doubtful circumstances it will be better to take blood locally, particularly when there are pleuritic symptoms: blisters may be used at the same time. The bowels must be well evacuated in the first instance, and subsequently kept regular; and antimonials may be given with great advantage, to promote the discharges from the skin and lungs. Peripneumony is one of the cases in which the use of very large doses of emetic tartar has been especially advocated. It is a much less certain remedy however than blood-letting, and more permanently debilitating in its effects. See *Antimonium tartarizatum* and *Inflammation*. Digitalis is proper also, as lessening the activity of the circulation. The antiphlogistic regimen is to be observed, except that the patient will not bear too free exposure to cold. To quiet the cough, demulcents may be of some use, or cooling sialagogues; but where the urgency of the symptoms is lessened by copious depletion, opiates are more to be relied upon: a little syrup of poppy, for instance, swallowed slowly, from time to time: or a full dose of opium may be given at night to procure sleep, joined with calomel and antimony, that it may not heat the system, but, on the contrary, assist them in promoting the secretions. Inhaling steam will occasionally assist in bringing about expectoration; or, where there is a wheezing respiration, squill in nauseating, or sometimes even emetic, doses may relieve the patient from the viscid matter collected in the air passages. When the expectoration is copious in the decline of the complaint, tonic medicines, particularly myrrh, with a more nutritious diet, become necessary to support the strength; and the same means will be proper, if it should go on to suppuration. Where there is a pthisical disposition, inflammation of the lungs frequently occasions the rapid development of tubercles, and consumption ensues.

PNEUMO'NIC. (*Pneumonicus*; from πνευμων, the lung.) Appertaining to th lungs.

PNEUMOPLEURI'TIS. (*is, idis.* f.; from πνευμων, the lung, and πλευρα, the pleura.) An inflammation of the lungs and pleura.

PNIGA'LIUM. (*um, i.* n.; from πνιγω, to suffocate.) The nightmare. A disorder in which the patient appears to be suffocated.

PNIX. (From πνιγω, to suffocate.) A sense of suffocation.

Pod. See *Siliqua.*

PO'DAGRA. (*a, æ.* f.; from πους, the foot, and αγρα, a taking, or seizure.) See *Gout.*

Podagra'ria. (*a, æ.* f.; from *podagra*, the gout: so called because it was thought to expel the gout.) See *Ægopodium.*

Pode'cium. (*um, ii.* n.; from πους, a foot.) The name given by Acharus to the peculiar footstalk of the tubercles in the cup lichens.

Podoni'ptrum. (*um, i.* n.; from πους, a foot, and νιπτω, to wash.) A bath for the feet.

PODOPHY'LLUM. (*um, i.* n.; from πους, a foot, and φυλλον, a leaf: so named from the shape of the leaf.) A genus of North American plants.

Podophyllum pelta'tum. May apple. The fruit of this plant is edible. The root is cathartic in the dose of a scruple. The leaves are said to be poisonous.

PODOTHE'CA. (*a, æ.* f.; from πους, a foot, and τιθημι, to put.) A shoe or stocking. An anatomical preparation, consisting of a kind of shoe of the scarf-skin, with the nails adhering to it, taken from a dead subject.

POECI'LIA. (*a, æ.* f. Ποικιλια; from ποικιλος, *versicolor.*) The piebald skin, or that affection found among negroes, in which it is marbled with alternate spots, or patches of black and white.

POISON. *Venenum. Toxicum.* That which, when applied externally, or taken into the human body, uniformly effects such a derangement in the animal economy as to produce disease, may be defined a poison. It is extremely difficult, however, to give a definition of a poison; and the above is subject to great inaccuracy.

Poisons are divided, with respect to the kingdom to which they belong, into animal, vegetable, mineral, and halituous, or aërial.

Poisons, in general, are only deleterious in certain doses; for the most active, in small doses form the most valuable medicines. There are nevertheless, certain poisons, which are really such in the smallest quantity, and which are never administered medicinally; as the poison of hydrophobia or the plague. There are likewise substances which are innocent when taken into the stomach, but which prove deleterious when taken into the lungs, or when applied to an abraded surface: thus carbonic acid is continually swallowed with fermented liquors, and thus the poison of the viper may be taken with impunity; whilst inspiring carbonic acid kills and the poison of the viper, inserted into the flesh, often proves fatal.

Several substances also act as poisonous when applied either externally or internally; as arsenic.

When a substance produces disease, not only in mankind, but in all animals, it is distinguished

by the term *common poison;* as arsenic, sublimate, &c.; whilst that which is poisonous to man only, or to animals, and often to one genus merely, is said to be a *relative poison;* thus aloes are poisonous to dogs and wolves; the *phellandrium aquaticum* kills horses, whilst oxen devour it greedily, and with impunity. It appears, then, that substances act as poisons only in regard to their *dose, the part of the body they are applied to,* and the *subject.*

Poisons enter the body in the following ways: —

1. Through the œsophagus by deglutition.
2. Through the anus, by clysters.
3. Through the lungs, by inhalation.
4. Through the absorbents of the skin with or without lesion of the cuticle.

The manner in which poisons enter the system, and act upon the textures or organs peculiarly liable to their influence, has been matter of much discussion. It is evident that every poison must act in one of two ways, either by being absorbed into the blood, and conveyed by the circulation to the parts which they especially affect, or by an impression made on the nerves of the part to which they are applied and communicated to distant parts by sympathy. The discoveries of M. Magendie on venous absorption, have induced many to believe that all poisons act through the blood; but the extraordinary rapidity of the action of several poisons, as prussic acid, and the poison of several highly venomous serpents, appears almost conclusive against such a supposition, as far as these poisons are concerned. With reference to others of slower operation, it is unquestionable that they are absorbed into the circulation, whether this be the sole condition of their operation or not. On the whole it seems probable, that in this, as in most other cases, truth lies between the extremes, and that some poisons act solely through nervous sympathy, and that others act chiefly, if not entirely, through the medium of the circulation.

Poisons have been arranged by Orfila, into four classes, namely, *irritant, narcotic, narcotico-acrid,* and *septic* or putrefiant. Dr. Christison, with apparent propriety, excludes the last or septic class, thus reducing poisons to three classes. The following enumeration of poisons is taken from his excellent treatise on poisons.

I. Irritant Poisons.

The characteristic operation of these is to excite inflammation of the alimentary canal in some part, or throughout the whole of its course. To this class belong

The three Mineral Acids.
Phosphorus.
Sulphur.
Chlorine.
Iodine.
Hydriodate of potash.
Bromine.
Oxalic acid.
The fixed alkalis.
Nitre.
Alkaline and earthy chlorides.
Lime.
Ammonia and its salts.
Alkaline sulphurets.
The compounds of arsenic.
The compounds of mercury.
The compounds of copper.
The compounds of antimony.
The compounds of tin, silver, gold, bismuth, chrome, and zinc.
The compounds of lead.
Baryta.
Euphorbia.
Castor oil seeds.
Physic nut.
Bitter cassada.
Manchineel.
Croton.
Bryony.
Colocynth.
Elaterium.
Ranunculus.
Anemone.
Caltha.
Clematis.
Trollius.
Mezereon.
Cuckoo-pint.
Gamboge.
Daffodil.
Jalap.
Savin.
Cantharides.
Poisonous fish.
Venomous serpents and insects.
Diseased and decayed animal matter.
Mechanical irritants.

II. Narcotic Poisons.

These are such as produce chiefly, or solely, symptoms of disorder of the nervous system. To this class belong

Opium.
Hyoscyamus.
Lactuca.
Solanum.
Hydrocyanic acid.
The vegetable substances which contain hydrocyanic acid — Bitter almonds — Cherry-laurel — Peach — Cluster cherry — Mountain ash.
Carbazotic acid.
Nitric oxide gas.
Chlorine gas.
Ammoniacal gas.
Muriatic acid gas.
Sulphuretted hydrogen.
Carburetted hydrogen.
Carbonic acid.
Carbonic oxide.
Nitrous oxide.
Cyanogen.
Oxygen.

III. Narcotico-acrid Poisons.

These possess a double action, being both local irritants, like those of the first class, and producing a remote effect on the nervous system, like those of the second. To this class belong

Nightshade.
Thornapple.
Tobacco.
Hemlock.
Water hemlock.
Hemlock dropwort.
Fool's parsley.

Monk's-hood.
Black hellebore.
Ipecacuan.
Squill.
White hellebore.
Meadow saffron.
Fox-glove.
Strychnia.
Nux vomica.
St. Ignatius's bean.
False angustura.
Camphor.
Cocculus indicus.
Upas antiar.
Coriaria myrtifolia.
Poisonous fungi.
Poisonous mosses.
Secale cornutum.
Mouldy bread.
Darnel grass.
Seeds of lathyrus cicera.
Seeds of the bitter vetch.
Seeds of the common laburnum.
Alkohol.
Ether.
Some empyreumatic oils.

Method of detecting Poisons.

When sudden death is suspected to have been occasioned by the administration of poison, either willfully or by accident, the testimony of the physician is occasionally required to confirm or invalidate this suspicion. He may also be sometimes called upon to ascertain the cause of the noxious effects arising from the presence of poisonous substances in articles of diet; and it may, therefore, serve an important purpose, to point out concisely the simplest and most practicable modes of obtaining, by experiment, the necessary information.

The only poisons, however, that can be clearly and decisively detected by chemical means, are those of the mineral kingdom. Arsenic and corrosive sublimate are most likely to be exhibited with the view of producing death; and lead and copper may be introduced undesignedly, in several ways, into our food and drink. The continued and unsuspected operation of the two last may often produce effects less sudden and violent, but not less baneful to health and life, than the more active poisons; and their operation generally involves, in the pernicious consequences, a greater number of sufferers.

Method of detecting arsenic. This is detailed under the head *Arsenious acid.*

Method of detecting corrosive sublimate, baryta, &c. — Corrosive sublimate (the bichloride or oxymuriate of mercury), next to arsenic, is the most virulent of the metallic poisons. It may be collected by treating the contents of the stomach in the manner already described; but as it is more soluble than arsenic, viz. in about nineteen times its weight of water, no more water must be employed than is barely sufficient, and the washings must be carefully preserved for examination.

If a powder should be collected by this operation, which proves, on examination, not to be arsenic, it may be known to be corrosive sublimate by the following characters: —

A. Expose a small quantity of it, without any admixture, to heat in a coated glass tube, as directed in the treatment of arsenic. Corrosive sublimate will be ascertained by its rising to the top of the tube, lining the inner surface in the form of a shining white crust.

B. Dissolve another portion in distilled water; and it may be proper to observe how much of the salt the water is capable of taking up.

C. To the watery solution add a little lime-water. A precipitate of an orange-yellow colour will instantly appear.

D. To another portion of the solution add a single drop of a dilute solution of subcarbonate of potash (salt of tartar). A white precipitate will appear: but, on a still further addition of alkali, an orange-coloured sediment will be formed.

E. The carbonate of soda has similar effects.

F. Sulphuretted water throws down a dark-coloured sediment, which, when dried and strongly heated, is wholly volatilised, without any odour of garlic.

For the detection of corrosive sublimate, Sylvester has recommended the application of galvanism, which exhibits the mercury in a metallic state. A piece of zinc wire, or, if that cannot be had, of iron wire about three inches long, is to be twice bent at right angles, so as to resemble the Greek letter Π. The two legs of this figure should be distant about the diameter of a common gold wedding ring from each other, and the two ends of the bent wire must afterwards be tied to a ring of this description. Let a plate of glass, not less than three inches square, be laid as nearly horizontal as possible, and on one side drop some sulphuric acid, diluted with about six times its weight of water, till it spreads to the size of a halfpenny. At a little distance from this, towards the other side, next drop some of the solution supposed to contain corrosive sublimate, till the edges of the two liquids join together; and let the wire and ring prepared as above be laid in such a way that the wire may touch the acid, while the gold ring is in contact with the suspected liquid. If the minutest quantity of corrosive sublimate be present, the ring in a few minutes will be covered with mercury on the part which touched the fluid.

Smithson remarks, that all the oxides and saline compounds of mercury, if laid in a drop of marine acid on gold, with a bit of tin, quickly amalgamate the gold. In this way, a very minute quantity of corrosive sublimate, or a drop of its solution, may be tried, and no addition of muriatic acid is then required. Quantities of mercury may thus be rendered evident, which could not be so by any other means. Even the mercury of cinnabar may be exhibited; but it must previously be boiled with a little sulphuric acid in a platinum spoon, to convert it into sulphate. An exceedingly minute quantity of metallic mercury in any powder may be discovered by placing it in nitric acid on gold, drying, and adding muriatic acid and tin.

The only mineral poison of great virulence that has not been mentioned, and which, from its being little known to act as such, it is very

improbable we should meet with, is the carbonate of baryta. This, in the country where it is found, is employed as a poison for rats, and there can be no doubt would be equally destructive to human life. It may be discovered by dissolving it in muriatic acid, and by the insolubility of the precipitate which this solution yields on adding sulphuric acid, or sulphate of soda. Soluble barytic salts, if these have been the means of poison, will be contained in the water employed to wash the contents of the stomach, and will be detected, on adding sulphuric acid, by a copious precipitate.

It may be proper to observe, that the failure of attempts to discover poisonous substances in the alimentary canal after death, is by no means a sufficient proof that death has not been occasioned by poison. For it has been clearly established, by experiments made on animals, that a poison may be so completely evacuated, that no traces of it shall be found, and yet that death may ensue from the morbid changes which it has occasioned in the alimentary canal, or in the general system.

Method of detecting copper or lead. — Copper and lead sometimes gain admission into articles of food, in consequence of the employment of kitchen utensils of these materials.

1. If copper be suspected in any liquor, its presence will be ascertained by adding a solution of pure ammonia, which will strike a beautiful blue colour. If the solution be very dilute, it may be concentrated by evaporation; and if the liquor contain a considerable excess of acid, like that used to preserve pickles, as much of the alkali must be added as is more than sufficient to saturate the acid. In this, and all other experiments of the same kind, the fluid should be viewed by reflected, and not by transmitted light.

If into a newly preparedt incture of guaiacum wood we drop a concentrated solution of a salt of copper, the mixture instantly assumes a blue colour. This effect does not take place when the solution is very weak, for example, when there is not above half a grain of the salt to an ounce of water; but then, by the addition of a few drops of prussic acid, the blue colour is instantly developed of great purity and intensity. This colour is not permanent, but soon passes to a green, and at length totally disappears. For want of prussic acid, distilled laurel water may be employed. The test produces its effect, even when the proportion of the salt of copper to the water does not exceed 1–45000th. In this minute proportion no other test, whether the prussiate of potash, soda, or ammonia, gives the least indication of copper. — *Quart. Journ.* x. 182.

2. Lead is occasionally found, in sufficient quantity to be injurious to health, in water that has passed through leaden pipes, or been kept in leaden vessels, and sometimes even in pump water, in consequence of that metal having been used in the construction of the pump. Acetate of lead has also been known to be fraudulently added to bad wines, with the view of concealing their defects.

Lead may be discovered by adding, to a portion of the suspected water, about half its bulk of water impregnated with sulphuretted hydrogen gas. If lead be present, it will be manifested by a dark brown or blackish tinge. This test is so delicate, that water condensed by the leaden worm of a still-tub, is sensibly affected by it. Lead is also detected by a similar effect ensuing on the addition of sulphuret of ammonia, or potash.

The adequacy of this method, however, to the discovery of very minute quantities of lead, has been set aside by the experiments of Dr. Lambe, the author of a skilful analysis of the springs of Leamington Priors, near Warwick. By new methods of examination, he has detected the presence of lead in several spring waters that manifest no change on the addition of the sulphuretted test; and has found that metal in the precipitate separated from such waters by the carbonate of potash, or of soda. In operating on these waters, Dr. Lambe noticed the following appearances: —

a. The test forms sometimes a dark cloud, with the precipitate affected by alkalies, which has been re-dissolved in nitric acid.

b. Though it forms, in other cases, no cloud, the precipitate itself becomes darkened by the sulphuretted test.

c. The test forms a white cloud, treated with the precipitate as in *a*. These two appearances may be united.

d. The test neither forms a cloud, nor darkens the precipitate.

e. In the cases *b*, *c*, *d*, heat the precipitate, in contact with an alkaline carbonate, to redness; dissolve out the carbonate by water, and treat the precipitate as in *a*. The sulphuretted test then forms a dark cloud with the solution of the precipitate. In these experiments, it is essential that the acid, used to re-dissolve the precipitate, shall not be in excess; and if it should so happen, that excess must be saturated before the test is applied. It is better to use so little acid, that some of the precipitate may remain undissolved.

f. Instead of the process *e*, the precipitate may be exposed, without addition, to a red heat, and then treated as in *a*. In this case, the test will detect the metallic matter; but with less certainty than the foregoing one.

The nitric acid used in these experiments should be perfectly pure; and the test should be recently prepared by saturating water with sulphuretted hydrogen gas. A few drops of nitric acid, added to a water containing lead, which has been reduced to 1–8th or 1–10th its bulk by evaporation, and then followed by the addition of a few drops of hydriodate of potash, produces a yellow insoluble precipitate.

Another mode of analysis, employed by Dr. Lambe, consists in precipitating the lead by solution of common salt; but as muriate of lead is partly soluble in water, this test cannot be applied to small portions of suspected water. The precipitate must be, therefore, collected from two or three gallons, and heated to redness with twice its weight of carbonate of soda. Dissolve out the soda; add nitric acid, saturating any superfluity, and then apply the sulphuretted test. Sulphate of soda would be

found more effectual in this process than the muriate, on account of the greater insolubility of sulphate of lead. This property, indeed, renders sulphate of soda an excellent test of the presence of lead, when held in solution by acids, for it throws down that metal, even when present in very small quantity, in the form of a heavy white precipitate, which is not soluble by acetic acid.

The third process, which is the most satisfactory of all, and is very easy, except for the trouble of collecting a large quantity of precipitate, is the actual reduction of the metal, and its exhibition in a separate form. The precipitate may be mixed with its own weight of alkaline carbonate, and exposed either with or without the addition of a small proportion of charcoal, to a heat sufficient to melt the alkali. On breaking the crucible, a small globule of lead will be found reduced at the bottom. The precipitate from about fifty gallons of water yielded Dr. Lambe, in one instance, about two grains of lead.

For discovering the presence of lead in wine, a test invented by Dr. Hahnemann, and known by the title of Hahnemann's wine test, may be employed. This test is prepared by putting together, into a small phial, sixteen grains of sulphuret of lime, prepared in the dry way (by exposing to a red heat, in a covered crucible, equal weights of powdered lime and sulphur, accurately mixed), and twenty grains of bitartrate of potash (cream of tartar). The phial is to be filled with water, well corked, and occasionally shaken for the space of ten minutes. When the powder has subsided, decant the clear liquor, and preserve it in a well-stopped bottle for use. The liquor, when fresh prepared, discovers lead by a dark-coloured precipitate. A farther proof of the presence of lead in wines is the occurrence of a precipitate on adding a solution of the sulphate of soda.

Sylvester has proposed the gallic acid as an excellent test of the presence of lead.

The quantity of lead which has been detected in sophisticated wine may be estimated at forty grains of the metal in every fifty gallons.

When a considerable quantity of acetate of lead has been taken into the stomach (as sometimes, owing to its sweet taste, happens to children), after the exhibition of an active emetic, the hydro-sulphuret of potash or of ammonia may be given; or probably a solution of sulphate of soda (Glauber's salt) would render it innoxious. — *Henry's Chemistry.*

Treatment of Poisoning.

In the instance of internal poisoning, the great object of the physician is to administer an antidote or counterpoison. Antidotes are of two kinds. One kind takes away the deleterious qualities of the poison before it comes within its sphere of action, by altering its chemical nature. The other controls its poisonous action after it has begun, by exciting a contrary action in the system. In the early ages of medicine almost all antidotes were believed to be of the latter description, but in fact very few antidotes of the kind are known.

The chemical antidotes operate in several ways, according to the mode of action of the poison for which they are given. If the poison is a pure corrosive, such as a mineral acid, it will be sufficient that the antidote destroy its corrosive quality: thus the addition of an alkali or earth will neutralize sulphuric acid, and destroy, or at least prodigiously lessen its poisonous properties. In applying this rule care must be taken to choose an antidote which is either inert, or, if poisonous, is, like the poison for which it is given, a pure corrosive or local irritant, and one whose properties are reciprocally neutralized.

If the poison, on the other hand, besides possessing a local action, likewise acts remotely through absorption, or by an impression on the inner coat of the vessels, mere neutralization of its chemical properties is not sufficient; for we have seen above that such poisons act throughout all their chemical combinations which are soluble. Here, therefore, it is necessary that the chemical antidote render the poison insoluble or nearly so; and insoluble not only in water, but likewise in the animal fluids, more particularly the juices of the stomach. The same quality is desirable even in the antidotes for the pure corrosives; for it often happens that in their soluble combinations these substances retain some irritating, though not any corrosive power. When we try by the foregoing criterions many of the antidotes which have been proposed for various poisons, they will be found defective, as precise experiments have in recent times actually proved them to be.

The other kind of antidote operates not by altering the form of the poison, but by exciting in the system an action contrary to that established by the poison. On considering attentively, however, the phenomena of the action of individual poisons, it will be found exceedingly difficult to say what is the essence of a contrary action, and still more how that counter action is to be brought about. Accordingly, few antidotes of the kind are known. Neither physiology nor experience has yet brought to light any mode of inducing an action counter to that caused by arsenic and most of the irritant class of poisons. It appears probable that the remote operation of lead may be sometimes corrected by mercury given to salivation, and that the violent salivation caused by mercury may be occasionally corrected by nauseating doses of antimony. But these are the only instances which occur to me at present of antidotes for irritant poisoning which operate by counter action, unless we choose to designate by the name of antidote the conjunction of remedial means which constitute the antiphlogistic method of cure. In the class of narcotics we are acquainted with equally few constitutional antidotes, although the nature of the action of these poisons seems better to admit of them. Ammonia is to a certain extent an antidote for hydrocyanic acid, but by no means so powerful as some persons believe; and it is doubtful whether in this class of poisons we can with any propriety mention another antidote of the constitutional kind.

On the whole, then, it is chiefly among the changes induced by chemical affinities that the practitioner must look for counter-poisons; and the ingenuity of the toxicologist has thence supplied the materia medica with many of singular efficacy. When given in time, magnesia or chalk is a complete antidote for the mineral acids and oxalic acid, albumen for corrosive sublimate and verdigris, bark for tartar emetic, common salt for lunar caustic, sulphate of soda or magnesia for sugar of lead and muriate of baryta, chloride of lime or soda for liver of sulphur, vinegar, or oil for the fixed alkalis; and these substances act either by neutralizing the corrosive power of the poison, or by forming with it an insoluble compound.

In the instance of external poisoning the main object of the practitioner is to prevent the poison from entering the blood, or to remove it from the local vessels which it has entered.

One mode which has been known to the profession from early times, and after being long in disuse was lately revived by Dr. Barry, and applied with success to man, is the application of cupping glasses to the part where the poison has been introduced. This method may act in various ways. It certainly prevents the farther absorption of the poison by suspending for a time the absorbing power of the vessels of the part covered by the cup. It also sucks the blood out of the wound, and consequently washes the poison away with it. But it possibly it likewise compresses the nerves around, and prevents the impression made by the poison on their sentient extremities from being transmitted along their filaments.

Another mode is by the application of a ligature between the injured part and the trunk, so as to check the circulation. This is a very ancient practice in the case of poisoned wounds, and is known even to savages. But as usually practised it is only a temporary cure. As soon as the ligature is removed the effects of the poison begin. It may be employed, however, for many kinds of poisoning through wounds, so as to effect a radical cure. We have seen that most poisons of the organic kingdom are in no long time either thrown off by the system or decomposed in the blood; hence, if the quantity given has not been too large, recovery will take place. Now, by means of a ligature, which is removed for a short time at moderately distant intervals, a poison, which has been introduced into a wound beyond the reach of extraction, may be gradually admitted into the system in successive quantities, each too small to cause death or serious mischief, and be thus in the end entirely removed and destroyed. Such is a practical application which may be made of some ingenious experiments performed not long ago by M. Bouillaud with strychnia, the poisonous principle of nux vomica.

The last mode to be mentioned is by a combination of the ligature with venesection, deduced by M. Vernière from his experimental researches. Suppose a fatal dose of extract of nux vomica has been thrust into the paw of a dog; M. Vernière applies a tight ligature round the limb, next injects slowly as much warm water into the jugular vein as the animal can safely bear, and then slackens the ligature. The state of venous *plethora* thus induced completely suspends absorption. The ligature is next tied so as to compress the veins without compressing the arteries of the limb, and a vein is opened between the wound and the ligature in such a situation, that the blood which flows out must previously pass through, or at least near, the poisonous wound. When a moderate quantity has been withdrawn, the ligature may be removed with safety; and the extraction of the poison may be farther proved by the blood that has been drawn being injected into the veins of another animal; for rapid death by tetanus will be the result. It is not improbable that in this plan the preliminary production of venous plethora may be dispensed with; and then the treatment may be easily and safely applied to the human subject. — *Christison.*

The following is a brief sketch of the treatment, in cases of the effects of some of the principal poisons.

Arsenic. For the treatment of poisoning by arsenic, see *Arsenious acid.*

Bismuth. No specific antidote is known for the oxide, or for the subnitrate of this metal. Milk and mucilaginous diluents should be given along with purgatives.

Salts of copper. The sulphurets of the alkalis, sugar, and albumen, have all gained reputation as antidotes to these poisons: the alkaline sulphurets are now entirely disregarded; albumen and sugar have each been made the subject of recent experiments, and both appear to be of some utility, though neither have any claim to rank as specifics.

Emetic tartar. See *Antimonium tartarizatum.*

Preparations of lead. The antidote to these is Epsom or Glauber's salts, the acid of which forms an insoluble and harmless sulphate.

Preparations of mercury. The only one of these much known as a poison is the corrosive sublimate. Its antidote is albumen: as soon, therefore, as it is known to have been swallowed, the white of eggs should be given, mixed with water, every two or three minutes. If eggs cannot be obtained, large draughts of milk may be useful as a substitute. Inflammation is to be combated by the ordinary means, as also the ptyalism occasioned by this in common with the other preparations of mercury.

Preparations of silver. Of these the nitrate only requires to be noticed. It is decomposed by muriate of soda. A table-spoonful of common salt may be dissolved in a pint of water, and a wine glassful given every five minutes. This may be followed by mucilaginous drinks.

Preparations of tin. These are decomposed by all vegetable infusions and animal fluids. Milk is as good an antidote as any.

Zinc. The sulphate of zinc or white vitriol will generally prove an antidote to itself, being one of the most powerful emetics known. The vomiting should be encouraged by diluents, and any bad consequences that may ensue, treated on ordinary principles.

Little is known of the effects of the oxide; it is however poisonous.

The mineral acids. When the sulphuric, nitric, or muriatic acid has been swallowed, calcined magnesia mixed with water should be immediately administered; or if this be not at hand, chalk, which can almost always be procured in one form or another, may be substituted for it. Neither chalk nor the alkaline carbonates are to be preferred, on account of the great extrication of gas occasioned by their decomposition; but either these or soap may be given in the absence of the more appropriate antidote. Water alone should not be given in the case of poisoning by sulphuric acid, on account of the strong heat generated by their mixture. Bland diluents are to be used when the acid is neutralised. Inflammation is to be obviated by the ordinary means.

Oxalic acid. The antidote for this is calcined magnesia or chalk, which give rise to the formation of insoluble salts. Alkalis are little better than useless, as they form with soluble salts, which are themselves irritant poisons, though in a less degree than the acid.

Hydrocyanic acid. In any considerable dose this is almost immediately fatal. The exhibition of strong stimuli, as brandy, ammonia, &c., form the only treatment likely to be useful. Emetics promise little on account of the highly diffusible nature of the poison.

Alkalis and their carbonates. These are best neutralised by vinegar.

Nitre. Mucilaginous diluents and opium are most serviceable: bleeding may also be required.

Lime. For this also the best antidote is vinegar.

Baryta and its salts. Sulphate of magnesia causes the formation of an insoluble sulphate, and should therefore be given largely, diluted with water.

Muriate of ammonia. Vomiting is to be encouraged by large draughts of warm water, and inflammatory or nervous symptoms to be treated in the ordinary way.

Phosphorus. No antidote is known for this. Large draughts of water are naturally indicated.

Alkohol. The effects of excessive intoxication from alkoholic liquors, are best counteracted by the immediate use of a strong emetic, as the sulphate of zinc or copper. Vomiting should be encouraged by draughts of warm water, and the intestines stimulated by saline enemata. Should there appear to be great determination of blood to the head, venesection and the application of cold to the head are indicated.

Acrid vegetable poisons. For these we have no specific antidote. The fruit of the *Feuillea cordifolia*, has indeed been recommended by M. Drapier, on the strength of numerous experiments, as possessed of great power; but these experiments require confirmation. The same general treatment is applicable in all cases of poisoning by acrid vegetable substances. If the poison has occasioned vomiting, it is to be encouraged by large draughts of warm water; and if the sensibility of the stomach has been over powered, vomiting is to be excited by the sulphate of zinc or other active emetic (not antimony), and the intestines stimulated by purgatives which are not of an acrid character. Inflammation of particular textures is to be treated on the usual principles.

Narcotic and narcotico-acrid vegetable poisons. The first indication is to evacuate the stomach by the sulphate of zinc, copper, or other active emetic, and to clear the bowels by strong cathartics administered by the mouth and rectum. When the poison is evacuated, a strong infusion of coffee or vinegar, diluted with water, may be given with advantage. Determination of blood to the head, and inflammation of particular textures are to be obviated by the usual means, but with due reference to the depressed state of the nervous power. If the surface become cold, friction, and the application of warmth are indicated, and the internal use of ammonia may sometimes be useful.

Poison of fish. The symptoms arising from eating poisonous fish, are so anomalous and variable, that general rules for their treatment can hardly be given, and the practitioner is thrown on his individual judgment in each particular case; vomiting and purging, and diluents, are indicated to get rid of the offending matter, and weak alkaline solutions have been thought useful. Spasm is to be allayed by opium, and inflammation by the ordinary means.

Cantharides. Sweet oil should be given in large quantity to excite vomiting, and linseed tea or milk, as a demulcent. Emollient enemata are to be administered. Inflammation of the intestinal canal or urinary passages is to be treated on ordinary principles.

Bite of venomous serpents. The first indication is to prevent the absorption of the poison, which is fulfilled by the instantaneous application of a tight ligature above the wound. The bitten part is then to be cut out, or destroyed by caustic. The application of a dry cupping-glass may suspend the absorption of the poison but such an apparatus is seldom at hand, under circumstances in which persons are liable to be bitten by serpents, and it also requires to be removed before the knife or caustic can be applied to the part; the ligature is, therefore every way preferable. Immediately sucking the wound is an efficacious mode of extracting at least some of the poison, and it may be done with impunity, if the cuticle of the lips and lining membrane of the mouth be every where entire. The second indication is to support the system against the effect of the virus, if absorbed: this is to be attempted by the use of powerful stimulants, especially ammonia combined with diaphoretics. The Tanjore pill so celebrated in India as an antidote to the bites of serpents, is said to consist of arsenic pepper, mercury, and the juice of the *Asclepias gigantea*. The inflammation of the surrounding parts, which follows the bite of some serpents, is of the unhealthy kind, tending to gangrene, and is to be treated accordingly.

Venomous insects. Hartshorn and oil may be gently rubbed on the injured part; and if much inflammation ensue, an emollient poultice may be applied.

Poison-oak. See *Rhus toxicodendron.*

POLEMO'NIUM. (*um, ii.* n.; an a

ient name derived from πολεμος, war, because, ccording to Pliny, kings had contended for he honour of its discovery.) 1. The name of a enus of plants in the Linnæan system. Class, Pentandria; Order, Monogynia.

2. Wild sage, or *Teucrium scorodonia* of Linæus.

POLEMONIUM CÆRULEUM. The systematic ame of the Greek valerian, or Jacob's ladder, he root of which is esteemed by some as a good stringent against diarrhœas and dysentery.

Poley-mountain. See *Teucrium.*

POLIO'SIS. (*is, is.* f.; from πολος, *canidus*, white or hoary.) A disease of the hairs, n which they are prematurely gray or hoary.

PO'LIUM. (*um, ii.* n.; from πολιος, white: o called from its white capillaments.) Poley. Teucrium of Linnæus.

Polium creticum. See *Teucrium.*

Polium montanum. See *Teucrium.*

Pollack. See *Gadus pollacius.*

PO'LLEN. (*en. inis.* n.; fine flour or ust.) Farina of flowers. The powder which dheres to the anthers of the flowers of plants, nd which is contained in the anther, and is arown out chiefly in warm dry weather, when he coat of the latter contracts and bursts. The ollen, though to the naked eye a fine powder, nd light enough to be wafted along by the air, so curiously formed, and so various in different plants, as to be an interesting and popular bject for the microscope. It is so minute, hat the naked eye cannot see its beauty; but, y the assistance of a glass, it is found to be ery different in different plants. Each grain it is commonly a membranous bag, round, angular, rough or smooth, which remains ntire till it meets with any moisture, being ontrary in this respect to the nature of the nther; then it bursts with great force, discharging its subtile and vivifying vapour. It is,

1. *Echinate* in the *Helianthus annuus.*
2. *Perforate* in *Geraniums.*
3. *Didymous* in *Symphytum.*
4. *Dentate* in *Mallow.*
5. *Angulate* in *Viola odorata.*
6. *Reniforme* in *Narcissus;* and,
7. *Convolute* in *Borago.*

PO'LENIN. The pollen of tulips has been certained by professor John to contain a peliar substance, insoluble in alkohol, ether, ater, oil of turpentine, naphtha, carbonated d pure alkalis; extremely combustible, rning with great rapidity and flame; and nce used at the theatres to imitate lightning.

PO'LLEX. (*ex, icis.* m.; so called, *quod et potestate inter ceteros digitus plurimum polt.*) The thumb, or great toe.

POLYADE'LPHIA. (*a, æ.* f.; from πολυς, any, and αδελφος, a brother.) The name a class of plants in the sexual system of nnæus, embracing plants with hermaphrodite wers, in which several stamina are united their filaments into three or more distinct ndles.

POLYA'NDRIA. (*a, æ.* f.; from πολυς, any, and ανηρ, a husband.) The name of a ass of plants in the sexual system of Linnæus. consists of plants with hermaphrodite flowers, furnished with several stamina, that are inserted into the common receptacle of the flower; by which circumstance this class is distinguished from *Icosandria*, in which the striking character is the situation of the stamina on the calyx or petals.

POLYCHRE'STUS. (From πολυς, much, and χρηστος, useful.) Polychrest. Having many virtues, or uses. An epithet formerly applied to several medicines, especially sulphate of potash. See *Sal polychrestus.*

POLY'CHROITE. (From πολυς, many, and χροα, colour: so called because it is susceptible of so many changes of colour.) The colouring matter of saffron. Its solution in water or alkohol is bright yellow. Sulphuric acid turns it first blue, and then lilac. Nitric acid gives it a green tint.

POLYDI'PSIA. (*a, æ.* f.; from πολυς, much, and διψη, thirst.) Excessive thirst. It is mostly symptomatic of fever, dropsy, excessive discharges, or poisons. See *Thirst.*

POLY'GALA. (*a, æ.* f.; from πολυς, much, and γαλα, milk: so named from the abundance of its milky juice.) 1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia;* Order, *Octandria.*

2. The pharmacopœial name of the common milk-wort. See *Polygala vulgaris.*

POLYGALA AMARA. This is a remarkably bitter plant, and, though not used in this country, promises to be as efficacious as those in greater repute. It has been given freely in phthisis pulmonalis, and, like other remedies, failed in producing a cure; yet, as a palliative, it claims attention. Its virtues are balsamic, demulcent, and corroborant.

POLYGALA SENEGA. The systematic name of the rattlesnake milk-wort. *Seneka. Polygala —floribus imperbibus spicatis, caule erecto herbaceo simplicissimo, foliis ovato-lanceolatis,* of Linnæus. The root of this plant was formerly much esteemed as a specific against the poison of the rattlesnake, and as an antiphlogistic in pleurisy, pneumonia, &c.; but it is now very little employed. Its dose is from ten to twenty grains; but when employed, it is generally used in the form of decoction, which, when prepared according to the formula of the Edinburgh Pharmacopœia, may be given every second or third hour.

POLYGALA VULGARIS. The systematic name of the common milk-wort. The root of this plant is somewhat similar in taste to that of the seneka, but much weaker. The leaves are very bitter, and a handful of them, infused in wine, is said to be a safe and gentle purge.

POLYGALIC ACID. An acid lately found by Peschier in the *Polygala senega*, and other species.

POLY'GALINE. A bitter alkaline principle found in several species of polygala.

POLYGA'MIA. (*a, æ.* f.; from πολυς, many, and γαμος, a marriage. Polygamy.) The name of a class of plants in the sexual system of Linnæus, consisting of polygamous plants, or plants having hermaphrodite flowers, and likewise male and female flowers, or both. The orders of this division are, according to the

beautiful uniformity or plan which runs through this ingenious system, distinguished upon the principles of the Classes *Monœcia*, *Diœcia*, and *Triœcia*. It has the five following orders: —

1. *Polygamia æqualis.* The name of an order of Class *Syngenesia*, of the sexual system of plants. The florets are all perfect or united; that is, each furnished with perfect stamens.

2. *Polygamia frustranea.* Florets of the disk, with stamens and pistil: those of the radius with merely an abortive pistil, or with not even the rudiments of any.

3. *Polygamia necessaria.* Florets of the disk, with stamens only: those of the radius, with pistils only.

4. *Polygamia segregata.* Several flowers, either simple or compound, but with united anthers, and with a proper calyx, included in one common calyx.

5. *Polygamia superflua.* Florets of the disk, with stamens and pistil: those of the radius with pistil only; but each, of both kinds, forming perfect seed.

POLYGO'NATUM. (*um, i.* n.; from πολυς, many, and γονυ, a joint: so named from its numerous joints or knots.) Solomon's seal. See *Convallaria polygonatum.*

POLY'GONUM. (*um, i.* n.; from πολυς, many, and γονυ, a joint: so named from its numerous joints.) The name of a genus of plants in the Linnæan system. Class, *Octandria*; Order, *Trigynia*. Knot-grass.

Polygonum aviculare. The systematic name of the knot-grass. *Centumnodia. Polygonum latifolium. Polygonum mas. Sanguinaria.* This plant is never used in this country: it is said to be useful in stopping hæmorrhages, diarrhœas, &c; but little credit is to be given to this account.

Polygonum bacci'ferum. A species of equisetum, or horse-tail.

Polygonum bistorta. The systematic name of the officinal bistort, called *bistorta* in the pharmacopœias. *Polygonum — caule simplicissimo monostachio, foliis ovatis in petiolum decurrentibus,* of Linnæus. This plant is a native of Britain. Every part manifests a degree of stypticity to the taste, and the root is esteemed to be one of the most powerful of the vegetable astringents, and frequently made use of as such in disorders proceeding from a laxity and debility of the solids, for restraining alvine fluxes, after due evacuations, and other preternatural discharges both serous and sanguineous. It has been sometimes given in intermittent fevers; and sometimes, also, in small doses, as a corroborant and antiseptic, in acute malignant and colliquative fevers; in which intentions Peruvian bark has now deservedly superseded both these and all other astringents. The common dose of bistort root, in substance, is fifteen or twenty grains: in urgent cases it is extended to a drachm. Its astringent matter is totally dissolved both by water and rectified spirits.

Polygonum divaricatum. The systematic name of the eastern buck-wheat plant. The roots, reduced to a coarse meal, are an ordinary food of the Siberians.

Polygonum fago'pyrum. The systematic name of the buck-wheat, the grain of which is in common use for making bread in Russia, Germany, and Switzerland.

Polygonum hydro'piper. The systematic name of the poor man's pepper: called also, biting arsmart, lake-weed, and water-pepper; and *Hydropiper* in the pharmacopœias. This plant is very common by the sides of our ditches and on waste lands: the leaves have an acrid burning taste, and seem to be nearly of the same nature with those of the arum. They have been recommended as possessing antiseptic, aperient, diuretic virtues; and given in scurvies and cachexies, asthmas, hypocondriacal and nephritic complaints, and wandering gout. A decoction of the leaves is used in Persia as a gargle against ulcerated sore throat with fever (our malignant sore throat). The first leaves have been applied externally, as a stimulating cataplasm.

Polygonum latifolium. Common knot-grass. See *Polygonum aviculare.*

Polygonum mas. See *Polygonum aviculare.*

Polygonum minus. Rupture-wort. See *Herniaria glabra.*

Polygonum persicaria. The systematic name of the *Persicaria* of the old pharmacopœias. *Persicaria mitis. Plumbago.* This plant is said to possess vulnerary and antiseptic properties; with which intentions it is given in wine to restrain the progress of gangrene.

Polygonum selenoides. Parsley break-stone.

POLYPE'TALOUS. (*Polypetalus*; from πολυς, many, and πεταλον, a leaf.) Many-petaled.

POLYPHY'LLOUS. (*Polyphyllus*; from πολυς, many, and φυλλον, a leaf.) Many-leaved.

POLYPO'DIUM. (*um, ii.* n.; from πολυς, many, and πους, a foot: so called because it has many roots.) The name of a genus of plants in the Linnæan system. Class, *Cryptogamia*; Order, *Filices.* Fern, or polypody.

Polypodium aculeatum. Spear-pointed fern. Fallen into disuse.

Polypodium barometz. This singular fern is commonly called the Tartarean or Scythian lamb; having more or less resemblance to a lamb. It is now referred to the genus *Aspidium.*

Polypodium calaguala. The root of this plant, called in the shops *radix calaualæ*, has been exhibited internally, with success, in dropsy; and it is said to be efficacious in pleurisy, contusions, abscesses, &c. It was first used in America, where it is obtained; and Italian physicians have since written concerning it, in terms of approbation.

Polypodium filix mas. See *Aspidium.*

Polypodium quercinum. See *Polypodium vulgare.*

Polypodium vulgare. Polypody of the oak. *Polypodium quercinum.* The root has a sweetish taste: a decoction of it was formerly used as a purgative.

Polypody of the oak. See *Polypodium vulgare.*

PO'LYPUS. (*us, i.* m.; from πολυς, many and πους, a foot: from its sending off many ramifications, like legs.) 1. The name of a genus of zoophytes.

2. A tumour, most commonly met with in the nose, uterus, or vagina, which has received its name from an erroneous idea that it usually had several roots or feet, like zoophyte polypi.

Polypi vary from each other, according to the different causes that produce them, and the alterations that happen in them. Sometimes a polypus of the nose is owing to a swelling of the pituitary membrane, which swelling may possess a greater or less space of the membrane, as also its cellular substance, and may affect either one or both nostrils. At other times it arises from an ulcer produced by a caries of some of the bones which form the internal surface of the nostrils. Polypi are sometimes so soft, that upon the least touch they are lacerated and bleed; at other times they are very compact, and even schirrhous. Some continue small a great while; others increase so fast as, in a short time, to push out at the nostrils, or extend backwards towards the throat. Le Dran mentions, that he has known them fill up the space behind the uvula, and, turning towards the mouth, have protruded the fleshy arch of the palate so far forwards as to make it parallel with the third *dentes molares*. There are others which, though at first free from any malignant disposition, become afterwards carcinomatous, and even highly cancerous. Of whatever nature the polypus is, it intercepts the passage of the air through the nostril, and, when large, forces *septum narium* into the other nostril, so that the patient is unable to breathe, unless through the mouth. A large polypus, pressing in like manner upon the spongy bones, gradually forces them down upon the maxillary bones, and thus compresses and stops up the orifice of the *ductus lachrymalis;* nor is it impossible for the sides of the *canalis nasalis* to be pressed together. In which case the tears, having no passage through the nose, the eye is kept constantly watering, and the *sacchus lachrymalis*, not being able to discharge its contents, is sometimes so much dilated as to form what is called a flat *fistula*. The above writer has seen instances of polypi so much enlarged as to force down the ossa palati.

The polypus of the uterus is of three kinds, in respect to situation. It either grows from the fundus, the inside of the cervix, or from the lower edge of the os uteri. The first case is the most frequent, the last most uncommon. Polypi of the uterus are always shaped like a pear, and have a thin pedicle. They are almost invariably of that species which is denominated fleshy, hardly ever being schirrous, cancerous, or ulcerated.

3. The coagulated substance which is found in the cavities of the heart of those who are some time *in articulo mortis*, is improperly called a polypus.

POLYSA'RCIA. (*a*, *æ*. f.; from πολυς, much, and σαρξ, flesh.) Troublesome corpulency, obesity, or fatness. It is an increased bulk of the body, beyond what is sightly and healthy, from a superabundant accumulation of fat in the adipose membrane. In these cases the animal oil is secreted very rapidly, almost as much so as water in anasarca; on which account some writers have called obesity a dropsy of fat. Those who have been accustomed to hard exercise of body or mind, and suddenly relinquish it, and more especially if they indulge in strong ale, are apt to become obese, especially if the mind be tranquil and the disposition cheerful; but where the disposition to form fat is great, it matters not what food is taken. In some cases of polysarcia the bulk of the body has been enormous. Bright, of Maldon, weighed seven hundred and twenty-eight pounds; Lambert of Leicester, seven hundred and thirty-nine pounds, a little before his death, which was in the fortieth year of his age. In the Philosophical Transactions for 1813, there is an account of a girl who weighed two hundred and fifty-six pounds, though only four years old.

In attempting the cure, the first step is to avoid all the common and more obvious causes, —as indolence, indulgence at the table; and to take severe, regular, and habitual exercise. The plan cannot be better illustrated than in the case of Mr. Wood, the noted miller of Billericay, in Essex, related in the second volume of the Medical Transactions. Born of intemperate parents, he was accustomed to indulge himself in excessive eating, drinking, and indolence, till, in the forty-fourth year of his age, he became unwieldy from his bulk, was almost suffocated, laboured under very ill health from indigestion, and was subject to fits of gout and epilepsy. Fortunately, a friend pointed out to him the Life of Cornaro, and he instantly determined to take Cornaro for his model, and, if necessary, to surpass his abridgments. With great prudence, however, he made his change from a highly superfluous to a very spare diet, gradually; first, diminishing his ale to a pint a day, and using a much smaller portion of animal food, till at length, finding the plan work wonders, as well in his renewed vigour of mind as of body, he limited himself to a diet of simple pudding, made of sea-biscuit, flour, and skimmed milk, of which he allowed himself a pound and a half, about four or five o'clock in the morning, for his breakfast, and the same quantity at noon for his dinner. Besides this he took nothing, either of solids or fluids; for he had at length brought himself to abstain even from water, and found himself easier without it. He went to bed about eight or nine o'clock, rarely slept for more than five or six hours, and hence rose usually at one or two in the morning, and employed himself in laborious exercise, of some kind or other, till the time of his breakfast. By this regimen he reduced himself to the condition of a middle-sized man, of firm flesh, well-coloured complexion, and sound health.

It sometimes happens that obesity takes place only, or principally, in the belly; forming what is called the Falstaff, or pot-belly. This is from an accumulation of fat in the omentum, and requires, in addition to the above plan, the use of strong purgatives.

POLYSOMA'TIA. (From πολυς, much, and σωμα, a body.) Corpulency. See *Polysarcia*.

POLYSPA'STUM. (From πολυς, much, and σπαω, to draw.) A forcible instrument for reducing luxations.

POLYSPE'RMAL. (*Polysperma*; from πολυς, many, and σπερμα, a seed.) The same as *polyspermous*.

POLYSPE'RMOUS. (*Polyspermus*; from πολυς, many, and σπερμα, a seed.) Having many seeds.

POLY'STOMA. (*a, atos.* n.; from πολυς, many, and στομα, a mouth.) A genus of worms in Rudolphi's classification.

POLYSTOMA PINGUICULA. This species has been found by Treutler in a fatty tumour covering the ovary of a female who died in labour.

POLY'TRICHUM. (*um, i.* n.; from πολυς, many, and θριξ, hair: so called from its resemblance to a woman's hair, or because, in ancient times, women used to dye the hair with it, to keep it from shedding.) *Polytrycon.* 1. The name of a genus of plants in the Linnæan system. Class, *Cryptogamia*; Order, *Musci.*

2. The pharmacopœial name of the golden maidenhair. See *Polytrichum commune.*

POLYTRICHUM COMMUNE. The systematic name of the golden maidenhair. *Adianthum aureum.* It possesses, in an inferior degree, astringent virtues; and was formerly given in diseases of the lungs and calculous complaints.

POMA'CEÆ. (From *pomum*, an apple.) The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of those which have a fruit of an esculent, pulpy, apple, berry, or cherry kind.

POMA'CEUM. (*um, i.* n.; from *pomum*, an apple.) Cider, or the fermented juice of apples.

POMA'MBRA. *Pomum ambræ.* An odoriferous ball made of ambergris, musk, civet, aromatics, &c. It was used by embalmers to put into the orbits, after taking out the eyes.

POMA'TUM. A fragrant ointment made with lard and apples, was formerly so called. The term is applied now only to solid greasy substances, used in dressing the hair.

Pomegranate. See *Punica.*

POMPHOLYGO'DES. (From πομφολυξ, a bubble, and ειδος, resemblance.) Applied to urine, with bubbles on the surface.

PO'MPHOLYX. (*yx, ygis.* f.; from πομφος, a bladder.) I. A small vesicle or bubble.

II. A cutaneous disease described by Dr. Willan as an eruption of bullæ, appearing without any inflammation round them, and without fever, and therefore differing most materially from the pemphigus described by nosologists. Dr. Willan applied to it the appellation of pompholyx, of which he has described three varieties: —

1. The *pompholyx benignus* exhibits a succession of transparent bullæ, about the size of a pea, or sometimes of a hazel-nut, which break in three or four days, discharge their lymph, and soon heal. They appear chiefly on the face, neck, and extremities; and occur in boys in hot weather, in infants during dentition, and in young persons of irritable habit from eating acrid vegetable substances, or from swallowing a few grains of mercury.

2. The *pompholyx diutinus* is a tedious and painful disorder, and is usually preceded for some weeks by languor and lassitude, headach, sickness, and pains in the limbs. Numerous red pimple-like elevations of the cuticle appear, with a sensation of tingling, which are presently raised into transparent vesications, that become as large as a pea within twenty-four hours, and, if not broken, afterwards attain the size of a walnut. If they are rubbed off prematurely, the excoriated surface is sore and inflamed, and does not readily heal. The bullæ continue to arise in succession on different parts of the body, and even reappear on the parts first affected, in some cases for several weeks, so that the whole number of bullæ is very great; and when the excoriations are thus multiplied, a slight febrile paroxysm occurs every night, and the patient suffers much from the irritation and from want of sleep.

This disease chiefly affects persons of debilitated habits, and is very severe in the aged. It seems to originate under different conditions of the body, but often after continued fatigue and anxiety, with low diet; sometimes from intemperance; and not unfrequently it is connected with anasarca, or general dropsy, with scurvy, purpura, and other states of the constitution, in which the powers of the cutaneous circulation are feeble. It has in some instances appeared after profuse sweating, during which cold liquors were copiously swallowed, in common with several other forms of chronic cutaneous disease. In the fevers in which it has been observed, it was obviously symptomatic, for it has not only occurred at various periods and varied much in its duration, but has accompanied fevers of the continued, remittent, and intermittent type, as well as arthritic and other secondary fevers.

It is sufficiently clear, from the statements of the writers just referred to, that the pompholyx is never communicated by contagion; and that the fluid contained in the vesicles is not ichorous, but a bland lymph, resembling that which is poured into the ventricles of the brain in hydrocephalus. In several of the persons who cases are recorded, the disease occurred more than once. The pompholyx is most troublesome and obstinate in old persons, in whom the transparent bullæ sometimes equal the size of a turkey's egg, while others of a smaller size are intermixed with them, which appear dark and livid. When broken, they leave a black excoriated surface, which sometimes ulcerates.

The warm-bath, used every second day, was considered by Dr. Willan as the most active palliative, and the best remedy. The decoction of cinchona, with cordials and diuretics, has been found of considerable advantage in the cases, especially when the eruption was combined with anasarca. In young persons, in whom the pompholyx is seldom severe, the remedies are affirmed by Dr. Willan to be successful within two or three weeks; but the warm bath seems to increase both the tingling in the skin and the number of the vesications in these patients.

3. The *pompholyx solitarius* is a rare form of the disease, which seems to affect only women. One large vesication appears usually in a night, after a sensation of tingling in the skin

and rapidly distends itself, so as to contain sometimes a teacupful of lymph: within forty-eight hours it breaks, discharging its fluid, and leaving a superficial ulceration. Near this another bulla arises in a day or two, and goes through the same course; and it is sometimes followed, in like manner, by two or three others in succession; so that the whole duration shall be eight or ten days. Cinchona internally, and linseed poultices, followed by light dressings to the sores externally, were employed with advantage in three cases seen by Dr. Willan.

III. The whitish oxide of zinc which adheres to the covers of crucibles, in making brass, in the form of small bubbles.

Po'MPHOS. (*Pomphus, i.* m.; from πεμπω, to put forth.) A bladder of air or watery fluid.

PO'MUM. (*um, i.* n.) 1. An apple.

2. In botanical language it is a fleshy pericarpium or seed-vessel, containing a capsule within it, with several seeds. Its species are,—

1. *Oblong;* as in *Pyrus communis.*
2. *Baccate;* as in *Pyrus baccata.*
3. *Muricate;* as in *Momordica trifoliata.*
4. *Hispid;* as in *Momordica elaterium.*

The navel-like remains are part of the calyx.

The pomum is comprehended by Gærtner under the different kinds of bacca, it being sometimes scarcely possible to draw the line between them.

POMUM ADAMI. (Adam's apple: so called in consequence of a whimsical supposition that part of the forbidden apple which Adam ate stuck in the throat, and caused the prominence.) Adam's apple. The protuberance in the anterior part of the neck, formed by the forepart of the thyroid gland.

Pomum amoris. See *Solanum.*

PO'NS. (*s, tis.* m.) A bridge.

PONS VARO'LII. (So termed because it was first described by Varolius.) Varolius's bridge: called also *Tuber annulare, Corpus annulare, Processus annularis,* and *Eminentia annularis.* An eminence of the medulla oblongata, first described by Varolius: called *pons* from its arched appearance. See *Encephalos.*

PONTICUM MEL. A poisonous kind of honey found in Heraclea, which was said to produce the same effects as aconite.

Poor man's pepper. See *Polygonum hydropiper,* and *Lepidium.*

Poplar. See *Populus.*

PO'PLES. (*es, itis.* m.) The ham, or back part of the knee-joint.

POPLITE'AL. (*Popliteus;* from *poples,* the ham.) Appertaining to the ham or back part of the knee-joint.

POPLITEAL ANEURISM. Aneurism in the ham. See *Aneurism.*

POPLITEAL ARTERY. *Arteria poplitea.* The continuation of the crural artery, through the hollow of the ham.

POPLITÆ'US. A small muscle which arises from the external condyle of the femur, and back part of the capsular ligament of the knee-joint, and is inserted into the ridge at the upper and inner part of the tibia, a little below the head. The use of the popliteus is to assist in bending the leg, and to rotate it inwards when bent; also to prevent the capsular ligament from being pinched in the motions of the knee-joint.

Poppy. See *Papaver.*

Poppy, red corn. See *Papaver rhœas.*

Poppy, white. See *Papaver somniferum.*

POPULA'GO. (*o, inis.* f.; from *populus,* the poplar: because its leaves resemble those of the poplar.) See *Caltha.*

Populine. See *Populus tremula.*

PO'PULUS. (*us, i.* f.; from πολυς, many; because of the multitude of its shoots.) 1. The name of a genus of plants in the Linnæan system. Class, *Diœcia;* Order, *Octandria.*

2. The pharmacopœial name of the black poplar. See *Populus nigra.*

POPULUS BALSAMIFERA. One of the trees supposed to produce *tacamahaca.*

POPULUS NIGRA. The systematic name of the black poplar. *Ægeiros.* The young buds, *oculi,* or rudiments of the leaves, which appear in the beginning of the spring, were formerly employed in an officinal ointment. At present they are almost entirely disregarded, though they have been recommended in chronic pulmonary complaints. They have a yellow, unctuous, odorous, balsamic juice.

POPULUS TREMULA. The aspen. The properties of this are similar to those of the preceding species. Braconnot has found an alkali in the bark, which he names *populine.*

PORCE'LLIO. A genus of apterous insects, or, more properly, of isopodous annelides.

PORCELLIO SCABER. The animal called in Scotland *Sclater.* The same virtues have been ascribed to it as to the other millepedes. See *Millepes.*

Po'RCUS. (*us, i.* m.) A hog. See *Sus scrofa.*

Po'RI BILIA'RII. The biliary pores or ducts that receive the bile from the penicilli of the liver, and convey it to the hepatic duct. See *Liver.*

PORIFO'RMIS. Poriform: resembling a pore. Applied to a nectary, when of that appearance; as that of the hyacinth, which has three similar pores in the germen.

Pork. See *Sus scrofa.*

POROCE'LE. (Πωροκηλη; *e. es.* f.; from πωρος, a callus, and κηλη, a tumour.) A hard tumour of the scrotum.

PORO'MPHALUM. (From πωρος, a callus, and ομφαλος, the navel.) A hard tumour of the navel.

Porphyra. See *Scorbutus.*

Porret. See *Allium porrum.*

PORRI'GO. (*o, inis.* f.; *à porrigendo:* from its spreading abroad.) Ringworm of the scalp. Scald head. A genus of disease in Dr. Willan's arrangement, which is contagious, and principally characterised by an eruption of the pustules called *favi* and *achores,* unaccompanied by fever.

The several appearances which it assumes are reducible to the following species:—

1. *Porrigo larvalis.* This is the *crusta lactea* of writers, which is almost exclusively a disease

of infancy. It commonly appears first on the forehead and cheeks, in an eruption of numerous minute and whitish achorous pustules, which are crowded together upon a red surface. These soon break, and discharge a viscid fluid, which concretes into thin yellowish scabs. As the pustular patches spread, the discharge is renewed, and continues also from beneath the scabs, increasing their thickness and extent, until the forehead, cheeks, and even the whole face, become enveloped as by a mask, whence the epithet *larvalis*, the eyelids and nose alone remaining exempt from the incrustation. The eruption is liable, however, to considerable variation in its course; the discharge being sometimes profuse, and the surface red and excoriated; and at other times scarcely perceptible, so that the surface remains covered with a dry and brown scab. When the scab ultimately falls off, and ceases to be renewed, a red, elevated, and tender cuticle, marked with deep lines, and exfoliating several times, is left behind; differing from that which succeeds to impetigo, inasmuch as it does not crack into deep fissures.

Smaller patches of the disease not unfrequently appear about the neck and breast, and sometimes on the extremities; and the ears and scalp are usually affected in the course of its progress. In general the health of the child is not materially affected, especially when the eruption does not appear in the early period of lactation; but it is always accompanied with considerable itching and irritation, which, in young infants, often greatly diminish the natural sleep and disturb the digestion. Whence much debility sometimes ensues; the eyes and eyelids become inflamed, and purulent discharges take place from them and from the ears; the parotid, and subsequently the mesenteric glands, become inflamed; and marasmus, with diarrhœa and hectic, cut off the patient.

Most commonly, however, the disease terminates favourably, though its duration is often long and uncertain. It sometimes suddenly puts on the appearance of cessation, and afterwards returns with severity. Sometimes it disappears spontaneously soon after weaning, or after the cutting of the first teeth; and sometimes it will continue from two or three months to a year and a half, or even longer. It is remarkable, however, that whatever excoriation may be produced, no permanent deformity ensues.

In the commencement, while the discharge is copious and acrid, it is necessary to clear the surface two or three times a day by careful ablution with some tepid and mild fluid, as milk and water, thin gruel, or a decoction of bran; and to apply a mild ointment, such as the unguentum zinci, or a combination of this with a saturnine cerate. The latter will be useful to obviate excoriation, while the surface remains red and tender, after the discharge has ceased.

The removal of the disease is much accelerated by the use of alterative doses of mercurial purgatives, especially where the biliary secretion is defective, the abdomen tumid, or the mesenteric glands enlarged, which should be continued for three weeks longer, according to circumstances. Small doses of the submuriate may be given twice a day, alone, or in combination with soda and a testaceous powder; or, if the bowels are very irritable, the hydrargyrus cum cretâ, or the cinereous oxide, may be substituted. But if the general health appear sound, the inflammatory condition of the skin, and the profuse exudation, may be alleviated by the internal use of soda, with precipitated sulphur, or with the testacea.

When the state of irritation is removed, and the crusts are dry and falling off, the unguentum hydrargyri nitrati, much diluted, may be applied with advantage. And now some gentle tonic should be administered; such as the decoction of cinchona, or the chalybeates, which are more readily taken by children, especially the saturated solution of the tartrite, or the vinum ferri.

2. *Porrigo furfurans.* In this form of the disease, which commences with the eruption of small *achores*, the discharge from the pustules is small in quantity, and the excoriation slight; the humour, therefore, soon concretes, and separates in innumerable thin laminated scabs, or scale-like exfoliations. At irregular periods the pustules reappear, and the discharge being renewed, the eruption becomes moist; but it soon dries again and exfoliates. It is attended with a good deal of itching, and some soreness of the scalp, to which the disease is confined, and the hair, which partially falls off, becomes then, less strong in its texture, and sometimes lighter in its colour. Occasionally the glands of the neck are swelled and painful.

This species occurs principally in adults, especially in females, in whom it is not always easily distinguished from the scaly disease, pityriasis, psoriasis, or lepra, affecting the hairy scalp. The circumstances just enumerated, however, will serve to establish the diagnosis; as, in those diseases, no pustules appear in the beginning, there is no moisture or ulceration, and the hair is not detached, nor changed in texture and colour; neither are they communicable by contact.

In the treatment, it is absolutely necessary to keep the scalp closely shaven. The bran scabs should then be removed by gentle washing, with some mild soap and water, twice a day; and an oil silk cap should be worn, partly for the purpose of keeping the surface moist as well as warm, and partly for the convenience of retaining an ointment in contact with it.

The nature of the ointments employed in this, as in the other species, must be varied, according to the period of the disease, and the irritability of the part affected. In the commencement of the eruption, when the surface is moist, tender, and somewhat inflamed, the zinc ointment should be applied; or, what is more beneficial, an ointment prepared with the cocculus indicus in the proportion of two drachms of the powdered berry to an ounce of lard. But when the scalp becomes dry and inirritable, in the progress of the complaint, it may be washed with the common soft soap and water; or with a lath-

made by mixing equal portions of soft soap and unguentum sulphuris in warm water. More stimulant ointments will then be requisite, such as the unguentum hydrargyri nitrati, unguentum hydrargyri nitrico-oxidi, the tar and sulphur ointments, or the unguentum acidi nitrosi of the Edinburgh Pharmacopœia. These, and other stimulant applications, succeed in different individuals, in the inert state of the disease; but they must be intermitted, in case the inflammation and discharge return.

3. The *Porrigo lupinosa* is characterised by the formation of dry, circular scabs, of a yellowish-white colour, set deeply in the skin, with elevated edges and a central indentation or depression, sometimes containing a white scaly powder, and resembling, on the whole, the seeds of lupines. These scabs are formed upon small separate clusters of *achores*, by the concretion of the fluid, which exudes when they break; and they acquire, when seated on the scalp, the size of a sixpence. Frequently there is also a thin white incrustation, covering the intervening parts of the scalp, which commonly exfoliates; but, if allowed to accumulate through inattention to cleanliness, it forms an elevated crustaceous cap. The disease, however, is not exclusively confined to the head; but sometimes appears on the extremities, where the little white and indented scabs do not exceed two lines in diameter. This variety of porrigo is liable to increase much, if neglected; and is usually tedious, and of long duration.

The first object in the management of this species, is to remove the crusts and little indented scabs, by a diligent application of soap and water, or other emollient applications. If the scalp be the seat of the disease, the previous removal of the hair will be necessary. If the scabs are not penetrable by these ablutions or by ointments, or if any thick intervening incrustation is present, a lotion of the liquor potassæ, or of the muriatic acid in a diluted state may be employed. When the surface is cleared, the ointment of cocculus indicus may be applied to the red and shining cuticle; and afterwards the more stimulant unguents, as in the case of porrigo, furfurans, with regular daily ablution, will complete the cure.

4. The *Porrigo scutulata*, popularly termed the *ringworm of the scalp*, appears in distinct and even distant patches, of an irregular circular figure, upon the scalp, forehead, and neck. It commences with clusters of small light-yellow pustules, which soon break, and form thin scabs over each patch, which, if neglected, become thick and hard by accumulation. If the scabs are removed, however, the surface of the patches is left red and shining, but studded with slight elevated points, or papulæ, in some of which minute globules of pus again appear in a few days. By these repetitions of the eruption of *achores*, the incrustations become thicker, and the areas of the patches extend, often becoming confluent, if the progress of the disease be unimpeded, so as to affect the whole head. As the patches extend, the hair covering them becomes lighter in its colour, and sometimes breaks off short; and, as the process of pustulation and scabbing is repeated, the roots of the hair are destroyed, and at length there remains uninjured only a narrow border of hair round the head.

This very unmanageable form of porrigo generally occurs in children of three or four years old and upwards, and often continues for several years. Whether the circles remain red, smooth, and shining, or become dry and scurfy, the prospect of a cure is still distant; for the pustules will return, and the ulceration and scabbing will be repeated. It can only be considered as about to terminate, when the redness and exfoliations disappear together, and the hair begins to grow of its natural colour and texture.

The disease seems to originate spontaneously in children of feeble and flabby habit, or in a state approaching to marasmus, who are ill-fed, uncleanly, and not sufficiently exercised: but it is principally propagated by contagion; *i. e.* by the actual conveyance of the matter from the diseased to the healthy, by the frequent contact of the heads of children, but more generally by the use of the same towels, combs, caps, and hats. Whence the multiplication of boarding schools appears to have given rise to an increased prevalence of this disease, among the more cleanly classes of the community, at the present time: for such is the anxiety of parents to regain the lost years of education, that they too often send their children to these schools, when capable of communicating the infection, although supposed to be cured; against which no vigilance on the part of the superintendents can afford a sufficient security.

The principles of local treatment already laid down, are particularly applicable in this species of porrigo. While the patches are in an inflamed and irritable condition, it is necessary to limit the local applications to regular ablution, or sponging, with warm water, or some emollient fomentation. Even the operation of shaving, which is necessary to be repeated at intervals of eight or ten days, produces a temporary increase of irritation. At this time, the patient should wear a light linen cap, which should be frequently changed; and all stimulant lotions and ointments, which tend only to aggravate the disease, should be proscribed.

In the progress of the disorder, various changes take place, which require corresponding variations of the method of treatment. By degrees the inflammatory state is diminished, and a dry exfoliation and scabbing ensue: but again the pustular eruption breaks out, and the patches become again red and tender: or, in some cases, without much redness, there is an acrimonious exudation, with considerable irritability of the scalp. In other instances, the surface becomes inert, and in some degree torpid, while a dry scaly scab constantly appears, and active stimulants are requisite to effect any change in the disorder. It is very obvious, as Dr. Willan used to remark, that the adoption of any one mode of practice, or of any single pretended *specific*, under these varying circumstances of the disease, must be unavailing, and often extremely injurious.

In the more irritative states, the milder ointments, such as those prepared with cocculus indicus, with the submuriate of mercury, the oxide of zinc, the superacetate of lead, or with opium or tobacco, should be employed; or sedative lotions, such as decoctions or infusion of poppy heads, or of tobacco, may be substituted. Where there is an acrimonious discharge, the zinc and saturnine ointments, with the milder mercurial ones, — such as the unguentum hydrargyri præcipitati, or the ointment of calomel, or a lotion of lime-water with calomel, — are advantageous.

According to the different degrees of inertness which ensue, various well-known stimulants must be resorted to, and may be diluted, or strengthened, and combined, according to the circumstances. The mercurial ointments, as the unguentum hydrargyri præcipitati, hydrargyri nitrico-oxidi, and especially of the hydrargyrus nitratus, are often effectual remedies: and those prepared with sulphur, tar, hellebore, and turpentine, the unguentum elemi, &c., separately or in combination, occasionally succeed; as well as preparations of mustard, staves-acre, black pepper, capsicum, rue, and other acrid vegetable substances. Lotions containing the sulphates of zinc and copper, or the oxymuriate of mercury, in solution, are likewise occasionally beneficial.

In the very dry and inert state of the patches, the more caustic substances are often extremely successful. A lotion, containing from three to six grains of the nitrate of silver in an ounce of distilled water, has effectually removed the disease in this condition. Touching the patches with the muriated tincture of iron, or with the sulphuric or muriatic acids, slightly diluted, in some cases removes the morbid cuticle, and the new one assumes a healthy action. The application of a blister, in like manner, sometimes effectually accomplishes the same end. But, in many instances, the effect of these renovations of the cuticle is merely temporary, and the disease returns, in a week or two, upon the new surface.

Professor Hamilton, of Edinburgh, who considers the ringworm of the scalp, as "quite different from the scald head," affirms, in a late publication, that he has seldom failed to cure the former, by the use of the unguentum and scabiem of Banyer. For delicate children, he dilutes this ointment with an equal portion of simple cerate, and sometimes alternates the use of it with that of the common basilicon.

These various applications are enumerated, because not one of them is always successful, singly, even under circumstances apparently the same. They must be varied, and combined; and the best criterion in the choice and combination of them, is the degree of existing irritation in the morbid parts, or in the general habit. The rude and severe employment of depilatories, which some practitioners have recommended, is to be deprecated, as often inflicting great injury to the scalp, and retarding, rather than expediting, the progress to recovery.

Nothing has been said respecting the administration of internal medicine in the porrigo scutulata; because it is often merely local, being communicated by contagion to children in other respects healthy. But in those in whom it appears in combination with cachectic symptoms, chalybeate medicines, or the decoction of cinchona, and alteratives, must be prescribed, according to the particular indications; and the diet, clothing, and exercise of the patient, must be carefully regulated.

5. *Porrigo decalvans.* This singular variety of the disease presents no appearance whatever, except patches of simple baldness, of a more or less circular form, on which not a single hair remains, while that which surrounds the patches is as thick as usual. The surface of the scalp, within these areæ, is smooth, shining, and remarkably white. It is probable, though not ascertained, that there may be an eruption of minute achores about the roots of the hair, in the first instance, which are not permanent, and do not discharge any fluid. The disease, however, has been seen to occur, in one or two instances, in a large assemblage of children, among whom the other forms of the porrigo prevailed. But in other cases, and also in adults, it has appeared where no communication could be traced or conjectured. The areæ gradually enlarge, and sometimes become confluent, producing extensive baldness, in which condition the scalp remains many weeks, especially if no curative measures are adopted. The hair, which begins to grow, is of a softer texture, and lighter colour than the rest; and, in persons beyond the middle age, it is grey.

If the scalp is cleared by constant shaving, and at the same time some stimulant liniment be steadily applied to it, this obstinate affection may be at length overcome, and the hair will regain its usual strength and colour. In fact, until this change takes place, the means of cure must not be intermitted. Some of the more active ointments, mentioned under the preceding head, may be employed, with friction; but liniments containing an essential oil dissolved in spirit (for instance, two drachms of the oil of mace, in three or four ounces of alkohol), or prepared with oil of tar, petroleum Barbadense, camphire, turpentine, &c., are more efficacious.

6. *Porrigo favosa.* This species of the disorder consists of an eruption of the large, soft straw-coloured pustules, denominated *favi*. These are not in general globular, with a regularly circular margin; but somewhat flattened, with an irregular edge, and surrounded by a slight inflammation. They occur on all parts of the body; sometimes on the scalp alone, and sometimes on the face, or on the trunk and extremities only; but most commonly they spread from the scalp, especially from behind the ears, to the face, or from the lips and chin to the scalp, and occasionally from the extremities to the trunk and head. They are usually accompanied with considerable itching. Children from six months to four years of age are most liable to this eruption; but adults are not unfrequently affected with it.

The pustules, especially on the scalp, appear at first distinct, though near together; but on the face and extremities they generally rise in

irregular clusters, becoming confluent when broken, and discharging a viscid matter, which gradually concretes into greenish, or yellowish, semi-transparent scabs. The disease extends, by the successive formation of new blotches, which sometimes cover the chin, or surround the mouth, and spread to the cheeks and nose; and, on the scalp, the ulceration ultimately extends, in a similar manner, over the whole head, with a constant discharge, by which the hair and moist scabs are matted together. Under the last-mentioned circumstances, pediculi are often generated in great numbers, and greatly aggravate the itching and irritation of the disease. On the face, too, a similar aggravation of the symptoms is occasioned, in children, by an incessant picking and scratching about the edges of the scabs, which the itching demands, and by which the skin is kept sore, and the ulceration extended; while the scabs are thickened into irregular masses, not unlike honey-comb, by the multiplied and concreting discharge. On the lower extremities considerable ulceration sometimes form, especially about the heels and roots of the toes; and the ends of the toes are sometimes ulcerated, the pustules arising at their sides, and even under the nails.

The ulcerating blotches seldom continue long, or extend far, before the lymphatic system exhibits marks of irritation, probably from the acrimony of the absorbed matter. When the scalp or face is the seat of the disease, the glands on the sides of the neck enlarge and harden, being at first perceived like a chain of little tumours, lying loose under the skin; and the sub-maxillary and parotid glands are often affected in a similar manner. At length some of them inflame, the skin becomes discoloured, and they suppurate slowly, and with much pain and irritation. The eruption, in these situations, is likewise often accompanied by a discharge from behind the ears, or from the ears themselves, with a tumid upper lip, and inflammation of the eyes, or obstinate ulcerations of the edges of the eyelids. When the eruption appears on the trunk, although the pustules there are smaller and less confluent, and the scabs thinner and less permanent, the axillary glands are liable to be affected in the same way.

The discharge from the ulcerated surfaces, especially on the scalp, when the crusts and coverings are removed, exhales an offensive rancid vapour, not only affecting the organs of smell and taste, but the eyes, of those who examine the diseased parts. The acrimony of the discharge is also manifested by the appearance of inflammation, followed by pustules, ulceration, and scabbing, on any portion of the sound skin which comes into frequent contact with the disease: thus, in young children, the breast is inoculated by the chin, and the hands and arms by contact with the face. The arm and breast of the nurse are also liable to receive the eruption in the same manner; but it is not so readily communicated to adults as to children.

The duration of this form of porrigo is very uncertain; but it is, on the whole, much more manageable than the porrigo scutulata and decalvans. Young infants often suffer severely from the pain and irritation of the eruption, and of the glandular affections which it induces; and those who are bred in large towns, and are ill fed and nursed, are thus sometimes reduced to a state of fatal marasmus.

The porrigo favosa requires the exhibition of the same alteratives internally, which have been recommended for the cure of the porrigo larvalis, in doses proportioned to the age and strength of the patients. The diet and exercise should also be regulated with care: all crude vegetables and fruits on the one hand, and stimulating substances, whether solid or fluid, on the other, should be avoided; and milk, puddings, and a little plain animal food or broths, should be alone recommended. If the patient be of a squalid habit, or the glandular affections severe, the bark and chalybeates, or the solution of muriate of barytes united with the former, will contribute materially to the restoration of health.

There is commonly some degree of inflammation present, which contraindicates the use of active stimulants externally. The unguentum zinci, or the unguentum hydrargyri præcipitati, mixed with the former, or with a saturnine ointment, will be preferred as external applications, especially where the discharge is copious: and the ointment of the nitrate of mercury, diluted with about equal parts of simple cerate and of the ceratum plumbi superacetati, is generally beneficial; but the proportion of the unguentum ceræ must be varied according to the degree of inflammation. All stiff and rigid coverings, whether of oiled silk, or, according to a popular practice, of the leaves of cabbage, beet, &c. should be prohibited; for they often excite a most severe irritation.

Po'RRUM. (*um*, *i.* n.) The leek. See *Allium porrum*.

Po'RRUS. (*us*, *i.* m.) The same.

PO'RTA. (*a*, *æ.* f.; a door or gate: *à portando*, because through it the blood is carried to the liver.) That part of the liver where its vessels enter.

Portæ vena. See *Vena portæ*.

PORTAIGUILLE. The French name for the *acutenaculum*.

PO'RTIO. (*o*, *onis.* f.) A portion or branch: applied to two nerves.

PORTIO DURA. (One branch of the seventh pair of nerves is called *portio dura*, the hard portion, from its being of a firm consistence; and the other the *portio mollis*, or soft portion, from its softer consistence.) The *portio dura* or facial nerve arises near the pons, from the crus of the brain, enters the petrous portion of the temporal bone, gives off a branch into the tympanum, which is called the chorda tympani, and then proceeds to form the *pes anserinus* on the face, from which the integuments of the face are supplied with nerves. See *Auris*.

PORTIO MOLLIS. Auditory nerve. Acoustic nerve. This nerve arises from the medulla oblongata and fourth ventricle of the brain, enters the petrous portion of the temporal bone, and is distributed on the internal ear, by innumerable branches, not only to the cochlea, but

also to the membrane lining the vestibulum and semicircular canals, and is the immediate organ of hearing. See *Auris.*

PORTLAND POWDER. A celebrated gout remedy. It consists of equal parts of gentian, birthwort, the tops and leaves of germander, ground-pine, and lesser centaury, dried, powdered, and sifted. It is now fallen into disuse.

PORTONA'RIUM. (From *porta*, a door; because it is, as it were, the door or entrance of the intestines.) The pylorus, or right orifice of the stomach. Also the duodenum.

PORTULA'CA. (*a*, *æ*. f.; from *porto*, to carry, and *lac*, milk: because it increases the flow of milk.) 1. The name of a genus of plants in the Linnæan system. Class, *Dodecandria*; Order, *Digynia.*

2. The pharmacopœial name of the purslane. See *Portulaca oleracea.*

PORTULACA OLERACEA. The systematic name of the eatable purslane. *Andrachne. Allium gallicum.* The plant which is so called in dietetical and medical writings, abounds with a watery and somewhat acid juice, and is often put into soups, or pickled with spices. It is said to be antiseptic and aperient.

PO'RUS. (*us*, *i*. m.) A pore, or duct. A term used in *Anatomy* and *Botany*; as the pores of the skin; and particularly applied, in botany, to the small puncture-like openings in the inferior surface of the genus *Boletus.*

Po'SCA. Vinegar and water mixed.

POSE. An old English term for a cold in the head, or common catarrh. To pose is still used in the sense of to stupify, and the real meaning of *posie* is a "narcotic charm." and hence a nosegay of tranquillising odour, inducing repose or sleep.

POSSE'TUM. (*um*, *i*. n.) Posset. Milk curdled with wine, treacle, or any acid.

POSTE'RIOR. Parts are so named from their relative situation.

POSTERIOR ANNULARIS. *Musculus posterior annularis.* An external interosseal muscle of the hand, that extends and draws the ring-finger inwards.

Posterior auris. See *Retrahens auris.*

POSTERIOR INDICIS. *Musculus posterior indicis.* An internal interosseal muscle of the hand, that extends the fore-finger obliquely, and draws it outwards.

POSTERIOR MEDII. An external interosseal muscle of the hand, that extends the middle finger, and draws it outwards.

POSTI'CUS. Situated behind. Applied to muscles from their position; as *Serratus posticus*; *Tibialis posticus.*

POTAMOGEI'TON. (*um*, *i*. n.; from ποταμος, a river, and γειτων, adjacent: so named because it grows about rivers.) The name of a genus of plants in the Linnæan system. Class, *Tetrandria*; Order, *Tetragynia.*

PO'TASH. (*Potassa*, *æ*. f.; so called from the pots, or vessels, in which it was first made.) Vegetable alkali: so called because it is obtained in an impure state by the incineration of vegetables. *Kali.* An hydrated protoxide of potassium. See *Potassium.*

Table of the saline product of one thousand lbs. of ashes of the following vegetables: —

	Saline products.
Stalks of Turkey wheat or maise	198 lbs.
Stalks of sun-flower	349
Vine branches	162·6
Elm	166
Box	78
Sallow	102
Oak	111
Aspen	61
Beech	219
Fir	132
Fern cut in August	116 or 125 according to Wildenheim.
Wormwood	748
Fumitory	360
Heath	115 Wildenheim.

On these tables Kirwan makes the following remarks: —

1. That in general weeds yield more ashes, and their ashes much more salt, than woods; and that, consequently, as to salts of the vegetable alkali kind, as potash, pearlash, cashup, &c., neither America, Trieste, nor the northern countries have any advantage over Ireland.

2. That of all weeds fumitory produces more salt, and next to it wormwood. But if we attend only to the quantity of salt in a given weight of ashes, the ashes of wormwood contain most. The *Trifolium fibrinum* also produces more ashes and salt than fern.

The process for obtaining pot and pearlash is given by Kirwan, as follows: —

1. The weeds should be cut just before they seed, then spread, well dried, and gathered clean.

2. They should be burned within doors, on a grate, and the ashes laid in a chest as fast as they are produced. If any charcoal be visible it should be picked out, and thrown back into the fire. If the weeds be moist, much coal will be found. A close smothered fire, which has been recommended by some, is very prejudicial.

3. They should be lixiviated with twelve times their weight of boiling water. A drop of the solution of corrosive sublimate will immediately discover when the water ceases to take up any more alkali. The earthy matter that remains is said to be a good manure for clayey soils.

4. The ley thus formed should be evaporated to dryness in iron pans. Two or three at least of these should be used, and the ley, as fast as it is concreted, passed from the one to the other. Thus, much time is saved, as weak leys evaporate more quickly than the stronger. The salt thus produced is of a dark colour, and contains much extractive matter, and, being formed in iron pots, is called potash.

5. This salt should then be carried to a reverberatory furnace, in which the extractive matter is burnt off, and much of the water dissipated: hence it generally loses from ten to fifteen per cent. of its weight. Particular care should be taken to prevent its melting, as the

extractive matter would not then be perfectly consumed, and the alkali would form such a union with the earthy parts as could not easily be dissolved. Kirwan adds this caution, because Dr. Lewis and Dossie have inadvertently directed the contrary. This salt, thus refined, is called pearlash, and must be the same as the Dantzic pearlash.

To obtain this alkali pure, Berthollet recommends to evaporate a solution of potash, made caustic by boiling with quicklime, till it becomes of a thickish consistence; to add about an equal weight of alkohol, and let the mixture stand some time in a close vessel. Some solid matter, partly crystallised, will collect at the bottom; above this will be a small quantity of a dark-coloured fluid; and on the top another lighter. The latter, separated by decantation, is to be evaporated quickly in a silver basin in a sand-heat. Glass, or almost any other metal, would be corroded by the potash. Before the evaporation has been carried far, the solution is to be removed from the fire, and suffered to stand at rest; when it will again separate into two fluids. The lighter, being poured off, is again to be evaporated with a quick heat; and, on standing a day or two in a close vessel, it will deposit transparent crystals of pure potash. If the liquor be evaporated to a pellicle, the potash will concrete without regular crystallisation. In both cases a high-coloured liquor is separated, which is to be poured off; and the potash must be kept carefully secluded from air.

A perfectly pure solution of potash will remain transparent on the addition of lime-water; show no effervescence with dilute sulphuric acid; and not give any precipitate on blowing air through it by means of a tube.

Pure potash for experimental purposes may most easily be obtained by igniting cream of tartar in a crucible, dissolving the residue in water, filtering, boiling with a quantity of quicklime, and, after subsidence, decanting the clear liquid, and evaporating in a loosely covered silver capsule, till it flows like oil, and then pouring it out on a clean iron plate. A solid white cake of pure hydrate of potash is thus obtained, without the agency of alkohol. It must be immediately broken into fragments, and kept in a well-stoppered phial.

As 100 parts of subcarbonate of potash are equivalent to about 70 of pure concentrated oil of vitriol, if into a measure-tube, graduated into 100 equal parts, we introduce the 70 grains of acid, and fill up the remaining space with water, then we have an alkalimeter for estimating the value of commercial pearlashes, which, if pure, will require for 100 grains 100 divisions of the liquid to neutralise them. If they contain only 60 per cent. of genuine subcarbonate, then 100 grains will require only 60 divisions, and so on. When the alkalimeter indications are required in pure or absolute potash, such as constitutes the basis of nitre, then we must use 102 grains of pure oil of vitriol, along with the requisite bulk of water, to fill up the volume of the graduated tube.

The hydrate of potassium, as obtained by the preceding process, is solid, white, and extremely caustic; in minute quantities, changing the purple of violets and cabbage to a green, reddening litmus to purple, and yellow turmeric to a reddish brown. It rapidly attracts humidity from the air, passing into the *oleum tartari per deliquium* of the chemists; a name, however, also given to the deliquesced subcarbonate. Charcoal applied to the hydrate of potash at a cherry-red heat, gives birth to carburetted hydrogen, and an alkaline subcarbonate; but at a heat bordering on whiteness, carburetted hydrogen, carbonous oxide, and potassium are formed. Several metals decompose the hydrate of potash, by the aid of heat; particularly potassium, sodium, and iron. The fused hydrate of potash consists of 6 deutoxide of potassium + 1·125 water = 7·125, which number represents the compound prime equivalent. It is used in surgery, as the potential cautery for forming eschars; and it was formerly employed in medicine, diluted with broths, as a lithontriptic. In chemistry, it is very extensively employed, both in manufactures and as a reagent in analysis. It is the basis of all the common soft soaps. The oxides of the following metals are soluble in aqueous potash: — Lead, tin, nickel, arsenic, cobalt, manganese, zinc, antimony, tellurium, tungsten, molybdenum.

The preparations of this alkali that are used in medicine are, —

Liquor potassæ.
Potassa cum calce.
Carbonas potassæ.
Bicarbonas potassæ.
Chloridum potassii.
Chloras potassæ.
Hydras potassæ.
Hydriodas potassæ.
Sulphas potassæ.
Bisulphas potassæ.
Tartras potassæ.
Bitartras potassæ.
Acetas potassæ.
Citras potassæ.
Arsenias potassæ.
Sulphuretum potassæ. See *Potassium.*

Potash, acetate of. See *Potassæ acetas.*

Potash, carbonate of. See *Potassæ carbonas.*

Potash, fused. See *Potassa fusa.*

Potash, hyperoxymuriate of. See *Potassæ chloras.*

Potash, solution of. See *Potassæ liquor.*

Potash, subcarbonate of. See *Potassæ carbonas.*

Potash, subcarbonate of, solution of. See *Potassæ carbonatis liquor.*

Potash, sulphate of. See *Potassæ sulphas.*

Potash, sulphuret of. See *Potassæ sulphuretum.*

Potash, supersulphate of. See *Potassæ bisulphas.*

Potash, super-tartrate of. See *Tartarum.*

Potash, tartrate of. See *Potassæ tartras.*

Potash, with lime. See *Potassa cum calce.*

Potassa cum calæ. *Calx cum kali puro. Causticum commune fortius.* Take hydrate of potash, lime, of each an ounce. Rub them together and preserve in a well-stopped bottle. This is the caustic in common use with sur-

geons for making issues, and for other purposes.

Potassa fusa. See *Potassæ hydras.*

Potassa impura. See *Potash.*

Potassæ acetatis. Acetate of potash. *Kali acetatum, sal diureticus.* Take of carbonate of potash a pound, acetic acid twenty-six fluid ounces; distilled water twelve fluid ounces; add the carbonate of potash to the acid, previously mixed with the water, to saturation, then strain. Evaporate the liquor in a sand-bath, the heat being cautiously applied, until the salt is dried.

Acetate of potash is considered a good diuretic, and it is perhaps as good and as uncertain as most medicines of this class. The dose is from ten grains to two scruples every eight hours.

Potassæ arsenias. See *Arsenic acid.*

Potassæ arsenis. Arsenite of potash. See *Arsenic* and *Arsenicalis liquor.*

Potassæ bicarbonas. Bicarbonate of potash. This salt is now in general use for all purposes in which it is desirable to disengage the greatest quantity of carbonic acid, and it is made in considerable quantity for the market. There is a formula for preparing it in the last London pharmacopœia.

The *bicarbonate of potash* crystallises in square prisms, the apices of which are quadrangular pyramids. It has a urinous but not caustic taste; changes the syrup of violets green: boiling water dissolves five-sixths of its weight, and cold water one-fourth; alkohol, even when hot, will not dissolve more than 1-1200th. Its specific gravity is 2·012. When it is very pure and well crystallised it effloresces on exposure to a dry atmosphere, though it was formerly considered as deliquescent. It was thought that the common salt of tartar of the shops was a compound of this carbonate and pure potash; the latter of which, being very deliquescent, attracts the moisture of air till the whole is dissolved. From its smooth feel, and the manner in which it was prepared, the old chemists called this solution *oleum tartari per deliquium.*

The bicarbonate of potash melts with a gentle heat, looses its water of crystallisation, amounting to $\frac{3}{10}$, and gives out a portion of its carbonic acid, though no degree of heat will expel the whole of the acid. Thus, as the carbonate of potash is always prepared by incineration of vegetable substances, and lixiviation, it must be in the intermediate state, or that of a carbonate with excess of alkali: and to obtain the true carbonate we must saturate this salt with carbonic acid, which is best done by passing the acid in the state of gas through a solution of the salt in twice its weight of water; or, if we want the potash pure, we must have recourse to lime, to separate that portion of acid which fire will not expel.

The bicarbonate, usually called *super-carbonate* by the apothecaries, consists of 2 primes of carbonic acid = 5·500, 1 of potash = 6, and 1 of water = 1·125, in all 12·625.

Potassæ bisulphas. *Potassæ supersulphas,* bisulphate of potash. Take of the salt which remains after the distillation of nitric acid two pounds, sulphuric acid one pound, boiling water six pints; dissolve the salt in the water, and add the acid to it, and mix. Lastly, boil down and set aside, that crystals may be formed.

This salt consists of two equivalents of sulphuric acid, one of water and two of potash. It has a very acid bitter taste, and is very soluble in water. It is purgative, and is given in combination with other medicines of that class, especially rhubarb, in the dose of from ten grains to a drachm.

This salt has the same properties as the neutral carbonate, but is preferable for the effervescing draught, because it contains more carbonic acid.

A scruple is neutralised by fourteen grains of citric acid.

Potassæ carbonas. Carbonate of potash. *Kali præparatum; potassæ subcarbonas; sal absinthii; sal tartari.* Subcarbonate of potash. Take of impure carbonate of potash two pounds, distilled water a pint and a half; dissolve the impure carbonate of potash in the water, and strain; then pour it off into a proper vessel, and evaporate the water, that the liquor may thicken; then stir it constantly with a spatula until the salt concretes.

Carbonate of potash may be prepared more pure from crystals of bicarbonate of potash heated to redness.

This salt contains one equivalent of each ingredient. It is antacid and diuretic. The dose is from ten grains to half a drachm. It is in common use for forming the effervescent saline draught in the proportion of a scruple to the juice of one lemon. It is more accurately neutralised by seventeen grains of citric acid. The citrate of potash thus formed is a light diaphoretic.

Potassæ bitartras. See *Potassæ supertartras.*

Potassæ chloras. Formerly called oxymuriate of potash. This has been recommended as an alterative and anti-scrofulous medicine, but appears to have but little virtue. It may be given with bark and bitters, in the dose of from ten grains to a scruple three times a day.

Potassæ hydras. See the *Supplement.*

Potassæ hydriodas. See *Potassii iodiodum.*

Potassæ liquor. Solution of potash. *Aqua kali puri. Lixivium saponarium.* Take of carbonate of potash, fifteen ounces; lime, eight ounces; boiling distilled water, a gallon. Dissolve the carbonate of potash in half a gallon of the water; sprinkle a little of the water upon the lime in an earthen vessel, and when the lime is slacked, add the rest of the water. The liquors being immediately mixed together in a close vessel, shake them frequently until they are cold. Then set by that the carbonate of lime may subside. Lastly, keep the supernatant liquor, when poured off, in a green glass bottle well stopped.

This preparation is antacid and diuretic, and possesses great power in allaying irritability of the mucous membranes, especially those of the intestinal canal and urinary passages. The dose is from ♏ x. to ʒ j. in almond emulsion or some other bland liquid.

Potassæ murias. See *Potassii chloridum.*

Potassæ nitras. See *Nitre.*

Potassæ orymurias. See *Potassæ chloras.*

Potassæ subcarbonas. See *Potassæ carbonas.*

Potassæ subcarbonatis liquor. See *Potassæ carbonatis liquor.*

Potassæ sulphas. Formerly called, *Kali vitriolatum*, *Alkali vegetabile vitriolatum*, *Sal de duobus*, *Arcanum duplicatum*, *Sal polychrestus*, *Nitrum vitriolatum*, and *Tartarum vitriolatum*. Take of the salt which remains, after the distillation of nitric acid, two pounds; boiling water, two gallons. Ignite the salt in a crucible until the excess of sulphuric acid is entirely expelled, then boil it in the two gallons of water until a pellicle floats, and the liquor being strained, set it aside that crystals may be formed. The liquor being poured off, dry them. The crystals are in hexahedral prisms, terminated by hexagonal pyramids, but susceptible of variations. Its crystallisation by quick cooling is confused. The taste of this salt is bitter, acrid, and a little saline. It is soluble in 5 parts of boiling water, and 16 parts at 60°. In the fire it decrepitates, and is fusible by a strong heat. It is decomposable by charcoal at a high temperature. It consists of one equivalent of sulphuric acid, and one of potash. It may be prepared by direct mixture of its component parts; but the usual and cheapest mode is to neutralise the acidulous sulphate left after distilling nitric acid, the *sal enixum* of the old chemists, by the addition of carbonate of potash. The *sal polychrest* of old dispensatories, made by deflagrating sulphur and nitre in a crucible, is a compound of the sulphate and sulphite of potash.

The virtues of this salt are cathartic, diuretic, and deobstruent; with which intentions it is administered in a great variety of diseases, as constipation, suppression of the lochia, fevers, icterus, dropsies, milk tumours, &c. The dose is from one scruple to half an ounce.

Potassæ sulphuretum. See *Potassii sulphuretum.*

Potassæ supersulphas. See *Potassæ bisulphas.*

Potassæ supertartras. Now called *Potassæ bitartras.* Supertartrate of potash. Cream of tartar. This is made by purifying the tartar of commerce. See *Tartar.* It consists of tartaric acid and potash, with more of the acid than that which is combined with the alkali, and forms the tartrate. This loose acid renders it very agreeably acidulous to the palate. Dissolved in water, with the addition of a little sugar, and a slice or two of lemon-peel, it forms an agreeable cooling drink by the name of *imperial*; and if an infusion of green balm be used instead of water, it makes one of the pleasantest liquors of the kind with which we are acquainted. It is given internally as a diuretic and purgative; and in the latter character, formed into an electuary with a little jalap and ginger, it is perhaps as certain and as good an hydragogue as we possess.

Potassæ tartras. Tartrate of potash; formerly called, *Kali tartarisatum*, *Tartarum solubile*, *Tartarus tartarisatus*, *Sal vegetabilis*, and *Alkali vegetabile tartarisatum.* Take of bitartrate of potash, powdered, three pounds; carbonate of potash, sixteen ounces, or as much as may be sufficient; boiling water, six pints. Dissolve the carbonate of potash in the boiling water, then add the bitartrate of potash, and boil. Strain the liquor, and afterwards boil it down until a pellicle floats, and set it aside, that crystals may be formed. The liquor being poured off, dry these, and again evaporate the liquor that crystals may be produced.

This is a mild and excellent purgative, and is also diuretic; the dose is from one to six drachms. It is most frequently given in combination with senna, or the resinous cathartics, the operation of which it accelerates and renders milder.

Potassii bro'midum. Bromide of potassium. Take of bromine, two ounces; carbonate of potash, two ounces and one drachm; iron filings, an ounce; distilled water, three pints. First add the iron, and afterwards the bromine, to a pint and a half of the distilled water. Set them by for half an hour, frequently stirring them with a spatula. Apply a gentle heat, and when a greenish colour appears, pour in the carbonate of potash dissolved in the remainder of the water. Strain, and wash what remains in two pints of boiling distilled water, and again strain. Let the mixed liquors be evaporated, so that crystals may be formed.

This is a stimulant and deobstruent medicine, somewhat resembling the iodide of potassium in its action, but more powerful. M. Magendie has used it in scrofula, amenorrhœa, and hypertrophy of the heart, and Dr. Robert Williams has found it beneficial in cases of enlarged spleen. When dissolved in water it becomes a *hydrobromate of potash.* It often passes in our shops under the improper name of *bromate of potash.* The dose is from five to ten grains twice or thrice a day, in solution.

Potassii chloridum. See the *Supplement.*

Potassii iodidum. Iodide of potassium. *Hydriodate of potash.* Take of iodine, six ounces; carbonate of potash, four ounces; iron filings, two ounces; distilled water, six pints. Mix the iodine with four pints of the water, and add the iron, stirring them frequently with a spatula for half an hour. Apply a gentle heat, and when a greenish colour occurs, add the carbonate of potash, first dissolved in the two pints of water, and strain. Wash what remains with two pints of boiling distilled water, and again strain. Let the mixed liquors be evaporated, so that crystals may be formed.

This is always given in solution, and then only is properly a *hydriodate of potash.* It is given in the same cases as iodine, and generally in solution with it, as it has the property of rendering iodine more soluble in water. The dose is one grain, gradually increased to two, or somewhat more, three times a day. Externally it is applied in the form of an ointment. See *Unguentum potassæ hydriodatis.*

Liquor potassii iodidi compositus. Compound solution of iodide of potassium. Take of iodide of potassium, ten grains; iodine, five grains; distilled water, a pint. Mix, that they may be dissolved.

In this mixture the iodine is rendered more soluble by the presence of the hydriodate of potash. It is called also *iodureted iodide of*

potassium. The dose is from two to six drachms.

Potassii sulphuretum. *Hepar sulphuris. Kali sulphuratum*. Sulphuret of potassium. Improperly called sulphuret of potash. Liver of sulphur. Take of sulphur, an ounce; carbonate of potash, four ounces. Rub them together, and place them upon the fire in a covered crucible, until they have united.

Sulphuret of potassium is inodorous when dry, but when moistened with or dissolved in water, a partial decomposition of both the water and the sulphuret takes place, and sulphuretted hydrogen gas is evolved. The sulphuret of potassium has an acrid, bitter taste; it changes the vegetable blues to green; it is hard, brittle, of a liver colour, and stains the skin brown. By exposure to the air it attracts moisture; its colour changes to a pale green; it exhales sulphuretted hydrogen, and is gradually converted into hydroguretted sulphuret of potash, combined with a small proportion of sulphate of potash. All the acids decompose it, forming salts of potash, and precipitating the sulphur.

The liver of sulphur has been employed in gouty and rheumatic cases, and in cutaneous diseases. It has also been in esteem as an antidote to arsenical, mercurial, and saturnine poisons; but no reliance is now placed upon it.

POTA'SSIUM. (*um, ii.* n.) The metallic basis of potash. If a thin piece of solid hydrate of potash be placed between two discs of platinum, connected with the extremities of a voltaic apparatus of 200 double plates, four inches square, it will soon undergo fusion; oxygen will separate at the positive surface, and small metallic globules will appear at the negative surface. These consist of the substance called potassium, first exhibited to the world by Sir H. Davy, early in October, 1807.

If iron turnings be heated to whiteness in a curved gun-barrel, and potash be melted and made slowly to come in contact with the turnings, air being excluded, potassium will be formed, and will collect in the cool part of the tube. This method of procuring it was discovered by MM. Gay Lussac and Thenard in 1808. It may likewise be produced by igniting potash with charcoal, as M. Curaudau showed the same year.

M. Brunner, by acting on calcined tartar in a bottle of wrought iron, has succeeded in obtaining potassium at a comparatively moderate heat. The bottle is spheroidal, about half an inch in thickness, and capable of holding about a pint of water: a bent gun-barrel of 10 or 12 inches in length screws into the mouth of the bottle. The bottle, well luted over with fire-clay, is set in a strong air furnace, so as the tube may dip down externally beneath the surface of naphtha contained in a cylindric copper vessel, standing in a tub containing ice and water. The top of the naphtha vessel has a cover fixed on it, pierced with a hole to receive the end of the gun-barrel; and from the side of the upper part of the vessel, a small tube goes off at right angles, to let the air and vapours escape. It is advantageous to mix a little ground charcoal with the tartar previously calcined in a covered vessel, in the same iron bottle for example. Nearly 300 grains of potassium have been procured by this apparatus from 24 ounces of crude tartar. — *Biblioth. Universelle*, t. xxii. p. 36.

Potassium is possessed of very extraordinary properties. It is lighter than water; its sp. gr. being 0·865 to water 1·0. At common temperatures it is solid, soft, and easily moulded by the fingers. At 150° F. it fuses, and in a heat a little below redness it rises in vapour. It is perfectly opaque. When newly cut, its colour is splendent white, like that of silver, but it rapidly tarnishes in the air. To preserve it unchanged, we must enclose it in a small phial with pure naphtha. It conducts electricity like the common metals. When thrown upon water, it acts with great violence, and swims upon the surface, burning with a beautiful light of a red colour, mixed with violet. The water becomes a solution of pure potash. When moderately heated in the air it inflames, burns with a red light, and throws off alkaline fumes. Placed in chlorine, it spontaneously burns with great brilliancy.

On all fluid bodies which contain water, or much oxygen or chlorine, it readily acts; and in its general powers of chemical combination, says its illustrious discoverer, potassium may be compared to the alkahest or universal solvent, imagined by the alchemists.

Potassium combines with oxygen in different proportions. When potassium is gently heated in common air or in oxygen, the result of its combustion is an orange-coloured fusible substance. For every grain of the metal consumed about $1\frac{7}{10}$ cubic inches of oxygen are condensed. To make the experiment accurately, the metal should be burned in a tray of platina covered with a coating of fused muriate of potash.

The substance procured by the combustion of potassium at a low temperature was first observed, in October, 1807, by Sir H. Davy, who supposed it to be the protoxide; but MM. Gay Lussac and Thenard, in 1810, showed that it was in reality the deutoxide or peroxide. When it is thrown into water, oxygen is evolved, and a solution of the protoxide results, constituting common aqueous potash. When it is fused and brought in contact with combustible bodies they burn vividly, by the excess of its oxygen. If it be heated in carbonic acid, oxygen is disengaged, and common subcarbonate of potash is formed.

Mr. Phillips found, in decomposing nitre by heat, that a residuum of peroxide of potassium was left in the gun-barrel; for, on pouring water into it, oxygen was evolved in such quantity as to inflame an ignited stick, and to maintain its combustion for some time. See *Barium* for an analogous result.

When it is heated very strongly upon platina, oxygen gas is expelled from it, and there remains a difficultly fusible substance of a grey colour, vitreous fracture, soluble in water without effervescence, but with much heat. Aqueous potash is then produced. The above ignited solid is protoxide of potassium, which becomes pu-

potash by combination with the equivalent quantity of water. When we produce potassium with ignited iron-turnings and potash, much hydrogen is disengaged from the water of the hydrate, while the iron becomes oxidised from the residuary oxygen. By heating together pure hydrate of potash and boracic acid, Sir H. Davy obtained from 17 to 18 of water from 100 parts of the solid alkali.

By acting on potassium with a very small quantity of water, or by heating potassium with fused potash, the protoxide may also be obtained. The proportion of oxygen in the protoxide is determined by the action of potassium upon water. Eight grains of potassium produce from water about $9\frac{1}{2}$ cubic inches of hydrogen; and for these the metal must have fixed $4\frac{3}{4}$ cubic inches of oxygen. But as 100 cubic inches of oxygen weigh 33·9 gr., $4\frac{3}{4}$ will weigh 1·61. Thus, 9·61 gr. of the protoxide will contain 8 of metal; and 100 will contain 83·25 metal + 16·75 oxygen. From these data, the prime of potassium comes out 4·969; and that of the protoxide 5·969. Sir H. Davy adopts the number 75 for potassium, corresponding to 50 on the oxygen scale.

When potassium is heated strongly in a small quantity of common air, the oxygen of which is not sufficient for its conversion into potash, a substance is formed of a greyish colour, which, when thrown into water, effervesces without taking fire. It is doubtful whether it be a mixture of the protoxide and potassium, or a combination of potassium with a smaller proportion of oxygen than exists in the protoxide. In this case it would be a suboxide, consisting of 2 primes of potassium = 10 + 1 of oxygen = 11.

When thin pieces of potassium are introduced into chlorine, the inflammation is very vivid; and when potassium is made to act on chloride of sulphur, there is an explosion. The attraction of chlorine for potassium is much stronger than the attraction of oxygen for the metal. Both of the oxides of potassium are immediately decomposed by chlorine, with the formation of a fixed chloride, and the extrication of oxygen.

The combination of potassium and chlorine is the substance which has been improperly called muriate of potash, and which, in common cases, is formed by causing liquid muriatic acid to saturate solution of potash, and then evaporating the liquid to dryness, and igniting the solid residuum. The hydrogen of the acid here unites to the oxygen of the alkali, forming water, which is exhaled; while the remaining chlorine and potassium combine. It consists of 5 potassium + 4·5 chlorine.

Potassium combines with hydrogen, to form potassuretted hydrogen, a spontaneously inflammable gas, which comes over occasionally in the production of potassium by the gun-barrel experiment. MM. Gay Lussac and Thenard describe also a solid compound of the same two ingredients, which they call a hydruret of potassium. It is formed by heating the metal a long while in the gas, at a temperature just under ignition. They describe it as a greyish solid, giving out its hydrogen on contact with mercury.

When potassium and sulphur are heated together, they combine with great energy, with disengagement of heat and light even *in vacuo*. The resulting sulphuret of potassium is of a dark grey colour. It acts with great energy on water, producing sulphuretted hydrogen, and burns brilliantly when heated in the air, becoming sulphate of potash. It consists of 2 sulphur + 5 potassium, by Sir H. Davy's experiments. Potassium has so strong an attraction for sulphur, that it rapidly separates it from hydrogen. If the potassium be heated in the sulphuretted gas, it takes fire and burns with great brilliancy; sulphuret of potassium is formed, and pure hydrogen is set free.

Potassium and phosphorus enter into union with the evolution of light; but the mutual action is feebler than in the preceding compound. The phosphuret of potassium, in its common form, is a substance of a dark chocolate colour, but when heated with potassium in great excess, it becomes of a deep grey colour, with considerable lustre. Hence it is probable, that phosphorus and potassium are capable of combining in two proportions. The phosphuret of potassium burns with great brilliancy, when exposed to air; and when thrown into water produces an explosion, in consequence of the immediate disengagement of phosphuretted hydrogen.

Charcoal, which has been strongly heated in contact with potassium, effervesces in water, rendering it alkaline, though the charcoal may be previously exposed to a temperature at which potassium is volatilised. Hence, there is probably a compound of the two formed by a feeble attraction.

Of all known substances, potassium is that which has the strongest attraction for oxygen; and it produces such a condensation of it, that the oxides of potassium are denser than the metal itself. Potassium has been skilfully used by Sir H. Davy and MM. Gay Lussac and Thenard, for detecting the presence of oxygen in bodies. A number of substances, undecomposable by other chemical agents, are readily decomposed by this substance.

Potassiuretted hydrogen. See *Potassium.*

POTATO. (A corruption of *batatas*, the provincial name of the root in that part of Peru from which it was first obtained.) See *Solanum tuberosum.*

Potato, Spanish. See *Convolvulus.*

Potential cautery. See *Cautery.*

POTENTI'LLA. (*a*, *æ*. f.; *à potentia*, from its efficacy.) 1. The name of a genus of plants in the Linnæan system. Class, *Icosandria*; Order, *Polygynia.*

2. The pharmacopœial name of the wild tansy. See *Potentilla anserina.*

Potentilla anseri'na. The systematic name of the silver-weed, or wild tansy. *Argentina. Anserina.* The leaves of this plant, *Potentilla —foliis dentatis, serratis, caule repente, pedunculis unifloris*, of Linnæus, possess mildly astringent and corroborant qualities; but are seldom used, except by the peasantry.

Potentilla reptans. The systematic name of the common cinquefoil, or five-leaved grass.

Pentaphyllum. The roots of this plant, *Potentilla — foliis quinatis, caule repente, pedunculis unifloris*, of Linnæus, have a bitterish styptic taste. They were used by the ancients in the cure of intermittents, and to arrest hæmorrhage; and in later times they have been in esteem as an astringent in diarrhœa and other fluxes.

POTE'RIUM. (*um, ii.* n.; from ποτηριον, a cup: so named from the shape of its flowers.) The name of a genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Polyandria*.

POTERIUM SANGUISORBA. The systematic name of the Burnet saxifrage, the leaves of which are often put into cool tankards: they have an astringent quality.

POUCH. 1. In *Anatomy, sacculus*, a morbid dilatation of any part of a canal; as the intestine.

2. In *Botany*, — see *Silicula*.

POUPART'S LIGAMENT. *Ligamentum Poupartii*. See *Obliquus externus abdominis*.

Powder, antimonial. See *Antimonialis pulvis*.

Powder of burnt hartshorn with opium. See *Pulvis cornu usti cum opio*.

Powder, compound, of aloes. See *Pulvis aloes compositus*.

Powder, compound, of chalk. See *Pulvis cretæ compositus*.

Powder, compound, of chalk, with opium. See *Pulvis cretæ compositus cum opio*.

Powder, compound, of cinnamon. See *Pulvis cinnamomi compositus*.

Powder, compound, of contrayerva. See *Pulvis contrayervæ compositus*.

Powder, compound, of ipecacuanha. See *Pulvis ipecacuanhæ compositus*.

Powder, compound, of kino. See *Pulvis kino compositus*.

Powder, compound, of scammony. See *Pulvis scammoneæ compositus*.

Powder, compound, of senna. See *Pulvis sennæ compositus*.

Powder, compound, of tragacanth. See *Pulvis tragacanthæ compositus*.

POWDER OF FAYNARD. A styptic powder, said to consist of the charcoal of beech wood.

Power, muscular. See *Irritability*, and *Muscular motion*.

Power, tonic. See *Irritability*.

Precipitate, red. See *Hydrargyri nitrico-oxidum*.

Precipitate, white. See *Hydrargyri ammonio-chloridum*.

PRÆCO'RDIA. (*a, orum*. n. pl.; from *præ*, before, and *cor*, the heart.) The forepart of the region of the thorax.

PRÆFU'RNIUM. (From *præ*, before, and *furnus*, a furnace.) The mouth of a chemical furnace.

PREDISPOSING CAUSE. *Causa prædisponens*. See *Ætiologia*.

PREDISPOSITION. *Prædispositio*. That constitution, or state of the solids, or fluids, or both, which disposes the body to assume any particular diseased action.

PRÆMO'RSUS. (From *præmordeo*, to bite off.) Præmorse: bitten off. In *Botany* this term is differently applied: the *radix præmorsa* is an abrupt root, naturally, it is supposed, inclined to a taper root, but from some decay or interruption in its descending point it becomes abrupt, or, as it were, bitten off; as in the *Scabiosa succisa*, and *Hedypnois hirta*.

The old opinion of this formed root is thus described in Gerarde's Herbal: — "The greater part of the root seemeth to be bitten away: old fantasticke charmers report, that the divel did bite it for envie, because it is an herbe that hath so many good vertues, and is so beneficiall to mankinde."

The *folium præmorsum* is jagged-pointed, very blunt, with various irregular notches; as in *Epidendum præmorsum*, &c.

PRÆPARANTIA VASA. The spermatic vessels of the testicles.

PRE'PUCE. (*Præputium, ii.* n.; from *præputio*, to cut off before: because some nations used to cut it off in circumcision.) *Epagogion* of Dioscorides. *Posthe*. The membranous or cutaneous fold that covers the glans penis or men, and is partly cut off by the operation of circumcision. The clitoris of the female has the same covering in miniature, called *præputium clitorides*.

PRA'SINUS. (From πρασον.) *Prasine:* applied to designate the grass green colour of the purest kind. See *Colour*.

PRA'SIUM. (*um, ii.* n.; from πρασια, a square border: so called from its square stalks.) Horehound. See *Marrubium vulgare*.

PRA'SUM. (Πρασον; from πραω, to burn, because of its hot taste.) The leek.

Prawn. See *Cancer squilla*.

PRA'XIS. (*is, eos.* f.; from πρασσω, to perform.) The practice of any thing, as of medicine.

Precipitant. See *Precipitation*.

PRECIPITA'TION. (*Præcipitatio, onis.* f. from *præcipito*, to cast down.) When two bodies are united, for instance, an acid and an oxide, and a third body is added, such as an alkali which has a greater affinity with the acid than the oxide has, the consequence is, that the alkali combines with the acid, and the oxide thus deserted, appears in a separate state at the bottom of the vessel in which the operation is performed. This decomposition is commonly known by the name of *precipitation*, and the substance that sinks is named a *precipitate*. The substance, by the addition of which the phenomenon is produced, is denominated the *precipitant*.

PREGNANCY. *Gestatio uterina*. The particular manner in which pregnancy takes place has hitherto remained involved in obscurity, notwithstanding the laborious investigation of the most eminent philosophers of all ages. Although a state which (with a few exceptions) is natural to all women, it is in general the source of many disagreeable sensations, and often the cause of diseases, which might be attended with the worst consequences if not properly treated.

It is now, however, universally acknowledged that those women who bear children enjoy, usually, more certain health, and are much less

liable to dangerous diseases, than those who are unmarried, or who prove barren.

Signs of pregnancy. — The womb has a very extensive influence, by nervous sympathies, on many other parts of the body: hence the changes which are produced on it by impregnation, must be productive of changes on the state of the general system. These constitute the signs of pregnancy.

During the first fourteen or fifteen weeks, the signs of pregnancy are very ambiguous, and cannot be depended on; for, as they proceed from the irritation of the womb on other parts, they may be occasioned by every circumstance which can alter the natural state of that organ.

The first circumstance which renders pregnancy probable, is the suppression of the periodical evacuation, which is generally accompanied with fulness in the breasts, headach, flushings in the face, and heat in the palms of the hands.

These symptoms are commonly the consequences of suppression, and therefore are to be regarded as signs of pregnancy, in so far only as they depend on it.

As, however, the suppression of the periodical evacuation often happens from accidental exposure to cold, or from the change of life in consequence of marriage, it can never be considered as an infallible sign.

The belly, some weeks after pregnancy, becomes flat, from the womb sinking, and hence drawing down the intestines along with it; but this cannot be looked upon as a certain sign of pregnancy, because an enlargement of the womb from any other cause will produce the same effect.

Many women, soon after they are pregnant, become very much altered in their looks, and have peculiar irritable feelings, inducing a disposition of mind which renders their temper easily rufiled, and inciting an irresistible propensity to actions of which, on other occasions, they would be ashamed.

In such cases, the features acquire a peculiar sharpness, the eyes appear larger, and the mouth wider than usual; and the woman has a particular appearance, which cannot be described, but with which women are well acquainted.

These breeding symptoms, as they are called, originate from the irritation produced on the womb by impregnation; and as they may proceed from any other circumstance which can irritate that organ, they cannot be depended on when the woman is not young, or where there is not a continued suppression for at least three periods.

The irritations on the parts contiguous to the womb are equally ambiguous; and therefore the signs of pregnancy, in the first four months, are always to be considered as doubtful, unless every one enumerated be distinctly and unequivocally present.

From the fourth month, the signs of pregnancy are less ambiguous, especially after the womb has ascended into the cavity of the belly. In general, about the fourth month, or a short time after, the child becomes so much enlarged, that its motions begin to be felt by the mother; and hence a sign is furnished at that period called *quickening*. Women very improperly consider this sign as the most unequivocal proof of pregnancy; for though, when it occurs about the period described, preceded by the symptoms formerly enumerated, it may be looked upon as a sure indication that the woman is with child, yet, when there is an irregularity, either in the preceding symptoms or in its appearance, the situation of the woman must be doubtful.

This fact will be easily understood; for, as the sensation of the motion of the child cannot be explained or accurately described, women may readily mistake other sensations for that of quickening. Flatus has often been so pent up in the bowels, that the natural pulsation of the great arteries, of which people are conscious only in certain states of the body, has frequently been mistaken for this feeling.

After the fourth month, the womb rises gradually from the cavity of the pelvis, enlarges the belly, and pushes out the navel: hence the protrusion of the navel has been considered one of the most certain signs of pregnancy in the latter months. Every circumstance, however, which increases the bulk of the belly occasions this symptom; and therefore it cannot be trusted to, unless other signs occur.

The progressive increase of the belly, along with suppression, after having been formerly regular, and the consequent symptoms, together with the sensation of quickening at the proper period, afford the only true marks of pregnancy.

These signs, however, are not to be entirely depended on; for the natural desire which every woman has to be a mother, will induce her to conceal, even from herself, every symptom which may render her situation doubtful, and to magnify every circumstance which can tend to prove that she is pregnant.

Besides quickening and increase of bulk of the belly, another symptom appears in the latter months, which, when preceded by the ordinary signs, renders pregnancy certain beyond a doubt. It is the presence of milk in the breasts. When, however, there is any irregularity in the preceding symptoms, this sign is no longer to be considered of any consequence.

As every practitioner must naturally wish to distinguish pregnancy from disease, the disorders which resemble it should be thoroughly understood, and also their diagnostics. Generally speaking, there is no difficulty in ascertaining whether a woman be pregnant or not after the fifth month; but, before this period, the most skilful examination may not be able to resolve the point; and a judicious practitioner, in case of doubt, will be careful not to commit himself by a rash decision. One of the most certain signs of pregnancy is the *ballottement*, or passive motion of the fœtus, when the uterus is acted upon by the hands in a particular manner. See *Ballottement*. Towards the end of the fifth month, the active movements of the fœtus may often be excited by striking with the finger on the cervix uteri; this is unequivocal. The same movements, perceived through the parietes of the abdomen, afford less certain indications, because the movements of gas in the

intestines have been mistaken for them, though they can hardly be so by an intelligent observer. The signs of pregnancy derived from auscultation are quite conclusive where they exist; but the converse of the proposition does not hold, and we must by no means decide that a woman is not pregnant because the auscultatory signs are absent. See *Auscultation*.

An enlargement and dark colour of the areola round the nipple generally attends pregnancy: it has been regarded by some as a very unequivocal sign; but it is, in reality, no criterion at all, as it may sometimes be observed in women who have never conceived.

PREHE'NSIO. (From *prehendo*, to surprise: so named from its sudden seizure.) The catalepsy.

Premature labour. See *Abortion*.

PRESBYO'PIA. (*a*, *æ*. f.; from πρεσβυς, old, and ωψ, the eye: because it is frequent with old men.) That defect of the sight by which objects close are seen confusedly, but at remoter distances distinctly. The proximate cause is a tardy adunation or contraction of the iris.

1. It is sometimes caused, however, by a flatness of the cornea. By so much the cornea is flatter, so much the less and more tardy it refracts the rays into a focus. This evil may arise, 1st., From a want of aqueous or vitreous humour, which is common to the aged; or from some disease. 2d, From a cicatrix, which diminishes the convexity of the cornea. 3d, From a natural conformation of the cornea.

2. Another cause of it is too flat a crystalline lens. This evil is most common to the aged, or it may happen from a wasting of the crystalline lens.

3. It may likewise be produced by too small density of the cornea or humours of the eye. By so much more these humours are thin or rarified, so much the less they refract the rays of light. Whosoever is affected from this cause is cured in older age; for age induces a greater density of the cornea and lens. From this it is an observed fact, that the *presbyopes* are often cured spontaneously, and throw away their glasses, which younger persons in this disease are obliged to use.

4. A custom of viewing continually remote objects may also give rise to it: hence artificers who are occupied in viewing remote objects are said to contract this malady. The reason of this phenomenon is not very clear.

5. From a multitude of causes aged persons are presbyopes; from a penury of humours, which render the cornea and lens flatter, and the bulb shorter. When in senile age, from dryness, the bulb of the eye becomes flatter and shorter, and the cornea flatter, those who were short-sighted or myopes before, see now without their concave glasses.

6. Another cause is too close a proximity of objects. The focus is shorter of distant, but longer of nearer objects.

7. *Presbyopia* from a coarctated pupil.

The best remedy for supplying the deficient convexity of the cornea, as well as the deficient irritability of the iris, is convex spectacles; adapting their power to the precise demand of the eye, and increasing it as the demand grows more urgent.

Presbyte. See *Presbyopia*.

PRESBY'TIA. (*a*, *æ*. f.; from πρεσβυς, old: because it is frequent in old people.) See *Presbyopia*.

PRESCRIPTION. *Præscriptio*. A recipe or formula for the exhibition of medicines. We distinguish in prescriptions, 1. The *basis*, or active ingredient. 2. The *adjuvans*, or that which promotes the operation of the former. 3. The *corrigens*, or that which corrects any thing injurious or unpleasant in the operation of the active ingredient. 4. The *constituens*, or that which gives the whole a commodious or agreeable form.

PRESMUCHUM. An alchemical name of cerusse. — *Ruland*.

PRESMUCKIS. The same.

Priapeia. See *Nicotiana rustica*.

PRIAPI'SCUS. (From πριαπος, the penis.) 1. A tent made in the form of a penis.

2. A bougie.

PRI'APISM. (*Priapismus*, *i*. m.; from Πριαπος, a heathen god.) A continual erection of the penis.

PRIA'PUS. (*us*, *i*. m. Πριαπος, a heathen god, remarkable for the largeness of his genitals and whose penis is always painted erect.) The penis, or membrum virile. The dried penis of many animals as the stag, whale, bull, &c., was formerly used in medicine.

Prickle. See *Aculeus*.

Prickly. See *Aculeatus*.

Prickly heat. See *Lichen tropicus*.

PRIMÆ VIÆ. The first passages. The stomach and the intestinal tube are so called, because they are the first passages for what is taken into the stomach; the lacteals, the *secundæ viæ*, because the nourishment next goes into them; and lastly, the blood-vessels, which are supplied by the lacteals, are called *viæ tertiæ*.

PRIMARY. *Primarius*. A term in very general use in *Pathology*. It is applied to diseases, to their symptoms, causes, &c. and denotes priority in opposition to what follows, or what is *secondary*: thus, when inflammation of the diaphragm produces furious delirium, the *primary* disease is the paraphrenitis; so when gall-stones produce violent pain and vomiting, which are followed by jaundice, white fæces, porter-coloured urine, &c. the pain and vomiting are *primary* symptoms, the jaundice and white stools are secondary, &c.

Primary teeth. See *Teeth*.

Primrose. See *Primula vulgaris*.

PRI'MULA. *a*, *æ*. f.; from *primulus*, very early; so called because it flowers in the beginning of the spring.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia*.

PRIMULA VERIS. (From *primulus*, the beginning: so called because it flowers in the beginning of the spring.) *Verbasculum. Herba petri.* The cowslip, paigil, or peagle. The flowers of this plant have a moderately strong and pleasant smell, and a somewhat rough bitter taste. Vinous liquors, impregnated with their flavour by maceration or fermentation, a

strong infusions of them drank as tea, are supposed to be mildly corroborant, antispasmodic, and anodyne. An infusion of three pounds of the fresh flowers in five pints of boiling water is made in the shops into a syrup of a fine yellow colour, and agreeably impregnated with the flavour of the cowslip.

PRIMULA VULGARIS. The primrose. The leaves and root of this common plant possess sternutatory properties.

PRI'NCEPS ALEXIPHARMACO'RUM. The angelica was formerly so much esteemed as to obtain this name.

PRINCIPLE. *Principium.* A term somewhat vaguely used by chemists. Sometimes it means a component part; thus we speak of the *constituent principles* of bodies. At other times it means a substance, on the presence of which, certain qualities, common to a number of bodies, depend; thus we speak of an *acidifying principle.* Lastly, the substances peculiar to animal and vegetable bodies which result from particular modes of combination of ordinary matter, are termed the *proximate principles* of animal and vegetable bodies.

PRIONO'DES. (From πριων, a saw.) Serrated: applied in old writings to the serrated union of bones, or *sutures.*

PRI'OR. The first. A term applied to some muscles and various parts from their order.

PRIOR ANNULARIS. *Musculus prior annularis.* Fourth *interosseous* of Winslow. An internal interosseous muscle of the hand. See *Interossei annus.*

PRIOR INDICIS. *Extensor tertii internodii indicis,* of Douglas. An internal interosseal muscle of the hand, which draws the forefinger inwards towards the thumb, and extends it obliquely.

PRIOR MEDII. *Musculus prior medii. Second interosseous,* of Douglas. An external interosseous muscle of the hand. See *Interossei annus.*

PRISMA'TIC. *Prismaticus.* 1. Prism-shaped.

2. The colours which arise from the action of a transparent prism on the solar beam, are called *prismatic colours.*

PRO RE NATA. A term frequently used in extemporaneous prescriptions, and implying occasionally, as circumstances may require: as an aperient dose is required to be taken *pro re natâ.*

PRO'BANG. A flexible piece of whalebone with an oval piece of ivory or a piece of sponge fixed to the end. It is used by surgeons to push down into the stomach foreign bodies which stick in the œsophagus.

PROBE. (From *probo,* to try; because surgeons try the depth and extent of wounds, etc. with it.) *Stylus.* A surgical instrument, of a long and slender form.

PRO'BOLE. (Προβολη, a prominence; from βαλλω, to project.) See *Apophysis.*

PROBO'SCIS. (*is, idis.* f.; from προ, before, and βοσκω, to feed.) A snout or trunk, as that of an elephant, by which it feeds itself.

PROCA'RDIUM. (From προ, before, and καρδια, the orifice of the stomach.) The pit of the stomach.

PROCATA'RCTIC. (*Procatarcticus;* from προκαταρχω, to go before.) Occasional: applied to a remote cause of disease; as exposure to cold, unusual exertion, &c. See *Ætiologia.*

PRO'CESS. (*Processus, ûs.* m.; from *procedo,* to go before.) In *Anatomy,* a production of any part.

Processus cæci vermiformes. See *Intestine.*

Processus caudatus. See *Liver.*

Processus ciliaris. See *Oculus.*

PROCE'SSUS MAMILLA'RES. A name formerly applied to the bulbs of the olfactory nerves.

PROCIDE'NTIA. (*a, æ.* f.; from *procido,* to fall down.) A complete falling down of any part; thus, *procidentia ani, uteri, vaginæ,* &c. See *Prolapsus.*

PROCO'NDYLUS. (From προ, before, and κονδυλος, the middle joint of the finger.) The first joint of the finger next the metacarpus.

PROCTA'LGIA. (*a, æ.* f.; from πρωκτος, the fundament, and αλγος, pain.) A violent pain in the anus. It sometimes takes place suddenly from exposure to cold, from irritating fæces, but it is mostly symptomatic of some disease, as piles, scirrhus, prurigo, cancer, &c.

PROCTI'CUS. (From πρωκτος, the fundament.) Appertaining to the anus, or fundament.

PROCTI'TIS. (*is, idis.* f.; from πρωκτος, the anus.) *Clunesia. Cyssotis.* Inflammation of the internal or mucous membrane of the lower part of the rectum.

PRO'CTOLEUCORRHŒ'A. (*a, æ.* f.; from πρωκτος, the anus, λευκος, white, and ῥεω, to flow.) A purging of white mucus.

PROCTORRHŒ'A. (From πρωκτος, the anus, and ῥεω, to flow.) A purging of mucus.

PROCU'MBENS. Procumbent: trailing, and a little bent upwards. Applied to stems, when lying upon the ground, and not sending out roots, &c.; as that of the *Lysimachia nemorum.*

Productio. See *Apophysis.*

PROEGU'MINOS. (Προηγουμενος; from προηγεομαι, to precede or go before.) Proeguminal. Precedent: the same as predisposing; applied to the causes of disease. See *Ætiologia.*

PRŒO'TIA. (*a, æ.* f. Πρωιωτης; from πρωιος, *matutinus.*) Genital precocity.

PROFLU'VIA. Fluxes. The fifth order of Cullen's class *Pyrexiæ.*

Profluvii cortex. See *Nerium antidysentericum.*

PROFLU'VIUM. (*um, ii.* n.; from *profluo,* to flow out.) A flux.

Profundus. See *Flexor profundus perforans.*

PROFU'SIO. A flow of any of the fluids, not attended by fever; as a loss of blood.

PROGLO'SSIS. (From προ, before, and γλωσσα, the tongue.) The tip of the tongue.

PROGNO'SIS. (*is, is.* f.; from προ, before, and γινωσκω, to know.) The foretelling the event of diseases from their symptoms.

PROGNO'STIC. (*Prognosticus;* from προγινωσκω, to know beforehand.) 1. Adjectively, relating to *prognosis.*

2. Substantively, a *prognosis.*

Projectu'ra. See *Apophysis.*

PROLA'PSUS. (*us*, *i.* m.; from *prolabor*, to slip down.) A protrusion or falling down of a part of a viscus that is uncovered: applied to the uterus, anus, &c.

Prolapsus ani. A falling down of the lower part or extremity of the bowel. It is a very common occurrence in infancy, and indeed not uncommon at any period of life. It is a prominent protrusion of the internal membrane of the gut, through the sphincter, beyond what is natural; for a small portion always protrudes every time the fæces are expelled, and goes back as the sphincter contracts. In most instances this protruded part is easily returned by gentle pressure with the fingers. Cold and astringent lotions and stimulants mostly effect a cure after removing the apparent causes: if these should fail, clipping off a small portion of the relaxed and protruded membrane will be beneficial, or applying a ligature, if there should be any fear of hæmorrhage. Where such treatment is not deemed improper, an instrument must be contrived to keep the bowel in its place.

Prolapsus uteri. A falling down of the womb. When the relaxation is so great that the uterus protrudes through the external parts, the case is called *Procedentia uteri*.

Prole'pticus. (From προλαμβανω, to anticipate.) Applied to those diseases, the paroxysms of which anticipate each other, or return after less and less periods of intermission.

PRO'LIFER. (From *proles*, an offspring, and *fero*, to bear.) Prolific, or proliferous: applied to those stems which shoot out new branches from the summit of the former ones; as in the Scotch fir, *Pinus sylvestris*, and *Hypnum proliferum*: and to blossoms, when one grows out of another, as frequently happens in the genus *Polyanthus*.

Prometopi'dium. (From προ, before, and μετωπον, the forehead.) *Prometopis*. The skin upon the forehead.

Prometopis. See *Prometopidium*.

PROMINENT. *Prominens*. Projecting: standing out beyond the surrounding parts. Besides its general application, it is particularly used, in botanical language, to express the parts of a seed-vessel which project beyond the valves, as in many of the tetradynamic plants.

PRONA'TION. *Pronatio*. The act of turning the palm of the hand downwards. It is performed by rotating the radius upon the ulna, by means of several muscles, which are termed pronators.

PRONA'TOR. (*or*, *oris*. m.) A name given to two muscles of the hand, the pronator radii quadratus, and pronator radii teres; the use of which is to perform the opposite action to that of the supinators, viz. pronation.

Pronator quadratus. See *Pronator radii quadratus*.

Pronator radii brevis. See *Pronator radii quadratus*.

Pronator radii quadratus. *Pronator quadratus*, of Douglas and Albinus. *Pronator quadratus sive transversus*, of Winslow. *Pronator radii brevis seu quadratus*, of Cowper. This, which has got its name from its use and its shape, is a small fleshy muscle, situated at the lower and inner part of the fore-arm, and covered by the tendons of the flexor muscles of the hand. It arises tendinous and fleshy from the lower and inner part of the ulna, and runs nearly in a transverse direction, to be inserted into that part of the radius which is opposite to its origin, its inner fibres adhering to the interosseous ligament. This muscle assists in the pronation of the hand, by turning the radius inwards.

Pronator radii teres. *Pronator teres*, of Albinus and Douglas. *Pronator teres, sive obliquus*, of Winslow. A small muscle situated at the upper and anterior part of the fore-arm. It is called *teres*, to distinguish it from the pronator quadratus. It arises tendinous and fleshy from the anterior and inferior part of the outer condyle of the os humeri; and tendinous from the coronoid process of the ulna, near the insertion of the brachialis internus. The median nerve passes between these two portions. From these origins the muscle runs obliquely downwards and outwards, and is inserted, tendinous and fleshy, into the anterior and convex edge of the radius, about the middle of that bone. This muscle, as its name indicates, serves to turn the hand inwards.

Pronerva'tio. (From *pro*, before, and *nervus*, a string.) A tendon or aponeurosis.

PRO'NUS. (*Pronus*, having the face downwards.) Applied to the under surface of a leaf.

Prop. See *Fulcrum*.

PROPA'GO. (*o*, *inis*. f.) A slip, layer, or cutting of a vine. Some anatomists have called the smaller branches of vessels and nerves *propagines*.

PROPHYLA'CTIC. (*Prophylacticus*; from προφυλασσω, to guard against.) Any means used with a view to guard against diseases are so called.

PRO'PRIUS. Proper. Belonging to an individual thing; hence *tunica propria renis*, &c.

PROPTO'SIS. (*is*, *is*. f.; from προπιπτω, to fall down.) *Proptoma*. 1. A protrusion or falling down of any part: applied, like prolapsus, to the uterus, rectum, &c.

2. A relaxation of parts, as the scrotum, breasts, &c.

Propye'ma. (From προ, before, and πυον, pus.) A premature collection of pus.

PRO'RA. (*a*, *æ*. f.; from πρωρα, the prow of a vessel.) The occiput.

Prosarthro'sis. (From προς, to, and αρθρωω, to articulate.) Synonymous with *Diarthrosis*.

Prose'ctor. (From *proseco*, to cut.) The person who dissects the subject for anatomical demonstration is now generally so called.

Prospe'gma. (From προσπηγνυμι, to fix near.) A fixing of humours in one spot.

Pro'stasis. (From προιστημι, to predominate.) An abundance of morbid humours.

PRO'STATE. (*Prostatus*; from προιστημι, to stand before: because it is situated before the urinary bladder.) Standing before; jutting out.

Prostate gland. *Glandula prostata*. Cor-

glandulosum. Adenoides. A very large, heart-like, firm gland, situated between the neck of the urinary bladder and the bulbous part of the urethra. It secretes the lacteal fluid, which is emitted into the urethra by ten or twelve ducts, that open near the verumontanum, during coition. This gland is very liable to inflammation, scirrhus, and cancer.

Prostate, inferior muscle of the. See *Transversus perinei alter.*

PROSTA'TIC. *Prostaticus.* Appertaining to the prostate gland.

PROSTRA'TUS. Prostrate: applied synonymously with *depressus*, depressed, to a stem which lies naturally remarkably flat, spreading horizontally over the ground; as in *Coldenia procumbens*, and *Coronopus ruelli.*

PROTO'GALA. (*a, æ.* f.; from πρωτος, first, and γαλα, milk.) The milk first secreted after delivery. See *Colostrum.*

PROTOPA'THIC. (*Protopathicus*; from πρωτος, first, and παθος, a disease.) Applied to the symptoms of diseases in the same sense as *primary.*

Protoxide. See *Oxide.*

PROTUBERA'NTIA. 1. A protuberance in any part.

2. An apophysis.

PRO'XIMATE. *Proximus.* The next in order.

PROXIMATE CAUSE. (*Causa proxima*; so called, because when the exciting cause begins to have effect it is the *proximum*, or next thing that happens.) The proximate cause of a disease is the disordered action in which the disease consists: in other words, the disease itself.

Proximate principle. See *Principle.*

PRUI'NA. (*a, æ.* f.; hoar-frost.) The powdery substance observed on ripe fruit, especially plums.

PRU'NA. (*a, æ.* f.; a live coal: so called by Avicenna from its assuming the colour, and often the oval figure, of the sloe, or fruit of the *Prunus spinosa.* — *Good.*) The carbuncle.

Prune. See *Prunus domestica.*

PRUNE'LLA. (*a, æ.* f.; from *pruno*, a burn: because it heals burns.) 1. The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Gymnospermia.*

2. The pharmacopœial name of the self-heal. See *Prunella vulgaris.*

3. The name given by Paracelsus to sore throat.

PRUNELLA VULGARIS. The systematic name of the self-heal or bugle; called also, *Prunella; consolida minor*, and *Symphitum minus. Prunella* — *foliis omnibus ovato-oblongis, serratis, petiolatis*, of Linnæus. It is recommended as an astringent in hæmorrhages and fluxes, as also in gargles against aphthæ and inflammation of the fauces.

PRUNE'LLO. The Brignole plum; a variety of the common plum.

PRU'NUM. (*um, i.* n.; from *prunus*, the tree which bears it.) A plum or prune. *Prunus* is the name of the tree, and *Prunum* is the name of the fruit.

Prunum gallicum. See *Prunus domestica.*

Prunum sylvestre. See *Prunus spinosa.*

PRU'NUS. (*us, i.* f.; the name of the tree which bears the fruit called prunum.) The name of a genus of plants in the Linnæan system. Class, *Icosandria*; Order, *Monogynia.*

Prunus armeniaca. See *Armeniaca vulgaris*, in the Supplement.

PRUNUS AVIUM. The systematic name of the black cherry tree. *Prunus* — *umbellis sessilibus, foliis ovato-lanceolatis, subtus pubescentibus, conduplicatis*, of Linnæus. The flavour of the ripe fruit is esteemed by many; and, if not taken in too large quantities, it is sufficiently wholesome. A gum exudes from the tree, whose properties are similar to those of gum-arabic.

PRUNUS CERASUS. The systematic name of the red cherry-tree. *Prunus* — *umbellis subpedunculatis, foliis ovato-lanceolatis, glabris, conduplicatis*, of Linnæus. The fruit of this tree, *Cerasa rubra, anglica, sativa*, possess a pleasant, acidulated, sweet flavour, and are proper in fevers, scurvy, and bilious obstructions. Red cherries are mostly eaten as a luxury, and are very wholesome, except to those whose bowels are remarkably irritable.

PRUNUS DOMESTICA. The systematic name of the plum or damson tree. *Prunus* — *pedunculis subsolitariis, foliis lanceolato-ovatis convolutis, ramis muticis; gemmæ floriferæ aphyllæ*, of Linnæus. Plums are a sufficiently wholesome fruit when eaten, though they generally bear the blame of the bowels complaints, which are really produced by the sudden vicissitudes of temperature in autumn. Plums dried with sugar are called *prunes*, or French plums. They are a good mild laxative, especially when stewed. Prunes form an ingredient in confection of senna. The *damson* is only a variety of the plum, which, when perfectly ripe, affords a wholesome material for tarts, &c., gently opening the body: but when damsons are not perfectly mature, they produce colicky pains and diarrhœa.

PRUNUS LAURO-CERASUS. The systematic name of the poison-laurel: called also, common cherry laurel, bay laurel, and Alexandrian laurel. *Lauro-cerusus. Prunus* — *floribus racemosis foliis sempervirentibus dorso biglandulosis*, of Linnæus. The leaves of the lauro-cerasus have a bitter styptic taste, accompanied with a flavour resembling that of bitter almonds, or other kernels of the drupaceous fruits: the flowers also manifest a similar flavour. The powdered leaves, applied to the nostrils, excite sneezing, though not so strongly as tobacco. The kernel-like flavour which these leaves impart, being generally esteemed grateful, has sometimes caused them to be employed for culinary purposes, and especially in custards, puddings, blancmange, &c.; and as the proportion of this sapid matter of the leaf to the quantity of the milk is commonly inconsiderable, bad effects have seldom ensued. But as the poisonous quality of this laurel is now indubitably proved, and known to be the prussic acid, which can be obtained in a separate form (see *Hydrocyanic acid*), the public ought to be cautioned against its internal use.

The following communication to the Royal Society, by Dr. Madden, of Dublin, contains

the first and principal proofs of the deleterious effects of this vegetable upon mankind: — "A very extraordinary accident that fell out here some months ago, has discovered to us a most dangerous poison, which was never before known to be so, though it has been in frequent use among us. The thing I mean is a simple water, distilled from the leaves of the lauro-cerasus: the water is at first milky, but the oil which comes over being in a good measure separated from the phlegm, by passing it through a flannel bag, it becomes as clear as common water. It has the smell of bitter almonds, or peach-kernel, and has been for many years in frequent use among our housewives and cooks, to give that agreeable flavour to their creams and puddings. It has also been much in use among our drinkers of drams; and the proportion they generally use it in has been one part of laurel-water to four of brandy. Nor has this practice, however frequent, ever been attended with any apparent ill consequences, till some time in the month of September, 1728, when it happened that one Martha Boyse, a servant, who lived with a person who sold great quantities of this water, got a bottle of it from her mistress, and gave it to her mother. Ann Boyse made a present of it to Frances Eaton, her sister, who was a shopkeeper in town, and who, she thought, might oblige her customers with it. Accordingly, in a few days, she gave about two ounces to a woman named Mary Whaley, who drank about two thirds of what was filled out, and went away. Frances Eaton drank the rest. In a quarter of an hour after Mary Whaley had drunk the water (as I am informed), she complained of a violent disorder in her stomach, soon after lost her speech, and died in about an hour, without vomiting or purging, or any convulsion. The shopkeeper, F. Eaton, sent word to her sister, Ann Boyse, of what had happened, who came to her upon the message, and affirmed that it was not possible the cordial (as she called it) could have occasioned the death of the woman; and, to convince her of it, she filled out about three ounces, and drank it. She continued talking with F. Eaton about two minutes longer, and was so earnest to persuade her of the liquor's being inoffensive, that she drank about two spoonfuls more, but was hardly well seated in her chair when she died without the least groan or convulsion. Frances Eaton, who, as before observed, had drank somewhat more than a spoonful, found no disorder in her stomach, or elsewhere; but to prevent any ill consequences, she took a vomit immediately, and has been well ever since." — Dr. Madden mentions another case, of a gentleman at Kilkenny, who mistook a bottle of laurel-water for a bottle of ptisan. What quantity he drank is uncertain, but he died in a few minutes, complaining of a violent disorder in the stomach. In addition to this, we may refer to the unfortunate case of Sir Theodosius Boughton, whose death, in 1780, an English jury declared to be occasioned by this poison. In this case, the active principle of the lauro-cerasus was concentrated by repeated distillations, and given to the quantity of one ounce; the suddenly fatal effects of which must be still in the recollection of the public. To brute animals this poison is almost instantaneously mortal, as amply appears by the experiments of Madden, Mortimer, Nicholls, Fontana, Langrish, Vater, and others. The experiments conducted by these gentlemen, show that the laurel-water is destructive to animal life, not only when taken into the stomach, but also on being injected into the intestines, or applied externally to different organs of the body. It is remarked by Abbé Fontana, that this poison, even "when applied in a very small quantity to the eyes, or to the inner part of the mouth, without touching the œsophagus, or being carried into the stomach, is capable of killing an animal in a few minutes: whilst, applied in a much greater quantity to wounds, it has so little activity, that the weakest animals, such as pigeons, resist its action."

The poisonous quality of this species of laurel is the prussic acid; and, if we judge from its sensible qualities, an analogous principle seems to pervade many other vegetable substances, especially the kernels of drupaceous fruits; and in various species of the amygdalus, this sapid principle extends to the flowers and leaves. It is of importance to notice, that this is much less powerful in its action upon human subjects than upon dogs, rabbits, pigeons, and reptiles. To poison man, the essential oil of the lauro-cerasus must be separated by distillation, as in the spirituous or common laurel-water; and unless this is strongly embued with the oil, or given in a large dose, it proves innocent. Dr. Cullen observes, that the sedative power of the lauro-cerasus acts upon the nervous system in a different manner from opium and other narcotic substances, whose primary action is upon the animal functions; for the lauro-cerasus does not occasion sleep, nor does it produce local inflammation, but seems to act directly upon the vital powers. Abbé Fontana supposes that the poison destroys animal life, by exerting its effects upon the blood; but the experiments and observations from which he draws this opinion are evidently inconclusive. It may also be remarked, that many of the Abbé's experiments contradict each other. Thus, it appears from the citation given above, that the poison of the vegetable, when applied to wounds, does not prove fatal: but future experiments led the Abbé to assert that the oil of the lauro-cerasus, whether given internally, or applied to the wounds of animals, is one of the most terrible and deadly poisons known. Though this vegetable seems to have escaped the notice of Stoerck, yet it is not without advocates for its medical use. Linnæus informs us, that in Switzerland it is commonly and successfully used in pulmonary complaints. Langrish mentions its efficacy in agues; and, as Bergius found bitter almonds to have this effect, we may, by analogy, conclude that this power of the lauro-cerasus is well established. Baylies found that it possessed a remarkable power of diluting the blood, and, from experience, recommended it in those cases of disease supposed to proceed from too dense a state of that fluid: adducing particular instances of its efficacy in rheumatisms, asthma,

and schirrhous affections. Nor does this author seem to have been much afraid of the deleterious quality of lauro-cerasus, as he directs a pound of its leaves to be macerated in a pint of water, of which he gives from thirty to sixty drops three or four times a day.

PRUNUS PADUS. The systematic name of the wild cluster, or bird-cherry tree. *Padus.* The bark and berries of this shrub are used medicinally. The former, when taken from the tree, has a fragrant smell, and a bitter, subastringent taste, somewhat similar to that of bitter almonds. Made into a decoction, it cures intermittents, and it has been recommended in the cure of several forms of syphilis. The latter are said to cure the dysentery.

PRUNUS SPINOSA. The systematic name of the sloe tree. *Prunus sylvestris. Agrio-cocymela. Prunus — pedunculus solitariis foliis lanceolatis, glabris, ramis spinosis,* of Linnæus. It is sometimes employed in gargles, in tumefactions of the tonsils and uvula, and, from its astringent taste, was formerly much used in hæmorrhages, &c.

PRURIGO. (*o, inis.* f.; from *prurio,* to itch.) *Pruritus.* Prurigo is a papulous eruption. As it arises from different causes, or at different periods of life, and exhibits some varieties in its form, it is described by Dr. Willan under the titles of prurigo mitis, prurigo formicans, and prurigo senilis. In these the whole surface of the skin is usually affected; but there are likewise many cases of local prurigo, which will be afterwards noticed according to their respective situations.

1. The *prurigo mitis* originates without any previous indisposition, generally in spring, or the beginning of summer. It is characterised by soft and smooth elevations of the cuticle, somewhat larger than the papulæ of the lichen, from which they also differ by retaining the usual colour of the skin; for they seldom appear red, or much inflamed, except from violent friction. They are not, as in the other case, accompanied with tingling, but with a sense of itching almost incessant. This is, however, felt more particularly on undressing, and often prevents rest for some hours after getting into bed. When the tops of the papulæ are removed by rubbing or scratching, a clear fluid oozes out from them, and gradually concretes into thin thick scabs.

This species of prurigo mostly affects young persons; and its cause may, Dr. Willan observes, in general be referred to sordes collected on the skin, producing some degree of irritation, and also preventing the free discharge of the cutaneous exhalation; the bad consequences of which must necessarily be felt at that season of the year when perspiration is most copious. Those who have originally a delicate or irritable skin, must likewise, in the same circumstances, be the greatest sufferers.

The eruption extends to the arms, breast, back, and thighs, and often continues during two or three months of the summer, if not relieved by proper treatment. When persons affected with it neglect washing the skin, or are uncleanly in their apparel, the eruption grows more inveterate, and at length, changing its form, often terminates in the itch. Pustules arise among the papulæ, some filled with lymph, others with pus. The acarus scabiei begins to breed in the furrows of the cuticle, and the disorder becomes contagious. A steady perseverance in tepid lotions of water, and of the warm bath, is mostly of infinite service. Sulphur, magnesia, soda, nitrate of potash, are useful internally; and also, where there is debility, the internal use of cinchona and the mineral acids.

2. The *Prurigo formicans* is a much more obstinate and troublesome disease than the foregoing. It usually affects persons of adult age, commencing at all seasons of the year indifferently; and its duration is from four months to two or three years, with occasional short intermissions. The papulæ are sometimes larger, sometimes more obscure, than in the preceding species; but are, under every form, attended with an incessant, almost intolerable itching. They are diffused over the whole body, except the face, feet, and palms of the hands: they appear, however, in greatest number on those parts which, from the mode of dress, are subjected to tight ligatures; as about the neck, loins, and thighs.

The itching is complicated with other sensations, which are variously described by patients. They sometimes feel as if small insects were creeping on the skin; sometimes as if stung all over with ants; sometimes as if hot needles were piercing the skin in divers places. On standing before a fire, or undressing, and more particularly on getting into bed, these sensations become more violent, and usually preclude all rest during the greater part of the night. The prurigo formicans is, by most practitioners, deemed contagious, and confounded with the itch. In endeavouring to ascertain the justness of this opinion, Dr. Willan has been led to make the following remarks: — 1. The eruption is, for the most part, connected with internal disorder, and arises where no source of infection can be traced. 2. Persons affected may have constant intercourse with several others, and yet never communicate the disease to any of them. 3. Several persons of one family may have the prurigo formicans about the same time; but he thinks this should be referred rather to a common predisposition than to contagion, having observed that individuals of a family are often so affected at certain seasons of the year, even when they reside at a distance from each other.

Although the prurigo formicans is never, like the former species, converted into the itch, yet it does occasionally terminate in a pustular disease, not contagious. For the most part, it is necessary, in attempting the cure of this species, to attend to, and remove, if possible, some hepatic or other visceral obstruction, by an alterative course of medicine. When there is a state of debility, tonics with mineral acids and nourishing diet must be resorted to. Steel is also serviceable. Chlorine, soda, and bitters, with saline aperients, are, in common cases, of great benefit.

With respect to the external applications,

warm water, with a little spirit or liquor ammonia acetate, or Harrogate sulphureous water, will frequently allay the itching: all greasy applications are to be avoided.

3. *Prurigo senilis.* This affection does not differ much in its symptoms and external appearances from the prurigo formicans; but has been thought by medical writers to merit a distinct consideration, on account of its peculiar inveteracy. The prurigo is perhaps aggravated, or becomes more permanent in old age, from the dry, condensed state of the skin and cuticle which often takes place at that period. Those who are affected with it in a high degree have little more comfort to expect during life, being incessently tormented with a violent and universal itching. The state of the skin, in the prurigo senilis, is favourable to the production of an insect, the pediculus humanus, more especially to the variety of it usually termed body-lice.

These insects, it is well known, are bred abundantly among the inhabitants of filthy dwellings, of gaols, workhouses, &c., and in such situations prey upon persons of all ages indiscriminately. But in the prurigo senilis they arise, notwithstanding every attention to cleanliness or regimen, and multiply so rapidly that the patient endures extreme distress from their perpetual irritation. The nits or eggs are deposited on the small hairs of the skin, and the pediculi are only found on the skin, or on the linen, not under the cuticle, as some authors have represented. Warm bathing gives temporary ease in this complaint. The Harrogate water is beneficial. Lotions of nitric acid and oxymuriatic acid are very useful; thirty minims of the former to ten fluid ounces of pure water, and as much muriatic acid in addition when the former fails. Sea-water bathing, and the application of sea-water, are also very beneficial. Internally, such medicines must be given as are calculated to meet constitutional defects. Tonics with mineral acids are, in most cases, useful; and, when dyspepsia exists, bitters with the mineral alkali.

In connection with the foregoing series of complaints, Dr. Willan mentions some pruriginous affections which are merely local. He confines his observations to the most troublesome of these, seated in the podex, præputium, urethra, pubes, scrotum, and pudendum muliebre. Itching of the nostrils, eyelids, lips, or of the external ear, being generally symptomatic of other diseases, do not require a particular consideration.

1. *Prurigo podicis.* Ascarides in the rectum excite a frequent itching and irritation about the sphincter ani, which ceases when the cause is removed by proper medicines. A similar complaint often arises, independently of worms, hæmorrhoidal tumours, or other obvious causes, which is mostly found to affect persons engaged in sedentary occupations, and may be referred to a morbid state of secretion in the parts, founded, perhaps, on a diminution of constitutional vigour. The itching is not always accompanied with an appearance of papulæ or tubercles: it is little troublesome during the day-time, but returns every night soon after getting into bed, and precludes rest for several hours. The complaint continues in this form during three or four months, and has then an intermission, till it is produced again by hot weather, fatigue, watching, or some irregularity in diet. The same disease occurs at the decline of life, under a variety of circumstances.

Women, after the cessation of the catamenia, are liable to be affected with this species of prurigo, more especially in summer or autumn. The skin between the nates is rough and papulated, sometimes scaly, and a little humour is discharged by violent friction. Along with this complaint, there is often an eruption of itching papulæ on the neck, breast, and back; a swelling and inflammation of one or both ears, and a discharge of matter from behind them, and from the external meatus auditorius. The prurigo podicis sometimes occurs as a symptom of the lues venerea.

2. The *prurigo præputii* is owing to an altered state of secretion on the glans penis, and inner surface of the præputium. During the heat of summer there is also, in some persons, an unusual discharge of mucus, which becomes acrimonious, and produces a troublesome itching and often an excoriation of these parts. Washing them with water, or soap and water, employed from time to time, relieves the complaint, and should, indeed, be practised as an ordinary point of cleanliness, where no inconvenience is immediately felt. If the fluid be secreted in too large a quantity, that excess may be restrained by washes made with the liquor plumbi acetatis, or by applying the unguentum plumbi acetatis.

3. *Prurigo urethralis.* A very troublesome itching sometimes takes place at the extremity of the urethra in females, without any manifest cause. It occurs as well in young women as those who are of an advanced age. On examination, no stricture nor tumour has been found along the course of the urethra. Probably, however, the itching may be occasioned by a morbid state of the neck of the bladder, being in some instances connected with pain and difficulty in making water.

An itching at the extremity of the urethra in men is produced by calculi, and by some diseases of the bladder. In cases of stricture an itching is also felt, but near the place where the stricture is situated. Another cause of it is small broken hairs, which are sometimes drawn back from the pubes, between the præputium and glans, and which afterwards becoming fixed at the entrance of the urethra, occasion an itching or slight stinging, particularly on motion. By removing the small hairs from the urethra gives immediate relief.

4. *Prurigo pubis.* Itching papulæ often break on the pubes, and become extremely sore if their tops are removed by scratching. They are occasioned sometimes by neglect of cleanliness, but more commonly by a species of pediculus, which perforates the cuticle, and thus derives nourishment, remaining fixed in the same situation. These insects are termed by Linnæus, &c. *pediculi pubis;* they do not, however, infest the pubes only, but often adhere to the eyebrows

eyelids, and axillæ. They are often found, also, on the breast, abdomen, thighs, and legs, in persons of a sanguine temperament, who have those parts covered with strong hairs. It is remarkable that they seldom or never fix upon the hairy scalp. The great irritation produced by them on the skin solicits constant scratching, by which they are torn from their attachments; and painful tubercles arise at the places where they had adhered. When the pediculi are diffused over the greater part of the surface of the body, the patient's linen often appears as if sprinkled with drops of blood.

5. *Prurigo scroti.* The scrotum is affected with a troublesome and constant itching from ascarides within the rectum, from friction by violent exercise in hot weather, and very usually from the pediculi pubis. Another and more important form of the complaint appears in old men, sometimes connected with the prurigo podicis, and referable to a morbid state of the skin, or superficial gland of the part. The scrotum, in this case, assumes a brown colour, often also becoming thick, scaly, and wrinkled. The itching extends to the skin covering the penis, more especially along the course of the urethra; and has little respite, either by day or night.

6. The *Prurigo pudendi muliebris*, is somewhat analogous to the prurigo scroti in men. It is often a symptomatic complaint in the lichen and lepra: it likewise originates from ascarides irritating the rectum; and is, in some cases, connected with a discharge of the fluor albus.

A similar affection arises in consequence of a change of state in the genital organs at the time of puberty, attended with a series of most distressing sensations. Dr. Willan confines his attention to one case of the disorder, which may be considered as idiopathic, and which usually affects women soon after the cessation of the catamenia. It chiefly occurs in those who are of the phlegmatic temperament, and inclined to corpulency. Its seat is the labia pudendi, and entrance to the vagina. It is often accompanied with an appearance of tension or fulness of those parts, and sometimes with an inflamed itching pustulæ on the labia and mons veneris. The distress arising from a strong and almost perpetual itching in the above situation may be easily imagined. In order to allay it in some degree, the sufferers have frequent recourse to friction, and to cooling applications; whence they are necessitated to forego the enjoyment of society. An excitement of venereal sensations also takes place from the constant direction of the mind to the parts affected, as well as from the means employed to procure alleviation. The complicated distress thus arising renders existence almost insupportable, and often produces a state of mind bordering on phrensy.

Deep ulcerations of the parts seldom take place in the prurigo pudendi; but the appearance of the apthæ on the labia and nymphæ is by no means unusual. From intercourse with females, under these circumstances, men are liable to be affected with small ulcerations on the penis, and inside of the præputium, which prove troublesome for a length of time, and often create an alarm, being mistaken for chancres.

Women, after the fourth month of their pregnancy, often suffer greatly from the prurigo pudendi, attended with aphthæ. These, in a few cases, have been succeeded by extensive ulcerations: such instances are, however, extremely rare. The complaint has, in general, some intervals or remissions; and the small ulcers usually disappear soon after delivery, whether at the full time or by a miscarriage.

PRURI'TUS. (*us, ûs.* m.; from *prurio*, to itch.) See *Prurigo.*

Prussian alkali. See *Alkali, phlogisticated.*

PRUSSIAN BLUE. A compound of a rich blue colour well known as a pigment. This substance, the discovery of which was made in 1710, has been studied by several chemists, especially by Proust, (An. de Chimie, lx.) by Berzelius and Robiquet, and by Porrett, whose essay was referred to in the description of ferrocyanic acid. The colouring matter of this pigment is ferrocyanate of peroxide of iron, which is mixed with alumina and peroxide of iron, together with the subsulphates of one or both of those bases. It is prepared by heating to redness dried blood, or other animal matters, with an equal weight of pearlash, until the mixture has acquired a pasty consistence. The residue, which consists chiefly of cyanuret of potassium and carbonate of potash, is dissolved in water, and after being filtered, is mixed with a solution of two parts of alum and one part of protosulphate of iron. A dirty-greenish precipitate ensues, which absorbs oxygen from the atmosphere, and passes through different shades of green and blue, until at length it acquires the proper colour of the pigment.

The chemical changes which take place in this process are of a complicated nature. The precipitate, which is at first thrown down, is occasioned by the potash, and consists chiefly of alumina and protoxide of iron. Ferrocyanic acid is generated by the protoxide reacting upon some of the hydrocyanic acid, so as to form water, and cyanuret of iron, which then unites with undecomposed hydrocyanic acid. The ferrocyanic acid, thus produced, combines with oxide of iron; and when the latter has attained its maximum of oxidation, the compound acquires its characteristic blue tint. The only apparent use of protoxide of iron is to convert hydrocyanic into ferrocyanic acid; a purpose for which its presence is essential, because peroxide of iron does not produce this effect, or at least in a very slow and imperfect manner. In every good specimen of Prussian blue which Dr. Turner examined, the ferrocyanic acid was in combination with peroxide of iron only. — *Turner.*

PRU'SSIATE. A salt formed by the union of the prussic or hydrocyanic acid with a salifiable basis.

PRU'SSIC ACID. *Acidum prussicum.* An acid, so called because it was first obtained from Prussian blue. See *Hydrocyanic acid.*

Pru'ssine. See *Cyanogen.*

PSALLOI'DES. (From ψαλλος, a stringed instrument, and ειδος, a likeness.) An appearance on the under surface of the fornix of the brain is called *corpus psalloides.*

PSALTE'RIUM. (*um*, *ii*. n.; a harp: because it is marked with lines that give it the appearance of a harp.) *Lyra*. The *corpus psalloides*. See *Encephalos*.

PSAMMI'SMUS. (From ψαμμος, sand.) An application of hot sand to any part of the body.

PSAMMO'DES. (From ψαμμος, sand.) Sand-like. Applied to urine which deposits a sandy sediment.

PSELLI'SMUS. (*us*, *i*. m.; from ψελλιζω, to stammer or hesitate in speech.) Defect of speech, in which the articulation is imperfect or depraved. Stammering and hesitation of speech, and the mispronunciation of words, are generally arranged by nosologists under this head. See *Lallatio*, *Lambdacismus*, &c.

Psellotes. See *Psellismus*.

PSEUDACORUS. (From ψευδης, false, and ακορον, the acorus plant: because it resembled and was substituted for that plant.) See *Iris pseudacorus*.

PSEUDOBLE'PSIS. (*is*, *is*. f.; from ψευδης, false, and βλεψις, sight.) Imaginary vision of objects, characterised by depraved sight, creating objects, or representing them different from what they are. Species: —

Imaginary objects floating before the sight, or real objects appearing with imaginary qualities: constituting two varieties. The most common of ocular spectres is *dark spots*, the *muscæ volitantes* of writers. They are seen in full light, and may often be seen to change their form with the motions of the eye. Another form is that of a *network*, which is sometimes permanent, sometimes transitory. A third appearance is *sparks*, or scintillations. The eye is also affected with an imaginary sense of dazzling, sometimes the ocular spectres assume an iridescent appearance, or exhibit in succession all the colours of the rainbow.

The other variety of false sight, in which real objects appear changed in their natural qualities, affords an *error of form*, in which objects appear too large, too small, cut in half, or in some way distorted; or an *error of motion*, in consequence of which they seem to be dancing, nodding, or in rapid succession; or *error of number*, and then they appear double, triple, or otherwise increased or multiplied; or *error of colour*, in which case one hue is mistaken for another, as red for green, or green for yellow, or every hue appears alike.

Exposure to cold, spasmodic affections, or structural disease of some part, have produced these affections, but the causes are not well known. Where no organic disease is known to exist, and debility or an opposite condition of the optic nerves, blood-vessels, or iris is suspected, blisters, local bleeding, or stimulating applications should be resorted to.

The appearances constituting false sight are mostly symptomatic or sympathetic, and accompany inflammation of or about the eyes or brain; also fevers, hysteria, syncope, lethargy, apoplexy, &c.

PSEU'DOCYE'SIS. (*is*, *is*. f.; from ψευδης, false, and κυησις, pregnancy.) False conception.

PSEU'DÆSTHE'SIA. (*a*, *æ*. f.; from ψευδος, false, and αισθανομαι, to feel.) Imaginary or false feeling, or imaginary sense of touch in organs which have no existence. This is frequently mentioned by persons who have suffered amputation; who, for a long time after the loss of the separated limb, have still a sense of its forming a part of the body, and suffer in idea the same kind of pain or other inconvenience they endured before its removal. It proceeds from that close sympathy which prevails between the extremities of the living fibres in all organs whatever. A like imaginary sensation is frequently complained of in hypochondriacism, and various mental affections.

PSEU'DOMELA'NTHIUM. (*um*, *i*. n.; from ψευδης, false, and μελανθιον, the herb gith, the name of a plant.) See *Agrostemma githago*.

PSEUDOME'MBRANE. (A hybrid term.) A false membrane, or organised layer of lymph, effused in consequence of inflammation.

PSEUDOPYRE'THRUM. (*um*, *i*. n.; from ψευδης, false, and πυρεθρον: so called because when the flowers are chewed they impart a warmth somewhat like that of pyrethrum root.) See *Achillæa ptarmica*.

Pseudo-syphilis. See *Syphilis*.

PSI'DIUM. (*um*, *i*. n.; altered by Linnæus from ψιδιας of the ancient Greeks.) The name of a genus of plants in the Linnæan system. Class, *Icosandria*; Order, *Monogynia*.

PSIDIUM POMI'FERUM. The systematic name of the apple guava. This plant, and the *pyriferum*, bear fruits, the former like apples, the latter like pears. The apple kind is most cultivated in the Indies, on account of the pulp having a fine acid flavour, whereas the pear species is sweet, and therefore not so agreeable in warm climates. Of the inner pulp of either the inhabitants make jellies; and of the outer rind they make tarts, marmalades, &c. The latter they also stew and eat with milk, and prefer them to any other stewed fruits. They have an astringent quality, which exists also in every part of the tree, and abundantly in the leaf-buds, which are occasionally boiled with barley and liquorice, as an excellent drink against diarrhœas. A simple decoction of the leaves, used as a bath, is said to cure the itch, and most cutaneous eruptions.

PSIDIUM PYRI'FERUM. The guava pear-tree. See *Psidium pomiferum*.

PSILO'THRA. (From ψιλοω, to denudate.) Applications to remove the hair.

PSILO'THRUM. (From ψιλοω, to depilate: so called because it was used to remove the hair.) The white bryony.

PSIMMY'THIUM. (From ψιω, to smooth: so called because of its use as a cosmetic.) Cerusse, or white lead.

PSO'Æ. (Ψοαι, the loins.) *Alopeces*. *Nephrometræ*. *Neurometeres*. 1. The loins.

2. The name of two pair of muscles in the loins.

PSO'AS. (From ψοαι, the loins.) Belonging to the loins.

Psoas abscess. See *Lumbar abscess*.

PSOAS MAGNUS. *Psoas, seu lumbaris in-*

ternus, of Winslow. This is a long, thick, and very considerable muscle, situated close to the fore-part and sides of the lumbar vertebræ. It arises from the bodies of the last vertebræ of the back, and of all the lumbar vertebræ laterally, as well as from the anterior surfaces of their transverse processes, by distinct tendinous and fleshy slips, that are gradually collected into one mass, which becomes thicker as it descends, till it reaches the last of the lumbar vertebræ, where it grows narrower again, and, uniting its outer and posterior edge (where it begins to become tendinous) with the iliacus internus, descends along with that muscle under the ligamentum Fallopii, and goes to be inserted tendinous at the bottom of the trochanter minor of the os femoris, and fleshy into the bone a little below that process. Between the tendon of this muscle and the ischium we find a considerable bursa mucosa. This muscle, at its origin, has some connexion with the diaphragm, and likewise with the quadratus lumborum. It is one of the most powerful flexors of the thigh forwards, and may likewise assist in turning it outwards. When the inferior extremity is fixed, it may help to bend the body forwards; and in an erect posture it greatly assists in preserving the equilibrium of the trunk upon the upper part of the thigh.

Psoas parvus. This muscle, which was first described by Riolanus, is situated upon the psoas magnus, at the anterior part of the loins. The psoas parvus arises thin and fleshy from the side of the uppermost vertebra of the loins, and sometimes also from the lower edge of the last vertebra of the back, and from the transverse processes of each of these vertebræ: it then extends over part of the psoas magnus, and terminates in a thin flat tendon, which is inserted into that part of the brim of the pelvis where the os pubis joins the ilium. From this tendon a great number of fibres are sent off, which form a thin fascia, that covers part of the psoas magnus and iliacus internus, and gradually loses itself on the fore-part of the thigh. In the human body this muscle is very often wanting; but in a dog, according to Douglas, it is never deficient. Riolanus was of opinion, that it occurs oftener in men than in women. Winslow asserts just the contrary; but the truth seems to be, that it is as often wanting in one sex as in the other. Its use seems to be to assist the psoas magnus in bending the loins forwards; and when we are lying upon our back, it may help to raise the pelvis.

Psoas sive lumbaris internus. See *Psoas magnus.*

PSO'RA. (*a*, *æ*. f. Ψωρα.) The itch. See *Scabies.*

PSORA'LEA. (*a*, *æ*. f.; from ψωραλεος, scabby: because the calyx, and other parts of the plant, are more or less besprinkled with glandular dots, causing a scurfy roughness.) The name of a genus of plants. Class, *Diadelphia*; Order, *Decandria.*

Psoralea pentaphy'lla. The systematic name of the Mexican contrayerva, *Contrayerva nova*, which is by many as much esteemed as the Dorstenia. It was introduced into Europe soon after the true plant, from Guiana as well as Mexico.

PSORI'ASIS. (*is*, *is*. f.; from ψωρα, the itch.) The disease to which Dr. Willan gives this title is characterised by a rough and scaly state of the cuticle, sometimes continuous, sometimes in separate patches, of various sizes, but of an irregular figure, and for the most part accompanied with rhagades or fissures of the skin. From the lepra it may be distinguished, not only by the distribution of the patches, but also by its cessation and recurrence at certain seasons of the year, and by the disorder of the constitution with which it is usually attended. Dr. Willan gives the following varieties: —

1. *Psoriasis guttata.* This complaint appears in small, distinct, but irregular patches of laminated scales, with little or no inflammation round them. The patches very seldom extend to the size of a sixpence. They have neither an elevated border, nor the oval or circular form by which all the varieties of lepra are distinguished; but their circumference is sometimes angular, and sometimes goes into small serpentine processes. The scale formed upon each of them is thin, and may be easily detached, leaving a red shining base. The patches are often distributed over the greatest part of the body, but more particularly on the back part of the neck, the breasts, arms, loins, thighs, and legs. They appear also upon the face, which rarely happens in lepra. In that situation they are red, and more rough than the adjoining cuticle, but not covered with scales. The psoriasis guttata often appears on children in a sudden eruption, attended with a slight disorder of the constitution, and spreads over the body within two or three days. In adults it commences with a few scaly patches on the extremities, proceeds very gradually, and has a longer duration than in children. Its first occurrence is usually in the spring season, after violent pains in the head, stomach, and limbs. During the summer it disappears spontaneously, or may be soon removed by proper applications, but it is apt to return again early in the ensuing spring, and continues so to do for several successive years. When the scales have been removed, and the disease is about to go off, the small patches have a shining appearance, and they retain a dark red, intermixed with somewhat of a bluish colour, for many days, or even weeks, before the skin is restored to its usual state. In the venereal disease there is an eruption which very much resembles the psoriasis guttata, the only difference being a slighter degree of scaliness, and a different shade of colour in the patches, approaching to a livid red, or very dark rose colour. The patches vary in their extent, from the section of a pea to the size of a silver penny, but are not exactly circular. They rise at first very little, if at all, above the cuticle. As soon, however, as the scales appear on them, they become sensibly elevated; and sometimes the edge, or circumference of the patch is higher than the little scales in its centre. This eruption is usually seen upon the forehead, breast, between the shoulders, or in the inside of the fore-arms, in the groins, about the inside of the

thighs, and upon the skin covering the lower part of the abdomen. The syphilitic psoriasis guttata is attended with, or soon followed by, an ulceration of the throat. It appears about six or eight weeks after a chancre has been healed by an ineffectual course of mercury. A similar appearance takes place, at nearly the same period, in some cases where no local symptoms had been noticed. When a venereal sore is in a discharging state, this eruption, or other secondary symptoms, often appear much later than the period above mentioned. They may also be kept back three months, or even longer, by an inefficient application of mercury. If no medicine be employed, the syphilitic form of the psoriasis guttata will proceed during several months, the number of the spots increasing, and their bulk being somewhat enlarged, but without any other material alteration.

2. The *Psoriasis diffusa* spreads into large patches, irregularly circumscribed, reddish, rough, and chappy, with scales interspersed. It commences, in general, with numerous minute asperities, or elevations of the cuticle, more perceptible by the touch than by sight. Upon these small distinct scales are soon after formed, adhering by a dark central point, while their edges may be seen white and detached. In the course of two or three weeks all the intervening cuticle becomes rough and chappy, appears red, and raised, and wrinkled, the lines of the skin sinking into deep furrows. The scales which form among them are often slight, and repeatedly exfoliate. Sometimes, without any previous eruption of papulæ, a large portion of the skin becomes dry, harsh, cracked, reddish, and scaly, as above described. In other cases, the disorder commences with separate patches of an uncertain form and size, some of them being small, like those in the psoriasis guttata, some much larger. The patches gradually expand till they become confluent, and nearly cover the part or limb affected. Both the psoriasis guttata and diffusa likewise occur as a sequel of the lichen simplex. This transition takes place more certainly after frequent returns of the lichen. The parts most affected by psoriasis diffusa are the cheeks, chin, upper eyelids, and corners of the eyes, the temples, the external ear, the neck, the fleshy parts of the lower extremities, and the fore-arm, from the elbow to the back of the hand, along the supinator muscle of the radius. The fingers are sometimes nearly surrounded with a loose scaly incrustation; the nails crack and exfoliate superficially. When limited to the back of the hand, where it often appears in bakers, it is called the *bakers' itch*. The scaly patches likewise appear, though less frequently, on the forehead and scalp, on the shoulders, back, and loins, on the abdomen and instep. This disease occasionally extends to all the parts above mentioned at the same time; but, in general, it affects them successively, leaving one place free, and appearing in others; sometimes again returning to its first situation. The psoriasis diffusa is attended with a sensation of heat, and with a very troublesome itching, especially at night. It exhibits small, slight, distinct scales, having less disposition than the lepra to form thick crusts. The chaps, or fissures of the skin, which usually make a part of this complaint, are very sore and painful, but seldom discharge any fluid. When the scales are removed by frequent washing, or by the application of unguents, the surface, though raised and uneven, appears smooth and shining; and the deep furrows of the cuticle are lined by a slight scaliness. Should any portion of the diseased surface be forcibly excoriated, there issues out a thin lymph, mixed with some drops of blood, which slightly stains and stiffens the linen, but soon concretes into a thin dry scab; this is again succeeded by a white scaliness, gradually increasing, and spreading in various directions. As the complaint declines, the roughness, chaps, scales, &c. disappear, and a new cuticle is formed, at first red, dry, and shrivelled, but which, in two or three weeks, acquires the proper texture. The duration of the psoriasis diffusa is from one to four months. If, in some constitutions, it does not then disappear, but becomes, to a certain degree, permanent, there is, at least, an aggravation or extension of it, about the usual periods of its return. In other cases, the disease, at the vernal returns, differs much as to its extent, and also with respect to the violence of the preceding symptoms. The eruption is, indeed, often confined to a single scaly patch, red, itching, and chapped, of a moderate size, but irregularly circumscribed. This solitary patch is sometimes situated on the temple, or upper part of the cheek, frequently on the breast, the calf of the leg, about the wrist, or within and a little below the elbow joint, but especially at the lower part of the thigh, behind. It continues in any of these situations several months, without much observable alteration. The complaint, denominated with us the bakers' itch, is an appearance of psoriasis diffusa on the back of the hand, commencing with one or two small, rough, scaly patches, and finally extending from the knuckles to the wrist. The rhagades, or chaps and fissures of the skin, are numerous about the knuckles and ball of the thumb, and where the back of the hand joins the wrist. They are often highly inflamed and painful, but have no discharge of fluid from them. The back of the hand is a little raised or tumefied, and, at an advanced period of the disorder, exhibits a reddish, glossy surface, without crusts or numerous scales. However, the deep furrows of the cuticle are, for the most part, whitened by a slight scaliness. This complaint is not general among bakers: that it is only aggravated by their business, and affects those who are otherwise disposed to it, may be collected from the following circumstances: — 1. It disappears about Midsummer, and returns in the cold weather at the beginning of the year. 2. Persons constantly engaged in the business, after having been once affected with the eruption, sometimes enjoy a respite from it for two or three years. 3. When the business is discontinued, the complaint does not immediately cease. The grocers' itch has some

affinity with the bakers' itch, or tetter; but, being usually a pustular disease at its commencement, it properly belongs to another genus. Washerwomen, probably from the irritation of soap, are liable to be affected with a similar scaly disease on the hands and arms, sometimes on the face and neck, which, in particular constitutions, proves very troublesome, and of long duration.

3. The *Psoriasis gyrata* is distributed in narrow patches or stripes, variously figured: some of them are nearly longitudinal; some circular, or semicircular, with vermiform appendages; some are tortuous or serpentine; others like earth-worms or leeches: the furrows of the cuticle being deeper than usual, make the resemblance more striking, by giving to them an annulated appearance. There is a separation of slight scales from the diseased surface, but no thick incrustations are formed. The uniform disposition of these patches is singular. A large circular one is sometimes situated on each breast above the papillæ; and two or three others, of a serpentine form, in analogous situations along the side of the chest. The back is often variegated in like manner, with convoluted tetters, similarly arranged on each side of the spine. They likewise appear, in some cases, on the arms and thighs, intersecting each other in various directions. A slighter kind of this complaint affects delicate young women and children in small scaly circles or rings, little discoloured: they appear on the cheeks, neck, or upper part of the breast, and are mostly confounded with the herpetic or pustular ringworm. The psoriasis gyrata has its remissions and returns, like the psoriasis diffusa: it also exhibits, in some cases, patches of the latter disorder on the face, scalp, or extremities, while the trunk of the body is chequered with the singular figures above described.

4. *Psoriasis palmaria.* This very obstinate species of tetter is nearly confined to the palm of the hand. It commences with a small, harsh, or scaly patch, which gradually spreads over the whole palm, and sometimes appears in a slighter degree on the inside of the fingers and wrist. The surface feels rough from the detached and raised edges of the scaly laminæ: its colour often changes to brown, or black, as if dirty; yet the most diligent washing produces no favourable effect. The cuticular furrows are deep, and cleft at the bottom longitudinally, in various places, so as to bleed on stretching the fingers. A sensation of heat, pain, and stiffness in the motions of the hand, attend this complaint. It is worse in winter or spring, and occasionally disappears in autumn or summer, leaving a soft, dark red cuticle; but many persons are troubled with it for a series of years, experiencing only very slight remissions. Every return or aggravation of it is preceded by an increase of heat and dryness, with intolerable itching. Shoemakers have the psoriasis palmaria locally, from the irritation of the wax they so constantly employ. In braziers, tinmen, silversmiths, &c. the complaint seems to be produced by handling cold metals. A long predisposition to it, from a weak, languid, hectical state of the constitution, may give effect to different occasional causes. Dr. Willan has observed it in women after lying-in: in some persons it is connected or alternates with arthritic complaints. When the palms of the hands are affected as above stated, a similar appearance often takes place on the soles of the feet; but with the exception of rhagades or fissures, which seem less liable to form there, the feet being usually kept warm and covered. Sometimes, also, the psoriasis palmaria is attended with a thickness of the præputium, with scaliness and painful cracks. These symptoms at last produce a phimosis, and render connubial intercourse difficult or impracticable: so great, in some cases, is the obstinacy of them, that remedies are of no avail, and the patient can only be relieved by circumcision. This affection of the præputium is not exactly similar to any venereal appearance; but rhagades or fissures, and indurated patches within the palm of the hand, take place in syphilis, and somewhat resemble the psoriasis palmaria. The venereal patches are, however, distinct, white and elevated, having nearly the consistence of a soft corn. From the rhagades there is a slight discharge, very offensive to the smell. The soles of the feet are likewise, in this case, affected with the patches, not with rhagades. When the disease yields to the operation of mercury, the indurated portions of cuticle separate, and a smooth new cuticle is found formed underneath. The fingers and toes are not affected with the patches, &c. in venereal cases.

5. *Psoriasis labialis.* The psoriasis sometimes affects the lip without appearing on any other part of the body. Its characteristics are, as usual, scaliness, intermixed with chaps and fissures of the skin. The scales are of a considerable magnitude, so that their edges are often loose, while the central points are attached, a new cuticle gradually forms beneath the scales, but is not durable. In the course of a few hours it becomes dry, shrivelled and broken; and, while it exfoliates, gives way to another layer of tender cuticle, which soon in like manner perishes. These appearances should be distinguished from the light chaps and roughness of the lips produced by very cold or frosty weather, but easily removed. The psoriasis labialis may be a little aggravated by frost or sharp winds, yet it receives no material alleviation from an opposite temperature. It is not, indeed, confined within any certain limit, or period of duration, having, in several instances, been protracted through all the seasons. The under lip is always more affected than the upper; and the disease takes place more especially in those persons whose lips are full and prominent.

6. *Psoriasis scrotalis.* The skin of the scrotum may be affected in the psoriasis diffusa like other parts of the surface of the body; but sometimes a roughness and scaliness of the scrotum appears as an independent complaint, attended with much heat, itching, tension, and redness. The above symptoms are succeeded by a hard, thickened, brittle texture of the skin, and by painful chaps or excoriations, which are not easy to be healed. This complaint is sometimes produced under the same circumstances as the prurigo

scroti, and appears to be in some cases a sequel of it. A species of the psoriasis scrotalis likewise occurs in the lues venerea, but merits no particular attention, being always combined with other secondary symptoms of the disease.

7. *Psoriasis infantilis.* Infants between the ages of two months and two years are occasionally subject to the dry tetter. Irregular scaly patches, of various sizes, appear on the cheeks, chin, breast, back, nates, and thighs. They are sometimes red, and a little rough or elevated; sometimes excoriated, then again covered with a thin incrustation; and, lastly, intersected by chaps or fissures. The general appearances nearly coincide with those of the psoriasis diffusa; but there are several peculiarities in the tetters of infants which require a distinct consideration.

8. The *Psoriasis inveterata* is characterised by an almost universal scaliness, with a harsh, dry, and thickened state of the skin. It commences with a few irregular though distinct patches on the extremities. Others appear afterwards on different parts, and, becoming confluent, spread at length over all the surface of the body, except a part of the face or sometimes the palms of the hands, and soles of the feet. The skin is red, deeply furrowed or wrinkled, stiff and rigid, so as somewhat to impede the motion of the muscles, and of the joints. So quick, likewise, is the production and separation of scales, that large quantities of them are found on the bed on which a person affected with the disease has slept. They fall off in the same proportion by day, and being confined within the linen, excite a troublesome and perpetual itching.

The same general plan of treatment is applicable to the different modifications of psoriasis, the period of its duration and the degree of irritability being carefully attended to. In the commencement of the eruption, when it appears suddenly, and the constitution is obviously disordered, a moderate antiphlogistic treatment must be pursued. A gentle purgative should be administered, and the diet made light, by abstracting every thing stimulant. This regimen, indeed, is requisite throughout the course of the disease, which is immediately aggravated in sympathy with irritation of the stomach, whether by spices, fermented liquors, pickles, or vegetable acids; whence the disuse of these articles contributes materially to its cure. But if the constitutional disturbance has subsided, the use of the fixed alkali, combined with sulphur lotum, or with an infusion of cinchona, together with tepid washing with simple water, or milk and water, will gradually remove the complaint. If the scaly patches have extended over a considerable part of the body, it must be viewed in a similar light with the lepra, and the remedies recommended for the first and second species of that disease must be resorted to. The shooting and burning pain and itching, in the early and more inflammatory stages of psoriasis, induce the patient to seek anxiously for relief from local external applications; but he is mortified to find that even the mildest substances prove irritants, and aggravate his distress. A decoction of bran, a little cream, or oil of almonds, sometimes produce ease; but any admixture, even of the oxide of zinc, or preparations of lead, with these liniments, is commonly detrimental. But the more local and less inflammatory eruption of psoriasis is considerably alleviated by local expedients. The palmar variety is deprived of its dryness and itching by exposure to the vapour of hot water, and by the application of the unguentum hydrargyri nitratis, diluted with the unguentum cetacei or ceræ, according to the degree of irritation in the skin. The scrotal and ophthalmic varieties are also relieved by the same application, or the unguentum hydrargyri precipitati albi: but great care is requisite, in the former case, to keep the parts clean by frequent ablution, and to prevent attrition. In the psoriasis of the lips, nothing acrid can be borne; and much of the cure depends upon securing the parts from irritation, even from heat and cold, by a constant covering of some mild ointment or plaster. In all these cases, some of the internal remedies above mentioned must be at the same time employed, according to the period and other circumstances of the disease.

PSO'RIC. (*Psoricus*; from ψωρα, the itch.) Appertaining to the itch, or *psora*.

PSOROPTHA'LMIA. (*a*, *æ*. f.; from ψωρα, the itch, and οφθαλμος, the eye.) Psorophthalmy. An inflammation of the eyelids, attended with ulcerations, which itch very much. The cause is an acrimony secreted by the glands of the eyelids. See *Ophthalmitis*.

PSYCHAGO'GICUS. (From ψυχη, the mind, and αγω, to move.) Applied by Schneider to medicines which have the power of restoring the senses; as volatiles and stimulants, which recover a patient from syncope.

PSYCHOLOGY. (*Psychologia*, *æ*. f.; from ψυχη, the soul, and λογος, a discourse.) The doctrine of the mind or soul. Mental philosophy.

PSYCHROLU'TRUM. (From ψυχος, cold, and λουω, to wash.) A cold bath.

PSY'CHTICUS. (From ψυχω, to refrigerate.) Having a cooling property: applied to refrigerating medicines.

PSYDRA'CIUM. (*um*, *ii*. n.; from ψυχος, cold.) A species of pustule. See *Pustule*.

PSY'LLIUM. (*um*, *ii*. n.; from ψυλλος, a flea: so called because it was thought to destroy fleas.) See *Plantago psyllium*.

PTA'RMICA. (*a*, *æ*. f.: from πταιρω, to sneeze: so called, because it irritates the nose, and provokes sneezing.) Sneezewort. See *Achillæa ptarmica*.

PTA'RMICUS. (Πταρμικος; from πταιρω, to sneeze.) Ptarmic. Sternutatory.

PTE'RIS. (*is*, *idis*. f.; from πτερον, a wing, so called from the likeness of its leaves to wings.) The name of a genus of plants in the Linnæan system. Class, *Cryptogamia*; Order, *Filices*.

PTERIS AQUILI'NA. The systematic name of the common brake, or female fern. *Filix. Filix fœmina*. The plant which is thus called in the pharmacopœias, is not the *Polypodium filix fœmina*, but the *Pteris—frondibus supra-*

decompositis, *foliolis pinnatis*, *pinnis lanceolatis*, *infimis*, *pinnatifidis*, *superioribus minoribus*, of Linnæus. The root is esteemed as an anthelmintic, and is supposed to be as efficacious in destroying the tapeworm as the root of the male fern.

PTEROCA'RPUS. (*us*, *i.* m.; from πτερον, a wing, and καρπος, fruit.) The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria*.

Pterocarpus draco. This is one of the species which yields dragon's blood. See *Dragon's blood*.

Pterocarpus erina'ceus. The tree which is supposed to yield the African kino. See *Kino*.

Pterocarpus santali'nus. The systematic name of the red saunders tree. *Santalum rubrum*. There is some reason to believe that several red woods, capable of communicating this colour to spirituous liquors, are sold as red saunders; but the true officinal kind appears, on the best authority, to be of this tree, which is extremely hard, of a bright, garnet-red colour, and bears a fine polish. It is only the inner substance of the wood that is used as a colouring matter, and the more florid red is the most esteemed. On being cut, it is said to manifest a fragrant odour, which is more especially observed in old trees. According to Lewis, this wood is of a dull red, almost blackish colour on the outside, and a deep brighter red within; its fibres are now and then curled, as in knots. It has no manifest smell, and little or no taste; even of extracts made from it with water, or with spirit, the taste is not considerable.

To watery liquors it communicates only a yellowish tinge, but to rectified spirit a fine deep red. A small quantity of an extract made with this menstruum tinges a large one of fresh spirit of the same colour; though it does not, like most other resinous bodies, dissolve in expressed oils. Of distilled oils, there are some, as that of lavender, which receive a red tincture from the wood itself, and from its resinous extract, but the greater number do not. Red saunders has been esteemed as a medicine; but its only use attaches to its colouring property. The juice of this tree, like that of some others, affords a species of sanguis draconis.

PTERY'GIUM. (*um*, *ii.* n. Πτερυξ, a wing.) 1. In *Pathology*, a membraneous excrescence which grows upon the internal canthus of the eye chiefly, and expands itself over the albuginea and cornea towards the pupil. It appears to be an extension or promulgation of the fibres and vessels of the caruncula lachrymalis, or semilunar membrane, appearing like a wing. It is sometimes a pellucid pellicle, thin, of a cineritious colour, and unpainful, growing out from the caruncula lachrymalis. In other cases it is thick, of a red colour, attended with fulness of the vessels on the white of the eye, and stretches over the cornea like fasciculi of vessels. This was called *pannus*: this pannus is occasionally of various colours, painful and cancerous. The *pterygium pingue*, or *pinguicula*, is a small substance, like lard or fat, soft, without pain, and of a light yellow colour, which commonly is situated in the external angle of the eye, and rarely extends to the cornea; but often remains through life.

2. In *Botany*, a wing. See *Ala*.

Pte'rygo-pharyngæ'us. See *Constrictor pharyngeus superior*.

Pte'rygo-staphili'nus exte'rnus. See *Levator palati*.

PTE'RYGOID. (*Pterygoides*. *Pterygoideus*; from πτερυξ, a wing, and ειδος, resemblance.) Resembling the wing of a bird.

Pterygoid processes. The wing-like processes of the sphenoid bone. See *Sphenoides os*.

Pterygoideum os. See *Sphenoides os*.

Pterygoide'us externus. (*Pterygoideus*, from its belonging to the processus pterygoides.) *Pterygoideus minor*, of Winslow. *Musculus alaris externus*. A muscle placed, as it were, horizontally along the basis of the skull, between the pterygoid process and the condyle of the lower jaw. It usually arises by two distinct heads, one of which is thick, tendinous, and fleshy, from the outer wing of the pterygoid process of the os sphenoides, and from a small part of the os maxillare adjoining to it; the other is thin and fleshy, from a ridge in the temporal process of the sphenoid bone, just behind the slit that transmits the vessels to the eye. Sometimes this latter origin is wanting, and, in that case, part of the temporal muscle arises from this ridge. Now and then it affords a common origin to both these muscles. From these origins the muscle forms a strong fleshy belly, which descends almost transversely outwards and backwards, and is inserted, tendinous and fleshy, into a depression in the forepart of the condyloid process of the lower jaw, and into the anterior surface of the capsular ligament that surrounds the articulation of that bone. All that part of this muscle, which is not hid by the pterygoideus internus, is covered by a ligamentous expansion, which is broader than that belonging to the pterygoideus internus, and originates from the inner edge of the glenoid cavity of the lower jaw, immediately before the styloid process of the temporal bone, and extends obliquely downwards, forwards and outwards, to the inner surface of the angle of the jaw. When these muscles act together, they bring the jaw horizontally forwards. When they act singly, the jaw is moved forwards, and to the opposite side. The fibres that are inserted into the capsular ligament, serve likewise to bring the moveable cartilage forwards.

Pterygoideus internus. *Pterygoideus major*, of Winslow. This muscle arises tendinous and fleshy from the whole inner surface of the external ala of the pterygoid process, filling all the space between the two wings; and from that process of the os palati that makes part of the pterygoid fossa. Thence growing larger the muscle descends obliquely downwards, forwards, and outwards, and is inserted, by tendinous and fleshy fibres, into the inside of the lower jaw, near its angle. This muscle covers a great part of the *pterygoideus externus*; and along its posterior edge we observe a ligamentous band, which extends from the back part of the styloid process to the bottom of the angle of the lower jaw. The use of this muscle is

to raise the lower jaw, and to pull it a little to one side.

Pterygoideus major. See *Pterygoideus internus.*

Pterygoideus minor. See *Pterygoideus externus.*

PTE'RYGO-STAPHYLI'NUS. Chaussier's name for the circumflexus palati muscle.

PTILO'SIS. (From πτιλος, bald.) See *Madarosis.*

PTI'SANA. (*a*, *æ*. f.; from πτισσω, to decorticate, bruise, or pound.) A ptisan. A decoction made of decorticated barley, raisins, liquorice, or other vegetable matters. The French physicians use a variety of ptisans. See *Tisane.*

PTO'SIS. (*is*, *is*. f.; from πιπτω, to fall.) A falling down of the upper eyelid. See *Blepharoptosis.*

PTYA'LAGOGUE. (*Ptyalagogus*; from πτυαλον, spittle, and αγω, to excite.) A medicine, or any thing which promotes a discharge of the saliva or causes salivation.

Ptyali'smus. See *Ptyalism.*

PTY'ALISM. (*Ptyalismus*, *i*. m.; from πτυαλιζω, to spit.) A ptyalism: salivation, or increased secretion of saliva.

An increased and involuntary flow of saliva may be caused in a variety of ways. Fits of anger, and many excitements of the mind, will cause it; chewing sialagogues; the sight, smell, or even thought of agreeable food; it is a common effect of mercury, and is symptomatic of many diseases of the mouth and neighbouring parts. Its species are,

1. *Salivation from sialagogues.* — There are numerous plants which stimulate the salivary glands, so as to cause a very considerable salivation, but particularly the root of the *Anthemis pyrethrum*, or pellitory of Spain; the leaves of the *Nicotiana tabacum*, or tobacco; the root of the *Daphne mezereum*; the *Pimpinella saxifraga*, or smaller burnet saxifrage; the *Imperatoria ostruthrum*, or master-wort. The increased flow of saliva which they cause, generally ceases after an hour, and does not return unless they are used again.

2. *Mercurial ptyalism.* — In whatever mode introduced into the system, quicksilver generally produces salivation, and that after a short time, and even from a small quantity. The discontinuance of mercury is the cure: it soon subsides: but it is often attended with much inconvenience; as a high degree of irritation, not only of the mouth and fauces, but of the system generally. The common course of symptoms is this: the mouth feels uncommonly hot, and there is a coppery or metallic taste; the lingual and sublingual glands swell; aphthous vesicles appear, and terminate in minute and offensive ulcerations; the tongue swells; the throat becomes sore; feverishness and sleeplessness supervene, and are often present from an early period of the disease; and, in habits of great irritability, the surface of the body is, in particular parts or wholly, reddened with a peculiar erythematic inflammation, continuous or in patches, to which the names of *hydrargyria* and *erythema mercuriale* have been given by some writers. See *Eczema.* It is not at all understood by what means mercury produces this singular effect on the salivary glands.

In attempting the cure of mercurial salivation, the attention is to be directed to the local state of the fauces, and the general state of the system. The use of all mercurials is to be avoided, both externally and internally. The patient is to be moved into a pure air, and warmth is to be guarded against, as well as exposure to cold: but there is no reason why the person should not be exposed to pure and open air in the summer time. The bowels are to be kept soluble with saline aperients. Acidulated gargles of barley-water, with nitre, citric acid, and the like, will often be sufficient, or very dilute compound infusion of roses; but the best of all gargles by far is the chlorate of soda or lime, so diluted as not to produce more than just a sensible sting in the mouth.

3. *Symptomatic salivation.* — This is produced by dentition, small-pox, scarlatina, palsy, and some diseases of the mouth; and requires the gargles just mentioned, and the remedies calculated to relieve the disease of which it is symptomatic.

4. *Critical salivation.* — This occurs sometimes in fevers, and is relieved by the gargles before enumerated, and by bark and wine.

5. *Chronic ptyalism.* — The long use of tobacco causes this sometimes; and it is an attendant on old age and idiotism.

PTY'ALUM. (From πτυω, to spit up.) The mucus ejected from the bronchia.

PTYSMAGO'GUS. (From πτυσμα, *sputum*, and αγω, to expel.) Expectorant.

PU'BERTY. The transition from childhood to youth; or that period of life when the individual acquires the power of propagation. The age of puberty varies extremely according to climate. In torrid climates boys arrive at puberty at twelve years of age; in temperate ones at fourteen or fifteen; while in high northern latitudes this change is frequently deferred till eighteen or twenty. Girls arrive at puberty about two years earlier than boys. The law of England fixes the age of puberty at fourteen in the male, and twelve in the female; but this, as a general estimate, is earlier than the truth as a large proportion of individuals at these ages are still children. Puberty in man is marked by a sudden increase of strength and stature; a change in the tone of the voice, which after remaining for some time cracked and discordant settles into a graver tone than it formerly possessed; the development of hair on the pubes and in the arm-pits, succeeded at some distance of time by the development of the beard; lastly, the desire for the female, and the power of secreting a fertile semen. In woman, the phenomena of puberty consist chiefly in a change of shape in the genital organs: the growth of hair on the pubes and in the arm-pits; the enlargement of the breasts; lastly, the appearance of the menses and the aptitude for conception. These physical changes in both sexes are accompanied with corresponding alterations in the moral constitution.

PU'BES. (*es*, *is*. f.) 1. In *Anatomy*, the external part of the organs of generation of both sexes, which, after puberty, is covered with hair.

2. In *Botany*, the down or pubescence on the leaves, seeds, &c. of some plants. See *Pubescence.*

PU'BES. *Puber.* Adolescent. Arrived at the age of puberty.

Pubes seminis. See *Pappus.*

PUBE'SCENCE. *Pubescentia.* Under this term are included all kinds of down, hairs, and bristle-like bodies found on the surface of the leaves, stems, pods, &c., of plants. They differ considerably in form and texture, but consist of small slender bodies, which are either soft and yielding to the slightest impression, or rigid and comparatively unyielding: the former are, properly speaking, *pili*, or hairs; the latter bristles, *setæ*; and therefore, under these two heads, every kind of pubescence may be arranged. See *Pilus*, and *Seta.*

PUBE'SCENS. Pubescent: clothed with a soft wool or hair. Applied to the leaves, stems, &c., of plants.

Pubis os. A separate bone of the fœtal pelvis. See *Innominatum os.*

PUDE'NDAGRA. (*a*, *æ*. f.; from *pudenda*, the private parts, and αγρα, a seizure.) Any disease of the genital organs. An ill constructed and superfluous term.

PUDE'NDUM. (*um*, *i*. n.; from *pudes*, to be ashamed.) *Pudenda.* The parts of generation.

Pudendum muliebre. The female parts of generation.

PU'DIC. (*Pudi'cus*; from *pudor*, shame.) Belonging to the *pudenda.*

Pudic arteries. *Arteriæ pudi'cæ.* Pudendal arteries. The arteries which supply the parts of generation. These are, 1. the *internal pudic.* Sometimes simply called the *pudic*, which is a branch of the internal iliac, and gives off the external hæmorrhoidal and perineal arteries, and those of the penis. 2. The *external pudic arteries*, varying in number, and rising from the common femoral artery.

Pudic nerve. This is formed on each side by fibrils from all the cords which enter into the constitution of the great sciatic nerve. It arises in two fasciculi, which pass through the lower part of the iliac notch, and between the sacro-sciatic ligaments to join the pudic artery, the branches of which they accompany, bearing the same names.

Pueri'lis morbus. The epilepsy.

PUE'RPERAL. *Puerperalis.* Appertaining to child-bearing; as puerperal convulsions, puerperal fever, &c.

Puerperal fever. Several distinct affections have been treated of under this name. There has been much controversy as to what puerperal fever really is. Now the following appears to be the proper answer to this question. Puerperal fever is a vague term, meaning nothing more than a fever occurring in a woman who has recently lain in: but lying-in women, like other persons, are subject to divers forms of febrile disease; and, accordingly, certain authors have described one kind of febrile affection of lying-in women, and called it *puerperal fever*, and maintained that no other disease ought to be so called; while other authors have described another form of febrile disease incident to lying-in women, and called that *puerperal fever*, and maintained its exclusive right to the denomination; and so on with other authors and other affections. The real point at issue, therefore, is, not as to the pathology of any one given disease, but as to the respective claims of a number of different diseases to the particular title *puerperal fever*: hence the dispute is about words, and the best way of settling it, like others of a similar kind, would be to discard the term that has given rise to it.

The principal diseases which have passed under the name of puerperal fever are,

1. Peritonitis.

2. An adynamic febrile disease, supposed to be of a contagious nature, and of which peritoneal inflammation is a prominent feature; it being, at the same time, doubtful whether the inflammation should be considered as a complication of an idiopathic fever, or the fever as symptomatic of a peculiar and malignant form of inflammation: just as in the disease called *malignant pneumonia*, it frequently admits of a doubt whether the inflammation of the lungs be the primary affection or a complication of typhous fever.

3. Inflammation of the uterus or its appendages.

4. Inflammation of the uterine veins and lymphatics.

Puerperal peritonitis.—The peritonæum lining the abdomen, or that covering the intestines, may be inflamed alone, or the disease may be combined with inflammation of the uterus.

Peritonæal inflammation may be caused by violence during delivery, or the application of cold, or the injudicious use of stimulants. Those who have suffered from uterine hæmorrhage, after delivery, are most liable to this disease, as well as to inflammation of the uterus. It may not come on for three weeks after delivery, but it usually appears on the second day; and it may often be observed that the pulse continues frequent from the time of delivery. It is preceded or attended by shivering, and sickness or vomiting, and is marked by pain in the belly, which is sometimes very universal, though, in other cases, it is, at first, confined to one spot. The abdomen very soon becomes swelled and tense, and the tension rapidly increases. The pulse is frequent, small, and sharp, the skin hot, the tongue either clean, or white and dry, the patient thirsty; she vomits frequently, and the milk and lochia usually are obstructed. These symptoms often come on very acutely, but it ought to be deeply impressed on the mind of the student that they may also approach insidiously. Wandering pain is felt in the belly, neither acute nor altogether constant. It passes for afterpains, but it is attended with frequency of pulse and some fulness of the belly, and a little sickness. But, whether the early symptoms come on rapidly or slowly, they soon increase, the belly becomes as large as before delivery, and is often so tender that the weight of the bedclothes can scarcely be endured; the patient also feels much pain when she turns. The respiration becomes difficult, and, sometimes, a cough comes on, which

aggravates the distress; or, it appears from the first, attended with pain in the side, as a prominent symptom. Sometimes the patient has a great inclination to belch, which always gives pain. The bowels are either costive or the patient purges bilious or dark-coloured fæces. These symptoms are more or less acute, according to the extent to which the peritonæum is affected. They are, at first, milder and more protracted in those cases where the inflammation begins in the uterus; and, in such, the pain is often not very great nor very extensive for some time. If the disease be to prove fatal, the swelling and tension of the belly increase, so that the abdomen becomes round and prominent, the vomiting continues, the pulse becomes very frequent and irregular, the fauces are aphthous, death is marked in the countenance, the extremities are cold, and the pain usually ceases rather suddenly. The patient has unrefreshing slumber, and sometimes *delirium mite*, but she may also remain sensible to the last. The disease usually proves fatal within five days, but may be protracted for eight or ten days, or even longer. If the patient be to recover, the swelling does not proceed to a great degree, the pain gradually abates, the vomiting ceases, the pulse becomes fuller and slower, the breathing easier, so that the patient can lie better down in bed, and she can turn more easily. Sometimes this disease ends in suppuration, and the abscess points and bursts externally. Dr. Gordon, in his Treatise on Puerperal Fever, relates three cases of this kind. In one of these, the matter was discharged from the umbilicus a month after the attack; in another, six weeks after delivery; and in the third, after two months, it came from the urethra. Similar cases have come under the observation of Dr. Burns.

Upon dissection, the peritonæum is found in a state of high inflammation; but it is rare to find it mortified. The omentum is often inflamed. A considerable effusion of serous fluid, mixed with curdy substance, is found in the belly.

The patient is only to be saved by vigorous means, and great attention. If the pulse continue above a hundred in the minute, for twenty-four hours after delivery, there is reason to apprehend that some serious mischief is about to happen; and, therefore, unless the frequency depend, decidedly, on debility, produced by great hæmorrhage, &c., we ought to open the bowels freely, and give a diaphoretic. We must carefully examine the belly, and, if it be full, or painful on pressure, or, if the patient be inclined to vomit, we ought instantly to open a vein, and use purgatives. One copious bleeding, on the very invasion of the disease, is more useful than ten afterwards; and the delay of two hours may be the loss of the patient, whose danger, even under the most active practice, is extreme. Many are unwilling to bleed women in the puerperal state; and the condition of the pulse may seem, to young practitioners, to forbid it. But, in cases of peritonæal inflammation, blood-letting is imperiously called for at a very early period; and the evacuation is to be repeated or not, according to its effects, and the constitution of the patient. If she have borne it ill, and not been relieved, when it was used first, there is reason to apprehend that the case has not been simple peritonæal inflammation, but malignant puerperal fever. If she bear it well, and the pulse becomes slower and fuller, and the pain abate, we are encouraged to repeat it. The fatal consequence of neglecting blood-letting in this disease, cannot be too strongly represented. The lancet is the anchor of hope: it may indeed be pushed too far; it may be used by young practitioners in cases of spasm, mistaken for peritonitis; but the error is safer than the contrary extreme, for, of two evils, debility is more easily removed than inflammation. It is not intended, however, to urge the senseless and extravagant use of the lancet. A prudent practitioner will bleed early and freely so long as he is thereby abating inflammation; but he will stop in time, and observe whether he be really gaining advantage by evacuation, or, on the contrary, sinking the patient, and destroying that vigour which is necessary for an effort to recover. He will never bleed late in the disease, unless it be to subdue an exacerbation, and when the effect of former depletion leads him to hope for renewed benefit. Whilst some have been dilatory and too timid, others, it is to be feared, have sunk their patients as effectually by inordinate evacuation, as if they had left the inflammation quite uncontrolled. After the lancet has been early used, if pain continue, many leeches, or the scarificator, should be applied to the most painful part. The abdomen should then be covered by a warm poultice. A large dose of opium, that is, three grains, is to be administered after the bleeding, and repeated according to circumstances, in smaller doses. The bowels are, at the very first, to be opened freely with calomel, or some other purgative, which ought to be given in a large dose, particularly calomel, for ordinary doses do no good. Dr. Armstrong, who is also a powerful advocate for the use of opium, gives half a drachm of calomel, and, afterwards, a purgative draught of senna and salts to work it off, and the practice is safe provided we regulate the dose of the medicine by the constitution and habits of the patient. In an advanced state of the disease, after effusion has taken place, we must employ purges alone, rather than blood-letting. Sinapisms and blisters have been advised, but are chiefly useful when the pain is circumscribed. Fomentations or warm poultices, if the weight do not give pain, are more generally useful. Digitalis has been given, either to abate inflammation or promote absorption, after effusion has taken place; but Dr. Burns declares that he has never, in one single instance, found it useful. After effusion has begun, and debility is produced, cordials, of which wine is the best, should be given, and anodyne clysters are to be administered. There are one or two cases recorded where the fluid has been either spontaneously discharged by an opening taking place in the intestine, or, artificially, by paracentesis, and with a good effect.

A modification of this disease is not unfrequent, in which the inflammatory affection,

so far as traces are left after death, is apparently very limited in extent, as well as inconsiderable in degree. The pain seems to arise more from high sensibility of the nerves, than from actual inflammation of the parts, and it often shoots in the direction of some particular abdominal nerve, for instance, the ilio-pubal. There is, at first, either circumscribed pain, or wandering pain, like gripes. The pulse is frequent, but not sharp. The skin hot. The belly little swelled, and the pain felt chiefly on pressure, or in turning, or breathing deeply. The discharge usually continues. This disease generally comes on about the second or third day, and, if not checked, the pain increases greatly; the belly swells and becomes tense; and the patient dies, with the usual symptoms of peritonitis. But, on inspection, the peritonæum is not found to be inflamed; often it is pale, or, at most, rather more injected than usual. The bowels are inflated, and there is some serum in the abdomen. The uterus is contracted, and apparently healthy; but more minute examination usually discovers some slight or limited mark of inflammation in the veins, or cervix, or appendages. The state of the abdominal nerves has not been particularly attended to. The diagnosis is difficult. There is seldom shivering or coldness, the pulse is soft, the pain is soon more acute than usually happens in peritonitis; but the chief practical mark is, that venesection, although it may give momentary mitigation, affords no permanent relief, and, if repeated, is as little beneficial. It is, however, always proper to take away some blood at first, and it is found to be sizy. Then we give an opiate, either by the stomach or in form of clyster, and apply a large linseed meal poultice to the abdomen; after this, if necessary, a saline clyster or mild laxative is to be given. In some cases, Dr. Burns has found most benefit from opiates; in others, from poultices. The feverishness lasts for some days. If there be continued local pain, leeches should be applied to the part. Dr. Gooch has detailed several cases of this disease, which, in some instances, seemed to proceed from the griping operation of a brisk purgative; in others, from severe afterpains, more especially when the patient, in her ordinary state, was delicate and nervous. He is against bleeding, and advises Dover's powder and poultices.

Peritonæal inflammation may take place during pregnancy, and not prove fatal. After delivery, the pulse continues quick, the face is flushed, the belly is swelled, and fluctuation is perceived. The patient dies of rapid hectic, and, on inspection, the intestines are found inflamed and pushed aside, with much pus. If the disease be not checked, by bleeding, in the commencement, I believe nothing can do good in the hectic stage. Paracentesis may be proposed, but its effects are not to be depended on.

Chronic, or slow inflammation of the peritonæum, is not very unfrequent, and may last for some weeks. It is attended with constant pain in some parts of the abdomen, but it is not unbearable; the belly is tender, the pulse frequent, the thirst urgent, and, often, the mind is affected as in hysteria, or a train of hysterical symptoms supervenes, which may lead off the attention from the seat of the disease. It requires, at first, blood-letting, and then the frequent use of laxatives, with repeated blisters.

When upon this subject, it may not be improper to mention that a young practitioner may mistake spasmodic affections or colic pains for puerperal inflammation; for, in such cases, there is often retching and sensibility of the muscles, which renders pressure painful. But there is less heat of the skin, the tongue is moist, the pulse, though it may be frequent, is soft, the feet are often cold, the pain has great remissions; if it do not go off completely, there is little fulness of the belly, and the patient is troubled with flatulence. It requires laxatives, antispasmodics, anodyne clysters, and friction with camphorated spirits. If these means do not give speedy relief, then we use the lancet. Blood drawn in this disease, after it has continued for some hours, even when the woman is not in childbed, is sizy; and it is always so in the puerperal as well as the pregnant state, although the woman be well. — *Burns.*

Malignant puerperal fever. — There can be no doubt that in particular seasons a contagion has prevailed, inducing fever in the puerperal state, attended with the symptoms of the preceding inflammatory diseases, varying, however, according as one or other of these predominated in the individual cases. In some instances, proving fatal, rather from mere exhaustion than from inflammation. In others, leaving marks of great inflammation or of suppuration. It is not, therefore, to be expected that either the *post mortem* examination or the individual symptoms, during life, should be very different from peritonitis, &c., the chief distinction being in the complication with a malignant influence, and in the patient being neither benefited by, nor bearing depletion so copiously as should have been both warranted and useful in the simple affection.

The description, therefore, in many of the essential points, must be much the same as that of hysteritis, &c.

Malignant puerperal fever sometimes begins in an insidious manner, without that shivering which usually gives intimation of the approach of a serious malady. But, generally, shivering is perceived, and varies considerably in degree, being either slight or pretty severe. The first symptoms, independent of the shivering, are, frequency of pulse, oppression, nausea, or retching, pain in the head, particularly over the eyebrows. The night is passed with little sleep, much confusion, and, occasionally, some delirium. It must not, however, be unnoticed that, in many instances, there is no headach in any stage of the disease, nor any sickness or vomiting in the beginning. In some, the temper is, from the first, uncommonly irritable; in others, there is much timidity, or listlessness, or apathy. Hysterical symptoms not unfrequently supervene; or particular nerves become more sensible; or organs of sense are affected; thus, some imagine they hear the performance of a piece of music. From the beginning of the attack,

or very soon afterwards, pain is felt in the belly, at first slight, but it presently increases; and, in some instances, the abdomen becomes so tender that even the weight of the bedclothes is productive of distress. A general fulness of the belly precedes this, or, at least, accompanies it from the first; and this usually increases pretty rapidly, and may proceed so far as to make the patient nearly as large as she was before delivery, and, in such cases, the breathing becomes very much oppressed; indeed, in every instance, the respiration is more or less affected; the free action of the abdominal muscles, which are concerned in that function, being productive of pain. The degree of pain, its seat, and period of accession, vary in different cases. In some, it evidently begins in the uterus, never going entirely off, yet being subject to severe exacerbation, accompanied with sense of bearing-down. The uterine region is painful, particularly toward one side. The os uteri, if examined, is not much more sensible than usual. There is, generally, pain in the back. In other cases, it is first felt about the lower ribs, on one side, and is accompanied by cough; the belly is tumid and tender when pressed, but, excepting then, or when the patient turns, she complains little of it. Sometimes severe pain, like spasm, attacks the iliac region, and extends down the thigh, and towards the bladder and pubis. The face is sometimes flushed at first, or the cheeks are suffused; but the countenance, in general, is pale and ghastly, the eyes are without animation, and the lips and angles of the eyes are white. When the face is flushed, the cheeks are generally covered with a broad patch of deep red, whilst the brow and other parts are cadaverous or covered with perspiration. The whole features indicate anxiety, if not terror, and great debility. Vomiting frequently occurs at the very commencement, and, in that case, it is bilious. In the course of the disease, it sometimes becomes so frequent that nothing will stay in the stomach; and, towards the conclusion of the fever, the fluid thrown up is dark coloured, and frequently fœtid. There is a great dejection of mind, languor, with general debility of the muscular fibres, and the patient lies chiefly on her back; or there is so much listlessness that she sometimes makes little complaint. The skin is not very hot, but is rather clammy and relaxed. The tongue is pale or white at first, but presently becomes brown, and, uniformly, aphthæ appear in the throat, and extend down the œsophagus, and over all the inside of the mouth. From the irritability of the stomach and bowels, it is probable that these organs participate in the tender state; and, from the cough which is excited, the upper part of the larynx seems also to be affected. It has already been mentioned that, from the first, the pulse is very frequent, and is, at that period, fuller than in simple peritonæal inflammation, but it soon becomes feeble. The thirst is not always great, at least the patient often is careless about drink. The bowels are often, at first, bound, but afterwards, especially about the third day, they usually become loose, and the stools are dark, fœtid, and often frothy. This evacuation seems to give relief. It is, indeed, peculiarly deserving of remark, that often in this disease, either from spontaneous or artificial evacuation, or sometimes without any perceptible cause, there is a delusive calm, and the patient is supposed to be better: in such cases, Dr. Burns says that he does not remember ever to have found a corresponding improvement in the pulse, and, therefore, places no reliance on the apparent relief. The urine is dark coloured, has a brown sediment, and is passed frequently, and with pain. The lochial discharge is diminished and has a bad smell, or is changed in appearance, or gradually ceases; and it is observable, that the reappearance of the lochia, if they had been entirely suppressed, which is not common, is not critical. The secretion of milk stops, and the patient inquires very seldom about the child. In some cases pleuritic symptoms occur. As the disease advances, the pulse becomes more frequent, and weaker, or tremulous. In bad cases, the swelling of the belly increases rapidly; but the pain does not always keep pace with the swelling, being sometimes least when the swelling is greatest, and in the end it generally goes entirely off. The breathing becomes laborious, in proportion as the belly enlarges. The strength sinks; the pulse, always frequent, becomes weak and tremulous; the throat and mouth become sloughy; perhaps the stools are passed involuntarily; hiccup sometimes takes place; and the patient usually dies before the fifth day of the disease, but in some cases not until the fourteenth; in others so early as the second day. In some instances, death is preceded by low delirium or stupor. In others, the mind continues unimpaired till within a few minutes of dissolution, and the patient is carried off after a fit of a convulsive kind.

This fever attacks generally on the second, or sometimes on the third day after delivery, but it has also occurred so late as after a week. The earlier it attacks the greater is the danger, and few women recover who have the belly much swelled.

On dissection, there is found in the abdomen a considerable quantity of fluid, similar to that met with in peritonitis. The omentum and peritonæum are inflamed in a variable degree, sometimes considerably, sometimes very slightly, and gangrene is unusual. The swelling is neither proportioned to the inflammation nor effusion, nor, in every instance, dependent on these, but on the inflation of the bowels which results from that relaxation of the muscular fibres of the bowels, which is so common in the puerperal state, particularly in puerperal disease. The uterus, although sometimes the first seat of the pain, and occasionally found considerably inflamed, yet, in general, is not more affected than the intestines. In some cases, the thoracic viscera are inflamed, as well as the intestines, or they may be almost exclusively affected. In either case, sero-purulent effusion is found in the chest.

It is most frequent and most fatal in hospitals. In private practice, it is less malignant, though still very dangerous. It is sometimes

epidemic, and, in some instances, it has been easy to trace the contagion from one woman to another. In hospitals, it has conspicuously appeared as a contagious disease. There has been much dispute whether the contagion were one, *sui generis*, or that of typhus, or erysipelas, or hospital gangrene; or if the disease depended on some noxious state of the atmosphere, conjoined with the absorption of putrid matter. When this fever is prevalent, women, after abortion, are liable to it, as well as those who have reached the full time. Unmarried women who attended the sick, have also died with many of its symptoms. Patients who miscarry during typhus fever, are in great danger of dying, and when they do so, there is almost invariably pain in the belly, with tympanitic swelling; and in most cases inflammation and suppuration are found on inspection. The disease appears to depend on inflammation of the peritonæum, conjoined with the operation of some debilitating poison, more or less contagious. It is not connected with the state of the labour, except in so far as that hæmorrhage seems to predispose to it; but when epidemic, it occurs after a rapid and easy, as well as after a more painful labour. It seems to be established, not only that different individuals may have more or less violent symptoms of inflammation, but also that particular epidemics have the peritonitic state, more or less prominent and acute: in some, there is much swelling, with little pain.

We attempt the diagnosis, rather, perhaps, by our knowledge of the existence of an epidemic, than, at first, by any special symptom. We also find that, very soon, the symptoms of depression are greater than should be expected at the period in simple inflammation, and venesection does less good, even for a few minutes.

This disease is dangerous in proportion to the malignancy of the cause, and the situation of the patient. All writers agree that in hospitals it is peculiarly fatal, and that few recover from it. In private practice, the disease is milder, but still, it is most formidable. — *Burns.*

The treatment of the low fever of lying-in women does not differ materially from that of epidemic typhus, complicated with local inflammation. Venesection, to a moderate extent, is sometimes useful at the commencement of the disease; but large or repeated bleeding can never be borne, nor must bleeding be practised at all in an advanced stage of the disease. Leeches to the abdomen are more useful than general blood-letting. The bowels should, at first, be cleared out by a full dose of calomel and a saline purgative, and laxatives may afterwards be given as they are required; but as the disease advances, diarrhœa is more common than constipation. There is, perhaps, no medicine so serviceable in this disease, as opium. It allays pain and irritation, checks the vomiting, which is so frequent and distressing, and obviates diarrhœa. Opiate enemata are frequently serviceable in allaying tenesmus. Blisters to the abdomen are recommended by some practitioners, but objected to by others as increasing irritation. Cloths wet with warm oil of turpentine seem to be much preferable, and often produce a very soothing effect on the internal pain, while they excite a degree of counter irritation on the surface. In the advanced stage of the disease, stimulants are indicated, and wine, camphor, and the sulphate of quinine may be administered; but when the powers of the constitution begin to sink in this disease, it is hardly possible to rally them, and the case is almost always fatal.

Inflammation of the uterus or its appendages. — A general description of this will be found in the article *Hysteritis.*

Inflammation of the veins and lymphatics of the uterus. — Uterine *phlebitis* is an affection which has only attracted attention of late years. An interesting account of it has been given by Dr. Robert Lee, from which the following is taken. Dr. Lee considers a large proportion of the cases called typhoid puerperal fever as referrible to uterine phlebitis, but, as before observed, the question, What is puerperal fever? is one about words, and therefore not worth arguing.

In women who have enjoyed good health during pregnancy, and in whom the process of parturition has been easily accomplished, uterine phlebitis occasionally commences within twenty-four hours after delivery, with pain, more or less acute, in the region of the uterus, accompanied or followed by a severe rigor, or a succession of rigors, a suppression of the lochial discharge, acceleration of the pulse, cephalalgia, or slight incoherence of intellect, with most distressing sensation of general uneasiness, and sometimes by nausea and vomiting. These symptoms, after a short duration, are succeeded by increased heat of the body, tremors of the muscles of the face and extremities, rapid feeble pulse, anxious and hurried respiration, great thirst, with brown dry tongue, and frequent vomiting of green-coloured matters. The sensorial functions usually become much affected, and there is a state of drowsy stupor or violent delirium and agitation, which is followed by symptoms of extreme exhaustion; the whole surface of the body not unfrequently assumes a deep and peculiar sallow or yellow colour; the abdomen sometimes becomes swollen and tympanitic, and some of the remote organs of the body, such as the lungs, heart, brain, liver, and spleen, or the articulations and cellular membrane of the extremities, suffer disorganisation from congestion, or a rapid and destructive inflammation.

There is scarcely an organ of the body which has not been observed to become secondarily affected from suppuration of the uterine veins. The vessels of the brain sometimes become greatly congested, and lymph is effused upon the surface of the pia mater, or serum into the ventricles; portions of the brain have become softened and disorganised, or purulent infiltrations have taken place into the cerebral substance.

In other individuals, whose lungs had previously been healthy, a rapid and destructive inflammation of the pleura has taken place, or portions of the pulmonary texture have become condensed, of a dark red colour, or infiltrated with pus. In three cases, where there had only

been obscure pain in the chest during life, with slight cough and dyspnœa, a copious effusion of lymph and serum was found to have taken place into the cavities of the thorax; the pleura was covered with false membranes, and portions of the lung had fallen into a state of complete gangrene. In one individual the pleura had given way by sloughing, and the right side of the chest was distended with air.

In uterine phlebitis, the mucous membrane lining the stomach has also been observed by M. Dance to have been reduced to the state of a diffluent pulp, and the substance of the spleen has been extensively softened and disorganised; the eyes have also become suddenly affected with destructive inflammation, and the vision has been lost many days before the termination of life. In two cases which came under our care, the conjunctiva of both eyes, without much pain, suddenly became intensely red, the corneæ opaque, and the eyelids much swollen, and under their lining membrane a large serous deposition took place; lymph and pus were also effused into the anterior chamber, and in one the cornea ultimately burst. In a case related by M. Cruveilhier, the nose became black and gangrenous, yet the patient recovered.

Deposits or infiltrations of pus, of enormous extent, also take place into the cellular membrane, between the muscles of the extremities, and often in the neighbourhood of the joints; the cartilages of the joints themselves become ulcerated, and pus is formed within the capsular ligaments.

In other individuals, who have never been subject to attacks of rheumatism, severe pain is experienced in various parts of the body, more particularly in the joints and extremities, with an exhausting fever.

All these affections appear to have a common origin, and cannot be referred to any other cause than to the morbid condition of the veins of the uterus. The purulent or other secretions, formed by inflammation within the cavities of these vessels, probably produce the whole of the injurious effects now described, by entering the system, and contaminating the mass of blood in like manner as poisons do when absorbed into the body.

In some cases uterine phlebitis commences at a later period after delivery than above described, and in a much more obscure and insidious form, without pain or sense of uneasiness in the region of the uterus, or any other local symptom by which the affection can be recognised. The uterus may return to the reduced volume it usually assumes after delivery; the lochial discharge may continue; and the inflammation and suppuration of the veins, which have caused the whole of the violent constitutional disturbance and destructive lesions in distant parts of the body, may have been wholly overlooked during life. In many cases which we have witnessed, this error was committed by the medical attendant, and stimulants were liberally administered to obviate the debility supposed to exist in a specific form without any local affection of the uterine organs.

The effects of inflammation in the uterine veins are the formation of adventitious membranes on their inner surface, and the deposition of coagula of lymph, or of purulent matter, within their cavities.

Coagula of the fibrine of the blood, which often extend a considerable distance into the uterine veins, are formed in the orifices of these vessels after every labour, and are the principal means employed by nature for the permanent suppression of uterine hemorrhage. These may be distinctly perceived for a long period after delivery, and they have a form and colour different from the coagula produced by inflammation. In opening the body of a patient four weeks after confinement, we absorbed distinct traces of these coagula, partially absorbed, in the muscular substance of the uterus, at the part where the placenta had adhered.

The inflammation may be limited to the veins, but not unfrequently the muscular tissue contiguous to them participates in the inflammation, and becomes of a dark red, or blackish brown colour, and of an unusually soft consistence. The peritoneal covering may also be affected, and the usual consequences of puerperal peritonitis then ensue.

The veins which return the blood from the uterus and its appendages may be either wholly or in part inflamed: generally, however, (and this is a circumstance in the history of uterine phlebitis deserving particular attention,) the inflammation attacks the spermatic veins alone, and for the most part the one only on that side of the uterus to which the placenta has been attached; and it may either confine itself to a small portion of the vessel, or extend throughout its whole course from the uterus to the vena cava. The usual consequences of inflammation of veins are then apparent, viz. injection and condensation of the cellular membrane in which they are imbedded, thickening, induration, and contraction of their coats, and the deposition of lymph, mixed with pus and coagula of blood, within their cavities.

The same is the case with regard to the hypogastric veins, one only being generally affected. These are, however, more rarely affected than the spermatic veins; and this would seem to depend on the latter veins being invariably employed to return the blood from that part of the uterus to which the placenta had been attached.

But inflammation having once begun, it is liable to spread continuously to the veins of the whole uterine system, to those of the ovaria, of the Fallopian tubes, and broad ligaments. The vena cava itself does not always escape, the inflammation spreading to it from the iliac or from the spermatic veins. This occurrence seldom takes place to a great extent through the medium of the spermatic, the inflammation usually terminating abruptly at the opening of the spermatic into it on the right side, or of the renal on the left. If it pursue, as it sometimes does, the direction of the kidneys, the substance of these organs, as well as their veins, may be involved in the disease.

When the inflammation affects the hypo

gastric veins, it may extend from these to the iliac and femoral veins, and thus give rise to all the phenomena observed in phlegmasia dolens.

Uterine phlebitis would appear to result either from the mechanical injury inflicted by protracted labour, from the force required for the extraction of the placenta in uterine hæmorrhage, from retained portions of placenta undergoing decomposition in the uterus, and from any of the causes which produce the other varieties of uterine inflammation.

Though a most dangerous disease, uterine phlebitis is not invariably fatal. That it often occurs in puerperal women where it is not suspected to exist during life, is demonstrated by the fact that in the spermatic and hypogastric veins of females advanced in life, calcareous concretions and various kinds of disorganisations have frequently been observed, which must have been the consequence of attacks of acute inflammation at some remote period.

With respect to the treatment of uterine phlebitis, Dr. Lee states that, in cases where venesection at the invasion of the disease has been employed, the relief obtained has only been temporary, if at all experienced, and, in some instances, the abstraction of only a few ounces of blood from the arm has produced alarming syncope. When the local pain is severe, leeches and warm fomentations seem to be the appropriate remedies; but as far as our observations go, we are in possession of no remedial means which effectually control these varieties of inflammation of the deeper seated structures of the uterus, which we have attempted to describe. The French practitioners have great confidence in the action of mercury pushed quickly to salivation. Dr. Lee states that he gave this practice a fair trial, and that it failed, although he carried it to a great extent, and brought the system under the influence of mercury in less than twenty-four hours: yet the progress of the symptoms was not arrested, and the patients died, as others had done where the remedy had not been administered.

Inflammation of the uterine absorbents is not a common case. Dr. Robert Lee has given four examples of it, in one of which the absorbents were found filled with pus. The local symptoms are often so obscure as altogether to escape detection during life; while the constitutional affection, which often strikingly resembles the effect of a specific poison, is so violent as to yield to no treatment, however early or vigorously employed.

Puffball. See *Lycoperdon.*

PUGI'LLUS. (*us, i.* m.; and *um, i.* n.; from *pugnus*, the fist.) A pugil or eighth part of a handful. A very indefinite measure.

PULE'GIUM. (*um, ii.* n.; from *pulex*, a flea: because the smell of its leaves, burnt, destroys fleas.) See *Mentha pulegium.*

PULEGIUM CERVI'NUM. Hart's pennyroyal. The *Mentha cervina*, of Linnæus.

PULICA'RIA. (*a, æ.* f.; from *pulex*, a flea: so named because it was thought to destroy fleas if hung in a chamber.) See *Plantago psyllium.*

PULICULARIS MORBUS. Typhus has been so named from the petechiæ, resembling flea-bites, which accompany it.

PU'LMO. (*o, onis.* m. Πνευμων: Atticè πλευμων, *unde, per metathesin, pulmo.*) The lung. See *Lung.*

PULMONA'RIA. (*a, æ.* f.; from *pulmo*, the lung: so called because of its virtues in affections of the lungs.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia*. Lung-wort.

Pulmonaria arborea. See *Lichen pulmonarius.*

Pulmonaria lutea. See *Hypochæris.*

Pulmonaria maculata. See *Pulmonaria officinalis.*

PULMONARIA OFFICINALIS. The systematic name of the spotted lung-wort. Jerusalem cowslips. Jerusalem sage. *Pulmonaria maculata. Symphytum maculosum.* This plant is rarely found to grow wild in England; but is very commonly cultivated in gardens, where its leaves become broader, and approach more to a cordate shape. The leaves, which are the part medicinally used, have no peculiar smell; but, in their recent state, manifest a slightly astringent and mucilaginous taste; hence it seems not wholly without foundation that they have been supposed to be demulcent and pectoral. They have been recommended in hæmoptoes, tickling coughs, and catarrhal defluxions upon the lungs. The name pulmonaria, however, seems to have arisen rather from the speckled appearance of these leaves resembling that of the lungs, than from any intrinsic quality which experience discovered to be useful in pulmonary complaints.

PU'LMONARY. *Pulmonalis.* Belonging to the lungs.

PULMONARY ARTERY. The pulmonary artery, *arteria pulmonalis*, arises from the right ventricle of the heart, and soon divides into the right and left branches, which ramify throughout the lungs, and form a beautiful network on the air vesicles, where they terminate in the veins, *venæ pulmonales*, whose branches at length form four trunks, which empty themselves into the left auricle of the heart.

Pulmonary consumption. See *Phthisis.*

PULMONARY PLEXUS. *Bronchial plexus.* The plexus of nerves formed at the back of the bronchia by the par vagum and great sympathetic. See *Trachea.*

Pulmonary vein. See *Pulmonary artery.*

PULMO'NICUS. (From *pulmo*, the lungs.) Of or belonging to the lungs.

PULMONI'TIS. (*is, idis.* f.; from *pulmo*, the lung.) An inflammation of the lungs. See *Pneumonitis.*

PULPEZIA. *Pulpelzia.* A barbarous name of apoplexy.

PULPO'SUS. Pulpy: soft.

PULSATI'LLA NIGRICANS. (*Pulsatilla*; from *pulso*, to beat about: so called from its being perpetually agitated by the air.) See *Anemone pratensis.*

PULSATION. The beating of the pulse, or any movement resembling it.

PULSATIVE. *Pulsativus.* Applied to a pain accompanied with throbbing.

PULSE. *Pulsus.* The beating of the heart and arteries. The pulse is generally felt at the wrist, by pressing the radial artery with the fingers. The action depends upon the impulse given to the blood by the heart: hence physicians feel the pulse to ascertain the quickness or tardiness of the blood's motion, the strength of the heart, &c. See *Circulation.*

PULSILO'GIUM. (*um, ii.* n.; from *pulsus*, the pulse, and λεγω, to tell.) An instrument for measuring the pulse.

PULVI'NAR. (A cushion; from *pulvis*, dust or chaff, with which it is filled.) *Pulvinarium.* A medicated cushion.

PU'LVIS. (*is, eris.* m.) A powder. This form of medicine is either coarse or very fine, simple or compound. In the compounded powders the intimate and complete admixture of the several ingredients, and more especially in those to which any of the more active substances, as opium, scammony, &c., are added, cannot be too strongly recommended; and for this purpose it may be proper to pass them, after they are mixed mechanically, through a fine sieve.

PULVIS ALOES COMPOSITUS. Compound powder of aloes. Formerly called *pulvis aloes cum guaiaco.* Take of aloes, an ounce and half; guaiacum resin, an ounce; compound powder of cinnamon, half an ounce: powder the extract of aloe and guaiacum resin separately; then mix them with the compound powder of cinnamon. The dose is from gr. x. to ʒj. It is a warm, aperient, laxative powder, calculated for the aged, and those affected with dyspeptic gout, attended with costiveness and spasmodic complaints of the stomach and bowels.

PULVIS ALOES CUM CANELLA. A cathartic, deobstruent powder, possessing stimulating and aloetic properties; now omitted in the London Pharmacopœia, as rather suited to the purpose of extemporaneous prescription.

PULVIS ALOES CUM FERRO. This possesses aperient and deobstruent virtues; and is mostly given in chlorosis and constipation. In the London Pharmacopœia this formula is omitted for the same reason as pulvis aloes cum canellâ.

Pulvis aloes cum guaiaco. See *Pulvis aloes compositus.*

Pulvis antimonialis. See *Antimonialis pulvis.*

Pulvis aromaticus. See *Pulvis cinnamomi compositus.*

Pulvis arthriticus Ducis Portlandi. See *Portland powder.*

PULVIS ARTHRITICUS TURNERI. Turner's gout powder. This consisted of turbeth mineral, hermodactyl, scammony, and the berries of the dwarf elder, of each equal parts. It was given at intervals with a view of preventing the return of the gout. Dose from grains xv. to ʒij.

PULVIS BASILICUS. Basilic powder. Royal powder. This consisted of diagrydium, cream of tartar, and calomel, of each equal parts. It was used principally as a vermifuge for children, in a dose of from six to fifteen grains.

PULVIS CEPHALICUS. There are many powders prepared under this name, and most of them contain some agreeable aromatic, and many some asarabacca.

PULVIS CERUSSÆ COMPOSITUS. This is mostly used in the form of collyrium, lotion, or injection, as a mucilaginous sedative.

PULVIS CHELARUM CANCRI COMPOSITUS. An antacid and astringent powder, mostly given to children with diarrhœa and acidity of the primæ viæ.

PULVIS CINNAMOMI COMPOSITUS. Compound powder of cinnamon. Formerly called, *pulvis aromaticus, species aromatica,* and *species diambræ sine odoratis.* Take of cinnamon bark, two ounces; cardamom-seeds, an ounce and a half; ginger root, an ounce; long pepper, half an ounce: rub them together, so as to make a very fine powder. The dose is from five to ten grains. An elegant stimulant, carminative, and stomachic powder.

PULVIS COBBII. *Pulvis Tunguinensis.* Cobb's powder. Tonquin powder. This once celebrated powder consists of sixteen grains of musk, and forty-eight grains of cinnabar, to be taken mixed in a gill of arrack. It was regarded as a specific in hydrophobia.

Pulvis Comitis Warwicensis. See *Cornachinus pulvis.*

PULVIS CONTRAYERVÆ COMPOSITUS. Take of contrayerva root, powdered, five ounces; prepared shells, a pound and a half: mix. A febrifuge diaphoretic, given in the dose of from one to two scruples.

PULVIS CORNU USTI CUM OPIO. Powder of burnt hartshorn with opium. *Pulvis opiatus.* Take of hard opium, powdered, a drachm; hartshorn, burnt and prepared, an ounce; cochineal, powdered, a drachm: mix. This preparation affords a convenient mode of exhibiting small quantities of opium, ten grains containing one of the opium. It is absorbent and anodyne.

PULVIS CRETÆ COMPOSITUS. Compound powder of chalk. *Pulvis è bolo compositus sine opio. Species è scordio sine opio.* Take of prepared chalk, half a pound; cinnamon bark four ounces; tormentil root, acacia gum, of each three ounces; long pepper, half an ounce reduce them separately into a very fine powder and then mix. The dose is from ʒss. to ʒj. An astringent, carminative, and stomachic powder, exhibited in the cure of diarrhœa, pyrosis and diseases arising from acidity of the bowels inducing much pain.

PULVIS CRETÆ COMPOSITUS CUM OPIO. Compound powder of chalk with opium. Take of compound powder of chalk, six ounces and a half; hard opium, powdered, four scruples mix. An anodyne astringent. The dose from one scruple to two.

PULVIS IPECACUANHÆ COMPOSITUS. Compound powder of ipecacuanha. Take of ipecacuanha root, powdered, hard opium, powdered, of each a drachm; sulphate of potass powdered, an ounce: mix. A diaphoretic powder, similar to that of Dr. Dover, which gained such repute in the cure of rheumatism and other diseases arising from obstructed perspiration and spasm. The dose is from five grains to a scruple.

PULVIS JALAPÆ COMPOSITUS. Compound

powder of jalap. Take of jalap, three ounces; bitartrate of potash, six ounces; ginger, two drachms: rub them separately to powder; then mix them. A hydragogue purgative, in which the action of the jalap is rendered milder by the salt. Dose from one to two scruples.

PULVIS KINO COMPOSITUS. Compound powder of kino. Take of kino, 15 drachms; cinnamon bark, half an ounce; hard opium, a drachm: reduce them separately to a very fine powder, and then mix. The proportion of opium this astringent contains is one part in twenty. The dose is from five grains to a scruple.

PULVIS MYRRHÆ COMPOSITUS. A stimulant, antispasmodic, and emmenagogue powder, exhibited in the dose of from fifteen grains to two scruples, in uterine obstructions and hysterical affections.

Pulvis opiatus. See *Pulvis cornu usti cum opio.*

PULVIS SCAMMONII COMPOSITUS. Compound powder of scammony. Take of scammony, hard extract of jalap, of each two ounces; ginger-root, half an ounce: reduce them separately to a very fine powder, and then mix. From ten to fifteen grains or a scruple are exhibited as a stimulating cathartic.

PULVIS SCAMMONII CUM ALOE. A stimulating cathartic, in the dose of from ten to fifteen grains.

PULVIS SCAMMONII CUM CALOMELANE. A vermifuge cathartic, in the dose of from ten to fifteen grains.

PULVIS SENNÆ COMPOSITUS. Compound powder of senna. *Pulvis diasennæ.* Take of senna leaves, supertartrate of potash, of each two ounces; scammony gum resin, half an ounce; ginger-root, two drachms: reduce the scammony gum resin separately, the rest together, to a very fine powder, and then mix. The dose is from one scruple to one drachm. A saline stimulating cathartic.

Pulvis stypticus Helvetii. See *Stypticum Helvetii.*

PULVIS TRAGACANTHÆ COMPOSITUS. Compound powder of tragacanth. *Species diatragacanthæ frigidæ.* Take of tragacanth, powdered, acacia gum, powdered, starch, of each an ounce and half; sugar, three ounces: powder the starch and sugar together; then add the tragacanth and acacia gum, and mix the whole. Tragacanth is difficult to be reduced to powder. The dose is from ten grains to a drachm. A very useful demulcent powder, which may be given in coughs, diarrhœas, strangury, &c.

Pumpion. See *Cucurbita.*

Puncta lachrymalia. See *Lachrymal apparatus.*

PUNCTA'TUS. Dotted: applied to parts of plants, &c.; as the petals of the *Melanthium capense,* and the receptacle of the *Leontodon taraxacum.*

PU'NCTUM. (*um, i.* n.; from *pungo,* to prick.) A point. Applied, in anatomy, to several minute objects.

PUNCTUM AUREUM. Formerly, when a hernia of the intestines was reduced by an incision made through the skin and membrana adiposa, quite down to the upper part of the spermatic vessels, a golden wire was fixed and twisted, so as to prevent the descent of any thing down the tunica vaginalis. This operation was called *Punctum aureum.*

Punctum lachrymale. See *Lachrymal apparatus.*

PUNCTUM SALIENS. The first appearance of the heart in the embryo. See *Ovum.*

PU'NICA. (*a, æ.* f.) The name of a genus of plants in the Linnæan system. Class, *Icosandria;* Order, *Monogynia.*

PUNICA GRANA'TUM. The systematic name of the pomegranate. *Granatum. Punica — foliis lanceolatis, caule, arboreo,* of Linnæus. The rind of the fruit, and the flowers called *Balaustine flowers,* are the parts directed for medicinal use. In their smell there is nothing remarkable, but to the taste they are very astringent, and have successfully been employed as such in diseases, both internal and external.

PUNI'CEUS. (From *punica,* the pomegranate, the flowers of which are of a peculiar colour.) Puniceal, or of a fine bright red colour, like that of the flowers of the pomegranate. See *Colour.*

PUPIL. (*Pupilla, æ.* f.; from *pupa,* a babe: because it reflects the diminished image of the person who looks upon it, like a puppet.) The round opening in the middle of the iris. See *Oculus.*

Pupil, closed. See *Synizesis.*

PUPILLA'RIS. (From *pupilla,* the pupil.) Of or belonging to the pupil.

Pupillaris membrana. See *Membrana pupillaris.*

Pupillæ velum. See *Membrana pupillaris.*

PURGAME'NTUM. A purge.

PURGATIVE. Applies adjectively and substantively to whatever increases the peristaltic motion of the bowels, so as to considerably increase the alvine evacuations. See *Cathartic.*

Purging flax. See *Linum catharticum.*

Purging-nut. See *Jatropha curcas.*

PU'RIFORM. (*Puriformis;* from *pus,* and *forma,* resemblance.) Resembling pus.

PURL. A beverage prepared by infusing common wormwood in ale.

Purple powder of Cassius. See *Aurum.*

PU'RPURA. (*a, æ.* f. Πορφυρα, the name of a shell of a purple colour: hence *purpura,* a purple colour.) An efflorescence consisting of small, distinct, purple specks and patches, attended with general debility, but not always with fever, which are caused by an extravasation of the vessels under the cuticle. It is divided into the five following species: —

1. *Purpura simplex.*—This has the appearance of petechiæ, without much disorder of the constitution, except languor, pain in the limbs, and a sallow complexion. The petechiæ are most numerous on the breast, inside of the arms and legs, and are of various sizes, and commonly circular. There is no itching or other sensation attending the petechiæ.

2. *Purpura hæmorrhagica* is considerably more severe: the petechiæ are of larger size, and interspersed with vibices and ecchymoses, resembling the marks left by the strokes of a whip, or by violent bruises. They appear first

on the legs, and afterwards on the thighs, arms, and trunk of the body; the hands being more rarely spotted with them, and the face generally free. They are of a bright red colour when they first appear, but soon become purple or livid; and when about to disappear they change to a brown or yellowish hue: the cuticle over them appears smooth and shining, but is not sensibly elevated; in a few cases, however, it has been seen raised into a sort of vesicle, containing black blood. This more particularly happens in the spots which appear on the tongue, gums, and palate, and inside of the cheeks and lips, where the cuticle is extremely thin: the gentlest pressure on the skin, even feeling the pulse, will often produce a purple blotch, like that which is left after a severe bruise.

The same state of habit which gives rise to these effusions under the cuticle, produces likewise copious discharges of blood, especially from the internal parts: they are often very profuse, and suddenly prove fatal; but in other cases they are less copious; sometimes returning every day at stated periods, and sometimes less frequently, and at regular intervals; and sometimes there is a slow and almost incessant oozing of blood. The bleeding occurs from the gums, nostrils, throat, inside of the cheeks, tongue, and lips, and sometimes from the lining membrane of the eyelids, the urethra, and external ear; and also from the internal cavities of the lungs, stomach, bowels, uterus, kidneys, and bladder.

This disease is often preceded by great lassitude, faintness, and pains in the limbs; but not unfrequently it appears suddenly in the midst of apparent good health. It is always accompanied with extreme debility and depression of spirits; the pulse is commonly feeble, and sometimes quickened; and heat, flushing, perspiration, and other symptoms of febrile irritation, occasionally attend. When the disease has continued for some time, the patient becomes sallow, and much emaciated; and some degree of œdema appears on the lower extremities, which afterwards extends to other parts of the body. This disease is extremely uncertain in its duration: in some instances it has terminated in a few days, while in others it has continued, not only for many months, but even for years.

The causes of this disease are by no means clearly ascertained: it occurs at every period of life, and in both sexes, but especially in women and in boys before the age of puberty, particularly those who are employed in sedentary occupations, and who live in close and crowded situations. It has sometimes occurred as a sequæla of small-pox, and of measles, and sometimes in the third or fourth week of puerperal confinement. It is supposed that some local visceral obstruction is the cause of the disease in different instances, as artificial bleeding and purging tend greatly to relieve it. The ancient physicians attributed the hæmorrhages from the nose, gums, and other parts, to the morbid enlargement of the spleen.

In the slighter degrees of purpura occurring in children who are ill-fed and nursed, and who reside in close places, or in women shut up in similar situations, and debilitated by anxiety of mind, want of proper food, and by fatigue, the use of tonics, with the mineral acids, and wine, will doubtless be adequate to the cure of the disease, especially where exercise in the open air can be employed at the same time. But when it occurs in adults, especially those who already have the benefit of exercise in the air of the country, and who have suffered no privation with respect to diet, when it is accompanied with a white and loaded tongue, a quick and somewhat small though sharp pulse, occasional chills and heats, and other symptoms of feverishness, however moderate, and if there be at the same time fixed internal pains, a dry cough, and an irregular state of the bowels (symptoms which may be presumed to indicate some local congestion), then the administration of tonic medicines, particularly wine, cinchona, and other warmer tonics, will be found inefficacious, if not decidedly injurious. In such cases, free and repeated doses of medicines containing the submuriate of mercury, and regulated by their effects on the symptoms of the complaint, and by the appearance of the excretions from the intestines, will be found most beneficial.

If the pains are fixed, the marks of febrile irritation considerable, and the spontaneous hæmorrhage not profuse, local or general bloodletting may be employed with great benefit, especially in robust adults. When the urgency of hæmorrhagic tendency has been diminished by these means, the constitution rallies, though not rapidly, with the assistance of the mineral acids, and cinchona or cascarilla, or some preparation of iron, together with moderate exercise and nutritious diet.

3. *Purpura urticans* is distinguished by commencing in the form of rounded and reddish elevations of the cuticle, resembling wheals, which are not accompanied, like the wheals of urticaria, by any sensation of tingling and itching. These tumours gradually dilate; but within one or two days they subside to the level of the surrounding cuticle, and their hue becomes darker, and at length livid. They are most common on the legs, where they appear with petechiæ, but also appear on the arms, thighs, breast, &c.

It usually occurs in summer and autumn, and lasts from three to five weeks. Some œdema of the extremities usually accompanies it, and it is occasionally preceded by a stiffness and weight of the limbs. The same rules of treatment apply to this as to the preceding varieties of the disease.

4. *Purpura senilis* appears principally along the outside of the fore-arm, in elderly women in successive dark purple blotches, of an irregular form, and various magnitude: each of these continues from a week to ten days, when the extravasated blood is absorbed.

Tonics or any other expedient do not appear to exert any influence over the eruption.

5. *Purpura contagiosa* is an eruption of petechia which occasionally accompanies typhoid fevers: where they occur in close situations, they are merely symptomatic, and are very rarely seen.

Purpura alba. *Purpura rubra.* Many writers term the miliary fever, when the pus

tules are white, *purpura alba;* and, when they are red, *purpura rubra.*

Purpura scorbutica. The dark-coloured blotches which appear on the skin in scurvy.

PURPU'REUS. Purple: applied to designate a particular colour. See *Colour.*

Purpu'ric acid. *Acidum purpuricum.* The excrements of the *Boa constrictor* serpent contain lithic acid. Dr. Prout found that, on digesting this, or the same acid from urinary calculi, in dilute nitric acid, an effervescence takes place, and the lithic acid is dissolved, forming a beautiful purple liquid. The excess of nitric acid being neutralised with ammonia, and the whole concentrated by slow evaporation, the colour of the solution becomes of a deeper purple; and dark red granular crystals, sometimes of a greenish hue externally, soon begin to separate in abundance. These crystals are a compound of ammonia with the acid principle in question. The ammonia was displaced by digesting the salt in a solution of caustic potash, till the red colour entirely disappeared. This alkaline solution was then gradually dropped into dilute sulphuric acid, which, uniting with the potash, left the acid principle in a state of purity.

This acid principle is likewise produced from lithic acid by chlorine, and also, but with more difficulty, by iodine. Dr. Prout, the discoverer of this new acid, has, at the suggestion of Dr. Wollaston, called it purpuric acid, because its saline compounds have for the most part a red or purple colour.

This acid, as obtained by the preceding process, usually exists in the form of a very fine powder, of a slightly yellowish or cream colour; and when examined with a magnifier, especially under water, appears to possess a pearly lustre. It has no smell nor taste. Its specific gravity is considerably above water. It is scarcely soluble in water. One tenth of a grain, boiled for a considerable time in 1000 grains of water, was not entirely dissolved. The water, however, assumed a purple tint, probably, Dr. Prout thinks, from the formation of a little purpurate of ammonia. Purpuric acid is insoluble in alkohol and ether. The mineral acids dissolve it only when they are concentrated.

Purslane. See *Portulaca.*

PU'RULENT. (*Purulens;* from *pus.*) Of the nature of pus.

Purulent ophthalmia. See *Ophthalmitis.*

PUS. (*us, uris.* n.; pl. *pura.* Πύος.) Matter. A whitish, bland, cream-like fluid, heavier than water, found in abscesses, or on the surface of sores. It is distinguished, according to its nature, into laudable or good pus, scrofulous, serous, and ichorous pus, &c.

Pus taken from a healthy ulcer, near the source of circulation, as on the arm or breast, readily separates from the surface of the sore, the granulations underneath being small, pointed, and of a florid red colour, and has the following properties: it is nearly of the consistence of cream; is of a white colour; has a mawkish taste; and, when cold, is inodorous; but, when warm, has a peculiar smell. Examined in a microscope, it is found to consist of two parts,—of globules, and a transparent colourless fluid; the globules are probably white, at least they appear to have some degree of opacity. Its specific gravity is greater than that of water. It does not readily go into putrefaction. Exposed to heat, it evaporates to dryness, but does not coagulate. It does not unite with water in the heat of the atmosphere, but falls to the bottom; yet, if kept in a considerable degree of heat, it rises and diffuses itself through the water, and remains mixed with it, even after having been allowed to cool, the globules being decomposed.

Pus varies in its appearance according to the different circumstances which affect the ulcer that forms it; such as the degree of violence of the inflammation, also its nature, whether healthy or unhealthy; and these depend upon the state of health, and strength of the parts yielding pus. These changes arise more from indolence and irritability than from any absolute disease; many specific diseases, in healthy constitutions, producing no change in the appearance of the matter from their specific quality. Thus, the matter from a gonorrhœa, from the small-pox pustules, or the chicken-pock, has the same appearance, and seems to be made up of similar parts, consisting of globules floating in a transparent fluid, like common pus; the specific properties of each of these poisons being superadded to those of pus. Matter from a cancer may be considered as an exception; but a cancerous ulcer is never in a healthy state.

In indolent ulcers, whether the indolence arises from the nature of the parts, or the nature of the inflammation, the pus is made of globules and flaky particles, floating in a transparent fluid; and globules and flakes are in different proportions, according to the degree of indolence: this is particularly observable in scrofulous abscesses, preceded by a small degree of inflammation. That this flaky appearance is no part of true pus, is well illustrated by observing, that the proportion it bears to the globules is greatest where there is the least inflammation: and in those abscesses that sometimes occur, which have not been preceded by any inflammation at all, the contents are wholly made up of a curdy or flaky substance of different degrees of consistence, which is not considered to be pus, from its not having the properties stated in the definition of that fluid.

The constitution and part must be in health to form good pus; for very slight changes in the general health are capable of producing an alteration in it, and even of preventing its being formed at all, and substituting in its place coagulating lymph.

This happens most readily in ulcers in the lower extremities, owing to their distance from the source of the circulation rendering them weaker. And it is curious to observe the influence that distance alone has upon the appearance of pus.

The cases in which pus is formed are, properly speaking, all reducible to one, which is, the state of parts consequent to inflammation. For, as far as we yet know, observes Sir E. Home, pus has in no instance been met with unless preceded by inflammation; and although

in some cases a fluid has been formed independent of preceding inflammation, it differs from pus in many of its properties.

In considering the time required for the formation of pus, it is necessary to take notice of the periods which are found, under different circumstances, to intervene between a healthy or natural state of the parts, and the presence of that fluid after the application of some irritating substance to the skin.

In cases of wounds made into muscular parts, where blood-vessels are divided, the first process which takes place is the extravasation of red blood; the second is the exudation of coagulating lymph, which afterwards becomes vascular; and the third, the formation of matter, which last does not in common take place in less than two days: the precise time will, however, vary exceedingly, according to the nature of the constitution, and the state of the parts at the time.

If an irritating substance is applied to a cuticular surface upon which it raises a blister, pus will be formed in about twenty-four hours. As pus and mucus greatly resemble each other, several pathologists have exercised their ingenuity to find a criterion between them. According to Dr. C. Darwin, the following chemical distinctions are to be depended upon:— 1. Sulphuric acid dissolves it, and the solution is decomposed by water, which *precipitates* the pus. Sulphuric acid also dissolves mucus; but the addition of water separates it in flakes, which *float upon the surface*. 2. Pus is diffusible through dilute sulphuric acid, and through water and brine; but mucus is not. 3. Caustic alkalis dissolve both pus and mucus; but, when water is added, a difference is exhibited, the pus becoming separated, but not the mucus. Professor Brande states, however, that he has not found the last of these alleged criteria accurate; and that, even supposing all these statements correct, they are of no practical utility; because where pus is mixed with mucus in various proportions, the tests are not sufficiently delicate to distinguish it.

Another test of pus has been recommended by Grasmeyer. Triturate the substance to be examined with an equal quantity of warm water; then add to it an equal quantity of a concentrated solution of subcarbonate of potass. If pus be present, a transparent jelly subsides in a few hours, which is not the case where only mucus is present. These experiments repeated by Mr. Brande did not yield satisfactory results. The late Dr. T. Young proposed an optical test, which he regarded as a very certain one. He very justly regards the globules as the essential characteristic of pus; and it is from their presence that the test about to be described is derived, while the colour indicates that there is no mixture of blood. If we put a small quantity of the substance to be examined between two pieces of plate-glass, and holding it near the eye, look through it at a distant candle, we shall observe the appearance, even in the day-time, of a bright circular corona of colours, of which the candle is the centre; a red area, surrounded by a circle of green, and this again by another of red; the colours being so much the brighter, as the globules are more numerous and more equable. If the substance be simply mucus, there will be no rings of colours, although sometimes there is a sufficient mixture of heterogeneous particles even in mucus, to cause the appearance of a reddish area only about the candle.

Much less importance is now attached to these criteria than formerly. They were supposed to be of great moment in the diagnosis of phthisis, which, however, in the present day, is deduced from much more certain data. See *Phthisis*.

For the consideration of the circumstances connected with the formation of pus, see *Abscess*.

Pustula oris. See *Aphtha*.

PU'STULE. (*Pustula*, a little pustule; from *pus*, matter.) An elevation of the cuticle, sometimes globate, sometimes conoidal in its form, and containing pus or lymph, which is in general discoloured.

Pustules are various in their size, but the diameter of the largest seldom exceeds two lines. There are many different kinds of pustules, properly distinguished in medical authors, by specific appellations; as,

1. *Phlyzacium*, a small pustule containing pus, and raised on a hard, circular, inflamed base of a vivid red colour. It is succeeded by a thick, hard, dark-coloured scab.

2. *Psydracium*, according to Dr. Willan, a minute pustule, irregularly circumscribed, producing but a slight elevation of the cuticle, and terminating in a laminated scab. Many of these pustules usually appear together, and become confluent. When mature, they contain pus; and, after breaking, discharge a thin watery humour. Pustules originate from an inflammation of the skin, and the consequent partial effusion of purulent matter under the cuticle, by which the latter is elevated into small circumscribed tumours. Sometimes several of these elevations arise upon a common inflamed surface; but most frequently, the inflammation of the base of each is distinct and circumscribed. They often terminate in a scabby incrustation, varying in hardness according to the various tenacity of the contained fluid, and sometimes in superficial ulceration. The genera impetigo, porrigo, ecthyma, variola, and scabies, which Dr. Willan includes under the order of pustulæ, have nothing in common in their character, except the appearance of pustules in some stage of their progress; for some are contagious and others not, some are acute and others chronic.

PUTA'MEN. (*en, inis.* n.; from *puto*, to cut.) The bark or paring of any vegetable; as the walnut. See *Juglans regia*.

PUTAMI'NEÆ. The name of an order in Linnæus's Fragments of a Natural Method, embracing those which have an outer shell, or putamen, over a hard fruit; as in *Capparis* and *Merisoma*.

PUTREFACTION. (*Putrefactio*; from *putrefacio*, to make rotten, to cause to putrefy. Putrid fermentation. Putrefactive fermentation. The spontaneous decomposition of animal and vegetable matters attended with a fœtid exhalation. The solid and the fluid matters are re-

solved into gaseous compounds and vapours, which escape, and earthy matters, which remain. The requisites to this process are — 1. A certain degree of humidity. 2. The access of atmospheric air. 3. A certain degree of heat: hence the abstraction of the air and water, or humidity, by drying, or its fixation by cold, by salt, sugar, spices, &c., will counteract the process of putrefaction, and favour the preservation of food, on which principle some patents have been obtained.

Putrid fever. See *Typhus.*

PYLO'RIC. (*Pyloricus;* from *pylorus.*) Belonging to the pylorus.

PYLORIC ARTERY. *Arteria pylorica.* A branch of the hepatic artery.

PYLO'RUS. (*us, i.* m.; from πυλη, an entrance, and ωρεω, to guard: because it guards, as it were, the entrance of the bowels.) The inferior aperture of the stomach, which opens into the intestines.

PYOPOIE'TIC. (From πυον, pus, and ποιεω, to make.) Suppurative.

PYORRHŒ'A. (From πυον, pus, and ῥεω, to flow.) A purulent discharge.

PYOTU'RIA. (From πυον, pus, and ουρον, urine.) *Pyuria.* A purulent state of the urine.

PYRA'MIDAL. (*Pyramidalis:* so called from its form.) Of the figure of a pyramid.

Pyramidalia corpora. See *Corpus pyramidale.*

PYRAMIDA'LIS. (From πυραμις, a pyramid.) A muscle in the front of the belly. Fallopius, who is considered as the first accurate describer of this muscle, gave it the name of *pyramidalis,* from its shape: hence it is called *pyramidalis Fallopii,* by Douglas. But Vesalius seems to have been acquainted with it, and to have described it as a part of the rectus. It is called *pyramidalis vel succenturiatus,* by Cowper. It is a very small muscle, situated at the bottom of the forepart of the rectus, and is covered by the same aponeurosis that forms the anterior part of the sheath of that muscle. It arises, by short tendinous fibres, from the upper and forepart of the os pubis. From this origin, which is seldom more than an inch in breadth, its fibres ascend somewhat obliquely, to be inserted into the linea alba, and inner edge of the rectus, commonly at about the distance of two inches from the pubes, and frequently at a greater or less distance, but always below the umbilicus. In some subjects the pyramidalis is wanting on one or both sides; and when this happens, the internal oblique is usually found to be of greater thickness at its lower part. Now and then, though rarely, there are two at one side, and only one at the other; and Sabatier has even seen two on each side. Fallopius, and many others after him, have considered it as the congener of the internal oblique; but its use seems to be to assist the lower part of the rectus.

Pyramidalis faciei. See *Levator labii superioris alæque nasi.*

PYRENOI'DES. (From πυρην, a kernel, and ειδος, likeness: so called from its kernel-like shape.) Kernel-shaped: applied to the odontoid process of the second vertebra.

PYRETE'RIUM. (From πυρ, fire, and τηρεω, to keep.) The fire-hole of a furnace.

PYRE'THRUM. (*um, i.* n.; from πυρ, fire, because of the hot taste of its root.) See *Anthemis pyrethrum.*

Pyrethrum sylvestre. See *Achillea.*

PYRE'TIC. (*Pyreticus;* from πυρ, fire.) Appertaining to fever.

PYRETO'LOGY. (*Pyretologia, æ.* f.; from πυρετος, fever, and λογος, a discourse.) The doctrine of fevers.

PYRE'XIA. (*a, æ.* f.; from πυρ, fire.) Fever.

PYREXIÆ. Febrile diseases. The first class of Cullen's Nosology; characterised by frequency of pulse after a cold shivering, with increase of heat, and especially, among other impaired functions, a diminution of strength.

PYRE'XIAL. (*Pyrexialis;* from *pyrexia,* fever.) Febrile. Appertaining to fever.

PY'RIFORM. (*Pyriformis;* from *pyrus,* the pear, and *forma,* likeness.) Pear-like; pear-shaped.

PYRIFO'RMIS. (From *pyrus,* a pear, and *forma,* a shape: shaped like a pear.) A small radiated muscle of the pelvis, situated under the glutæus maximus, along the inferior edge of the glutæus minimus. *Periformis, seu iliacus externus,* of Douglas and Cowper. Spigelius was the first who gave a name to this muscle, which he called *pyriformis,* from its supposed resemblance to a pear. It is the *pyriformis sive pyramidalis,* of Winslow. It arises by three and sometimes four tendinous and fleshy origins, from the anterior surface of the second, third, and fourth pieces of the os sacrum, so that this part of it is within the pelvis. From these origins the muscle grows narrower, and passing out of the pelvis, below the niche in the posterior part of the ilium, from which it receives a few fleshy fibres, is inserted by a roundish tendon, of an inch in length, into the upper part of the cavity, at the root of the trochanter major. The use of this muscle is to assist in moving the thigh outwards, and moving it a little upwards.

PYRMONT. The name of a village in the circle of Westphalia, in Germany, which has a celebrated acidulous chalybeate water. Pyrmont water, *Aqua Pyrmontana,* is of an agreeable, though strongly acidulated taste, and emits a large portion of gas, which affects the persons who attend at the well, and also those who drink the fluid, with a sensation somewhat resembling that produced by intoxication. The Pyrmont water contains muriates of soda and magnesia; sulphates of soda and magnesia; carbonates of iron, lime, and magnesia; and a quantity of free carbonic acid. The diseases in which this mineral water may be advantageously used, are the same as those for which the Spa, and others of the acidulated chalybeates, are resorted to, that is, all cases of debility which require an active tonic not permanently heating; as various disorders in the alimentary canal, especially bilious vomiting, and diarrhœa, and complaints that originate from obstructed menstruation. The quantity of the water drunk, is two, three, or more English pints in the morning. Its common operation is by urine; but, if taken

copiously, it generally proves laxative; and when it has not this effect, and that effect is wanted, they commonly mix, with the first glass drunk in the morning, from one to five or six drachms of some purging salts.

PY'RO-ACE'TIC. (*Pyro-aceticus*: so called because it is an acetic acid obtained by the aid of fire.) Appertaining to the acid so called.

Pyro-acetic spirit. *Pyro-acetic æther.* A substance obtained along with acetic acid by the destructive distillation of the acetates. It was first observed by Derosne. When pure, it is a colourless limpid liquid of a peculiar penetrating odour. It is highly inflammable. Its specific gravity is 0·792. It boils at 132°. It mixes readily with water, alkohol, æther, and turpentine. It is called *pyro-acetic*, because it is formed by the action of fire, πυρ, on the acetic acid.

Pyro-ci'tric acid. *Acidum pyro-citricum.* An acid obtained by M. Lassaigne by subjecting citric acid to destructive distillation, saturating the acid liquor which results with lime, and decomposing the precipitate with oxalic acid. A peculiar acid is thus set free, which is the pyro-citric.

Pyro-ga'llic acid. An acid obtained by the action of heat upon gallic acid.

Pyro-ki'nic acid. An acid obtained by the action of heat on kinic acid.

PY'ROLA. (*a, æ.* f.; from *pyrus*, a pear: so named because its leaves resemble those of the pear-tree.) 1. The name of a genus of plants in the Linnæan system. Class, *Decandria*; Order, *Monogynia*.

2. The pharmacopœial name of the winter-green. See *Pyrola rotundifolia.*

Pyrola rotundifolia. The systematic name of the round-leaved winter-green. This elegant little plant, common in our woods, is now forgotten in the practice of medicine. It possesses gently astringent qualities, and has a somewhat bitter taste.

Pyrola umbellata. The exotic species is a strong diuretic. The leaves are infused in boiling water, and the tea drunk rather freely.

Pyroligneous acid. *Acidum pyrolignosum.* Pyrolignous acid. In the destructive distillation of any kind of wood, an acid is obtained, which was formerly called *acid spirit of wood*, but now pyroligneous acid. Fourcroy and Vauquelin showed that this acid was merely the acetic, contaminated with empyreumatic oil and bitumen. See *Acetum.*

Pyroli'thic acid. *Pyro-uric acid* When uric acid concretions are distilled in a retort, silvery white plates sublime. These are pyrolithate of ammonia. When their solution is poured into that of subacetate of lead, a pyrolithate of lead falls, which, after proper washing, is to be shaken with water, and decomposed by sulphuretted hydrogen gas. The supernatant liquid is now a solution of pyrolithic acid, which yields small acicular crystals by evaporation.

Pyroma'lic acid. *Acidum pyromalicum.* When malic or sorbic acid, for they are the same, is distilled in a retort, an acid sublimate, in white needles, appears in the neck of the retort, and an acid liquid distils into the receiver. This liquid, by evaporation, affords crystals, constituting a peculiar acid, to which the above name has been given.

Py'romeco'nic acid. An acid obtained from meconic acid by the aid of heat.

PYROMU'CIC. (*Pyromucicus*; from πυρ, fire, and mucic acid.) Of or belonging to the peculiar acid so called.

Pyromucic acid. *Acidum pyromucicum.* Pyromucous acid. This acid is one of the products of the distillation of mucic acid.

Pyromucous acid. See *Pyromucic acid.*

PYRO'METER. (*Pyrometrum, i.* n.; from πυρ, fire, and μετρον, measure.) To measure those higher degrees of heat to which the thermometer cannot be applied, there have been other instruments invented by different philosophers: these are called *pyrometers.* The most celebrated instrument of this kind, and which has been adopted into general use, is that invented by the late ingenious Mr. Wedgwood.

PYRO'PHORUS. An artificial product, which takes fire or becomes ignited on exposure to the air.

PYRO'SIS. (*is, is.* f.; from πυροω, to burn.) A disease called in Scotland the water-brash; in England, black-water: known by a burning pain in the stomach, attended with copious eructation, generally of a watery insipid fluid. See *Cardialgia.*

Pyrosorbic acid. See *Pyromalic acid.*

Pyrotartaric acid. *Acidum pyrotartaricum.* Into a coated glass retort introduce tartar, or rather tartaric acid, till it is half full, and fit to it a tubulated receiver. Apply heat, which is to be gradually raised to redness. Pyrotartaric acid of a brown colour, from impurity, is found in the liquid products, which is to be purified by evaporation, solution, and filtration, several times.

Pyrote'chnia. (From πυρ, fire, and τεχνη, an art.) Formerly applied to chemistry, or that art by which the properties of bodies are examined by fire, but now used to designate the art of making fireworks.

Pyro'tica. (From πυροω, to burn.) Caustics.

Pyro-uric acid. See *Pyrolithic acid.*

PY'RUS. The name of a genus of plants in the Linnæan system. Class, *Icosandria*; Order, *Pentagynia.*

Pyrus communis. The pear-tree. The fruit is analogous to that of the apple, but more delicately flavoured. Its juice, when fermented, forms perry. Pears, when ripe, are easy of digestion, when not taken in excess.

Pyrus cydonia. The systematic name of the quince-tree. The fruit is termed *Cydonium malum*, or quince. The tree which affords this fruit is the *Pyrus — foliis integerrimis, floribus solitariis*, of Linnæus. Quince seeds are directed by the London College to be made into a decoction, which is recommended in aphthous affections, and excoriations of the mouth and fauces.

Pyrus malus. The systematic name of the apple-tree. The common crab-tree is the parent of all the vast variety of apples at present cultivated. Apples, in general, when ripe, afford

a pleasant and easily digestible fruit for the table; but, when the stomach is weak, they are very apt to remain unaltered for some days, and to produce dyspepsia. Sour fruits are to be considered as unwholesome, except when boiled or baked, and rendered soft and mellow with the addition of sugar.

PYU'LCA. (From πυον, *pus*, and ελκω, to draw.) Medicines which draw pus towards the surface.

PYU'LCUM. (From πυον, pus, and ἑλκω, to draw.) An instrument to extract the pus from the cavity of any sinuous ulcer. The instrument so called by Ambroise Paré and other old surgeons, was a kind of syringe. Galen mentions a pyulcum, but it is not clear what sort of instrument it was.

Pyuria. See *Pyoturia.*

PYXACA'NTHA. (From πυξος, the box tree, and ακανθα, a thorn.) The barberry, or thorny box-tree.

PY'XIS. (*is, idis.* f.; so called because it was made of the wood of the πυξος, or box-tree.) Properly a box; but, from its resemblance, the cavity of the hip-bone, or acetabulum, has been sometimes so called.

Q.

Q. P. An abbreviation of *quantum placet*, as much as you please.

Q. S. The contraction for *quantum sufficiat*, as much as may suffice.

Q. V. An abbreviation of *quantum vis*, as much as you will.

QUADRA'NGULAR. *Quadrangularis.* Four-cornered: often used to express the form of muscles, leaves, &c. The receptacle of the *Dorstenia Houstonii*, and *contrayerva*, is quadrangular.

Quadrates. See *Depressor labii inferioris.*

QUADRA'TUS. (From *quadra*, a square: so called from its figure.) Square-figured.

QUADRATUS FEMORIS. A muscle of the thigh, situated on the outside of the pelvis. It is a flat, thin, and fleshy muscle, but not of the shape its name would seem to indicate. It is situated immediately below the gemini. It arises tendinous and fleshy from the external surface and lower edge of the tuberosity of the ischium, and is inserted by short tendinous fibres into a ridge which is seen extending from the basis of the trochanter major to that of the trochanter minor. Its use is to bring the os femoris outwards.

Quadratus genæ. See *Platisma-myoides.*

Quadratus labii inferioris. See *Depressor labii inferioris.*

QUADRATUS LUMBORUM. *Quadratus, seu lumbaris externus*, of Winslow. A muscle situated within the cavity of the abdomen. This is a small, flat, and oblong muscle, that has got the name of *quadratus*, from its shape, which is that of an irregular square. It is situated laterally, at the lower part of the spine. It arises tendinous and fleshy from about two inches from the posterior part of the spine of the ilium. From this broad origin it ascends obliquely inwards, and is inserted into the transverse processes of the four superior lumbar vertebræ, into the lower edge of the last rib, and, by a small tendon that passes up under the diaphragm, into the side of the last vertebra of the back. When this muscle acts singly, it draws the loins to one side: when both muscles act, they serve to support the spine, and perhaps to bend it forwards. In laborious respiration, the quadratus lumborum may assist in pulling down the ribs.

Quadratus maxillæ inferioris. See *Platysma-myoides.*

Quadratus radii. See *Pronator radii-quadratus.*

QUADRIDENTA'TUS. (From *quatuor*, four, and *dens*, a tooth.) Four-toothed.

QUADRI'FIDUS. (From *quatuor*, and *findo*, to cleave.) Four-cleft.

QUADRI'GA. (From *quatuor*, four, and *jugum*, a yoke.) A bandage which resembles the trappings of a four-horse cart.

QUADRILOBA'TUS. (From *quatuor*, and *lobatus*, lobed.) Four-lobed.

QUADRILOCULA'RIS. (From *quatuor*, and *locularis*, having cells.) Quadrilocular, or four-celled.

QUADRIPARTI'TUS. (From *quatuor*, and *partitus*, divided.) Quadripartite; having four divisions.

QUADRIVA'LVUS. Quadrivalve, or having four valves.

QUADRU'MANA. (*Quatuor*, four, and *manus*, a hand.) An order of mammiferous animals which have four hands, as monkeys.

QUA'DRUPED. (*Quadrupes, dis.*; from *quatuor*, four, and *pes*, a foot.) An animal having four feet. The term is generally confined to *mammiferous* animals having four feet. Thus a spider has four feet, but we do not call it a quadruped.

QUARANTI'NE. (From the Italian *quarantana*, which is from *quaranta*, forty, because forty days is its ordinary duration.) The term during which persons or goods coming from an infected port are kept from landing, or confined in a lazzaretto. The term of the quarantine is often not nearly so long as forty days.

QUARS. A gall-stone. — *Ruland.*

QUA'RTAN. (*Quartanus*, fourth.) Occurring every fourth day. See *Ague.*

QUARTA'RIUS. The fourth part of a gallon. A quart.

QUARTA'TION. An operation in assaying, by which the quantity of one thing is made

equal to a fourth part of the quantity of another thing.

QUA'SSIA. (*a, æ.* f.; from a slave of the name of *Quassi*, who first used it with uncommon success as a secret remedy in the malignant endemic fevers which frequently prevailed at Surinam.) 1. The name of a genus of plants in the Linnæan system. Class, *Decandria*; Order, *Monogynia*.

2. The pharmacopœial name of the bitter quassia. See *Quassia amara*.

QUASSIA AMARA. The systematic name of the bitter quassia tree. *Quassia — floribus hermaphroditis, foliis impari-pinnatis, foliolis oppositis, sessilibus, petiolo articulato alato, floribus racemosis*, of Linnæus. The root, bark, and wood of this tree are all comprehended in the catalogues of the Materia Medica. The tree is a native of South America, particularly of Surinam, and also of some of the West India islands.

The roots are perfectly ligneous: they may be medically considered in the same light as the wood, which is now most generally employed, and seems to differ from the bark in being less intensely bitter: the latter is, therefore, thought to be a more powerful medicine. Quassia has no sensible odour; its taste is that of a pure bitter, more intense and durable than that of almost any other known substance; it imparts its virtues more completely to watery than to spirituous menstrua, and its infusions are not blackened by the addition of sulphate of iron. The watery extract is from a sixth to a ninth of the weight of the wood, the spirituous about a twenty-fourth. This bitter extract has been considered as a principle *sui generis*, and named *quassina*. Quassia, as before observed, derived its name from a negro named Quassi, who employed it with uncommon success as a secret remedy in the malignant endemic fevers which frequently prevailed at Surinam. In consequence of a valuable consideration, this secret was disclosed to Daniel Rolander, a Swede, who brought specimens of the quassia wood to Stockholm, in the year 1756; and, since then, the effects of this drug have been generally tried in Europe, and numerous testimonies of its efficacy published by many respectable authors. Various experiments with quassia have likewise been made, with a view to ascertain its antiseptic powers; from which it appears to have considerable influence in retarding the tendency to putrefaction; and this, Professor Murray thinks, cannot be attributed to its sensible qualities, as it possesses no astringency whatever; nor can it depend upon its bitterness, as gentian is much bitterer, yet less antiseptic. The medicinal virtues ascribed to quassia are those of a tonic, stomachic, antiseptic, and febrifuge. It has been found very effectual in restoring digestion, expelling flatulencies, and removing habitual costiveness, produced from debility of the intestines, and common to a sedentary life. Dr. Lettsom, whose extensive practice gave him an opportunity of trying the effects of quassia in a great number of cases, says: "In debility, succeeding febrile diseases, the Peruvian bark is most generally more tonic and salutary than any other vegetable hitherto known; but in hysterical atony, to which the female sex is so prone, the quassia affords more vigour and relief to the system than the other, especially when united with the vitriolum album, and still more with the aid of some absorbent." In dyspepsia, arising from hard drinking, and also in diarrhœas, the doctor exhibited the quassia with great success. But, with respect to the tonic and febrifuge qualities of quassia, he says: "I by no means subscribe to the Linnæan opinion, where the author declares, 'me quidem judice chinchinam longe superat.'" It is very well known that there are certain peculiarities of the air, and idiosyncrasies of constitution, unfavourable to the exhibition of Peruvian bark, even in the most clear intermissions of fever; and writers have repeatedly noticed it. But this is comparatively rare. About midsummer, 1785, Dr. Lettsom met with several instances of low remittent and nervous fevers, wherein the bark uniformly aggravated the symptoms, though given in intermissions the most favourable to its success, and wherein quassia or snake-root was successfully substituted. In such cases he mostly observed, that there was great congestion in the hepatic system, and the debility at the same time discouraged copious evacuations. And in many fevers, without evident remissions to warrant the use of the bark, whilst at the time increasing debility began to threaten the life of the patient, the doctor found that quassia, or snake-root, singly or combined, upheld the vital powers, and promoted a critical intermission of fever, by which an opportunity was afforded for the bark to effect a cure. It may be given in infusion, or in pills made from the watery extract: the former is generally preferred, in the proportion of three or four scruples of the wood to twelve ounces of water.

QUASSIA EXCELSA. *Simarouba excelsa*. Mountain damson. A great part of the quassia wood found in the market is the produce of this tree.

Quassia simarouba. See *Simarouba officinalis*.

Quassina. See *Quassia*.

QUA'TRIO. (From *quatuor*, four: so called because it has four sides.) The astragalus.

QUAULI. An alchemical name of lead.

Queen of the meadow. See *Spiræa ulmaria*.

Quercera. See *Epialus*.

Quercitron bark. See *Quercus tinctoria*.

QUE'RCULA. (A diminutive of *quercus*, the oak: so called because it has leaves like the oak.) See *Teucrium chamædrys*.

QUE'RCUS. (*us, ûs.* f.) The oak.

1. The name of a genus of plants in the Linnæan system. Class, *Monœcia*; Order *Polyandria*.

2. The pharmacopœial name of the oak. See *Quercus robur*.

Quercus cerris. See *Quercus infectoria*.

QUERCUS E'SCULUS. The Italian oak; the acorns of which are, in times of scarcity, said to afford a meal of which bread is made.

QUERCUS INFECTO'RIA. *Quercus cerris*. The name of the tree which affords the excrescence

called *Galla*, *Galla maxima orbiculata*, and *Nux galla*, or gall-nut. By the name of gall-nut is usually denoted any protuberance, tubercle, or tumour, produced by the puncture of insects on plants and trees of different kinds. These galls are of various forms and sizes, and no less different with regard to their internal structure. Some have only one cavity, and others a number of small cells, communicating with each other. Some of them are as hard as the wood of the tree they grow on, whilst others are soft and spongy; the first being termed gall-nuts, and the latter berry-galls, or apple-galls.

The gall-nut used in medicine is thus produced:—The *cynips quercus folii*, an insect of the fly kind, deposits its eggs in the leaves and other tender parts of the tree. Around each puncture an excrescence is presently formed, within which the egg is hatched, and the worm passes through all the stages of its metamorphosis, until it becomes a perfect insect, when it eats its way out of its prison. The best oak-galls are heavy, knotted, and of a bluish colour, and are obtained from Aleppo. They are nearly entirely soluble in water, with the assistance of heat. From 500 grains of Aleppo galls, Sir Humphry Davy obtained, by infusion, 185 grains of solid matter, which, on analysis, appeared to consist of *tannin*, 130; mucilage, and matter rendered insoluble by evaporation, 12; gallic acid, with a little extractive matter, 31; the remainder, calcareous earth and saline matter, 12. Another sort comes from the south of Europe, of a light brownish or whitish colour, smooth, round, easily broken, less compact, and of a much larger size. The two sorts differ only in size and strength, two of the blue galls being supposed equivalent in this respect to three of the others.

Oak-galls are supposed to be the strongest astringent in the vegetable kingdom. Both water and spirit take up nearly all their virtue, though the spirituous extract is the strongest preparation. The powder is, however, the best form; and the dose is from a few grains to half a drachm.

They are not much used in medicine, though they are said to be beneficial in intermittents. Dr. Cullen has cured agues by giving half a drachm of the powder of galls every two or three hours during the intermission; and by it alone, or joined with chamomile flowers, has prevented the return of the paroxysms. But the doctor states the amount of his results only to be this:—"that, in many cases, the galls cured the intermittents; but that it failed also in many cases in which the Peruvian bark afterwards proved successful." A fomentation, made by macerating half an ounce of bruised galls in a quart of boiling water for an hour, has been found useful for the piles, the prolapsus ani, and the fluor albus, applied cold. An injection, simply astringent, is made by diluting this fomentation, and used in gleets and leucorrhœa. The camphorated ointment of galls has been found also serviceable in piles, after the use of leeches; and is made by incorporating half a drachm of camphire with one ounce of hog's lard, and adding two drachms of galls in very fine powder. In fact, galls may be employed for the same purposes as oak-bark, and are used under the same forms.

Quercus marina. Sea oak. See *Fucus vesiculosus*.

Quercus phellos. The systematic name of the willow-leaved oak, the acorns of which are much sweeter than chestnuts, and much eaten by the Indians. They afford, by expresssion, an oil little inferior to oil of almonds.

Quercus robur. The oak-tree. *Balanos. Quercus—foliis oblongis, glabris sinuatis, lobis rotundis, glandibus oblongis*, of Linnæus. This valuable tree is indigenous to Britain. Its astringent effects were sufficiently known to the ancients, but it is the bark which is now directed for medicinal use by our Pharmacopœias. Oak-bark manifests to the taste a strong astringency, accompanied with a moderate bitterness. Like other astringents, it has been recommended in agues, and for restraining hæmorrhages, alvine fluxes, and other immoderate evacuations. A decoction of it has likewise been advantageously employed as a gargle, and as a fomentation or lotion in *procidentia recti et uteri*.

The fruit of this tree was the food of the first ages; but when corn was cultivated, acorns were neglected. They are of little use with us, except for fattening hogs and other cattle and poultry. Among the Spaniards, the acorn, or *glans iberica*, is said to have long remained a delicacy, and to have been served up in the form of a dessert. In dearths, acorns have been sometimes dried, ground into meal, and baked as bread. Bartholin relates, that they are used in Norway for this purpose. The inhabitants of Chio held out a long siege without any other food; and in a time of scarcity in France, A. D. 1709, they recurred to this food. But they are said to be hard of digestion, and to occasion headachs, flatulency, and colics. In Smoland, however, many instances occur in which they have supplied a salutary and nutritious food. With this view they are previously boiled in water and separated from their husks, and then dried and ground; and the powder is mixed with about one half or one third of corn flour. A decoction of acorns is reputed good against dysenteries and colics; and a pessary of them is said to be useful in immoderate fluxes of the menses. Some have recommended the powder of acorns in intermittent fever; and in Brunswick, they mix it with warm ale, and administer it for producing a sweat in cases of erysipelas. Acorns, roasted and bruised, have restrained a violent diarrhœa. For other medical uses to which they have been applied, see Murray's Appar. Medic. vol. i. page 100.

From some late reports of the Academy of Sciences at Petersburg, we learn that acorns are the best substitute for coffee that has been hitherto known. To communicate to them the oily properties of coffee, the following process is recommended:—When the acorns have been toasted brown, add fresh butter in small pieces to them, while hot in the ladle, and stir them with care: cover the ladle and shake it, that the whole may be well mixed. The acorns of the Holm oak are formed at Venice into cups

about one inch and a half in diameter, and somewhat less in depth. They are used for dressing leather, and instead of galls for dyeing woollen cloth black.

Quercus suber. The systematic name of the cork-tree. *Suber.* The fruit of this tree is much more nutritious than our acorns, and is sweet, and often eaten, when roasted, in some parts of Spain. The bark, called cork, when burnt, is applied as an astringent application to bleeding piles, and to allay the pain usually attendant on hæmorrhoids, in the form of ointment. Pessaries and other chirurgical instruments are also made of this useful bark. By the action of nitric acid, cork becomes acidified. See *Suberic acid.*

Quercus tinctoria. This species is a native of North America, and yields the quercitron bark used as a yellow dye.

Quick-grass. See *Triticum repens.*

Quick-lime. See *Lime.*

Quicksilver. See *Mercury.*

Quid pro quo. These words are applied synonymously with *succedaneum*, or one thing made use of to supply the defect of another.

Quiescent affinity. See *Affinity.*

QUI'NA. (*a*, *æ*. f.; so called by the French because obtained from Peruvian bark, which they call *Quinquina.*) *Quinina. Quinea.* Quinine: the alkali obtained from the bark of the *Cinchona cordifolia*. It may be obtained by the following process. The cinchona is deprived of its bitterness by means of boiling alkohol, and the tincture distilled to dryness in a water-bath. The alkoholic extract is entirely dissolved in boiling water, strongly impregnated with hydrochloric acid. Calcined magnesia is then added in excess to fix the red colouring matter, and to clarify the liquor, the latter being effected by some minutes' boiling. It is allowed to cool, filtered, and the magnesian precipitate washed with cold water. The precipitate having been dried on a stove, is repeatedly treated with boiling alkohol, in order to remove all bitterness. The alkoholic liquors are now mixed, and the cinchona crystallises on cooling. The cinchona thus obtained is still impure, from the presence of the green fatty matter, which may be got rid of by solution in a highly diluted acid; if the acid were too concentrated, it would dissolve a portion of the fatty matter, and the end would be frustrated. By the above process quina is obtained from the yellow bark, and cinchona from the grey.

As the sulphate of quina is now prepared on a large scale for medical use, the readiest way of obtaining the quina is to decompose a solution of the sulphate by means of ammonia.

Quina, when pure, is of a white colour. Its taste is intensely bitter. It is very sparingly soluble in water even when boiling. It is readily soluble in boiling alkohol, which, when evaporated, leaves it in the form of a viscid mass. It is distinctly alkaline, and forms salts with the acids. It crystallises with difficulty; but M. Pelletier has obtained it crystallised in fine silky flocculi, by submitting to spontaneous evaporation a very pure alkoholic solution. MM. Henri and Delondre have also obtained it crystallised in a hydrated form. Quina, unlike cinchonia, is very soluble in ether.

According to Dumas and Pelletier, quina consists of,

Carbon	75·00
Azote	8·45
Hydrogen	6·66
Oxygen	10·40

The analysis of Liebig and Brande agree very nearly with the above.

The medicinal properties of quina agree as nearly as possible with those of its sulphate; and as the latter is more readily prepared, the uncombined alkali is seldom used.

The other salts of quina, as the acetate, citrate, &c., have the properties of the sulphate, but in an inferior degree. The disulphate of quina is accordingly the only preparation of this alkali in general use. See *Quinæ disulphas.*

Quina-quina. See *Cinchona.*

Quinæ disulphas. *Disulphate of quina.* Take of heart-leaved cinchona, bruised, seven pounds; sulphuric acid, nine ounces; purified animal charcoal, two ounces; hydrated oxide of lead, solution of ammonia, distilled water, each as much as may be sufficient: mix four ounces and two drachms of the sulphuric acid with six gallons of distilled water, and add the cinchona to them; boil for an hour and strain. In the same manner again boil what remains in acid and water, mixed in the same proportions, for an hour, and again strain. Lastly, boil the cinchona in eight gallons of distilled water for three hours, and strain. Wash what remains frequently with boiling distilled water. To the mixed liquors add oxide of lead, while moist nearly to saturation. Pour off the supernatant liquor, and wash what is thrown down with distilled water. Boil the liquors for a quarter of an hour, and strain; then gradually add solution of ammonia to precipitate the quina. Wash this until nothing alkaline is perceptible. Let what remains be saturated with the rest of the sulphuric acid diluted. Afterwards digest with two ounces of animal charcoal, and strain. Lastly, the charcoal being thoroughly washed, evaporate the liquor cautiously that crystals may be produced. The above preparation is a hydrated disulphate of quina. As a medicine, it possesses the febrifuge power of the cinchona bark in the highest degree, and it is applicable to every instance in which the bark is exhibited except as a stomachic bitter in dyspepsia, in which case it often proves too stimulating, and inferior in efficacy to a decoction of the bark. The dose is from one grain to ten. In cases of ague, after the primæ viæ have been properly cleared, three grains of the sulphate given every three hours during the intermission, will prevent the access of the paroxysm with a certainty that seems almost magical.

Quinæ sulphas. Sulphate of quina. Quina combines with sulphuric acid in two proportions, forming a neutral sulphate and a disulphate. The former consists of one equivalent of the acid and of the alkali, and eight of water; the

latter of one equivalent of acid, two of quina, and eight of water. The *disulphate* only is used in medicine. This, however, is the preparation known in our shops as the *sulphate*.

Quince. See *Pyrus cydonia.*

Quinsy. See *Cynanche.*

Quinia. See *Quina.*

Quinina. See *Quina.*

QUINATE. A salt formed by the *quinic* or *kinic* acid with a base. See *Kinic acid.*

Quinine, sulphate of. See *Quinæ sulphas.*

QUINQUEFO'LIUM. (*um, i.* n.; from *quinque*, five, and *folium*, a leaf: so called because it has five leaves on each foot-stalk.) See *Potentilla reptans.*

Quinquina, Mexican. See *Iva frutescens.*

Quinquina. See *Cinchona.*

QUINTA ESSENTIA. The quintessence. A term used by the alchemists to signify the active principle of any thing, in which its properties and virtues reside, separated by art from the inert matters with which it was combined. The term was also used in several mysterious and unintelligible acceptations.

Quintessence. See *Quinta essentia.*

Quotidian. See *Ague.*

R.

R. or R. This letter is placed at the beginning of a prescription, as a contraction of *Recipe*, take: thus, R *Magnes.* ℥j. signifies, Take a drachm of magnesia. "In ancient times," says Dr. Paris, in his excellent work on pharmacology, "of planetary influence, that it was usual to prefix a symbol of the planet under whose reign the ingredients were to be collected; and it is not, perhaps, generally known, that the character which we at this day place at the head of our prescriptions, and which is understood and supposed to mean *recipe*, is a relic of the astrological symbol of Jupiter, as may be seen in many of the older works on pharmacy.

Rabbit. See *Lepus cuniculus.*

RA'BIES. (*es, ei.* f.) Madness: generally applied to the disease in dogs, otherwise called hydrophobia. See *Hydrophobia.*

Rabies canina. See *Hydrophobia.*

RACE'MUS. (*us, i.* m.; from *ramus.*) A raceme, cluster, or bunch. A species of inflorescence, consisting of a cluster of flowers, rather distant from each other, each on its own proper stalk, the tops of the lower ones not coming near to the tops of the upper ones, as in a corymb, and all connected by one common stalk; as a bunch of currents. It is therefore a kind of pedunculated spike.

From the *division* of the common stalk, it is denominated,

1. *Simple*, not having any branches; as in *Ribes rubrum*, and *Acer pseudo-platanus.*

2. *Compound*, being branched; as in *Vitis vinifera.*

3. *Conjugate*, two clusters from the end of the common peduncle.

4. *Aggregate*, several being gathered together; as in *Actæa racemosa.*

5. *Unilateral*, the proper stalks of the flowers proceeding from one side only of the common stalk; as in *Pyrola secunda.*

6. *Secund*, the proper stalks of the flowers coming from every part of the common stalk, but all looking to one side only; as in *Andromeda racemosa*, *Teucrium scorodonia*, &c.

From the *direction* of the racemus, —

7. *Erectus*; as in *Chenopodium album*, *Ribes alpinum*, and *Astragalus austriacus.*

8. *Pendulus*; as in *Cytisus laburnum.*

9. *Laxus*, easily bent; as in *Celosia trigyna*, and *Solanum carolinense.*

10. *Strictus*, bent with difficulty; as in *Ononis cernua.*

From its *vesture*, —

11. *Nudus*; as in *Vaccinium legustrinum.*

12. *Pilosus*; as in *Ribes nigrum.*

13. *Foliatus*; as in *Chenopodium ambrosioides.*

14. *Bracteatus*; as in *Andromeda racemosa.*

Rachialgia. See *Rhachialgia.*

Rachitis. See *Rhachitis.*

Rackasiri balsamum. See *Balsamum rackasiri.*

RACO'SIS. (*is, is.* f.; from ῥάκος, a rag.) A relaxation of the scrotum.

RA'DIAL. (*Radialis*; from *radius*, the name of a bone.) Belonging to the radius.

RADIAL ARTERY. *Arteria radialis.* A branch of the humeral artery that runs down the side of the radius. See *Artery.*

Radialis externus brevior. See *Extensor carpi radialis brevior.*

Radialis externus longior. See *Extensor carpi radialis longior.*

Radialis externus primus. See *Extensor carpi radialis longior.*

Radialis internus. See *Flexor carpi radialis.*

Radialis secundus. See *Extensor carpi radialis brevior.*

RADIA'TUS. Radiate. Applied to a sort of compound flower, in which the florets of the centre differ in form from those in the circumference: thus the flower of the *Bellis perennis*, or daisy, is a radiate flower.

RA'DICAL. (*Radicalis*; from *radix*, the root or base.) 1. In *Chemistry*, applied to that which is considered as constituting the distinguishing part of an acid, by its union with oxygen or some other acidifying principle Thus sulphur is the radical of the sulphuric and sul-

phurous acids. It is sometimes called the base of the acid; but base is a term of more extensive application.

2. In *Botany*, applied to leaves. *Folia radicalia* are such as spring from the root, like those of the cowslip.

Radical vinegar. See *Acetum.*

RA'DICANS. A botanical term, applied to a stem which clings to any other body for support, and strikes root by means of fibres which do not imbibe nourishment; as the ivy, *Hedera helix.*

RADI'CULA. (*a*, *æ.* f.; diminutive of *radix*, a root.) 1. A radicle, rootlet, or little root. It probably means the fibres which come from the main root, and which are the most essential to the life of the plant, they alone imbibing the nourishment.

2. Applied to the origin of vessels and nerves.

3. The common radish is so sometimes called. See *Raphanus sativus.*

Radish. See *Cochlearia armoracia.*

Radish, garden. See *Raphanus sativus.*

Radish, horse. See *Cochlearia armoracia.*

RA'DIUS. (*us, ii.* m.) 1. In *Anatomy*, a bone of the fore-arm, which has got its name from its supposed resemblance to the spoke of a wheel, or to a weaver's beam; and sometimes, from its supporting the hand, it has been called *manubrium manus.* Like the ulna, it is of a triangular figure, but it differs from that bone, in growing larger as it descends, so that its smaller part answers to the larger part of the ulna, and *vice versâ.* Of its two extremities, the uppermost and smallest is formed into a small rounded head, furnished with cartilage, and hollowed at its summit, for an articulation with the little head at the side of the pully of the os humeri. The round border of this head, next the ulna, is formed for an articulation with the lesser sigmoid cavity of that bone. This little head of the radius is supported by a neck, at the bottom of which, laterally, is a considerable tuberosity, into the posterior half of which is inserted the posterior tendon of the biceps, while the anterior half is covered with cartilage, and surrounded with a capsular ligament, so as to allow this tendon to slide upon it as upon a pulley. Immediately below this tuberosity, the body of the bone may be said to begin. We find it slightly curved throughout its whole length, by which means a greater space is formed for the lodgment of muscles, and it is enabled to cross the ulna without compressing them. Of the three surfaces to be distinguished on the body of the bone, the external and internal ones are the broadest and flattest. The anterior surface is narrower and more convex. Of its angles, the external and internal ones are rounded; but the posterior angle, which is turned towards the ulna, is formed into a sharp spine, which serves for the attachment of the interosseous ligament, of which mention is made in the description of the ulna. This strong ligament, which is a little interrupted above and below, serves not only to connect the bones of the fore-arm to each other, but likewise to afford a greater surface for the lodgment of muscles. On the fore-part of the bone, and at about one third of its length from its upper end, we observe a channel for vessels, slanting obliquely upwards. Towards its lower extremity, the radius becomes broader, of an irregular shape, and somewhat flattened, affording three surfaces, of which the posterior one is the smallest; the second, which is a continuation of the internal surface of the body of the bone, is broader and flatter than the first; and the third, which is the broadest of the three, answers to the anterior and external surface of the body of the bone. On this last we observe several sinuosities, covered with a thin layer of cartilage, upon which slide the tendons of several muscles of the wrist and fingers. The lowest part of the bone is formed into an oblong articulating cavity, divided into two by a slight transverse rising. This cavity is formed for an articulation with the bones of the wrist. Towards the anterior and convex surface of the bone, this cavity is defended by a remarkable eminence, called the *styloid* process of the radius, which is covered with a cartilage that is extended to the lower extremity of the ulna; a ligament is likewise stretched from it to the wrist. Besides this large cavity, the radius has another much smaller one, opposite its styloid process, which is lined with cartilage, and receives the rounded surface of the ulna. The articulation of the radius with the lesser sigmoid cavity of the ulna, is strengthed by a circular ligament which is attached to the two extremities of that cavity, and from thence surrounds the head of the radius. This ligament is narrowest, but thickest at its middle part. But, besides this ligament, which connects the two bones of the fore-arm with each other, the ligaments which secure the articulation of the radius with the os humeri, are common both to it and the ulna, and therefore cannot well be understood till both these bones are described. These ligaments are a capsular and two lateral ligaments. The capsular ligament is attached to the anterior and posterior surface of the lower extremity of the os humeri, to the upper edges and sides of the cavities, we remarked, at the bottom of the pully and little head, and likewise to some part of the condyles: from thence it is spread over the ulna, to the edges of the greater sigmoid cavity, so as to include in it the end of the olecranon, and of the coronoid process and it is likewise fixed round the neck of the radius, so as to include the head of that bone within it. The lateral ligaments may be distinguished into external and internal, or, according to Winslow, into *brachio-radialis* and *brachio-cubitalis.* They both descend laterally from the lowest part of each condyle of the os humeri and, from their fibres spreading wide as they descend, have been compared to a goose's foot. The internal ligament, or brachio-cubitalis, which is the longest and thickest of the two, is attached to the coronoid process of the ulna. The external ligament, or brachio-radialis, terminates in the circular ligament of the radius. Both these ligaments adhere firmly to the capsular ligament, and to the tendons of some of the adjacent muscles. In considering the articu-

lation of the fore-arm with the os humeri, we find that when both the bones are moved together upon the os humeri, the motion of the ulna upon the pully allows only of flexion and extension: whereas, when the palm of the hand is turned downwards or upwards, or, in other words, in pronation and supination, we see the radius moving upon its axis, and in these motions its head turns upon the little head of the os humeri at the side of the pully, while its circular edge rolls in the lesser sigmoid cavity of the ulna. At the lower end of the fore-arm the edge of the ulna is received into a superficial cavity at the side of the radius. This articulation, which is surrounded by a loose capsular ligament, concurs with the articulation above, in enabling the radius to turn with great facility upon its axis; and it is chiefly with the assistance of this bone that we are enabled to turn the palm of the hand upwards or downwards, the ulna having but a very inconsiderable share in these motions.

2. In *Botany*, the marginal part of the corolla of compound flowers: thus, in the daisy, the marginal white florets form the rays or radius, and the yellow central ones the discus or disk. See *Discus*.

The radii of a peduncle of a compound umbel are the *common stalks* or spokes of the umbel, and *pedicelli* are the stalks of the flowrets.

RA'DIX. (*ix, icis. f.*) A root. 1. In *Botany*, that part of a plant which imbibes its nourishment, producing the herbaceous part and the fructification, and which consists of the *caudex*, or body, and *radicles*. — *Linnæus*.

That part of the plant by which it attaches itself to the soil in which it grows, or to the substance on which it feeds, and is the principal organ of nutrition. — *Keith*.

In all plants the primary root is a simple elongation of that part which, during the germination of the seed, is first protruded, and is denominated the radicle; and, as the plant continues to grow, the root gradually assumes a determinate form and structure, which differs materially in different plants, but always is found similar in all the individuals of the same species. From the figure, duration, direction, and insertion, roots are variously arranged.

From its *figure*, a root is called,

1. *Fusiform*, spindle-shaped, of an oblong, tapering form, pointed at its extremity; as in *Daucus carota*, the carrot; *Beta vulgaris*, beet; *Pastinaca sativa*, parsnip, &c.

2. *Ramose*, branched, which consists of a *caudex*, or main root, divided into lateral branches, which are again subdivided; so that it resembles in its divisions the stem and branches inverted. Most trees, shrubs, and many herbaceous plants, have this form of root.

3. *Fibrose*, fibrous, consisting wholly of small radicles; as the *Hordeum vulgare*, common barley, and most grasses.

4. *Præmorse*, abrupt, or truncated, appearing as if bitten off close to the top; as in *Scabiosa succisa*, the devil's bit; *Plantago major*, larger plantain; *Hieracium præmorsum*, &c.

5. *Globose*, having the caudex round, or subround, sending off radicles in many places; as in *Cyclamen europeum*, sow-bread; *Brassica rapa*, turnip, &c.

6. *Tuberose*, furnished with farinaceous tubers; as in *Solanum tuberosum*, the potato; *Helianthus tuberosus*, Jerusalem artichoke, &c.

7. *Pendulous*, consisting of tubers connected to the plant by thin or filiform portions; as in *Spiræa filipendula*, common drop-wort; *Pæonia officinalis*, pæony, &c.

8. *Granulate*, formed of many small globules; as in *Saxifraga granulata*, meadow saxifrage, &c.

9. *Articulate*, articulated, or jointed, apparently formed of distinct pieces, united, as if one piece grew out of another, with radicles proceeding from each joint; as in *Oxalis acetosella*, woodsorrel; *Asarum canadense*, wild ginger, &c.

10. *Dentate*, toothed, which has a fleshy caudex, with teeth-like prolongations; as in *Ophrys corallorhiza*.

11. *Squamose*, scaly, covered with fleshy scales; as in *Lathræa squamaria*, toothwort, &c.

12. *Fascicular*, bundled, or fasciculate; as in *Ophrys nidus avis*, &c.

13. *Hollow*; as in *Fumaria cava*.

There are other distinctions of modern botanists derived from the form; as conical, subrotund, napiform, placentiform, filiform, capillary, tufted, funiliform, geniculate, contorted, moniliform, &c.

From the *direction*, roots are distinguished into, —

14. *Perpendicular*, which descend in a straight direction; as in *Daucus carota*, *Beta vulgaris*, *Scorzonera hispanica*, &c.

15. *Horizontal*, which is extended under the earth transversely; as in *Laserpitium parthenium*, &c.

16. *Oblique*, descending obliquely; as in *Iris germanica*, &c.

17. *Creeping*, descending transversely, but here and there sending off new plants; as in *Sambucus ebulus*, *Glycyrrhiza glabra*, *Ranunculus repens*, &c.

The *duration* affords, —

18. *Annual*, yearly, which perishes the same year with the plant; as *Draba verna*, and all annuals.

19. *Biennial*, which vegetates the first year, flowers the next, and then perishes; as the *Œnothera biennis*, *Beta vulgaris*, &c.

20. *Perennial*, which lives for many years; as trees and shrubs.

Roots are also distinguished from their *situation* into, —

21. *Terrene*, earth-root, which grow only in the earth; as the roots of most plants.

22. *Aquatic*, water-root, which grow only in the water, and perish when out of it; as *Trapa natans*, *Nymphæa alba*.

23. *Parasitic*, parasitical, which inserts the root into another plant; as in *Epidendrum vanilla*, &c.

24. *Arrhize*, which does not insert radicles, but coheres to other plants by an anastomosis of vessels; as in *Viscum album*, *Horanthus europæus*, &c.

II. In *Anatomy*, the term radix is applied to some parts which are inserted into others, or spring from them as a root from the earth; as the fangs of the teeth, the origin of some of the nerves, &c.

Radix bengale. See *Cassumuniar.*

Radix brasiliensis. See *Callicocca ipecacuanha.*

Radix dulcis. See *Glycyrrhiza.*

Radix indiana. See *Callicocca ipecacuanha.*

Radix rosea. See *Rhodiola.*

Radix rubra. See *Rubia tinctorum.*

Radix ursina. See *Æthusa meum.*

RA'DULA. (From *rado*, to scrape.) A wooden spatula, or scraper.

Ragwort. See *Senecio Jacobæa.*

RA'IA. (*a*, *æ*. f.) The name of a genus of fishes of the order *Chondropterygia*. There are many species, all inhabitants of the sea. The following are sometimes eaten as food: —

Raia batis. The skate. This flat fish grows to a great size, weighing from 50 to 200 pounds. It is considered as more difficult of digestion than the more tender-fibred fishes; but, when kept a certain time, it becomes very tender, and is considered a wholesome and delicate fish.

Raia clavata. The thornback. Very inferior to the skate, but eaten where it is abundant.

Raia oxyri'nchus. The sharp-nosed ray. Found in abundance in the Mediterranean. It is a wholesome fish, easy of digestion, and is often salted and sent into the interior of Germany.

Raia torpe'do. The torpedo or electric ray. This inhabits the Mediterranean sea, but is caught about Torbay and Waterford. The touch of this fish conveys an electric shock. It is hard of digestion, and seldom eaten.

Rainbow worm. A name of the *Herpes iris.* See *Herpes.*

Raisin. See *Vitis vinifera.*

Râle. See *Rhonchus.*

Rama'lis vena. (From *ramale*, a dead bough.) Applied to the vena portæ, from its numerous ramifications, which resemble a bough stripped of its leaves.

RAME'NTUM. (*um*, *i*. n.; *à radendo.*) A species of pubescence of plants, consisting of hairs in form of flat, strap-like portions, resembling shavings, seen on the leaves of some of the genus *Bigonia.* See *Pilus.*.

Rame'nta. Filings, as those of iron, zinc, &c.

Ra'mex. (From *ramus*, a branch: from its protruding like a branch.) An obsolete term for a rupture.

Ramolli'ssement. The term applied by the French pathologists to morbid softening of the texture of an organ; as *ramollissement du cerveau*, softening of the substance of the brain. This word has been very unnecessarily adopted into the language of our own country; it means nothing more nor less than *softening.*

RAMOSI'SSIMUS. Much branched. Applied to a stem which is repeatedly subdivided into a great many branches, without order; as those of the apple, pear, and gooseberry.

RA'MOUS. *Rameus. Ramosus.* Branched. Of or belonging to a bough or branch: applied to branch leaves, which are so distinguished, because they sometimes differ from those of the main stem; as is the case in *Melampyrum arvense:* and also to a leaf-stalk when it comes directly from the main branch; as in *Eugenia Malaccensis.*

RA'MULUS. A little branch, or the branch of a branch.

RA'MUS. (*us*, *i*. m.) A branch, or primary division of a stem into lateral stems. In the language of botanists, rami, or branches, are denominated, —

1. *Opposite*, when they go off, or pair opposite to each other, as they do in *Mentha arvensis.*

2. *Alternate*, one after another, alternately; as in *Althæa officinalis.*

3. *Verticillate*, when more than two go from the stem in a whorled manner; as in *Pinus abies.*

4. *Scattered*, without any order.

5. *Erect*, rising close to the stem; as in *Populus dilatata.*

6. *Patent*, or *expanding*, descending from the stalk at an obtuse angle; as in *Galium mollugo*, and *Cistus italicus.*

7. *Very spreading*, descending at a right angle; as in *Ammannia ramosior.*

8. *Brachiate*, the opposite spreading branches crossing each other; as in *Pisonia aculeata*, and *Banisteria brachiata.*

9. *Deflex*, arched, with the apex downwards; as in *Pinus larix.*

10. *Reflex*, hanging perpendicularly from the trunk; as in the *Salex babylonica.*

11. *Retroflex*, turned backwards; as in *Solanum dulcamara.*

12. *Fastigiate*, forming a kind of pyramid as in *Chrysanthemum corymbosum.*

13. *Vergate*, twig-like, long and weak: as in *Salix viminalis.*

RA'NA. The name of a genus of animals Class, *Amphibia;* Order, *Reptilia.* The frog.

Rana esculenta. The French frog. The flesh of this species of frog, very common in France, is highly nutritious and easily digested.

RANI'NUS. (From *rana*, a frog.) Ra nine. 1. Appertaining to a frog.

2. The name of an artery, called also *Arter ranina.* Sublingual artery. The second branch of the external carotid.

RA'NULA. (*a*, *æ*. f.; from *rana*, a frog said to be so called because the tumour resembles a frog, or because the patient croaks like a frog; neither of which however is true *Batrachos. Hypoglossus. Hypoglossum. Ran* An inflammatory or indolent tumour, under the tongue. These tumours are of various sizes and degrees of consistence, seated on either side of the frænum. Children, as well as adults are sometimes affected with tumours of this kind: in the former, they impede the action of sucking; in the latter, of mastication, and even speech. The contents of them are various: in some they resemble the saliva; in others, the glairy matter found in the cells of swelled joints. Sometimes it is said that a fatty matter has been found in them; but, from the nat

and structure of the parts, we are sure that this can seldom happen: and, in by far the greatest number of cases, we find that the contents resemble the saliva itself. This, indeed, might naturally be expected, for the cause of these tumours is universally to be looked for in an obstruction of the salivary ducts. Obstructions here may arise from a cold, inflammation, violent fits of the tooth-ach, attended with swelling in the inside of the mouth; and, in not a few cases, we find the ducts obstructed by a stony matter, seemingly separated from the saliva, as the calculous matter is from the urine; but where inflammation has been the cause we always find matter mixed with the other contents of the tumour. As these tumours are not usually attended with much pain, they are sometimes neglected, till they burst of themselves, which they commonly do when arrived at the bulk of a large nut. As they were produced originally from an obstruction in the salivary duct, and this obstruction cannot be removed by the bursting of the tumour, it hence happens that they leave an ulcer extremely difficult to heal, nay, which cannot be healed at all till the cause is removed.

RANUNCULOI'DES. (From *ranunculus*, and εἶδος, resemblance: so named from its resemblance to the ranunculus.) See *Caltha palustris*.

RANU'NCULUS. (*us*, *i.* m.; diminutive of *rana*, a frog: because it is found in fenny places, where frogs abound.) The name of a genus of plants in the Linnæan system. Class, *Polyandria*; Order, *Polygynia*.

The great acrimony of most of the species of ranunculus is such, that, on being applied to the skin, they excite itching, redness, and inflammation, and even produce blisters, tumefaction, and ulceration of the part. On being chewed, they corrode the tongue; and, if taken into the stomach, bring on all the deleterious effects of an acrid poison. The corrosive acrimony which this family of plants possesses was not unknown to the ancients, as appears from the writings of Dioscorides; but its nature and extent had never been investigated by experiments, before those instituted by C. Krapf, at Vienna, by which we learn that the most virulent of the Linnæan species are the bulbosus, sceleratus, acris, arvensis, thora, and illyricus.

The effects of these were tried either upon himself or upon dogs, and show that the acrimony of the different species is often confined to certain parts of the plant, manifesting itself either in the roots, stalks, leaves, flowers, or buds; the expressed juice, extract, decoction, and infusion of the plants, were also subjected to experiments. In addition to these species mentioned by Krapf, we may also notice the R. flammula, and especially the R. alpestris, which, according to Haller, is the most acrid of this genus. Curtis observes, that even pulling up the ranunculus acris, the common meadow species, which possesses the active principle of this tribe in a very considerable degree throughout the whole herb, and carrying it to some little distance, excited a considerable inflammation in the palm of the hand in which it was held. It is necessary to remark, that the acrimonious quality of these plants is not of a fixed nature; for it may be completely dissipated by heat; and the plant, on being thoroughly dried, becomes perfectly bland. Krapf attempted to counteract this poisonous acrimony of the ranunculus by means of various other vegetables, none of which were found to answer the purpose, though he thought that the juice of sorrel, and that of unripe currants, had some effect in this way; yet these were much less availing than water; while vinegar, honey, sugar, wine, spirit, mineral acids, oil of tartar, and other sapid substances, manifestly rendered the acrimony more corrosive. It may be also noticed, that the virulency of the most of the plants of this genus depends much upon the situation in which they grow, and is greatly diminished in the cultivated plant.

RANUNCULUS ABORTIVUS. The systematic name of a species of ranunculus, which possesses acrid and vesicating properties.

RANUNCULUS ACRIS. The systematic name of the meadow crowfoot. *Ranunculus pratensis.* This and some other species of ranunculus have, for medical purposes, been chiefly employed externally as a vesicatory, and are said to have the advantage of a common blistering plaster, in producing a quicker effect, and never causing a strangury; but, on the other hand, it has been observed, that the ranunculus is less certain in its operation, and that it sometimes occasions ulcers, which prove very troublesome and difficult to heal. Therefore their use seems to be applicable only to certain fixed pains, and such complaints as require a long-continued topical stimulus, or discharge from the part, in the way of an issue, which, in various cases, has been found to be a powerful remedy.

RANUNCULUS ALBUS. The plant which bears this name in the pharmacopœias is the *Anemone nemorosa*, of Linnæus. See *Anemone nemorosa*.

RANUNCULUS BULBOSUS. Bulbous-rooted crowfoot. The roots and leaves of this plant, *Ranunculus — calycibus retroflexis, pedunculis sulcatis, caule erecto multifloro, foliis compositis*, of Linnæus, have no considerable smell, but a highly acrid and fiery taste. Taken internally, they appear to be deleterious, even when so far freed from the caustic matter by boiling in water, as to discover no ill quality to the palate. The effluvia, likewise, when freely inspired, are said to occasion headachs, anxieties, vomiting, &c. The leaves and roots, applied externally, inflame and ulcerate, or vesicate the parts, and are liable to affect also the adjacent parts to a considerable extent.

RANUNCULUS FICARIA. The systematic name of the pilewort. *Chelidonium minus. Scrophularia minor. Chelidonia rotundifolia minor. Cursuma hæmorrhoidalis herba. Ranunculus vernus.* Lesser celandine, and pilewort. The leaves and root of this plant, *Ranunculus — foliis cordatis angulatis petiolatis, caule unifloro*, of Linnæus, are used medicinally. The leaves are deemed antiscorbutic, and the root reckoned a specific, if beat into cataplasms, and applied to the piles.

RANUNCULUS FLAMMULA. The systematic name of the smaller water crow-foot, or spear-

wort. *Surrecta alba.* The roots and leaves of this common plant, *Ranunculus — foliis ovatis-lanceolatis, petiolatis, caule declinato,* of Linnæus, taste very acrid and hot, and when taken in a small quantity, produce vomiting, spasms of the stomach, and delirium. Applied externally, they vesicate the skin. The best antidote, after clearing the stomach, is cold water acidulated with lemon-juice, and then mucilaginous drinks.

RANUNCULUS PALUSTRIS. Water crow-foot. See *Ranunculus sceleratus.*

RANUNCULUS PRATENSIS. Meadow crow-foot. See *Ranunculus acris.*

RANUNCULUS SCELERATUS. The systematic name of the marsh crow-foot. *Ranunculus palustris.* The leaves of this species of crow-foot are so extremely acrid, that the beggars in Switzerland are said, by rubbing their legs with them, to produce a very fetid and acrimonious. ulceration.

RA'PA. (*a, æ.* f.) See *Brassica napus.*

Rape. See *Brassica napus.*

Rape oil. See *Brassica napus.*

Rape seed. See *Brassica napus.*

RAPHA'NIA. (*a, æ.* f.; from *raphanus,* the radish, or charlock: because the disease is said to be produced by eating the seeds of a species of raphanus.) *Convulsio ab ustilagine. Convulsio raphania. Convulsio cereale. Eclampsia typhodes. Convulsio soloniensis. Necrosis ustilaginea.* Cripple disease. A genus of disease in the class *Neuroses,* and order, *Spasmi,* of Cullen; characterised by a spasmodic contraction of the joints, with convulsive motions, and a most violent pain returning at various periods. It begins with cold chills and lassitude, pain in the head, and anxiety about the præcordia. These symptoms are followed by spasmodic twichings in the tendons of the fingers and of the feet, discernible to the eye, heat, fever, stupor, delirium, sense of suffocation, aphonia, and horrid convulsions of the limbs. After these, vomiting and diarrhœa come on, with a discharge of worms, if there are any. About the eleventh or the twentieth day, copious sweats succeed, or purple exanthemata, or tabes, or rigidity of all the joints.

RAPHANI'STRUM. The trivial name of a species of raphanus.

RA'PHANUS. (*us, i.* m. Ῥαφανος παρα το ῥαδιως φαινεσθαι: from its quick growth.) 1. A genus of plants in the Linnæan system. Class, *Tetradynamia;* Order, *Siliculosa.*

2. The radish. See *Raphanus sativus.*

Raphanus hortensis. See *Raphanus sativus.*

Raphanus niger. See *Raphanus sativus.*

Raphanus rusticanus. See *Cochlearia armoracia.*

RAPHANUS SATIVUS. The systematic name of the radish-plant. *Raphanus hortensis. Radicula. Raphanus niger.* The radish. The several varieties of this plant are said to be employed medicinally in the cure of calculous affections. The juice, made into a syrup, is given to relieve hoarseness. Mixed with honey or sugar, it is administered in pituitous asthma; and, as antiscorbutics, their efficacy is generally acknowledged.

Raphanus sylvestris. See *Lepidium sativum.*

RA'PHE. (*e, es.* f. Ῥαφη, a suture.) A suture. Applied to parts which appear as if they were sewed together.

RAPHE CEREBRI. The longitudinal eminence of the corpus collosum of the brain is so called, because it appears somewhat like a suture.

RAPHE SCROTI. The rough eminence which divides the scrotum, as it were, in two. It proceeds from the root of the penis inferiorly towards the perinæum.

RAPHIDA. (From ῥαφη, a suture.) The name given by Necker to the bivalve pericarp of the genera *Anthoceros* and *Targionia.*

RAPHIDES. (Ῥαφιδες, needles.) The name given by De Candolle to the small acicular bodies found in the texture of some plants. M. Raspail has found that they are acicular crystals of phosphate of lime.

RAPI'STRUM. (*um, i.* n.; from *rapa,* the turnip: because its leaves resemble those of the turnip.) 1. The name of a genus of plants. Class, *Tetradynamia;* Order, *Siliculosa.*

2. The name of two species of *Crambe,* the *orientalis* and *hispanica.*

RA'PTUS. (*us, us.* m.; from *rapio,* to seize violently.) A sudden or violent seizure.

RAPTUS HÆMORRHAGICUS. The outbreaking of a hæmorrhage.

RAPTUS NERVORUM. The cramp.

RAPTUS SUPINUS. Opisthotonos.

RA'PUM. (*um, i.* n.; derivation uncertain.) 1. The turnip. See *Brassica rapa.*

2. The *Campanula rapunculus.*

RAPU'NCULUS. (*us, i.* m.; diminutive of *rapa,* the turnip.) The trivial name of a species of *Campanula.*

Rapunculus corniculatus. See *Phyteuma orbiculare.*

Rapunculus virginianus. The blue cardinal flower. See *Lobelia.*

Rapus. See *Brassica rapa.*

RAREFA'CTION. (From *rarefacio,* to make thin.) The diminution of the density of a body, as of a gas, by the agency of caloric.

Rash. See *Exanthema.*

RASPATO'RIUM. (From *rado,* to scrape. *Rasorium. Scalprum.* A raspatory. An instrument for rasping bones.

Raspberry. See *Rubus idæus.*

RASU'RA. (*a, æ.* f.; from *rado,* to scrape. 1. A rasure or scratch.

2. The raspings or shavings of any substance.

RATIFI'A. A liquor prepared by imparting to ardent spirits the flavour of various kinds of fruits.

Rattle. See *Rhonchus.*

RATTLES. A term very generally applied by nurses to the rattle-like, noisy breathing often heard in persons who are *in articulo mortis,* and which arises from an accumulation of mucus in the air-passages.

Rattlesnake. See *Crotalus horridus.*

Rattlesnake-root. See *Polygala.*

RAUCE'DO. (*o, inis.* f.; from *raucus,* hoarse.) *Raucitas.* Hoarseness. A roughness of the voice, arising from some disease of the larynx or trachea, as catarrh, &c.

Ray of a flower. See *Radius.*

REA'GENT. Test. A substance used in chemistry to detect the presence of other bodies.

REA'LGAR. *Arlada. Arladar. Auripigmentum rubrum. Arsenicum rubrum factitium. Abessi.* The protosulphuret of arsenic. See *Arsenic.*

RECEIVER. A chemical vessel adapted to the neck or beak of a retort, alembic, or other distillatory vessel, to receive and contain the product of distillation.

RECEPTA'CULUM. (*um, i.* n.; from *recipio*, to receive.) I. In *Anatomy*, a name given by anatomists to a part of the thoracic duct. See *Receptaculum chyli.*

II. In *Botany*, the common basis or point of connexion of the other parts of the fructification of plants; by some called the *Thalamus* and the *Placenta.*

It is distinguished by botanists into *proper* and *common:* one flower only belongs to the *former*, and it is formed mostly from the apex of the peduncle or scape; as in *Tulipa gesneriana*, and *Lilium candidum.* The *latter* has many flowers; as in *Helianthus annuus.*

The proper receptacle or apex of the peduncle swells in some flowers, and becomes the fruit: thus the *Fragaria vesca* is not a berry, but a *fleshy receptacle*, with its naked seeds nestling on its surface; so, in the *Hovenia dulcis*, the peduncles swell into a thick *fleshy receptacle*, on which there are small capsules; and, in the *Anacardium occidentale*, the peduncle swells into a receptacle, on which the nut rests.

The varieties of the common receptacle are,—

1. *Flat;* as in *Helianthus annuus.*
2. *Convex;* as in *Leontodon taraxacum.*
3. *Conic;* as in *Bellis perennis.*
4. *Punctate;* as in *Leontodon taraxacum.*
5. *Globose;* as in *Cephalanthus.*
6. *Oval;* as in *Dorstenia drakenia.*
7. *Ovate;* as in *Omphalea.*
8. *Favose*, cellular on the surface, honeycomb-like; as in *Onopordium.*
9. *Scrobiculate*, having round and deep holes; as in *Helianthus annuus.*
10. *Subulate;* as in *Scabiosa atropurpurea.*
11. *Quadrangular;* as in *Dorstenia houstoni*, and *Contrayerva.*
12. *Turbinate;* as in *Ficus carica.*
13. *Digitiform;* as in *Arum maculatum*, and *Calla æthiopica.*
14. *Filiform*, thread-like; as in the catkins and *Corylus.*
15. *Occluse*, or shut. The *Ficus carica* is a connivent fleshy receptacle enclosing the florets.
16. *Nude*, naked, without any vesture; as in *Lactuca* and *Leontodon taraxacum.*
17. *Pilose;* as in *Carthamus tinctorius.*
18. *Villose;* as in *Artemisia absynthium.*
19. *Setose;* as in *Echinops sphærocephalus*, and *Centaurea.*
20. *Paleaceous*, covered with chaffy scales; as in *Xeranthemum dipsacus*, &c.

On the receptacle and seed down are founded the most solid generic characters of syngenesious plants, admirably illustrated by the inimitable Gærtner.

The term receptacle sometimes extended by Linnæus to express the base of a flower, or even its internal part between the stamens and pistils, provided there be any thing remarkable in such parts, without reference to the foundation of the whole fructification. It also expresses the part to which the seeds are attached in a seed vessel, and the common stalk of a spike or spikelet, in grasses.

RECEPTACULUM CHYLI. *Receptaculum Pecqueti*, because Pecquet was the first to describe it. *Diversorium. Sacculus chyliferus.* A dilatation at the commencement of the thoracic duct, generally opposite the third lumbar vertebra. This dilatation varies in size in different subjects, and in some there is none at all. See *Absorbents.*

RECLINA'TION. One of the operations used for the cure of cataract. See *Cataract.*

Reciprocal affinity. See *Affinity.*

RECLINA'TUS. Reclining: applied to stems, leaves, &c. which are curved towards the ground, so that the extremity is lower than the base; as the stem of the bramble, and leaves of the *Leonurus cardiaca.*

RECTIFICA'TION. (*Rectificatio, onis.* f.; from *rectus*, right, and *fio*, to be made.) A second distillation, in which substances are purified by their more volatile parts being raised by heat, carefully managed: thus, spirit of wine, ether, &c. are rectified by their separation from the less volatile and foreign matter which altered or debased their properties.

RE'CTUM. (*um, i.* n.: so named from an erroneous opinion that it was straight.) *Apeuthysmenos. Longanon. Longaon. Archos. Cyssaros.* The last portion of the large intestines, terminating in the anus. See *Intestine.*

RE'CTUS. Straight. Several parts of the body, particularly muscles, are so called from their direction. Parts of plants also have this term; as *caulis rectus*, the straight stem of the garden-lily, &c.

RECTUS ABDOMINIS. A long and straight muscle situated near its fellow, at the middle and fore-part of the abdomen, parallel to the linea alba, and between the aponeurosis of the other abdominal muscles. It arises sometimes by a single broad tendon from the upper and inner part of the os pubis, but more commonly by two heads, one of which is fleshy, and originates from the upper edge of the pubis, and the other tendinous, from the inside of the symphisis pubis, behind the pyramidalis muscle. From these beginnings, the muscle runs upwards the whole length of the linea alba, and becoming broader and thinner as it ascends, is inserted by a thin aponeurosis into the edge of the cartilago ensiformis, and into the cartilages of the fifth, sixth, and seventh ribs. This aponeurosis is placed under the pectoral muscle, and sometimes adheres to the fourth rib. The fibres of this muscle are commonly divided by three tendinous intersections, which were first noticed by Berenger, or, as he is commonly called, Carpi, an Italian anatomist, who flourished in the sixteenth century. One of these intersections is usually where the muscle runs over the cartilage of the seventh rib; another is at the umbilicus; and the third is between these two. Sometimes there is one,

and even two, between the umbilicus and the pubes. When one or both of these occur, however, they seldom extend more than halfway across the muscle. As these intersections seldom penetrate through the whole substance of the muscle, they are all of them most apparent on its anterior surface, where they firmly adhere to the sheath: the adhesions of the rectus to the posterior layer of the internal oblique are only by means of cellular membrane, and of a few vessels which pass from one to another.

Albinus and some others have seen this muscle extending as far as the upper part of the sternum.

The use of the rectus is to compress the fore-part of the abdomen, but more particularly the lower part: and, according to the different positions of the body, it may likewise serve to bind the trunk forwards, or to raise the pelvis. Its situation between the two layers of the internal oblique, and its adhesions to this sheath, secure it in its place, and prevent it from rising into a prominent form when in action; and, lastly, its tendinous intersections enable it to contract at any of the intermediate spaces.

Rectus abducens oculi. See *Rectus externus oculi.*

Rectus abducens oculi. See *Rectus internus oculi.*

Rectus anterior brevis. See *Rectus capitis internus minor.*

Rectus anterior longus. See *Rectus capitis internus major.*

Rectus attollens oculi. See *Rectus superior oculi.*

Rectus capitis anticus longus. See *Rectus capitis internus major.*

Rectus capitis internus major. A muscle situated on the anterior part of the neck, close to the vertebræ. *Rectus internus major*, of Albinus, Douglas, and Cowper. *Rectus anterior longus*, of Winslow. It was known to most of the ancient anatomists, but was not distinguished by any particular name until Cowper gave it the present appellation, and which has been adopted by most writers except Winslow. It is a long muscle, thicker and broader above than below, where it is thin, and terminates in a point. It arises, by distinct and flat tendons, from the anterior points of the transverse processes of the five inferior vertebræ of the neck, and, ascending obliquely upwards, is inserted into the anterior part of the cuneiform process of the occipital bone. The use of this muscle is to bend the head forwards.

Rectus capitis internus minor. Cowper, who was the first accurate describer of this little muscle, gave it the name of *rectus internus minor*, which has been adopted by Douglas and Albinus. Winslow calls it *rectus anterior brevis.* It is in part covered by the rectus major. It arises, fleshy, from the upper and fore-part of the body of the first vertebra of the neck, near the origin of its transverse process, and, ascending obliquely inwards, is inserted near the root of the condyloid process of the occipital bone, under the last described muscle. It assists in bending the head forwards.

Rectus capitis lateralis. *Rectus lateralis Fallopii*, of Douglas. *Transversalis anticus primus*, of Winslow. *Rectus lateralis*, of Cowper. This muscle seems to have been first described by Fallopius. Winslow calls it *transversalis anticus primus.* It is somewhat larger than the rectus minor, but resembles it in shape, and is situated immediately behind the internal jugular vein, at its coming out of the cranium. It arises fleshy from the upper and fore-part of the transverse process of the first vertebra of the neck, and, ascending a little obliquely upwards and outwards, is inserted into the occipital bone, opposite to the stylo-mastoid hole of the os temporis. This muscle serves to pull the head to one side.

Rectus capitis posticus major. This muscle, which is the *rectus major* of Douglas and Winslow, and the *rectus capitis posticus minor* of Albinus, is small, short, and flat, broader above than below, and is situated, not in a straight direction, as its name would insinuate, but obliquely, between the occiput and the second vertebra of the neck, immediately under the complexus. It arises, by a short thick tendon, from the upper and posterior part of the spinous process of the second vertebra of the neck; it soon becomes broader, and ascending obliquely outwards, is inserted, by a flat tendon, into the external lateral part of the lower semicircular ridge of the os occipitis. The use of this is to extend the head, and pull it backwards.

Rectus capitis posticus minor. This is the *rectus minor* of Douglas and Winslow. It is smaller than the last described muscle, but resembles it in shape, and is placed close by its fellow, in the space between the recti majores. It arises, by a short thick tendon, from the upper and lateral part of a little protuberance in the middle of the back part of the first vertebra of the neck, and, becoming broader and thinner as it ascends, is inserted, by a broad flat tendon, into the occipital bone, immediately under the insertion of the last described muscle. The use of it is to assist the rectus major in drawing the head backwards.

Rectus cruris. See *Rectus femoris.*

Rectus deprimens oculi. See *Rectus inferior oculi.*

Rectus externus oculi. The outer straight muscle of the eye: called also, *Abductor oculi*, *Iracundus*, and *Indignabundus.* It arises from the bony partition between the foramen opticum and lacerum, being the longest of the straight muscles of the eye, and is inserted into the sclerotic membrane, opposite to the outer canthus of the eye. Its use is to move the eye outwards.

Rectus femoris. A straight muscle of the thigh, situated immediately at the fore part. *Rectus sive Gracilis anterior*, of Winslow. *Rectus cruris*, of Albinus. It arises from the os ilium by two tendons. The foremost and shortest of these springs from the outer surface of the inferior and anterior spinous process of the ilium; the posterior tendon, which is thicker and longer than the other, arises from the posterior and outer part of the edge of the cotyloid cavity and from the adjacent capsular ligament. The

two tendons soon unite, and form an aponeurosis, which spreads over the anterior surface of the upper part of the muscle; and through its whole length we observe a middle tendon, towards which its fleshy fibres run on each side in an oblique direction, so that it may be styled a penniform muscle. It is inserted tendinous into the upper edge and anterior surface of the patella, and from thence sends off a thin aponeurosis, which adheres to the superior and lateral part of the tibia. Its use is to extend the leg.

RECTUS INFERIOR OCULI. The inferior of the straight muscles of the eye. *Depressor oculi. Deprimens. Humilis. Amatorius.* It arises within the socket, from below the optic foramen, and passes forwards to be inserted into the sclerotic membrane of the bulb on the under part. It pulls the eye downwards.

Rectus internus femoris. See *Gracilis.*

RECTUS INTERNUS OCULI. The internal straight muscle of the eye. *Adducens oculi. Adductor oculi. Bibitorius.* It arises from the inferior part of the foramen opticum, between the obliquus superior and the rectus inferior, being, from its situation, the shortest muscle of the eye, and is inserted into the sclerotic membrane opposite to the inner angle. Its use is to turn the eye towards the nose.

Rectus lateralis Fallopii. See *Rectus capitis lateralis.*

Rectus major capitis. See *Rectus capitis posticus major.*

RECTUS SUPERIOR OCULI. The uppermost straight muscle of the eye. *Attollens oculi. Levator oculi. Superbus.* It arises from the upper part of the foramen opticum of the sphenoid bone, below the levator palpebræ superioris, and runs forward to be inserted into the superior and fore part of the sclerotic membrane by a broad and thin tendon.

RECURRENT NERVE. *Nervus recurrens.* A branch given off from the par vagum, on each side, in the cavity of the thorax, is so called. The right is given off near the subclavian artery, which it surrounds, and is reflected upwards to the thyroid gland; the left a little lower, and reflected around the aorta to the œsophagus, as far as the larynx. They are both distributed to the muscles of the larynx and pharynx.

Recurvatus. See *Recurvus.*

RECU'RVUS. Recurved: bowed or turned backward. Applied to leaves, &c. See *Reflexus.*

Red saunders. See *Pterocarpus santalinus.*

RE'DDLE. A species of ochre or argillaceous earth, of a dark red colour, which has been used medicinally as a tonic and antacid.

REDU'CTION. 1. In *Surgery*, the returning of a dislocated bone into its proper place.

2. In *Chemistry*, revivification: applicable to all operations by which any substance is restored to its natural state, or which is considered as such; but custom confines it to operations by which metals are restored to their metallic state, after they have been deprived of this, either by combustion, as the metallic oxides, or by the union of some heterogeneous matters which disguise them, as fulminating gold, luna cornea, cinnabar, and other compounds of the like kind. These reductions are also called revivifications.

REFLEX. This name has been given to those instances of nervous action in which an impression made on the extremity of one nerve is propagated to the extremity of another, through the intervention of the nervous centres.

REFLE'XUS. Reflected; bent backward: applied in botany to leaves, as those of the *Erica retorta;* and to the border of the flower-cup of the *Œnothera biennis,* and the petals of the *Pancratium zeylanicum.*

REFRA'CTUS. Bent back, as if broken.

REFRI'GERANT. (*Refrigerans;* from *refrigero,* to cool.) Possessed of the property of allaying the heat of the body or of the blood.

REFRIGERATO'RIUM. (From *refrigero,* to cool.) A vessel filled with water to condense vapours, or to make cool any substance which passes through it.

RE'GIMEN. (*en, inis.* f.; from *rego,* to govern.) A term employed in medicine to express the regulation of the diet and habits of an individual, with a view to the preservation of health or the cure of disease.

REGINA PRATI. Queen of the meadow. See *Spiræa ulmaria.*

Regions of the body. See *Body.*

RE'GIUS. (From *rex,* a king.) Royal: applied, 1. in *Pathology,* to the jaundice: why so called it is not easy to understand, unless it be because the colour of the skin is like gold, which is a royal metal.

2. In *Chemistry,* to the noble metals, especially gold, and to a preparation, the *aqua regia,* which has the power of dissolving gold.

REGULAR. *Regularis.* 1. In *Pathology,* applied to diseases which observe their usual course, in opposition to irregular, in which the course of symptoms deviate from what is usual; as regular gout, regular small-pox, &c.

2. In *Botany,* applied to parts of plants; as blossoms, &c. when regular in their figure and size, and proportion of their parts; as the flowers of the *Lilium* and *Hyacinthus.*

Regular gout. See *Gout.*

Regular small-pox. See *Variola.*

RE'GULUS. (Diminutive of *rex,* a king: so called because the alchemists expected to find gold, the king of metals, collected at the bottom of the crucible after fusion.) The name regulus was given by chemists to metallic matters when separated from other substances by fusion. This name was introduced by the alchemists, who, expecting always to find gold in the metal collected at the bottom of their crucibles after fusion, called this metal, thus collected, regulus, as containing gold, the king of metals. It was afterwards applied to the metal extracted from the ores of the semi-metals, which formerly bore the name that is now given to the semi-metals themselves. Thus we had regulus of antimony, regulus of arsenic, and regulus of cobalt.

Regulus of antimony. See *Antimony.*

REGULUS ANTIMONII MARTIALIS. Martial regulus of antimony. An old preparation, made by heating purified iron filings in a crucible, adding sulphuret of antimony, fusing

them, then adding nitre, fusing the whole together, cooling, and separating the regulus from the scoriæ, then fusing a second and third time, with the addition of some more nitre each time.

Regulus of arsenic. See *Arsenic.*

Regulus jovialis. An alloy made by fusing antimony and tin.

Regulus veneris. An alloy of antimony and copper.

RELAXATION. In *Pathology*, diminution of the natural and healthy tone of parts.

REME'DIUM. (*um*, *ii*. n.; *à re*, and *medeor*, to cure.) A remedy, or that which is employed with a view to prevent, palliate, or remove a disease.

Remedium divinum. See *Imperatoria.*

REMITTENT. (*Remittens;* from *remitto*, to assuage or lessen.) Applied to diseases the symptoms of which diminish very considerably, but return again so as not to leave the person free from the disease until it changes its character or vanishes.

Remittent fever. A remittent fever is characterised by the usual symptoms of febrile action, which become much more intense once or oftener every four and twenty hours, and then remit. This *exacerbation*, as it is called, is widely different from the paroxysm of an intermittent, and the remission differs also very much from that subsidence of the febrile symptoms of an intermittent which constitutes the intermission. In a remittent, however marked the diminution of the fever, there is still a considerable degree of it, and nothing like an apyrexial state; and although, in many cases, the symptoms of the fever may approach somewhat in character those of the paroxysms of an intermittent, yet they are very different, and evidently consist merely of an increased violence of those which were severest during the remission. This genus of fever sometimes exists in a mild form, sometimes in the most malignant. It is a common disease with infants, and it may be observed that the febrile affections of children have almost always more or less tendency to the remittent type. The infantile remittent is generally produced by intestinal irritation; but remittent fevers in general are caused by marsh miasmata, and by peculiar poisons of vegetable and animal origin. Remittent fevers are distinguished into *mild* and *malignant*. Malignant remittent fever has been named according to the places where it has prevailed, the *Bulam*, *Philadelphian*, *Demerara*, *St. Domingo*, *Barbadoes*, *Jamaica*, *American*, *Hungarian*, *African*, *Gibraltar* fever. The malignant remittent of warm climates is called *bilious remittent*, from the great disorder of the hepatic system; *yellow fever* from the yellow tinge which it communicates to the skin; and *jungle fever*, from the origin of the poison which produces it in swamps and jungles.

The following are the principal species of remittents: —

1. The mild form. In this remittent the pulse is very frequent, but regular throughout, the debility is not considerable, and the skin soon becomes relaxed, and perspires freely. It attacks young persons of relaxed habits, who are weakly, and commences mostly with some disturbance of the bowels. It occurs at all seasons of the year, but more frequently in the autumn. Fatigue, cold, or long exposure to the sun's heat, often bring it in into action. The patient complains of drowsiness, and is very languid; is occasionally chilly, and afterwards flushed, but without perspiration; for the skin is hot and dry, and the thirst considerable, attended by nausea and total loss of appetite. In the course of the day, but usually towards evening, the pulse quickens, the heat increases, and at length terminates in a sweat, which after a time goes off, leaving the skin hot and dry, and the pulse still very quick. This exacerbation sometimes occurs at noon, and sometimes also in the night. If the disease be left to itself, the symptoms augment in severity daily; the head occasionally, but more frequently the liver, or some other abdominal viscus, gives proof of being loaded and oppressed, and the restlessness is intolerable: or a sudden bilious purging or vomiting supervenes, and carries off the complaint by a salutary crisis. Mild remittents seem to be occasionally produced by disordered states of the chylopoietic viscera, independently of marsh poison; but like the more formidable fevers of this type, they are most frequent in marshy localities. They generally give way to purgatives, especially mercurial ones. The submuriate of mercury should be given in doses of two or four grains to adults every second day, and followed by saline purgatives with senna, and the febrile symptoms mitigated in the intervals by saline sudorifics; and the diet should consist of very little more than farinaceous drinks, sago, arrow-root, or the like. The pulse will generally be found from ninety to a hundred strokes in a minute; but as soon as it sinks below this, or the sweat is considerable, or, without this, the skin is moist and not so much heated, mild tonics, especially the mineral acids with light infusion of colomba, gentian, quassia, chamomile, cascarilla, or cinchona, will complete the cure, though the disease usually runs on for ten days or a fortnight.

2. The infantile remittent does not essentially differ from the description just given. It is usually ascribed to worms, which are occasionally its cause; but the most common by far is crude accumulations in the bowels, from which the digestion proceeds imperfectly, producing great general irritation, and considerable languor. The belly becomes tumid and painful, and the food is nauseated. The head becomes hot, heavy, and often comatose, the disease similating in this stage the commencement of hydrocephalus, with which it is very frequently confounded. See *Hydrocephalus.* The skin is pale or livid, with occasional flushes in the cheeks. It is a singular fact, that, if the exacerbation or increase of fever take place in the night, there is watchfulness and perpetual jactitation; if in the day-time, drowsiness and stupor. Remittents in the infantile and juvenile periods of life are almost always accompanied by a sluggish state of the bowels, and require the exhibition of calomel, with jalap and scammony: the *pulvis scammonii cum calomelane* is an excellent form for children; and if this do not act, its operation

must be assisted by the infusion of senna, with sulphate of magnesia or potash. Until the bowels are well cleared, the fever goes on increasing; but under a course of brisk cathartics, in conjunction with perfect quiet, good ventilation, and light farinaceous drinks and diet, it will usually give way, in a week or a fortnight. Particular symptoms are to be opposed by their appropriate remedies: thus, if there be much coma, the head should be bathed with a cold or evaporating lotion of dilute acetic acid or spirit, or the feet fomented; if there be bilious diarrhœa, the purgative plan is to be abandoned, and the pains of the bowels allayed by absorbents, demulcents, and mild anodynes: if there be bilious or other vomitings, carbonic acid, with very mild aperients, until the irritability of the stomach is allayed.

3. Besides the infantile fever and mild form of this genus, there are others which are usually of a more malignant nature, and which, occurring towards the decline of summer, are called autumnal remittents: these we shall now describe. They are usually ushered in with extreme weakness, and irregularity of the voluntary motions; the muscular strength gradually goes, and the mind soon wanders: there is coldness and shrinking of the extremities, and a tendency to faint in the erect posture; nausea, vomiting, and a total disinclination for nourishment; and sooner or later, a putrid tendency of the fluids becomes apparent, by the skin being covered with fetid sweat; the breath being offensive, the tongue clammy, fetid, livid, or greenish black; the lips swelled, and purplish; the urine brown or blackish and offensive; a black discharge, often in great quantity, from the stomach; the stools blackish, colliquative, and very offensive, and parted with insensibly; the mind wandering; with twitching of the tendons, petechial spots, and purpura of large size, and hæmorrhages.

In this country such remittents have a strong tendency to assume the tertian or double tertian type; or, in other words, they have striking exacerbations every other day. Autumnal remittents commence with lassitude, a general soreness over the body, yawning, inquietude, and most of the other concomitants of febrile action. As some of the larger organs have been more affected by the influence of the season than the rest, we find them giving way in proportion: hence the head is sometimes severely affected with pain or heaviness; the bowels are overloaded with bile; or the stomach is exquisitely irritable, and rejects whatever is introduced into it. Generally, the stomach suffers more disturbance than any other organ; and, along with the sickness, there is in many cases a troublesome looseness. Sometimes, however, the bowels are costive, and the stomach but little affected. The violence of the symptoms is commonly in proportion to the violence of the incursion. The exacerbation ordinarily takes place at noon, or early in the afternoon, and consists in an increase of heat and of the pulse; for there is rarely any preceding chill, and as rarely any salutary moisture when the heat diminishes. The night is passed under extreme restlessness, vomiting, and mild delirium; and thus the fever continues, with strong exacerbations about noon or night, and obvious remissions.

At the very commencement of this fever, an emetic is generally found serviceable, as it not only clears the stomach of vitiated secretions, but is one of the best means of determining to the skin. The use of the lancet must depend on the circumstances of the particular case. Where the onset is violent, and particularly where the parient is plethoric, or of a vigorous habit, it may be employed with advantage instantly and freely; for without it, from the urgency of the symptoms, there can be little doubt that some large organ or other will soon become locally affected with congestion or effusion, which is always to be avoided as one of the worst symptoms that can occur: and if there be reason to suspect that such local affection exist at the time of the attack, and more especially that it be the cause of it, copious depletion will be still more necessary; for in this case, not only is the fever to be contended with, but an inflammation of the affected organ to be guarded against. Except in these cases there is no call for the lancet, but, on the contrary, the loss of blood is injurious.

The common saline diaphoretics, either effervescing or not, will commonly take off the burning heat of the skin; or, where the stomach is not in an irritable state, the antimonial powder, or small doses of the tartarised antimony, may be given: and with such remedies, and pediluvia or fomentation to the feet at night, the fever will mostly be diminished. Dilute acids are highly useful in form of drinks, as imperial, lemonade, orangeade, the subacid fruits, and infusions of mint, balm, &c., where the bowels are not irritable. Mild aperients of rhubarb, sulphate of potash, infusion of senna, or cassia electuary, are the best aperients from time to time, unless the bilious or constipated condition of the bowels demand the submuriate of mercury, or the more active purgatives.

4. The *yellow* and *jungle* fevers owe their production unquestionably to marsh miasm; and hence they are so common in the swampy soils and morasses of the intertropical regions, exposed to a high solar heat, and perpetually exhaling a decomposition of animal and vegetable materials. It has been matter of keen dispute whether yellow fever is contagious? The result of impartial inquiry appears to be, that it is not generally so; at the same time it would be rash to deny that it may possibly become so under particular circumstances. Dr. Mosely gives an excellent account of these malignant remittents: — "When a new comer," says he, "is seized with a sudden loss of strength, and a desire of changing for rest into every position, without finding it in any, those symptoms which constitute the endemial fever may be expected. The following day, but sometimes within twelve hours from the first indisposition, the violence of the disease will commence thus: — There will be a faintness, and generally a giddiness of the head, with a small degree of chilliness and horror, but never a rigor. Then immediately will succeed a high degree of fever with great heat, and strong beating in all the

arteries of the body, particularly observable in the carotid and temporal arteries; flushings in the face, gaspings for cool air, white tongue, but tinged with yellow, after the retchings have commenced; excessive thirst, redness, heaviness, and burning in the eyes; heaviness and darting pains in the head and small of the back, and often down the thighs; pulse quick, generally full and strong, in some cases quick, low, and vacillating; skin hot and dry, sometimes with a partial and momentary moisture; sickness of stomach from the first, which increases with the disease; and, immediately after any thing is taken to quench the thirst, retchings succeed, in which bilious matter is brought up; anxiety and stricture, soreness, and intense heat about the præcordia; great restlessness, heavy respiration, sighing, urine deep-coloured, and but little in quantity. This is the first stage of the fever, and may continue twenty-four, thirty-six, forty-eight, or sixty hours; and this constitutes its inflammatory period.

The second stage begins with the abatement of many of the preceding symptoms, and the rise of others: sometimes with a deceiving tranquillity, but with perturbation if the patient should fall into a sleep; then a yellow tinge is observed in the eyes, neck, and breast: the heat subsides, and sometimes with a chilliness; but not with that sort of strong rigor which, when it happens, terminates the disease by sweat, or by copious bilious evacuations upwards and downwards. The retchings are violent, and turn porraceous; the pulse flags, but is sometimes high and sometimes soft; the skin soft and clammy; the urine in small quantity, and of a dark croceous colour: the tongue, in some cases, is dry, harsh, and discoloured; in others, furred and moist: there is confusion in the head, and sometimes delirium, with the eyes glassy. This stage of the disease sometimes continues only for a few hours; sometimes for twelve, twenty-four, thirty-six, or forty-eight hours, but never longer.

In the third and last stage of the fever, the pulse sinks and becomes unequal and intermittent, sometimes very quick; frequent vomiting, with great straining and noise in vomiting, and what is brought up now is more in quantity, and has the appearance of the grounds of coffee, or is of a slate colour. Nothing can be retained in the stomach; difficult breathing, black tongue, cold clammy sweats, eyes hollow and sunk, yellowness round the mouth and temples, and soon after over the whole body.

The symptoms become gradually more aggravated, accompanied with subsultus tendinum, black urine, deadly coldness of the limbs, delirium, faltering speech, hæmorrhage, or oozing of blood from the mouth and nostrils, corners of the eyes and ears, black bloody vomiting and stools, vibices, hiccough, muttering, coma, death."

After the first prostration of strength, the disease runs on violently till the sensorial power is exhausted. Through its entire course, till the patient is sinking, the intellect is not particularly disturbed, and the organs principally affected are the abdominal: hence the intense heat and anxiety about the præcordia, the saffron dye of the urine, the yellow tint of the skin, and the vomitings, first of a bilious and afterwards of a chocolate or sanguineous colluvies. In some cases the disease opens with great violence, and rushes forward at once to its acme, and the patient is cut off in four and twenty hours. Though the remittents, in hot climates, generally pursue the course of febrile action that has been described, it is sometimes otherwise, and even in milder climatees; for it sometimes commences more like to an intermittent, and sometimes it more resembles a continued fever, as which it has terminated, and occasionally as an intermittent.

Every endemic marsh fever has its peculiarities. The bilious remittent of the West Indies differs from that of the East, and the fevers of Sierra Leone and the Campagna di Roma differ from both, and from each other.

With respect to the treatment of this fever, unfortunately the practitioners in warm climates have differed very much; some, alarmed at the debility which the system has to encounter in the second stage of the disease, or as soon as it has run through its inflammatory career, shuddered at the thought of the lancet, and commenced with mild saline purgatives, and immediately afterwards had recourse to the Peruvian bark. Others, somewhat less timid, have allowed the abstraction of blood to the extent of ten or twenty ounces at the very beginning; while others, again, regarding the inflammatory impetus as the sole cause of danger, resorted boldly to the lancet, and followed up the abstraction of blood as long as a single germ of an inflammatory diathesis was manifest, paying no regard to the appearance of the blood. This sanguineous depletion was accompanied by the free exhibition of purgatives. Another plan consisted in giving purgatives, especially the submuriate of mercury, in large doses. Ten grains of calomel, and as much of jalap, are often exhibited every six hours until the alvine canal is effectually evacuated. The sulphates of magnesia and soda, with infusion of senna, are also esteemed by some; and this milder practice should generally be preferred to repeated venesection, where there is not much impetuosity in the onset, no great derangement or prognostic of inflammatory congestion in the larger viscera, where the remissions are regular and the epidemic pretty uniform in its character. Under such circumstances, the loss of a large quantity of blood will not shorten the career of the disease, but will most probably convert the remittent into a continued fever, in the latter stage of which that strength will be wanted which might have been retained, but for the profuse and injudicious bleedings.

The common nervine and saline diaphoretics are useful to oppose the febrile action: acetate of ammonia, the citrate also, with sulphuric ether diluted with camphire mixture. Acids are continually called for as common drinks; and the dilute chlorine or oxygenated muriatic acid, in large doses, promises to be a good medicine.

In all cases where the remission is without any inflammatory condition,—in all cases where there is a flabby state of the fibre, and mo

especially where a septic diathesis, or putrid-tending state is apparent, bitters, such as calomba, serpentaria, Virginiana, and quassia, with mineral acids, will be required; and, in a more decided malignant state, cascarilla, cinchona, and the like, as directed against typhus, should be administered, with brandy and cordials *ad libitum*.

Particular symptoms call for particular remedies.

a. Where there is congestion in the vascular system of an organ, topical bleedings are necessary in addition to general blood-letting; and cold applications also, especially cold sea-water, iced water, diluted spirit, and evaporating lotions to the shaved head, the epigastric region, or wherever the congestion may be.

b. Nausea and vomiting will be best opposed by mild aperients in the effervescing state; by carbonic acid from yeast, beer, or soda-water: but the best remedy against continued vomiting of porraceous, chocolate-ground-like, or slate-coloured fluids from the stomach, is a punch made with brandy, lemon-juice, and cayenne pepper, from the last of which the benefit is said to result.

c. Comatose states call for stimulating cataplasms and fomentations, and cold evaporating lotions to the head. Blisters have very seldom been useful.

5. There is another form of malignant remittent, which is called *ardent remittent*, and which appears to be the same disease with the *causus* of the ancients. See *Causus*. It is characterised by extreme heat, violent thirst, a rough and black tongue, the complexion inclined to yellowness, and the saliva bilious. There is commonly an acute aching in the head, nausea, great anxiety of the præcordia, with frequently a gnawing pain at the stomach. The bowels are unusually costive, particularly at the commencement of the disease. The tongue, mouth, nostrils, and, indeed, the whole surface of the body, is parched and fiery hot; the pulse is full and strong; the voice hoarse; the breath short and quick; occasionally delirium. It chiefly attacks the young and vigorous, who bear it better than old persons. The treatment of this fever is precisely that of a synocha.

6. The several forms of remittent fevers which have been described, have shown a tendency to an inflammatory or a synochous, that is, a mixed type. There is, however, another which clearly evinces a typhoid tendency from the very commencement; for it is ushered in by extreme debility, both of the action of the heart, of the mental faculties and moving powers, and the common symptoms of typhus in the most aggravated form. It occurs in localities, where the marsh miasm is more than usually malignant and concentrated, or where its effects on the system are favoured by other depressing influences, as in the case of dispirited and ill-provided armies in unhealthy localities, or of a crowded, squalid, and ill-fed population. The disease then assumes the appearance of a highly congestive typhus, and the remedies which are applicable in the one, are equally so in the other.

RE'MORA. (*a*, *æ*. f.; from *remoror*, to hinder.) See *Ononis spinosa*.

REMOTE. 1. In *Pathology*, applied to the causes of diseases. See *Ætiology*.

2. In *Botany*, applied to flowers of verticillated plants when there is a considerable length of stem between each whorl.

REN. (*en*, *enis*. m. *Ren*, απο του ῥειν: because through them the urine flows.) The kidney. See *Kidney*.

RE'NAL. (*Renalis*; from *ren*, the kidney.) Appertaining to the kidney.

Renal artery. See *Emulgent*.

RENAL GLAND. *Glandula renalis*. Renal capsule. Supra-renal gland. The supra-renal glands are two hollow bodies, like glands in fabric, and placed one on each side upon the kidney. They are covered by a double tunic, and their cavities are filled with a liquor of a brownish red colour. Their figure is triangular, and they are larger in the fœtus than the kidneys; but in adults they are less than the kidneys. The right is affixed to the liver, the left to the spleen and pancreas, and both to the diaphragm and kidneys. They have arteries, veins, lymphatics, and nerves: their arteries arise from the diaphragmatic, the aorta, and renal arteries. The vein of the right supra-renal gland empties itself into the vena cava; that of the left into the renal vein: their lymphatic vessels go directly to the thoracic duct: they have nerves common alike to these glands and the kidneys. They have no excretory duct, and their use is at present unknown. It is supposed they answer one use in the fœtus, and another in the adult; but what these uses are is uncertain. Boerhaave supposed their use to consist in furnishing lymph to dilute the blood returned after the secretion of the urine in the renal vein; but this is very improbable, since the vein of the right supra-renal gland goes to the vena cava, and the blood carried back by the renal vein wants no dilution. It has also been said, that these glands not only prepare lymph, by which the blood is fitted for the nutrition of the delicate fœtus; but that in adults they serve to restore to the blood of the vena cava the irritable parts which it loses by the secretion of bile and urine. Some, again, have considered them as diverticula in the fœtus, to divert the blood from the kidneys, and lessen the quantity of urine. The celebrated Morgagni believed their office to consist in conveying something to the thoracic duct. It is singular, that in children who are born without the cerebrum, these glands are extremely small, and sometimes wanting.

Renal vein. See *Emulgent*.

RE'NIFORM. *Reniformis*. Kidney-shaped. 1. In *Anatomy*, this term is applied to any deviations of parts, assuming a kidney-like form.

2. In *Botany*, leaves, seeds, &c., are so called from their shape: it is a short, broad, roundish leaf, the base of which is hollowed out; as that of the *Asarum europæum* and *Sibthorpia europæa*, and the seeds of *Beta* and *Phaseolus*.

RE'NNET. Runnet. The gastric juice and contents of the stomach of calves. It is much

employed in preparing cheese, and in pharmacy, for making whey. To about a pound of milk, in a silver or earthen basin placed on hot ashes, add three or four grains of rennet, diluted with a little water: as it becomes cold, the milk curdles, and the whey, or serous part, separates itself from the caseous part. When these parts appear perfectly distinct, pour the whole upon a strainer, through which the whey will pass, while the curds remain behind. This whey is always rendered somewhat whitish, by a very small and much divided portion of the caseous part; but it may be separated in such a manner that the whey will remain limpid and colourless, and this is what is called clarifying it. Put into a basin the white of an egg, a glass of the serum of milk, and a few grains of tartaric acid in powder: whip the mixture with an ozier twig, and, having added the remainder of the unclarified whey, place the mixture again over the fire until it begins to boil. The tartaric acid completes the coagulation of the white part of the milk which remains; the white of egg, as it becomes hot, coagulates and envelops the caseous part. When the whey is clear, filter it through paper: what passes will be perfectly limpid, and have a greenish colour. This is clarified whey.

RE/NUENS. (From *renuo*, to nod the head back, in sign of refusal: so called from its office of jerking back the head.) An old epithet of the rectus anticus capitis minor muscle.

REPA'NDUS. Repand: wavy; serpentine. A leaf is so called which is bordered with many acute angles, and small segments of circles alternately; as that of the *Menyanthes nymphæoides*.

REPE'LLENT. (*Repellens*; from *repello*, to drive back.) Applications are sometimes so named which make diseases recede, as it were, from the surface of the body.

RE'PENS. Creeping. Often used in *Botany*; *caulis repens*, one that creeps along the earth; as that of the *Ranunculus repens*. Applied to a root, it means running transversely, and here and there giving off new plants; as that of the *Glycyrrhiza glabra*, and *Sambucus ebulus*.

REPLICA'TUS. Replicate: folded; plaited so as to form a groove or channel; as in the legumen of the *Astragalus hypoglottis*.

REPTI'LIA. (From *repo*, to creep.) A class of vertebrated animals. See *Animal kingdom*.

REPULSION. (*Repulsio, onis.* f.; from *repello*, to repel.) All matter possesses a power which is in constant opposition to attraction. This agency, which is equally powerful and equally obvious, acts an important part in the phænomena of nature, and is called *the power of repulsion*.

That such a force exists, which opposes the approach of bodies towards each other, is evident from numberless facts.

Newton has shown that when a convex lens is put upon a flat glass, it remains at a distance of the one hundred and thirty-seventh part of an inch, and a very considerable pressure is required to diminish this distance; nor does any force which can be applied bring them into actual mathematical contact. A force may indeed be applied sufficient to break the glasses into pieces, but it may be demonstrated that it does not diminish their distance much beyond the one thousandth part of an inch. There is, therefore, a repulsive force which prevents the two glasses from touching each other.

Boscovich has shown that when an ivory billiard-ball sets another in motion by striking against it, an equal quantity of its own motion is lost, and the ball at rest begins to move while the other is still at a distance.

There exists, therefore, a repulsion between bodies: this repulsion takes place while they are yet at a distance from each other; and it opposes their approach towards each other.

The cause or the nature of this force is equally inscrutable with that of attraction, but its existence is undoubted; it increases, as far as has been ascertained, inversely as the square of the distance; consequently at the point of contact it is infinite.

The following experiments will serve to prove the energy of repulsion more fully: —

Experiment.— When a glass tube is immersed in water, the fluid is attracted by the glass, and drawn up into the tube; but, if we make use of mercury instead of water, we shall find a different effect. If a glass tube of any bore be immersed in this fluid, it does not rise, but the surface of the mercury is considerably below the level of that which surrounds it when the diameter of the tube is very small. In this case, a repulsion takes place between the glass and the mercury, which is even considerably greater than the attraction existing between the particles of the mercury; and hence the latter cannot rise in the tube, but is repelled, and becomes depressed.

Experiment. — When we present the north pole of a magnet A, to the same pole of another magnet B, suspended on a pivot, and at liberty to move, the magnet B will recede as the other approaches; and, by following it with A, at a proper distance, it may be made to turn round on its pivot with considerable velocity. In this case there is some agency which opposes the approach of the north poles of A and B, which acts as an antagonist, and causes the moveable magnet to retire before the other. There is, therefore, a *repulsion* between the two magnets, a repulsion which increases with the power of the magnets, which may be made so great that all the force of a strong man is insufficient to make the two north poles touch each other. The same repulsion is equally obvious in electrical bodies. For instance:

Experiment. — If two small cork balls be suspended from a body so as to touch one another, and if we charge the body in the usual manner with electricity, the two cork balls separate from each other, and stand at a distance proportional to the quantity of electricity with which the body is charged: the balls of course repel each other.

Experiment. — If we rub over the surface of a sheet of paper the fine dust of lycopodium or puffball, and then let water fall on it in small

quantities, the water will instantly be repelled, and form itself into distinct drops, which do not touch the lycopodium, but roll over it with uncommon rapidity. That the drops do not touch the lycopodium, but are actually kept at a distance above it, is obvious from the copious reflection of white light.

Experiment. — If the surface of water contained in a basin be covered over with lycopodium, a solid substance deposited at the bottom of the fluid may be taken out of it with the hand without wetting it. In this case the repulsion is so powerful as to defend the hand completely from the contact of the fluid.

Res naturales. The naturals. According to Boerhaave, these are life, the cause of life, and its effects. These, he says, remain in some degree, however disordered the system may be.

Res non-naturales. See *Non-naturals.*

RESE'DA. (*a, æ.* f.; from *resedo*, to appease: so called from its virtue of allaying inflammation.) The name of a genus of plants in the Linnæan system. Class, *Dodecandria*; Order, *Trigynia.*

2. The name, in some pharmacopœias, of the dyers' weed. See *Reseda luteola.*

Reseda luteola. The dyers' weed. Dioscorides mentions it as useful in jaundice.

RESIN. (*Resina, æ.* f.; from *ῥέω*, to flow: because it flows spontaneously from the tree.) The name *resin* is used to denote sold inflammable substances, of vegetable origin, soluble in alkohol, usually affording much soot by their combustion. They are likewise soluble in oils, but not at all in water: and are more or less acted upon by the alkalis.

All the resins appear to be nothing else but volatile oils, rendered concrete by their combination with oxygen. The exposure of these to the open air, and the decomposition of acids applied to them, evidently prove this conclusion.

There are some among the known resins which are very pure, and perfectly soluble in alkohol, such as the balsam of Mecca and of Capivi, turpentines, tacamahaca, elemi: others are less pure, and contain a small portion of extract, which renders them not totally soluble in alkohol; such are mastic, sandarach, guaiacum, labdanum, and dragon's blood.

The essential properties of resin are, being in the solid form, insoluble in water, perfectly soluble in alkohol, and in essential and expressed oils, and being incapable of being volatilised without decomposition.

Resins are obtained chiefly from the vegetable kingdom, either by spontaneous exudation, or from incisions made into vegetables affording juices which contain this principle. These juices contain a portion of essential oil, which, from exposure to the air, is either volatilised or converted into resinous matter, or sometimes the oil is abstracted by distillation. In some plants the resin is deposited, in a concrete state, in the interstices of the wood, or other parts of the plant.

Resins, when concrete, are brittle, and have generally a smooth and conchoidal fracture; their lustre is peculiar, they are more or less transparent, and of a colour which is usually some shade of yellow, or brown; they are of a greater specific gravity than water; they are often odorous and sapid, easily fusible, and, on cooling, become solid.

Resin, black. See *Resina nigra.*

Resin of copper. Boyle gives this name to the protochloride of copper on account of its resinous appearance.

Resin, elastic. See *Caoutchouc.*

Resin tree, elastic. See *Caoutchouc.*

Resin, white. See *Resina alba.*

Resin, yellow. See *Resina flava.*

Resina alba. The inspissated juice of the *Pinus sylvestris*, &c. The residuum of the distillation of oil of turpentine is also called, by some, white resin. See *Resina flava.*

Resina elastica. See *Caoutchouc.*

Resina flava. Yellow resin is that which remains in the still after distilling oil of turpentine, by adding water to the common turpentine. It is of very extensive use in surgery as an active detergent, and forms the base of the *ceratum resinæ.*

Resina nigra. *Colophonia.* What remains in the retort after distilling the oil of turpentine from the common turpentine.

Resolutio nervorum. Palsy. — *Celsus.*

Resina novi belgii. Botany Bay gum. See *Xanthorrhœa hastilis.*

Resinatum vinum. Wine impregnated with the resin of fir. Anciently used as a stomachic.

RESOLUTION. (*Resolutio*; from *resolvo*, to loosen.) 1. A termination of inflammation, in which the disease disappears without any abscess, mortification, &c. See *Inflammation.*

2. The dispersion of swellings, indurations, &c.

RESOLVENT. (*Resolvens*; from *resolvo*, to loosen.) This term is applied by surgeons to such substances as discuss inflammatory and other tumours.

RESPIRA'TION. (*Respiratio, onis*, f.; from *respiro*, to take breath.) To comprehend the important function of breathing or respiration, it is not only necessary to have a knowledge of the structure of the thoracic viscera, the form of the parietes, of the chest, and to comprehend the mechanism by which the air enters and passes out of it, but also to be well acquainted with the chemical and physical properties of the air, and the circulation of the blood.

The lungs are two spongy and vascular organs of a considerable size, situated in the lateral parts of the chest. Their parenchyma is divided and subdivided into lobes and lobules, the forms and dimensions of which it is difficult to determine.

We learn, by the careful examination of a pulmonary lobule, that it is formed of a spongy tissue, the *areolæ* of which are so small that a strong lens is necessary to observe them distinctly: these *areolæ* all communicate with each other, and they are surrounded by a thin layer of cellular tissue which separates them from the adjoining lobules.

Into each lobule enters one of the divisions of the bronchia, and one of the pulmonary artery: this last is distributed in the body of the lobule

in a manner that is not well known: it seems to be transformed into numerous radicles of the pulmonary veins. Dr. Magendie believes that these numerous small vessels, by which the artery terminates and the pulmonary veins begin, by crossing and joining in different manners, form the *areolæ* of the tissue of the lobules. The small bronchial division that ends in the lobule, does not enter into the anterior of it, but breaks off as soon as it has arrived at the parenchyma. This last circumstance appears remarkable: because, since the bronchia do not penetrate into the spongy tissue of the lungs, it is not probable that the surface of the cells, with which the air is in contact, is covered by the mucous membrane. The most minute anatomy cannot prove its existence in this place.

A part of the nerve of the eighth pair, and some filaments of the sympathetic, are expended on the lungs, but it is not known how they are distributed: the surface of the organ is covered by the pleura, a serous membrane, similar to the *peritonæum* in its structure and functions.

Round the *bronchia*, and near the place where they enter into the tissue of the lungs, a certain number of lymphatic glands exist, the colour of which is almost black, and to which the small number of lymphatic vessels which spring from the surface and from the interior of the pulmonary tissue are directed.

With regard to the lungs, we receive from the art of delicate injection some information that we ought not to neglect.

If we inject mercury, or even coloured water, into the pulmonary artery, the injected matter passes immediately into the pulmonary veins, but at the same time a part enters the *bronchia*, and goes out by the *trachea*. If the matter be injected into a pulmonary vein, it passes partly into the artery and partly into the bronchia. Lastly, if it be introduced into the trachea, it very soon penetrates into the artery, into the pulmonary veins, and even into the *bronchial* artery and vein.

The lungs fill up a great part of the cavity of the chest, and enlarge and contract with it; and, as they communicate with the external air by the trachea and the larynx, every time that the chest enlarges it is distended by the air, which is again expelled when the chest resumes its former dimensions. We must, then, necessarily stop to examine this cavity.

The chest, or the thorax, is of the form of a *cone*, the summit of which is above, and the base below.

The apparent form and dimensions of the chest are determined by the length, disposition, and motions of the ribs upon the vertebræ.

The chest is capable of being dilated vertically, transversely, forward, and backward; that is, in the direction of its principal diameters.

The principal, and almost the only, agent of the vertical dilatation is the diaphragm, which, in contracting, tends to lose its vaulted form, and to become a plane; a motion which cannot take place without the pectoral portion of the thorax increasing, and the abdominal portion diminishing.

The sides of this muscle, which are fleshy, and correspond with the lungs, descend farther than the centre, which, being aponeurotic, can make no effort by itself, and which is, besides, retained by its union with the *sternum* and the *pericardium*.

In most cases this lowering of the diaphragm is sufficient for the dilatation of the chest; but it often happens that the sternum and the ribs, in changing the position between them and the vertebral column, produce a sensible augmentation in the thoracic cavity.

In the general elevation of the thorax, its form necessarily changes, as well as the relations of the bones of which it is composed. The cartilages of the ribs seem particularly intended to assist these changes: as soon as they are ossified, and consequently lose their elasticity, the chest becomes immoveable.

Whilst the sternum is carried upwards, its inferior extremity is directed a little forward: it thus undergoes a slight swinging motion; the ribs become less oblique upon the vertebral column; they remove a little from each other, and their inferior edge is directed outward by a small tension of the cartilage. All these phenomena are not very apparent, except in the superior ribs.

A general enlargement of the thorax takes place by its elevation, as well from front to back, as transversely, and upwards.

This enlargement is called *inspiration*. It presents three degrees: — 1st, Ordinary *inspiration*, which takes place by the depression of the diaphragm, and an almost insensible elevation of the thorax. 2dly, The *great* inspiration, in which there is an evident elevation of the thorax, and, at the same time, a depression of the diaphragm. 3dly, *Forced* inspiration, in which the dimensions of the thorax are augmented in every direction, as far as the physical disposition of this cavity will permit.

Expiration succeeds to the dilatation of the thorax; that is, the return of the thorax to its ordinary position and dimensions.

The mechanism of this motion is the reverse of what we have just described. It is produced by the elasticity of the cartilages, and by the ligaments of the ribs, which have a tendency to resume their former shape, by the relaxation of the muscles that had raised the thorax, and by the contraction of a great number of muscles so disposed that they lower and contract the chest.

The contraction of the thorax, or expiration, presents also three degrees: — 1st, *Ordinary expiration*; 2d, *Great expiration*; 3d, *Forced expiration*.

In ordinary expiration, the relaxation of the diaphragm, pressed upwards by the abdominal viscera, which are themselves urged by the anterior muscles of this cavity, produces the diminution of the vertical diameter: vehement expiration is produced by the relaxation of the inspiring muscles, and a slight contraction of those of expiration, which permits the ribs to assume their ordinary relations with the vertebral column. But the contraction of the chest may go still farther. If the abdominal an-

other expiratory muscles contract forcibly, a greater depression of the diaphragm takes place, the ribs descend lower, the base of the *conoid* shrinks, and there is, consequently, a greater diminution of the capacity of the thorax. This is called forced expiration.

We shall now consider the air as an elastic fluid, which possesses the property of exerting pressure upon the bodies it surrounds, and upon the sides of the vessels that contain it. This property supposes, in the particles of air, a continual tendency to repulse each other.

Another property of the air is *compressibility;* that is, its volume changes with the pressure which it supports.

The air expands by heat like all other bodies; its volume augments $\frac{1}{480}$ by an increase of one degree of Fahrenheit's thermometer.

The air has weight: this is ascertained by weighing a vessel full of air, and then weighing the same vessel after the air has been taken out by the air-pump.

The air is more or less charged with humidity.

Air, notwithstanding its thinness and transparency, refracts, intercepts, and reflects the light.

The air is composed of two gases that are very different in their properties: —

1st, Oxygen: this gas is a little heavier than air, in the proportion of 11 to 10, and it combines with all the simple bodies: it is an element of water, of vegetable and animal matters, and of almost all known bodies; it is essential for combustion and respiration. 2dly, Azote: this gas is a little lighter than air: it is an element of ammonia and of animal substances; it extinguishes bodies in combustion.

It has been thus found that 100 parts in weight of air contain 21 parts of oxygen and 79 of azote. These proportions are the same in every place and at all heights, and have not sensibly changed for these fifteen years, since they were positively established by chemistry.

Besides oxygen and azote, the air contains a variable quantity of the vapour of water, as we have already observed, and a *small quantity* of carbonic acid, the proportion of which has not yet been positively fixed.

The air is decomposed by almost all combustible bodies, at a temperature which is peculiar to each. In this decomposition they combine with the oxygen, and set the azote at liberty.

Of Inspiration and Expiration. — If we call to mind the disposition of the pulmonary lobules, the extensibility of their tissue, their communication with the external air by means of the bronchia, of the trachea, and of the larynx, it may easily be conceived that every time the breast dilates, the air immediately enters the pulmonary tissue, in a quantity proportionate to the degree of dilatation. When the breast contracts, a part of the air that it contains is expelled, and passes out by the glottis.

In order to arrive at the glottis in inspiration, and to go outwards in expiration, the air sometimes traverses the nasal canal, and sometimes the mouth: the position of the velum of the palate, in these two cases, deserves to be described. When the air traverses the nasal canals and the pharynx, to enter or to pass out of the larynx, the velum of the palate is vertical, and placed with its anterior surface against the posterior part of the base of the tongue, so that the mouth has no communication with the larynx. When the air traverses the mouth, in inspiration or expiration, the velum of the palate is horizontal, its posterior edge is embraced by the concave surface of the pharynx, and all communication is cut off between the inferior parts of the pharynx and the superior part of this canal, as well as with the nasal canals. Thence the necessity of making the sick breathe by the mouth, if it is necessary to examine the tonsils or the pharynx.

These two ways for the air to arrive at the glottis were necessary, for they assist each other: thus, when the mouth is full of food, the respiration takes place by the nose; it takes place by the mouth when the nasal canals are obstructed by mucus, by a slight swelling of the membrane, or any other cause. The glottis opens in the instant of inspiration, and, on the contrary, it shuts in the expiration.

It appears that in a given time the number of inspirations made by one person are very different from those of another. Haller thinks there are twenty in the space of a minute. A man upon whom Menzies made experiments respired only fourteen times in a minute. Sir H. Davy informs us that he respires in the same period twenty-six or twenty-seven times; Dr. Thomson says that he respires generally nineteen times; and Dr. Magendie only respires fifteen times. Taking twenty times in a minute for the mean, this will give 28,800 inspirations in twenty-four hours. But this number probably varies according to many circumstances, such as the state of sleep, motion, distension of the stomach by food, the capacity of the chest, moral affections, &c. What quantity of air enters the chest at each inspiration? What quantity goes out at each expiration? How much generally remains?

According to Menzies, the mean quantity of air that enters the lungs at each inspiration, is 40 cubic inches. Goodwin thinks that the quantity remaining, after a complete expiration, is 109 cubic inches; Menzies affirms that this quantity is greater, and that it amounts to 179 cubic inches.

According to Davy, after a forced expiration, his lungs contained 41 cubic inches.

After a natural expiration.....	118
After a natural inspiration.....	135
After a forced inspiration	254

By a forced expiration, after a forced inspiration, there passed out of the lungs ..... 190 cu. in.

After a natural inspiration.....	78·5
After a natural expiration.....	67·5

Dr. Thomson thinks that we should not be far from the truth in supposing that the ordinary quantity of air contained in the lungs is 280, and that there enter or go out at each inspiration, or expiration, 40 inches. Thus, supposing

twenty inspirations in a minute, the quantity of air that would enter and pass out in this time would be 800 inches; which makes 48,000 in the hour, and in 24 hours, 1,152,000 cubic inches. A great number of experiments have been made by chemists to determine if the volume of air diminishes while it remains in the lungs. In considering the latest experiments, it appears that, in most cases, there is no diminution; that is, a volume of expired air is exactly the same as one of inspired air. When this diminution takes place it appears to be only accidental.

By successively traversing the mouth or the nasal cavities, the pharynx, the larynx, the trachea, and the bronchia, the inspired air becomes of a similar temperature with the body. It most generally becomes heated, and consequently rarefied, so that the same quantity in weight of air occupies a much greater space in the lungs than it occupied before it entered them. Besides this change of volume, the inspired air is charged with the vapour that it carries away from the mucous membranes of the air-passages, and in this state always, hot and humid, it arrives in the pulmonary lobules; also this portion of air of which we treat mixes with that which the lungs contained before.

But expiration soon succeeds to inspiration: an interval only of a few seconds passes in general between them; the air contained by the lungs, pressed by the powers of expiration, escapes by the expiratory canal in a contrary direction to that of the inspired air.

We must here remark, that the portion of air expired is not exactly that which was inspired immediately before, but a portion of the mass which the lungs contained after inspiration; and, if the volume of air that the lungs usually contains is compared with that which is inspired and expired at each motion of respiration, we may be inclined to believe that inspiration and expiration are intended to renew in part the considerable mass of air contained by the lungs.

This renewal will be so much more considerable as the quantity of air expired is greater; and as the following inspiration is more complete.

Physical and Chemical Changes that the Air undergoes in the Lungs. — The air, in its passage from the lungs, has a temperature nearly the same as that of the body: there escapes with it from the breast a great quantity of vapour called *pulmonary transpiration*; besides, its chemical composition is different from that of the inspired air. The proportion of azote is much the same, but that of oxygen and carbonic acid is quite different.

In place of 0·21 of oxygen, and a trace of carbonic acid, which the atmospheric air presents, the expired air gives 0·18 or 0·19 of oxygen, and 0·3 to 0·4 of carbonic acid; generally the quantity of carbonic acid exactly represents the quantity of oxygen which has disappeared: nevertheless, the last experiments of Gay Lussac and Davy give a small excess of acid; that is, there is a little more acid formed than the oxygen absorbed.

In order to determine the quantity of oxygen consumed by an adult in twenty-four hours, we have only to know the quantity of air respired in this time. According to Lavoisier and Sir H. Davy, 32 cubic inches are consumed in a minute, which gives for 24 hours 46,037 cubic inches.

It is not difficult to appreciate the quantity of carbonic acid that passes out of the lungs in the same time, since it nearly represents the volume of oxygen that disappears. Thomson values it at 40,000 cubic inches, though he says it is probably a little less: now this quantity of carbonic acid represents nearly 12 ounces avoirdupois of carbon.

Some chemists say that a small quantity of azote disappears during respiration; others think, on the contrary, that its quantity is sensibly augmented: but there is nothing positive in this respect.

We are informed of the degree of alteration that the air undergoes in our lungs by a feeling which inclines us to renew it: though this is scarcely sensible in ordinary respiration, because we always continue it, it nevertheless becomes very painful if we do not satisfy it quickly; carried to this degree, it is accompanied with anxiety and fear, an instinctive warning of the importance of respiration.

Whilst the air contained in the lungs is thus modified in its physical and chemical properties, the venous blood traverses the ramifications of the pulmonary artery, of which the tissue of the lobules of the lungs is partly formed; it passes into the radicles of the pulmonary veins and very soon into these veins themselves; but in passing from the one to the other, it changes its nature from venous to arterial blood.

Respiration, puerile. See *Auscultation.*

Rest-harrow. See *Ononis spinosa.*

Re'sta bo'vis. (So called because it hinders the plough.) See *Ononis spinosa.*

RESUPINA'TUS. Resupinate: reversed. Applied to leaves, &c. when the upper surface is turned downwards; as in the leaf of the *Pharus latifolius.*

RESUSCITATION. (*Resuscitatio, onis.* f.; from *resuscito*, to rouse or awake.) Revivification. The restoring of persons, apparently dead, to life. See *Asphyxia.*

RE'TE. (*e, is.* n.; so called *à retinendis piscibus.*) A net: a term applied very generally, in *Anatomy* and *Natural History*, to cellular membrane, nerves, vessels, and other parts which appear like a net or web.

Rete malpighi. The rete mucosum. See *Cutis.*

Rete mirabile. The network of blood-vessels at the basis of the brain of quadrupeds.

Rete mucosum. A mucous substance situated between the cuticle and true skin. See *Cutis.*

RETENTION. (*Retentio, onis.* f.; from *retineo*, to keep back.) The keeping back of any thing which should be expelled: applied to the excretions, but particularly to the urine. See *Suppression.*

Retention of the menses. See *Amenorrhœa.*

Retention of urine. *Retentio urinæ.* The collection of urine within the bladder, the

son not being able to expel it. This is sometimes partial, and sometimes total. It is known, in both cases, by a tumour in the region of the bladder, subsequent to the person having passed his urine, and by his not having the power so to do, when partial small quantities of urine dribble away. This disease occasionally occurs in old age from debility: it is frequently the result of an affection of the nerves of the bladder, over-distension of the bladder, inflammation, hernia, and other displacements of the abdominal viscera; pressure on the neck of the bladder from several causes, and from strictures; and pressure of tumours in the course of the urethra, as enlarged prostate gland, uterus, &c.; and from foreign bodies lodging in the urethra. For the cure of this disease, attention must be given to the removal of those diseases from which it arises, and to the removal of all obstructions. The palliative cure is drawing off the urine by a catheter. A want of tone in the bladder is most relieved by chalybeates and bark; and spasmodic stricture, by fomentations, warm bath, and cinchona and opium.

RETI'CULAR. (*Reticularis*; from *rete*, a net.) *Reticulatus.* Interwoven like a web.

Reticulatus. See *Reticular.*

RETI'CULUM. (*um, i.* n.; from *rete*, a net.) A little net or web.

RE'TIFORM. (*Retiformis*; from *rete*, a net, and *forma*, resemblance.) Net-like.

RE'TINA. (*a, æ.* f.; from *rete*, a net.) The fourth or innermost membrane of the eye, expanded within the choroid coat, to the ciliary ligament. It is the true organ of vision, and is formed by an expansion of the pulp of the optic nerve. See *Oculus*, and *Vision.*

RETINA'CULUM. (From *retineo*, to hold or restrain.) An old surgical instrument for keeping the bowels in their place during the operation for hernia, or that of castration.

RETINI'TIS. (*is, idis.* f.; from *retina*, the name of the part, and the terminal *itis*, which imports inflammation.) Inflammation of the retina. See *Ophthalmitis.*

RETORT. (*Retorta, æ.* f.; from *retorqueo*, to bend back again: probably so called because its neck was curved and bent back again.) A chemical vessel employed for many distillations, and most frequently for those which require a degree of heat superior to that of boiling water. They differ in form and materials: when pierced with a little hole in their roof, they are called tubulated retorts. They are made of common glass, stone-ware, or iron.

RETRA'CTOR. A muscle, the office of which is to retract the part into which it is inserted.

Retractor anguli oris. See *Buccinator.*

RE'TRAHENS. Drawing back.

RETRAHENS AURIS. *Posterior auris*, of Winslow. *Retrahens auriculæ*, of Albinus. *Depriens auriculæ*, of Douglas. *Retrahens auriculum*, of Cowper. Two small bundles of muscular fibres which arise from the external and posterior part of the mastoid process of the temporal bone, immediately above the insertion of the sterno-cleido-mastoideus muscle. They are inserted into that part of the back of the ear which is opposite to the septum, which divides the concha and scapha. Their use is to draw the ear backwards, and stretch the concha.

RETROCE'DENT. *Retroce'dens. Retrogradus.* When a disease that moves about from one part to another, and is sometimes fixed, has been some time in its more common situation, and retires from it, it is said to be retrocedent.

Retrocedent gout. See *Arthritis.*

Retrograde. See *Retrocedent.*

RETROVE'RSION. *Retroversio.* Turning back: applied to the uterus, bladder, and other organs.

Retroversion of the uterus. See *Uterus, retroversion of.*

RETU'SUS. Retuse: dented. Applied to a leaf which ends in a broad shallow notch; as in the *Rumex digynus.*

Reverberatory. See *Furnace.*

Revery. See *Aphelxia.*

REVOLU'TUS. Revolute, rolled back. Applied to a leaf, the margin of which is turned or rolled backwards; as in *Andromeda polifolia.*

REVULSION. (*Revulsio*; from *revello*, to draw away.) An old term used by the humoral pathologists, signifying the drawing of humours a contrary way.

RHABA'RBARUM. (*um, i.* n.; from *Rha*, and *barbarus*, wild: so called because it was brought from the banks of the Rha, now called the Wolga, in Russia.) See *Rheum.*

Rhabarbarum album. See *Convolvulus mechoacan.*

Rhabarbarum antiquorum. See *Rheum.*

Rhabarbarum Dioscoridis. See *Rheum.*

Rhabarbarum monachorum. See *Rumex patientia.*

Rhabarbarum rhaponticum. See *Rheum rhaponticum.*

Rhabarbarum sibericum. See *Rheum.*

Rhabarbarum tartaricum. See *Rheum.*

Rhabarbarum verum. See *Rheum.*

RHACHIA'LGIA. (*a, æ.* f.; from ῥαχις, the spine of the back, and αλγος, pain.) A pain in the spine of the back. It was formerly applied to some species of colic, when attended with severe pain in the back, and more particularly to the *colica pictonum.*

RHA'CHIS. (*is, eos.* f. Ῥαχις, the spine of the back.) 1. In *Anatomy*, the spine. See *Spine.*

2. In *Botany*, the common stalk or spike-stalk, or receptacle of the florets in the spikelets of grasses, or of the spikelets themselves; as in *Lolium, Triticum, Hordeum*, &c. It also means the rib or leaf-stalk of ferns, which is often winged or bordered.

RHACHISAGRA. (*a, æ.* f.; from ῥαχις, the spine of the back, and αγρα, a seizure.) A sudden pain in the spine: applied to gout fixed in the spine of the back. An ill-constructed term.

RHACHI'TIS. (*is, idis.* f.; from ῥαχις, the spine of the back: so called because the spine is distorted in severe cases.) *Cyrtonosos.* The English disease. The rickets. A disease known by a large head, prominent forehead, protruded sternum, flattened ribs, big belly, and emaciated limbs, with great debility. It is usually con-

fined in its attack between the two periods of nine months and two years of age, seldom appearing sooner than the former, or showing itself for the first time after the latter period. The muscles become flaccid, the head enlarges, the carotids are distended, the limbs waste away, and their epiphyses increase in bulk. The bones and spine of the back are variously distorted; disinclination to muscular exertion follows; the abdomen swells and grows hard; the stools are frequent and loose; a slow fever succeeds, with cough and difficulty of respiration: atrophy is confirmed, and death ensues. Frequently it happens that nature restores the general health, and leaves the limbs distorted.

After death, the liver and the spleen have been found enlarged and scirrhous, the mesenteric glands indurated, and the lungs either charged with vomicæ or adhering to the pleura; the bones soft, the brain flaccid, or oppressed with lymph, and the distended bowels loaded most frequently with slime, sometimes with worms.

It is remarkable, that in the kindred disease, which Hoffmann and Sauvages call the atrophy of infants, we have many of the same symptoms, and the same appearances nearly after death. They who perish by this disease, says Hoffmann, have the mesenteric glands enlarged and scirrhous; the liver and spleen obstructed, and increased in size; the intestines are much inflated, and are loaded with black and fœtid matters; and the muscles, more especially of the abdomen, waste away.

In the treatment of rickets, besides altering any improprieties in the regimen which may have co-operated in producing it, those means should be employed by which the system may be invigorated. Tonic medicines are therefore proper, particularly chalybeates, which are easily given to children; and the cold-bath may be essentially beneficial. The child should be regularly well exercised, kept clean and dry, and a pure air selected; the food nutritious and easy of digestion. When the appetite is much impaired, an occasional gentle emetic may do good; more frequently tonic aperients, as rhubarb, will be required to regulate the bowels; or sometimes a dose of calomel in gross habits. Of late, certain compounds of lime have been strongly recommended, particularly the phosphate, which is the earthy basis of the bones; though it does not appear likely to enter the system, unless rendered soluble by an excess of acid. Others have conceived the disease to arise from an excess of acid, and therefore recommended alkalies; which may certainly be useful in correcting the morbid prevalence of acid in the primæ viæ, so frequent in children. Where the bones are inclined to bend, care must be taken not to throw the weight of the body too much upon them.

RHA'GAS. (*as, adis.* f.; from *ῥηγνυμι*, to break or bruise.) 1. A common fissure, chap, or cleft.

2. A malignant, dry, and deep cutaneous fissure.

RHAGOI'DES. (From *ῥαξ*, a grape-stone, and *εἰδος*, a likeness: so called from its likeness in colour to a grape-seed.) Grape-seed-like. Applied to the uvea of the eye.

RHA'MNUS. (*us, i.* m. *Ῥαμνος.*) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Monogynia.* Buckthorn.

2. The pharmacopœial name of the purging buckthorn. See *Rhamnus catharticus.*

RHAMNUS CATHARTICUS. Buckthorn. Purging buckthorn. *Spina cervina. Rhamnus solutivus. Spina infectoria. Cervispina.* The fruit or berries of this shrub, *Rhamnus — spinis terminalibus floribus quadrifidis dioicis, foliis ovatis, caule erecto,* of Linnæus, have been long received into the Materia Medica: they contain a pulpy deep green juice, of a faint unpleasant smell, a bitterish, acrid, nauseous taste, which operates briskly by stool, producing thirst, dryness of the mouth, and fauces, and severe gripings, unless some diluting liquor be drank plentifully after it: at present it is rarely prescribed, except as a drastic purge. The dose is said to be about twenty of the fresh berries in substance; twice or thrice that number in decoction; a drachm or a drachm and a half of the dried berries; an ounce of the expressed juice, or half an ounce of the rob or extract, obtained by inspissating the juice.

RHAMNUS FRANGULA. The systematic name of the black alder. *Frangula alnus. Alnus nigra. Rhamnus frangula — inermis floribus monogynis hermaphroditis, foliis integerrimis,* of Linnæus.

All the parts of this tree, as well as of the common alder, are astringent and bitter. The bark is most astringent; a decoction of it has cured agues, and is often used to repel inflammatory tumours of the throat, by way of gargle. The inner yellow bark of the trunk, or root given to ʒij., vomits, purges, and gripes; but joined with aromatics, it operates more agreeably. An infusion, or decoction in water, inspissated to an extract, acts yet more mildly than these. It is mostly employed by the common people in dropsy and other disorders. The berries of alder are purgative. They are not in use under their own name, but are often substituted for buckthorn berries; to discover which it should be observed, that the berries of the black alder have a black skin, a blue juice, and two seeds in each of them: whereas the buckthorn berries have a green juice, and commonly four seeds. The substitution of one for the other is not of material consequence, as the plants belong to the same genus, and the berries do not differ greatly.

Dr. Murray, of Gottingen, recommends, from his own experience, the leaves of alder chopped in small pieces, and heated over the fire, as the best remedy with which he is acquainted for dispersing milk in the breasts.

RHAMNUS ZIZYPHUS. The name of the tree which affords the jujubes. A half-dried fruit of the plum kind, about the size and shape of an olive. Jujubes, when in perfection, have an agreeable, sweet taste; and in the southern parts of Europe, where they are common, they make an article of food in their recent state, and are medicine when half dried.

RHAPO'NTICUM. (*um, i.* n.; the Rha of Pontus, *i. e.* the Rha, in Russia, a river on the banks of which it grew.) See *Rheum rhaponticum.*

Rhapontic rhubarb. See *Rheum rhaponticum.*

Rhaponticum vulgare officinarum. See *Centaurea.*

Rhatania. See *Krameria.*

Rhatany root. See *Krameria.*

RHE'IN. The name given by M. Vaudin to a substance procured by treating rhubarb with ether.

Rheum. See *Rheuma.*

RHE'UM. (*um, i.* n.; from *Rha*, a river in Russia, now called the Wolga, from the banks of which it was first brought.) 1. The name of a genus of plants in the Linnæan system. Class, *Enneandria;* Order, *Trigynia.* Rhubarb.

2. The pharmacopœial name of the officinal rhubarb. See *Rheum palmatum.*

RHEUM PALMA'TUM. The systematic name of the officinal rhubarb. *Rhabarbarum. Rheon. Rhœum. Barbaria. Lapathum orientale. Lapathum chinense. Rhabarbarum verum. Rhabarbarum tartaricum.* It was not until the year 1732 that naturalists became acquainted with any plant which seemed to afford the rhabarbarum officinale; when some plants received from Russia by Jussieu at Paris, and Rhand at Chelsea, were said to supply this important desideratum, and as such were adopted by Linnæus, in his first edition of the Species Plantarum, under the name of *Rheum rhabarbarum.* This, however, was not generally received as the genuine rhubarb plant; and with a view to ascertain this matter more completely, Kaan Boerhaave procured from a Tartarian rhubarb merchant the seeds of those plants, whose roots he annually sold, and which were admitted at Petersburg to be the true rhubarb. These seeds were soon propagated, and were discovered by De Gorter to produce two distinct species; viz. the *Rheum rhabarbarum* of Linnæus, or, as it has since been called, the *Rheum undulatum;* and another species, a specimen of which was presented to Linnæus, who declared it to be a new one; and it was first mentioned in the second edition of the Species Plantarum, in 1762, by the name of *Rheum palmatum.* Previous to this time, De Gorter had repeatedly sent its seeds to Linnæus, but the young plants which they produced constantly perished; at length he obtained the fresh root, which succeeded very well at Upsal, and afterwards enabled the younger Linnæus to describe this plant, in 1767. But two years antecedent to this, Dr. Hope's account of the *Rheum palmatum*, as it grew in the Botanic Garden near Edinburgh, had been read before the Royal Society at London; and of the great estimation in which this plant was held by him, we have the following proof: — "From the perfect similarity of this root with the best foreign rhubarb, in taste, smell, colour, and purgative qualities, we cannot doubt of our being at last possessed of the plant which produces the true rhubarb, and may reasonably entertain the agreeable expectation of its proving a very important acquisition to Britain."

But, from the relation we have given, it appears that both the seeds of the R. palmatum, and the R. undulatum, were transmitted to Petersburg as those of the true rhubarb. We are therefore to conclude, that the former species has an equal claim to this importance with the latter; and, from further inquiries made in Russia, there is the best authority for believing that the R. compactum also affords this very useful drug. The seeds of the R. palmatum were first introduced into Britain in 1762 by Dr. Hounsy (who sent them from Russia), and were supposed to be a part of that already mentioned; and since their prosperous cultivation by the late professor of botany at Edinburgh, the propagation of this plant has been gradually extended to most of our English gardens, and with a degree of success which promises, in time, to supersede the importation of the foreign root. Three sorts of rhubarb roots are usually imported into this country for medical use; viz. the Turkey rhubarb; the Russian or Tartarian rhubarb, which is exactly similar to the former; and the Chinese or East India rhubarb. The Indian is in oblong pieces, flattish on one side, and convex on the other; compact, hard, heavy; internally of a dull red colour, variegated with yellow and white, and when recently powdered appears yellow, but on being kept becomes gradually redder. The Russian is the most valuable, and is brought to us in roundish pieces, with a large hole through the middle of each; it is more soft and friable than the former sort, and exhibits, when broken, many streaks of a bright red colour. The marks of the goodness of rhubarb are, the liveliness of its colour when cut; its being firm and solid, but not flinty or hard; its being easily pulverable, and appearing when powdered of a fine bright yellow colour; its imparting to the spittle, when chewed, a deep saffron tinge, and not proving slimy or mucilaginous in the mouth; its taste is subacrid, bitterish, and somewhat styptic; the smell slightly aromatic.

The purgative qualities of rhubarb are extracted more perfectly by water than by rectified spirit: the part remaining after the action of water is almost, if not wholly, inactive; whereas, after repeated digestion in spirit, it proves still very considerably purgative. The virtue of a watery infusion, on being inspissated by a gentle heat, is so much diminished, that a drachm of the extract is said to have scarcely any greater effect than a scruple of the root in substance. The chemical analysis of rhubarb is still very imperfect, and the active principle is not known. According to the analysis of Brande, it consists of

Water	8·2
Gum	31·0
Resin	10·0
Extract, tan, and gallic acid	26·0
Phosphate of lime	2·0
Malate of lime	6·5
Woody fibre	16·3

According to most other analyses the *oxalic* is the acid with which the lime is combined. The *Rhabarbarine* of Caventon is the colouring matter merely. M. Hornemann has found a principle

which he calls *rheumine*, and believes to be the characteristic one, but little is known of it. The two kinds of rhubarb differ considerably in their chemical composition. The spirituous tincture loses less; half a drachm of this extract proving moderately purgative. The qualities of this root, says Dr. Cullen, are those of a gentle purgative; and so gentle, that it is often inconvenient on account of the bulk of the dose required, which, in adults, must be from ʒss. to ʒj. When given in a large dose it will occasion some griping, as other purgatives do; but it is hardly ever heating to the system, or shows the other effects of the more drastic purgatives. The purgative quality is accompanied with a bitterness, which is often useful in restoring the tone of the stomach when it has been lost; and, for the most part, its bitterness makes it sit better on the stomach than many other purgatives do. Its operation joins well with neutral laxatives; and both together operate in a lesser dose than either of them would singly. Some degree of stypticity is always evident in this medicine; and as this quality acts when that of the purgative has ceased, so in cases of diarrhœa, when any evacuation is proper, rhubarb has been considered as the most proper remedy to be employed. It must, however, be remarked here, that, in many cases of diarrhœa, no further evacuation than what is occasioned by the disease is necessary or proper. The use of rhubarb, in substance, for keeping the belly regular, for which it is frequently employed, is by no means proper, as the astringent quality is ready to undo what the purgative has done; but it is found that the purpose mentioned may be obtained by it, if the rhubarb is chewed in the mouth, and no more is swallowed than what the saliva has dissolved. And it must be remarked, that in this way employed it is very useful to dyspeptic persons. Analogous to this, is the use of rhubarb in solution, in which it appears that the astringent quality is not so largely extracted as to operate so powerfully as when the rhubarb was employed in substance.

The officinal preparations of this drug are, a watery and a vinous infusion, a simple and a compound tincture, and an extract. It is also an ingredient in different compositions.

Rheum rhaponticum. The systematic name of the rhapontic rhubarb. *Rhaponticum. Rhabarbarum Dioscoridis. Rhabarbarum antiquorum.* The root of this species appears to have been the true rhubarb of the ancients. By some it is confounded with the modern rhubarb, though considerably different from that root in appearance, as well as in quality. The rhapontic is of a dusky colour on its surface, and a loose spongy texture; is more astringent than rhubarb, and less purgative: in this last intention, two or three drachms are required for a dose.

Rheum undulatum. The systematic name of the Siberian rhubarb. The *Rheum undulatum — foliis subvillosis undulatis petiolis æqualibus*, of Linnæus. It possesses similar virtues to those of the palmate species, and is in common use in Russia.

RHE'UMA. (*a, atis.* n.; from ῥέω, to flow.) Rheum. The discharge from the nostrils, or air-passages, arising from cold.

RHEU'MATISM. (*Rheumatismus, i.* m.; ῥευματισμος, from ῥευματιζω, to be afflicted with defluxions.) *Dolores rheumatici et arthritici*, of Hoffmann. *Myositis*, of Sagar. Rheumatism is an affection of the extremities and external coverings of the human body, occupying the muscular, tendinous, and fibrous textures, and characterised by pain, stiffness, and swelling of a joint, with or without fever, according to the violence of the disorder. In common life, a threefold distinction is made, *viz.*, into the true rheumatism, the rheumatic gout, and the rheumatic fever. The two latter alone merit the title of *inflammations*, but there is obviously a close analogy in the pathology of all these affections. In their symptoms and mode of treatment, however, sufficient difference exists to entitle them to separate examination. It is certainly a curious circumstance, considering the frequency of this complaint, that there should still be so much obscurity in regard to several of the fundamental doctrines connected with rheumatic inflammation. This may be partly explained, perhaps, from its being a disease of so little danger, as never to have received any elucidation from the labours of the morbid anatomist.

Acute rheumatism. — We shall begin by the consideration of that highest grade of rheumatism, called the rheumatic fever, the acute rheumatism of nosologists, a painful and severe disease, thus characterised. It is ushered in by a sudden attack of rigors, followed by the usual symptoms of pyrexia, and is particularly distinguished by the great pain and swelling which affect one or more joints, coupled with an utter inability to move them, and very commonly with considerable redness. The affected joints are acutely tender to the touch. The pains are aggravated towards night, and for the most part, at all times, by external heat. The swelling, except in certain cases hereafter to be specified, does not take the form of the joint, but is diffused over the cellular membrane in its neighbourhood. Several joints are commonly affected at the same time, but one of the most singular phenomena of rheumatic inflammation is the strong tendency which it exhibits to *shift its situation*; to abate in one or two joints, often very suddenly, and to become as suddenly violent in another, and a distant part.

The accompanying fever presents several important peculiarities. The pulse seldom exceeds 100 or 110 in the minute; but instead of the hardness which characterises inflammatory fever it is full, soft, and as it were *round*. The skin instead of being hot, harsh, and dry, is commonly in a state of profuse perspiration; and a remarkable acid odour of its secretions may be noticed. The tongue is always deeply loaded. The papillæ appear elongated, and covered with a thick and abundant mucus. The functions of the brain are in a peculiar manner exempt. Headach is seldom present in any form of rheumatic inflammation, acute or chronic; and delirium is almost unknown. There is great thirst, but rarely any nausea or vomiting. Th

bowels are costive, though easily made to move. There is a sallowness in the aspect, and a peculiar expression of the countenance, sufficiently distinct from that of common febrile anxiety.

Terminations. — Different as are the local and constitutional symptoms from those of other phlegmasiæ, the terminations of rheumatic inflammation are no less peculiar. The local inflammation may run high, but it never proceeds to suppuration. It is seldom, indeed, that any permanent injury is done to the joints; for if effusions of a transparent gelatinous fluid into, or around the sheaths of tendons and the capsular ligaments, take place, they are commonly absorbed in a short time. The most important consideration in this view of the subject, is the disposition which exists, in a state of acute rheumatism, to an affection of some internal organ by *metastasis*, or rather by extension of inflammation; for it is not often that the joints are relieved when this event takes place. The organ chiefly liable to be so affected is the heart, and its investing membrane, the pericardium, and it is from this occurrence alone that any danger in the progress of the disease is to be apprehended. The symptoms that result are those already described when treating of pericarditis. It was then remarked, that the circumstances which occasion this extension of rheumatic inflammation to an internal organ have never yet been satisfactorily determined.

Recurrence of rheumatic fever. — No disease is more liable to relapse on slight occasions than acute rheumatism. Going out a little too early in the open air, too much exercise of a particular joint, or an excess in diet, have frequently brought it back in all its former violence. Acute rheumatism is characterised also by a tendency to recurrence after a long interval. Those who have once suffered from an attack of the disease, should therefore be particularly careful to avoid what we shall point out as its exciting causes, or to obviate them by proper attention to clothing. Rheumatism is certainly the most tedious of all the acute inflammations. In many cases it appears to run a defined course, which does not admit of being shortened by any process of treatment, and in a certain length of time to wear itself out. This is seldom less than a month, or longer than six weeks. That the acute sometimes terminates in a state of chronic rheumatism, cannot be doubted; but, instead of being a frequent occurrence, as is often imagined, this is in fact rare; and though the recovery from genuine acute rheumatism is seldious, it is usually perfect.

Remote causes. — Children are very seldom the subjects of acute rheumatism. It most commonly occurs from the age of puberty to the thirtieth or thirty-fifth year of life, and chiefly affects those of sanguine temperament, robust form, and plethoric habit of body. It prevails principally in the months of December and January, and least frequently in August and September. Cold, with moisture, particularly when long applied, is certainly the most common, and perhaps it might be added, its only exciting cause. Hence it is that we find it attributed, in a large proportion of cases, to sleeping in damp beds, living within damp walls, sitting in damp clothes, or working in damp situations.

Seat of rheumatism. — Very little is known regarding the precise seat of inflammation in acute rheumatism. It appears to be situated primarily in capsular ligaments, tendinous sheaths, and aponeurotic expansions; but the cellular membrane around the joints also partakes of inflammation in the active form of the complaint. In this, perhaps, consists the principal local distinction between acute and chronic rheumatism.

Arthritis, or inflammation of synovial membrane. — In some instances of disease, not usually distinguished by the physician from those of common rheumatism, though known to the world by the name of the *rheumatic gout*, the swelling will be found to take the exact form of the joint, or of a bursa in its neighbourhood. This affection is simple inflammation of the synovial membrane. By some pathologists it is imagined that such a disease is altogether distinct from true rheumatism, and the term *arthritis* has been applied to it. It occurs both with and without fever. It is said to differ from rheumatism in its causes, progress, and treatment, as well as in the character of its symptoms. It is this form of fibrous inflammation which occurs as a secondary effect of gonorrhœa. It is frequently confined to a single joint, as the knee or the elbow, and then commonly falls under the cognisance of the surgeon. It exhibits less tendency to shift its situation from one joint to another. Lastly, it has been observed, that the synovial or bursal rheumatism is more under the control of local remedies, especially leeches and blisters, than the more common or *diffuse* form of rheumatism. All distinctions among diseases, even the most minute, which serve to facilitate treatment, are useful. On this account the separation of arthritis from rheumatism may be considered as an improvement in pathology, but the student will remember that in all their important relations, the two affections are closely associated.

Treatment. — If an opinion were formed from the various, and even opposite modes of treatment which have been recommended in the common acute rheumatism, not upon theoretical grounds, but after ample and successful experience, it might rationally be supposed, that the disease occurs in the most opposite states of the system; but this opinion is at variance with common observation. I believe the better conclusion to be, that acute rheumatism is at all times a tedious, and rarely a dangerous disease; that a large proportion of cases would recover with very slight care; and that, in many, medical treatment is of little further service than as obviating the tendency to internal inflammation. It cannot, I think, be doubted, with regard to the power of *cutting short* the disease, that a considerable difference exists between rheumatism and common inflammation.

Three plans of treatment have been advised in the acute rheumatism. 1. The usual antiphlogistic system, consisting of blood-letting,

purgatives, saline and antimonial medicines. 2. Calomel and opium. 3. Bark.

1. The authority of Sydenham is in favour of the first; and though it is impossible to call in question the very remarkable efficacy of opium, and of calomel in combination with opium, in many cases of this disease, yet the plan of treatment which that judicious physician employed, will be found, upon the whole, the most generally efficacious. The important distinction to be kept in view between the practice in acute rheumatism and that in other inflammatory affections is, that while, in the latter, a continuance of the same symptoms calls for a repetition of the same evacuation, it does not do so in the former. To subdue rheumatic inflammation by the lancet alone (even if possible), would be to weaken the system unnecessarily; for it is to be remembered, that, in this disease, the inflammation is not in an organ essential to life. Sixteen ounces of blood may at first be taken from the arm, and repeated two days afterwards, if the pain continues urgent, and the pulse active, with much feeling of general oppression. The blood will always be found highly cupped, and buffy. The further treatment of the disease may commonly be intrusted to purgatives, calomel and opium, antimony, colchicum, and the common saline diuretics; but venesection must be again had recourse to, at any period, if symptoms of cardiac or other internal inflammation supervene.

2. The power of opium, and of calomel in combination with opium, in relieving pain, and repressing acute rheumatic inflammation, is very remarkable; and in almost all cases this medicine may be employed with advantage. Calomel in acute rheumatism is best given in full doses. It is seldom that mercury affects the salivary glands while the system is labouring under rheumatic fever.

3. Bark was introduced as a remedy in acute rheumatism, with the highest encomiums, by Dr. George Fordyce and Dr. Haygarth; but as far as my observation extends, it has not answered the expectations which might have been formed of it from the testimony of these authors. It has appeared to me to be of use only in the latter periods of the disease, when considerable pain and stiffness of the joints are frequently found to exist, but with a *natural* state of the pulse and tongue.

Regimen. — In the true acute rheumatism, local applications to the affected joints are of little service; or rather, in most cases, of no service at all. This remark applies equally to fomentations, cold lotions, rubefacient liniments, and blisters. Not so, however, is it with regard to diet. In acute rheumatism, the functions of the stomach are often little impaired; but a free indulgence of the appetite protracts the complaint, frustrates the effects of other remedies, and has certainly contributed to give to rheumatism that character of tediousness, which makes it the opprobrium of physic. Broths and jellies, animal food in every shape, as well as wine and porter, are to be prohibited; and a cool, spare, vegetable diet, strictly enforced.

Chronic rheumatism. — In the great majority of cases primary rheumatism is of the chronic kind. Indeed the very rarity of acute rheumatism is sufficient to point out that the chronic is not often the sequel of the acute form of the disease. Chronic rheumatism is characterised by pain of the joints aggravated by motion, stiffness of the joints, thickening of the several structures in their vicinity, or increased effusion into the synovial bags. It is readily distinguished from the acute rheumatism by the absence of inflammatory fever, and of redness in the affected part. To this kind of affection the term *rheumatism* is, in common language, specially appropriated.

1. Three species of true rheumatism may be distinguished. The first is that which is connected with a certain degree of obscure febrile excitement in the system, and which would be more correctly designated by the term *subacute rheumatism*. It is known by the pains occasionally shifting their situation suddenly, as in the acute form of the disease, and by their being increased by warmth, and especially, at night, by the warmth of the bed. The frequent occurrence of œdema along with the affection of the joints, may serve to distinguish this from the other species of the disease. Those joints which are surrounded by a large mass of muscular substance, and which are the most constantly exerted, are especially liable to it, such as the hip, and the joints of the lumbar vertebræ. This state of chronic rheumatism is accompanied by a white tongue, thirst, a quickened pulse, and a costive state of the bowels.

2. The second species of chronic rheumatism is marked, not by any degree of excitement in the system, but by the absence of constitutional symptoms. Hence it is not unreasonable to believe, that there may be a loss of tone in the vessels of the affected part. It is not so common as the preceding species, but it sometimes follows it. Stiffness of the joint is here the prominent symptom. *Pain*, in this form of the complaint, is often not at all felt except on motion, or on occasion of changes in the heat or moisture of the atmosphere. It is relieved rather than increased by the warmth of bed. The pain and stiffness do not shift from joint to joint. Spontaneous coldness of the limb, and even a degree of paralytic torpor, are often complained of by the patient. The pulse is seldom quick, or the tongue white.

3. The third species of chronic rheumatism is attended with permanent derangement in the structure of the joint; and it is that form of the disease which has been so ably described by Dr. Haygarth, under the title of Nodosity of the Joints. The ends of the bones, the periosteum, and ligaments, become thickened; and nodes form upon them, often to such an extent as to distort the joint in the most unsightly manner. This form of rheumatism chiefly affects the fingers, but I have seen it also in the knees and ancles. It is principally met with in women, after they have passed the period of menstruation. It is attended with pain of the joint, particularly severe at night.

Causes and seats. — The usual causes of chronic rheumatism are exposure to cold and

moisture, or to partial currents of air, and local injuries, such as strains and bruises. It is also one of the common effects of the syphilitic poison, and of mercury. The structures affected in chronic rheumatism are those called by Bichat *fibrous: viz.* the periosteum in every part of its extent, the tendons and tendinous sheaths of muscles, the ligaments around the joints, the investing membranes of the nerves and of the teeth, and not unfrequently the substance of muscle itself. The sclerotic coat of the eye, which has a dense structure of an analogous kind, is subject also to a species of *rheumatic* inflammation. To distinguish this affection is by no means easy; nor is this the only instance in which chronic rheumatism has given occasion to difficulties in diagnosis. Lumbago has been mistaken for nephralgia or lumbar abscess; rheumatism of the intercostal muscles for pleurisy; and sciatica for ulceration within the cavity of the acetabulum.

Prognosis. — The obstinacy of chronic rheumatism is proverbial, but being a disease that affects only the exterior of the frame, it may continue for years, without material injury to the general health. Under good management many cases may be cured; and life, under all circumstances, rendered at least more comfortable.

Treatment. — No general rules of much importance can be laid down for the guidance of the student in the treatment of chronic rheumatism. Attention must always be paid to the state of the constitution; and the remedies, both internal and external, varied according to the greater or less degree of feverish excitement present. The number of cures for the rheumatism, both popular and scientific, is so great, that it is difficult for a student to believe that any case can occur, for which some appropriate remedy may not be found. Instead, however, of a bare enumeration of the several plans that have been tried, and occasionally found useful in chronic rheumatism, it may be advisable to attempt, at least, to point out a few *principles* that may prove of general application.

1. In some of the forms of subacute rheumatism, particularly lumbago and sciatica, *the local abstraction of blood* by cupping will be productive of great benefit. Where the pains are very severe, it may be even necessary to take blood from the arm, which in this state of disease will always be found cupped and buffy. Leeches are well adapted to those cases of *arthritic* rheumatism, where there is pain and swelling of a joint from distension of the synovial membrane. Dr. Haygarth recommends their application where an enlargement of the extremities of the bones has taken place.

2. The cure of chronic rheumatism may occasionally be effected by promoting *diaphoresis*. This mode of treatment is adapted to those cases where there exists some degree of febrile excitement, where the pains are of recent date, and shift from one joint to another. The warm bath may be directed twice in the week (provided the pulse be perfectly free from all activity), and the following diaphoretic draught given repeatedly during the day: —

℞ Misturæ camphoræ, ℥ vj.
Liquoris ammoniæ acetatis, ℥ iij.
Pulveris ipecac. compos. gr. vj.
Pulveris acaciæ, gr. iv.
Syrupi, ℥ j. Misce.
Fiat haustus sextis horis sumendus.

It is unnecessary to add, that neither in this, nor in any other form of chronic rheumatism, can any thing be hoped for without proper attention to clothing, and, above all, the use of flannel as an under dress. In the same description of cases which are benefited by diaphoretics, the vinum colchici may be given with great advantage. Where there is any considerable degree of effusion, either within the capsular ligaments or the bursæ, or where the cellular membrane in the neighbourhood of the joint is œdematous, a draught of the following kind will be found useful: —

℞ Aquæ menthæ piperitæ, ℥ vij.
Liquoris ammoniæ acetatis, ℥ ij.
Vini colchici, ♏ xv.
Syrupi tolutani, ℥ j. Misce.
Fiat haustus ter in die sumendus.

Where the colchicum irritates the bowels, it should be omitted, and a common saline effervescing draught substituted.

3. Great benefit is experienced in all forms of chronic rheumatism by strict attention to the bowels. In some cases the daily use of an enema will be found to supersede the necessity of aperient medicine. Where this is insufficient, a mild aperient draught should be directed twice, or even three times during the week: —

℞ Infusi rhei, ℥ x.
Magnesiæ sulphatis, ℥ ij.
Tincturæ sennæ,
———— cardam. compos. *sing.* ℥ j.
Sacchari albi, ʒ j. Misce.
Fiat haustus, pro re natâ sumendus.

A more active purgative, containing calomel and antimony, may be given, should the symptoms of feverish excitement (from cold or any other accidental cause) be unexpectedly renewed.

4. Where great torpor and debility of the general system prevail, stimulant and tonic medicines of different kinds have been administered with advantage, the principal of which are gum guaiacum and the volatile alkali (or their combination, the volatile tincture of guaiacum), the oil of turpentine, the balsam of Peru, and mezereon. Bark, both in the form of decoction and powder, unquestionably possesses considerable power over certain forms of chronic rheumatism attended with general torpor; and arsenic has proved successful, even when the *structures* about the joints had become partially disorganised. The good effects of all these remedies will be considerably aided by the diligent use of stimulating embrocations (such as the compound camphor or soap liniment), friction alone appearing to be a powerful means of exciting the languid action of the vessels,

The following formula is strongly recommended by Dr. Bardsley: —

℞ Linimenti saponis compositi, ℥ ij.
Liquoris ammoniæ,
Tincturæ cantharidis,
——— opii, *sing.* ℥ ij. Misce.
Fiat linimentum.

In all cases of chronic rheumatism of long standing, permanent stiffness of the joint is chiefly to be dreaded, to which nothing contributes so much as neglect of the due exercise of the joint. Exercise, therefore, should always be strongly recommended to a rheumatic patient. In a few cases, where torpor and stiffness predominate, the introduction of needles into the skin and subjacent cellular membrane, has proved serviceable. This practice is called acupuncturation.

5. Mercury, pushed so as to affect the mouth, is very effectual in the cure of rheumatic affections of a chronic nature. It appears to operate as a general *stimulant*. The best mode of administration is five grains of Plummer's pill (pilula submur. hydrarg. compos.), taken every night at bed-time. In many of these cases it has been supposed, that a syphilitic taint may have existed in the constitution, and kept up the disease; but very frequently there is no foundation for such a suspicion. Where rheumatic pains can be traced to cold while the system was under the influence of mercury, decoctions of sarsaparilla, guaiacum, and elm bark, or the powder of sarsaparilla, carefully prepared, in doses of two drachms three times a day, may be given with a reasonable prospect of advantage. The sarsaparilla should be continued, in full doses, for five or six weeks.

6. No one remedy, perhaps, is of such general application in the treatment of chronic rheumatism as warm bathing, general and topical. In that severe form of the disease, which has been called nodosity of the joints, scarcely anything else can be relied on to soothe the pain, and relax the rigid fibres. The efficacy of the waters of Bath and Buxton, even in very obstinate cases, is generally acknowledged. They are applicable, however, only in that species of rheumatism which is unattended by inflammatory excitement. The vapour bath is a remedy of very decided efficacy, when there is effusion into the joints of long standing, which the usual antiphlogistic measures have failed to reduce.

7. In all cases of chronic rheumatism, *pain* is, if possible, to be relieved; and, generally, opium will be found the only effectual resource. The best forms of administering opium in this disease are Dover's powder (pulv. ipecac. compos.), in the dose of ten grains every night at bed-time; or the liquor opii sedativus in combination with antimonial wine, and in doses sufficient to lull pain and procure sleep. The headach and costiveness which opium occasions, and which constitute the great bar to its employment, must be obviated, as far as possible, by the use of enemata, or the aperient formerly recommended. Where opium in every form disagrees with the system, the extracts of conium, or hyoscyamus, may be substituted; but the relief they afford is very trifling.

There are three forms of chronic rheumatism which have acquired specific denominations. They are sciatica, lumbago, and pleurodyne. A few observations upon the peculiarities, which have entitled them to such a distinction, may not be out of place.

Sciatica. — This is rheumatism of the cellular envelope of the great sciatic nerve. It is characterised by an excruciating pain, extending from the loins down the back part of the thigh, particularly urgent during the night, and totally preventing sleep. When occurring in its utmost intensity, sciatica is accompanied with high irritative fever, a hard pulse, and deeply loaded tongue. It occurs in all habits, but chiefly in the robust. It can be traced in almost all cases to the combined influence of cold and moisture. Cupping, blistering, and active purgatives long and steadily continued, are required for its cure. A pill, containing three grains of calomel and one of opium, should also be given every night at bed-time, until the system has been brought under the influence of mercury. In obstinate cases an issue should be directed. The application of the *moxa* has occasionally given relief; and, as a last resource, is certainly worthy of a trial.

Lumbago and pleurodyne. — Lumbago is the rheumatism of the lumbar vertebræ, or rather of the large masses of muscular substance attached to them, and serving for the support of the body. It is distinguished from nephritis by the aggravation of pain on stooping. It is a less violent form of ailment than the preceding, and yields, for the most part, to strong stimulating embrocations, a blister, active aperients, and Dover's powder, in full doses, taken at bed-time.

Rheumatism of the thoracic parietes is called pleurodyne, or bastard pleurisy. It is to be distinguished from true pleurisy by the character of the pulse, and the absence of constitutional derangement. It is a very transient form of rheumatism, best combated by the warm bath, and frictions with anodyne liniments. — *Gregory.*

Rheu'mic acid. (*Acidum rheumicum. Rheumicus*; from rheum, from which it is obtained.) An acid found by Mr. J. Henderson in rhubarb, and thought by him to be peculiar; but, according to Lassaignes, it is merely oxalic acid.

Rhinæ'us. (*us, i.* m.; from ῥὶν, the nose.) See *Compressor naris.*

Rhine'nchytes. (From ῥὶν, the nose, and ἐγχυω, to pour in.) A syringe for the nose.

Rhinopho'nia. (*a, æ.* f.; from ῥὶν, the nose, and φωνη, the voice.) Nasal voice.

Rhi'zagra. (From ῥιζα, a root, and αγρευω, to seize.) An instrument for taking out the roots or stumps of teeth.

RHIZO'PHORA. (*a, æ.* f.; from ῥιζα, a root, and φερω, to bear or carry.) The name of a genus of a plants. Class, *Dodecandria*. Order, *Monogynia.*

Rhizophora gymnorhi'za. The mangrove tree, the juice of the root of which is applied in the East to the bites of serpents.

Rhodia. See *Rhodiola.*

RHODI'OLA. (*a, æ.* f.; a diminutive of *rhodia*; from *ῥοδον*, a rose: so called because its root smells like the damask rose.) The name of a genus of plants. Class, *Dioecia*; Order, *Octandria*.

RHODIOLA ROSEA. Rosewort. The *radix rhodiæ* of some pharmacopœias is the produce of this plant. When dry, it has a very pleasant smell, resembling that of the damask rose. In this odorous matter the medical virtue of the root resides. Poultices in which this root enters as a chief ingredient, are said to allay violent pains of the head.

RHO'DIUM. (*um, ii.* n.; from *ῥοδον*, a rose.) A metal found by Dr. Wollaston among the grains of crude platina, and so named on account of the rose colour of some of its compounds. Neither this metal, nor any of its combinations, have yet been used medicinally.

Rhodium lignum. See *Rosewood.*

RHODODE'NDRON. (*on, i.* n.; from *ῥοδον*, a rose, and *δενδρον*, a tree: so called because its flowers resemble the rose.) The name of a genus of plants in the Linnæan system. Class, *Decandria*; Order *Monogynia.*

RHODODENDRON CHRYSANTHUM. The yellow rhododendron. This species of rhododendron, — *foliis oblongis impunctis supra scabris venosissimis, corolla rotata irregulari gemma florifera ferrugineo-tomentosa*, — has not yet been introduced in Britain; it is a native of Siberia, affecting mountainous situations, and flowering in June and July.

This plant and its medical virtues were first described, in 1747, by Gmelin and Hallier. Little attention, however, was paid to it till the year 1779, when it was strongly recommended by Koelpin as an efficacious medicine, not only in rheumatism and gout, but even in venereal cases; and it is now very generally employed in chronic rheumatisms, in various parts of Europe. The leaves, which are the part directed for medicinal use, have a bitterish subastringent taste. Taken in a large dose, they prove a narcotic poison; and in moderate doses, they are said to occasion heat, thirst, a degree of delirium, and a peculiar sensation of the parts affected.

As a powerful and active medicine, this shrub, says Dr. Woodville, may probably be found an addition to the materia medica. Dr. Home, who tried it unsuccessfully in some cases of acute rheumatism, says, "It appears to be one of the most powerful sedatives which we have, for, in most of the trials, it made the pulse remarkably slow, and in one patient reduced it to thirty-eight beats. And in other cases, in which the rhododendron has been used at Edinburgh, it has been productive of good effects, and accordingly it is now introduced into the Edinburgh Pharmacopœia. The manner of using this plant by the Siberians, was by putting two drachms of the dried leaves in an earthen pot, with about ten ounces of boiling water, keeping it near a boiling heat for a night; and this they took in the morning, and, by repeating for three or four times, generally effected a cure.

RHODO'MELI. (From *ῥοδον*, the rose, and *μελι*, honey.) Honey of roses.

RHŒA'DEÆ. (From *rhœas*, the red poppy.) The name of an order in Linnæus's Fragments of a Natural Method, consisting of poppy and similar plants, the calyx of which is caducous, and the fruit a capsule.

RHŒ'AS. (*as, ados.* m.; from *ῥεω*, to flow.) See *Papaver rhœas.*

RHOMBOIDE'US. (From *ῥομβος*, the rhomb, a geometrical figure, and *ειδος*, resemblance.) 1. In *Anatomy*, the name of a muscle of the scapula. *Rhomboideus major* and *minor. Rhomboideus* of Douglas, Winslow, and Cowper. This muscle, which is so named from its shape, is situated immediately under the trapezius. We find it usually, though not always, divided into two portions, which Albinus describes as two distinct muscles. The uppermost of these, or *Rhomboideus minor*, arises tendinous from the spinous processes of the three inferior vertebræ of the neck, and from the ligamentum colli; the lowermost, or *rhomboideus major*, arises tendinous from the spinous processes of the back: the former is inserted into the basis of the scapula, opposite to its spine; the latter into all the basis of the scapula below its spine. Its use is to draw the scapula obliquely upwards, and directly backwards.

2. In *Botany*, applied to leaves, &c. the shape of which is rhomboidal, or nearly diamond-shaped, but broader one way than the other.

RHO'NCHUS. (*us, i.* m. *Ῥογχος, rhonchus, stertor.*) A rattling or wheezing sound. The term is applied in auscultation to any preternatural sound accompanying respiration, occasioned either by the passage of the air through fluids obstructing the bronchia or air cells, or by constriction of the bronchial tubes. It is also called *rattle* — râle of the French writers.

There are five species of rattle or rhoncus.

1. The *crepitous.* — This is produced by the successive bursting of minute bubbles of an uniform size, and resembles in sound the decrepitation of salt over a gentle fire. It takes place when the air cells are filled with blood, or some fluid of similar consistence; hence, it is observed in the first degree of pneumonia, in œdema of the lungs, and in the state called *engouement.*

2. The *mucous.* — This is similar to the sound heard in the windpipe of dying persons, vulgarly known by the name of *dead rattles.* It is produced by the passage of air through a liquid of some tenacity forming bubbles, varying in size and number; hence, the sound of the mucous rattle varies considerably, according to circumstances. It occurs when the bronchia are obstructed with blood, mucus, pus, or a mixture of these. Hence it is met with in bronchitis, hæmoptysis, phthisis, and pneumonia. When the mucous rattle occurs in an excavation of the lungs, arising from an abscess or any other cause, the sound is augmented, and it is called *cavernous rattle.*

3. The *sonorous.* — This is a sound which, when slight, resembles the cooing of a dove, but when stronger, is not unlike the sound of snoring. It arises from narrowing of the bronchial tubes. It is heard in bronchitis.

4. The *sibilant*. — This has a great variety of sound: sometimes it resembles a slight chirping, or the clicking of a small valve, at others, it is like whistling, more or less sharp or grave. It arises from narrowing of the smaller bronchial tubes, or from their obstruction by very viscid mucus. It is therefore heard in bronchitis.

5. The *crackling*. — This resembles the sound caused by the inflation of a dry bladder. It is heard only during inspiration, and arises from the penetration of air into dry and unequally diluted cells. It is heard in pulmonary emphysema.

The different rattles above described are heard during coughing as well as breathing, and are generally more distinct.

Rhopalo'sis. (*is, is.* f.; from ῥοπαλον, a club.) A disorder in which the hair cleaves together, and hangs down in clusters resembling clubs. See *Plica*.

Rhubarb. See *Rheum*.

Rhubarb, monk's. See *Rumex patientia*.

Rhubarb, rhapontic. See *Rheum*.

RHUS. (*us, i.* f. and m.; from ῥεω, to flow: so called because it stops fluxes.) The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Trigynia*. The sumach-tree.

Rhus Belgica. See *Myrica gale*.

Rhus coriaria. Sumach. Elm-leaved sumach. This plant, *Rhus coriaria — foliis pinnatis obtusiuscule serratis ovalibus subtus villosis*, of Linnæus, is a small tree, a native of the south of Europe. It is singular that this is the only species of the genus rhus which is perfectly innocent; the others being active poisons. Both the leaves and berries of this plant are used medicinally, as astringents and tonics; the former are the most powerful, and have been long in common use, where they may be easily obtained, in various complaints, indicating this class of remedies. The berries, which are red, and of a roundish compressed figure, contain a pulpy matter, in which is lodged a brown, hard, oval seed, manifesting a considerable degree of astringency. The pulp, even when dry, is grateful, aud has been discovered to contain an essential salt, similar to that of wood sorrel. An infusion of the dried fruit is not rendered black by a solution of iron: hence it appears to be destitute of astringency. But its acidity is extremely grateful; therefore, like many other fruits, these berries may be advantageously taken to allay febrile heat, and to correct bilious putrescency.

Rhus radicans. See *Rhus vernix*.

Rhus tiphinum. The systematic name of the Virginian sumach, the seeds of which are said to be useful in stopping hæmorrhages.

Rhus toxicodendron. Poison oak, or sumach. This plant is a native of North America. The stems, when cut, exude a milky juice, which inflames the skin. The leaves, now inserted in the Pharmacopœia, are inodorous, and have a mawkish subacrid taste. Their virtues are extracted more perfectly by water than by alkohol. They prove stimulant and narcotic, when taken internally. Dr. Alderson, of Hull, found them successful in several cases of paralysis. They excite a sense of heat and pricking, and irregular twitches in the affected limbs. They have been sometimes useful, also, in herpetic eruptions. The dose may be from half a grain, gradually increased to four grains, two or three times a day.

Rhus vernix. *Rhus radicans*. The systematic name of a poisonous plant, the efficacy of which M. Fresnoy has endeavoured to prove in the disease called paralysis, and herpetic affections. He, in order that others should not suffer by his experiments, began by taking an infusion of one of the three foliola of which each leaf of this plant consists; and as this dose produced no sensible effect, he increased the number to twelve. His urine and perspiration were increased in quantity; and he had some pains in his belly. He relates seven cases, in which he thinks he can remove all doubt of the efficacy of this infusion in herpetic affections.

RHY'AS. (*as, adis.* f. Ῥυας.) A disease of the eye, consisting in a decrease or defect of the lachrymal caruncle. The defect may be congenital, or it may originate from excision, erosion, or acrimony. This disorder is commonly incurable, and it induces an incurable *epiphora*, or a continual weeping.

Rhytido'sis. Ῥυτιδωσις. Corrugation of any part. Atrophy or shrivelling up of the eye-ball.

Rib. See *Costa*.

Ribbed. See *Nervosus*.

RI'BES. (*es, is.* n.; an Arabic name properly belonging to an acid-leaved species of rheum; but which botanists, for about 200 years past, have by mistake applied to the currant and gooseberry family, and with these it now remains.) The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Monogynia*. The currant-tree.

Ribes nigrum. Black currant. This indigenous plant, *Ribes nigrum — racemis pilosis floribus oblongis*, of Linnæus, affords larger berries than those of the red, which are said to be peculiarly useful in sore throats, and to possess a diuretic power in a very considerable degree. The leaves of the black currant are extremely fragrant, and have been likewise recommended for their medicinal virtue, which Bergius states to be mundificans, pellens diuretica. The officinal preparations of the berries are, the *syrupus ribis nigri*, and the *succus ribis nigri inspissatus*.

Ribes rubrum. The red currant. *Grossularea non spinosa. Ribes rubrum — inerme; racemis glabris pendulis, floribus planiusculis*, of Linnæus. The white-currant tree is merely a variety of the red; the fruit of both is perfectly analogous: therefore, what is said of the one applies to the other. The red currant is abundantly cultivated in gardens; and, from its grateful acidity, is universally acceptable, either as nature presents it, or variously prepared by art, with the addition of sugar. Considered medicinally, it is esteemed to be moderately refrigerant, antiseptic, attenuant, and aperient. It may be used with considerable advantage to allay thirst in most febrile complaints, to lessen an increased secretion of bile, and to correct a putrid and scorbutic state of the fluids, especially

in sanguine temperaments; but, in constitutions of a contrary kind, it is apt to occasion flatulency and indigestion.

Ribless. See *Enervis.*

Ribwort. See *Plantago lanceolata.*

Rice. See *Oryza.*

RI'CINUS. (*us, i.* m.; said to be so called from the resemblance of its seeds to the vermin called a tick *ricinus.*) 1. The name of a genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Monadelphia.*

2. The pharmacopœial name of the plant that affords the seed from which the castor-oil is prepared.

RICINUS COMMUNIS. The systematic name of the castor-oil plant. *Cataputia major. Kerva. Ricinus vulgaris. Palma christi. Ricinus communis—foliis peltatis subpalmatis serratis,* of Linnæus. This plant appears to be the Κικι, or Κροτων, of Dioscorides, who observes, that the seeds are powerfully cathartic: it is also mentioned by Aëtius, Paulus Ægineta, and Pliny. The ricinus was first cultivated in England, in the time of Turner, and is now annually reared in many gardens in the neighbourhood of London; and in that of Dr. Saunders, at Highbury, the plant grew to a state of great perfection. An oil extracted from the seeds of this plant, and known by the name of oleum ricini, palma christi, or castor oil, is the drug to which the pharmacopœias refer, and which has lately come into frequent use, as a quick but gentle purgative. The London College directs this oil to be expressed from the seeds in the same way as the oil from almonds, and without the assistance of heat, by which the oil would seem to be obtained in the purest state. However, we have some reason to believe that this method is seldom practised, and that the oil usually employed here is imported from the West Indies, where it is commonly prepared in the following manner:—"The seeds being freed from the husks, or pods, which are gathered upon their turning brown, and when beginning to burst open, are first bruised in a mortar, afterwards tied up in a linen bag, and then thrown into a large pot, with a sufficient quantity of water (about eight gallons to one gallon of the seeds), and boiled till the oil is risen to the surface, when it is carefully skimmed off, strained, and kept for use. Thus prepared, the oil is entirely free from acrimony, and will stay upon the stomach when it rejects all other medicines." Mr. Long remarks, that the oil intended for medicinal use, is more frequently cold drawn, or extracted from the bruised seeds by means of a hand-press. But this is thought more acrimonious than that prepared by coction. Dr. Brown is also of this opinion, and prefers the oil prepared by coction to that by expression. He attributes its greater mildness to the action of the fire; observing that the expressed oil, as well as the mixed juices of the seeds, are far more active and violent in their operation.

Dr. Cullen observes, that "this oil, when the stomach can be reconciled to it, is one of the most agreeable purgatives we can employ. It has this particular advantage, that it operates sooner after its exhibition than any other purgative I know of, as it commonly operates in two or three hours. It seldom gives any griping, and its operation is generally moderate, producing one, two, or three stools only. It is particularly suited to cases of costiveness, and even to cases of spasmodic colic.

In the West Indies, it is found to be one of the most certain remedies in the dry belly-ach, or colica pictonum. It is seldom found heating or irritating to the rectum; and, therefore, is sufficiently well suited to hæmorrhoidal persons.

The only inconvenience attending the use of this medicine is, that, as an oil, it is nauseous to some persons; and that, when the dose is large, it occasions sickness at the stomach for some time after it is taken. To obviate these inconveniences, several means have been tried; and it is found that the most effectual means is the addition of a little ardent spirit. In the West Indies, they employ rum; but that I might not withdraw any part of the purgative, I employ the *Tinct. sennæ comp.* This, added in the proportion of one to three parts of the oil, and very intimately mixed, by being shaken together in a phial, both makes the oil less nauseous to the taste, and makes it sit more easy on the stomach. The common dose of this oil is a table-spoonful, or half an ounce; but many persons require a double quantity."

Castor-oil possesses the general properties of the fixed vegetable oils, except that it is heavier than most of them. MM. Busy and Lecanu have obtained from it three distinct acids, the *ricinic, elaiodic,* and *margaritic.* The seeds of this plant are a drastic cathartic, though the expressed oil is so mild in its operation.

Ricinus major. See *Jatropha curcas.*

Ricinus vulgaris. See *Ricinus.*

Rickets. See *Rachitis.*

RI'CTUS. (*us, ûs.* m.; from *ringo,* to grin.) The grinning mouth or opening between the two lips of a ringent or personate flower.

RIGID. *Rigidus.* Hard, with some degree of brittleness. In *Botany,* it means inflexible, not easily bending: opposed to limber and flexible.

RI'GOR. (*or, oris.* m.; from ῥιγεω, to shiver.) A sudden coldness, attended by a shivering, more or less perfect,—a symptom which ushers in many diseases, especially fevers and acute inflammation of internal parts: it also is produced by nervous complaints, and by some operations, as passing a bougie, &c. &c.

RI'MA. (*a, æ.* f.) A fissure or opening.

RIMA GLO'TTIDIS. The opening of the larynx, through which the air passes in respiration.

RIMO'SUS. Full of cracks.

RI'MULA. (*a, æ.* f.; diminutive of *rima,* a fissure.) A small fissure.

Rinæus. See *Rhinæus.*

Ring. See *Annulus.*

Ring-worm. See *Porrigo.*

RI'NGENT. *Ringens.* Gaping: applied to flowers or their corollæ, which are irregular and gaping, like the mouth of an animal; as those of the nettle, &c.

A ringent flower is also called lipped or labiate by some botanists.

Risagon. See *Cassumuniar.*

Risigallum. An old name of orpiment.

RI'SUS. (*us, ûs.* m.) Laughter.

Risus caninus. See *Spasmus cynicus.*

Risus sardonicus. *Sardonic laugh. Sardiasis.* A kind of convulsive grin observed chiefly in cases of tetanus and inflammation of the diaphragm. It gives a peculiarly horrible aspect to the countenance. It is named *sardonicus* because it was said to have been produced by eating of a species of ranunculus which grew round certain fountains in Sardinia.

ROASTING. A chemical process, generally performed in crucibles, by which mineral substances are divided, some of their principles being volatilised, and others changed, so as to prepare them for other operations.

ROB. (*Rob*, dense. Arabic.) An old term for an inspissated juice.

Rob antisyphilitique. A French medicine, which consists of a rob or syrup, made of the *arundo phragmites*, sarsaparilla, and aniseed, with the addition of corrosive sublimate.

RO'BORANT. (*Roborans*; from *roboro*, to strengthen.) Synonymous with *corroborant.*

Roccella. See *Lichen roccella.*

Roch alum. Sometimes improperly called *rock* alum. See *Alum.*

Roche's embrocation. A celebrated nostrum for the hooping-cough. It consists of olive oil, mixed with about half its quantity of the oils of cloves and amber.

Rochelle salt. See *Soda tartarisata.*

Rockambole. The *Allium scorodoprasum*, of Linnæus. The root is used for pickles and high-seasoned dishes.

Rock-oil. See *Petroleum.*

Rock-samphire. See *Crithmum.*

Rocket. See *Brassica eruca.*

Rocket, Roman. See *Brassica eruca.*

Rocket, wild. See *Brassica erucastrum.*

Rod-shaped. See *Virgatus.*

ROLLER. A long narrow bandage in common use with surgeons.

Rorella. See *Drosera rotundifolia.*

ROS. (*os, oris.* m.; from the Hebrew.) Dew.

Ros calabrinus. The officinal manna is sometimes so termed.

Ros marinus. See *Rosmarinus.*

Ros solis. See *Drosera rotundifolia.*

RO'SA. (*a, æ.* f.; an ancient and popular name, derived, most probably, from the Celtic, *ros*, or *rhos*; whence comes, also, its Greek synonym ῥοδον, and the name of the same flower in various languages, *rosa, rose*, &c.) 1. The name of a genus of plants in the Linnæan system. Class, *Icosandria*; Order, *Polygynia.* The rose.

2. A name sometimes given to the erysipelas, because it begins with a redness like that of a rose.

Rosa alba. The white rose. The flowers of this species possess similar, but inferior virtues to those of the damask.

Rosa canina. The dog-rose, or wild brier, or hip-tree. *Rosa sylvestris. Cynorrhodon. Cynosbatos. Cynocyticis. Rosa canina — germinibus ovatis pedunculisque glabris, caule petiolisque aculeatis*, of Linnæus. The fruit of this tree, called heps, or hips, has a sourish taste, and obtains a place in the London Pharmacopœia, in the form of conserve. It is seldom employed but to give form to more active remedies, in pills, boluses, linctuses, &c.

Rosa centifolia. The pharmacopœial and systematic name of the damask rose. *Rosa damascena. Rosa pallida.* The pharmacopœias direct a syrup to be prepared from the petals of this rose, *Rosa centifolia — germinibus ovatis pedunculisque hispidis, caule hispido aculeato petiolis inermibus*, of Linnæus; which is found to be a pleasant and useful laxative for children, or to obviate costiveness in adults. Most of the roses, though much cultivated in our gardens, are far from being distinctly characterised. Those denominated varieties are extremely numerous, and often permanently uniform; and the specific differences, as hitherto pointed out, are, in many respects, so inadequate to the purpose of satisfactory discrimination, that it becomes a difficult matter to distinguish which are species and which are varieties only. The damask rose seems to be another species, widely different from the centifolia, as appears from the description given of it by Du Roi and Miller.

The petals are directed for medicinal use: they are of a pale red colour, and of a very fragrant odour, which, to most people, is extremely agreeable; and therefore this, and most of the other roses, are much used as nosegays. We may remark, however, that, in some instances, they have, under certain circumstances, produced alarming symptoms. The petals impart their odorous matter to watery liquors, both by infusion and distillation. Six pounds of fresh roses impregnate, by distillation, a gallon or more of water strongly with their fine flavour. On distilling large quantities, there separates from the watery fluid a small portion of a fragrant butyraceous oil, which liquefies by heat, and appears yellow, but concretes in the cold into a white mass. A hundred pounds of the flowers, according to the experiments of Tachenius and Hoffmann, afforded scarcely half an ounce of oil. The smell of the oil exactly resembles that of roses, and is therefore much used as a perfume. It possesses very little pungency, and has been highly recommended for its cordial and analeptic qualities. These flowers also contain a bitterish substance, which is extracted by water along with the odorous principle, and remains entire in the decoction after the latter has been separated by distillation or evaporation.

This fixed sapid matter of the petals manifests a purgative quality; and it is on this account that the flowers are received in the Materia Medica.

Rosa damascena. See *Rosa centifolia.*

Rosa gallica. The pharmacopœial and systematic name of the red rose. *Rosa rubra.* The flowers of this species, *Rosa gallica — germinibus ovatis pedunculisque hispidis, caule petiolisque hispido aculeatis*, of Linnæus, are valued for their astringent qualities, which are most considerable before the petals expand; and therefore, in this state they are chosen for me-

licinal use, and ordered by the pharmacopœias n different preparations, as those of a conserve, r confection, a honey, an infusion, and a syrup. The infusion of roses is a grateful, cooling sub-stringent, and useful in hæmoptysis, and other æmorrhagic complaints: its efficacy, however, lepends chiefly on the sulphuric acid added.

Rosa pallida. See *Rosa centifolia.*

Rosa rubra. See *Rosa gallica.*

Rosa sylvestris. See *Rosa canina.*

ROSA'CEÆ. A natural family of plants, f which the rose is the type.

ROSA'CEUS. Rose-like. 1. Applied to orolla which spread like a rose; as those of the *Dryas.*

2. The term *gutta rosacea* is applied to little osy-coloured spots upon the face and nose.

ROSACIC ACID. *Acidum rosacicum.* There s deposited from the urine of persons labouring nder gout and inflammatory fevers a sediment f a rose colour, occasionally in reddish crystals. This was first discovered to be a peculiar acid y M. Proust, and afterwards examined by M. Vauquelin. This acid is solid, of a lively cin-abar hue, without smell, with a faint taste, but eddening litmus very sensibly. On burning oal it is decomposed into a pungent vapour, hich has not the odour of burning animal atter. It is very soluble in water, and it even oftens in the air. It is soluble in alkohol. It orms soluble salts with potash, soda, ammonia, arytes, strontites, and lime. It gives a slight ose-coloured precipitate with acetate of lead. t also combines with lithic acid, forming so timate a union, that the lithic acid, in pre-pitating from urine, carries the other, though deliquescent substance, down along with it. t is obtained pure by acting on the sediment of rine with alkohol.

ROSA'LIA. (*a*, *æ*. f.) A name which ems to have been applied both to measles and arlatina.

Rose. See *Rosa.*

Rose, Christmas. See *Helleborus niger.*

Rose, damask. See *Rosa centifolia.*

Rose, dog. See *Rosa canina.*

Rose, red. See *Rosa gallica.*

Rose, white. See *Rosa alba.*

Rose-root. See *Rhodiola.*

Rosea radix. See *Rhodiola.*

Rosebay willow-herb. See *Epilobium angus-folium.*

Rosemary. See *Rosmarinus.*

ROSE'OLA. (*a*, *æ*. f.; from *rosa*, a rose: called from the colour of the rash.) A rose-loured efflorescence, variously figured, with-t wheals, or papulæ, and not contagious. is mostly symptomatic, occurring in con-ection with different febrile complaints, and quiring no deviation from the treatment re-ectively adapted to them.

Its principal varieties are comprised under e seven following heads: —

1. The *Roseola æstiva* appears first on the ce and neck, and in the course of a day or two distributed over the whole body, producing a nsiderable degree of itching and tingling. is distributed into separate small patches, of rious figure, but larger and more irregular forms than in the measles. It is at first red, but soon assumes its deep roseate hue. The fauces are tinged with the same colour, and a slight roughness of the tonsils is felt in swallowing.

The rash continues vivid through the second day; after which it declines in brightness, slight specks only remaining of a dark hue on the fourth day; which, with the constitutional affection, wholly disappear on the fifth.

The efflorescence sometimes is partial, extending only over portions of the face, neck, and upper part of the breast and shoulders, in patches, slightly elevated, and itching considerably; but in this form the disease continues a week or longer, the rash appearing and disappearing several times; sometimes from taking warm liquors, and sometimes without any apparent cause. The retrocession is usually accompanied with disorder of the stomach, headach, and faintness, which are immediately relieved on its appearance. It commonly occurs in females of irritable constitution in summer. Light diets and acidulated drinks, with occasional laxatives, palliate the symptoms.

2. The *Roseola autumnalis* occurs in children in the autumn, in distinct circular or oval patches, which gradually increase to the size of a shilling, and are of a dark damask rose hue. It appears chiefly on the arms, sometimes desquamating, and its decline seems to be expedited by the internal use of sulphuric acid.

3. The *Roseola annulata* occurs on almost every part of the body, in rose-coloured rings, with central areas of the usual colour of the skin. When accompanied with fever, its duration is short: at other times, without any constitutional disorder, it continues for a considerable and uncertain period. The rings are, at first, from a line to two lines in diameter, but, gradually dilating, leave a larger central space, sometimes of the diameter of half an inch. The efflorescence is less vivid (and in the chronic form usually fades) in the morning, but increases in the evening or night, and produces a heat and itching in the skin. When it becomes very faint in colour for several days, the stomach is disordered, and languor, giddiness, and pains of the limbs ensue, which are relieved by the use of the warm bath.

Sea-bathing and the mineral acids afford much relief in the chronic forms of this rash.

4. *Roseola infantilis* is a closer rash, occurring in infants during the irritation of dentition, of disordered bowels, and in fevers. It is very irregular in its appearances, sometimes continuing only for a night, sometimes appearing and disappearing for several successive days, with violent disorder, and sometimes arising in single patches in different parts of the body successively. It is alleviated by the remedies adapted to relieve bowel complaints, painful dentition, and other febrile affections with which it is connected.

5. *Roseola variolosa* occurs previously to the eruption both of the natural and inoculated small-pox, but seldom before the former. It appears in the inoculated disease, on the second

day of the eruptive fever, which is generally the ninth or tenth after inoculation. It is first seen on the arms, breast, and face; and on the following day it extends over the trunk and extremities.

Sometimes it is distributed in oblong irregular patches, sometimes diffused with numerous interstices, and sometimes it forms an almost continuous redness over the whole body, being in some parts slightly elevated. It continues about three days; on the second or last of which the variolous pustules may be distinguished, in the general redness, by their rounded elevation, hardness, and whiteness of their tops.

6. *Roseola vaccina* appears generally in a congeries of dots and small patches, but sometimes diffuse, like the former; it takes place on the ninth or tenth day after vaccination, at the place of inoculation, and at the same time with the areola that is formed round the vesicle, from whence it spreads irregularly over the whole surface of the body.

It is usually attended with a very quick pulse, white tongue, and great restlessness.

7. *Roseola miliaris* often accompanies an eruption of miliary vesicles after fever. It is sometimes connected with attacks of the gout, and of the febrile rheumatism, accompanied with considerable fever, extreme languor and depression of spirits, total loss of appetite, and torpid bowels, and terminates on the seventh day by desquamation.

RO'SEUS. (From *rosa*, the rose.) Of a rose-red colour. See *Colour*.

Rosewood. A beautiful wood well known in commerce. It is said by Don to be the produce of the *Physocalymnia floribunda*. The powder has been used as an errhine.

Rosewort. See *Rhodiola*.

Rosin. See *Resina*.

ROSMARI'NUS. (*us*, *i*. m. No probable derivation has been given of this word.) 1. The name of a genus of plants in the Linnæan system. Class, *Diandria*; Order, *Monogynia*.

2. The pharmacopœial name of the common rosemary. See *Rosmarinus officinalis*.

Rosmarinus hortensis. See *Rosmarinus officinalis*.

Rosmarinus officinalis. The systematic name of the common rosemary. *Rosmarinus hortensis*. *Libanotis coronaria*. *Dendrolibanus*. The leaves and tops of this plant have a fragrant aromatic smell, and a bitterish pungent taste. Rosemary is reckoned one of the most powerful of those plants which stimulate and corroborate the nervous system; it has therefore been recommended in various affections supposed to proceed from debility, or defective excitement of the brain and nerves, as in certain headachs, deafness, giddiness, and in some hysterical and dyspeptic symptoms. The officinal preparations of rosemary are, an essential oil from their leaves, or from the herb in flower, a conserve of the flowers, and a spirit formerly called Hungary water, from the flowery tops. The tops are also used in the compound spirit of lavender and soap liniment.

Rosmarinus sylvestris. See *Ledum*.

ROSTE'LLUM. (*um*, *i*. n.) A little beak. Applied to that part of the seed of a plant which is pointed, penetrates the earth, and becomes the root. See *Corculum*.

ROSTRA'TUS. Rostrate: having a bill or beak. Applied to parts of plants, as the pod of the *Sinapis alba*.

ROS'TRUM. (*um*, *i*. n.; from *rodo*, to gnaw: because birds use it to tear their food with.) 1. A beak.

2. The piece of flesh which hangs between the division of the hare-lip is called *rostrum leporinum*.

3. Applied, in *Botany*, to some elongation of a seed-vessel, originating from the permanent style, as in *Geranium*; though it is also applied to similar prolongations of naked seeds, as in *Scandix*.

Rosy-drop. See *Acne*.

ROTA'CEÆ. (From *rota*, a wheel.) The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of those which have one flat wheel-shaped petal.

ROTA'CEUS. Rotaceous, or wheel-like.

ROTACI'SMUS. (*us*, *i*. m.) The harsh or aspirated vibration of the letter *r* or *ρ*, which is very common in the northern parts of England. It is commonly called a *burr*.

Rotang. See *Calamus rotang*.

ROTA'TOR. (*or*, *oris*. m.; from *roto*, to turn.) A muscle the office of which is to rotate the part upon which it acts.

ROTA'TUS. Rotate, or wheel-like. Applied to the corols, nectary, &c.; as the nectary of the *Cyssampelos*, the corolla of the *Borago officinalis*.

ROTIFERA. An order of infusory animals. See *Animal kingdom*.

RO'TULA. (*a*, *æ*. f.; diminutive of *rota*, a wheel: so called from its shape.) See *Patella*.

Rotundus. See *Round*.

Rouge. See *Carthamus tinctorius*.

ROUND. *Rotundus*. Many parts of animals and vegetables receive this trivial name from their shape; as round ligaments, round foramen, &c., and leaves, stems, seeds, &c.; as the seeds of the *Pisum*, *Brassica*, &c.

Round-leaved sorrel. See *Rumex scutatus*.

Round ligament. *Ligamentum rotundum*. A bundle of vessels and fibres contained in a duplicature of the peritonæum, that proceeds one from each side of the uterus, through the abdominal rings, and disappears in the pudenda.

Rousseau's drops. *Gouttes de l'Abbe Rousseau*. *Laudanum Abbatis Rousseau*. *Vinum opii fermentatione paratum*. Take of honey ℥xij.; warm water, ℔ij.; set it in a warm place till it begins to ferment, then add opium ℥iv. dissolved in ℥xij. of water; let it ferment for a month; evaporate it to ℥x.; strain and add rectified alkohol, ℥iv. ss.

Royal preventive. A quack lotion, consisting of a solution of acetate of lead. It is sold as a preventive against the venereal disease.

Royal stitch. An old operation for the cure of inguinal hernia, which consisted in putting a ligature round the neck of the sac whereby adhesive inflammation was excited.

RUBE'DO. (*o, inis.* f.; from *ruber*, red.) A diffused, but not spotted, redness in any part of the skin; such as that which arises from blushing.

RUBEFA'CIENT. (*Rubefaciens*; from *rubefacio*, to make red.) Any substance is so called which, when applied a certain time to the skin, induces a redness without blistering.

RUBE'OLA. (*a, æ.* f.; from *ruber*, red; or from *rubeo*, to become red.) The measles; called also, *Morbilli*. This disease is known by inflammatory fever, hoarseness, dry cough, sneezing, drowsiness; about the fourth day, eruption of small red points, discernible by the touch, which, after three days, end in mealy desquamation. The blood, after venesection, exhibits an inflammatory crust. In addition to the symptoms already related, it is remarkable, that the eyes and eyelids always show the presence of this disease, being somewhat inflamed and suffused with tears. The fever continues during the whole progress of the disease. In systems of nosology, several varieties of measles are mentioned, but they may all be comprehended under two heads: the one attended with more or less of the symptoms of general inflammation; the other accompanied by a typhoid diathesis.

The measles may prevail at all seasons of the year as an epidemic, but the middle of winter is the time they are usually most prevalent; and they attack persons of all ages, but children are most liable to them. They prove most unfavourable to such as are of a plethoric or scrofulous habit. Like the small-pox, they very seldom affect persons more than once in their life: their contagion appears to be of a specific nature. The eruption is usually preceded by a general uneasiness, chilliness, and shivering; pain in the head, in grown persons; but in children, a heaviness and soreness in the throat; sickness and vomiting, with other affections, such as happen in most fevers; but the chief characteristic symptoms are, a heaviness about the eyes, with swelling, inflammation, and a defluxion of sharp tears, and great acuteness of vision, so that they cannot bear the light without pain, together with a discharge of serous humour from the nostrils, which produces sneezing. The heat, and other febrile symptoms, increase very rapidly; to which succeeds a frequent and dry cough, a stuffing, great oppression, and oftentimes retching to vomit, with violent pains in the loins, and sometimes a looseness; at other times there is great sweating, the tongue foul and white, the thirst very great, and, in general, the fever runs much higher than in the milder sort of the regular small-pox. The eruptions appear about the fourth or fifth day, and sometimes about the end of the third. On the third or fourth day from their first appearance, the redness diminishes, the spots, or very small papulæ, dry up, the cuticle peels off, and is replaced by a new one. The symptoms do not go off on the eruption, as in the small-pox, but kept the vomiting; the cough and headach continue, with the weakness and defluxion on the eyes, and a considerable degree of fever. On the ninth or eleventh day, no trace of redness is to be found, but the skin assumes its wonted appearance; yet, unless there have been some considerable evacuations, either by the skin or by vomiting, the patient will hardly recover strength, but the cough will continue, the fever return with new violence, and bring on great distress and danger.

In the more alarming cases, spasms of the limbs, subsultus tendinum, delirium, or what more frequently happens, coma, supervene. This last symptom so frequently attends the eruptive fever of measles, that by some practitioners it is regarded as one of its diagnostics.

In measles, as in other febrile diseases, the symptoms generally suffer some remission towards the morning, returning, however, in the evening with increased severity.

The measles, even when violent, do not generally manifest a typhoid tendency; but it sometimes happens that such a disposition prevails both in the course of the disease and at its termination. In such cases, petechiæ are to be observed interspersed among the eruptions; and these last become livid, or assume almost a black colour. Hæmorrhages break out from different parts of the body; the pulse becomes frequent, feeble, and perhaps irregular; universal debility ensues; and the patient is destroyed.

In those cases where there is much fever, with great difficulty of breathing, and other symptoms of pneumonic inflammation, or where there is great debility, with a tendency to putrescency, there will always be considerable danger; but the consequences attendant on the measles are in general more to be dreaded than the immediate disease; for although a person may get through it, and appear for a time to be recovered, still hectic symptoms and pulmonary consumption may afterwards arise, and destroy him, or a troublesome ophthalmia perhaps ensue.

Measles, as well as small-pox, not unfrequently call into action a disposition to scrofula, where such happens to exist in the habit. Another bad consequence of the measles is, that the bowels are often left by them in a very weak state; a chronic diarrhœa remaining, which has sometimes proved fatal. Dropsy has also been known as a consequence of measles.

The morbid appearances to be observed on dissections of those who die of measles are pretty much confined to the lungs and intestines, the former of which always show strong marks of inflammation, and sometimes a tendency to sphacelus. Where the patient dies under the eruption, the trachea and its branches, as in the small pox, are often covered with it, which may account for the increase of the cough after the appearance of the eruption.

In the treatment of this disorder, as it usually appears, the object is to moderate the accompanying fever, and attend to the state of certain organs, particularly the lungs and the bowels. When there are no urgent local symptoms, it will be commonly sufficient to pursue the general antiphlogistic plan (avoiding, however, too free or sudden exposure to cold,) keeping the bowels open, and encouraging diaphoresis by mild antimonials, &c. Sometimes, however,

in plethoric habits, especially where the lungs are weak, it will be proper to begin by a moderate abstraction of blood. Where the eruption has been imprudently checked, much distress usually follows, and it will be advisable to endeavour to bring it out again by the warm bath, with other means of increasing the action of the cutaneous vessels. Should an inflammatory determination to the lungs occur, more active evacuations must be practised, as explained under the head of *Pneumonitis*. The cough may be palliated by opium, joined with expectorants, demulcents, &c.; and an occasional emetic will be proper, when there is much wheezing. Where diarrhœa takes place, it is better not to attempt to suppress it at once; but, if troublesome, moderate it by small doses of opium, assisted perhaps by astringents. At the decline of the disorder, much attention is often required to prevent phthisis pulmonalis supervening. Should the disorder ever put on a typhoid character, the general plan pointed out under *Typhus* must be pursued.

Ruber. Red. See *Colour*.

RU'BIA. (*a, æ.* f.; from *ruber*, red: so called from its red roots.) 1. The name of a genus of plants in the Linnæan system. Class, *Tetrandria*; Order, *Monogynia*.

2. The pharmacopœial name of the madder plant. See *Rubia tinctorum*.

Rubia tinctorum. The madder plant. Dyer's madder. *Erythrodanum. Rubia major. Radix rubra. Rubia — foliis annuis, caule aculeato*, of Linnæus. The roots of this plant have a bitterish, somewhat austere taste, and a slight smell, not of an agreeable kind. It was formerly considered as a deobstruent detergent, and diuretic, but it is now very seldom used.

RUBI'GO. (*o, inis.* f.; *à colore rubro*, from its red colour.) Rust.

Rubigo cupri. See *Verdigris*.

Rubigo ferri. See *Ferri sesquioxydum*.

Rubi'nus. (From *ruber*, red: so named from its colour.) See *Anthrax*.

Rubinus verus. See *Anthrax*.

RU'BULA. (*a, æ.* f.; a diminutive of *rubus*, a blackberry, or raspberry.) The specific name, in Good's Nosology, of the yaws. — *Anthracia rubula*.

RU'BUS. (*us, i.* m.; from *ruber*, red: so called from its red fruit.) The name of a genus of plants in the Linnæan system. Class, *Icosandria*; Order, *Polygynia*.

Rubus arcticus. The systematic name of the shrubby strawberry. *Rubus arcticus — foliis alternatis, caule inermi unifloro*. The berries, *Baccæ norlandicæ*, are recommended by Linnæus as possessing antiseptic, refrigerant, and antiscorbutic qualities.

Rubus cæsius. The systematic name of the dewberry plant, the fruit of which resembles the blackberry in appearance and qualities.

Rubus chamæmo'rus. The systematic name of the cloudberry tree, and knot-berries. *Chamæmorus. Chamærubus foliis ribis Anglicæ. Rubus palustris humilis. Vaccinium Lancastrense. Rubus alpinus humilis Anglicus*. The ripe fruit of this plant, *Rubus chamæmorus — foliis simplicibus lobatis, caule interno unifloro*, of Linnæus, is prepared into a jam; and is recommended to allay thirst, &c. in fevers, phthisical diseases, hæmoptysis, &c. As an antiscorbutic, it is said to excel the scurvy-grass, and other vegetables of that tribe in common use.

Rubus fruticosus. The systematic name of the common bramble, which affords blackberries. The berries are eaten in abundance by children, and are wholesome and gently aperient. Too large quantities, however, when the stomach is weak, produce vomiting and great distension of the belly, from flatus.

Rubus idæus. The systematic name of the raspberry. *Batinon. Moron. Rubus idæus — foliis quinato-pinnatis ternatisque, caule aculeato, petiolis canaliculatis*, of Linnæus. The fruit of this plant has a pleasant sweet taste, accompanied with a peculiar grateful flavour, on account of which it is chiefly valued. Its virtues consist in allaying heat and thirst, and promoting the natural excretions. A grateful syrup prepared from the juice was formerly officinal.

RU'CTUS. (*us, ús.* m.) An eructation.

Rue. See *Ruta graveolens*.

Rue, goat's. See *Galega*.

Rue, wall. See *Asplenium murale*.

Rufi pilulæ. Rufus's pills. A compound very similar to the aloëtic pills with myrrh. See *Pilula aloes cum myrrhâ*.

Ru'fus. Of a brownish-red orange or carrot colour.

RUGO'SUS. Rugged; wrinkled: applied to a leaf, when the veins are tighter than the surface between them, causing the latter to swell into little inequalities; as the various species of sage. The seeds of the *Lithospermum arvense* are rugose.

RUM. *Spiritus Jamaicensis*. A spirituous liquor, the produce of the sugar-cane. See *Alkohol*.

RU'MEX. (*ex, icis.* m.; a sort of pike spear, or halberd, which the shape of the leaves in various species much resembles.) The name of a genus of plants in the Linnæan system. Class, *Hexandria*; Order, *Trigynia*. The dock.

Rumex acetosa. The systematic name of the common sorrel. Sour-dock. *Acetosa. Acetosa vulgaris. Acetosa pratensis. Acetosa arvensis. Rumex acetosus — foliis, oblongis sagittatis, floribus diœciis*, of Linnæus. The leaves of this plant are sour, but not the root, which is bitter. It grows in the meadows and common fields.

Rumex acutus. The systematic name of the sharp-pointed wild-dock. *Oxylapathum. Lapathum. Rumex acutus — floribus hermaphroditis, valvulis dentatis graniferis, foliis cordato-oblongis acuminatis*, of Linnæus. The decoction of the root of this plant is used in Germany to cure the itch; and it appears to have been used, in the time of Dioscorides, in the cure of leprous and impetiginous affections, both alone and boiled with vinegar.

Rumex alpinus. The systematic name of the plant which affords the monks' rhubarb. The root is laxative.

Rumex aquaticus. See *Rumex hydrolapathum*.

Rumex crispus. The systematic name of

the crisp-leaved dock, which was formerly used as an antiscorbutic.

RUMEX HYDROLAPATHUM. The systematic name of the water-dock. *Hydrolapathum. Rumex aquaticus. Herba Britannica. Lapathum aquaticum. Rumex hydrolapathum — floribus hermaphroditis, valvulis integris graniferis, foliis lanceolatis*, of Linnæus. The leaves of this plant manifest considerable acidity, and are said to possess a laxative quality. The root is strongly astringent, and has been much employed, both externally and internally, for the cure of some diseases of the skin, as scurvy, lepra, lichen, &c. The root, powdered, is said to be an excellent dentifrice.

RUMEX PATIENTIA. The systematic name of the garden patience. *Lapathum sativum. Hippolapathum. Patientia.* The root of this plant, and that of the *Rumex alpinus*, according to Professor Murray, is supposed to possess the virtues of rhubarb, but in an inferior degree. It is obviously more astringent than rhubarb, but comes very far short of its purgative virtue.

RUMEX SANGUINEUS. The systematic name of the bloody dock, the root of which has an austere and astringent taste, and is sometimes given by the vulgar in the cure of dysentery.

RUMEX SCUTATUS. The systematic name of the French sorrel. Roman, or garden sorrel. Sometimes called *acetosa rotundifolia* in the shops. *Acetosa Romana. Acetosa rotundifolia hortensis. Rumex scutatus — foliis cordato-hastatis, ramis divergentibus, floribus hermaphroditis*, of Linnæus. It is common in our gardens, and in many places is known by the culinary name of green-sauce. Its virtues are similar to those of common sorrel. See *Rumex acetosa*.

RUMINA'TION. (*Ruminatio, onis.* f.) A second mastication, or the chewing of the food that has been swallowed and is again brought back into the mouth. It is commonly called chewing the cud. Among quadrupeds this function is peculiar to the order of animals called *Pecora* by Linnæus and *Ruminantia* by Cuvier.

All *Pecora* have a plurality of stomachs, some two, others three, and some four. In all of them, the stomach is compound, and more complicated, both in structure and appearance, than in any other order of mammalia. Taking the *ox* for a general example of the structure of this organ, the *first* stomach is the *ventriculus*, or *paunch*, which occupies a great part of the abdomen, especially in the left side. It is by much the largest of the four. It has two sacs or appendices externally, and is slightly divided into four apartments internally. The inner surface is covered with innumerable papillæ, of different size in different parts.

The *second* stomach is termed *reticulum*, *bonnet*, or *honey-comb bag*, and appears as a globular appendage of the paunch. It is placed at the left side of the œsophagus, and anterior part of the first, and has generally a thicker muscular coat than the former. Its inner surface is arranged into regular pentagonal cells, and covered with fine papillæ.

The *third* is the smallest, and called *omasum*, or *many plies*. It is situated on the right side of the paunch, is of a globular form, and has a thinner muscular coat than the two former. It consists of numerous broad laminæ sent off from the internal coat, running in a longitudinal direction, alternately varying in breadth, and covered with small granulous papillæ.

The *fourth* stomach, the *obomasum, ventriculus intestinalis, caille* or *red*, has a pyriform appearance, and is next in size to the paunch. It has large longitudinal rugæ, covered with villi, in which circumstance it is somewhat like the stomach of the *dog*. The muscular coat is still thinner than that of the former. The fourth stomach, in the fœtus, with milk curdled in it, forms the *runnet*; but it is observed that in all animals, there is only one digestive stomach, and this has also the power of curdling milk. The inner surface of the three first stomachs is covered only with a fine cuticle, while that of the fourth has the appearance of being a real mucous or secreting membrane.

Upon examining the openings of the stomachs, the œsophagus is observed to open into the right of the paunch, and at the same place by a gutter, into the second and third stomachs. The third leads in, by a narrow opening, to the fourth; and this terminates in the duodenum, which has a pylorus at its origin.

In the different individuals of this order, the stomach varies in proportion as the animal advances towards maturity. While it is young, and fed upon milk, its fourth stomach is the largest. The milk passes at once into this cavity, very little going into the other three. As soon as the creature begins to eat solid food, it acquires the power of ruminating. It lays hold of the grass, &c. by pressing it with the tongue, against the roof of the mouth, and, by the gums of the upper and teeth of the under jaw, assisted by a twist of the head, tears it across. After a slight mastication, the aliment passes into the paunch, and from that, by small portions, into the second stomach. When a considerable quantity has been swallowed, a morsel is thrown back with velocity from the stomach into the mouth, where it is accurately ruminated, and then carried directly to the third stomach, the groove being contracted between this and the two first. This process is continued till the whole of the food has undergone the same operation. In the third and fourth stomachs, a more complete digestion takes place.

The stomachs of the other horned *ruminants* differ little in their nature from that of the *ox*. In the *deer*, the paunch has three pouches appearing externally, and the papillæ are less conspicuous than in the *ox*.

In the *dromedary, camel*, and *lama*, there are four stomachs, as in horned *ruminants*, but the structure is different. In the *camel* and *lama*, there are numerous cells in the substance of the first and second stomachs, formed by strong muscular bands crossing each other at right angles. By the action of these, it is supposed the animals can open or contract at pleasure the mouths of the cells, which serve as reservoirs of the drink, so as to expel the contained fluids, or retain them even for several days. The water they take in is observed to be rendered turbid in

the first stomach, by the mixture with the food, but becomes pure in the second. After rumination, the animal can draw the third stomach to the œsophagus, and receive the ruminated food, without polluting the water in the cells.—*Fyfe.*

A less perfect kind of rumination is observed in some fish, and, as a morbid phenomenon, it sometimes occurs in the human species.

RUNCINA'TUS. (From *runcina*, a saw.) Runcinate: notched. Applied to leaves which are shaped like the tooth of a lion: that is, cut into several transverse acute segments, pointing backwards; as in *Leontodon taraxacum*, called, from the shape of its leaf, *dens de lion*, and hence dandelion.

Rundle. See *Umbel.*

Rundlet. See *Umbellule.*

Runner. See *Sarmentum.*

RUPELLENSIS SAL. (From *Rupella*, *Rochelle*, where it was first made.) See *Soda tartarizata.*

RUPIA. (*a*, *æ*. f.; from ῥυπος, *sordes*, as indicative of the ill smell and sordid condition of the diseased parts.) An eruptive disease, characterised by an appearance of broad and flattish vesicles, in different parts of the body, which do not become confluent: they are slightly inflamed at the base, slow in their progress, and succeeded by an ill-conditioned discharge, which concretes into thin and superficial scabs, that are easily rubbed off, and presently regenerated; which circumstance serves to mark the distinction between rupia and ecthyma, independently of the pustular form, and highly inflamed hard base, of the latter: for the scab of Ecthyma is hard, deeply indented, and surrounded by a deep-seated hardness in the muscular flesh, especially in the larger forms of it. It appears under some varieties of form, which may be included under the following heads: —

1. *Rupia simplex* consists of little vesications, containing, on their first appearance, a clear lymph, and appearing on many parts of the body. In a short time, the fluid included in them begins to thicken, and becomes at length opake and somewhat puriform; a slight ulceration of the skin takes place, with a sanious discharge, followed by scabbing; and, when this heals, it leaves the surface of a livid or blackish colour, as if from a thickening of the rete mucosum.

2. *Rupia prominens* is distinguished by elevated, conical scabs, which are gradually formed upon the vesicated bases. A fluted scab is first generated, and with some rapidity, (*e. g.* in the course of the night), as the fluid of the vesication concretes. This extends itself by the successive small advancement of the red border, upon which a new scab arises, raising the concretion above it, so as ultimately to form a conical crust, not unlike the shell of a small limpet. This scab is quite superficial, and, if it be rubbed off, a new incrustation covers the excoriated spot in the space of six hours. The ulceration, however, is not phagedenic, but at length heals; although it often proves very tedious, especially in old and intemperate persons, in whom, and in young persons of delicate constitution, it most commonly occurs.

These varieties of rupia are to be combated by the means recommended for the cure of ecthyma; *i. e.* by supporting the system, by means of good, light, nutritious diet, and by the use of alterative and tonic medicines; such as Plummer's pill, cinchona, and sarsaparilla.

3. *Rupia escharotica* affects only infants and young children, when in a cachectic state, whether induced by previous diseases, especially the small-pox, or by imperfect feeding and clothing, &c.; whence, among the poor, where it is commonly seen, it often terminates fatally. The vesicles generally occur on the loins, thighs, and lower extremities, and appear to contain a corrosive sanies: many of them terminate with gangrenous eschars, which leave deep pits.

Ruptura. See *Hernia.*

Rupture. See *Hernia.*

Rupture-wort. See *Herniaria.*

RU'SCUS. (ος, *i*. m.; *à russo colore*, from the carnation colour of its berries.) 1. The name of a genus of plants in the Linnæan system. Class, *Diœcia*; Order, *Syngenesia.*

2. The pharmacopœial name of the butcher's-broom. *Ruscus aculeatus.*

RUSCUS ACULEATUS. The systematic name of butcher's-broom, knee-holly. Alexandrian laurel, or wild myrtle. *Bruscus. Oxymyrrhine. Oxymyrsine. Myrtacantha. Myacantha. Scopa regia.* A small evergreen shrub, the *Ruscus aculeatus—foliis supra floriferis nudis*, of Linnæus. It grows in woods and thickets in this country. The root, which is somewhat thick, knotty, and furnished with long fibres, externally brown, internally white, and of a bitterish taste, has been recommended as an aperient and diuretic in dropsies, urinary obstructions, and nephritic cases. It is seldom used in this country.

RUSCUS HYPOGLOSSUM. The systematic name of the *Uvularia.* This plant was formerly used against relaxation of the uvula, but is now laid aside for more astringent remedies.

Rush. See *Arundo.*

Rush-nut. See *Cyperus esculentus.*

Rush, sweet. See *Andropogon schœnanthus* and *Acorus calamus.*

RUSPINI'S STYPTIC. According to Dr. A. Thomson this consists chiefly of a solution of gallic acid in alkohol, diluted with rose-water.

RUSPINI'S TINCTURE. This consists of orris root, cloves, and ambergris, digested in alkohol. It is intended to preserve the teeth.

RUSSIA ASHES. The impure potash, as imported from Russia.

RUST. The powder or crust which forms on metals, especially iron, when exposed to the air.

RU'TA. (*a*, *æ*. f.; from ῥυω, to defend, because it preserves health. (?)) 1. The name of a genus of plants in the Linnæan system. Class, *Decandria*; Order, *Monogynia.*

2. The pharmacopœial name of the common rue. See *Ruta graveolens.*

RUTA GRAVE'OLENS. The systematic name of the common rue. *Ruta graveolens—foliis decompositis, floribus lateralibus quadrifidis*, of Linnæus. Rue has a strong unpleasant smell and a bitter, hot, penetrating taste; the leaves

re so acrid, that by much handling they have been known to irritate and inflame the skin; and the plant, in its natural or uncultivated state, is said to possess these sensible qualities still more powerfully. The imaginary quality of the rue, in resisting and expelling contagion, is now disregarded. It is doubtless a powerful stimulant, and is considered, like other medicines of the fœtid kind, as possessing attenuating, deobstruent, and antispasmodic powers. In the older London Pharmacopœias it was directed in the form of an extract; and was also an ingredient in the *pulvis è myrrhâ comp.*, but these are now omitted. The dose of the leaves is from fifteen grains to two scruples.

Ruta muraria. See *Asplenium murale.*

RUTA'CEÆ. A natural family of plants, of which the genus *Ruta* is the type.

RUTA'CEUM. An infusion of rue in vinegar.

RU'TULA. (From *ruta*, rue.) A small species of rue.

RUYSCHIA'NA TU'NICA. The internal surface of the choroid membrane of the human eye, which Ruysch imagined was a distinct lamina from the external surface.

Ryas. See *Rhœas.*

Rye. See *Secale cereale.*

Rye, spurred. See *Secale cornutum.*

RYMER'S CARDIAC TINCTURE. This consists of capsicum, camphor, cardamom seeds, rhubarb, aloes, and castor, infused in proof spirit, with the addition of a very small quantity of sulphuric acid.

S.

S. A. The contraction of *secundum artem.*

S, or *ss.* Immediately following any quantity, imports *semis*, or half.

Sabadilla. See *Cevadilla.*

Sabadilline. See *Veratria.*

SABI'NA. (*a*, *æ*. f.; named from the Sabines, whose priests used it in their religious ceremonies.) See *Juniperus sabina.*

SA'BULOUS. (*Sabulosus*; from *sabulum*, the gravel.) Gritty; sandy. Applied particularly to the calcareous matter in urine.

SABU'RRA. (*a*, *æ*. f.) Dirt; sordes; filth. Foulness of the stomach, of which authors mention several kinds, as the acid, the bitter, the dyspyreumatic, the insipid, the putrid.

SACCA'TUS. Saccated: encysted, or contained in a bag-like membrane. Applied to dropsical tumours, &c.

Sacchari acidum. See *Mucic acid.*

SA'CCHARUM. (*um*, *i*. n.; Σακχαρον, from *sacchar*, Arabic.) 1. The name of a genus of plants in the Linnæan system. Class, *Triandria*; Order, *Digynia.* The sugar-cane. 2. The sweet substance called sugar. See *Saccharum officinale.*

SACCHARUM ACERNUM. Maple sugar. See *Acer.*

SACCHARUM ALBUM. Refined sugar.

SACCHARUM ALUMINIS. Alum mixed with dragon's blood and dried.

SACCHARUM CANADENSE. Maple sugar. See *Acer.*

SACCHARUM CANDIDUM. Sugar candy.

SACCHARUM NON PURIFICATUM. Brown or unpurified sugar.

SACCHARUM OFFICINALE. The systematic name of the cane from which sugar is obtained. *Arundo saccharifera*, of Sloane. *Saccharum officinarum. Suchar. Succhar. Sutter. Zuchar. Zucro. Zozar* of the Arabians. Σακχαρ and σακχον, of the Greeks. Sugar is prepared in the West and East Indies from the expressed juice of this plant, boiled with the addition of quicklime or common vegetable alkali. It may be extracted also from a number of plants, as the maple, birch, wheat, corn, beet-root, skirret, parsnips, and dried grapes, &c. by digesting in alkohol. The alkohol dissolves the sugar, and leaves the extractive matter untouched, which falls to the bottom. It may be taken into the stomach in very large quantities, without producing any bad consequences, although proofs are not wanting of its mischievous effects, by relaxing the stomach and thus inducing disease. It is much used in pharmacy, as it forms the basis of syrups, lozenges, and other preparations. It is very useful as a medicine, although it cannot be considered to possess much power, to favour the solution or suspension of resins, oils, &c. in water, and is given as a purgative for infants. Dr. Cullen classes it with the attenuantia, and Bergius states it to be saponacea, edulcorans, relaxans, pectoralis, vulneraria, antiseptica, nutriens. In catarrhal affections, both sugar and honey are frequently employed: it has also been advantageously used in calculous complaints; and, from its known power in preserving animal and vegetable substances from putrefaction, it has been given with a view to its antiseptic effects. Sugar-candy, by dissolving slowly in the mouth, is well suited to relieve tickling coughs and hoarseness. Sugar is every where the basis of that which is called sweetness, except, perhaps, in the instance of manna, the sweet principle of which is supposed to be peculiar. See *Mannite.* Its presence is previously necessary in order to the taking place of vinous fermentation. Its extraction from plants, which afford it in the greatest abundance, and its refinement for the common uses of life, in a pure state, are among the most important of the chemical manufactures.

Molasses, or treacle, is the uncrystallisable

part of the juice of the sugar cane which is the refuse of the process for extracting the sugar.

The Indians likewise extract sugar from the pith of the bamboo.

The beet has lately been much cultivated in Germany, for the purpose of extracting sugar from its root. For this the roots are taken up in autumn, washed clean, wiped, sliced lengthwise, strung on threads, and hung up to dry. From these the sugar is extracted by maceration in a small quantity of water; drawing off this upon fresh roots, and adding fresh water to the first roots, which is again to be employed the same way, so as to get out all their sugar, and saturate the water as much as possible with it. This water is to be strained and boiled down for the sugar. Some merely express the juice from the fresh roots, and boil this down; others boil the roots; but the sugar extracted in either of these ways is not equal in quality to the first.

Sugar is very soluble in water, and is a good medium for uniting that fluid with oily matters. It is much used for domestic purposes, and appears, on the whole, to be a valuable and wholesome article of food, the uses of which are most probably restricted by its high price.

It appears that sugar has the property of rendering some of the earths soluble in water.

The union of sugar with the alkalis has been long known; but this is rendered more strikingly evident by carbonated potash or soda, for instance, decomposing the solutions of lime and strontia in sugar, by double affinity.

Kirchoff, an ingenious Russian chemist, accidentally discovered that starch is convertible into sugar, by being boiled for some time with a very dilute sulphuric acid. Saussure showed, that 100 parts of starch yield 110 of sugar.

The varieties of sugar are, — cane sugar, maple sugar, liquid sugar of fruits, sugar of figs, sugar of grapes, starch sugar, the mushroom sugar of Braconnot, manna, sugar of gelatine, sugar of honey, and sugar of diabetes.

All honeys contain two species of sugar; one similar to sugar of the grape, another like the uncrystallisable sugar of the cane (molasses). These, combined and mingled in different proportions with an odorant matter, constitute the honeys of good quality. Those of inferior quality contain, besides, a certain quantity of wax and acid: the honeys of Brittany contain even an animal secretion (*couvain*), to which they owe their putrescent quality. A slight washing with a little alkohol separates the uncrystallisable sugar, and leaves the other, which may be purified by washing with a very little more alkohol.

Saccharum officinarum. See *Saccharum officinale.*

Saccharum purificatum. Refined or loaf-sugar.

Saccharum saturni. See *Plumbi acetas.*

Saccho-lactic acid. (*Acidum saccho-lacticum*; from *saccharum*, sugar, and *lac*, milk.) See *Mucic acid.*

Saccholactate. (*Saccholactas, atis.* f.) A salt formed by the combination of the saccholactic acid with salifiable bases; as saccholate of iron, saccholate of ammonia, &c. &c.

SA'CCULUS. (*us, i.* m.; diminutive of *saccus*, a bag.) A little bag.

Sacculi adiposi. The bursæ mucosæ of the joints.

Sacculus chyliferus. See *Receptaculum chyli.*

Sacculus cordis. The pericardium.

Sacculus lachrymalis. The lachrymal sac. See *Lachrymal apparatus.*

SA'CCUS. (*us, i.* m.) A bag.

Saccus lachrymalis. The lachrymal sac. See *Lachrymal apparatus.*

SA'CER. (From *sagur*, secret, Heb.) Sacred. Applied to some diseases which were supposed to be immediately inflicted on mankind by the Divinity or his ministers: hence *morbus sacer*, the epilepsy; *ignis sacer*, the erysipelas, &c.

A bone is called the *os sacrum*, because it was once offered in sacrifices. See *Sacrum.*

SACK. (This word is probably derived from *sec*, dry.) A wine used by our ancestors, which some have taken to be Rhenish, and others Canary wine. Probably it was what is called dry mountain, or some Spanish wine of that sort. Howell, in his French and English Dictionary, 1650, translated sack by the words vin d'Espagne, vin sec.

SACLA'CTATE. A combination of saccho-lactic acid with a salifiable basis.

SACLA'CTIC. *Saclacticus.* An abbreviation of saccharo-lactic; and so called, because it is obtained from sugar of milk. Of or belonging to the peculiar acid to which the term is applied.

Saclactic acid. See *Saccholactic acid.*

Sacra herba. See *Verbena officinalis.*

Sacra tinctura. Made of aloes, canella alba, and mountain wine.

SA'CRAL. *Sacralis.* Of or belonging to the sacrum; as sacral arteries, veins, nerves, &c.

Sa'cro-coccygæus. A muscle arising from the sacrum, and inserted into the os coccygis.

Sa'cro-lumba'lis. *Sacro-lumbaris*, of authors. A long muscle, thicker and broader below than above, and extending from the os sacrum to the lower part of the neck, under the serrati postici rhomboideus, trapezius, and latissimus dorsi. It arises, in common with the longissimus dorsi, tendinous without, and fleshy within, from the posterior part of the os sacrum; from the posterior edge of the spine of the ilium; from all the spinous processes; and from near the roots of the transverse processes of the lumbar vertebræ. At the bottom of the back it separates from the longissimus dorsi, with which it had before formed, as it were, only one muscle, and ascending obliquely outwards, gradually diminishes in thickness, and terminates above in a very narrow point. From the place where it quits the longissimus dorsi, to that of its termination, we find it fleshy at its posterior, and tendinous at its anterior edge. This tendinous side sends off as many long and thin tendons as there are ribs. The lowermost of these tendons are broader, thicker, and shorter than those above: they are inserted into the inferior edge of each rib, where it begins to be curved forwards towards the sternum, excepting only the

uppermost and last tendon, which ends in the posterior and inferior part of the transverse process of the last vertebra of the neck. From the upper part of the five, six, seven, eight, nine, ten, or eleven lower ribs (for the number, though most commonly seven or eight, varies in different subjects), arise as many thin bundles of fleshy fibres, which, after a very short progress, terminate in the inner side of this muscle, and have been named by Steno, *musculi ad sacro lumbalem accessorii*. Besides these, we find the muscle sending off a fleshy slip from its upper part, which is inserted into the posterior and inferior part of the transverse processes of the five inferior vertebræ of the neck, by as many distinct tendons. This is generally described as a distinct muscle. Diemerbroeck, and Douglas and Albinus after him, call it *cervicalis descendens*; Winslow names it *transversalis collateralis colli*. Morgagni considers it as an appendage to the sacro-lumbalis. The uses of this muscle are to assist in erecting the trunk of the body, in turning it upon its axis or to one side, and in drawing the ribs downwards. By means of its upper slip, it serves to turn the neck obliquely backwards, or to one side.

SA'CRO-SCIA'TIC LIGAMENTS. The ligaments which connect the ossa innominata with the os sacrum.

SA'CRUM. (*um*, *i.* n.; so called from *sacer*, sacred: because it was formerly offered in sacrifices.) *Os sacrum*. *Os basilare*. The os sacrum derives its name from its being offered in sacrifice by the ancients, or perhaps from its supporting the organs of generation, which they considered as sacred. In young subjects it is composed of five or six pieces, united by cartilage; but in more advanced age it becomes one bone, in which, however, we may still easily distinguish the marks of the former separation. Its shape has been sometimes compared to an irregular triangle; and sometimes, and perhaps more properly, to a pyramid flattened before and behind, with its basis placed towards the lumbar vertebræ, and its point terminating in the coccyx. We find it convex behind, and slightly concave before, with its inferior portion bent a little forwards. Its anterior surface is smooth, and affords four, and sometimes five transverse lines, of a colour different from the rest of the bone. These are the remains of the intermediate cartilages by which its several pieces were united in infancy. Its posterior convex surface has several prominencies, the most remarkable of which are its spinous processes: these are usually three in number, and gradually become shorter, so that the third is not so long as the second, nor the second as the first. This arrangement enables it to sit with ease. Its transverse processes are formed into one oblong process, which becomes gradually smaller as it descends. At the superior part of the bone we observe two oblique processes, of a cylindrical shape, and somewhat concave, which are articulated with the last of the lumbar vertebræ. At the base of each of these oblique processes is a notch, which, with the like another in the vertebræ above it, forms a passage for the twenty-fourth spinal nerve. In viewing this bone, either before or behind, we observe four, and sometimes five holes on each side, situate at each extremity of the transverse lines which mark the divisions of the bone. Of these holes, the anterior ones, and of these again, the uppermost, are the largest, and afford a passage to the nerves. The posterior holes are smaller, covered with membranes, and destined for the same purpose as the former. Sometimes at the bottom of the bone there is only a notch, and sometimes there is a hole common to it and the os coccygis. The cavity between the body of this bone and its processes, for the lodgment of the spinal marrow, is triangular, and becomes smaller as it descends, till at length it terminates obliquely on each side at the lower part of the bone. Below the third division of the bone, however, the cavity is no longer completely bony, as in the rest of the spine, but is defended posteriorly only by a very strong membrane; hence a wound in this part may be attended with the most dangerous consequences. This bone is articulated above, with the last lumbar vertebræ; laterally, it is firmly united, by a broad irregular surface, to the ossa innominata, or hip-bones; and below it is joined to the os coccygis. In women the os sacrum is usually shorter, broader, and more curved than in men, by which means the cavity of the pelvis is more enlarged.

Safety lamp. See *Carburetted hydrogen*.

Safflower. See *Carthamus*.

Saffron. See *Crocus*.

Saffron, bastard. See *Carthamus*.

Saffron flower. See *Carthamus*.

Saffron, meadow. See *Colchicum*.

SAFFRON OF STEEL. A red oxide of iron.

SAGAPE'NUM. (*um*, *i.* n.; the name is derived from some eastern dialect.) *Serapinum*. It is conjectured that this concrete gummi-resinous juice is the production of an umbelliferous plant. What that plant is, remains unknown. Sagapenum is brought from Persia and Alexandria, in large masses, externally yellowish, internally paler, and of a horny clearness. Its taste is hot and biting, its smell of the alliaceous and fœtid kind, and its virtues are similar to those which have been ascribed to assafœtida, but weaker, and consequently it is less powerful in its effects.

Sage. See *Salvia*.

Sage of Bethlehem. See *Pulmonaria*.

Sage of Jerusalem. See *Pulmonaria*.

Sage of virtue. See *Salvia hortensis minor*.

SAGI'TTAL. (*Sagittalis*; from *sagitta*, an arrow.) Shaped like an arrow.

SAGITTAL SUTURE. (*Sutura sagittalis*; so named from its lying between the coronal and lambdoidal sutures, as an arrow betwixt the string and the bow.) *Sutura virgata*, *obelwa*, *rhabdoides*. The suture which unites the two parietal bones.

SAGITTA'RIA. (*a*, *æ.* f.; so called from *sagitta*, an arrow, in allusion to the shape of the leaves in the original species and some others.) The name of a genus of plants in the Linnæan system. Class, *Monœcia*; Order, *Polyandria*.

SAGITTARIA ALEXIPHARMACA. The systematic name of the plant, — called also, *Malacca*,

Canna indica, and *Arundo indica*, — cultivated with great care in the West Indies, for its root, which is supposed to be a remedy for the wounds of poisoned arrows. The root of this species, called *radix malacca*, is sometimes used medicinally.

SAGITTARIA SAGITTIFOLIA. The systematic name of the common arrow-head, the roots of which are esculent, but not very nutritious.

SAGITTA'TUS. (From *sagitta*, an arrow.) Arrow-shaped: applied to leaves, &c. which are triangular and hollowed out very much at the base; as the leaves of the *Sagittaria sagittifolia*.

Sago. See *Cycas circinalis*.

Sagu. See *Cycas circinalis*.

St. Anthony's fire. See *Erysipelas*.

St. Ignatius's bean. See *Ignatia amara*.

St. James's wort. See *Senecio jacobæa*.

St. John's wort. See *Hypericum*.

St. Peter's wort. See *Hypericum*.

St. Vitus's dance. See *Chorea*.

SAL. (*al, alis*. m. and, rarely, neut.; from the Greek ἁλς, salt.) Salt. This term has been usually employed to denote a compound, in definite proportions, of acid matter, with an alkali, earth, or metallic oxide. When the proportions of the constituents are so adjusted, that the resulting substance does not affect the colour of infusion of litmus, or red cabbage, it is then called a neutral salt. When the predominance of acid is evinced by the reddening of these infusions, the salt is said to be acidulous, and the prefix, *super*, or *bi*, is used to indicate this excess of acid. If, on the contrary, the acid matter appears to be in defect, or short of the quantity necessary for neutralising the alkalinity of the base, the salt is then said to be with excess of base, and the prefix *sub* is attached to its name. The discoveries of Sir H. Davy have, however, taught chemists to modify their opinions concerning the constitution of salts. Many bodies, such as culinary salt, and muriate of lime, to which the appellation of *salt* cannot be refused, have not been proved to contain either acid or alkaline matter; but must, according to the strict logic of chemistry, be regarded as compounds of chlorine with metals.

Sal absinthii. See *Potassæ carbonas*.

Sal acetosellæ. See *Oxalis acetosella*.

SAL ÆGYPTIACUM. Nitre.

Sal alembroth. See *Alembroth*.

Sal alkalinus fixus. See *Alkali fixum*.

Sal alkalinus volatilis. See *Ammonia*.

SAL AMMONIAC. (So called, because it was found in Egypt, near the temple of Jupiter Ammon.) See *Ammoniæ murias*.

Sal ammoniacum acetosum. See *Ammoniæ acetatis liquor*.

Sal ammoniacum liquidum. See *Ammoniæ acetatis liquor*.

Sal ammoniacum martiale. See *Ferri ammonio-chloridum*.

Sal ammoniacum secretum glauberi. See *sulphas ammoniæ*.

Sal ammoniacum vegetabile. See *Ammoniæ acetatis liquor*.

SAL AMMONIACUS FIXUS. The muriate of lime was formerly so termed.

Sal ammoniacus nitrosus. See *Nitras ammoniæ*.

SAL ANTIMONII. Tartar emetic.

SAL ARGENTI. Nitrate of silver.

Sal catharticus amarus. See *Magnesiæ sulphas*.

Sal catharticus Anglicanus. See *Magnesiæ sulphas*.

Sal catharticus Glauberi. See *Sodæ sulphas*.

SAL CHALYBIS. Salt of steel. Sulphate of iron.

Sal communis. See *Sodii chloridum*.

Sal cornu cervi volatilis. See *Ammoniæ subcarbonas*.

Sal culinaris. See *Sodii chloridum*.

Sal de duobus. See *Potassæ sulphas*.

SAL DIGESTIVUS. Muriate of potash.

SAL DIGESTIVUS SYLVII. Acetate of potash.

Sal diureticus. See *Potassæ acetas*.

Sal epsomensis. See *Magnesiæ sulphas*.

SAL FEBRIFUGUS SYLVII. Muriate of potash.

Sal fontium. See *Sodæ murias*.

Sal fossilis. See *Sodæ murias*.

Sal gemmæ. See *Sodæ murias*.

Sal glauberi. See *Sodæ sulphas*.

Sal herbarum. See *Potassæ carbonas*.

Sal marinus. See *Sodii chloridum*.

Sal martis. See *Ferri sulphas*.

Sal martis muriaticum sublimatum. See *Ferri ammonio-chloridum*.

SAL MICROCOSMICUS. Microcosmic salt. The compound saline matter obtained by inspissating human urine.

Sal mirabilis Glauberi. See *Sodæ sulphas*.

Sal muriaticus. See *Sodii chloridum*.

SAL PERLATUM. Phosphate of soda.

Sal plantarum. See *Potassæ carbonas*.

Sal polychrestus. See *Potassæ sulphas*.

Sal polychrestus Glaseri. See *Potassæ sulphas*.

Sal polychrestus Seignetti. See *Soda tartarizata*.

SAL PRUNELLÆ. Nitrate of potash, cast into flat cakes or round balls.

Sal Rupellensis. See *Soda tartarizata*.

Sal saturni. See *Plumbi acetas*.

Sal sedativus. See *Boracic acid*.

SAL SEIDLICENSIS. Sulphate of magnesia. See *Sedlitz*.

Sal Seignetti. See *Sodæ tartarizata*.

Sal succini. See *Succinic acid*.

Sal tartari. See *Tartaric acid*.

Sal thermarum carolinarum. See *Magnesiæ sulphas*.

Sal vegetabilis. See *Potassæ tartras*.

Sal volatilis. See *Spiritus ammoniæ aromaticus*, and *Ammoniæ subcarbonas*.

Sal volatilis salis ammoniaci. See *Ammoniæ subcarbonas*.

SALEP. *Salap*. See *Orchis morio*.

SALICA'RIA. (*a, æ*. f.; from *salix*, a willow from the resemblance of its leaves to those of the willow.) See *Lythrum salicaria*.

SA'LICINE. *Salicina*. An alkali discovered by M. Leroux in the bark of several species of willow. It is an intense bitter, and for a time gained reputation as a substitute for quinine in ague, which, however, it has failed to maintain. It is a very valuable stomachic bitter, and often

rees with the stomach where quinine proves o stimulating.

SALICO'RNIA. (*a*, *æ*. f.) The name of genus of plants in the Linnæan system. lass, *Monandria*; Order, *Monogynia*.

SALICORNIA EUROPÆA. The systematic name the jointed glasswort. This plant is gathered the country-people, and sold for samphire. forms a good pickle with vinegar, and is ttle inferior to the samphire.

SALIFI'ABLE. Having the property of rming a salt. The alkalis, and those earths d metallic oxides which have the power of utralising acidity, entirely or in part, and oducing salts, are called salifiable bases.

SALI'NE. (*Salinus*; from *sal*, salt.) Of a t nature. The number of saline substances very considerable, and they possess peculiar aracters by which they are distinguished from ner substances. These characters are founded certain properties, which, it must be conssed, are not accurately distinctive of their e nature. All such substances, however, as ssess several of the four following properties considered as saline: — 1. A strong tenncy to combination, or a very strong affinity composition. 2. A greater or lesser degree sapidity. 3. A greater or lesser degree of ubility in water. 4. Perfect incombustiity.

Salinuca. See *Valeriana celtica*.

SALI'VA. (*a*, *æ*. f.; so called, *à salino ore*, from its salt taste, or from σιαλος, spit-) The fluid which is secreted by the salivary nds into the cavity of the mouth. The *retory organ* is composed of three pair of vary glands: —

1. The *parotid glands*, which evacuate their va by means of the *Stenonian duct*, behind middle dens molaris of the upper jaw.

2. The *submaxillary glands*, which pour out ir saliva through the *Warthonian ducts*, on h side of the frenulum of the tongue, by a row osculum.

3. The *sublingual glands*, situated between the rnal surface of the maxilla and the tongue, ch pour out their saliva through numerous *vinian ducts* at the apex of the tongue.

The saliva in the cavity of the mouth has ed with it, 1. The *mucus of the mouth*, ch exhales from the labial and genal glands. A *roscid vapour*, from the whole surface of cavity of the mouth. The saliva is conally swallowed with or without masticated d, and some is also spit out. It has no *ur* nor *smell*; it is *tasteless*, although it con- s a little salt, to which the nerves of the gue are accustomed. Its *specific gravity* is ewhat greater than water. Its *consistence* ather plastic and spumous, from the engled atmospheric air. The *quantity* of twelve nds is supposed to be secreted in twelve rs. During mastication and speaking, the etion is augmented, from the mechanical ssure of the muscles upon the salivary ds. Those who are hungry secrete a great ntity, from the sight of agreeable food. It mperfectly dissolved by water; somewhat gulated by alkohol; and congealed with more difficulty than water. It is inspissated by a small dose, and dissolved in a large dose, of mineral acids. It is also soluble in carbonated alkali. Caustic alkali and quicklime extract volatile alkali from saliva. It corrodes copper and iron; and precipitates silver and lead from containing muriatic acid. It assists the spirituous fermentation of farinaceous substances; hence barbarous nations prepare an inebriating drink from the chewed roots of the *Jatropha manihot* and *Piper methisticum*. It possesses an antiseptic virtue, according to the experiments of the celebrated Pringle. It easily becomes putrid in warm air, and gives off volatile alkali.

Constituent principles. Saliva appears to consist, in a healthy state of the body, of water, which constitutes at least four fifths of its bulk, mucilage, albumen, muriate of soda, phosphate of soda, phosphate of lime, and phosphate of ammonia.

The use of the saliva. 1. It augments the taste of the food, by the evolution of sapid matter. 2. During mastication, it mixes with, dissolves, and resolves into its principles, the food, and changes it into a pultaceous mass, fit to be swallowed: hence it commences chymification. 3. It moderates thirst, by moistening the cavity of the mouth and fauces.

SALI'VAL. (*Salivalis*; from *saliva*, the spittle.) Of or belonging to the saliva.

SALIVAL DUCTS. The excretory ducts of the salival glands. That of the parotid gland is called the *Stenonian* duct; those of the submaxillary glands, the *Warthonian* ducts; and those of the sublingual, the *Rivinian* ducts.

SALIVAL GLANDS. Those glands which secrete the saliva are so termed. See *Saliva*.

SALI'VANS. (From *saliva*, spittle.) Productive of salivation.

SALIVA'RIA. (*a*, *æ*. f.; from *saliva*, the spittle: so called because it excites a discharge of saliva.) See *Anthemis pyrethrum*.

Salivaris herba. See *Anthemis pyrethrum*.

SA'LIVARY. The same as *salival*.

SALIVA'TION. (*Salivatio*, *onis*. f.; from *saliva*, the spittle.) See *Ptyalism*.

SA'LIX. (*ix*, *icis*. f.; from *sala*, Heb.) 1. The name of a genus of plants in the Linnæan system. Class, *Diœcia*; Order, *Diandria*. The willow.

2. The pharmacopœial name of *Salix*. See *Salix fragilis*.

Salix alba. See *Salix fragilis*.

SALIX CAPREA. The systematic name of a species of willow, the bark of the branches of which possesses the same virtues with that of the fragilis.

Salix Ægyptica. See the *Supplement*.

SALIX FRAGILIS. The systematic name of the common crack willow. The bark of the branches of this species manifests a considerable degree of bitterness to the taste, and is very astringent. It is recommended as a good substitute for Peruvian bark, and is said to cure intermittents and other diseases requiring tonic and astringent remedies. Not only the bark of this species of salix, but those also of several others, possess similar qualities, particularly of

the *Salix alba* and *Salix pentandra*, both of which are recommended in the foreign pharmacopœias. But Dr. Woodville is of opinion that the bark of the *Salix triandra* is more effectual than that of any other of this genus; at least its sensible qualities give it a decided preference. The trials Dr. Cullen made were with the bark of the *Salix pentandra*, taken from its branches, the third of an inch diameter, and of four or five years' growth. Nevertheless, he adds, in intermittent fevers, Bergius always failed with this bark. Willow bark contains a peculiar alkali. See *Salicine*.

Salix pentandra. The bark of the branches of this species of willow possesses the same virtues as that of the fragilis.

Salix vitulina. The bark of the branches of this species of willow may be substituted for the fragilis.

SA'LMO. (*o, onis.* m.; so called *à saliendo.*) The name of a genus of fishes, of the order *Abdominales*. The salmon.

Salmo alpinus. The red charr. This beautiful and delicate little fish, and the *Salmo carpio*, or gilt charr, are found in our lakes of Westmorland, in Wales, and Scotland. They are very rich, and hard of digestion.

Salmo eperlanus. The smelt. A beautiful little fish, found in great abundance in the Thames and river Dee, and in the European seas, between November and February. It is a great delicacy when in season, but not easy of digestion in weak stomachs.

Salmo fario. The common fresh-water trout, the flesh of which is very delicate and rich, but hard of digestion.

Salmo lacustris. The lake-trout.

Salmo salar. The common salmon. This fish is considered as one of the greatest delicacies. It is rich, and of difficult digestion to weak stomachs, and with some whose stomachs are not particularly feeble, it uniformly disagrees. The pickled, salted, and smoked, though much eaten, are only fitted for the very strong and active.

Salmo salmulus. The samlet: the least of the British species of the salmo genus. It is found in the river Wye, and up the Severn.

Salmo thymallus. The grayling salmon, which is somewhat like the trout. It inhabits the rivers of Derbyshire, and some of the north, and near Christchurch in Hampshire. It is much esteemed for the delicacy of its flesh, which is white, firm, and of a fine flavour; and is considered as in the highest season in the depth of winter.

Salmo trutta. The bill trout.

Salmon. See *Salmo salar.*

Salpi'ngo-pharynge'us. (From σαλπιγξ, a trumpet, and φαρυγξ, the pharynx.) This muscle is composed of a few fibres of the palato-pharyngeus, which it assists in dilating the mouth of the Eustachian tube.

Salpi'ngo-staphili'nus. [(From σαλπιγξ, a trumpet, and σταφυλη, the uvula.) See *Levator palati.*

Salpingo-staphilinus internus. See *Levator palati.*

Salsafy. See *Tragopogon pratense.*

SALSO'LA. (*a, æ.* f.; so called from its saline properties; hence the English word salt-wort, most of the species affording the fossile alkali.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia*.

Salsola kali. *Kali spinosum cochleatum. Tragus sive Tragum Matthioli.* Snail-seeded glass-wort or salt-wort. The systematic name of a plant which affords the mineral alkali. See *Soda.*

Salsola sativa. The systematic name of a plant, which also affords the mineral alkali. See *Soda.*

Salsola soda. The systematic name of a plant which likewise affords mineral alkali. See *Soda.*

Salt. See *Sal.*

Salt, acid. 1. A salt which has an acid for one of its constituents.

2. A salt in which there is some free acid, which is known by its sour taste when diluted with water.

Salt, alkaline. One which has an alkali as one of its constituents. See *Alkali.*

Salt, ammoniacal fixed. Muriate of lime.

Salt, bitter purging. Sulphate of magnesia.

Salt, cathartic. See *Magnesiæ sulphas*, and *Sodæ sulphas.*

Salt, common. See *Sodæ murias.*

Salt, digestive. The muriate of potash.

Salt, diuretic. The acetate of potash.

Salt, Epsom. See *Magnesiæ sulphas.*

Salt, febrifuge of Sylvius. The muriate of potash.

Salt, fossil. The muriate of soda found in the earth.

Salt, fusible. Phosphate of ammonia.

Salt, fusible, of urine. A triple phosphate of soda and ammonia.

Salt, microcosmic. A triple phosphate of soda and ammonia.

Salt, nitrous ammoniacal. Nitrate of ammonia.

Salt, neutral. Under the name of neutral or secondary salts are comprehended such matters as are composed of two primitive saline substances, combined together in a certain proportion. These salts are called neutral, because they do not possess the characters of primitive salts; that is to say, they are neither acid nor alkaline; such as Epsom salts, nitre, &c. But in many secondary salts the qualities of one ingredient predominate; thus tartar, or supertartrate of potash, has an excess of acid; borax, or subborate of soda, an excess of base. The former are termed acidulous, the latter subalkaline salts.

Salt of amber. Succinic acid.

Salt of benzoin. Benzoic acid.

Salt of colcothar. Sulphate of iron.

Salt of Saturn. Acetate of lead.

Salt of Sedlitz. Sulphate of magnesia.

Salt of sorrel. Superoxalate of potash.

Salt, Rochelle. See *Soda tartarizata.*

Salt, sea. See *Sodii chloridum.*

Salt of steel. See *Ferri sulphas.*

Salt, polychrest. Sulphate of potash.

Salt, secondary. See *Neutral salt.*
SALT, SEDATIVE. Boracic acid.
SALT, SPIRIT OF. Muriatic acid.
SALT OF VITRIOL. Sulphate of zinc.
SALT OF WISDOM. Sal alembroth.
SALT, PRIMITIVE. Under this order is comehended those salts which are thought to be mple or primitive, and which are occasionally lled simple salts. This order is divided into ree genera, comprehending saline terrestrial bstances, alkalis, and acids.
Saltpetre. See *Nitre.*
Saltwort. See *Salsola kali.*
SALVATE'LLA. (From *salus*, health; cause the opening of this vein was formerly ought to be of singular use in melancholy.) his vein runs along the little finger, unites on the back of the hand with the cephalic of e thumb, and empties its blood into the interl and external cubital veins.
SALVE. The common name for an ointment. e *Unguentum.*
Salver-shaped. See *Hypocrateriform.*
SA'LVIA. (*a*, *æ*. f.; *à salvendo.*) 1. The me of a genus of plants in the Linnæan sysm. Class, *Diandria*; Order, *Monogynia.* Sage. 2. The pharmacopœial name of the common ge. See *Salvia officinalis.*
SALVIA HORTENSIS MINOR. The small sage, sage of virtue. A variety of the officinal ge, possessing similar virtues.
Salvia lyrata. See the *Supplement.*
SALVIA OFFICINALIS. The systematic name the garden sage: called also, *Elelisphacos. via — foliis lanceolato ovatis integris crenulatis, ribus spicatis, calicybus acutis,* of Linnæus. ancient times sage was celebrated as a remedy great efficacy, as would appear from the foling lines of the school of Salernum: —

"*Cur moriatur homo, cui salvia crescit in horto?*
Contra vim mortis, non est medicamen in hortis?
Salvia salvatrix, naturæ conciliatrix.
Salvia cum ruta faciunt tibi pocula tuta."

t at present it is not considered as an article much importance. It has a fragrant strong ell; and a warm, bitterish, aromatic taste, other plants containing an essential oil. It aid to have the property of resisting the puaction of animal substances, and is in frequent among the Chinese as a tonic, in the form ea, in debility of the stomach and nervous em.
SALVIA SCLAREA. The systematic name of garden clary, called *Horminum* in the pharopœias, and anciently *Bisermas*, and *Sclarea anica.* The leaves and seeds are recomded as corroborants and antispasmodics, icularly in leucorrhœas and hysterical weakses. They have a bitterish, warm taste, and rong smell, of the aromatic kind. The s are infused in white wine, and imitate cadel.
Salvia vitæ. See *Asplenium murale.*
SAMARA. (*a*, *æ*. f.; the name, according Pliny, of the fruit of the elm.) 1. The e of a genus of plants in the Linnæan em. Class, *Tetrandria*; Order, *Monogynia.*

2. A species of capsule of a compressed form, and dry coriaceous texture, with one or two cells, never bursting, but falling off entire, and dilated into a kind of wing at the summit or sides. In *Fraxinus*, it goes from the summit of the seed: in *Acer* and *Batula*, from the side: in *Ulmus campestris*, it goes all round.
SAMBU'CUS. (*us*, *i*. f.; from *sabucca*, Heb. a musical instrument formerly made of this tree.) Elder. 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Trigynia.*
2. The pharmacopœial name of the elder-tree. See *Sambucus nigra.*
SAMBUCUS E'BULUS. The systematic name of the dwarf-elder, or dane-wort; called also, *Ebulus, Chamæacte, Sambucus humilis,* and *Sambucus herbacea.* The root, interior bark, leaves, flowers, berries, and seeds of this herbaceous plant, *Sambucus — cymis trifidis, stipulis foliaceis, caule herbaceo,* of Linnæus, have all been administered medicinally, in moderate doses, as resolvents and deobstruents, and, in larger doses, as hydragogues. The plant is chiefly employed by the poor of this country, amongst whom it is in common use as a purgative; but Dr. Cullen speaks of it as a violent remedy.
SAMBUCUS NIGRA. The systematic name of the elder tree; which is also called, *Sambucus vulgaris, Sambucus arborea, Acte,* and *Infelix lignum.* The *Sambucus — cymis quinquepartitis, foliis pinnatis, caule arboreo,* of Linnæus. This indigenous plant has an unpleasant narcotic smell, and some authors have reported its exhalations to be so noxious, as to render it unsafe to sleep under its shade. The parts of this tree that are proposed for medicinal use in the pharmacopœias are the inner bark, the flowers, and the berries. The first has scarcely any smell, and very little taste: on first chewing, it impresses a degree of sweetness, which is followed by a very slight but durable acrimony, in which its powers seem to reside. From its cathartic property it is recommended as an effectual hydragogue by Sydenham and Boerhaave: the former directs three handfuls of it to be boiled in a quart of milk and water, till only a pint remains, of which one half is to be taken night and morning, and repeated for several days: it usually operates both upwards and downwards, and upon the evacuation it produces its utility depends. Boerhaave gave its expressed juice in doses from a drachm to half an ounce. In smaller doses it is said to be an useful aperient and deobstruent in various chronic disorders. The flowers have an agreeable flavour; and infusions of them, when fresh, are gently laxative and aperient. When dry, they are said to promote chiefly the cuticular excretion, and to be particularly serviceable in erysipelatous and eruptive disorders. Externally they are used in fomentations, &c.; and in the London Pharmacopœia are directed in the form of an ointment. The berries in taste are somewhat sweetish, and not unpleasant; on expression they yield a fine purple juice, which proves an useful aperient and resolvent in some chronic diseases, gently loosening the belly, and promoting the urine and perspiration.

Samphire. See *Crithmum.*

Sampsu'chus. See *Sampsuchum.*

SAMPSUCHUM. (From σαω, to preserve, and ψυχη, the mind; because of its cordial qualities.) See *Amaracum.*

SA'NATIVE. (From *sano*, to cure.) That which cures diseases.

Sancti Antonii ignis. See *Erysipelas.*

SANCTUM SEMEN. The wormseed, or santonicum.

SANDALIFO'RMIS. Sandal or slipper-like: applied to the nectary of the *Cypripedium calceolus.*

SA'NDARACH. (*Sandaracha*, æ. f.; from *saghad narak*, Arabic.) This name has been given to a kind of gum resin, and also to realgar, or sulphuret of arsenic.

SANDARA'CHA A'RABUM. Gum sandarach. See *Juniperis communis.*

SANDARACHA GRÆCORUM. Realgar, or sulphuret of arsenic.

Sandbath. See *Bath.*

Sanders. See *Pterocarpus santalinus.*

Sandrack. See *Sandarach.*

SA'NDYX. (Σανδυξ; from *sani duk*, red, Arabian.) Cerusse burnt till it becomes red.

SANGUIFICA'TION. (*Sanguificatio*; from *sanguis*, blood, and *facio*, to make.) A natural function of the body, by which the chyle is changed into blood. The uses of sanguification are, the generation of blood, which serves to fill the blood-vessels, to irritate and stimulate the heart and arteries, to generate or cause heat, to secrete the humours, and to excite the vital actions.

SANGUINA'LIS. (From *sanguis*, blood: so named from its use in stopping bleedings.) The *Polygonum aviculare*, or knot-grass, is sometimes so called.

SANGUINA'RIA. (From *sanguis*, blood: so named from its use in stopping bleedings.) 1. The herb knot-grass. See *Polygonum aviculare.*

2. The name of a genus of plants.

SANGUI'NARINE. An alkaline principle, discovered by Dana in the root of the *Sanguinaria canadensis.*

SANGUI'NEOUS. (*Sanguineus*; from *sanguis*, blood.) Bloody; appertaining to the blood. 1. In *Natural History*, applied very generally to designate a red or blood colour. See *Colour.*

2. In *Physiology* and *Pathology*, applied to certain conditions of the body, to diseases, and to appearances of the solids and fluids; as sanguineous temperament, sanguineous apoplexy.

Sanguineous apoplexy. See *Apoplexy.*

SANGUIPU'RGIUM. (From *sanguis*, blood, and *purgo*, to purge.) A gentle fever, or such a one as by its discharges was supposed to purify the blood.

SA'NGUIS. (*is, inis.* m.) The blood. The nutritious fluid which circulates through every part of the living frame, supplying it with the power and the materials of life. It is warm and red in the vertebral animals; but cold, and generally white in the invertebral.

The blood in the human subject is a slightly alkaline fluid, of a red colour; of a peculiar odour; its taste is rather saline and nauseous; its temperature about 96° of Fahrenheit; it is glutinous to the touch; its specific gravity, though different in different individuals, may be generally estimated at 1050, water being 1000. Blood from arteries is florid, and from veins of a dark red, which the translucence of the venous coats renders bluish when seen through them: and the specific gravity of the former is said by Dr. John Davy to be 1049, and in the latter 1051. When fresh drawn and received into a vessel, it exhibits the following appearances: —

At first, especially while still warm, it emits a vapour which, if collected in a bell glass, forms drops resembling dew, of a *watery* nature, but affording a nidorous smell, which is most remarkable in the blood of carnivorous animals, is peculiar, and truly animal. Much of this watery liquor still remains united with the other parts of the blood, hereafter to be mentioned.

In the mean time the blood begins to separate into two portions. A coagulum is first formed, from the surface of which exudes, as it were, a fluid of a yellowish slightly red colour denominated *serum*: the more abundantly this exudes, the greater is the contraction of the glutinous coagulum, which has received the appellations of *crassamentum*; and, from some resemblance to the liver in colour and texture of hepar sanguineum; of placenta; and, from the circumstance of its being surrounded by the serum, of insula.

Some have thought that heat is evolved during its coagulation; others have denied this. M. Raspail says that the temperature falls.

The crassamentum may, by agitation or repeated ablution, be easily separated into two constituent parts, — the *cruor*, which gave the blood its purple colour — and the *fibrin*, which on washing is forsaken by the cruor, and called, from its greater solidity, the basis of the crassamentum.

Besides the watery fluid first mentioned there are the three constituents of the blood, viz. the *serum*, the *cruor*, and the *fibrin*, each of which we shall presently treat more particularly. These, however, while perfect, recent, and in possession of their native heat, are intimately mixed, and form an equable, homogeneous fluid. Their relative proportions are astonishingly diversified, according to age, temperament, diet, and similar circumstances which constitute the peculiar health of each individual.

The quantity of blood in a well-formed adult is estimated by "Allen, Mullen, and Abildgaard, at little more than 8 pounds; by Harvey at 9; Borelli, 20; Haller, 30; Riolan, 40; Hamberger, 80; and Keil, 100. The former are evidently nearer the truth." M. Le Canu says, that the quantity of its *water*, in a healthy person, varies from 853·135 to 778·625 in 1000 parts, and the medium quantity is greater in females and in the phlegmatic temperament; of its *albumen*, from 78·270 to 57·890, and has no relation to sex, age, or temperament: of the *fibrin* dry, from 1·360 to 2·236, is the greatest in the young or middle-aged, in the sanguine temperament, and in the inflammatory state.

least in the phlegmatic temperament, the aged, and under congestion or hæmorrhage: of its *globules*, from 148·450 to 68·349 — being the most remarkable variation — is greatest in males, the same between the ages of twenty and sixty, much greater in the sanguineous than the phlegmatic temperament, and much less after losses of blood, which do not affect the quantity of the albumen.

The *blood*, according to M. Le Canu, consists of the following constituents: —

	1st Analysis.	2d Analysis.
Water	780·145	786·500
Fibrin	2·100	3·565
Albumen	65·090	69·415
Colouring matter	133·000	119·626
Crystallisable fatty matter	2·430	4·300
Oily matter	1·310	2·270
Extractive matter soluble in alkohol and water	1·790	1·920
Albumen combined with soda	1·265	2·010
Chloruret of sodium and potassium, alkaline phosphate, sulphate, and subcarbonates	8·370	7·304
Subcarbonate of lime and magnesia, phosphates of lime, magnesia, and iron, peroxide of iron	2·100	1·414
Loss	2·400	2·586
	1000·000	1000·000

When blood, venous or arterial, is immediately placed in the vacuum of an air-pump, or coagulates in the air, or is received from a vein into pure hydrogen, it emits a large quantity of carbonic acid gas. Professor Brande obtained two cubic inches from every ounce of blood; Sir C. Scudamore, less than half a cubic inch from six ounces. The quantity is said to be much greater after a meal, and much less if the blood is buffy.

Chevreul, Lassaigne, and others discover a yellow colouring matter like that of the bile and urine. Dumas and Prevost and others discern something like urea, which M. Raspail suggests may be the effect of their experiments, as Woehler discovers urea to be a cyanite of ammonia, and capable of artificial production by passing cyanogen (bicarburet of nitrogen) through ammoniacal gas.

"The *serum* is a peculiar fluid, the chief cause of the viscidity of the blood, and easily separable by art into different constituent principles. If subjected to a temperature of 150° Fahr., a portion is converted into a white scissile substance, resembling boiled white of egg," and is in truth albumen; the watery portion which remains was termed serosity by Cullen, and contains various substances.

If mixed with six parts of cold water, serum does not coagulate by heat.

Under the influence of the galvanic pile, soda collects at the negative wire, and the albumen coagulates at the positive, on account, M. Raspail says, probably, of the decomposition of the salts and also of the waters, and the consequent oxygenation of every thing at the positive pole, where the oxygen collects; and of the increase of temperature attending the decomposition of organised bodies.

M. Le Canu gives the following analysis of serum: —

	1st Analysis.	2d Analysis.
Water	906·00	901·00
Albumen	78·00	81·20
Animal matter soluble in water and alkohol	1·69	2·05

The *cruor* consists of globules; and Mr. Hewson asserts that they have a nucleus and an enveloping colouring portion. The nucleus is said to be colourless: perhaps about $\frac{1}{5000}$ of an inch in diameter, and the whole globule nearly one fourth larger. M. Raspail says, that, though the form and dimensions of the particles are different in different species, and nearly the same in the same individual, they still vary within very narrow limits in individuals, and the dimensions in even the same drop of blood, especially if not examined immediately that the blood is taken from the vessels. In man, he says, they are from $\frac{1}{100}$ to $\frac{1}{200}$ of a millimètre, flat and circular. MM. Prevost and Dumas believe that the internal portion is spherical, but the outer or vesicular, as Hewson noticed, flattened. The inner part, according to these enquirers, rolls in the outer, and, in the frog's web and bat's wing, at least, the whole particle is carried, steadily balanced, in the current of blood, sometimes flat, sometimes oblique, sometimes gently turning upon itself, and lengthening if driven into a vessel of diameter hardly sufficient for its admission; the old assertion of Reichel being thus corroborated. Kalk, Treviranus, and others, have noticed a rotatory motion of the entire particles, each at a distance from the other; and Professor Schultz of Berlin has confirmed their observations. But M. Raspail considers these motions as accidental and mechanical results, such as have deceived so many microscopic investigators. Mr. Bauer says he has discovered a third set of smaller colourless globules in the blood, $\frac{1}{2500}$ of an inch in diameter, which appear to belong to the fibrin, and are accordingly denominated

lymph globules; and it is thought probable that the central globule of the red particles is the same, and thus really fibrin. Colourless globules gradually form also in serum. It is also asserted that the globules of pus form gradually, and that pus is originally an homogeneous fluid.

The globules of the blood, independent of their covering of red substance, M. Raspail regards as mere particles of albumen not dissolved in the serum, and, after proving their albuminous nature, shows how albumen dissolved in an excess of concentrated hydrochloric acid forms minute, spherical, equal globules, in proportion as the decanted acid *spontaneously* evaporates, scarcely distinguishable from the globules of the blood. One takes breath while reading M. Raspail, after the strange and varying statements of so many experimenters, especially of those who use microscopes.

If arterial blood is exposed to ammoniacal gas, it becomes of a cherry red; if to gaseous oxide of carbon, the deutoxide of azote, or carburetted hydrogen, of a violet red; if to carbonic acid, though covered by two inches depth of serum, azote, hydrogen, or protoxide of azote, of a brown red; if to arseniuretted or sulphuretted hydrogen, of a deep violet inclining to a greenish brown; if to hydrochloric gas, of a chesnut brown; if to sulphureous gas, of a blackish brown; and if to chlorine, of a blackish brown inclining to greenish white. These gases are of course partly absorbed or decomposed. The dark colour produced in arterial blood by carbonic acid or azotic gas takes place if blood is placed in vacuo, though less rapidly and deeply than if exposed to hydrogen gas, and in vacuo, though covered by two inches and a half of serum. Arterial blood extravasated or included between two ligatures in an artery, nay, left in contact with oxygen, gradually acquires the same dark colour, and no oxygen will afterwards render it scarlet. Acids, if stronger than just enough to neutralise a weak salt, and alkalis, darken arterial blood. If deprived of all saline matter by washing, the reddest clot of blood becomes black, and will not grow florid by oxygen: whereas if saline matter is added, it becomes florid, even in an atmosphere of carbonic acid.

Venous blood acquires a florid colour by exposure to oxygen or atmospheric air (and it does so even when covered by a bladder, provided this is moistened), carbonic acid gas is formed, and an equal volume of oxygen gas disappears, and this the more if the temperature is high. If exposed to nitrous oxide, it becomes of a brighter purple, and much of the gas is absorbed; carbonic acid gas renders it darker, and is a little absorbed: nitrogen and hydrogen have the same effect. Electricity blackens the blood, and, according to Dr. Stevens, the poison of the rattle-snake, and other poisons, though floating only in the air. Putrefaction makes the blood dark. Alkaline and some other neutral salts make venous blood florid; and this, if added in considerable quantities, even when the blood is exposed, not to oxygen or air, but to a blackening gas.

Dr. Stevens seems to have proved that the colouring matter of the blood is really black, and acquires redness only by the action of the salts upon the hematosine; and that venous blood is of a dark red through the presence of carbonic acid, and but for the salts would be black. If blood is black from want of salts, very little of them will make it florid; if it is black from the presence of carbonic acid, azote, &c., the quantity of salts requisite will be proportionate to the quantity of the blackening agent. Oxygen indirectly renders blood florid, by removing the carbonic acid gas, and thus allowing the salts of the serum to brighten it; for if these are washed away, we see that oxygen has no effect, and we see that in proportion to the disappearance of oxygen is carbonic acid evolved. The same interchange of carbonic acid takes place in hydrogen, and the blood remains black; but then hydrogen blackens blood as well as carbonic acid. It is possible that oxygen may have the property of making blood florid, just as hydrogen, nitrogen, carbonic acid, &c. have to make it dark. But if it have, still it does not make the blood florid unless salts be present, and carbonic acid always appears; and when blood is darkened by putrefaction, so that air will not make it florid, the addition of most neutral salts instantly brightens it. Such are the statements of Dr. Stevens.

Berzelius finds the colouring particles only concerned in these changes. Prevost and Dumas found more fibrin and red particles in arterial than in venous blood; and the venous must contain a larger quantity of carbonic acid, and the arterial an abundance of oxygen: Macaire and Marcet, on *ultimate* analysis, find about five per cent. more oxygen in arterial, and five per cent. more carbon in venous, blood.

It is in the red covering of the particles, or hematosine, as the colouring matter is now called, that the iron of the blood exists. Berzelius informs us that serum, although able to dissolve a small portion of the oxides, not indeed of the phosphates, of iron, does not acquire a red colour by their addition, and that he has never discovered iron nor lime in the entire blood, although both are so abundant in its ashes. He concludes that the blood contains the *elements* of phosphate of iron and of lime and of carbonate of lime, and also of phosphate of magnesia, united in a manner different from their combination in the salts. M. Raspail seven years ago, showed that certain coagulable substances will protect a metal from the strongest re-agent — that a mixture of oil and the salts of iron will afford no signs of the metal till some days after it has been placed in acidulated ferrochyazate of potass. Rose obtained the same result on mixing albumen or gelatine with peroxide of iron. But Dr. Engelhart has shown iron to exist in blood, by the usual liquid tests after passing a stream of chlorine through a solution of red particles.

The last constituent principle of the blood to be noticed, is the plastic *lymph*, formerly confounded with the serum. This has been called the basis of the crassamentum, the glutinous

art, the fibre or fibrous matter of the blood. t is now termed *fibrin*.

It is properly denominated plastic, because affords the chief materials from which the imilar parts, especially the muscles, are immeiately produced; nourishes the body throughut life; repairs wounds and fractures in an xtraordinary manner; fills up the areæ of large lood-vessels when divided; and forms those ncretions which accompany inflammations, nd that remarkable deciduous membrane found the recently impregnated uterus for the atchment of the ovum.

We will now consider the coagulation of the brin more minutely.

Blood coagulates when it has escaped from e body, whether warm or cold, in the air or vacuo, diluted within certain limits, or unluted, at rest or in motion. Within the vesls, rest, which causes a cessation of intercourse tween the motionless portion and the general ass, always disposes it to coagulate. Yet its agulation, after escape from the body, is said be accelerated by motion, a high temperature, d a vessel calculated to preserve its temperare, by a vacuum, and by the stream from the od-vessel being slow, and *vice versâ*: in short, every circumstance which favours the escape carbonic acid gas, and to be proportioned to quantity of carbonic acid gas evolved; this ing evolved during the coagulation, and ceasg to escape when the coagulation is complete. alvanism and oxygen gas raise its temperare and hasten coagulation, while carbonic acid s, azote, and hydrogen, have the opposite efts. Dilute mineral acids coagulate the blood: alis and their carbonates retain its fluid.

The coagulation of the blood is ascribed by Hunter to its life; by Mr. Thackrah, on the ntrary, to its death, as the separation of a tion from the mass, by escape from a vessel, likely to kill it if alive; as every change ly to impair life promotes coagulation, for mple, debility, fainting; and as blood frozen, ll therefore likely to be killed if alive, and ain thawed, instantly coagulates. But the gulation appears, in most instances, if Sir Scudamore's experiments be accurate, though ers have not found the same results, attriable merely to the escape of carbonic acid; l as coagulated blood or fibrin (and the coulated part of effused blood is fibrin) benes vascular, one can hardly, if the fluid is e, regard a coagulum as necessarily dead.

Large quantities of blood are found fluid in ry dead body, showing that simple loss of llity is not sufficient to cause coagulation. eed, the blood of the various parts of the rt and vessels is found, most frequently, in osite states, fluid in one part, coagulated in ther; yet it is all equally dead. From all e contradictory circumstances, the coagulaof the blood may possibly be quite uncon-ed with its vitality or lifelessness, and entirely emical result. That it, however, is influenced he vital properties of the containing vessels ossible, but these may operate upon the od, in this respect, as a mere chemical comnd; and even, if it be alive, and they influence its life, still the influence, as far as respects coagulation, may in effect be chemical.

The blood generally coagulates in the living body on escaping from its vessels, and even in its vessels if its motion be prevented by ligatures; and when it does not, its subsequent escape from the body almost always produces instant coagulation. It almost always coagulates also in the vessels running through healthy parts to others in a state of mortification, and in large vessels adjoining a pulmonary abscess; in which cases, the final cause or purpose — prevention of hæmorrhage, is evident. The efficient cause, however, in all these examples, is unknown. In all, the blood is in contact with living parts: in the last two it is perhaps not at rest till it coagulates. J. Hunter, after mentioning that in a mortification of the foot and leg he found the crural and iliac arteries completely filled with strongly coagulated blood, adds, that this could not have arisen from rest, because the same thing ought then to happen in amputation, or in any case where the larger vessels are tied up. Besides, coagulation after extravasation, or when a quantity is included in a vessel between two ligatures, is not an invariable occurrence.

These facts, in addition to those stated above, show that fluidity or coagulation is not dependent on the simple presence or absence of vitality. Whatever connexion coagulation out of the body may have with the escape of carbonic acid gas, there is no proof of it in the case of internal coagulation.

Some have imagined the globules to be not only endowed, through vitality, with spontaneous motion, but with repulsion, which ceases with life, and thus by their death to run together and produce the phenomenon of coagulation. But M. Raspail contends, as we have noticed, that such spontaneous motion is a microscopic accident, and that, so far from being organised, they are merely minute precipitations of albumen; and he shows that, when the blood coagulates, the globules are seen under the microscope enveloped in the coagulum, which, therefore, cannot be a mere union of them. He asserts that fibrin and albumen are identical, and that the fibrin is preserved liquid by the alkalis of the blood, — soda and ammonia; which, if they become saturated by the carbonic acid of the atmosphere and that which forms in blood when exposed to the air, can no longer act as a solvent, and the fibrin accordingly coagulates. The escape of the ammonia and of a certain quantity of the water of the blood augments this effect, and blood coagulates the sooner in proportion as it is less watery. Coagulation within the blood-vessels he regards as produced by the escape of some of the water of the blood through the coats of the vessels. Some glutinous saps, as that of the *chara hispida* (stone-wort), coagulate, like the blood, chyle, and milk, and they all have albumen in the state of globular precipitation and solution, have the same salts, and their coagulation ceases when the solvent of the albumen is saturated, evaporated, or weakened. In sap, the solvent is acetic acid.

The fibrin may be separated from the red particles by agitation, and in inflammatory diseases it very frequently separates when drawn. Some conceive, that in health the cruor has a greater affinity for fibrin than for the serum, and therefore unites with it in preference. But to suppose any affinity of the red particles for either the fibrin or the serum is erroneous. Leeuwenhoek and Hartsoeker long since proved that serum merely suspends them; for if, when separated, they are triturated in some serum, part of them is taken up and the serum assumes a red colour; but, if the fluid is allowed to settle in a cylindrical glass, they slowly precipitate themselves to the bottom, and the serum above becomes clear as before. When blood is drawn, the serum easily separates on the coagulation of the fibrin. But the fibrin coagulates before the colouring particles have time to fall to the bottom, and entangling them acquires a red colour, forming the crassamentum: if, however, the fibrin coagulates slowly and is thinner, as in the phlogistic diathesis and pregnancy, the greater specific gravity of the cruor detaches it very considerably from the fibrin, which remains colourless above, constituting what is called the inflammatory coat, crust, or buff. Berzelius even believes the fibrin to be in a state of solution in the serum, while the cruor is simply suspended in this solution. In the phlogistic diathesis both the fibrin and the serum are more abundant, and the blood lighter.

Thinness of the blood and a disposition to slow coagulation generally co-exist. But the rapidity of the stream greatly affects the rate of coagulation, so that one portion of the same blood coagulates slowly that is drawn quickly, and another quickly that is drawn slowly.

The appearance of the buffy coat does not arise from the slow coagulation, though increased by it; because, of two portions of the same blood, one has afforded no buffy coat, although it remained fluid at least ten minutes after the buffy coat began to be formed on the other, proving too, if the buffy coat arise from thinness of the fibrin, as appears from Mr. Hewson's experiments, the red particles continuing of their usual weight, that slow coagulation is not altogether dependent on mere thinness of the blood, though generally connected and proportional with it. Yet rapid coagulation, by means of a slow stream when the blood is thin, may prevent the buffy coat, by not allowing time for the difference in the weight of the fibrin and red particles to have effect. Stirring such blood, or receiving it into a shallow vessel, has the same consequence, and the slower the coagulation of thin blood, occasioned, for instance, by rapid bleeding, the greater will be the buffy coat.

If one portion of the same blood is received into a shallow, and another into a deep vessel, the coagulum of the former is looser and spongy, and the quantity of separated serum less.

The different cups of blood drawn in an inflammatory disease may vary as to the buffy coat, according to accidental variations in the stream; but generally it is the first cup that abounds in buff, and the last frequently has none. This occurs when there is no difference in the stream. Therefore, if the buff arise from thinness of the fibrin, we must conclude with Hewson that its qualities may be changed even during bleeding. Sir C. Scudamore finds much more fibrin in buffy blood; and, consequently, that not merely the thinness, as Hewson observed, but the quantity of fibrin may vary during the flow of blood.

The greater the strength of the patient and the intensity of the inflammation, the firmer is the coagulum of fibrin and the more cupped its appearance.

Sir C. Scudamore did not find a buffy coat in blood drawn immediately after violent exercise.

Fibrin is inodorous and tasteless, whitish, insoluble in alcohol and acids, slightly soluble in boiling water long applied; coagulates, as already said, when separated from the body; dries hard, brittle, and semitransparent.

Albumen is inodorous, tasteless, colourless, soluble in water, and coagulates by a temperature of 150°, by pure potass, the mineral acids, tannin, and many metallic salts, especially by bichloride of mercury, and by prussiate of potass if a little dilute acid is previously mixed with it. Acetic and some other acids dissolve it, and even render it to a certain point soluble in alcohol and boiling water, according to M. Raspail; who also, under the microscope, discovers albumen to consist of two substances, the one an insoluble and organised tissue, the other a fluid contained in the cells of this. The insoluble portion, however, forms gradually only, and in fresh eggs can scarcely be distinguished from the soluble; just as is the case with the woody fibres of vegetables, that gradually form from a gum. Dr. Wollaston stated that the soda of albumen prevents it from al coagulating by heat, and the addition of an acid by neutralising the alkali, renders it completely coagulable. Raspail says, "alkaline solutions even alkaline carbonates," prevent heat from coagulating albumen. Mr. Brande thinks i liquid only through alkali.

Chemists all allow that fibrin, albumen, an colouring matter afford, on decomposition, th same saline and gaseous products. Berzeliu views them all three as modifications of the sam substance. Albumen contains a greater propor tion of oxygen than fibrin, and has sulphur fo a constituent part, which, however, cannot b detected while the albumen is entire, any mo than the iron while the cruor is entire. Th chief differences between the colouring matte and fibrin are, colour; the spontaneous coagu lation of fibrin at all temperatures, while th colouring matter may be dried without losin its solubility in water and becomes insolub only at a certain temperature; and the pecu liarity in the latter of not diminishing in volum like fibrin during exsiccation. According most chemists, albumen is intermediate betwee the two; and its only character of distinctio from fibrin is, that it does not coagulate spo taneously, but requires a high temperature some chemical agent. M. Raspail maintai that albumen and fibrin are identical; and th

the slight differences between the two are referable to the natural and adventitious salts of albumen, varying according to the organs from which it is obtained. The following results are given by Gay-Lussac and Thénard, in regard to them and gelatine: —

	Carbon.	Hydrogen.	Oxygen.	Nitrogen.
Gelatine ..	47·881	7·924	27·207	16·998
Albumen ..	52·883	7·540	23·872	15·705
Fibrin	53·360	7·021	12·685	19·934

Besides which, they, as well as the colouring matter of the blood, contain a very minute portion of the earthy phosphates.

We formerly saw that Dr. Prout is of opinion, at present, that, when oxygen and hydrogen exist united, it is in the form of actual water, as an essential constituent of unazotised vegetable bodies, one atom of carbon being united with one of water. Now M. Raspail makes it highly probable that the nitrogen of vegetable gluten, of albumen, fibrin, gelatine, and other animal matters, exists combined with another portion of hydrogen in the form of ammonia, which again is combined, as a base, with some acid, making an ammoniacal salt. The remaining small quantity of the hydrogen, not united with oxygen into water, is united with carbon into carburetted hydrogen; so that substances called azotised are really not azotised. He shows that the numbers given by Thénard are such as will give so much water, ammonia, and carburetted hydrogen, with pure carbon. Vegetable substances have been hitherto considered as ternary compounds of oxygen, hydrogen, and carbon: animal substances, and vegetable gluten, quaternary compounds of oxygen, hydrogen, carbon, and nitrogen; for most animal substances usually afford nitrogen, and but few vegetable substances excepting gluten. In M. Raspail's views, organised bodies consist of water, ammonia, carbon, and salts. And here it must be remarked, that the alkaline, earthy, and other substances, found in minute quantities in animal and vegetable compounds, and which have usually been regarded as foreign and unimportant, are, with great reason, considered by Dr. Prout as integrants in the compounds, and chiefly productive of the striking differences observed in substances having otherwise the same essential composition. The importance of minute quantities of matter is known, he remarks, in the experiments of Sir John Herschel, who found that a power, not less than 50,000 times greater than the power of gravity, is constantly generated (under the galvanic influence, for example) by the alloy of mercury with a millionth part of its weight of sodium. Dr. Prout regards these incidental particles as in a state of mutual repulsion, because, instead of being equally diffused as they are, they would otherwise be collected into a mass or crystal.

Dr. Prout also says, that it may perhaps be laid as a general law, that no substance, entering into the composition of a living plant or animal, is so pure as to be capable of assuming a regularly crystallised form. Instead, therefore, of being defined by straight lines and angles, all solid organised substances are more or less rounded, and their intimate structure is any thing but crystallised. The composition of organised fluids is equally heterogeneous; and, though the basis of nearly every one of such fluids is water, many of them contain a variety of other matters.

M. Raspail remarks further, that the constituents of organic solids or fluids are not combined in definite proportions, like those of inanimate bodies, but are ever variable, so that the varieties of each compound are infinite. — *Elliotson.*

Sanguis draconis. See *Dragon's blood.*

SANGUISO'RBA. (*a*, *æ.* f.; probably so named originally from the blood-red colour of its flowers, although, the juice of this plant being astringent, the medicinal properties it possesses of stopping hæmorrhages may be a better warrant for its name.) The name of a genus of plants in the Linnæan system. Class, *Tri-andria*; Order, *Monogynia.*

SANGUISORBA OFFICINALIS. The systematic name of the Italian pimpinel, which was formerly much esteemed as an astringent, but is not now in use.

SANGUISU'GA. (*a*, *æ.* f.; from *sanguis*, blood, and *sugo*, to suck.) The leech or blood-sucker. See *Leech.*

SANGUISUGUM. A barbarous term for a congestion of blood in the heart.

Sanicle. See *Sanicula.*

Sanicle, Yorkshire. See *Pinguicula.*

SANI'CULA. (*a*, *æ.* f.; from *sano*, to heal: so called from its virtues in healing.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia.*

2. The pharmacopœial name of sanicle.

Sanicula Eboracensis. See *Pinguicula.*

SANICULA EUROPÆA. The systematic name of the sanicle: called, also, *Cucullata*, *Dodecatheon*, *Cortusa*, *Symphytum petræum*, *Sanicula mas*, and *Diapensia cortusa.* This herb was formerly recommended as a mild astringent, and received its name from its supposed vulnerary qualities. Its sensible qualities are a bitterish and somewhat austere taste, followed by an acrimony which chiefly affects the throat. It is only in use in the present day amongst the country-people.

Sanicula mas. See *Sanicula europæa.*

SA'NIES. (*es*, *ei.* f.) A thin unhealthy discharge, with or without an admixture of blood or pus, from fistulæ or ill-conditioned sores.

SA'NTALUM. (*um*, *i.* n.; from *zandal*, Arabic.) The name of a genus of plants in the Linnæan system. Class, *Tetrandria*; Order, *Monogynia.* Saunders.

SANTALUM ALBUM. The systematic name of the white and yellow saunders: called, also, *Santalum citrinum* and *Santalum pallidum.* White saunders wood is of a pale white colour, often with a yellowish tinge, and, being destitute of taste or odour, it is superseded by the santalum citrinum, which is of a brownish yellow colour, of a bitterish aromatic taste, and of a pleasant smell, approaching to that of the rose. Both kinds are brought from the East Indies in billets, consisting of large thick pieces, which, according to Rumphius, are sometimes taken from the same, and sometimes from different, trees. For though the white and yellow saunders are

the wood of the same species of tree, yet the latter, which forms the central part of the tree, is not always to be found in sufficient quantity to repay the trouble and expense of procuring it, especially unless the trees be old; while the white, which is the exterior part of the wood, is always more abundant, and is, consequently, much cheaper.

Yellow saunders, distilled with water, yields a fragrant essential oil, which thickens in the cold to the consistence of a balsam, approaching in smell to ambergris, or a mixture of ambergris and roses; the remaining decoction, inspissated to the consistence of an extract, is bitterish and slightly pungent. Rectified spirit extracts, by digestion, considerably more than water; the colour of the tincture is a rich yellow. The distilled spirit is slightly impregnated with the flavour of the wood; the remaining brownish extract has a weak smell, and a moderate balsamic pungency. The wood is valued highly on account of its fragrance: hence the Chinese are said to fumigate their clothes with it, and to burn it in their temples in honour of their gods. Though still retained in the Materia Medica, it cannot be thought to possess any considerable share of medicinal power. Hoffmann considers its virtues as similar to those of ambergris: and some others have esteemed it in the character of a corroborant and restorative.

Santalum rubrum. See *Pterocarpus.*

SANTOLI'NA. (*a, æ.* f.; from *santalum*, saunders: because it smells like the saunders wood.) See *Artemisia santonica.*

SANTOLINA CHAMÆ-CYPARISSUS. The systematic name of the lavender cotton.

SANTO'NICUM. (From *Santonia*, its native place.) See *Artemisia santonica.*

SANTORI'NI FISSU'RÆ. The fissures or interruptions in the cartilaginous portion of the meatus auditorius externus are so named, after Santorini.

SANTORINI TUBERCULA. The little projections on the top of the arytenoid cartilages which support the ligaments of the glottis.

Santorini venæ emissoriæ. See *Emissoria santorini.*

SAPHADA. A name given by Paracelsus to a scaly disease of the hairy scalp, resembling tinea, except that the scales are reddish.

SAPHE'NA. (*a, æ.* f.; from σαφης, conspicuous.) *Vena saphena.* The large vein of the leg, which ascends along the little toe over the external ankle, and evacuates part of the blood from the foot into the popliteal veins.

SAPI'NDUS. (*us, i.* f.; that is, *Sapo Indus*, Indian soap: the rind of the fruit serving instead of soap to cleanse linen; but not without hazard of injury to the texture of the cloth.) The name of a genus of plants. Class, *Octandria;* Order, *Digynia.* The soap-tree.

SAPINDUS SAPONARIA. The systematic name of the plant which affords the soap-nuts, or soap-berries; called, also, *Baccæ bermudenses.* A globular fruit, about the size of a cherry, the cortical part of which is yellow, glossy, and so transparent as to show the spherical black nut which rattles within, and which includes a white kernel. The tree grows in Jamaica. It is said that the cortical part of this fruit has a bitter taste, and no smell; that it raises a soapy froth with water, and has similar effects with soap in washing; that it is a medicine of singular and specific virtue in chlorosis. It is not known in the shops of this country.

SA'PO. (*o, onis.* m.) Soap. A compound, in definite proportions, of certain principles in oils, fats, or resins, with a salifiable base. When this base is potash or soda, the compound is used as a detergent in washing clothes. When an alkaline earth, or oxide of a common metal, as litharge, is the salifiable base, the compound is insoluble in water. The first of these combinations is scarcely applied to any use, if we except that of linseed-oil with lime-water, sometimes prescribed as a liniment against burns; and the last is known only in surgery as the basis of certain plasters. Concerning the chemical constitution of soaps, and saponification, no exact ideas were entertained prior to Chevreuil's researches. An abstract of these will be found in the article *Adeps.*

When fat is treated with a hot ley of potash or soda, the constituents re-act on one another, so as to generate the solid pearly matter, *margaric acid*, and the fluid matter, *oleic acid*, both of which enter into a species of saline combination with the alkali; while the third matter that is produced, the *sweet principle*, remains free. We must, therefore, regard our common soap as a mixture of an alkaline margarate and oleate, in proportions determined by the relative proportions of the two acids producible from the peculiar species of fat.

The specific gravity of soap is, in general, greater than that of water. Its taste is faintly alkaline. When subjected to heat it speedily fuses, swells up, and is then decomposed. Exposed to the air in thin slices it soon becomes dry; but the whole combined water does not leave it, even by careful desiccation on a sand-bath.

Soap is much more soluble in hot than in cold water. This solution is instantly disturbed by the greater number of acids, which, seizing the alkali, either separate the fatty principles, or unite with them into an acido-soapy emulsion. The solution is likewise decomposed by almost all the earthy and metallic salts, which give birth to insoluble compounds of the oleic and margaric acids with the salifiable bases.

Soap is soluble in alkohol, and in large quantity, by the aid of heat. When boiling alkohol is saturated with soap, the liquid, on cooling, forms a consistent transparent mass of a yellow colour. When this mass is dried it still retains its transparency, provided the soap be a compound of tallow and soda; and in this state it is sold by the perfumers in this country.

Good soap possesses the property of removing from linen and cloth the greater part of fatty substances which may have been applied to them.

The medicinal soap, *sapo amygdalinus*, is made with oil of sweet almonds and half its weight of caustic alkali. Common or soft soap, *sapo mollis*, is made of potash and oil or tallow. Spanish, or Castile soap, *sapo durus*, of oil of olives and soda or barilla. Black soap is a composition of

train-oil and an alkali; and green soap, of hemp, linseed, or rape-oil, with an alkali. The white Spanish soap, being made of the finer kinds of olive-oil, is the best, and therefore preferred for internal use. Soap was imperfectly known to the ancients. It is mentioned by Pliny as made of fat and ashes, and as an invention of the Gauls. Aretæus and others inform us that the Greeks obtained their knowledge of its medical use from the Romans. Its virtues, according to Bergius, are detergent, resolvent, and aperient; and its use recommended in jaundice, gout, calculous complaints, and obstruction of the viscera. The efficacy of soap in the first of these diseases was experienced by Sylvius, and since recommended very generally by various authors who have written on this complaint; and it has also been thought of use in supplying the place of bile in the primæ viæ. The utility of this medicine in icterical cases was inferred chiefly from its supposed power of dissolving biliary concretions; but this medicine has lost much of its reputation in jaundice, since it is now known that gall-stones have been found in many after death who had been daily taking soap for several months, and even years. Of its good effects in urinary calculous affections we have the testimonies of several, especially when dissolved in lime-water, by which its efficacy is considerably increased; for it thus becomes a powerful solvent of mucus, which an ingenious modern author supposes to be the chief agent in the formation of calculi. It is, however, only in the incipient state of the disease that these remedies promise effectual benefit, though they generally abate the more violent symptoms where they cannot remove the cause. With Boerhaave soap was a general medicine; for, as he attributed most complaints to viscidity of the fluids, he, and most of the Boerhaavian school, prescribed it, in conjunction with different resinous and other substances, in gout, rheumatism, and various visceral complaints. Soap is also externally employed as a resolvent, and gives names to several officinal preparations.

Sapo terebi'nthinæ. Starkey's soap. This is made of one part of dried and warm subcarbonate of potash, and three parts oil of turpentine. The heated alkali is to have the oil of turpentine gradually blended with it in a warm mortar. Indolent swellings were formerly rubbed with this application, and, perhaps, some chronic affections of the joints might still be benefited by it.

SAPONA'RIA. (*a, æ.* f.; from *sapo*, soap; so called because its juice, like soap, cleans cloths.) 1. The name of a genus of plants in the Linnæan system. Class, *Decandria*; Order, *Digynia*.

2. The pharmacopœial name of the soap-wort. See *Saponaria officinalis*.

Saponaria nu'cula. The soap nut. See *Sapindus*.

Saponaria officinalis. The systematic name of the soap-wort: called also, bruise-wort, and *Struthium*, *Lanaria*, *Lychnis sylvestris*, and *Ibixuma*. The root of this plant *Saponaria—calycibus cylindricis, foliis ovato-lanceolatis*, of Linnæus, is employed medicinally; it has no peculiar smell; its taste is sweetish, glutinous, and somewhat bitter. On being chewed for some time, it is said to discover a degree of acrimony, which continues to affect the mouth a considerable time. According to Newman, two ounces of the root yielded eleven drachms of watery extract; but Cartheuser, from a like quantity, only obtained six drachms and twenty-four grains. This extract manifested a sweetish taste, followed by an acrid quality. The spirituous extract is less in quantity, but of a more penetrating acrid taste. Decoctions of the root, on being sufficiently agitated, produce a saponaceous froth: a similar soapy quality is observable, also, in the extract, and still more manifestly in the leaves, insomuch that they have been used by the mendicant monks as a substitute for soap for washing their clothes; and Bergius, who made several experiments with the saponaria, declares that it had all the effects of soap itself.

From these peculiar qualities of the saponaria, there can be little doubt of its possessing a considerable share of medical efficacy, which Dr. Woodville says he could wish to find faithfully ascertained.

The diseases for which the saponaria is recommended, as syphilis, gout, rheumatism, and jaundice, are not, perhaps, the complaints in which its use is most availing; for a fancied resemblance of the roots of saponaria with those of sarsaparilla seems to have led physicians to think them similar in their effects; and hence they have both been administered with the same intentions, particularly in fixed pain, and venereal affections. Bergius says, "in arthritide, cura mercuriale, &c. nullum aptiorem potum novi." However, according to several writers, the most inveterate cases of syphilis were cured by a decoction of this plant, without the use of mercury.

Haller informs us that Boerhaave entertained a high opinion of its efficacy in jaundice and other visceral obstructions.

Sapo'nea. The name of a pectoral medicine, prepared with infusion of violets, sugar, and oil of almonds.

SAPONULE. *Saponulus.* A combination of a volatile or essential oil with different bases; as *saponule of ammonia*, &c.

Sapo'ta. (The West Indian name of several sorts of fruits of the plum kind.) See *Achras sapota*.

Sappan lignum. See *Cæsalpinia*.

Saracen's consound. See *Solidago*.

SARATO'GA. The name of a country in America, in the state of New York, celebrated for its springs of mineral water, which are numerous, throughout a circuit of several miles, near the centre of that country. The ground throughout this circuit is, generally speaking, flat, and in two or three places is covered with extensive sheets of limpid water, which are fed by streams that take their origin in the neighbouring mountains of granite and gneiss. The soil in which the springs rise is sandy, and rests upon a bed of compact limestone, or argillaceous slate, or grey wacke; and they are apparently more numerous where these specimens of the transition and secondary formation are as-

certained to meet. There is more variety in the degree of mineral impregnation at two points, about seven miles distant from each other, where accommodation has been more liberally provided for visitors, and which have taken the names of Saratoga and Ballston Spa. The former of these seems to have been known to the Indians before the formation of European settlements, and was pointed out by them to Sir William Johnson, in 1767. It was called in their language the *Spring of Life*, and is in temperature about 50° of Fahrenheit. Most of the American chemists have made the analysis of the Saratoga water an object of inquiry and publication; and, though one or two of them differ as to the existence of some of the more trifling impregnations, they agree, generally, that it contains carbonic acid gas, muriate of soda, carbonate of soda, carbonate of lime, carbonate of iron, and carbonate of magnesia.

In two or three of the springs there is, besides, sulphuretted hydrogen gas, and in one, at least, traces of silica and alumina. These incidental varieties give rise to slight differences in the medicinal effects of the springs; but, as a general rule for guiding strangers in their selection, it may be stated, that the more abundant the muriate of soda, and carbonates of soda, lime, and magnesia, the more aperient and diuretic will be the water: while the greater the quantity of carbonic acid and of iron, in proportion to the former ingredients, the more powerful will be its tonic effects.

The Saratoga springs and those of Ballston are much frequented.

The diseases in which the Saratoga waters have been found to be productive of the best effects, are dyspepsia, cutaneous diseases, scrofulous tumours, dropsy, chlorosis and other affections peculiar to the female sex, nephritic disorders, and gravel.

SARCIMINA'LIS. The allantoid membrane is sometimes so called. See *Allantoid*.

SARCI'TES. (From σαρξ, flesh.) See *Anasarca*.

SA'RCIUM. (*um, ii.* n.; diminutive of σαρξ, flesh.) A caruncle, or small fleshy excrescence.

SARCOCE'LE. (*e, es.* f.; from σαρξ, flesh, and κηλη, a tumour.) *Hernia carnosa*. This is a disease of the body of the testicle, and, as the term implies, consists, in general, in such an alteration made in the structure of it as produces a resemblance to a hard fleshy substance, instead of that fine, soft, vascular texture of which it is, in a natural and healthy state, composed.

The ancient writers have made a great number of distinctions of the different kinds of this disease, according to its different appearances, and according to the mildness or malignity of the symptoms with which it may chance to be attended. Thus, the *sarcocele*, the *hydro-sarcocele*, the *scirrhus*, the *cancer*, the *caro adnata ad testum*, and the *caro adnata ad vasa*, which are really little more than descriptions of different states and circumstances of the same disease, are reckoned as so many different complaints, requiring a variety of treatment, and deriving their origin from a variety of different humours.

Every species of sarcocele consists, primarily, in an enlargement, induration, and obstruction of the vascular part of the testicle; but this alteration is, in different people, attended with such a variety of circumstances as to produce several different appearances, and to occasion the many distinctions which have been made.

If the body of the testicle, though enlarged and indurated to some degree, be perfectly equal in its surface, void of pain, has no appearance of fluid in its tunica vaginalis, and produces very little uneasiness, except what is occasioned by its mere weight, it is usually called a simple sarcocele, or an indolent scirrhus; if, at the same time that the testis is enlarged and hardened, there be a palpable accumulation of fluid in the vaginal coat, the disease has, by many, been named a *hydro-sarcocele*; if the lower part of the spermatic vessels and the epididymis were enlarged, hard, and knotty, the old surgeons supposed it to be a fungous accretion, and called it the *caro adnata ad vasa*; if the testicle itself was unequal in its surface, but at the same time not painful, they distinguished it by the title of *caro adnata ad testem*; if it was tolerably equal, not very painful, nor frequently so, but at the same time hard and large, they gave it the appellation of an occult or benign cancer; if it was ulcerated, subject to frequent acute pain, to hæmorrhage, &c., it was known by that of a malignant or confirmed cancer. These different appearances, though distinguished by different titles, are really no more than so many stages (as it were) of the same kind of disease, and depend a great deal on several accidental circumstances, such as age, habit, manner of living, &c. It is true, that many people pass several years with this disease under its most favourable appearances, and without encountering any of its worst; but, on the other hand, there are many who, in a very short space of time, run through all its stages. They who are most conversant with it know how very convertible its mildest symptoms are into its most dreadful ones, and how very short a space of time often intervenes between the one and the other.

There is hardly any disease affecting the human body which is subject to more variety than this is, both with regard to its first manner of appearance, and the changes which it may undergo.

Sometimes the first appearance is a mere simple enlargement and induration of the body of the testicle, void of pain, without inequality of surface, and producing no uneasiness or inconvenience, except what is occasioned by its mere weight. And some people are so fortunate to have it remain in this state for a very considerable length of time, without visible or material alteration. On the other hand, it sometimes happens that, very soon after its appearance in this mild manner, it suddenly becomes unequal and knotty, and is attended with very acute pains, darting up to the loins and back, but still remaining entire, that is, not bursting through the integuments. Sometimes

the fury of the disease brooks no restraint, but, making its way through all the membranes which envelope the testicle, it either produces a large, foul, stinking, phagedænic ulcer, with hard edges, or it thrusts forth a painful gleeting fungus, subject to frequent hæmorrhage.

Sometimes an accumulation of water is made in the tunica vaginalis, producing that mixed appearance called the *hydro-sarcocele*.

Sometimes there is no fluid at all in the cavity of the tunica vaginalis; but the body of the testicle itself is formed into cells, containing either a turbid kind of water, a bloody sanies, or a purulent fœtid matter. Sometimes the disorder seems to be merely local, that is, confined to the testicle, not proceeding from a tainted habit, nor accompanied with diseased viscera, the patient having all the general appearances and circumstances of health, and deriving his local mischief from an external injury. At other times, a pallid, leaden countenance, indigestion, frequent nausea, colicky pains, sudden purgings, &c. sufficiently indicate a vitiated habit and diseased viscera, which diseased viscera may also sometimes be discovered and felt.

The progress, also, which it makes from the testis upward, toward the process, is very uncertain; the disease occupying the testicle only, without affecting the spermatic process, in some subjects, for a great length of time; while in others it totally spoils the testicle very soon, and almost as soon seizes on the spermatic cord.

Sarcoco'lla. (*a*, *æ*. f.; from σαρξ, flesh, and κολλα, glue: because of its supposed power of gluing together wounds.) See *Penæa mucronata*.

Sarcoco'lline. A peculiar principle which exists in *sarcocolla*, of which it forms the greater part. It may be obtained by evaporating to dryness an alkoholic or watery solution of sarcocolla.

Sa'rcoepiploce'le. An omental herni acomplicated with a fleshy tumour.

SARCO'LOGY. (*Sarcologia*, *æ*. f.; from σαρξ, flesh, and λογος, a discourse.) The anatomy of the soft parts.

SARCO'MA. (*a*, *atis*. n.; from σαρκοω, *carneum reddo*.) A fleshy tumour or excrescence.

SARCO'MATOUS. *Sarcomatosus*. Fleshy tumours are called *sarcomatous tumours*.

Sarco'mphalus. (*us*, *i*. m.; from σαρξ, flesh, and ομφαλος, the navel.) A fleshy excrescence about the navel.

Sarcophyi'a. (From σαρξ, flesh, and φυω, to grow.) A fleshy excrescence.

SARCO'SIS. (*is*, *is*. f.; σαρκωσις.) 1. The generation of flesh.

2. A fleshy tumour.

Sarcosto'sis. The same as *Osteasarcoma*.

Sarco'ticus. (From σαρκοω, to incarnate.) Synonymous with incarnative. Sarcotic: that which promotes the generation of flesh in wounds.

Sardi'asis. See *Risus sardonicus*.

Sardius lapis. *Sarda*. Cornelian, so called because it was found in Sardinia. It was formerly used in medicine as a cordial.

Sardonic laugh. See *Risus sardonicus*.

Sarfar. An alchemical name of iron.

Sarma'tica lu'es. The *Plica polonica*.

Sarmenta'ceæ. (From *sarmentum*, a runner.) The name of a natural order of Linnæus's *Fragmenta*, embracing the plants with twining or trailing stems.

SARMENTA'CEUS. Sarmentaceous: having twigs or runners.

SARMENTO'SUS. (From *sarmentum*, a twig or trailing stalk.) Trailing, or having runners: applied to a creeping stem, barren of flowers, thrown out from the root for the purpose of increase.

SARME'NTUM. (*um*, *i*. n.; from *sarpio*, to prune, lop, or cut off.) A twig, a runner.

SARSAPARI'LLA. (*a*, *æ*. f.; from *zarza*, a briar, and *parilla*, a little vine, Spanish — a thorny little vine.) See *Smilax sarsaparilla*.

Sarsaparilla Germanica. See *Carex hirta*.

SARTO'RIUS. (From *sartor*, a tailor: because tailors cross their legs with it.) *Sartorius seu longissimus femoris* of Cowper. This flat and slender muscle, which is the longest of the human body, and from an inch and a half to two inches in breadth, is situated immediately under the integuments, and extends obliquely, from the upper and anterior part of the thigh, to the upper, anterior, and inner part of the tibia, being enclosed by a thin membraneous sheath, which is derived from the adjacent *fascia lata*. It arises, by a tendon of about half an inch in breadth, from the outer surface and inferior edge of the anterior superior spinous process of the ilium, but soon becomes fleshy, and runs down a little way obliquely inwards, and then for some space upon the rectus, nearly in a straight direction; after which it passes obliquely over the vastus internus, and the lower part of the adductor longus, and then, running down between the tendons of the adductor magnus and the gracilis, is inserted, by a thin tendon, into the inner part of the tibia, near the inferior part of its tuberosity, and for the space of an inch or two below it. This tendon sends off a thin aponeurosis, which is spread over the upper and posterior part of the leg. This muscle serves to bend the leg obliquely inwards, or to roll the thigh outwards, and at the same time to bring one leg across the other; on which account Spigelius first gave it the name of *sartorius*, or the tailor's muscle.

SA'SSAFRAS. (*Quasi saxifraga*; from *saxum*, a stone, and *frango*, to break: so called because a decoction of its wood was supposed good for the stone; or, which is most probable, from the river Sassefras, in America, on the banks of which it grows in abundance.) See *Laurus sassafras*.

Satanus devorans. Antimony.

SATE'LLITES. The veins which accompany the arteries are called *venæ satellites*.

Sa'thE. Σαθη. The penis.

Satura'ntia. Medicines which neutralise acid in the stomach.

SATURA'TION. (*Saturatio*, *onis*. f.) A term employed, in *Chemistry* and *Pharmacy*,

to express that state of a body in which it has dissolved as much of another body as it is capable of doing. Some substances unite in all proportions. Such, for example, are acids in general, and some other salts, with water, and many of the metals with each other. But there are, likewise, many substances which cannot be dissolved in a fluid at a certain temperature, in any quantity beyond a certain proportion. Thus, water will dissolve only about one third of its weight of common salt, and, if more be added, it will remain solid. A fluid, which holds in solution as much of any substance as it can dissolve, is said to be saturated with it. But saturation with one substance does not deprive the fluid of its power of acting on and dissolving some other bodies; and in many cases it increases this power. For example, water saturated with salt will dissolve sugar; and water saturated with carbonic acid will dissolve iron, though without this addition its action on this metal is scarcely perceptible.

The word saturation is likewise used in another sense by chemists. The union of two principles produces a body, the properties of which differ from those of its component parts, but resemble those of the predominating principle. When the principles are in such proportion that neither predominates, they are said to be saturated with each other; but, if otherwise, the most predominant principle is said to be sub-saturated or under-saturated, and the other, super-saturated or over-saturated.

SATUREI'A. (*a*, *æ*. f.; from *σατυροι*, the satyrs: because it is said to make those who eat it lascivious.) 1. The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Gymnospermia*.

2. The pharmacopœial name of the summer savory.

Satureia capitata. The systematic name of the ciliated savory: called in the shops *Thymus creticus*. It possesses similar virtues to our thyme, but in a stronger degree.

Satureia hortensis. The systematic name of the summer savory: called, also, *Satureia sativa*, *Culina sativa Plinii*, and *Thymbra*. This low shrub is cultivated in our gardens for culinary purposes. It has a warm, aromatic, penetrating taste, and smells like thyme, but milder. It is an ingredient in most of the warm stews and made dishes.

Satureia sativa. See *Satureia hortensis*.

SATU'RNUS. (From the planet of that name.) Saturn. The old chemical name of lead.

SATYRI'ASIS. (*is*, *is*. m.; from *σατυρος*, a satyr: because they are said to be greatly addicted to venery.) Excessive and violent desire for coition in men.

Saty'rion. (*on*, *ii*. n.; from *σατυρος*, a satyr: so called because it was supposed to excite venery if only held in the hand.) See *Orchis mascula*.

Satyrium. See *Orchis mascula*.

Sauce-alone. See *Erysimum alliaria*.

Saucer. See *Scutella*.

Saunders. See *Santalum album*.

Saunders, red. See *Pterocarpus*.

Sau'nia. The name of an old demulcent medicine, prepared with sweet almonds, sugar, starch, oil of almonds, and violet water, made into square cakes.

Saur-kraut. Cabbage preserved in brine. An article of food common in Germany, like our pickled cabbage.

Savine. See *Juniperus sabina*.

Savine ointment. See *Ceratum sabinæ*.

Savina. See *Juniperus sabina*.

Savory. See *Satureia*.

SAXI'FRAGA. (*a*, *æ*. f.; from *saxum*, a stone, and *frango*, to break: so called because it was supposed to be good against the stone in the bladder.) The name of a genus of plants in the Linnæan system. Class, *Decandria*; Order, *Digynia*.

Saxifraga alba. See *Saxifraga granulata*.

Saxifraga anglica. See *Peucedanum*.

Saxifraga crassifolia. The root of this species of saxifrage is extolled, by Professor Pallas, as an antiseptic.

Saxifraga granulata. The systematic name of the white saxifrage. *Saxifraga alba*. Called, by Oribasius, *Besto*. *Sanicula sedum*. Linnæus describes the taste of this plant to be acrid and pungent, which we have not been able to discover: neither the tubercles of the root nor the leaves manifest to the organs of taste any quality likely to be of medicinal use; and, therefore, though this species of saxifrage has been long employed as a popular remedy in nephritic and gravelly disorders, yet we do not find, either from its sensible qualities, or from any published instances of its efficacy, that it deserves a place in the Materia Medica. The superstitious doctrine of signatures suggested the use of the root, which is a good example of what Linnæus has termed radix granulata. The bulbs or tubercles of such roots answer an important purpose in vegetation, by supplying the plants with nourishment and moisture, and thereby enabling them to resist the effects of that drought to which the dry soils they inhabit peculiarly expose them.

Saxifraga rubra. See *Spiræa*.

Saxifraga vulgaris. See *Peucedanum*.

Saxifrage. See *Saxifraga*.

Saxifrage, burnet. See *Pimpinella*.

Saxifrage, English. See *Peucedanum*.

Saxifrage, meadow. See *Peucedanum*.

Saxifrage, white. See *Saxifraga*.

Saxon blue. See *Blue, Saxon*.

Saxo'nicus pu'lvis. A powder formerly in vogue as an alexipharmic. It consisted of the roots of wild and cultivated angelica, of vincetoxicum, marsh-mallow, polypody of the oak, nettle, and valerian, with the bark of mezereon root, and seeds of herb Paris.

SCAB. A hard substance covering superficial ulcerations, and formed by a concretion of the fluid discharged from them.

SCA'BER. Rough to the touch, from any little rigid inequalities: applied to several parts of plants.

SCA'BIES. (*es*, *ei*. f.; from *scabo*, to scratch.) *Psora*. The itch. This disease is characterised by an eruption of pustules, or of

small vesicles, which are subsequently intermixed with, or terminate in, pustules; it is accompanied by constant and importunate itching, but not with fever; and is in all its varieties contagious. It appears occasionally on every part of the body, the face only excepted; but most abundantly about the wrists and fingers, the fossa of the nates, and the flexures of the joints.

Among the varieties which the disease assumes, four have been distinguished with considerable accuracy by the vulgar, who have, indeed, the most ample opportunities of becoming acquainted with its character; and to these they have given the epithets of *rank*, *watery*, *pocky*, and *scorbutic* itch. Their division was adopted by Dr. Willan, with the appropriate titles of papuliform, lymphatic, purulent, and cachectic.

1. The *Scabies papuliformis*, or *rank* itch, consists in an extensive eruption of minute itching vesicles, which are slightly inflamed and acuminated, resembling papulæ when examined by the naked eye. They commonly arise first about the bend of the wrist and between the fingers, or in the epigastrium; on which parts, as well as about the axillæ and nates, and in the flexures of the upper and lower limbs, they are at all periods most numerous, and often intermixed with a few phlyzacious pustules, containing a thick yellow matter. The itching is extremely troublesome in this form of scabies, more especially when the patient becomes warm after getting into bed. The appearance of the disease is modified by the abrasion of the tops of the vesicles and pustules, and even of the rest of the skin, by the frequent scratching, which cannot be withheld. Hence long red lines are here and there left; and the blood and humour concrete upon the vesicles into little brown or blackish scabs.

These mixed appearances, partly belonging to the disease, and partly the result of abrasion by the nails, being in some measure common to the lichen and prurigo, where much scratching is also often employed, render the diagnosis of the scabies papuliformis more difficult than it would be from the mere similarity in the form of the eruption. But, as the most effectual remedy for the scabies is detrimental in the latter affections, the distinction is of great practical importance.

With respect to the eruption itself, the unbroken elevations in scabies papuliformis, when carefully examined, are found to be vesicular, and not papular: they are often intermixed, in particular situations, with pustules; and, when they break, are succeeded by scabs: whereas, in lichen, the papulæ terminate spontaneously in scurfy exfoliations. In scabies the eruption is unconnected with any constitutional or internal disorder, and the itching is severe: but in lichen there is commonly some constitutional affection, and a tingling sensation, as well as itching. The highly contagious nature of scabies will, in many cases, have already manifested itself, and remove all doubt; for the lichen is not thus communicable.

In prurigo, the papulæ, where no friction has been applied, retain the usual colour of the skin, are commonly flatter, or less acuminated, and present no moisture or scab, except when their tops have been forcibly abraded: they are not particularly numerous in the parts above mentioned; and they remain long distinctly papular, without showing any contagious property.

2. The *Scabies lymphatica*, or *watery* itch, is distinguished by an eruption of transparent vesicles, of a considerable size, and without any inflammation at their base. They arise in succession, with intense itching, chiefly round the wrists, between the fingers, on the back of the hands, and on the feet and toes: they often occur, also, about the axillæ, the hams, the bend of the elbows, and fossa of the nates, where they are intermixed with pustules: but they do not frequently appear, like the papuliform species, over the breast and epigastrium, nor on the thighs and upper parts of the arms.

In a day or two the vesicles break, and some of them heal, under the little scab that concretes upon them. But others inflame, and become pustules, which discharge, at length, a yellow matter, and extend into small ulcerated blotches, over which a dark scab is ultimately formed. — So that, during the progress of the eruption, all these appearances are intermixed with each other: the vesicles, and pustules, the excoriated blotches discharging pus, the minute dry scabs, and the larger ones succeeding the ulceration, may be observed at the same time. This circumstance constitutes one of the points of diagnosis between this and other vesicular diseases.

3. The *Scabies purulenta*, or *pocky* itch, is often mistaken by those who confine their notion of the disease to the ordinary small and ichorous vesicle of the two former species. The eruption consists of distinct, prominent, yellow pustules, which have a moderate inflammation round their bases, and which maturate and break in two or three days, and then ulcerate, with increasing pain and inflammation. These pustules commonly appear first, and attain the largest size, on the hands and feet, especially about the knuckles and roots of the toes, between the fingers, and particularly between the fore-finger and thumb, and round the wrists. In these situations, the pustules often exceed two lines in diameter, and assume a prominent globular form: whence, from their general resemblance to the large well-maturated pustules of smallpox, and not from any allusion to syphilis, as some have erroneously supposed, the popular term *pocky* has been applied to them. If the disease continue a few weeks, the pustules begin to appear on the other parts of the body which scabies usually attacks, especially about the axillæ, on the back and shoulders, and on the arms and thighs, near the joints of the knee and elbow, in the fossa of the nates, and sometimes, though of a smaller size, even about the epigastrium. In several of these situations, where the pustules are largest and numerous, they coalesce, and form irregular blotches, which ulcerate to some extent, with hardness and elevation of the surface; but at

length hard and dry scabs are formed, which adhere tenaciously for a considerable time.

4. *Scabies cachectica.* This variety of scabies exhibits, in different parts of the body, all the appearances which belong to the three foregoing species. It is occasionally, also, combined with patches resembling lichen, psoriasis, or impetigo, especially in adults, or young persons approaching the term of puberty; whence it assumes an ambiguous character. In several instances, this form of scabies has been obviously contagious in its double character; and, after the scabious affection has disappeared, the impetiginous patches have remained for some time, in a drier form, and yielded very slowly to medicine. For, although this form of scabies does not so readily spread by contagion, it is much more obstinate, under the use of remedies, than the preceding.

Another peculiarity of the scabies cachectica is, that it often originates, independently of contagion, in weakly children, and also in adults, when the constitution is suffering under some chronic malady, or debilitated by some previous acute disease; and, however it is produced, it is liable to return at intervals, especially in the spring and autumnal seasons, after it has been, to all appearance, cured.

The most ordinary cause of scabies is contagion; the virus being communicated by the actual contact of those already affected with it, or of their clothes, bedding, &c.; especially where there is much close intercourse. It seems to originate, however, in crowded, close, and uncleanly houses; and is, therefore, extremely prevalent in workhouses, gaols, and hospitals, where the means of great cleanliness are not easily obtained, and is most easily seen among the families of the poor. When the contagion has been introduced, however, into families, where every attention to cleanliness is enforced, it will frequently spread to all the individuals, children and adults, and continue, in spite of the utmost cleanliness, until the proper remedies are resorted to.

Some writers have ascribed the origin of the itch, in all cases, to the presence of a minute insect, breeding and burrowing in the skin; while others have doubted the existence of such an insect. Both these opinions appear to be incorrect; and, probably, that of Sauvages is right, who considers the insect as generated only in some cases of scabies, and, therefore, speaks of a scabies *vermicularis* as a separate species.

The existence of such an insect, in some cases of scabies, has been fully demonstrated; but the breeding of these acari in the scabious skin is a rare and casual circumstance; and the contagious property of scabies exists in the fluid secreted in the pustules, and not in the transference of insects.

Among the remedies appropriated to the cure of scabies, sulphur has long been deemed to possess *specific* powers. The common people treated the disease with this substance alone a century ago, administering it internally in milk, and applying it externally in butter. In the less violent degrees of scabies, and in the purulent species affecting the hands and wrists, perhaps no improvement can be made upon this practice. The latter species, when it occurs in children, is often readily removed by the internal use of this medicine alone, or in combination with a neutral salt, independently of any external application; and there are few cases of scabies which will not yield to the steady employment of the sulphur ointment, continued a sufficient time, and rubbed on the parts affected, nightly, with assiduity. Five or six applications are commonly sufficient for the cure of the disease; but sometimes it is necessary to persevere in the inunction for the space of a fortnight, or even longer, from which no detriment ensues to the constitution.

The disgusting odour of the sulphur, however, has led practitioners to resort to various other stimulating applications, some of which have been recommended from ancient times for the cure of scabid and pruriginous eruptions. Both the smell and sordid appearance of the sulphur ointment may be in a considerable degree obviated by the following combination: —

℞ Potassæ subcarbonatis, ℥ss.
Aquæ rosæ, ℥j.
Hydrarg. sulphurati rubri, ʒj.
Olei essent. bergamot, ℥ss.
Sulphuris-sublimati,
Adipis suillæ, aa ℥ix. Misce secundum artem.

SCABIO'SA. (*a*, *æ*. f.; from *scaber*, rough: so called from its rough hairy surface.) 1. The name of a genus of plants in the Linnæan system. Class, *Tetrandria;* Order, *Monogynia.*

2. The pharmacopœial name of the common scabious. See *Scabiosa arvensis.*

Scabiosa arvensis. The systematic name of the common field scabious. This herb, *Scabiosa — corollis quadrifidis radiantibus; foliis pinnatifidis, incisis; caule hispido*, of Linnæus, and its flowers, are sometimes used medicinally. The whole plant possesses a bitter and subastringent taste, and was formerly much employed in the cure of some leprous affections, and diseases of the lungs.

Scabiosa succisa. The systematic name of the devil's-bit scabious. It has similar properties with the preceding species.

Scabri'deæ. (From *scaber*, rough.) The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of plants with rough leaves, incomplete and inelegant flowers.

SCABRI'DEUS. Rough: applied to plants.

SCABRI'TIES. Roughness.

SCA'LA. A ladder or staircase.

Scala ty'mpani. The superior spiral cavity of the cochlea. See *Auris.*

Scala vesti'buli. The inferior spiral cavity of the cochlea. See *Auris.*

Scald. See *Ambustio.*

Scald-head. See *Porrigo favosa.*

SCALE. *Squama.* 1. In *Natural History*, the small laminæ, called *scales*, which cover the surface of fishes, serpents, &c., are appendages of the cuticle analogous to nails and horns. In

fishes they consist of alternate layers of membrane and phosphate of lime; in serpents of a horny membrane without earthy matter. Scales are also found on the stems, involucres, and other parts of plants.

2. In *Pathology*, a lamina of morbid cuticle, hard, thickened, whitish, and opake, of a very small size, and irregular, often increasing into layers, denominated crusts. Both scales and crusts repeatedly fall off, and are reproduced in a short time.

SCALE'NUS. (From σκαληνος, irregular, or unequal.) A muscle about which anatomical writers have differed greatly in their descriptions. It is situated at the side of the neck, between the transverse processes of the cervical vertebræ and the upper part of the thorax. The ancients, who gave it its name from its resemblance to an irregular triangle, considered it as one muscle. Vesalius and Winslow divide it into two, Fallopius and Cowper into three, Douglas into four, and Albinus into five portions, which they describe as distinct muscles. Without deviating in the least from anatomical accuracy, it may be considered as one muscle divided into three portions. The anterior portion arises commonly from the transverse processes of the six inferior vertebræ of the neck, by as many short tendons, and, descending obliquely outwards, is inserted, tendinous and fleshy, into the upper side of the first rib, near its cartilage. The axillary artery passes through this portion, and sometimes divides it into two slips, about an inch and a half above its insertion. The middle portion arises, by distinct tendons, from the transverse processes of the four last vertebræ of the neck, and, descending obliquely outwards and a little backwards, is inserted, tendinous, into the outer and upper part of the first rib, from its root to within the distance of an inch from its cartilage. The space between this and the anterior portion affords a passage to the nerves going to the upper extremities. It is in part covered by the third or posterior portion, which is the thinnest and longest of the three. This arises from the transverse processes of the second, third, fourth, and fifth vertebræ of the neck by distinct tendons, and is inserted into the upper edge of the second rib, at the distance of about an inch and a half from its articulation, by a broad flat tendon. The use of the scalenus is to move the neck to one side, when it acts singly, or to bend it forwards, when both muscles act; and, when the neck is fixed, it serves to elevate the ribs, and dilate the chest.

Scalenus primus. See *Scalenus.*

Scalenus secundus. See *Scalenus.*

Scalenus tertius. See *Scalenus.*

Scallop. See *Ostrea maxima.*

SCALPE'LLUM. (*um, i.* n.; from *scalpo*, to scratch or carve.) A scalpel or common dissecting knife.

SCA'LPRUM. A denticular raspatory, used in trepanning.

Scaly. See *Squamosus.*

SCAMMO'NIUM. (*um, ii.* n.; a corruption of the Arabic word *chamozah.*) See *Convolvulus scammonia.*

Scammony. See *Convolvulus.*

Scammony, Montpellier. See *Cynanchum montpeliacum.*

SCA'NDENS. Climbing: applied to stems, &c. of plants which climb, either with spiral tendrils for support, or by adhesive fibres; as the stems of the *Vitis vinifera*, and *Bryonia dioica.*

SCA'NDIX. (*ix, icis.* f.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia.*

SCANDIX CEREFOLIUM. The systematic name of the officinal chervil. *Cerefolium. Chærophyllum. Chærefolium. Chervillum. Daucus sepinius.* Chervil. This plant, *Scandix — seminibus nitidis, ovato-subulatis; umbellis sessilibus, lateralibus*, of Linnæus, is a salubrious culinary herb, sufficiently grateful both to the palate and stomach, slightly aromatic, gently aperient, and diuretic.

SCANDIX ODORATA. The systematic name of the sweet cicely, *myrrhis*, which possesses virtues similar to the common chervil. See *Scandix cerefolium.*

SCA'PHA. (*a, æ.* f.; a skiff, or cockboat: from σκαπτω, to make hollow, because formerly it was made by excavating a large tree.) 1. The cavity of the external ear, between the helix and antihelix.

2. The name of a double-headed roller.

SCA'PHOID. (*Scaphoides*; from σκαφη, a little vessel, or boat, and ειδος, resemblance.) Boat-like. See *Naviculare os.*

SCA'PULA. (*a, æ.* f.; from the Hebrew *schipha.*) *Omoplata. Os homoplatæ. Scoptula. Epinotion.* The shoulder-blade. This bone, which approaches nearly to a triangular figure, is fixed, not unlike a buckler, to the upper, posterior, and lateral part of the thorax, extending from the first to about the seventh rib. The anterior and internal surface is irregularly concave, from the impression, not of the ribs, as the generality of anatomists have supposed, but of the sub-scapularis muscle. Its posterior and external surface is convex, and divided into two unequal fossæ by a considerable spine, which, rising small from the posterior edge of the scapula, becomes gradually higher and broader, as it approaches the anterior and superior angle of the bone, till at length it terminates in a broad and flat process, at the top of the shoulder, called the *processus acromion.* On the anterior edge of this processus acromion we observe an oblong, concave, articulating surface, covered with cartilage, for the articulation of the scapula with the clavicle. At its lower part the acromion is hollowed, to allow a passage to the supra and infra spinati muscles. The ridge of the spine affords two rough flat surfaces, for the insertion of the trapezius and deltoid muscles. Of the two fossæ into which the external surface of the bone is divided by the spine, the superior one, which is the smaller, serves to lodge the supra spinatus muscle; and the inferior fossa, which is much larger than the other, gives origin to the infra spinatus. The triangular shape of the scapula leads us to consider its angles and its sides. The upper posterior angle is neither so thick, nor has so rough a

surface, as the inferior one; but the most remarkable of the three angles of this bone is the anterior one, which is of great thickness, and formed into a glenoid cavity of an oval shape, the greatest diameter of which is from below upwards. This cavity, in the recent subject, is furnished with cartilage, and receives the head of the os humeri. The cartilaginous crust, which surrounds its brims, makes it appear deeper in the fresh subject than in the skeleton. A little beyond this glenoid cavity, the bone becomes narrower, so as to give the appearance of a neck; and above this rises a considerable process, which, from being thick at its origin, becomes thinner, and, in some degree, flattened at its extremity. This process projects considerably, and is curved downwards. From its supposed resemblance to a beak of a bird it is called the *caracoid* process. From the whole external side of this process a strong and broad ligament is stretched to the processus acromion, becoming narrower as it approaches the latter process, so as to be of a somewhat triangular shape. This ligament, and the two processes with which it is connected, are evidently intended for the protection of the joint, and to prevent a luxation of the os humeri upwards. Of the three sides of the scapula, the posterior one, which is the longest, is called the *basis*. This side is turned towards the vertebræ. Its other two sides are called *costæ*. The superior costa, which is the upper and shortest side, is likewise thinner than the other two, having a sharp edge. It is nearly horizontal, and parallel with the second rib; and is interrupted, near the basis of the caracoid process, by a semicircular niche, which is closed by a ligament that extends from one end of it to the other, and affords a passage to vessels and nerves. Besides this passage, there are other niches in the scapula for the transmission of vessels; viz., one between the caracoid process and the head of the bone, and another between its neck and the processus acromion. The third side of the scapula, or the inferior costa, as it is called, is of considerable thickness, and extends obliquely from the neck of the bone to its inferior angle, reaching from about the third to the eighth rib. The scapula has but very little cellular substance, and is of unequal thickness, being very thin at its middle part, where it is covered by a great number of muscles, and having its neck, the acromion, and caracoid process of considerable strength. In the fœtus, the basis and the neck of the scapula, together with its glenoid cavity, acromion, caracoid process, and the ridge of the spine, are so many epiphyses with respect to the rest of the bone, to which they are not completely united till a considerable time after birth. The scapula is articulated to the clavicle and os humeri, to which last it serves as a fulcrum; and, by altering its position, it affords a greater scope to the bones of the arm in their different motions. It likewise affords attachment to a great number of muscles, and posteriorly serves as a defence to the thorax.

SCAPULA'RIA. (*a*, *æ*. f.; from *scapula*, the shoulder bone.) A scapulary. A bandage for the shoulder blade.

SCA'PULARY. (*Scapularis*; from *scapula*, the shoulder bone.) Belonging to the scapula; as the scapulary arteries and veins, which are branches of the subclavian and axillary.

SCA'PUS. (*us*, *i*. m.; from σκηπτω, to lean or rest upon: because it rests, as it were, on the root or base. (?)) The scape, or a stalk which springs from the root, and bears the flowers and fruit, but not the leaves. The primrose and cowslip are good examples of it.

The following are the principal varieties: —

1. *Round*; as in *Plantago major*.
2. *Angular*; as in *Plantago lanceolata*.
3. *Ventricose*, hollow at the bottom; as in *Allium cepa*.
4. *Flexuose*; as in *Orchis flexuosa*.
5. *Two-edged*; as *Allium angulosum*.
6. *Filiform*; as *Bellis bellidioides*.
7. *Three-sided*; as *Allium triquetrum*.
8. *Spiral*; as *Anthericum spirale*, and that wonderful plant, *Valisneria spiralis*.
9. *Pentagonal*; as *Ophris paludosa*.
10. *Articulate*; as *Statice echioides*.
11. *Erect*; in *Tulipa gesneriana*.
12. *Ascending*; in *Sisymbrium vimineum*.
13. *Declinate*; as *Astragalus incanus*.
14. *Decumbent*; as *Potentilla sabacaulis*.
15. *Dichotomous*; as *Statice tartarica*.
16. *Nude*; as *Convallaria majalis*.
17. *Leafy*; as *Ophris insectifera*.
18. *Bracteate*; as most of the *Orchides*.
19. *Imbricate*; as *Tussilago farfara*.
20. *Setaceous*; as *Schænus bulbosus*.
21. *Vaginate*; as *Arethusa bulbosa*.

When several species of the same plant have a scapus, and it is wanting in one of the same species, it is termed *excapus*; as in *Astragalus excapus*.

Scar. See *Cicatrix*.

SCARBOROUGH. The name of a town in Yorkshire, noted for its ferruginous springs. There are two species of chalybeate water found in this spot, and they differ considerably in their composition, though they rise nearly contiguous to each other. The one is a simple carbonated chalybeate, similar to the Tunbridge water; the other, which is better known and more frequented, and more particularly distinguished as Scarborough water, has, in conjunction with the iron, an admixture of sulphate of lime, and of sulphate of magnesia, which gives it a purgative quality. The diseases in which it is ordered are similar to those in which Cheltenham water is prescribed, only it is necessary to increase the purgative effect of this water by adding similar salts. It is, therefore, chiefly as an alterative that this water can be employed in its natural state.

Scarborough has an advantage of situation which Cheltenham does not possess, that of affording an opportunity for sea-bathing, the use of which will, in many cases, much assist in the plan of cure for many of the disorders for which the mineral water is resorted to.

Scarf-skin. See *Cutis*.

SCARIFICA'TION. (*Scarificatio*; from *scarifico*, to scarify.) A superficial incision made with a lancet, or a chirurgical instrument called a scarificator, for the purpose of taking away blood, or letting out fluids, &c.

SCARIFICA'TOR. An instrument used by surgeons and cuppers to evacuate blood. It is made in form of a box, in which are fitted ten, twelve, or more lancets, all perfectly in the same plane. The instrument is so constructed that the depth to which the lancets penetrate may be made greater or less at the option of the operator. Immediately before the application of the scarificator to the part, the lancets are all, as it were, cocked by means of a spring, and all discharged at the same time, by pulling a kind of trigger, and thus they are driven equally within the skin. See *Cupping*.

Scari'ola. See *Lactuca scariola*.

Scariola gallorum. See *Lactuca*.

SCA'RIOUS. *Scariosus*. Applied, in *Botany*, to any part of a plant which is thin, dry, and semi-transparent.

SCARLATI'NA. (*a*, *æ*. f.; from *scarlatto*, the Italian for a deep red.) The scarlet fever. A disease characterised by contagious fever, the face swelling, and a scarlet eruption appearing on the skin in patches, which, after three or four days, ends in the desquamation of the cuticle. It has two species: —

1. *Scarlatina simplex*, the mild.
2. *Scarlatina cynanchica*, or *anginosa*, with ulcerated sore throat.

Dr. Willan has added to these a third, called *maligna*, which is now generally believed to be the same disease with the *cynanche maligna*, or malignant sore throat. See *Tonsillitis*.

Some have asserted that scarlatina never attacks the same person a second time: more extensive observation has confuted this opinion. It seizes persons of all ages, but children and young persons are most subject to it; and it appears at all seasons of the year; but it is more frequently met with towards the end of autumn, or beginning of winter, than at any other periods, at which time it very often becomes a prevalent epidemic. It is, beyond all doubt, a very contagious disease.

The malady to which it bears the greatest resemblance is the measles; but from this it is generally to be distinguished by the absence of the cough, watery eye, running at the nose, and sneezing, which are the predominant symptoms in the early stage of the measles, but which do not usually attend on scarlet fever, or, at least, in any high degree. In some cases, however, the diagnosis is very difficult; so much so that the disease almost appears to be hybrid between scarlet fever and measles.

It begins, like other fevers, with languor, lassitude, confusion of ideas, chills, and shiverings, alternated by fits of heat. The thirst is considerable, the skin dry, and the patient is often incommoded with anxiety, nausea, and vomiting. About the third day, the scarlet efflorescence appears on the skin, which seldom produces, however, any remission of the fever. On the departure of the efflorescence, which usually continues out only for three or four days, a gentle sweat comes on, the fever subsides, the cuticle or scarf-skin then falls off in small scales, and the patient gradually regains his former strength and health.

On the disappearance of the efflorescence, in scarlatina, it is, however, no uncommon occurrence for an anasarcous swelling to affect the whole body; but this, in most cases, yields easily to proper treatment. See *Anasarca*.

Scarlatina anginosa, in several instances, approaches very near to the malignant form. The patient is seized, not only with a coldness and shivering, but likewise with great languor, debility, and sickness, succeeded by heat, nausea, vomiting of bilious matter, soreness of the throat, inflammation and ulceration in the tonsils, &c., a frequent and laborious breathing, and a quick and small depressed pulse. When the efflorescence appears, which is usually on the third day, it brings no relief; on the contrary, the symptoms are much aggravated, and fresh ones arise.

In the progress of the disease, one universal redness, unattended, however, by any pustular eruption, pervades the face, body, and limbs, which parts appear somewhat swollen. The eyes and nostrils partake likewise more or less of the redness, and, in proportion as the former have an inflamed appearance, so does the tendency to delirium prevail.

On the first attack the fauces are often much inflamed; but this is usually soon succeeded by greyish sloughs, which give the parts a speckled appearance, and render the breath more or less fœtid. The patient is often cut off in a few days: and, even if he recovers, it will be by slow degrees; dropsical swellings, or tumours of the parotid and other glands, slowly suppurating, being very apt to follow.

Scarlatina maligna. The symptoms at first are pretty much the same as in the preceding; but some of the following peculiarities are afterwards observable: — The pulse is small, indistinct, and irregular; the tongue, teeth, and lips, covered with a brown or black incrustation; a dull redness of the eyes, with a dark red flushing of the cheeks, deafness, delirium, or coma; the breath is extremely fœtid; the respiration rattling and laborious, partly from viscid phlegm clogging the fauces; the deglutition is constricted and painful; and there is a fulness and livid colour of the neck, with retraction of the head. Ulcerations are observed on the tonsils and adjoining parts, covered with dark sloughs, and surrounded by a livid base; and the tongue is often so tender as to be excoriated by the slightest touch. An acrid discharge flows from the nostrils, causing soreness, or chaps, nay even blisters, about the nose and lips; the fluid discharged being at first thin, but afterwards thick and yellowish. The rash is usually faint, except in a few irregular patches, and it presently changes to a dark or livid red colour: it appears late, is very uncertain in its duration, and often intermixed with petechiæ: it sometimes disappears suddenly a few hours after it is formed, and comes out again at the expiration of two or three days. In an advanced stage of the disease, where petechiæ, and other symptoms characteristic of putrescency, are present, hæmorrhages frequently break forth from the nose, mouth, and other parts.

When scarlatina is to terminate in health, the fiery redness abates gradually, and is suc-

ceeded by a brown colour, the skin becomes rough, and peels off in small scales, the tumefaction subsides, and health is gradually restored. On the contrary, when it is to terminate fatally, the febrile symptoms run very high from the first of its attack, the skin is intensely hot and dry, the pulse is very frequent, but small, great thirst prevails, the breath is very fetid, the efflorescence makes its appearance on the second day, or sooner, and about the third or fourth is probably interspersed with large livid spots; and a high degree of delirium ensuing, or hæmorrhages breaking out, the patient is cut off about the sixth or eighth day. In some cases a severe purging arises, which never fails to prove fatal. Some again, where the symptoms do not run so high, instead of recovering, as is usual, about the time the skin begins to regain its natural colour, become dropsical, fall into a kind of lingering way, and are carried off in the course of a few weeks.

Scarlatina, in its inflammatory form, is not usually attended with danger, although a considerable degree of delirium sometimes prevails for a day or two; in some cases, however, it passes into a malignant form by a very rapid transition, so that it cannot at any time be considered as entirely divested of danger. On dissection of those who die of this disease, the fauces are inflamed, suppurated, and gangrenous; and the trachea and larynx are likewise in a state of inflammation, and lined with a viscid fetid matter. In many instances, the inflammatory affection extends to the lungs themselves. Large swellings of the lymphatic glands about the neck, occasioned by an absorption of the acrid matter poured out in the fauces, are now and then to be found. The same morbid appearances which are to be met with in putrid fever present themselves in other parts of the body.

The plan to be pursued will differ according to the form of the disease. In the scarlatina simplex little is required, except clearing the bowels, and observing the antiphlogistic regimen. But where the throat is affected, and the fever runs higher, more active means become necessary, varying according to the type of this, whether synochial or typhoid. In general, we may begin by exhibiting a nauseating emetic, which, besides its effect on the fever, may be useful in checking inflammation in the throat; and occasionally the repetition of such a remedy, after a time, may answer a good purpose: but commonly it will be better to follow up the first by some cathartic remedy of sufficient activity. Then, so long as the strength will allow, we may endeavour to moderate the fever by mercurial and antimonial preparations, or other medicines promoting the several secretions, by steadily pursuing the antiphlogistic regimen, and occasionally applying cold water to the skin, when this is very hot and dry. Sometimes severe inflammation in the throat, at an early period, may render it advisable to apply a few leeches externally, or blisters behind the ears; and gargles of nitrate of potash, the mineral acids, &c. should be used from time to time. But where the disorder exhibits the typhoid character, with ulcers in the throat, tending perhaps to gangrene, it is necessary to support the system by a nutritious diet, with a moderate quantity of wine, and tonic or stimulant medicines, as the cinchona, calumba, ammonia, capsicum, &c.; the acids will also be very proper, from their antiseptic as well as tonic power; and stimulant antiseptic gargles should be frequently employed, as the mineral acids sufficiently diluted, with the addition of tincture of myrrh, or these mixed with decoction of bark, &c. Besides the general measures, thus varied according to the character of the disease, particularly alarming symptoms may require to be palliated; as vomiting by the effervescing draught, and occasionally a blister to the stomach, if there be tenderness on pressure; diarrhœa, by small doses of opium, &c. The management of these, however, as well as of the dropsical swellings, and other sequels of the disease, will be understood from what is said under those heads respectively.

Scarlet fever. See *Scarlatina.*

Scarred. See *Cicatrisatus.*

SCELOTY'RBE. (*e, es.* f.; from σκελος, the leg, and τυρβη, tumult, disturbance.) The name of a disease, described by Galen as a species of atony or paralysis, in which a man is incapable of walking straight on, and is turned round to the left when the right leg is put forward, and to the right when the left is put forward, or alternately. Sometimes he is incapable of raising the foot, and hence drags it awkwardly, as those that are climbing up steep cliffs. This disease has been considered by some as identical with *chorea.* Others have regarded it as symptomatic of scurvy. According to some critics, the word scelotyrbe, as used by Pliny, is synonymous with scurvy. Sauvages makes *scelotyrbe* an order of diseases, including chorea, shaking palsy, and three other species.

SCHEELE'S GREEN. Arsenite of copper, used as a pigment.

SCHEELIUM. A name sometimes given to the metal more generally called Tungsten, because Scheele discovered the tungstic acid from which it is obtained.

SCHINELÆ'UM. (From σχινος, mastich, and ελαιον, oil.) Oil of mastich.

SCHI'NUS. A genus of plants of the order *Terebinthinæ.*

SCHINUS MULLI. The plant which yields the Peruvian mastich, of which it is so full that the resinous juice flows from the leaves spontaneously, especially after rain, diffusing a delightful fragrance. A kind of wine is made from the berries of the plant. The specific name is sometimes improperly written *molle* instead of *mulli.*

SCHNEIDER'S MEMBRANE. (So called from its discoverer.) See *Membrana Schneiderma.*

SCHŒNAN'THUS. (*us, i.* m.; from σχοινος, a rush, and ανθος, a flower.) See *Andropogon schœnanthus.*

SCHŒNOLAGU'RUS. (From σχοινος, a rush, λαγως, a hare, and ουρα, a tail: so called from its resemblance to a hare's tail.) Hare's tail, the *Trifolium arvense.*

SCIA'TIC. (*Sciaticus;* from *ischiaticus.*) Belonging to the ischium.

Sciatic artery. See *Ischiadic artery.*

Sciatic nerve. See *Sacrosciatic nerve.*

Sciatic notch. See *Innominatum os.*

SCIA'TICA. Two very different diseases have been confounded under this name,—rheumatism or rheumatic gout in the hip-joint, and neuralgia of the sacro-sciatic nerve.

Sciatica cresses. See *Lepidium iberis.*

SCI'LLA. (*a*, *æ*. f.; from σκιλλω, to dry: so called from its property of drying up humours.) 1. The name of a genus of plants in the Linnæan system. Class, *Hexandria*; Order, *Monogynia.*

2. The pharmacopœial name of the medicinal squill. See *Scilla maritima.*

Scilla hispanica. The Spanish squill.

Scilla maritima. The systematic name of the officinal squill: called, also, *Ornithogalum maritimum. Pancratium. Squilla. Scilla—nudiflora, bracteis refractis*, of Linnæus. A native of Spain, Sicily, and Syria, growing on the sea-coast. The red-rooted variety has been supposed to be more efficacious than the white, and is therefore still preferred for medicinal use. The root of the squill, which appears to have been known as a medicine in the early ages of Greece, and has so well maintained its character ever since, as to be deservedly in great estimation and of very frequent use at this time, seems to manifest a poisonous quality to several animals. In proof of this, we have the testimonies of Hillefield, Bergius, Vogel, and others. Its acrimony is so great that, even if much handled, it exulcerates the skin; and if given in large doses, and frequently repeated, it not only excites nausea, tormina, and violent vomiting, but it has been known to produce strangury, bloody urine hypercatharsis, cardialgia, hæmorrhoids, convulsions, with fatal inflammation, and gangrene of the stomach and bowels. But as many of the active articles of the Materia Medica, by injudicious administration, become equally deleterious, these effects of the scilla do not derogate from its medicinal virtues: on the contrary, we feel ourselves fully warranted, says Dr. Woodville, in representing this drug, under proper management, and in certain cases and constitutions, to be a medicine of great practical utility and real importance in the cure of many obstinate diseases. The acrimony of the squill, like that of the arum, seems to depend on some unknown volatile principle, and is entirely dissipated if the drug be long kept or exposed to a high temperature. According to Vogel's analysis, squill consists of gum, a bitter principle, named *scillitine*, tannin, citrate of lime, saccharine matter, and woody fibre. Its effects, as stated by Bergius, are incidens, diuretica, emetica, subpurgans, hydragoga, expectorans, emmenagoga. In dropsical cases it has long been esteemed the most certain and effectual diuretic with which we are acquainted; and in asthmatic affections, or dyspnœa, occasioned by the lodgment of tenacious phlegm, it has been the expectorant usually employed. The squill, especially in large doses, is apt to stimulate the stomach, and to prove emetic; and it sometimes acts on the intestines, and becomes purgative; but, when these operations take place, the medicine is prevented from reaching the blood-vessels and kidneys, and the patient is deprived of its diuretic effects, which are to be obtained by giving the squill in smaller doses, repeated at more distant intervals, or by the joining of an opiate to this medicine, which was found by Dr. Cullen to answer the same purpose. The doctor further observes, that, from a continued repetition of the squill, the dose may be gradually increased, and the interval of its exhibitions shortened; and when, in this way, the dose comes to be tolerably large, the opiate may be most conveniently employed to direct the operation of the squill more certainly to the kidneys. In cases of dropsy, that is, when there is an effusion of water into the cavities, and therefore less water goes to the kidneys, we are of opinion that neutral salt, accompanying the squill, may be of use in determining this fluid more certainly to the kidneys; and, whenever it can be perceived that it takes this course, we are persuaded that it will be always useful, and generally safe, during the exhibition of the squills, to increase the usual quantity of drink.

The diuretic effects of squills have been supposed to be promoted by the addition of some mercurial; and the less purgative preparations of mercury, in the opinion of Dr. Cullen, are best adapted to this purpose: he therefore recommends a solution of corrosive sublimate as being more proper than any other, because most diuretic. Where the primæ viæ abound with mucous matter, and the lungs are oppressed with viscid phlegm, this medicine is likewise in general estimation.

As an expectorant, the squill may be supposed, not only to attenuate the mucus in the follicles, but also to excite a more copious secretion of it from the lungs, and thereby lessen the congestion upon which the difficulty of respiration very generally depends. Therefore, in all pulmonic affections, excepting only those of actual or violent inflammation, ulcer, and spasm, the squill has been experienced to be a useful medicine. The officinal preparations of squills are, a conserve, dried squills, a syrup, and vinegar, and oxymel, and pills. Practitioners have not, however, confined themselves to these. When this root was intended as a diuretic, it has most commonly been used in powder, as being, in this state, less disposed to nauseate the stomach; and to the powder it has been the practice to add neutral salts, as nitre, or crystals of tartar, especially if the patient complained of much thirst: others recommend calomel; and, with a view to render the squills less offensive to the stomach, it has been usual to conjoin an aromatic. The dose of dried squills is from one to four or six grains once a day, or half this quantity twice a day; afterwards to be regulated according to its effects. The dose of the other preparations of this drug, when fresh, should be five times this weight; for this root looses in the process of drying four fifths of its original weight, and this loss is merely a watery exhalation.

Scilla nutans. This plant was, until very lately, called *Hyacinthus non scriptus.* It is well known by the name of blue-bells, and is

common in our hedges in spring. The roots are bulbous; the flowers agreeably scented. Galen considered the root as a remedy in jaundice. It is ranked among the astringents, but of very inferior power.

Scilli'tes. (From *σκιλλα*, the squill.) A wine impregnated with squills.

SCI'LLITINE. *Scillitina.* A white, transparent, acrid substance, extracted by Vogel from squills.

SCI'NCUS. (*us, i.* m.; *σκιγγος*, from *sheque*, Hebrew.) The skink. This amphibious animal is of the lizard kind, and caught about the Nile, and thence brought dried into this country, remarkably smooth and glossy, as if varnished. The flesh of the animal, particularly of the belly, has been said to be diuretic, alexipharmic, aphrodisiac, and useful in leprous disorders.

Scirrho'ma. (*a, atis.* n.; from *σκιρροω*, to harden.) See *Scirrhus.*

SCI'RRHUS. (*us, i.* m.; from *σκιρροω*, to harden.) *Scirrhoma. Scirrhosis.* This term has been applied to any very hard glandular tumour, but it is now usually restricted to the early or occult stage of cancer. See *Cancer.*

SCITAMINE'US. (From *scitamentum*, a dainty: so called because they are warm cordial luxuries.) Scitamineous: dainty. Applied to several plants which are considered as dainties.

Scitamine'æ. The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of those which have an herbaceous stalk, broad leaves, and the germen obtusely angled under an irregular corolla; as *Amomum, Canna, Musa*, &c.

SCLA'REA. (*a, æ.* f.; from *σκληρος*, hard: because its stalks are hard and dry.) Blanch. See *Salvia sclarea.*

Sclarea hispanica. See *Salvia sclarea.*

SCLERI'ASIS. (From *σκληροω*, to harden.) *Scleroma. Sclerosis.* A hard tumour or induration; a scirrhus.

SCLEROPHTHA'LMIA. (*a, æ.* f.; from *σκληρος*, hard, and *οφθαλμος*, the eye.) A dry painful state of the eye and eyelids, accompanied with swelling and hardness.

Sclerosarcoma. (From *σκληρος*, hard, and *σαρκωμα*, a fleshy tumour.) A hard fleshy excrescence.

Sclerosis. See *Scleriasis.*

SCLERO'TIC. (*Scleroticus*; from *σκληροω*, to harden.) Hard: applied to a membrane of the eye.

Sclerotic coat. *Tunica sclerotica. Membrana sclerotica. Sclerotis.* The membrane of the eye, situated immediately under the conjunctiva. See *Oculus.*

Sclerotis. See *Sclerotic coat.*

Sclopetaria aqua. (From *sclopetum*, a gun: so called from its supposed virtues in healing gun-shot wounds.) The arquebusade water has been so called. See *Eau d'arquebusade.*

Sclopetopla'ga. (*a, æ.* f.; from *sclopetum*, a gun, and *plaga*, a wound.) A gun-shot wound.

SCOLI'ASIS. (From *σκολιοω*, to twist.) A distortion of the spine.

Scolloped. See *Crenatus.*

SCOLOPAX. (*ax, acis.* f.) A genus of birds of the order *Grallæ.* It includes curlews and woodcocks.

Scolopax gallina'go. The common snipe. The flesh of this bird approaches that of the woodcock in flavour, but is reckoned less digestible.

Scolopax rusti'cola. The woodcock. The flesh of this bird is tender and easy of digestion; but the entrails, which generally come to table, sometimes disagree with weak stomachs.

Scolope'ndria. (*a, æ.* f.) See *Asplenium ceterach.*

SCOLOPE'NDRIUM. (*um, ii.* n.; from *σκολοπενδρα*, the earwig: so called because its leaves resemble the earwig.) The name of a genus of plants. Class, *Cryptogamia*; Order, *Filices.* Hart's-tongue, spleenwort.

Scolopendrium vulgare. *Phyllitis. Lingua cervina. Scolopendrium. Asplenium scolopendrium. Blechnium linguifolium.* This indigenous plant, *Asplenium — frondibus simplicibus, cordato lingulatis, integerrimis; stipitibus hirsutis,* of Linnæus, grows on most shady banks, walls, &c. It has a slightly astringent and mucilaginous sweetish taste. When fresh, and rubbed, it imparts a disagreeable smell. Hart's-tongue, which is one of the five capillary herbs, was formerly much used to strengthen the viscera, restrain hæmorrhages and alvine fluxes, and to open obstructions of the liver and spleen, and for the general purposes of demulcents and pectorals.

Scolopomachæ'rium. (From *σκολωπαξ*, the woodcock, and *μαχαιρα*, a knife: so called because it is bent a little at the end, like a woodcock's bill.) An incision-knife.

Sco'lymus. (*us, i.* m.; from *σκολος*, a thorn: so named from its prickly leaves.) See *Cinara scolymus.*

SCO'MBER. (*er, bri.* m. *Σκομβερος.*) The name of a genus of fishes, of the order *Thoracici.*

Scomber scomber. The systematic name of the common mackarel, a beautiful fish of easy digestion, which frequents our shore, in vast shoals, between the months of April and July.

Scomber thynnus. The systematic name of the tunny-fish, which frequents the shores of the Mediterranean, and, though a coarse fish, was much esteemed by the Greeks and Romans, and is still considered a delicacy by some.

Scopa regia. See *Ruscus aculeatus.*

SCORBU'TUS. (*us, i.* m.; from *schorboet*, Germ.) *Porphyra* of Dr. Good. The scurvy. A disease characterised by extreme debility; complexion pale and bloated; spongy gums; livid spots on the skin; breath offensive; œdematous swellings in the legs; hæmorrhages; foul ulcers; fœtid urine; and extremely offensive stools. The scurvy is a disease of an adynamic character, much more prevalent in cold climates than in warm ones, and which chiefly affects sailors, and such as are shut up in besieged places, owing, as is supposed, to their being deprived of fresh provisions, and a due quantity of ascescent food, assisted by the prevalence of cold and moisture, and by such other causes as depress the nervous energy, as intemperance, confinement, want of exercise, neglect of cleanliness, much labour and fatigue,

sadness, despondency, &c. These several debilitating causes, with the concurrence of a diet consisting principally of salted or putrescent food, will be sure to produce this disease. It seems, however, to depend more on a defect of nourishment than on a vitiated state; and the reason that salted provisions are so productive of the scurvy is, most probably, because they are drained of their nutrious juices, which are extracted and run off in brine. As the disease is apt to become pretty general amongst the crew of a ship when it has once made its appearance, it has been supposed by many to be of a contagious nature; but the conjecture seems by no means well founded.

A preternatural saline state of the blood has been assigned as its proximate cause. It has been contended, by some physicians, that the primary morbid affection in this disease is a debilitated state of the solids, arising principally from the want of aliment. The scurvy comes on gradually, with heaviness, weariness, and unwillingness to move about, together with dejection of spirits, considerable loss of strength, and debility. As it advances in its progress, the countenance becomes sallow and bloated, respiration is hurried on the least motion, the teeth become loose, the gums are spongy, the breath is very offensive, livid spots appear on different parts of the body, old wounds, which have been long healed up, break out afresh, severe wandering pains are felt, particularly by night, the skin is dry, the urine small in quantity, turning blue vegetable infusions to a green colour; and the pulse is small, frequent, and, towards the last, intermitting; but the intellect is, for the most part, clear and distinct. By an aggravation of the symptoms, the disease, in its last stage, exhibits a most wretched appearance. The joints become swelled and stiff, the tendons of the legs are rigid and contracted, general emaciation ensues, hæmorrhages break forth from different parts, fœtid evacuations are discharged by stool, and a diarrhœa or dysentery arises, which soon terminates the life of the patient.

Scurvy, as usually met with on shore, or where the person has not been exposed to the influence of the remote causes before enumerated, is unattended by any violent symptoms: slight blotches, with scaly eruptions on different parts of the body, and a sponginess of the gums, are the chief ones to be observed.

In forming our judgment as to the event of the disease, we are to be directed by the violence of the symptoms, by the situation of the patient with respect to a vegetable diet, or other proper substitutes, by his former state of health, and by his constitution having been impaired by previous diseases or otherwise.

Dissections of scurvy have always discovered the blood to be in a very dissolved state. The thorax usually contains more or less of a watery fluid, which, in many cases, possesses so high a degree of acrimony as to excoriate the hands by coming in contact with it; the cavity of the abdomen contains the same kind of fluid; the lungs are black and putrid; and the heart itself has been found in a similar state, with its cavity filled with a corrupted fluid. In many instances the epiphyses have been found divided from the bones, the cartilages separated from the ribs, and several of the bones themselves dissolved by caries. The brain seldom shows any disease.

In the cure as well as the prevention of scurvy much more is to be done by regimen than by medicines, obviating, as far as possible, the several remote causes of the disease, but particularly providing the patient with a more wholesome diet, and a large proportion of fresh vegetables; and it has been found that those articles are especially useful which contain a native acid, as oranges, lemons, &c. Where these cannot be procured, various substitutes have been proposed, of which the best appear to be the inspissated juices of the same fruits, or the crystallised citric acid. Vinegar, saur-kraut, and farinaceous substances, made to undergo the acetous fermentation, have likewise been used with much advantage: also brisk fermenting liquors, as spruce-beer, cider, and the like. Formerly many plants of the class *Tetradynamia*, as mustard, horse-radish, &c., likewise garlic, and others of a stimulant quality, promoting the secretions, were much relied upon, and, no doubt, proved useful to a certain extent. The spongy state of the gums may be remedied by washing the mouth with some of the mineral acids sufficiently diluted, or perhaps mixed with the decoction of cinchona. The stiffness of the limbs which remains may be removed by the warm bath and friction with the flesh brush: in hot climates the earth bath is said to have been sometimes very efficacious.

Sco'RDIUM. (*um*, *i.* n.; from σκοροδον, garlic: so called because it smells like garlic.) See *Teucrium scordium*.

SCO'RIÆ. (*a*, *æ.* f.; from σκωρ, excrement.) Dross. The refuse or useless parts of any substance.

Scoro'doprasum. (*um*, *i.* n.; from σκοροδον, garlic, and πρασον, the leek.) The wild garlic, a species of allium.

SCO'RODUM. (*um*, *i.* n. Απο του σκωρ οζειν, from its filthy smell.) Garlic.

Scorpioi'des. (From σκορπιος, a scorpion, and ειδος, a likeness: so called because its leaves resemble the tail of a scorpion.) The *Myosurus scorpioides*.

SCORPIU'RUS. (From σκορπιος, a scorpion, and ουρα, a tail.) 1. The name of a genus of plants. Class, *Diadelphia*; Order, *Decandria*.

2. See *Myosurus scorpioides*.

SCORZONE'RA. (*a*, *æ.* f.; from *scurzo*, an old Spanish word for a viper: so called because it is said to be effectual against the bite of all venomous animals.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia æqualis*.

2. The pharmacopœial name of the viper's-grass. See *Scorzonera humilis*.

Scorzonera hispanica. The systematic name of the esculent viper's-grass. *Serpentaria hispanica*. The root of this plant is mostly sold for that of the *humilis*.

Scorzonera humilis. The systematic name

of the officinal viper's-grass. Goat's-grass. Viper's-grass. *Escorzonera. Viperaria.* The roots of this plant, *Scorzonera — caule subnudo, unifloro; foliis lato-lanceolatis, nervosis, planis,* of Linnæus, have been sometimes employed medicinally as alexipharmics, and in hypochondriacal disorders and obstructions of the viscera. The *Scorzonera hispanica* mostly supplies the shops; the root of which is esculent, oleraceous, and, against diseases, inefficacious.

SCOTODI'NUS. (*us, i.* m.; σκοτοδινος, from σκοτος, darkness, and δινος, a giddiness.) *Scotodinia. Scotoma. Scotodinos. Scotodine.* Giddiness, with impaired sight. This may arise from some disease of the brain; but it is most commonly symptomatic of disorder of the digestive organs. It is frequently accompanied with ringing in the ears.

Scoto'ma. See *Scotodinus.*

SCROBICULA'TUS. (From *scrobiculus,* a little ditch, or furrow.) Hollowed, having deep round foramina. Applied to parts of plants, as the receptacle of the *Helianthus annuus.*

SCROBI'CULUS. (*us, i.* m.; diminutive of *scrobs,* a ditch.) A hollow: the pit of the stomach is called *scrobiculus cordis.*

SCRO'FA. The sow. See *Sus scrofa.*

SCRO'FULA. (*a, æ.* f.) The Greeks denominated this disease χοιρας; the nosologists of recent times, *scrofula:* thus literally translating the Greek, and importing *swine evil, swine swellings,* from a notion that pigs were particularly subject to this disease. Scrofula is a disease very difficult to define: it consists in hard indolent tumours of the conglobate glands in various parts of the body, but particularly in the neck, behind the ears, and under the chin, which, after a time, suppurate and degenerate into ulcers, from which, instead of pus, a white curdled matter, somewhat resembling the coagulum of milk, is discharged.

The first appearance of the disease is most usually between the third and seventh year of the child's age; but it may arise at any period between this and the age of puberty; after which it seldom makes its first attack.

Scrofula is a very prevalent disease in climates which are moist, rather cold, and very changeable, like those of England and Holland, while it is rare in hot climates, and in very cold ones, where the air is generally dry.

The scrofulous diathesis, when strongly marked, is generally indicated by certain external peculiarities of appearance. The greater part of scrofulous persons have a fair and soft skin, and fine rosy complexion, large blue eyes, and a tumid upper lip; their constitution is languid and yet irritable; the muscles are slender and deficient in tone, and there is a general irritability of the mucous membranes, indicated by a disposition to catarrh, diarrhœa, ophthalmia, &c. A smaller class of scrofulous individuals are characterised by a dark sallow complexion, black hair, a harsh skin, and a torpid constitution. This rarer aspect of scrofula is indicative of a disposition to its worst forms; and the disease, when it appears in such subjects, is very inveterate and intractable. Although scrofula be most frequently met with in one or other of the constitutions just noticed, it is by no means confined to them, nor is there any variety of temperament or habit exempt from its attacks.

Scrofula is by no means a contagious disease, but, beyond all doubt, is of an hereditary nature, and is often entailed by parents on their children. There are, indeed, some practitioners who wholly deny that this or any other disease can be acquired by hereditary transmission; but that a peculiar temperament of body, or predisposition in the constitution of some diseases, may extend from both father and mother to their offspring is very clearly proved.

Where there is any predisposition in the constitution to scrofula, and the person happens to contract a venereal taint, this frequently excites into action the causes of the former as soon as the virus is destroyed by mercury. Dr. Cullen supposed scrofula to depend upon a peculiar constitution of the lymphatic system. Whatever may be the proximate cause of scrofula, the most certain indication of its existence is the deposition of that kind of morbid matter called *tuberculous matter,* the nature of which is described in the article *Tubercle.* There is scarcely any organ of the body which is not occasionally the seat of scrofulous tubercle. In children, the lymphatic and mesenteric glands are most frequently affected. In those past puberty the lungs are most liable to tubercles, which give rise to the disease called *tubercular phthisis.* See *Phthisis.*

The remote causes of scrofula are all of a debilitating nature, and embrace every thing that lowers or reduces the tone of the living fibre, and puts the system out of that state of firm and vigorous action which keeps the scrofulous diathesis most effectually in a state of subjection; and hence the common debilitating powers of cold and damp, low and unwholesome food, want of cleanliness, and a close and suffocating atmosphere, are the most usual incidental sources of scrofula. But for these causes the scrofulous predisposition might be overcome, or remain dormant in the constitution through life, and show itself in the next generation, without having in the least disturbed the present. But the moment any other occasional causes become adjuncts with the scrofulous diathesis, scrofula, rather than any other disease which they may also be calculated to promote, will make its appearance, and commence its ravages. The attacks of the disease seem much affected or influenced by the periods of the seasons. They begin usually some time in the winter and spring, and often disappear, or are greatly amended, in summer and autumn. The first appearance of the disorder is commonly in that of small oval or spherical tumours under the skin, unattended by any pain or discolouration. These appear, in general, upon the sides of the neck, below the ear, or under the chin; but, in some cases, the joints of the elbows or ankles, or those of the fingers and toes, are the parts first affected. In these instances we do not, however, find small moveable swellings; but, on the contrary, a tumour almost uni-

formly surrounding the joint, and interrupting its motion.

After some length of time, the tumours become larger and more fixed; the skin which covers them acquires a purple or livid colour, and, being much inflamed, they at last suppurate and break into little holes, from which, at first, a matter, somewhat puriform, oozes out; but this changes, by degrees, into a kind of viscid serous discharge, much intermixed with small pieces of a white substance, resembling the curd of milk.

The tumours subside gradually, whilst the ulcers at the same time open more, and spread unequally in various directions. After a time some of the ulcers heal, but other tumours quickly form in different parts of the body, and proceed on, in the same slow manner as the former ones, to suppuration. In this manner the disease goes on for some years; and appearing at last to have exhausted itself, all the ulcers heal up, without being succeeded by any fresh swellings, but leaving behind them an ugly puckering of the skin, and a scar of considerable extent. This is one of the mildest forms under which scrofula presents itself. In more virulent cases, the eyes are particularly the seat of the disease, and are affected with ophthalmia, giving rise to ulcerations in the tarsi, and inflammation of the tunica adnata, terminating not unfrequently in an opacity of the transparent cornea.

In similar cases the joints become affected; they swell and are incommoded by excruciating deep-seated pain, which is much increased upon the slightest motion. The swelling and pain continue to increase, and the muscles of the limb become at length much wasted. Matter is soon afterwards formed; and this is discharged at small openings made by the bursting of the skin. If the progress of the disease be not arrested, it extends to the ligaments and cartilages, and produces a caries of the neighbouring bones. Hectic fever at last arises, and, in the end, often proves fatal.

When scrofula is confined to the external surface, it is by no means attended with danger, although, on leaving one part, it is apt to be renewed in others; but when the ulcers spread, erode, and become deep, without showing any disposition to heal; when deep-seated collections of matter form amongst the small bones of the hands and feet, or in the joints, or tubercles in the lungs, with hectic fever, arise, the consequences will be fatal.

On opening the bodies of persons who have died of this disease, many of the viscera are usually found in a diseased state, but more particularly the glands of the mesentery, which are not only much tumefied, but often ulcerated. The lungs are frequently discovered beset with a number of tubercles or cysts, which contain matter of various kinds.

Scrofulous glands, on being examined by dissection, feel somewhat softer to the touch than in their natural state, and, when laid open, they are usually found to contain a soft curdy matter, mixed with pus. Cullen distinguishes four species of scrofula: —

1. *Scrofula vulgaris*, when it is without other disorders, external, and permanent.

2. *Scrofula mesenterica*, when internal, with loss of appetite, pale countenance, swelling of the belly, and an unusual fœtor of the excrements. See *Tabes mesenterica*.

3. *Scrofula fugax*. This is of the most simple kind: it is seated only about the neck, and, for the most part, is caused by absorption from sores on the head.

4. *Scrofula Americana*, when it is joined with the yaws.

In conducting the treatment of this disease, we must always recollect that it is one of debility, so that our chief dependence must be on a tonic and stimulating plan, so modified as to meet the patient's age, idiosyncrasy, and manner of life.

It is of the utmost importance to select a dry and salubrious situation, so defended as not to be keen for the lungs; but the higher and drier the better for the most part. Such a situation by the sea-side is most desirable, as the sea air is very beneficial.

The clothing should be calculated to ensure a regular circulation on the surface, without being oppressive, or suffering the person to feel chilly.

The diet should be as invigorating as the stomach will bear, and consist of a free use of tender beef and mutton, dilute wine, and malt liquor.

Tonic and stimulant medicines are to be exhibited regularly, either alone or in combination with alkalis or acids, or some of the antiscrofulous remedies which will presently be noticed.

Tonics and Stimulants.

1. *Cinchona*. All of this family may be given, but the best is the *cinchona lancifolia*, of which, as of the other species, powders, infusions, decoctions, tinctures, and extracts may be made and given in their compounded states, varying them from time to time, and combining other medicines. An infusion of bark in lime-water has been found very serviceable. Bark combined with acids is in many cases useful; with the alkalis also, and more especially with the bicarbonates of soda and potash. Bark and steel together are frequently found beneficial, when neither have done any good separately. With most of the anti-scrofulous medicines, the Peruvian barks may also be exhibited.

2. *Chalybeates*. Of these, Dr. Griffiths' steel medicine, the mistura ferri cum myrrhâ, and pilula ferri composita, of the London Pharmacopœia, are the best. The tinctura ferri muriatis is also an excellent medicine against some forms, and in some constitutions which will not bear the others.

3. *Mercurials*. These are exhibited in alterative doses. With some constitutions they agree, and are of infinite service; whilst, on the other hand, they debilitate and increase the disease with others; and it cannot, *à priori*, be said in what cases they are likely to disagree and be injurious. The mercurial oxides are to be selected, in very small doses, and never so as to affect the

gums; for a mercurial salivation has, in almost every instance, been productive of great mischief.

A combination of submuriate of mercury and precipitated sulphuret of antimony, in what has been long called Plummer's pill, is, occasionally, an excellent medicine in the cure of many forms of scrofula.

4. The *Alkalis.* Whether or not an acrimonious principle exists primarily, or is generated when the disease is in an aggravated state, it is difficult to determine. This opinion, however, has had, and still has, many able advocates, who seem, accordingly, to have resorted to the use of the alkalis.

Soda, in the state of bicarbonate, is decidedly the best, because it agrees best with the stomach. Burnt sponge contains this alkali with carbon and iodine, and has been found useful, especially against bronchocele. The next is the bicarbonate of potash. The volatile alkali, though praised by some, has disappointed many.

All these preparations of the alkalis are to be exhibited in full doses: a drachm daily to an adult: and the patient must avoid every thing acid, or tending to an acid or acescent state, in the stomach.

5. The *Acids.* The best of these against scrofula are the muriatic and nitric. The oxygenated muriatic acid and the nitro-muriatic acid, and also the chloride of soda, have been found very serviceable in many cases.

6. *Mineral Waters.* The chalybeate and sulphureous spring waters are not without their efficacy in some cases, especially the chalybeates of Tunbridge Wells, Hampstead, Cheltenham, Leominster, and Harrowgate.

The Narcotics.

1. Conium, or hemlock, stands the first on the list; and a decidedly good medicine it is in some cases. All, however, depends not merely on its genuineness, but also on its preparation. It should be given in full doses, but so as never to cause any uneasiness of the head. Henbane is mostly exhibited as a quieter of irritation. Very little is now thought of the efficacy of any of the Solanum tribe. Digitalis is of no use whatever in the cure of scrofula.

Anti-scrofulous Specifics.

Sarsaparilla has long been esteemed as highly beneficial; so much so, that few cases of this disease have not been treated with it. Here, again, every thing depends on having the root of the true plant, and there is not, perhaps, one in the materia medica which is more adulterated; so much so, that little dependence can be placed on any of its preparations, unless they be made under proper inspection, or obtained from some trustworthy source. It is usual, when sarsaparilla is given, to exhibit the powder, or the decoction, or the extract; but the latter is very apt to lose its virtue by a strong fire, and should be prepared in *balneo mariæ.* A milk and vegetable diet is insisted on occasionally with it, but a generous diet will assist it much more.

Sarsaparilla, when of no utility alone, occasionally proves beneficial when combined with soda; and Peruvian bark, with sarsaparilla, is occasionally serviceable.

Coltsfoot, or the *Tussilago farfara*, is now seldom or ever given; although Dr. Cullen affirms that, when some ounces were given every day, it in several instances occasioned the healing of scrofulous sores.

Lime-water, the once extolled muriates of baryta and of lime, and oxide of zinc, are seldom exhibited in the present day.

Lastly, *iodine*, which has been given very generally, and very largely, has been found, in some instances beneficial from its powers as a general stimulant, and has very frequently promoted the absorption of scrofulous tumours; but it has failed altogether to realise the expectations which some practitioners entertained of its effects as a specific.

Of the External Applications.

When scrofula on the surface is tumid and inflamed, the antiphlogistic applications are all useful, especially the liquor plumbi acetatis dilutus, the liquor ammoniæ acetatis, well diluted; very dilute spirit of wine; very dilute acetic acid; sea-water; weak solutions of muriate of soda, to imitate sea-water; and these cold, so long as there is no pus formed. It is a subject that requires great consideration, whether warm applications should ever be applied; and also, when the suppuration or tumour is matured, whether the lancet should be used, unless it is in parts where nature should not be trusted to, lest the abscess burst into important viscera, or will not burst at all. The applications which some are very partial to, are, bread poultices, with a little vinegar or salt-water; poultices of sea-wrack, the *Fucus vesiculosus*, sea-tang, the sal-solas, &c.; all of which act by the saline matters, and probably also of the iodine they contain.

In the more indolent scrofulous tumours and ulcerations, iodine and the hydriodate of potash are useful stimulants.

It is of great importance, in the application and use of the several internal remedies, to begin always with small doses, carefully guarding against stimulating the system but in the gentle way, and afterwards augmenting the dose with due caution: for if the system be stimulated violently, more debility results, and the mischief is increased. Scrofula is strictly a chronic disease: it never has been, nor ever can be cured rapidly; and wherever any good has been produced upon it, it has always been by lenient means, and steady and patient perseverance.

Scrophula. See *Scrofula.*

SCROPHULA'RIA. (*a*, *æ*. f.; from *scrofula*, the king's evil: so called from the unequal tubercles upon its roots, like scrofulous tumours.) The name of a genus of plants in the Linnæan system. Class, *Didynamia;* Order, *Angiospermia.* The figwort.

SCROPHULARIA AQUATICA. Greater water-figwort. Water betony. *Betonica aquatica.* The leaves of this plant, *Scrophularia—foliis cordatis obtusis, petiolatis, decurrentibus; caule membranis angulato; racemis terminalibus,* of Linnæus, are celebrated as correctors of the ill flavour of senna. They were, also, formerly in high estimation against piles, tumours of a scrofulous nature, inflammations, &c.

Scrophularia minor. See *Ranunculus ficaria.*

Scrophularia nodosa. The figwort. *Scrophularia vulgaris. Millemorbia. Scrophularia.* Common figwort or kernel-wort. The root and leaves of this plant, *Scrophularia — foliis cordatis, trinervatis; caule obtusangulo*, of Linnæus, have been celebrated both as an internal and external remedy against inflammations, the piles, scrofulous tumours, and old ulcers; but they are now only used by the country people.

Scrophularia vulgaris. See *Scrophularia nodosa.*

SCRO'TAL. *Scrotalis.* Belonging to the scrotum.

Scrotal hernia. A protrusion of any of the contents of the abdomen into the scrotum. See *Hernia.*

Scrotifo'rmis. (From *scrotum*, the covering of the testicle, and *forma.*) Scrotiform: purse-like; bag-like. Applied to the nectary of the genus *Satyrium.*

Scrotoce'le. (*e, es.* f.; from *scrotum*, and κηλη, a tumour.) A scrotal hernia.

SCRO'TUM. (*um, i.* n.; *quasi scorteum*, a leather coat.) *Bursa testium. Oscheus. Oscheon. Orchea*, of Galen. The bag of common integuments which covers the testicles.

Scrotum cordis. The pericardium.

SCRU'PULUS. (Diminutive of *scrupus*, a draught man.) A scruple, or weight of twenty grains.

SCURF. *Furfura.* Small exfoliations of the cuticle, or scales like bran, which occur naturally on the scalp, and take place after some eruptions on the skin, a new cuticle being formed underneath during the exfoliation.

Scurvy. See *Scorbutus.*

Scurvy-grass. See *Cochlearia officinalis.*

Scurvy-grass, lemon. See *Cochlearia.*

SCU'TIFORM. (*Scutiformis*; from *scutum*, a shield, and *forma*, likeness. Shield-like.

Scutiform cartilage. See *Thyroid cartilage.*

SCUTE'LLA. A little dish or cup. Applied to the round, flat, or shallow conceptacle of lichens, as in *Lichen stellaris.*

SCUTELLA'RIA. (*a, æ.* f.; from *scutella*, a small dish, or saucer, apparently in allusion to the little concave appendage which crowns the calyx. Some have thought it to be more directly derived from *scutellum*, a little shield, to which they have compared the appendage.) The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Gymnospermia.*

Scutellaria galericula'ta. The systematic name of the scull-cap. *Tertianaria.* The *Scutellaria — foliis cordato-lanceolatis, crenatis; floribus axillaribus*, of Linnæus, which is common in the hedges and ditches of this country. It has a bitter taste and a garlic smell, and is said to be serviceable against that species of ague which attacks the patient every other day.

Scutellaria lateriflo'ra. This plant, according to Dr. Lyman Spalding, of New York, is prophylactic against the effects of the bite of a mad dog.

Scute'llum. (*um, i.* n.) A little shield: sometimes used for the fructification of lichens, instead of *scutella.*

SCY'BALUM. (*um, i.* n. Σκυβαλον.) Dry hard excrement: applied to such as has become hard, and formed into small rounded nodules, like sheep's dung, or larger. There are two kinds of scybala noticed: —

1. *Feculent.* These are small balls, varying in size from a pea to a walnut, formed of excrement which has become dry, and can be cut into pieces, when they are found to be of the same material throughout.

2. *Oleaginous.* These are obviously of a fatty consistence; are mostly round, of a cream-colour, slightly translucent. May not this species be a modification of, or a mixture with, cholesterine?

Scymetar-shape. See *Acinaciformis.*

SCY'PHIFORM. Goblet-shaped; as the fructification of some of the lichens.

Scythica radix. Liquorice root.

SCYTODE'PSIC. (*Scytodepsicus.* Σκυτοδεψικος; from σκυτοδεψεω, to tan hides, from σκυτος, a hide and δεφω, to excoriate.) Appertaining to the business of a tanner. Tannin has been called the *scytodepsic principle*, and gallic acid has been called *scytodepsic acid.*

Scytodepsic acid. See *Scytodepsic.*

Scytodepsic principle. See *Scytodepsic.*

SEA. *Mare.* The air of the sea, the effects produced on the system by the motion of a vessel, the water of the ocean, and its contents, all come under the attention of the physician.

1. *Sea-air* is prescribed in a variety of complaints, being considered as more medicinal and salubrious than that on land, though not known to possess in its composition a greater quantity of oxygen. This is a most powerful and valuable remedy. It is resorted to with the happiest success against most cases of debility, and particularly against scrofulous diseases affecting the external parts of the body.

2. *Sea sickness.* An intense nausea with violent retching, which varies, in respect of duration, in different persons upon their first going to sea, and which seems to arise from a depressing effect on the brain produced by the motion of the vessel; though why this should be we know not. With some it continues only for a day or two; while with others it remains throughout the voyage; and in a few cases has been so severe and long-continued as to prove fatal. Various remedies have been proposed for sea-sickness, but the only one which is of any use is lying perfectly still with the head low, by which an increased quantity of blood is thrown on the brain.

3. *Sea-water.* This is arranged amongst the simple saline waters. Its chemical analysis gives a proportion of one of saline contents to about twenty-three and one fourth of water; but on our shores it is not greater than one of salt to about thirty of water. Sea-water on the British coast may therefore be calculated to contain in the wine pint, of muriated soda 186·5 grains, of muriated magnesia 51, of selenite 6 grains; total 243½ grains, or half an ounce and 3½ grains of saline contents. Bathing in the sea is one of the powerful tonics we possess, and owes its efficacy no less to the free exposure of the body to the brasing sea-breeze, than to the quality of the water. See *Balneum.* The disorders for which the internal use of sea-water has been and

may be resorted to, are, in general, the same for which all the simple saline waters may be used. The peculiar power of sea-water and sea-salt as a discutient, employed either internally or externally, in scrofulous habits, is well known, and is attended with considerable advantage when judiciously applied.

Sea-belts. (So called from the supposed resemblance of its leaves to a belt or girdle.) See *Fucus saccharinus.*

Sea green. See *Glaucous.*

Sea-holly. See *Eryngium.*

Sea-moss. See *Conferva rupestris*, and *Corallina officinalis.*

Sea-oak. See *Fucus vesiculosus.*

Sea-onion. See *Scilla.*

Sea-salt. See *Sodii chloridum.*

Sea-wrack. See *Fucus vesiculosus.*

Sealed earth. See *Sigillata terra.*

Seam. See *Sutura.*

Searching. See *Sounding.*

SEBA'CEOUS. (*Sebaceous;* from *sebum*, suet.) Suety: applied to glands, which secrete a suety humour, and to the matter secreted.

SEBA'CIC. (*Sebacicus;* from *sebum*, suet.) Of or belonging to suet, or such fatlike substances.

Sebacic acid. (*Acidum sebacicum;* so called because found largely in suet.) The sebacic acid may be obtained by distilling suet, lard, &c.; it is inodorus; its taste is slight, but it perceptibly reddens litmus paper; its specific gravity is above that of water, and its crystals are small white needles of little coherence. Exposed to heat, it melts like fat, is decomposed, and partially evaporated. The air has no effect upon it. It is much more soluble in hot than in cold water; hence boiling water saturated with it, assumes a nearly solid consistence on cooling. It combines with earthy, alkaline, and metallic bases, and forms salts called sebates.

Sebadilla. See *Cevadilla.*

SE'BATE. (*Sebas, atis.* f.; from *sebum*, suet.) The name of the neutral compound of the acid of fat with a salifiable base.

Sebel. An Arabic name for the disease of the eye, called *pannus.*

Sebesten. (An Egyptian word.) See *Cordia myxa.*

SECA'LE. (*e, i.* neut.; a name in Pliny, which some etymologists, among whom is De Theis, derive from the Celtic *segal.* This, says he, comes from *sega*, a sickle, in the same language, and thence *seges*, the Latin appellation of all grain that is cut with a similar instrument. Those who have looked no farther for an etymology than the Latin *seco*, to cut or mow, have come to the same conclusion.) 1. The name of a genus of plants in the Linnæan system. Class, *Triandria;* Order, *Digynia.* Rye.

2. The common name of the seed of the *Secale cereale* of Linnæus.

Secale cereale. The systematic name of the rye plant. Rye corn is principally used as an article of diet, and, in the northern countries of Europe, is employed for distilling an ardent spirit. Rye-bread is in common use in the northern parts of Europe. Rye is less nourishing than wheat, but a sufficiently nutritive and wholesome grain. It is, more than any other grain, strongly disposed to acescency: hence it is liable to ferment in the stomach, and to produce purging, which people on the first using it commonly experience.

Secale cornutum. *Secale corniculatum. Clavus secalinus. Mutterkom kornzapfeu*, of the Germans. *Ergot; Seigle ergote* of the French. A black, curved, morbid, excrescence, like the spur of a fowl, which is found in the spike of the *Secale cereale* of Linnæus, especially in hot climates, when a great heat suddenly succeeds to much moisture. The seed, which has this diseased growth, gives off, when powdered, an odour which excites sneezing, and titillates the nose, like tobacco. It has a mealy, and then a rancid, nauseous, and biting taste, which remains a long time, and causes the mouth and fauces to become dry; which sensation is not removed by watery fluids, but is soon relieved by milk. The cause of this excrescential disease in rye appears to be an insect which penetrates the grain, feeds on its amylaceous part, and leaves its poison in the parenchyma: hence it is full of small foramina or perforations made by the insect.

The secale cornutum has a singular effect on the animal economy. The meal or flower sprinkled on a wound, coagulates the blood, excites a heat and then a numbness in the part, and soon after in the extremities. Bread, which contains some of it, does not ferment well, nor bake well, and is glutinous and nauseous. The bread when eaten produces intoxication, lassitude, a sense of something creeping on the skin, weakness of the joints, with convulsive movements occurring periodically. This state is what is called *raphania*, and *convulsiones cereales.* Of those so affected, some can only breathe in an upright posture; some become maniacal; others epileptic; or tabid, and some have a thirst not to be quenched; and livid eruptions and cutaneous ulcers are not uncommon. The disease continues from ten days to two or three months, and longer. Those who have formication, pain, and numbness of the extremities in the commencement, generally lose the feeling in these parts, and the skin, from the fingers to the fore-arm, or from the toes to the middle of the tibia, becomes dry, hard, and black, as if covered with soot. This species of mortification is called *Necrosis cerealis.*

As a medicine, the secale cornutum is given internally to excite the action of the uterus in an atonic state of that organ, producing amenorrhœa, &c.; and, during parturition, to excite the contraction of the uterus when this is insufficient. The accounts of this specific operation of the ergot on the uterus were for some time received with scepticism, and properly so, since it is well known that there is no organ more under the control of the imagination than the uterus during labour; whence a number of perfectly inert substances have acquired reputation for expediting delivery: the reality of such a power in the ergot seems, however, to be now established by a great mass of testimony. It is observed that the uterine contractions, brought on by the use of

this medicine, are quite different in their character from ordinary labour-pains, being highly spastic, and continued almost without intermission till delivery is effected. It is of the utmost importance in the use of this powerful agent, that the position of the child be natural, or at least such as to admit of its free expulsion; that is, the head must present in the normal position, or the feet must be coming down. In all cross births the administration of the ergot would not only be entirely ineffectual as to the expulsion of the child, but would have a direct tendency to rupture the uterus. It is of equal importance that the shape and capacity of the pelvis be such as to admit of the free expulsion of the child by the efforts of the uterus, otherwise there is the same danger of rupture of the organ. The ergot has been used in powder, tincture, decoction, and infusion. The powder is given in the dose of from gr. x. to ʒss., in any appropriate vehicle. The decoction may be made with ʒ iij. to ℥ xij. of water, boiled down to one half, and given in doses of ℥ i. at intervals, according to the effect. The infusion, which is the form generally preferred, may be made with half a drachm to half a pint of boiling water, and one half administered at a time. The tincture is little used. The medicine must be fresh, and well preserved in close vessels, or it will have lost its efficacy. A great part of the ergot found in the shops is good for nothing.

The antidote to the ill effects produced in the mouth and fauces by eating bread which has this poison, is milk. Against the convulsions, vomits, saline purgatives, glysters, submuriate of mercury as a purgative, are first to be given; and, after the primæ viæ have been duly cleaned, stimulants of camphire, ammonia, and ether with opium. In the necrosis, rectified oil of turpentine is very beneficial in stopping its progress, and then warm stimulating fomentations and poultices.

SECONDARY. Something that acts as second or in subordination to another. Thus, in diseases, we have *secondary symptoms.*

SECONDARY AMPUTATION. When, in cases of compound fracture, or other severe injury, amputation is immediately performed, it is called *primary amputation;* but when it is deferred till the immediate effects of the injury on the constitution have passed away and suppuration is established, it is called *secondary amputation.*

Secondary fever. That febrile affection which arises after a crisis, or the discharge of some morbid matter, as after the declension of the small-pox or the measles.

SECONDARY HÆMORRHAGE. Hæmorrhage occurring after wounds or operations, not immediately, but at a time when, supposing a healthy state of the parts, it would not have happened. Thus, after amputation, when the arteries have been tied, the stump has been dressed, and the patient been in bed some hours, a hæmorrhage will sometimes take place from the small vessels. Again after the ligature of an aneurismal artery, the vessel may ulcerate, and hæmorrhage ensue. These cases are called *secondary hæmorrhage.*

SECRETION. (*Secretio, onis.* f.) A function in a living body, arranged by physiologists under the head of natural actions. It is by this function that a part of the blood escapes from the organs of circulation, and diffuses itself without or within; either preserving its chemical properties, or dispersing after its elements have undergone another order of combinations.

The animal secretions are arranged by Bostock into the *aqueous, albuminous, mucous, gelatinous, fibrinous, oleaginous, resinous,* and *saline.* Magendie's arrangement is into three sorts: —

1. The *exhalations.*
2. The *follicular secretions;* and,
3. The *glandular secretions.*

EXHALATIONS.

The exhalations take place as well within the body as at the skin, or in the mucous membranes: thence their division into *external* and *internal.*

Internal Exhalations. — Whenever large or small surfaces are in contact, an exhalation takes place; whenever fluids are accumulated in a cavity without any apparent opening, they are deposited there by exhalations: the phenomenon of exhalation is also manifested in almost every part of the animal economy. It exists in the serous, the synovial, the mucous membranes; in the cellular tissue, the interior of vessels, the adipose cells, the interior of the eye, of the ear, the parenchyma of many of the organs, such as the thymus, thyroid glands, the *capsulæ suprarenales,* &c., &c. It is by exhalation that the watery humour, the vitreous humour, the liquid of the labyrinth, are formed and renewed.

Serous Exhalation. — All the viscera of the head, of the chest, and the abdomen are covered with a serous membrane, which also lines the sides of these cavities, so that the viscera are not in contact with the sides, or with the adjoining viscera, except by the intermediation of this same membrane; and, as its surface is very smooth, the viscera can easily change their relation with each other, and with the sides. The principal circumstance which keeps up the polish of their surface is the exhalation of which they are the seat: a very thin fluid constantly passes out of every point of the membrane, and mixing with that of the adjoining parts, forms with it a humid layer that favours the frictions of the organs.

It appears that this facility of sliding upon each other is very favourable to the action of the organs; for as soon as they are deprived of it by any malady of the serous membrane, their functions are disordered, and they sometimes cease entirely.

In the state of health, the fluid secreted by the serous membranes appears to be the serum of the blood, a certain quantity of albumen excepted. Independently of the serosity, a fluid is found in many parts of the cellular tissue of a very different nature, which is the fat.

Under the relation of the presence of the fat, the cellular tissue may be divided into three sorts: that which contains it always; that which contains it sometimes; and that which never contains it. The orbit, the sole of the foot, the pulp of the fingers, that of the toes, always present fat; the subcutaneous cellular tissue, and

that which covers the heart, the veins, &c. present it often; lastly, that of the scrotum, of the eyelids, of the interior of the skull, never contain it.

The fat is contained in distinct cells that never communicate with the adjoining ones. It has been supposed, from this circumstance, that the tissue that contains, and that forms the fat, was not the same as that by which the serosity is formed; but as these fatty cells have never been shown, except when full of fat, this anatomical distinction seems doubtful. The size, the form, the disposition of these cells, are not less variable than the quantity of fat which they contain. In some individuals scarcely a few ounces exist, whilst in others there are several hundred pounds.

According to the last researches, the human fat is composed of two parts, the one fluid, the other concrete, which are themselves compounded, but in different proportions, of two new proximate principles.

Round the moveable articulations a thin membrane is found, which has much analogy with the serous membranes; but which, however, differs from them by having small reddish prolongations that contain numerous blood-vessels. These are called *synovial fringes*: they are very visible in the great articulations of the limbs.

Serous exhalation takes place in the cellular membrane, the chambers of the eye, and the hyaloid membrane.

Bloody exhalations. — This takes place in the cavernous bodies of the penis and of the clitoris, the urethra and the glands, the spleen and the breasts. Many other interior exhalations exist also; as those of the cavities of the internal ear, of the parenchyma, of the thymus, of the thyroid gland; that of the cavity of the *capsulæ suprarenales*, &c. But the fluids formed in these different parts are scarcely understood: they have never been analysed, and their uses are unknown.

External exhalations. — These are composed entirely of the exhalations of the *mucous membranes*, and of that of the skin, or *cutaneous transpiration*.

Exhalations of Mucous Membrane. — There are two mucous membranes: the one covers the surface of the eye, the lachrymal ducts, the nasal cavities, the sinuses, the middle ear, the mouth, all the intestinal canal, the excretory canals which terminate in it; lastly, the larynx, the trachea, and the bronchia. The other mucous membrane covers the organs of generation and of the urinary apparatus.

Cutaneous Transpiration. — A transparent liquid, of an odour more or less strong, salt, acid, usually passes through the innumerable openings of the epidermis. See *Perspiration*.

FOLLICULAR SECRETIONS.

The follicles are divided into *mucous* and *cutaneous*, and into *simple* and *compound*. The simple mucous follicles are seen upon nearly the whole extent of the mucous membranes, where they are more or less abundant: however, there are points of considerable extent of these membranes where they are not seen.

The bodies that bear the name of fungous papillæ of the tongue, the tonsils, the glands of the cardia, the prostate, &c. are considered by anatomists as collections of simple follicles. The fluid that they secrete is little known: it appears analogous to the mucus, and to have the same uses. In almost all the points of the skin, little openings exist, which are the orifices of small hollow organs, with membraneous sides, generally filled with an albuminous and fatty matter, the consistence, the colour, the odour, and even the savour of which are variable, according to the different parts of the body, and which is continually spread upon the surface of the skin. These small organs are called the follicles of the skin; one of them, at least, exists at the base of each hair, and generally the hairs traverse the cavity of a follicle in their direction outwards.

The follicles form that mucous and fatty matter which is seen upon the skin of the cranium and on that of the pavillion of the ear: the follicles also secrete the *cerumen* in the auditory canal. That whitish matter, of considerable consistence, that is pressed out of the skin of the face in the form of small worms, is also contained in follicles: it is the same matter which, by its surface being in contact with the air, becomes black, and produces the numerous spots that are seen upon some persons' faces, particularly on the sides of the nose and cheeks.

The follicles also appear to secrete that odorous, whitish matter, which is always renewed at the external surface of the genital parts.

By spreading on the surface of the epidermis, of the hair of the head, of the skin, &c. the matter of the follicles support the suppleness and elasticity of those parts, renders their surface smooth and polished, favours their frictions upon one another. On account of its unctuous nature, it renders them less penetrable by humidity, &c.

GLANDULAR SECRETIONS.

The number of glands is considerable: the action of each bears the name of glandular secretion. There are six secretions of this sort: that of the tears, of the saliva, of the bile, of the pancreatic fluid, of the urine, of the semen, and, lastly, that of the milk. We may add the action of the mucous glands, and of the glands of Cowper.

It was at one time the common doctrine among physiologists, as well chemical as mechanical, that all the vast variety of animal productions which are traced in the different secretory organs, whether wax, or tears, or milk, or bile, or saliva, were formerly contained in the circulating mass; and that the only office of these organs was to *separate* them respectively from the other materials that entered into the very complex crasis of the blood; whence, indeed, the name of *secernents* or *secretories*, which mean nothing more than *separating powers*. This action was by the chemists supposed to depend on peculiar attractions, or the play of affinities, which was the explanation advanced by some; or on peculiar ferments, conveyed by the blood to the secernent organ, or pre-existing in it, which was the opinion of others. The mechanical physiologists, on the contrary, ascribed the

separation to the peculiar figure or diameter of the secretory vessels, which, by their make, were only fitted to receive particles of a given form, as prisms where the vessels were triangular, and cubes where they were square. Such was the explanation of Des Cartes; while Boerhaave, not essentially wandering from the same view, supposed the more attenuate secretions to depend upon vessels of a finer bore, and the more viscid upon those of a larger diameter.

Modern chemistry, however, has completely exploded all these and many other hypotheses founded upon the same common principle, by proving that most of the secerned materials are not formally existent in the blood; and, consequently, that it is not, strictly speaking, by an act of separation, but of new arrangement or recomposition, that they are produced out of its elements. And hence physiologists have been led to a critical enquiry into the fabric of the secerning organ, but hitherto without much satisfaction. In its simplest state it seems, as far as it can be traced, to consist of nothing more than single vessels possessing a capillary orifice, as in the Schneiderian membrane. In a somewhat more compound form we find this orifice opening into a follicle, or minute cavity, of an elliptic shape; and, in a still more complicated make, we meet with a glandular apparatus, more or less glomerate, consisting of a congeries of secernent vessels, with or without follicles, and occasionally accompanied with a basin or reservoir for a safe deposit of the secreted or elaborated matter against the time of its being wanted, of which the gall-bladder furnishes us with a well-known example. But in none of these instances are we able to discover any peculiar effect produced by this complication of machinery, beyond that of affording the means of accumulation: for, large as is the organ of the liver, it is in the penicilli, or the pori biliarii alone, that the bile is formed and completely elaborated: the liver is a vast bundle or combination of these, and hence affords an opportunity for a free formation of bile in a collective state, but it has not been ascertained that it affords any thing more. And although in the gall-bladder we find this fluid a little varied after its deposit, and rendered thicker, yellower, and bitterer, the change is nothing more than what must necessarily follow from absorption, or the removal of a part of the finer particles of the bile. The conglomerate glands of the mammæ offer us the same results; for the milk here secreted is as perfect milk in every separate lactiferous tube, as when it flows in an accumulated form from the nipple. And hence follicles themselves may be nothing more than minute reservoirs for the convenient accumulation of such fluids as are deposited in them till they are required for use. Mucus and sebum are inspissated by retention, but they rarely undergo any other change. We are obliged, therefore, to conclude, with Sir Everard Home, that the "organs of secretion are principally made up of arteries and veins; but there is nothing in the different modes in which these vessels ramify that can in any way account for the changes in the blood out of which secretions arise."

These organs, however, are largely supplied with twigs of small nerves, and it has been an idea long entertained by physiologists that secretion is chiefly effected through their instrumentality. Sir Everard Home, in his paper inserted in the volume of the Philosophical Transactions, has observed, "that in fishes which are capable of secreting the electric fluid, the nerves connected with the electrical organs exceed those that go to all the other parts of the fish, in the proportion of twenty to one:" and, in confirmation of this view of the subject, it may be remarked, that there are no parts of the body more manifestly affected, and few so much so, as the secretory organs, by mental emotion. The whole surface of the skin is sometimes bedewed with drops of sweat, and even of blood, by a sudden paroxysm of agony of mind: grief fills the eyes with tears: fear is well known to be a powerful stimulant to the kidneys, and very generally to the alvine canal: anger gives an additional flow, perhaps an additional acrimony, to the bile, and, if urged to violence, renders the saliva poisonous; and disappointed hope destroys the digestion, and turns the secreted fluids of the stomach acid.

All this should seem to prove that the secretory organs are chiefly influenced by the sensorial system; yet Haller has long ago observed that the larger branches of the nerves seldom enter into them, and seem purposely to avoid them: the secernent glands have little sensibility; and the secretions of plants, which have no nervous system, are as abundant and diversified, and as wonderful in every respect, as those of animals.

The means, therefore, by which the very extensive and important economy of secretion is affected, seem hitherto, in a very considerable degree, to have eluded all investigation. We behold, nevertheless, the important work proceeding before us, and are in some degree acquainted with its machinery.

The most simple, and, at the same time, perhaps, the most copious of the fluids, which are in this manner separated from the blood, is that discharged by very minute secernent vessels, supposed to be terminal or exhalent arteries, which open into all the cavities of the body, and pour forth a fine breathing vapour, or halitus, as it is called, which keeps their surfaces moist, and makes motion easy — an effluvium which must have been noticed by every one who has ever attended the cutting up of a bullock in a slaughter-house. It is well known that arteries terminate in two ways — in minute veins, and in exhalent vessels. The former termination can often be followed up by injections, and occasionally traced by the microscope; but no microscopic experiment has hitherto enabled the anatomist to discover the orifices of the exhalent branches of arteries. Their existence, however, is proved, as Mr. Cruikshank has observed, by their sometimes, and especially when enlarged in diameter or acted upon by a more than ordinary *vis à tergo*, pouring forth blood instead of vapour, of which we have a striking instance in bloody sweat; as also in the

menstrual flux, which, though not blood itself, proceeds from the mouths of the exhalent arteries of the uterus, periodically altered in their diameter and secernent power.

In different periods of life, many of the secretions vary considerably in their sensible properties, or relative quantity. Thus the bile of the fœtus is sweet, and only acquires a bitter taste after birth. In infancy perspiration flows more profusely than during manhood; and the testes, which secrete nothing before the age of puberty, at this time acquire activity, and again lose their power in old age.

There are also many of the secernent organs that, in case of necessity, become a substitute for each other. Thus the perspirable matter of the skin, when suppressed by a sudden chill or any other cause, is often discharged by the kidneys; the catamenia by the lungs; and the serum, accumulated in dropsies, by the intestines.

The secretions are, moreover, very much affected and increased by any violent commotion of the system generally. In hysteria the flow of urine is greatly augmented, while the absorption of bile seems diminished; and hence the discharge is nearly colourless. In violent agitation of the mind, we have already observed that the juices of the stomach become acid; and sometimes the secernents of the skin, and sometimes those of the larger intestines, are stimulated into increased action; whence colliquative perspiration, looseness, or both. The heat and commotion of a fever will sometimes produce the same effect, and sometimes a contrary; the skin being dry, parched, and pricking.

There are some parts of the body that waste and become renewed far more rapidly than others; the fat than the muscles; the muscles than the bones; and probably the bones than the skin.

It is from this mysterious power of reproduction, appertaining to every part of the system, that we are so often able to renew the substance and function of parts that have been wasted by fevers or atrophy, or abruptly destroyed or lopped off by accident.

In the progress of this general economy, every organ and part of the body secretes for itself the nutriment it requires, from the common pabulum of the blood which is conveyed to it, or from secretions which have already been obtained from the blood, and deposited in surrounding cavities, as fat, gelatine, and lymph. And it is probable that the several organs of secretion, like the eye, the ear, and the other distinct organs of sense, are peculiarly affected by peculiar stimulants, and excited to some diversity of sensation.

In Germany, this idea has been pursued so far as, in some hypotheses, and particularly that of M. Hubner, to lay a foundation for the doctrine of a sixth sense, to which has been given the name of "self-feeling," or "general feeling." The sensations, however, we are at present alluding to, are not so much general on those of the whole self, as particular or limited to the organs in which they originate; and seem rather to be a result of different modifications of the fluid that causes the common sense of touch, than produced by distinct sensorial secretions. In most parts of the system these modifications are so inconsiderable as to elude our notice, but in others we have the fullest proof of such an effect; for we see the stomach evincing a sense of hunger, the fauces of thirst, the genital organs of venereal orgasm. And, in like manner, we find the bladder stimulated by cantharides, and the intestinal canal by purgatives; and we may hence conjecture that every other part of the system, where any kind of secretion is going forwards, is endowed with a like peculiarity of irritability and sensibility, though not sufficiently keen to attract our attention.

It is hence we meet with that surprising variety of secretions which are furnished not only by different, but even by the same animal in different parts of the body. Hence sugar is secreted by the stomach, and sometimes by the kidneys; sulphur by the brain; wax by the ears; lime by the salivary glands, the secretories of the bones, and, in a state of disease, by the lungs, the kidneys, the arteries, and the exhalents of the skin; milk by the breasts; semen by the testes; the menstrual fluid by the uterus; urine by the kidneys; bile by the liver; muriate of soda by the secernents of almost every organ; and sweat from every part of the surface.

Hence some animals, as the bee, secrete honey; others, as the *coccus ilicis*, a large store of wax; others, as the viper and scorpion, gum, which is the vehicle of their poison; others thread, as the spider and some species of slug; and many silk, as the silk-worm and the *Pinna*, or nacre; whence Réaumur denominates the pinna the sea silk-worm: it is common to some of the Italian coasts, and its silky beard or byssus is worked at Palermo into very beautiful silk stuffs. There are great numbers of worms, insects, and fishes, that secrete a very pure, and some of them a very strong phosphorescent light, so as, in some regions, to enkindle the sea, and in others the sky, into a bright blaze at night. Many animals secrete air: man himself seems to do so under certain circumstances, but fishes of various kinds more largely, as those furnished with air-bladders, which they fill or exhaust at pleasure, and the *Sepia* or cuttle-fish, with numerous other sea-worms; and by this power they raise or sink themselves as they have occasion. The cuttle-fish secretes also a natural ink, which it evacuates when pursued by an enemy, and thus converts it into an instrument of defence; for, by blackening the water all around it, it obtains a sufficient concealment and easily effects its escape. Other animals, and these also chiefly fishes, secrete a very large portion of electric matter, so as to convert their bodies into a powerful battery. The torpedo-ray was well known by the Romans to possess this extraordinary power; and the *Gymnotus electricus*, or electric-eel, has since been discovered to possess it in a much larger proportion. The genus tetradon, in one species, secretes an electric fluid; in another, an irritating fluid that stings the hand that touches it;

and, in a third, poisonous matter diffused through the whole of its flesh.

From the same cause we meet with as great and innumerable a variety of secretions among plants; as camphires, gums, balsams, resins: and, as in animals, we often meet with very different secretions, in very different parts of the same plant. Thus the *Mimosa nilotica* secerns from its roots a fluid as offensive as that of assafœtida; in the sap of its step an astringent acid; its glands give forth gum arabic; and its flowers an odour of a very grateful fragrance.

Sectio Cæsarea. See *Cæsarian operation*

SE'CUNDINES. The after-birth, and membranes which are expanded from its edge, and which form a complete involucrum of the fœtus and its waters, go under the name of secundines. See *Placenta.*

SECUNDUM ARTEM. According to art. A term frequently used in prescription, and denoted by the letters S. A., which are usually affixed when the making up of the recipe in perfection requires some uncommon care and dexterity.

SECU'NDUS. Applied, by botanists, to leaves and parts of the fructification which are unilateral, all leaning towards one side; as the leaves and flowers of the *Convallaria majalis.*

Securida'ca. (From *securis*, an axe: so called because its leaves resemble a small axe.) A genus of plants. Class, *Diadelphia;* Order, *Decandria.* Axe-wort. Hatchet vetch.

SECU'RIFORM. (*Securiformis;* from *securis*, an axe, and *forma*, resemblance.) Shaped like an axe. Applied to leaves, &c.

SE'DATIVE. (*Sedati'vus;* from *sedo*, to ease or assuage.) Applied adjectively and substantively to medicines or other means which diminish the animal energy, without destroying life. Medicines which possess this power are arranged into *sedativa soporifica*, as opium, papaver, hyoscyamus; and *sedativa refrigerantia*, as neutral salts, acids, &c.

Sedative salt. See *Boracic acid.*

Sedentaria ossa. The bones on which we sit, — the os coccygis and ischia.

Sedge. See *Iris pseudacorus.*

SE'DIMENT. The heavy parts of liquids which fall to the bottom.

Sediment, lateritious. See *Lateritious.*

SE'DLITZ. *Seidlitz. Seydschutz.* The name of a village of Bohemia, in the circle of Saartz, where Hoffmann discovered a simple saline mineral water. *Aqua Sedlitziana.* It contains a large quantity of sulphate of magnesia; sulphates of soda and lime, carbonic acid, carbonates of lime and magnesia, and resinous matter. The diseases in which this water is recommended are. crudities of the stomach, hypochondriasis, amenorrhœa, and the anomalous complaints succeeding the cessation of the catamenia, œdematous tumours of the legs in literary men, hæmorrhoidal affections, and scorbutic eruptions.

Sedlitz powders. These consist of two different kinds of powders, one of which is sold wrapped up in blue papers, and the other in white, in order to distinguish them. One powder consists of a mixture of tartrate of soda ʒij, and bicarbonate of soda ʒij; the other consists of tartaric acid, grs. xxxv. For a dose, dissolve the former powder in half a pint of water, and the latter in a wine-glassful; then mix the solutions, and drink while effervescing. This, when, taken before breakfast, acts as a gentle cooling purgative. Its operation is pretty certain if it be taken on an empty stomach; but not otherwise. It is rendered more certain by dissolving the salts in luke-warm water. The Sedlitz powders do not, as their name would imply, bear any resemblance to the saline ingredients of the mineral waters of Sedlitz.

SE'DUM. (*um, i.* n.; from *sedo*, to assuage.) so called because it allays inflammation.) The name of a genus of plants in the Linnæan system. Class, *Decandria;* Order, *Pentagynia.*

Sedum acre. Wall-pepper. Stone-crop. *Illecebra. Vermicularis. Piper murale. Sedum minus.* The plant thus called is, in its recent state, extremely acrid, like the hydropiper: hence, if taken in large doses, it acts powerfully on the primæ viæ, proving both emetic and cathartic; applied to the skin as a cataplasm, it frequently produces vesications and erosions. Boerhaave therefore imagines that its internal employment must be unsafe; but experience has discovered that a decoction of this plant is not only safe, but of great efficacy in scorbutic complaints. For which purpose, a handful of the herb is directed, by Below, to be boiled in eight pints of beer, till they are reduced to four, of which three or four ounces are to be taken every, or every other morning. Milk has been found to answer this purpose better than beer. Not only ulcers simply scorbutic, but those of a scrofulous or even cancerous tendency, have been cured by the use of this plant; of which Marquet relates several instances. He likewise found it useful, as an external application, in destroying fungous flesh, and in promoting a discharge in gangrenes and carbuncles. Another effect for which this plant is esteemed, is that of stopping intermittent fevers.

Sedum majus. See *Sempervivum.*

Sedum minus. See *Sedum acre.*

Sedum telephium. The systematic name of the orpine. *Faba crassa. Telephium. Fabaria crassula. Anacampseros.* The plant which bears these names in various pharmacopœias, is the *Sedum — foliis planiusculis serratis, corymbo folioso, caule erecto,* of Linnæus. It was formerly ranked as an antiphlogistic, but is now forgotten.

Seed. See *Semen.*

Seed-bud. See *Germen.*

Seed-coats. See *Arillus.*

Seed-lobes. See *Cotyledon.*

Seed-vessel. See *Pericarpium.*

SEEDS, COLD. In the old pharmacy there were certain seeds which were denominated cold, from their supposed refrigerating properties. The seeds of cucumber, gourd, melon, and water-melon, were called *the four cold seeds:* the seeds of endive, lettuce, purslane, and succory, were called the *four lesser cold seeds.*

SEEDS, HOT. The old pharmaceutists called the seeds of anise, caraway, cummin, and fennel, *the four greater hot seeds:* the seeds of bishop's weed, stone parsley, smallage, and wild carrot, were called *the four lesser hot seeds.*

Seeing. See *Vision.*

SE'GMENT. *Segmentum.* Applied in botany to the parts of divided leaves, calyces, &c.

SEGMOID VALVES. The valves of the pulmonary artery have been so called from their resembling segments of circles.

SEGREGATA. Applied to the last order of the Class *Syngenesia*, in which the flowers are doubly compound, each floret or assemblage of florets having a partial calyx. See *Syngenesia.*

SELAA. A barbarous name for an encysted abscess.

Sela'go. See *Lycopodium selago.*

SELATUS. *Solat.* An alchemical name of quicksilver.

SELE'NIC ACID. *Acidum selenicum.* If selenium be heated to dryness, it forms, with nitric acid, a volatile and crystallisable compound, called selenic acid, which unites with some of the metallic oxides producing salts, called *seliniates.*

SELE'NIUM. (*um, ii.* n.) An elementary body, extracted by Berzelius from the pyrites of Fahlun, which, from its chemical properties, he places between sulphur and tellurium, though it has more properties in common with the former than with the latter substance. He named it *selenium*, after σελην, the moon: because he at first mistook it for *tellurium*, which is named after the earth.

Self-heal. See *Prunella.*

SELI'BRA. (*a, æ.* f.) Half a pound.

SELI'NE. (*e, es.* f.; from σελην, the moon: because it is opake, and looks like a little moon.) A disease of the nails, in which white spots are occasionally seen in their substance.

SELINI'TES. Wine impregnated with parsley. — *Dioscorides.*

SELI'NUM. (*um, i.* n.; Σελινον, the Greek name of parsley; said to be derived from παρα το εν ελει φυεσθαι, on account of its growing in mud; whence Homer's ελεοθρεπτον σελινον. De Theis says, that *selinum* is derived from σελην, the moon, because of the shape of its growing seeds; and that it is the foundation of many other compound names of umbelliferous plants among the Greeks, as ορεοσελινον, πετροσελινον, &c.) The name of a genus of plants. Class, *Pentandria;* Order, *Digynia.*

SE'LLA TU'RCICA. (So called from its supposed resemblance to a Turkish saddle.) *Ephippium. Sella equina.* A cavity in the sphenoid bone, containing the pituitary gland, surrounded by the four clinoid processes.

SELTZER. The name of a place in Germany, Neider Seltzer, about ten miles from Frankfort on the Maine, where there is a mineral water containing muriate of soda, carbonates of magnesia, soda, and lime; and a large quantity of free carbonic acid. It is said to be particularly serviceable in relieving some of the symptoms that indicate a morbid state of the lungs; in slow hectic fever, eruptions on the skin, foulness of the stomach, bilious vomiting, acidity and heartburn, spasmodic pains in any part of the alimentary canal, and bloody or highly offensive stools. On account of its relieving spasmodic pains, and from its rapid determination to the kidneys, and perhaps its alkaline contents, it has been sometimes employed with great advantage in diseases of the urinary organs, especially those that are attended with the formation of calculus. A large proportion of the Seltzer water, either genuine or artificial, that is consumed in this country is for the relief of these disorders. Even in gonorrhœa, either simple or venereal, Hoffmann asserts that advantage is to be derived from this medicine. The usual dose is from half a pint to a pint.

SEMIBE'LLA. (*a, æ.* f.) Half a pound. — *Varro.*

SEMECA'RPUS. (*us, i.* m.; from σημειοω, to mark, and καρπος, a fruit; a name evidently derived from the use that is made of its nut in the East Indies to mark table-linen and articles of apparel.) The name of a genus of plants. Class, *Pentandria;* Order, *Trigynia.*

SEMECARPUS ANACARDIUM. The marking-nut tree. This tree was supposed to afford the Malacca bean, which, however, is found to be the produce of the *Anacardium Indicum.*

SEMEIO'SIS. (From σημειοω, to notify.) See *Semeiotice.*

SEMEIO'TIC. (*Semeioticus*, from *semeiotice.*) *Semeiosis.* Relating to the signs of disease.

SEMEIO'TICE. (*e, es.* f.; from σημειον, a sign.) Semeiotics. That part of medicine which considers the signs of disease. It considers the nature of the symptoms of diseases, their degree of violence, their mode of accession, their continuance and course, in order that, by considering them and other circumstances connected with them, the judgment may be formed respecting the condition of the disease, and the probable tendency and termination of it. All the circumstances, therefore, of the persons, constitution, and habits; the knowledge of what may have formerly taken place and what now exists, form a part of semeiotics: for, without such enquiry and consideration, the judgment is not likely to be correctly formed, as to the probable tendency, duration, or termination of a disease. It is divided, therefore, into,

1. The *diagnosis*, or consideration of the signs or nature of the symptoms, with a view of ascertaining what the disease is; and these signs, which thus tell us what the disease is, are called diagnostic.

2. The *prognosis*, or the judgment respecting the course, tendency, and termination of a disease.

SE'MEN. (*en, inis.* n.; from *sero*, to sow.) 1. The seed or prolific liquor of animals secreted in the testicles, and carried through the epididymis and vas deferens into the vesiculæ seminales, to be emitted *sub coitu* into the female vagina, and there, by its aura, to penetrate and impregnate the ovulum in the ovarium.

In castrated animals, and in eunuchs, the vesiculæ seminales are small and contracted; and a little lymphatic liquor, but no semen is found in them. The semen is detained for some time in the vesiculæ seminales, and rendered thicker from the continual absorption of its very thin part, by the oscula of the lymphatic vessels. In lascivious men, the semen is sometimes, though rarely, propelled by nocturnal pollution from the vesiculæ seminales, through the ejaculatory ducts (which arise from the vesiculæ seminales, perforate the urethra transversely, and open themselves by narrow and very nervous mouths at the sides of the caput gallinaginis,) into the urethra, and from it to some distance. But in chaste men the greatest part is again gradually absorbed from the vesiculæ seminales through the lymphatic vessels, and conciliates strength to the body. The smell of semen is specific, heavy, affecting the nostrils, yet not disagreeable. The same odour is observed in the roots of the orchis, the iuli of chestnuts, and the antheræ of many plants. The smell of the semen of quadrupeds, when at heat, is so penetrating as to render their flesh fœtid and useless, unless castrated. Thus the flesh of the stag, *tempore coitus*, is unfit to eat. The taste of semen is fatuous, and somewhat acrid. In the testes its consistence is thin and diluted; but in the vesiculæ seminales, viscid, dense, and rather pellucid: and by venery and debility it is rendered thinner.

Specific gravity. The greatest part of the semen sinks to the bottom in water, yet some part swims on its surface, which it covers like very fine threads mutually connected together in the form of a cobweb.

Colour. In the testicles it is somewhat yellow, and in the vesiculæ seminales it acquires a deeper hue. That emitted by pollution or coition, becomes white from its mixture with the whitish liquor of the prostate gland during its passage through the urethra. In those people who labour under jaundice, and from the abuse of saffron, the semen has been seen yellow, and, in an atrabiliary young man, black.

Quality. Semen exposed to the atmospheric air, loses its pellucidity, and becomes thick, but after a few hours it is again rendered more fluid and pellucid than it was immediately after its emission. This phænomenon cannot arise from water or oxygene attracted from the air. At length it deposits phosphate of lime, and forms a corneous crust.

Experiments with semen prove that it turns the syrup of violets green, and dissolves earthy, neutral, and metallic salts. Fresh semen is insoluble in water, until it has undergone the above changes in atmospheric air. It is dissolved by alkaline salts. By ætherial oil it is dried into a pellucid pellicle, like the cortex of the brain. It is dissolved by all acids, except the oxymuriatic, by which it is coagulated in the form of white flakes. It is also acted upon by alkohol of wine.

It is found to be composed of water, 900; animal mucilage, 60; soda, 10; and phosphate of lime, 30.

Examined by the microscope, a multitude of animalcula are observed in it, which appear to have a round head and a long tail: these animalcula move with considerable rapidity; they seem to fly the light, and to seek the shade. It has also an odorous principle, which flies off immediately from fresh semen. It appears to consist of a peculiar vital principle, and by the ancients was called *aura seminis*.

Use. 1. Emitted into the female vagina, *subcoitu*, it possesses the wonderful power of impregnating the ovulum in the female ovarium. The odorous principle, or aura spermatica only, appears to penetrate through the cavity of the uterus and Fallopian tubes to the female ovarium, and there to impregnate the albuminous latex of the mature ovulum by its vital power. The other principles of the semen appear to be only a vehicle of the seminal aura. 2. In chaste men, the semen returning through the lymphatic vessels into the mass of the blood, gives strength to the body and mind: hence the bull is so fierce and brave, the castrated ox so gentle and weak; hence every animal languishes *post coitum*; and hence tabes dorsalis from Onanism. 3. It is by the stimulus of the semen absorbed at the age of puberty into the mass of the humours that the beard and hair of the pubes, but in animals the horns, are produced; and the weeping voice of the boy changed into that of the man.

II. The seeds of plants, or nucleus formed in the germen of a plant, for the purpose of propagating its species, — the sole "end and aim" of all the organs of fructification. Every other part is in some manner subservient to the forming, perfecting, or dispersing of these.

A seed consists of several parts, some of which are more essential than others; viz.

1. The *hilum*, or scar.

2. The *funiculus umbilicalis*, or filament, by which the immature seed is connected to the receptacle.

3. The *testa*, or *tunica seminis*.

4. The seed-lobes, or *cotyledons*. These parts are beautifully seen by macerating the seeds of a kidney, or other bean, or of the gourd, in water.

The less essential parts are,

1. The *arillus*.
2. The *pappus*.
3. The *cauda*.
4. The *capsula*.
5. The *ala*.

From the difference in the form, surface, situation, and number, arise the following distinctions of seeds: —

1. *Semina arillata*; as in *Jasminum*.

2. ——— *papposa*; as in *Leontodon taraxacum*.

3. ——— *caudata*; as in *Clematis vitalba*.

4. ——— *calyculata*, covered with a bony calyx; as in *Coix lachryma*.

5. ——— *alata*; as in *Bignonia*.

6. ——— *hamosa*, furnished with one or three hooks; as in *Daucus muricatus*.

7. ——— *lanata*, covered with wool; as in *Bombax*, *Gossipium*, and *Anemone hortensis*.

8. ——— *rotunda*; as in *Pisum* and *Brassica*.

9. *Semina rotundo-compressa*; as *Ervum lens*.

10. ——— *oblonga*; as in *Boerhaavia dif. fusa*.

11. *Semina conica;* as in *Bellium.*
12. ——— *ovata;* as in *Quercus robur.*
13. ——— *triquetra;* as in *Rheum,* and *Rumex.*
14. ——— *lanceolata;* as in *Fraxinus.*
15. ——— *acuminata;* as in *Cucumis sativus.*
16. ——— *reniformia;* as in *Phaseolus.*
17. ——— *aculeata;* as *Ranunculus arvensis.*
18. ——— *cochleata;* as in *Salsola.*
19. ——— *cymbiformia;* as in *Calendula officinalis.*
20. ——— *linearia;* as in *Crucianella.*
21. ——— *aristata;* as in *Holcus saccharatus.*
22. ——— *echinata;* as in *Verbena lapulacea.*
23. ——— *hispida;* as *Daucus carota.*
24. ——— *hirsuta;* as in *Scandix trichosperma.*
25. ——— *muricata;* as *Ranunculus parviflorus.*
26. ——— *glabra;* as in *Galium montanum.*
27. ——— *rugosa;* as in *Lithospermum arvense.*
28. ——— *callosa;* as in *Citrus medica.*
29. ——— *lapidea;* as in *Lithospermum.*
30. ——— *colorata;* as in *Chærophyllum aureum.*
31. ——— *striata;* as in *Conium maculatum.*
32. ——— *sulcata;* as in *Scandix odorata.*
33. ——— *transversim sulcata;* as in *Picris.*
34. ——— *nuda;* as in the gymnospermous plants.
35. ——— *tecta;* as in angiospermous plants.
36. ——— *nidulantia,* adhering to the external surface; as in *Fragaria vesca.*
37. ——— *pendula,* suspended by a filament external to the seed-vessel; as in *Magnolia grandiflora.*
38. ——— *pauca,* when few in number.
39. ——— *plurima,* many; as in *Papaver.*

The parts of a seed when germinating are,

1. *Cotyledones.*
2. *Corculum.*

The variety of forms of seeds are not without their uses; and the various modes by which seeds are dispersed, cannot fail to strike an observing mind with admiration. "Who has not listened," says Sir James Smith, "in a calm and sunny day, to the crackling of furze-bushes, caused by the explosion of their little elastic pods; nor watched the down of innumerable seeds floating on the summer breeze, till they are overtaken by a shower, which, moistening their wings, stops their further flight, and at the same time accomplishes its final purpose, by immediately promoting the germination of each seed in the moist earth? How little are children aware, as they blow away the seeds of dandelion, or stick burs, in sport, on each others' clothes, that they are fulfilling one of the greatest ends of Nature! Sometimes the calyx, beset with hooks, forms the bur; sometimes hooks encompass the fruit itself. Pulpy fruits serve quadrupeds and birds as food, while their seeds, often small, hard, and indigestible, pass uninjured by them through the intestines, and are deposited, far from their original place of growth, in a condition peculiarly fit for vegetation. Even such seeds as are themselves eaten, like the various sorts of nuts, are hoarded up in the cracked ground, and occasionally forgotten, or the earth swells and encloses them. The ocean itself serves to waft the larger kinds of seeds from their native soil to far distant shores."

Semen adjowaen. A seed imported from the East, of a pleasant smell, a grateful aromatic taste, somewhat like savory. It possesses exciting, stimulating and carminative virtues, and is given in the East in nervous weakness, dyspepsia, flatulency, and heartburn. It is the produce of the *Ammi copticum.*

Semen agave. An East Indian seed exhibited in atonic gout.

Semen contra. See *Artemisia.*

Semen sanctum. See *Artemisia.*

Semen veneris. Scales of brass. — *Ruland.*

SE'MI-AMPLEXICA'ULIS. Applied to a leaf, which half, or in part only, embraces the stem.

Semicircular canals. These canals are three in number, and take their name from their figure. They belong to the organ of hearing, are situated in the petrous portion of the temporal bone, and open into the vestibulum. See *Auris.*

SEMICU'PIUM. (*um, ii.* n.) A half-bath, or such as receives only the hips or extremities.

SE'MICYLI'NDRICAL. *Semicylindricalis.* Flat on one side, round on the other; as the leaves of the *Conchium gibbosum.*

SE'MIFLOSCULO'SUS. A compound flower is so termed when its florets have the limb of the corolla produced in a ligulate shape on the outer side only.

Semi-interosseus indicis, See *Abductor indicis manus.*

SEMILU'NAR. *Semilunaris.* Half-moon shaped. The ganglia formed by the great symphatic nerve on its entrance into the abdomen, from which nerves are sent to all the viscera. See *Intercostal nerve.*

Semilunar valves. The three valves at the beginning of the pulmonary artery and aorta ars so termed, from their half-moon shape.

SE'MI-MEMBRANO'SUS. A muscle of the thigh, so called from the long flat membrane like tendon at its upper part. It arises from the outer surface of the tuberosity of the ischium, by a broad flat tendon which is three inches in length. It then begins to grow fleshy, and runs at first under the long head of the biceps, and afterwards between that muscle and the semi-tendinosus. At the lower part of the thigh it becomes narrower again, and terminates in a short tendon, which is inserted chiefly into the upper and back part of the head of the tibia, but some of its fibres are spread over the posterior surface of the capsular ligament of the knee. Between this capsular ligament and the tendon of the muscle we find a small bursa mucosa. The tendons of this and the last-described muscle form the inner ham-

string. This muscle bends the leg, and seems likewise to prevent the capsular ligament from being pinched.

Semi-nervosus. See *Semi-tendinosus.*

Seminis cauda. See *Cauda seminis.*

Seminis ejaculator. See *Accelerator urinæ.*

SE'MI-ORBI'CULAR. *Semiorbicularis.* Having the shape of half a globe.

Semi-orbicularis oris. See *Orbicularis oris.*

SEMI-SPINALIS COLLI. *Semi-spinalis sive transverso-spinalis colli*, of Winslow. *Spinalis cervicis*, of Albinus. *Spinalis colli*, of Douglas. *Transversalis colli*, of Cowper. A muscle situated on the posterior part of the neck, which turns the neck obliquely backwards, and a little to one side. It arises from the transverse processes of the uppermost six vertebræ of the back by as many distant tendons, ascending obliquely under the complexus, and is inserted into the spinous processes of all the vertebræ of the neck, except the first and last.

SEMI-SPINALIS DORSI. *Semi-spinalis externus seu transverso-spinalis dorsi*, of Winslow. *Semi-spinatus*, of Cowper. A muscle situated on the back, which extends the spine obliquely backwards. It arises from the transverse processes of the seventh, eighth, ninth, and tenth vertebræ of the back, by as many distinct tendons, which soon grow fleshy, and then become tendinous again, and are inserted into the spinous processes of all the vertebræ of the back above the eighth, and into the lowermost of the neck, by as many tendons.

Semi-spinalis externus. See *Semi-spinalis dorsi.*

Semi-spinatus. See *Semi-spinalis dorsi.*

SEMI-TENDINOSUS. This muscle, which is the *semi-nervosus*, of Douglas and Winslow, is situated obliquely along the back part of the thigh. It arises tendinous and fleshy from the inferior, posterior, and outer part of the tuberosity of the ischium, in common with the long head of the biceps cruris, to the posterior edge of which it continues to adhere, by a great number of oblique fibres, for the space of two or three inches. Towards the lower part of the os femoris, it terminates in a round tendon, which passes behind the inner condyle of the thigh-bone, and, becoming flat, is inserted into the upper and inner part of the ridge of the tibia, a little below its tuberosity. This tendon sends off an aponeurosis, which helps to form the tendinous fascia that covers the muscles of the leg. This muscle assists in bending the leg, and at the same time draws it a little inwards.

SEMPE'RVIRENS. Evergreen. Applied to leaves which are permanent through one, two, or more winters, so that the branches are never stripped; and to plants possessed of such leaves as the laurel, holly, ivy, &c.

SEMPERVI'VUM. (*um*, *i.* n.; from *semper*, always, and *vivo*, to live: so called because it is always green.) The name of a genus of plants in the Linnæan system. Class, *Dodecandria*; Order, *Polygynia.*

SEMPERVIVUM ACRE. The stone-crop is occasionally so termed. See *Sedum acre.*

SEMPERVIVUM TECTORUM. The systematic name of the house-leek, or sengreen; called also, *Sedum majus*, *Æonion*, *Aizoum*, *Aizoon*, and *Barba Jovis.* The leaves of this plant have no remarkable smell, but discover to the taste a slight subacid austerity: they are frequently applied by the vulgar to bruises and old ulcers.

SENE'CIO. (*o*, *onis.* m.; from *senesco*, to grow old: so called because it has a greyish down upon it, like the beard of old men.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia superflua.*

2. The pharmacopœial name of the *Senecio vulgaris.*

SENECIO JACOBÆA. St. James's wort. Ragwort. *Jacobæa.* The leaves of this common plant have a roughish, bitter, subacrid taste, extremely nauseous. A decoction is said to have been of infinite service in the cure of epidemic camp dysentery. A poultice made of the fresh leaves is said to have a surprising effect in removing pains of the joints, and to remove the sciatica, or hip-gout, in two or three applications, when ever so violent. The root is of an astringent nature. A decoction of it was formerly deemed good for wounds and bruises.

Senecio madraspatanus. See *Senecio pseudo-china.*

SENECIO PSEUDO-CHINA. Bastard. China. *China supposita. Senecio madraspatanus.* This tree grows in Malabar. The root greatly resembles the China root in appearance and qualities.

SENECIO VULGARIS. Groundsel. *Erigerum. Senecio. Erigeron.* This very common plant is frequently applied bruised to inflammations and ulcers, as a refrigerant and antiscorbutic.

Senectæ anguium. See *Anguium senectæ.*

Senectus. See *Age.*

SE'NEGA. (*ka*, and *ga*, *æ.* f.; so called because the Seneca or Senegaw Indians use it against the bite of the rattlesnake.) See *Polygala senega.*

Senegal gum. See *Acacia vera.*

Senegaw milkwort. See *Polygala senega.*

SE'NEGINE. An alkaline principle found in the root of the *Polygala senega.*

Seneka. See *Senega.*

Sengreen. See *Sempervivum.*

SE'NNA. (*a*, *æ.* f.; from *senna*, an Arabic word, signifying acute: so called from its sharp-pointed leaves.) The senna of commerce is the produce of several plants. That which yields the best grows in the valleys of Nubia, where it is named *Abyreyga*; flowering in July and August. It rises with an erect branching stem, about two feet in height. At the base of the leaves, which are pinnate, and placed in alternate order, are two narrow pointed stipules: the leaflets, of which each leaf has five or six pair, are sessile, oblique at the base, oval, pointed, scarcely an inch in length, rather more than one-fourth of an inch broad, and of a yellowish green colour. The flowers are yellow, in loose axillary spikes: the calyx is deciduous, consisting of five narrow, obtuse, concave leaflets; the petals are roundish, concave, entire; the three lower ones larger than the two upper: the undermost filaments also are longer than the

others, and furnished with large rostrated curved anthers; and the germen is long and flat, with a short incurved style terminated by an obtuse stigma. The fruit is an ovate, reniform, membranous, leafy, compressed legume, torose and marked with capillary, transverse, parallel striæ; bivalve, with six or nine cells, divided by very thin transverse partitions, and each containing one oblong heart-shaped seed.

The best senna, named in Nubia *guebelly*, or *sena mekke*, grows wild, and yields two crops of leaves, the abundance of which depends on the periodical rains. The first crop is collected after the first rains about the middle of September; the second in the following March, at which time the fruit is at its full maturity. The plants are cut when the flowers begin to fall, and exposed on the rocks to dry in the sun. The leaves are then picked, packed up in bales, and sent to Boulac, the great entrepôt of senna, where they are mixed with two other species of cassia; one the *C. senna* of Forskal, with obtuse leaves; the other probably the *C. angustifolia* of Willdenow, the leaves of which are longer, narrower, and sharper pointed than those of the proper senna, and come from Mocha; but the leaf with which senna is chiefly adulterated is that of the *Cynanchum oleafolium*, known in Egypt by the name of *argel* or *arguel*. The proportions, according to Dr. Calloden, are five hundred parts lance-leafed senna, two hundred of obovate senna, and two hundred of argel. The two first are equally good, but the last is truly an adulteration. It can be readily distinguished by attending to the following rules: — 1. The leaf of argel is an inch or fourteen lines long, while that of senna never exceeds nine lines. 2. The leaf of argel has a straight side; and the lateral nerves are not seen on the under disk, while those of senna are conspicuous. 3. The leaf of argel is regular at its base, the two sides terminating at the same point on the petiole: but the senna leaflet is oblique, one of the sides being larger, and produced lower on the petiole than the other. There is also reason for thinking that it is further adulterated with the leaves of *Colutea arborescens*, bladder senna, and of box: but these are easily distinguished from senna leaves. The senna, after being thus mixed, is repacked in bales at Alexandria, whence it is exported to Europe. A good deal of senna has been imported from Calcutta, under the name of East Indian senna. It is evidently the *Cassia lanceolata*. It was formerly taken to India from the Persian Gulph, and was the growth of Mecca; but much of it is now cultivated at Tinnivelly, on the Malabar coast. It is called senna mecki and Tinnivelly senna, in the Indian bazaars. The officinal senna of America is the *Cassia marilandica*, or *Chamæ senna marilandica*.

Qualities. — The odour of senna-leaves is faint, rather disagreeable, and sickly; the taste slightly bitter, aromatic, sweetish, and nauseous. Boiling water extracts about one-third of the weight of the leaves employed, but it requires a pint of boiling water to extract all the active matter from ℥j. of senna leaves. The infusion has a deep reddish-brown colour, with the odour and taste of the leaves. This infusion, when exposed to the atmosphere, deposits a lemon-yellow colour, insoluble matter; and a precipitate is produced by the strong mineral acids, oxalic acid, the carbonates of the alkalies, and several other substances. (See *Infusum sennæ*, among the preparations.) Alkohol and sulphuric ether, digested on the powdered leaves, acquire a deep olive-green colour. When the ethereal tincture is poured on the surface of pure water, a dark olive pellicle remains after the evaporation of the ether, which is almost insipid, and has all the properties of resin; and a golden yellow colour is communicated to the water. The alkoholic tincture is rendered only slightly milky by the addition of water, and scarcely any precipitate is produced; but a copious one is thrown down by oxymuriatic acid. The active principle of senna, according to the experiments of M. M. Lassaigne and Fenuelle, is a saline substance, which they have named *cathartine* (cathartia). It is uncrystallisable, of a reddish-yellow colour, and has a bitter, nauseous taste. It is soluble in alkohol and in water, but insoluble in ether. According to Bouillon Lagrange, the residue of the watery infusion, evaporated to dryness and burnt, yields potass, sulphate of potass, carbonate of lime, magnesia and silica.

Medical properties and uses. — Senna is purgative, generally operating under four hours after it is taken; and is well adapted for all cases in which the bowels require to be certainly, yet moderately, evacuated. In many habits it is apt to occasion griping, and therefore requires the addition of some aromatic, as carraway or cardamom-seeds, or ginger; and its operation to be assisted by drinking plentifully of weak broths or gruel. The griping seems to be occasioned by the resinous matter, as the infusion made with cold water does not gripe, although it purges. Senna may be given in substance powdered; but the more usual form is that of infusion. Decoction is a bad form, as the activity of the medicine is much impaired by the boiling; owing, according to Gren, to the total dissipation of the nauseous and volatile principles; but, in our opinion, it is owing to the oxidisement of the extractive, which also accounts for the severe gripings induced by the decoction. The dose of the powder of the leaves is from ʒj. to ʒj.; but it is seldom given alone.

Officinal preparations. *Confectio sennæ*, L. E. *Electuarium sennæ*, D. *Extractum cassiæ sennæ*, E. *Infusum sennæ compositum*, L. D. *Infusum tamarindi cum senna*, E. D. *Tinctura sennæ composita*, L. E. D. *Syrupus sennæ*, L. — *A. T. Thomson.*

Senna alexandrina. See *Cassia.*

Senna italica. See *Cassia senna.*

Senna pauperum. Bastard senna, or milk-vetch, — the *Colutea arborescens* of Linnæus, the leaves of which purge and vomit.

Senna scorpium. The scorpion senna. Now named *Coronilla emerus*

SENSATION. *Sensatio.* When an impression made on the extremity of a nerve is

communicated to the sensorium, so as to excite the consciousness of the mind, it is called a sensation. See *Mind*. When the impression is produced by the action of a foreign body on an external part, it is called an *external sensation*; when it proceeds from some change taking place within the living system, and arising from its own actions, it is termed an *internal sensation*: thus the impression communicated to the mind by the effect of light on the retina, or the painful sensation produced by a blow, are external sensations; the feeling of hunger or of restlessness are internal sensations. This distinction is common in physiological writings; but there are sensations which it would not be easy to refer to either of these classes. Thus, if a person were to swallow a lump of lead, he would feel an uneasy sensation in his stomach: should this be called an external or an internal sensation? It resembles the external sensations with reference to the mode of its production, but is internal with reference to its seat. The external organs by which those impressions which cause sensation are primarily received, are called the organs of the senses; these are the eye, which ministers to vision; the ear, which receives the impressions of sound; the pituitary membrane lining the nasal cavities, which affords expansion to the olfactory nerve, by means of which we smell; the tongue, palate, &c., which constitute the organ of taste; and the extremities of nerves, dispersed under the common integuments, which give rise to the common sensation, feeling, or touch: the sense, more particularly called *touch*, is merely the exaltation of the common sensation in the nervous papilla at the ends of the fingers, aided by impressions derived from the consciousness of muscular action. See *Senses*.

SENSES. The channels of communication by which the mind derives the materials of thought from the external world, and the exercise of which depends on the property of sensibility modified by particular organs to especial ends. Man is generally considered to be endowed with five senses, namely, *sight*, *hearing*, *smell*, *taste*, and *touch*. See *Vision*, *Auris*, *Smell*, *Taste*, and *Touch*. Besides these, we have a very distinct consciousness of the action of our own muscles, or a *muscular sense*, which was first pointed out and ingeniously commented on by Dr. Browne, the late Professor of Moral Philosophy at Edinburgh. This, however, may perhaps be referrible to the sense of touch excited in the muscles by the pressure of their fibres on each other in the act of contracting. Several modifications of ordinary sensation have been, at different times, brought forward as a *sixth sense*, which, however (unless the muscular sense be considered as such), has evidently no existence. The several powers of the mind, as memory, imagination, judgment, the passions, &c., have been called *internal senses*.

SENSIBILITY. *Sensibilitas*. That faculty of living parts by which they are capable of receiving impressions, which increase, diminish, alter, or suspend their actions. Sensibility is usually divided into *animal sensibility*, which gives rise to sensations, and *organic sensibility*, which calls into action the organic contractility. For a shrewd remark of M. Broussais, on the subject of organic sensibility, see *Contractility*. Some parts are endowed with a high degree of animal sensibility, and hence any injury of such parts gives rise to acute pain; other parts possess hardly any animal sensibility, and hence, in common language, are said to be insensible.

Sensibility is infinitely variable: in certain persons it is very obtuse; in others it is very elevated: generally a good organisation keeps between the extremes.

Sensibility is vivid in infancy and youth; it continues in a degree something less marked until past the age of manhood; in old age it suffers an evident diminution; and very old persons appear quite insensible to all the ordinary causes of sensations.

SENSORIAL. Appertaining to the *sensorium*.

SENSO'RIUM. (*um*, *ii*. n.) The common centre, at which all the impressions of sense are received. This common centre is the brain.

Sensorium commune. The brain.

SE'NSUS. (*us*, *ûs*. m.; *à sentiendo*.)

Sentico'sæ. The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of such as resemble the bramble, rose, &c.

SENTICO'SUS. (From *sentis*, a brier.) Thorny; brier-like.

SE'NTIENT. *Sentiens*. This term is applied to those parts which are more susceptible of feeling than others; as the sentient extremities of the nerves, &c.

SENTIS. A thorn: applied to plants of the brier kind, which are prickly.

Sentis caninus. See *Rosa canina*.

SEPARATE. In the language of botany, the stamens and pistils of monœcious plants are said to be separate when they are found upon the same plant, but in different flowers. Thus, in *Cucumis*, *Buxus*, and other genera, some of the flowers contain stamens, and others have pistils, but none of them contain both together.

Separato'rium. (From *separo*, to separate.) 1. An instrument for separating the pericranium from the skull.

2. A chemical vessel for separating essential parts of liquids.

SE'PIA. (*a*, *æ*. f.) The name of a genus of cephalopodous mollusca. The cuttle-fish.

Sepia officinalis. The cuttle-fish. *Sepium*. *Præcipitans magnum*. The bone, or, more properly, the internal shell of this animal consists of membranous layers hardened by carbonate of lime. It was formerly used in medicine, but is now only employed as a dentifrice.

Sepiæ os. See *Sepia officinalis*.

SEPIA'RIÆ. (From *sepes*, a hedge.) The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of woody plants, which form a hedge-like appearance: the flowers are mostly a thymus or panicle.

Sepium. See *Sepia officinalis*.

Septfoil. See *Tormentilla*.

SE'PTIC. (*Septicus*; from σηπω, to putrefy.) Relating to putrefaction.

SE'PTUM. (*um, i.* n.; from *septo*, to separate.) A partition: applied to membranes, bones, &c. which divide parts; as *septum narium*, &c.

Septum cerebelli. A process of the dura mater, dividing the cerebellum perpendicularly into two principal parts.

Septum cerebri. The falciform process of the dura mater is sometimes so called. See *Falciform process.*

Septum cordis. The partition between the two ventricles of the heart.

Septum lucidum. *Septum pellucidum.* The thin and tender portion of the brain, dividing the lateral ventricles from each other.

Septum narium. The partition between the nostrils.

Septum pellucidum. See *Septum lucidum.*

Septum thoracis. See *Mediastinum.*

Septum transversum. See *Diaphragm.*

SEQUE'STRUM. (*um, i.* n.; from *sequestro*, to detach.) The dead portion of bone cast off by necrosis.

SERA'PIAS. (*as, adis.* f.; from *Serapis*, a lascivious idol: so called because it was thought to promote venery; or from the testiculated shape of its roots.) 1. The name of a genus of plants in the Linnæan system. Class, *Gynandria;* Order, *Diandria.*

2. The dried root of the *Orchis morio*, called salep.

Serapinum. See *Sagapenum.*

Serene-drop. See *Amaurosis.*

SE'RICEUS. Silky.

SERI'CUM. 1. Silk: a well-known substance produced by several animals, but principally by the silk-worm, *Bombyx mori.* Silk was formerly used in medicine as a cordial and alexipharmic. When burnt, it had a place in the dispensatories, under the name of *Sericum tostum.*

2. A species of hairy pubescence of plants, which consists of a white shining silkiness: thus the leaves of the *Potentilla anserina*, *Alchemilla alpina*, &c. are called *folia sericea.*

Sericum tostum. See *Sericum.*

Seris. Σερις. Endive.

Sermountain. See *Laserpitium.*

Serosity. Synonymous with serum.

SE'ROUS. (*Serosus;* from *serum.*) Relating to serum.

Serous apoplexy. See *Apoplexy.*

Serous plethora. See *Plethora.*

SERPENTA'RIA. (*a, æ.* f.; so called from the resemblance of the roots of the plant which first bore this name to the tail of the rattle-snake.) See *Aristolochia serpentaria.*

Serpentaria Gallorum. See *Arum.*

Serpentaria Hispanica. See *Scorzonera.*

Serpentaria Virginiana. See *Aristolochia serpentaria.*

Serpentum lignum. See *Ophioxylum.*

Serpentum radix. See *Ophiorrhiza.*

SERPI'GO. (From *serpo*, to creep: because it creeps on the surface of the skin by degrees.) A ringworm, or tetter. See *Herpes.*

Serpy'llum. (*um, i.* n.; from *serpo*, to creep, on account of its creeping mode of growth.) See *Thymus serpyllum.*

Serpyllum citratum. See *Thymus serphyllum.*

Serpyllum vulgare. See *Thymus vulgaris.*

Serra'ta. (*a, æ.* f.; from *serra*, a saw: so called from its serrated leaves.) See *Serratula.*

SERRA'TULA. (*a, æ.* f.; from *serra*, a saw: so called from its serrated leaves.) The name of a genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Polygamia æqualis.*

Serratula amara. The systematic name of a species of saw-wort, which is said to cure agues.

Serratula arvensis. The common creeping way-thistle. *Carduus arvensis. Carduus hæmorrhoidalis. Cirsium arvense. Ceanothus.* This plant was formerly used as an application to resolve scirrhous tumours, and is now considered useful against piles.

SERRA'TUS. (From *serra*, a saw.) Serrated. 1. Applied to leaves when the teeth are sharp, and resemble those of a saw, pointing towards the extremity of the leaf, as in *Urtica;* and to *petals*, as those of the *Dianthus arboreus*, and *Cystus polyfolius.*

Some leaves are called *duplicato-serrate:* these are doubly serrate, having a series of smaller serratures, intermixed with the larger; as in *Campanula trachelium.*

2. In *Anatomy*, applied to muscles and other parts, from their serrated appearance.

Serratus anticus. See *Pectoralis minor.*

Serratus magnus. *Serratus major anticus*, of Douglas and Cowper. *Serratus major*, of Winslow. This muscle is so named by Albinus. Douglas calls it *Serratus major anticus*, but improperly, as it is seated at the side, and not at the anterior part of the thorax. It is a broad fleshy muscle, of a very irregular shape, and is in part covered by the subscapularis, pectoralis, and latissimus dorsi. It arises by fleshy digitations, from the eight superior ribs, and is inserted fleshy into the whole basis of the scapula internally, between the insertion of the rhomboides and the origin of the subscapularis, being folded, as it were, about the two angles of the scapula. This muscle may easily be divided into two or even three portions. The latter division has been adopted by Winslow. The first of these portions is the thick and short part of the muscle that arises from the first and second ribs, and is inserted into the upper angle of the scapula, its fibres ascending obliquely backwards. The second portion arises from the second rib, behind the origin of the first portion, and likewise from the third and fourth ribs: this portion is thin and short, and its fibres run nearly in a horizontal direction, to be inserted into the basis of the scapula. The third, and most considerable portion, is that which arises from the fifth, sixth, seventh, and eighth ribs, and is inserted into the lower angle of the scapula. The serratus magnus serves to move the scapula forwards; and it is chiefly by the contraction of this muscle that the shoulder is supported, when loaded with any heavy weight. The ancients, and even many of the moderns, particularly Douglas and Cowper, supposed its chief use to be to dilate the thorax, by elevating

the ribs; but it can only do this when the scapula is forcibly raised.

Serratus major anticus. See *Serratus magnus.*

Serratus minor anticus. See *Pectoralis minor.*

Serratus posticus inferior. This is a thin muscle, of considerable breadth, situated at the bottom of the back, under the middle part of the latissimus dorsi. It arises by a broad thin tendon, in common with that of the last-mentioned muscle, from the spinous processes of the two, and sometimes of the three, inferior dorsal vertebræ, and from three, and sometimes four, of those of the lumbar vertebræ. It then becomes fleshy, and, ascending a little obliquely outwards and forwards, divides into three, and sometimes four, fleshy slips, which are inserted into the lower edges of the three or four inferior ribs, at a little distance from their cartilages. Its use seems to be to pull the ribs downwards, backwards, and outwards.

Serratus superior posticus. This is a small, flat, and thin muscle, situated at the upper part of the back, immediately under the rhomboideus. It arises, by a broad thin tendon, from the lower part of the ligamentum colli, from the spinous process of the last vertebræ of the neck, and the two or three uppermost of the back, and is inserted into the second, third, fourth, and sometimes fifth, ribs, by as many distinct slips. Its use is to expand the thorax, by pulling the ribs upwards and outwards.

SERRULA'TUS. (From *serrula*, a little saw.) Serrulate or minutely serrate: applied to such saw-like edged leaves which have their teeth very fine; as in *Polygonum amphibium.*

Sertula campana. See *Trifolium melilotus.*

SE'RUM. (*um*, *i.* n.; from *serus*, late: because it is the remainder of the milk, after its better parts have been taken from it.) 1. The whey of milk.

2. The yellow and somewhat greenish fluid, which separates from the blood when cold and at rest. See *Sanguis.*

Serum aluminosum. Alum whey. Made by boiling 3 ij. of alum in a pint of cow's milk, and straining. This was formerly esteemed as an astringent in the different profluvia. It is not much used at present. The dose is a quarter of a pint three or four times a day.

Serum catharticum. Purging whey. Take of fresh damask rose buds picked, an ounce; put them into two pounds of common whey over night, and strain and drink it next morning.

"This," says Quincy, "is a mighty purge with some of our country people; it will work very kindly and thoroughly, and is therefore good to cleanse the first passages."

Serum lactis. See *Whey.*

Serum scorbuticum. Take of the leaves of succory and sorrel, of each twelve handfuls; fir tops, scurvy grass, and watercresses, of each four ounces; coriander seeds, one ounce. When bruised, add to them of orange juice four ounces, and common whey four pounds. Let them stand for a little, then press out the liquor, sweeten it with a little refined sugar, and clarify for use. This used to be drunk as an antiscorbutic, in the quantity of two or three pints a day. It will not keep, and, therefore, must be made as it is wanted.

Serum sinapinum. Mustard whey. This is made by boiling a pint of milk, with half an ounce of bruised mustard seed, and straining. This is sometimes used as a diuretic in dropsy, in the dose of a quarter of a pint three times a day.

Service-tree. See *Sorbus aucuparia.*

SE'SAMOID. (*Sesamoideus*; from σησαμη, a kind of grain, and ειδος, likeness.) Like the sesamum seed. Applied in Anatomy to several parts, from their shape.

Sesamoid bones. *Ossa sesamoidea.* The little bones which are found at the articulations of the great toes, and sometimes at the joints of the thumbs; now and then we meet with them upon the condyles of the os femoris, at the lower extremity of the fibula, under the os cuboides of the tarsus, &c. They do not exist in the fœtus; but, as we advance in life, begin first to appear in a cartilaginous state, and, at length, in adult subjects, are completely ossified. Age and hard labour seem to add to the number and size of these bones, and, being most commonly found wherever the tendons and ligaments are most exposed to pressure from the action of the muscles, they are now generally considered by anatomists as the ossified parts of tendons and ligaments. These bones are usually smooth and flat on the side of the bone on which they are placed; their upper surface is convex, and, in general, adheres to the tendon that covers it, and of which it may, in some measure, be considered as a part. Although their formation seems to be owing to accidental circumstances, yet, as the two at the first joint of the great toe are much larger than the rest, and are seldom wanting in an adult, it would seem as if these bones were of some utility; perhaps, by removing the tendons farther from the centre of motion, and thus increasing the power of the muscles. The ossa sesamoidea of the great toe and thumb seem likewise to be of use, by forming a groove for lodging the flexor tendons secure from compression.

Sesamoidea corpora. See *Corpora sesamoidea.*

SE'SAMUM. (*um*, *i.* n.; an Egyptian word.) 1. The name of a genus of plants in the Linnæan system.

2. The pharmacopœial name of the oriental sesamum. See *Sesamum orientale.*

Sesamum orientale. *Sesamum.* The seeds of this plant are in much esteem in South Carolina, where they are called *oily grain*; they are made into soups and puddings, after the manner of rice. Toasted over the fire, they are mixed with other ingredients, and stewed into a delicious food. The fresh seed affords a considerable quantity of a warm pungent oil, otherwise not unpalatable. In a year or two the pungency leaves it, when the oil is used for salad, &c. The seeds of the *Sesamum indicum* are used in the same manner. The leaves are also used medicinally in some countries, being of a mucilaginous quality.

SE'SELI. (Gen. *Seseleos*; n. Σεσελι. The herb hart-wort.) 1. The name of a genus of plants. Class, *Pentandria*; Order, *Digynia.*

2. An old name of the hart-wort. See *Laserpitium siler*.

SESELI CRE'TICUM. There is great confusion amongst the species of the seseli. The plant which bears this epithet in the pharmacopœias is the *Tordylium officinale*, of Linnæus. The seeds are said to be diuretic.

Seseli Marsiliense. See *Seseli tortuosum*.

SESELI TORTUOSUM. The hart-wort of Marseilles. *Seseli Marsiliense*. The seeds of this plant are directed for medicinal use, and have a warm biting taste, and a greater degree of pungency than those of the *Laserpitium*.

SE'SQUI. This word, joined with any number, weight, measure, &c., signifies one integer and a half; as *sesqui granum*, a grain and a half. In the doctrine of definite proportions, it is used to designate compounds, in which an equivalent and a half of one ingredient is combined with one equivalent of another; thus, *sesqui-oxide of iron*, *sesqui-carbonate of ammonia*, &c. See *Combination, chemical*.

SE'SSILE. (*Sessilis*; setting close.) A term applied to any part of a plant that is not elevated on any kind of stalk: hence *flores sessiles*, *folia sessilia*, &c.

SE'TA. (*a*, *æ*. f.; from χαιτα, a bristle.) A bristle.

I. In *Anatomy*, a long rigid hair, such as is on the neck of swine.

II. A bristle, as applied in botanical language to a hollow, rigid, sharp-pointed pubescence, which either wounds the finger when it is pressed upon it, or gives a very harsh, scabrous, or prickly character to the surface of the stem, or of the leaves when the finger is rubbed over them.

Bristles are often arranged into *aculei* in elementary works, but they have more affinity to hairs. They are simple and compound.

1. *Setæ simplices* are of two kinds, awl-shaped and spindle-shaped.

a. The *subulate* is the most common of the simple bristles: it is slightly curved, and gradually tapering from the base to the apex, which is rigid and very sharp. These bristles, when they all incline in the same direction, produce the scabrous character of some leaves, as in *Symphytum orientale*. A variety of the awl-shaped bristle, found on the stem and branches of the sensitive plant, is barbed on its sides; and another variety, as exemplified on the leaves of the *Borago officinalis*, is seated on a vesicular tubercle containing a fluid, which is ejected through the bristle when it is compressed, so as to wound the finger, and which, being left in the wound, excites inflammation in the part. But the sting of the nettle is the best example of this form of bristle.

b. The *fusiform* is, as its name implies, thickest in the centre, and acuminated at each end. It lies parallel to the surface of the leaf, to which it is affixed by a very small footstalk, is hollow, and contains a coloured liquid, which apparently enters it through the footstalk. This form of bristle is peculiar to the genus *Malpighia*.

2. *Setæ compositæ*. These are almost always solid. The term comprehends two species of bristles, *furcatæ* and *fasciculatæ*.

a. The forked are, in some instances, merely rigid hair-like bodies, terminating in two or three diverging points, as in *Thrincia hispida*; but in other instances, as the stems and leaves of the hop plant, the stalk of the bristle, which is supported on a firm cellular tubercle, is very short, and its forking extremities resemble two flattish awl-shaped bristles, pointing in opposite directions.

b. The *fasciculated* consist of a number of simple, straight bristles, diverging from a papillary knob; as in *Cactus flagelliformis*.

There is still another species of pubescence which cannot properly be arranged with the pilus or seta: it is found on a species of houseleek, extending like a very fine thread, stretching from the tip of one leaf to that of another, and resembling so exactly a spider's web, that the plant has been named *Arachnoideum*. — *Thompson*.

Bristles are also distinguished into *erect*, as in *Leontodon hirtum*; *hamose*, as in the pericarp of the *Arctium lappa*; *stellate* and *plumose*. The bristles of plants have received other denominations: —

1. *Striga*, that variety of the subulate which is seen in *Borago officinalis*.

2. *Hamus*, that which is hooked at its extremity; as in *Galium aperine*, *Caucalis daucoides*, &c.

3. *Glochis*, when several sharp tooth-like processes are turned back from the apex of the bristle.

4. *Arista*, a long bristle proceeding from the husk of grasses; as in *Hordeum vulgare*.

c. The fruitstalk of mosses, which is either solitary, aggregate, terminal, axillary, or lateral.

SETA'CEUM. (*um*. *i*. n.; from *seta*, a bristle: because horse-hairs were first used to keep open the wound.) See *Seton*.

SETA'CEOUS. *Setaceus*. Bristly. Applied to various parts of plants; as the petals of *Tropæolum majus*.

SETIFO'RMIS. Setiform: bristly. Applied to parts of plants; as the nectary of the *Periploca græca*.

SE'TON. *Setaceum*. An artificial sinus made under the skin by means of an instrument called the seton-needle, which carries with it a portion of thread or silk, a portion of which is drawn through daily, and thus keeps up a constant irritation.

SETO'SUS. Setose: bristly. Applied to parts of plants; as the receptacle of the *Echinops sphærocephalus*, and of *Centaurea*.

Setterwort. See *Helleborus fœtidus*.

SE'VUM. Suet. The fat of the omentum. That of the sheep and ox is in common use for various purposes.

Sevum ceti. See *Physeter macrocephalus*.

SEVUM OVILE. *Sevum ovillum*. Mutton suet.

SEXUAL. *Sexualis*. Appertaining to the sexes.

SEXUAL ACTIONS. Sexual functions. Those functions proper to each sex, by which the species is propagated; as the excretion of semen in men; menstruation, conception, the evolution of the fœtus, parturition, &c., in women.

Sexual organs. See *Generation, organs of, Stamen*, and *Pistillum*.

Sexual system of plants. This system, invented by the immortal Linnæus, is founded on the parts of fructification. See *Vegetable Kingdom*.

Seydschutz. See *Sedlitz*.

SHADDOCK. So named after the captain who first brought it into the West Indies from China. The fruit of the *Citrus decumana*. It is very large. It is inferior in flavour to the orange, but keeps longer, and is hence an useful fruit at sea on long voyages.

Shaft. See *Stylus*.

Shaggy. See *Hirsutus*, and *Chorion*.

Shaking palsy. See *Synclonus agitans*.

SHALLOT. Eschalotte. The *Allium ascalonicum*, of Linnæus; an useful esculent root, possessing all the virtues of garlic, with less pungency.

Sharp-pointed dock. See *Rumex acutus*.

Sheath. See *Vagina*, and *Spatha*.

Sheathing. See *Vaginans*.

Shedding. See *Caducus*.

Shedding-teeth. See *Teeth*.

SHELL. The hard covering or external skeleton of testaceous and crustaceous animals, and of insects. The shells of the *testaceous mollusca* consist of carbonate of lime and animal matter; those of the *crustacea* of a mixture of carbonate and phosphate of lime, with animal matter.

SHERBET. (An Arabic word.) A cooling summer drink, prepared with the juice of fruits and water variously sweetened and flavoured. Sherbets are much used in the East.

Shield-laver. See *Ulva umbilicalis*.

Shingles. (Probably a corruption of the Latin *Cingulum*, a girdle.) See *Herpes*.

Shoot. See *Surculus*.

Short-sightedness. See *Myopia*.

Shrimp. See *Cancer crangon*.

SHRUB. 1. A low bushy tree. See *Frutex*.

2. A liquor, consisting of acid fruits, sugar, and various substances to give flavour, digested in rum or brandy.

Shrubby. See *Fruticosus*.

SI'AGON. Σιαγων. The jaw.

Siago'nagra. (From σιαγων, the jaw, and αγρα, a seizure.) The gout in the jaw.

SIA'LAGOGUE. (*Sialago'gus*; from σιαλον, saliva, and αγω, to expel.) Medicines are so called which excite an uncommon flow of saliva: such are mercurial preparations, pyrethrum, &c. They are divided into *sialagoga topica*, as scilla, nicotiana, piper, &c.; and *sialagoga interna*, as the various preparations of mercury.

SI'BBENS. *Sivvens.* A disease which is endemic in some of the western counties of Scotland. It strikingly resembles the yaws in many respects, but entirely differs in others. It is propagated, like syphilis, by the direct application of contagious matter. This disease has not yet been thoroughly investigated.

Si'ccans. (From *sicco*, to dry.) Having a drying property: applied to medicines.

Siccha'sia. (Σικχασια; from σικχος, weak, weary.) The lassitude, debility, and anorexia, peculiar to women with child.

SICKNESS. 1. A disease of any kind: in which sense, however, the word is little used in the present day.

2. A particular state of the stomach, which occurs under three forms, — nausea, retching, and vomiting.

Nausea is a tendency to vomit, but there is no rejection. It depends on a disposition in the peristaltic motion of the bowels and stomach to become inverted: if the inversion take place, *retching* and *vomiting* result; but if it do not, the effect is merely a nausea. These affections may exist separately; for the cause may be of a kind or strength sufficient to throw the stomach at once into a state of violent inversion, and, consequently, to produce vomiting without the intermediate changes. It is nevertheless curious, and of great importance, to observe the different and opposite effects produced on the animal frame by these stages of one and the same thing. Nausea lowers the pulse, contracts the small vessels, occasions cold perspiration, severe rigors, and trembling, and diminishes, as long as it lasts, the actions, and even the general powers of life. The act of retching, and vomiting, more especially, on the contrary, rouses rather than depresses, puts to flight all the preceding symptoms, and often restores the system to itself.

Nausea and vomiting are sometimes idiopathic affections, but more frequently symptomatic and sympathetic: hence they occur in colic, cholera, in the accession of fevers, repelled gout, many affections of the head.

From such a variety of causes, it is but natural to conclude the remedies must be very various. The sympathetic and symptomatic affections require the removal of the primary disease. The best palliatives against all nausea and vomiting are carbonic acid gas, in form of an effervescing saline draught, and small doses of opium. Lemon ice, or very cold lemonade, is often serviceable, and more especially if made with a strong infusion of the *Mentha viridis*.

Sickness, country. See *Nostalgia*.

Sickness, home. See *Nostalgia*.

Sickness, love. See *Pathemata animi*.

Si'cula. (Diminutive of *sica*, a short sword: so called from its dagger-like root.) The beet.

Sicye'don. (From σικυος, a cucumber.) A transverse fracture, like a cucumber broken in two parts.

Sicyo'ne. (From σικυος, a cucumber or gourd: so named from its resemblance to a gourd.) A cucurbit.

SI'DA. A genus of malvaceous plants.

Sida abu'tilon. This plant is mentioned by Avicenna. It is mucilaginous.

SIDERA'TIO. (*o, onis.* f.; from *sidus*, a planet: because it was thought to be produced by the influence of the planets.) An apoplexy. A palsy. A slight erysipelas.

Siderum. A name given by Bergman to phosphuret of iron, which he first examined, and believed to be a new metal.

SIGESBE'CKIA. (*a, æ.* f.; so named by Linnæus in memory of his antagonist, Dr. J. G. Sigesbeck, Superintendent of the Physic Garden at Petersburg, who raised various objections against the sexes of plants.) The name

of a genus of plants. Class, *Syngenesia*; Order, *Polygamia superflua*.

Sigesbeckia orientalis. The systematic name of a plant which is said to be useful in removing strangury, and in calculous diseases, gout, and fluor albus.

Sight. See *Vision*.

Sight by day. See *Hemeralopia*.

Sight by night. See *Nyctalopia*.

Sight, dimness of. See *Caligo*.

Sight, lateral. See *Dysopia*.

SIGILLA'TUS. Sealed: applied formerly to several earths, which were formed into little cakes and stamped or sealed, and were called *terræ sigillatæ*.

SIGI'LLUM. (*um, i.* n.; diminutive of *signum*, a sign.) A seal or image.

Sigillum beatæ mariæ. An old name of black briony, or *Tamus communis*.

Sigillum hermeticum. See *Hermetic seal*.

Sigillum solomonis. (Called *sigillum*, because there is the resemblance of an impression on the root.) See *Convallaria polygonatum*.

SI'GMOID. (*Sigmoides*; from the Greek letter Σ, *sigma*, and εἶδος, a likeness.) Resembling the Greek letter sigma. Applied to several parts; as the valves of the heart, the cartilages of the trachea, the semilunar cavities of the bones, and the flexure of the colon.

Sigmoid flexure. See *Intestine*.

Sigmoid valves. The semilunar valves of the aorta and pulmonary artery.

Signa critica. See *Crisis*.

Signa diagnostica. See *Diagnosis*.

SI'GNUM. A sign: the symptom of a disease. See *Semeiotice*.

Siler. See *Laserpitium siler*.

Silex. (*ex, icis.* m. and f.; from χαλιξ.) Flint. See *Silica*.

SI'LICA. (*a, æ.* f.; from *silex*, flint.) One of the primitive earths, and the principal constituent part of the silex or flint, and of a very great number of the compound earths and stones forming the immense mass of the solid nucleus of the globe. It is the basis of almost all the scintillating stones, such as *flint, rock crystal, quartz, agate, calcedony, jasper*, &c. The sand of rivers, and of the sea-shore, chiefly consist of it. It is deposited in vegetable substances, forming petrified wood, &c. It is likewise precipitated from certain springs in a stalactitic form. It has been discovered in several waters in a state of solution, and is found in many plants, particularly grasses and equisetums. A good method of obtaining silica exceedingly pure, is to separate it from fluoric acid.

The only acid that dissolves silica is the hydrofluoric. See *Fluosilicic acid*. Silica is soluble in alkaline solutions, and combines with many of the metallic oxides; hence it is regarded by some chemists as an acid, and called *Silicic acid*.

In consequence of Sir H. Davy's researches on the metallic bases of the alkalis and earths, this earth has been recently regarded as a compound of a peculiar combustible principle with oxygen. If we ignite powdered quartz with three parts of pure potash in a silver crucible, dissolve the fused compound in water, add to the solution a quantity of acid, sufficient to saturate the alkali, and evaporate to dryness, we shall obtain a fine gritty powder, which, being well washed with hot water, and ignited, will leave pure silica. By passing the vapour of potassium over silica in an ignited tube, Sir H. Davy obtained a dark-coloured powder, which he supposed to contain *silicium*, or the basis of the earth. This has since been obtained in a pure state by Berzelius, who places it among the simple nonmetallic combustibles. It appears to have a great analogy to boron.

Si'licate. (*Silicas, atis.* f.) A compound of the silicic acid, with a base. See *Silica*.

Sili'cium. The base of silica. See *Silica*.

SILI'CULA. (*a, æ.* f.; a diminutive of *siliqua*.) A pouch, or pod, that is scarcely longer than broad. It is,

1. *Orbiculate*, in *Thlaspi arvense*.
2. *Cordate*, in *Isatis Armena*.
3. *Obcordate*, in *Thlaspi bursa pastoris, alpestre*, and *Myagrum perfoliatum*.
4. *Lanceolate*, in *Lepidium alpinum*, and *Isatis tinctoria*.
5. *Angulate*, in *Myagrum Ægyptiacum*.
6. *Emarginate*, in *Cochlearia*.
7. *Drupaceous*, if the membrane is double, soft externally, and hard within; as in *Erucago*, and *Bunias*.

SILICULO'SA. The name of the first order of the class *Tetradynamia*, of the Linnæan system of plants, containing such as have a broad short pod.

SI'LIQUA. (*a, æ.* f.; from *silo*, one who has a turned up nose.) A long, dry, membranaceous pericarpium, pod, or seed-vessel, of two valves, separated by a linear receptacle, along the edges of each of which the seeds are arranged alternately. The dissepiment is a partition dividing a siliqua and silicula into two loculaments, or cells. Botanists distinguish a pod into,

1. *Round*; as in *Fumaria lutea*.
2. *Compressed*, with levelled valves; as in *Cheiranthus annuus*.
3. *Four-edged*; as in *Erysimum, Cheiranthus erysimoides*, and *Brassica orientalis*.
4. *Articulate*, in *Raphanus raphanistrum*.
5. *Tortulose*, which has elevated nodes here and there; as in *Raphanas sativus*.
6. *Rostrate*, having the partition very prominent at the apex; as in *Sinapis alba*.

Siliqua dulcis. See *Ceratonia siliqua*.

Siliqua hirsuta. See *Dolichos pruriens*.

Siliqua'strum. (From *siliqua*, a pod: named from its pods.) Judas-tree. The capsicum, or Guinea pepper, was so termed by Pliny. See *Capsicum*.

SILIQUO'SA. The name of the second order of the class *Tetradynamia*, of the Linnæan system of plants, containing such as have long pods.

Siliquo'sæ. The name of an order in Linnæus's Fragments of a Natural Method, consisting of such as have a siliqua or silicula, the flower tetradynamic and cruciate.

Siliquosa indica. An American plant. Its juice is said to be alexipharmic.

SILIQUO'SUS. (From *siliqua*, a pod.) Having pods.

Silk-worm, acid of. See *Bombic acid.*

SI'LPHIUM. (*Zalaph*, Arabian.) Asafœtida, or the plant which affords it.

Silver. See *Argentum.*

Silver, nitrate of. See *Argenti nitras.*

Silver-weed. See *Potentilla.*

SIMAROU'BA. (*a*, *æ*. f.) The name of a genus of plants. Class, *Decandria*; Order, *Monogynia.*

SIMAROUBA OFFICINALIS. *Quassia simarouba.* Mountain damson. The tree which yields the simarouba bark. It is a native of Carolina, the West Indies, and South America. The medicinal part is the bark of the root; the wood, though enumerated in the Materia Medica of the Dublin college, is entirely inert. It is tonic, and contains a peculiar bitter principle named *quassina.* The dose of the powder is from ℈j. to ʒ ss.; that of the infusion one to two ounces. See *Infusum simaroubæ.*

Simiæ lapis. See *Bezoar simiæ.*

Simple affinity. See *Affinity, simple.*

Simple elective attraction. See *Affinity, simple.*

Simple leaf. See *Leaf.*

Simple substance. See *Body.*

Sinape. See *Sinapis nigra.*

SINAPELÆ'UM. (*um*, *i*. n.; from σιναπι, mustard, and ελαιον, oil.) Oil of mustard.

Sinapi. See *Sinapis nigra.*

SINA'PIS. (*is*, *is*. f., and *e*, *is*. n., and *i*. n. indeclinable: so called because, σινει ωπας, it hurts the eyes.) 1. The name of a genus of plants in the Linnæan system. Class, *Tetradynamia*; Order, *Siliquosa.* Mustard.

2. The pharmacopœial name of the black mustard. See *Sinapis nigra.*

SINAPIS ALBA. The systematic name of the white mustard plant, which is directed for medicinal use in the Edinburgh Pharmacopœia. It is somewhat less pungent than the black species. Its activity seems to depend on a crystalline matter, which contains sulphur, and has been named sulpho-sinapisine by Henri and Garot, and *sinapine* by Berzelius. See *Sinapis nigra.*

SINAPIS NIGRA. The systematic name of the common black mustard: called also *Napus*, *Eruca*, *Sinape*, and *Sinapi.*

Sinapis — siliquis glabris racemo oppressis, of Linnæus. The seeds of this species of mustard, which are directed by the London College, and those of the *Sinapis alba*, which are preferred by that of Edinburgh, manifest no remarkable difference to the taste, nor in their effects, and, therefore, answer equally well for medicinal and culinary purposes. They have an acrid, pungent taste, and, when bruised, this pungency shows its volatility by powerfully affecting the organs of smell. The active principle of the black mustard is believed to reside in a volatile oil. Mustard is considered as capable of promoting appetite, assisting digestion, attenuating viscid juices, and, by stimulating the fibres, it proves a general remedy in paralytic affections. Joined to its stimulant qualities, it frequently, if taken in considerable quantity, opens the body, and increases the urinary discharge; and hence it has been found useful in dropsical complaints. Externally, flour of mustard is frequently used, mixed with vinegar, as a stimulant or sinapism.

SINAPI'SMUS. (*us*, *i*. m.; from *sinapis*, of which it is made.) *Sinapismum. Cataplasma sinapeos.* A sinapism, or mustard poultice. A name given to a mixture of mustard and vinegar, in form of poultice, generally applied to the calves of the legs or soles of the feet, as a stimulant, and employed in low states of fevers and other diseases, and intended to supersede the use of a blister. See *Cataplasma sinapis.*

SINA'PIUM. (*um*, *ii*. n.; from σιναπι, mustard.) An infusion or decoction of mustard-seed.

SI'NCIPUT. (*ut*, *itis*. n.) The forepart of the head. See *Caput.*

SI'NE PA'RI. Several muscles, veins, arteries, &c. are so called which are without a fellow. See *Azygos.*

Single elective attraction. See *Affinity.*

SINGU'LTUS. (*us*, *ús*. m.) The hiccough. A convulsive motion of the diaphragm and parts adjacent. The most common cause is some accidental irritation of the stomach from food or wind, and hence it is so common amongst children. It is also produced by the irritation of worms, acidity and bilious condition of the stomach. These excite the diaphragm to a spasmodic contraction, to which it must be predisposed by debility. It is usually removed in children by warm carminatives, and in youths and adults by a little cold water, camphire julep, volatile alkali, or a sudden fright.

It is sometimes, however, very troublesome, and is then mostly a symptomatic or sympathetic affection. In the latter state, it results from gall-stones, hepatic diseases, ulcers of the stomach, and many diseases of the abdominal viscera. Hiccough is one of the nervous symptoms which sometimes becomes habitual, and will not yield to remedies. An instance occurred, in a delicate young lady, whose digestive organs had been a long time in an ill condition, in which a hiccough continued for ten months, very strong and agitating during the day, but more passive during the night. During the whole of this period, there were seldom more than three hours' uninterupted sleep in the night; and the debility soon became so great as to oblige her to keep in bed. No medicines nor topical applications did any good. When opiates produced sleep, the disease returned on waking. She was at last cured by a fright. Many similar cases are on record.

SINUA'TUS. Sinuated: indented. Applied to leaves which are cut into rounded or wide openings, deeply scolloped, as it were, the lobes standing asunder, as if part of the leaf had been cut off; as that of the oak and turnip, and as in *Statice sinuata.*.

SI'NUS. (*us*, *ús*. m.) I. A cavity or depression.

II. In *Surgery*, a long, narrow, hollow track, leading from some abscess, diseased bone, &c.

III. The veins of the dura mater are termed sinuses. They are several in number, the principal of which are, 1. The *longitudinal sinus*, which rises anteriorly from the crista galli,

ascends and passes between the two laminæ of the falciform process to where this process ends. It then opens into, 2. *Two lateral sinuses*, distinguished into right and left, which lie in the crucical spine of the os occipitis. 3. The *inferior longitudinal*, which is a small sinus situated at the acute inferior margin of the falx. 4. The *torcular Herophili*, or fourth sinus. 5. The *cavernous sinuses*.

Sinus coxæ. The acetabulum.

Sinus genæ pituitarius. See *Antrum highmorianum*.

Sinus, lateral. See *Lateral sinuses*.

Sinus, longitudinal. See *Longitudinal sinus*.

Sinus, maxillary. See *Antrum*.

Sinus muliebris. The vagina.

Sinus uteri. Sinuses of the uterus. The large veins contained within the walls of the uterus. During gestation they become immensely enlarged.

Sinus venæ portarum. The entrance into the liver.

Sinus venarum cavarum. The right auricle of the heart.

Sinus venarum pulmonalium. The left auricle of the heart.

Sinuses, frontal. See *Frontis os*.

Sinuses, vertebral. The two large veins which run the whole length of the spinal canal. See *Spinal cord*.

Siphilis. See *Syphilis*.

Siphita parva. Chorea is thus named by Paracelsus.

Sira. An alchemical name of orpiment.

Sirsa. An eschar.— *Ruland*

SIRI'ASIS. (*is, is.* f.; from *σιρος*, the cavity of the fontanella.) An inflammation of the brain, said to be peculiar to children, and attended with a hollowness of the eyes and depression of the fontanella.

Siricon de plumbo. Oxide of lead. — *Ruland*.

Siringa. Lime. — *Ruland*.

Si'sarum. (From *sisa*, a Hebrew word.) See *Sium sisarum*.

Si'ser. (*er, eris.* m. and n.) See *Sium sisarum*.

SI'SON. (*on, i.* n. *Σισων*. A name adopted by Dioscorides.) The name of a genus of plants. Class, *Pentandria*; Order, *Monogynia*.

Sison ammi. The plant which affords the *ammi verum* of the shops. The seeds of this plant, *Sison — foliis tripinnatis, radicalibus linearibus, caulinis setaceis, stipularibus longioribus*, of Linnæus, have a grateful smell, somewhat like that of origanum, and were formerly administered as a carminative.

SISY'MBRIUM. (*um, ii.* n.; from *σισυβος*, fringed: so named from its fringed roots.) The name of a genus of plants in the Linnæan system. Class, *Tetradynamia*; Order, *Siliquosa*.

Sisymbrium nasturtium. The systematic name of the water-cress: called also, *Nasturtium aquaticum, Laver odoratum, Crateva sium, Cressi*, and *Cardamines*.

This indigenous plant, *Sisymbrium — siliquis declinatis, foliis pinnatis, foliolis subcordatis*, of Linnæus, grows plentifully in brooks and stagnant waters. The leaves have a moderately pungent taste, emit a quick penetrating smell, like that of mustard-seed, but much weaker. Water-cresses obtain a place in the materia medica for their antiscorbutic qualities, which have been long very generally acknowledged by physicians. The most pleasant way of administering them is in form of a salad.

Sisymbrium sophia. The systematic name of the herb sophia: which is also called *Sophia chirurgorum*. It is now almost banished from practice, though formerly in high estimation in the cure of wounds. It has been given internally in hysterical affections and uterine hæmorrhages, and the seeds are said to be efficacious in destroying intestinal worms.

SITIO'LOGY. (*Sitiologia, æ.* f.; from *σιτος*, aliment, and *λογος*, a discourse or treatise.) Synonymous with *diatetics*.

Sitis. (*is, is.* f.) See *Thirst*.

SI'UM. (*um, i.* n.; from *σειω*, to move: from its agitation in water.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia*.

2. The pharmacopœial name of the creeping water parsnip. See *Sium nodiflorum*.

Sium aromaticum. The amomum is sometimes so called.

Sium ninsi. The systematic name of the plant, the root of which is called, *radix ninsi, Ninzin*, and *Nindsin*. This root was long supposed to be the same as ginseng. It now appears, however, to be the produce of this plant. It possesses similar, though weaker properties, than ginseng.

Sium nodiflorum. The systematic name of the creeping water-parsnep: called also, *Berula gallica*. This plant was admitted into the London Pharmacopœia in the character of an antiscorbutic. It is not nauseous, and children take it readily if mixed with milk.

Sium sisarum. The siser or skirret. The root of this plant is eatable, but now out of use, though cultivated in the days of Gerarde and Parkinson. Its flavour is said to be aromatic, with a sweetness not acceptable to every palate, and of a flatulent and indigestible quality.

Skate. See *Raia batis*.

SKELETON. *Sceletos*. When the bones of the body are dried and preserved in their natural situation, and deprived of the flesh, the assemblage is called a skeleton; and the assemblage of all the bones of the animal, when hung in their respective situations by means of wire, is denominated an artificial skeleton, in opposition to a natural one, when the bones are retained in their proper places by means of their natural ligaments. See *Os*.

Skin. See *Cutis*.

Skin, scarf. See *Epidermis*.

Skink. See *Scincus*.

Skirret. See *Sium sisarum*.

Skull. See *Cranium*.

Slavering. See *Drivelling*.

SLEEP. *Somnus*. That state of the body in which the exercise of the external senses is suspended according to a natural law, and independently of any diseased state. The end and design of sleep is both to renew, during the silence and darkness of the night, the vital energy which has been exhausted through the day, and to assist nutrition.

When the time of being awake has continued for sixteen or eighteen hours, we have a general feeling of fatigue and weakness; our motions become more difficult, our senses lose their activity, the mind becomes confused, receives sensations indistinctly, and governs muscular contraction with difficulty. We recognise, by these signs, the necessity of *sleep:* we choose such a position as can be preserved with little effort: we seek obscurity and silence, and sink into the arms of oblivion.

The man who slumbers loses successively the use of his senses. The sight first ceases to act by the closing of the eyelids, the smell becomes dormant only after the taste, the hearing after the smell, and the touch after the hearing; the muscles of the limbs, being relaxed, cease to act before those that support the head; and these before those of the spine. In proportion as these phenomena proceed, the respiration becomes slower and more deep; the circulation diminishes; the blood proceeds in greater quantity to the head; animal heat sinks; the different secretions become less abundant. Man, although plunged in this sopor, has not, however, lost the feeling of his existence: he is conscious of most of the changes that happen in him, and which are not without their charms: ideas, more or less incoherent, succeed each other in his mind: he ceases, finally, to be sensible of existence — he is *asleep.*

During sleep, the circulation and respiration are retarded, as well as the different secretions, and, in consequence, digestion becomes less rapid.

It is not well explained on what foundation many authors say that absorption alone acquires more energy. Since the nutritive functions continue in sleep, it is evident that the brain has ceased to act, only with regard to muscular contraction, and as an organ of intelligence; and that it continues to influence the muscles of respiration, the heart, the arteries, the secretions, and nutrition.

Sleep is *profound* when strong excitants are necessary to arrest it: it is *light* when it ceases easily.

Sleep, such as it has been described, is perfect; that is, it results from the suspension of the action of the relative organs of life, and from the diminution of the action of the nutritive functions; but it is not extraordinary for some of the relative organs of life to preserve their activity during sleep, as it happens when one sleeps standing; it is also frequent for one or more of the senses to remain awake, and transmit the impressions which it perceives to the brain; it is still more common for the brain to take cognisance of different internal sensations that are developed during sleep, as wants, desires, pain, &c. The understanding itself may be in exercise in man during sleep, either in an irregular and incoherent manner, as in most dreams, or in a consequent and regular manner, sometimes more so than in the waking state.

The turn which the ideas assume during sleep, or the nature of dreams, depends much on the state of the organs. If the stomach is overcharged with indigested food, the respiration difficult on account of position, or other causes, dreams are painful, fatiguing; if hunger is felt, the person dreams of eating agreeable food; if it is the venereal appetite, the dreams are erotic, &c. The character of dreams is no less influenced by habitual occupations of the mind: the ambitious dreams of success or disappointments, the poet makes verses, the lover sees his mistress, &c. It is because the judgment is sometimes correctly exercised in dreams, with regard to future events, that in times of ignorance the gift of divination was attributed to them.

Nothing is more curious in the study of sleep than the history of *sleep-walkers.*

Those individuals being first profoundly asleep, rise all at once, dress themselves, see, hear, speak, employ their hands with ease, perform certain exercises, write, compose, then go to bed, and preserve, when they awake, no recollection of what happened to them. What difference is there, then, between a sleep-walker of this kind and a man awake? It must be acknowledged that the ingenuity of physiologists has hitherto been exercised in vain on the solution of this question.

Many hypotheses have been offered on the proximate cause of sleep, as the depression of the laminæ of the cerebrum, the afflux of blood to the brain, &c. Sleep, which is the immediate effect of the laws of organisation, cannot depend on any physical cause of this kind. Its regular return is one of the circumstances that contributes the most to the preservation of health: its suppression, even for a short time, is often attended with serious inconvenience; and in no case can it be carried beyond certain limits.

The ordinary duration of sleep is variable; generally, it is from six to eight hours. Fatigue of the muscular system, strong exertions of the mind, lively and multiplied sensations, prolong it, as well as habits of idleness, the immoderate use of wine, and of too strong aliments. Infancy and youth, whose life of relation is very active, have need of longer repose. Riper age, more frugal of time, and tortured with cares, devote to it but a small portion. Very old people present two opposite modifications: either they are almost always slumbering, or their sleep is very light; but the reason of this latter is not to be found in the foresight they have of their approaching end.

By uninterrupted peaceable sleep, restrained within proper limits, the powers are restored, and the organs recover the facility of action; but if sleep is troubled by disagreeable dreams, and painful impressions, or even prolonged beyond measure, very far from repairing, it exhausts the strength, fatigues the organs, and sometimes becomes the occasion of serious diseases, as idiotism and madness.

Sleeplessness. See *Agrypnia.*

Sloe. See *Prunus sylvestris.*

Smallage. See *Apium graveolens.*

Small-pox. See *Variola.*

Smalt. See *Zaffre.*

SMARAGDINUS. Smaragdine: of an emerald colour. Applied generally, in *Natural History,* to designate a pure green colour.

SMELL. *Olfactus.* There escapes from

almost every body in nature certain particles of an extreme tenuity, which are carried by the air often to a great distance. These particles constitute odours. There is one sense destined to perceive and appreciate them. Thus an important relation between animals and surrounding bodies is established.

All bodies of which the atoms are fixed are called inodorous.

The difference of bodies is very great, relative to the manner in which odours are developed. Some permit them to escape only when they are heated; others only when rubbed. Some, again, produce very weak odours, whilst others produce only those which are highly powerful. Such is the extreme tenuity of odoriferous particles, that a body may produce them for a very long time without losing weight in any sensible degree.

Every odoriferous body has an odour peculiar to itself.

As these bodies are very numerous, there have been attempts made to class them, which, however, have all failed.

Odours can be distinguished only into weak and strong, agreeable and disagreeable. We can recognise odours which are musky, aromatic, fœtid, rancid, spermatic, pungent, muriatic, &c. Some are fugitive, others tenacious. In most cases an odour cannot be distinguished but by comparing it with some known body. There have been attributed to odours properties which are nourishing, medical, and even venomous; but, in the cases which have given rise to these opinions, might not the influence of odours have been confounded with the effects of absorption? A man who pounds jalap for some time will be purged in the same manner as if he had actually swallowed part of it. This ought not to be attributed to the effects of odours, but rather to the particles which, being spread around, float in the air, and are introduced either with the saliva or with the breath. We ought to attribute to the same cause the drunkenness of persons who are exposed for some time to the vapours of spirituous liquors. The air is the only vehicle of odours: it transports them to a distance: they are also produced, however, *in vacuo*, and there are bodies which project odoriferous particles with a certain force. This matter has not yet been carefully studied: it is not known if, in the propagation of odours, there be any thing analogous to the divergence, the convergence, to the reflection, or the refraction of the rays of light. Odours mix or combine with many liquids, as well as solids. This is the means employed to fix or preserve them. Liquids, gases, vapours, as well as many solid bodies reduced to powder, possess the property of acting on the organs of smell.

Apparatus for smelling. — The olfactory apparatus ought to be represented as a sort of sieve, placed in the passage of the air, as it is introduced into the chest, and intended to stop every foreign body that may be mixed with the air, particularly the odours.

This apparatus is extremely simple: it differs essentially from that of the sight and the hearing, since it presents no part anterior to the nerve destined for the physical modification of the external impulse: the nerve is to a certain degree exposed. The apparatus is composed of the pituitary membrane, which covers the nasal cavities of the membrane which covers the *sinuses*, and of the olfactory nerve.

The pituitary membrane covers the whole extent of the nostrils, increases the thickness of the spongy bones very much, is continued beyond their edges and their extremities, so that the air cannot traverse the nostrils but in a long narrow direction. This membrane is thick, and adheres strongly to the bones and cartilages that it covers. Its surface presents an infinity of small projections, which have been considered by some as nervous *papillæ*, by others as mucous follicles, but which, according to all appearance, are vascular.

These small projections give to the membrane an appearance of velvet. The pituitary is agreeable and soft to the touch, and it receives a great number of vessels and nerves. The passages through which the air proceeds to arrive at the *fauces* deserve attention.

These are three in number. They are distinguished in anatomy by the names of inferior, middle, and superior passages. The inferior is the broadest and the longest, the least oblique and least crooked; the middle one is the narrowest, almost as long, but of greater extent from top to bottom. The superior is much shorter, more oblique, and narrower. It is necessary to add to these the interval, which is very narrow, and which separates the partition of the external side of the nostrils in its whole extent. These canals are so narrow, that the least swelling of the pituitary renders the passage of the air in the nostrils difficult, and sometimes impossible.

The two superior passages communicate with certain cavities, of dimensions more or less considerable, which are hollowed out of the bones of the head, and are called *sinuses*. These *sinuses* are the *maxillary*, the *palatine*, the *sphenoidal*, the *frontal*, and those which are hollowed out of the *ethmoid bone*, better known by the name of the ethmoidal cells.

The *sinuses* communicate only with the two superior *meatus*, or passages.

The *frontal*, the *maxillary sinus*, the anterior cells of the *ethmoid bone*, open into the middle *meatus*; the *sphenoidal*, the *palatine sinus*, the posterior cells of the *ethmoid*, open into the superior *meatus*. The *sinuses* are covered by other soft membranes, very little adherent to the sides, and which appear to be of the mucous kind. It secretes more or less abundantly a matter called *nasal mucus*, which is continually spread over the pituitary, and seems very useful in smelling. A more considerable extent of the *sinus* appears to coincide with a greater perfection of the smell. This is, at least, one of the most positive results of comparative physiology.

The olfactory nerve springs, by three distinct roots, from the posterior, inferior, and internal parts of the anterior lobe of the brain. Prismatic at first, it proceeds towards the per-

forated plate of the *ethmoid bone*. It swells all at once, and then divides itself into a great number of small threads, which spread themselves upon the *pituitary* membrane, principally on the superior part of it.

It is important to remark, that the filaments of the olfactory nerves have never been traced upon the inferior *spongy bones*, upon the internal surface of the middle *meatus*, nor in any of the *sinuses*. The *pituitary* membrane receives not only the nerves of the first pair, but also a great number of threads, which spring from the internal aspect of the *spheno-palatine ganglion*. These threads are distributed in the *meatus*, and in the inferior part of the membrane. It covers, also, for a considerable length, the ethmoidal thread of the nasal nerve, and receives from it a considerable number of filaments. The membrane which covers the sinus receives also a number of nervous ramifications.

The *nasal fossæ* communicate outwardly by means of the nostrils, the form and size of which are very variable. The nostrils are covered with hair on the inside, and are capable of being increased in size by muscular action. The nasal fossæ open into the *pharynx* by the posterior nostrils.

Mechanism of Smelling. — Smell is exerted essentially at the moment when the air traverses the nasal fossæ in proceeding towards the lungs. We very rarely perceive any odour when the air proceeds from the lungs; it happens sometimes, however, particularly in organic diseases of the lungs.

The mechanism of smell is extremely simple. It is only necessary that the odoriferous particles should be stopped upon the pituitary membrane, particularly in the places where it receives the threads of the olfactory nerves.

As it is exactly in the superior part of the nasal fossæ, where the extremes are so narrow, that they are covered with mucus, it is also natural that the particles should stop there.

We may conceive the utility of mucus. Its physical properties are such, that it appears to have a much greater affinity with the odoriferous particles than with air: it is also extremely important to the olfactory sense, that the *nasal mucus* should always preserve the same physical properties. Whenever they are changed, as it is observed in different degrees of *coryza*, the smell is either not exerted at all, or in a a very imperfect manner.

After what has been said of the distribution of the olfactory nerves, it is evident that the odours that reach the upper part of the nasal cavities will be perceived with greater facility and acuteness: for this reason, when we wish to feel more acutely, and with greater exactness, the odour of any body, we modify the air in such a manner that it may be directed towards this point. For the same reason, those who take snuff endeavour also to make it reach the upper part of the nasal fossæ. The internal face of the *ossa spongiosa* appears well disposed to stop the odours at the instant the air passes. And, as there is an extreme sensibility in this point, we are inclined to believe that here the smell is exerted, though the filaments of the first pair have not been traced so far.

Physiologists have not yet determnied the use of the external nose in smelling: it appears intended to direct the air charged with odours towards the superior part of the *nasal cavities*.

Those persons who have their noses deformed, particularly if broken, — those who have small nostrils directed forward, have in general almost no smell. The loss of the nose, either by sickness or accident, causes almost entirely the loss of smell. Such people recover the benefit of this sense by the use of an artificial nose.

The only use of the sinuses which is generally admitted, is that of furnishing the greater part of the nasal mucus. The other uses which are attributed to them are, to serve as a depôt to the air charged with odoriferous particles, to augment the extent of the surface which is sensible to odours, and to receive a portion of the air that we inspire for the purpose of putting the power of smell in action, &c. These are far from being certain.

Vapours and gases appear to act in the same manner upon the pituitary membrane as odours. The mechanism of it ought, however, to be a little different. Bodies reduced to a coarse powder have a very strong action on this membrane; even their first contact is painful; but habit changes the pain into pleasure, as is seen in the case of taking snuff. In medicine, this property of the pituitary membrane is employed for the purpose of exciting a sharp instantaneous pain.

In the history of smell, the use of those hairs with which the nostrils and the nasal fossæ are provided, must not be forgotten. Perhaps they are intended to prevent the entrance of foreign bodies along with the air into the nasal fossæ. In this case, they would bear a strong analogy to the eyelashes, and the hairs with which the ear is provided.

It is generally agreed that the olfactory nerve is especially employed in transmitting to the brain the impressions produced by odoriferous bodies; but there is nothing to prove that the other nerves, which are placed upon the pituitary membrane, as well as those near it, may not concur in the same function. — *Magendie's Physiology*.

Smellome's eye salve. This consists of half a drachm of verdigris, finely powdered, and rubbed with oil, and then mixed with an ounce of yellow basilicon.

Smelt. See *Salmo eperlanus*.

Smi'lacine. An alkaline principle detected by Folchi in the root of the *smilax sarsaparilla*.

SMI'LAX. (*ax, acis*. f.; from σμιλευω, to cut: so called from the roughness of its leaves and stalk.) The name of a genus of plants in the Linnæan system. Class, *Diœcia*; Order, *Octandria*. Rough bind-weed.

Smilax China. The systematic name of the China root tree. *China. China orientalis. Sankira. Guaquara. Smilax aspera Chinensis*. China root. It was formerly in esteem, as sarsaparilla now is, in the cure of the venereal disease, and cutaneous disorders.

Smilax, Chinese. See *Smilax china*.

Smilax sarsaparilla. The systematic name of the plant which affords the sarsaparilla. *Sarsaparilla. Smilax aspera Peruviana. Sarsa. Carivillandi. Iva pecanga. Macapatli. Zarza. Zarzaparilla. Salsaparilla. Zarcaparilla.* The root of this plant, *Smilax — caule aculeato angulato, foliis inermibus ovatis retuso mucronatis trinerviis*, of Linnæus, has a farinaceous, somewhat bitter taste, and no smell. Pallotta has found in the root of sarsaparilla an alkaline principle, which he has named parilline: the same substance has been named *smilacine* by Folchi, and *parillinic acid* by Bakta. Besides this substance, sarsaparilla root contains, according to the analysis of Thubeuf, colouring matter, resin, starch, lignin, fixed oil, wax, muriate of potash, and nitrate of potash. It is very doubtful whether the parilline is the active principle of the drug. About two centuries ago it was introduced into Spain, as an undoubted specific in syphilitic disorders; but, owing to difference of climate, or other causes, it has not answered the character which it had acquired in the Spanish West Indies. It is now considered as capable of improving the general habit of body, after it has been reduced by the continued use of mercury.

To refute the opinion that sarsaparilla possesses antisyphilitic virtues, Mr. Pearson, of the Lock Hospital, divides the subject into two distinct questions. 1. Is the sarsaparilla root, when given alone, to be safely relied on in the treatment of lues venerea? The late Mr. Bloomfield, his predecessor, and during some years his colleague, at the Lock Hospital, has given a very decided answer to this question: — "I solemnly declare," says he, "I never saw a single instance in my life where it cured that disorder without the assistance of mercury, either at the same time with it, or when it had been previously taken before the decoction was directed." Pearson's experience, during many years, coincides entirely with the observations of Bloomfield. He has employed the sarsaparilla, in powder, and in decoctions, in an almost infinite variety of cases, and feels himself fully authorised to assert, that this plant has not the power of curing any one form of the lues venerea. The sarsaparilla, indeed, like the guaiacum, is capable of alleviating symptoms derived from the venereal virus; and it sometimes manifests the power of suspending, for a time, the destructive ravages of that contagion: but where the poison has not been previously subdued by mercury, the symptoms will quickly return; and, in addition to them, we often see the most indubitable proofs that the disease is making an actual progress, during the regular administration of the vegetable remedy.

2. When the sarsaparilla root is given in conjunction with mercury, does it render the mercurial course more certain and efficacious? In replying to this query, it is necessary to observe that the phrase, "to increase the efficacy of mercury," may imply, that a smaller quantity of this mineral antidote will confer security on an infected person, when sarsaparilla is added to it; or it may mean, that mercury would be sometimes unequal to the cure, without the aid of sarsaparilla. If a decoction of this root did indeed possess so admirable a quality, that the quantity of mercury necessary to effect a cure might be safely reduced whenever it was given during a mercurial course, it would form a most valuable addition to our Materia Medica. This opinion has been, however, unfortunately falsified by the most ample experience; and whoever shall be so unwary as to act upon such a presumption, will be sure to find his own and his patient's expectations egregiously disappointed.

If the sarsaparilla root be a genuine antidote against the syphilitic virus, it ought to cure the disease when administered alone; but, if no direct proof can be adduced of its being equal to this, any arguments founded on histories where mercury has been previously given, or where both the medicines were administered at the same tine, must be ambiguous and undecisive.

It appears probable that Sir William Fordyce, and some other persons, entertained a notion, that there were certain venereal symptoms which commonly resisted the potency of mercury, and that the sarsaparilla was an appropriate remedy in these cases. This opinion, it is presumed, is not correct, for it militates against all Mr. P. has ever observed of the progress and treatment of the lues venerea. Indeed, those patients who have lately used a full course of mercury, often complain of nocturnal pains in their limbs; they are sometimes afflicted with painful enlargements of the elbow and knee joints; or they have membraneous nodes, cutaneous exulcerations, and certain other symptoms, resembling those which are the offspring of the venereal virus.

It may and does often happen, that appearances like these are mistaken for a true venereal affection, and, in consequence of this error, mercury is administered, which never fails to exasperate the disease. Now, if a strong decoction of sarsaparilla root be given to persons under these circumstances, it will seldom fail of producing the most beneficial effects: hence it has been contended, that symptoms derived from the contagion of lues venerea, which could not be cured by mercury, have finally yielded to this vegetable remedy. It must be acknowledged, that representations of this kind have a specious and imposing air; nevertheless, Mr. Pearson endeavours to prove, that they are neither exact nor conclusive. If any of the above-named symptoms should appear near the conclusion of a course of mercury, when that medicine was operating powerfully on the whole system, it would be a strange and inexplicable thing if they could possibly be derived immediately from the uncontrolled agency of the venereal virus.

This would imply something like a palpable contradiction, that the antidote should be operating with sufficient efficacy to cure the venereal symptoms, for which it was directed; while, at the same time, the venereal virus was proceeding to contaminate new parts, and to excite a new order of appearances.

One source, and a very common one, to which some of the mistakes committed upon

this subject may be traced, is a persuasion that every morbid alteration which arises in an infected person is actually tainted with the venereal virus, and ought to be ascribed to it as its true cause.

Every experienced surgeon must, however, be aware, that very little of truth and reality exists in a representation of this kind. The contagious matter and the mineral specific may jointly produce, in certain habits of body, a new series of symptoms, which, strictly speaking, are not venereal, which cannot be cured by mercury, and which are sometimes more to be dreaded than the simple and natural effects of the venereal virus.

Some of the most formidable of these appearances may be sometimes removed by sarsaparilla, the venereal virus still remaining in the system; and, when the force of that poison has been completely subdued by mercury, the same vegetable is also capable of freeing the patient from what may be called the sequelæ of a mercurial course. For a different view of this subject, see the *Supplement*.

The root of the sarsaparilla is sometimes employed in rheumatic affections, scrofula, and cutaneous complaints, where an acrimony of the fluids prevails.

SME'GMA. (*a, atis.* n. σμηγμα, from σμεω, to cleanse.) 1. Any thing used to cleanse the skin; as soap.

2. The matter secreted by the sebaceous follicles of the skin.

Smilacine. See the *Supplement*.

SMI'LE. Σμιλη. A curved bistoury sharp on both edges.

SMY'RNA. Σμυρνα. Myrrh.

Smyrnion hortense. See *Imperatoria ostruthium*.

SMY'RNIUM. (*um, ii.* n.; so called from σμυρνα, myrrh, the smell of the seed resembling that of myrrh very much.) The name of a genus of plants. Class, *Pentandria*; Order, *Digynia*.

SMYRNIUM OLUSA'TRUM. The plant called Alexanders; also denominated, *Hipposelinum, Macerona, Macedonisium, Herba Alexandrina, Grietum*, and *Agrioselinum*. This plant was formerly cultivated in our gardens, for culinary use, but is now superseded by celery. The seeds are bitter and aromatic, and the roots are more powerfully bitter. They stand recommended as resolvents, diuretics, and emmenagogues, though seldom ordered in medical prescriptions.

SMYRNIUM ROTUNDIFOLIUM. The blanched leaves of this species are said to be more agreeable than those of the olusatrum.

Snail. See *Helix*, in the *Supplement*.

Snail-seeded glasswort. See *Salsola kali*.

Snake, rattle. See *Crotalus*.

Snake-killing birthwort. See *Aristolochia anguicida*.

Snakeroot. See *Aristolochia serpentaria*, and *Polygala senega*.

Snakeweed. See *Polygonum bistorta*.

Snakewood. See *Colubrinum lignum*.

Snap-dragon. See *Antirrhinum*.

SNEEZEWORT. (So called, because the dried flowers and roots, when powdered, cause sneezing when applied to the nose.) See *Achillea ptarmica*.

SNEEZING. *Sternutatio.* A convulsive action of the muscles of the chest, arising commonly from irritation of the nostrils. It very seldom requires medical assistance. It sometimes, however, is otherwise; and cases are recorded in foreign, and particularly German works, of its having been sometimes both permanent and violent: sometimes periodical and fatal. The *Ephemerides Naturæ Curiosorum* contain one instance in which the sneezings continued for three hundred times in a single paroxysm. The most common cause of sneezing is irritation of the Schneiderian membrane from snuff, or some sharp or acrimonious gas, or some secretion from the membrane itself, as the mucus of catarrh, measles, &c. But the severest cases are usually produced by sympathy with some remote part; as the lungs, and stomach.

Sneezing, produced in the ordinary way, though convulsive, is a natural and healthy action, intended to throw off instinctively, from the delicate membrane of the nostrils, whatever irritable or offensive material may chance to be lodged there. When sneezing is frequently repeated, the nostrils should be syringed with warm water; and, if this be insufficient, a thin mucilage of acacia gum may be passed up with a pencil brush, or pellets of lint: solutions of opium are also proper; the smelling at opium and camphire, &c.

Snipe. See *Scolopax gallinago*.

Snoring. See *Stertor*.

Soap. See *Sapo*.

Soap-berry. See *Saponaria officinalis*.

Soap-wort. See *Saponaria*.

SO'DA. (*a, æ.* f.; an Arabic word.) The name now universally given to the mineral alkali.

This alkali is obtained from several sources, but principally from plants growing on the sea-coast. It occurs in the mineral kingdom, united with sulphuric, muriatic, and boracic acids; it is also found in large quantities in Egypt, combined with carbonic acid. It appears to be deposited in large impure masses, under the surface of the earth, in various countries, from which it is extracted by running waters. Thus it is found, after the spontaneous evaporation of the water, mixed with sand in the bottom of lakes in Hungary; in the neighbourhood of Bilin in Bohemia; and in Switzerland. It occurs also in China, and near Tripoli; in Syria, Egypt, Persia, and India. It frequently oozes out of walls, and crystallises on their surface. Like potash, it is procured by lixiviation from the ashes of burnt plants, but only from those which grow upon the sea-shores. The variety of plants employed for this purpose is very considerable. In Spain, soda is procured from different species of the *Salsola* and *Salicornia*, and the *Batis maritima*. The *Zostera maritima* is burnt in some places on the borders of the Baltic. In this country we burn the various species of *Fuci*, and their alkali is called *kelp*; and in France they burn the *Chenopodium maritimum*. See *Soda impura*.

The alkali thus procured is more or less pure

according to the nature of the particular plant from which it is obtained. The greatest part, however, is a subcarbonate of soda.

To procure pure soda, we must boil a solution of the pure carbonate with half its weight of quicklime, and after subsidence decant the clear ley, and evaporate in a clean iron or silver vessel, till the liquid flows quietly like oil. It must then be poured out on a polished iron plate. It concretes into a hard white cake, which is to be immediately broken in pieces, and put up, while still hot, in a phial, which must be well corked. If the carbonate of soda be somewhat impure, then, after the action of lime, and subsequent concentration of the ley, alkohol must be digested on it, which will dissolve only the caustic pure soda, and leave the heterogeneous salts. By distilling the alkohol in a silver alembic, the alkali may be obtained pure.

This white solid substance is, however, not absolute soda, but a hydrate, consisting of about 100 soda + 28 water; or of nearly 77 + 23, in 100. If a piece of this soda be exposed to the air, it softens and becomes pasty; but it never deliquesces into an oily-looking liquid, as potash does. The soda, in fact, soon becomes drier, because, by absorption of carbonic acid from the air, it passes into an efflorescent carbonate. Soda is distinguishable from potash by sulphuric acid, which forms a very soluble salt with the former, and a sparingly soluble one with the latter; by muriate of platina and tartaric acid, which occasion precipitates with potash salts, but not with those of soda.

The basis of soda is a peculiar metal, called *sodium*, discovered by Sir H. Davy in 1807, a few days after he discovered potassium, which may be procured in exactly the same manner as potassium, by electrical or chemical decomposition of the pure hydrate. A rather higher degree of heat, and greater voltaic power, are required to decompose soda than potash. Sodium resembles potassium in many of its characters. It is as white as silver, possesses great lustre, and is a good conductor of electricity. It enters into fusion at about 200° Fahr., and rises in vapour at a strong red heat. Its specific gravity is, according to Gay Lussac and Thénard, 0·972, at the temperature of 59° F. In the cold, it exercises scarcely any action on dry air, or oxygen. But when heated strongly in oxygen or chlorine, it burns with great brilliancy. When thrown upon water, it effervesces violently, but does not inflame; swims on the surface, gradually diminishes with great agitation, and renders the water a solution of soda. It acts upon most substances in a manner similar to potassium, but with less energy. It tarnishes in the air, but more slowly; and, like potassium, it is best preserved under naphtha.

Sodium forms two distinct combinations with oxygen: one is pure soda, the hydrate of which is above described; the other is the orange oxide of sodium, observed, like the preceding oxide, first by Sir Humphrey Davy in 1807, but of which the true nature was pointed out, in 1810, by Gay Lussac and Thénard.

Pure soda may be formed by burning sodium in a quantity of air, containing no more oxygen than is sufficient for its conversion into this alkali; *i. e.* the metal must be in excess: a strong degree of heat must be employed.

Pure soda, or hydrate of sodium, is of a grey colour; it is a non-conductor of electricity, of a vitreous fracture, and requires a strong red heat for its fusion. When a little water is added to it, there is a violent action between the two bodies; the soda becomes white, crystalline in its appearance, and much more fusible and volatile. It is then the substance commonly called *pure* or *caustic soda*.

The other oxide or peroxide of sodium may be formed by burning sodium in oxygen, in excess. It is of a deep orange colour, very fusible, and a non-conductor of electricity. When acted on by water, it gives off oxygen, and the water becomes a solution of soda. It deflagrates when strongly heated with combustible bodies.

The proportions of oxygen in the hydrate of sodium, and in the orange peroxide of sodium, are easily learned by the action of sodium on water and on oxygen. If a given weight of sodium, in a little glass tube, be thrown by means of the finger under a graduated inverted jar filled with water, the quantity of hydrogen evolved will indicate the quantity of oxygen combined with the metal to form soda; and when sodium is slowly burned in a tray of platina (lined with dry common salt), in oxygen in great excess, from the quantity of oxygen absorbed the composition of the peroxide may be learned. From Sir H. Davy's experiments, compared with those of Gay Lussac and Thénard, it appears that the prime equivalent of sodium is 3·0, and that of dry soda, or protoxide of sodium, 4·0; while the orange oxide or deutoxide is 5·0. The numbers given by Thénard, are for the first, 100 metal + 33·995 oxygen; and for the second, 100 metal + 67·990 oxygen.

Another oxide is described containing less oxygen; it is therefore a suboxide. When sodium is kept for some time in a small quantity of moist air, or when sodium in excess is heated with hydrate of soda, a dark greyish substance is formed, more inflammable than sodium, and which affords hydrogen by its action upon water.

Only one combination of sodium and chlorine is known. This is the important substance, *common salt*. It may be formed directly by combustion, or by decomposing any compound of chlorine by sodium. Sodium has a much stronger attraction for chlorine than for oxygen: and soda, or its hydrate, is decomposed by chlorine, oxygen being expelled from the first, and oxygen and water from the second.

Potassium has a stronger attraction for chlorine than sodium has; and one mode of procuring sodium easily, is by heating together to redness common salt and potassium. There is no known action between sodium and *hydrogen* or *azote*.

Sodium combines readily with *sulphur*, and with *phosphorus*, presenting similar phenomena to those presented by potassium. The sulphurets and phosphurets of sodium agree in their general properties with those of potassium, except that

they are are rather less inflammable. They form, by burning, acidulous compounds of sulphuric and phosphoric acid and soda.

Potassium and sodium combine with great facility, and form peculiar compounds, which differ in their properties, according to the proportions of the constituents. By a small quantity of sodium, potassium is rendered fluid at common temperatures, and its specific gravity is considerably diminished. Eight parts of potassium, and one of sodium, form a compound that swims in naphtha, and that is fluid at the common temperature of the air. Three parts of sodium, and one of potassium, make a compound fluid at common temperatures. A little potassium destroys the ductility of sodium, and renders it very brittle and soft. Since the prime of potassium is to that of sodium as 5 to 3, it will require the former quantity of potassium to eliminate the latter quantity of sodium from the chloride. The attractions of potassium for all substances that have been examined are stronger than those of sodium.

Soda is the basis of common salt, of plate and crown glass, and of all hard soaps.

The compounds of soda used in medicine are the following: —

1. Sodæ acetas
2. —— *biboras.*
3. —— carbonas.
4. —— carbonas exsiccata.
5. —— sesqui carbonas.
6. —— murias.
7. Sodæ phosphas.
8. —— sulphas.
9. —— tartras.
10. —— potassio-tartras.
11. Sapo durus.

Soda, acetate of. See *Sodæ acetas.*

Soda, borate of. See *Sodæ biboras.*

Soda boracicata. Borax.

Soda, carbonate of. See *Sodæ carbonas.*

Soda Hispanica. See *Soda impura.*

Soda Hispanica purificata. See *Sodæ carbonas.*

Soda, hyperoxymuriate of. See *Sodæ chloras.*

Soda impura. Impure soda. *Soda. Barilla. Bariglia. Barillor. Anatron. Natron. Anaton. Nitrum antiquorum. Aphronitrum. Baurach. Sal alkalinus fixus fossilis. Carbonas sodæ impurus. Subcarbonas sodæ impura.* Barilla is the term given, in commerce, to the impure mineral alkali, or imperfect carbonate of soda, imported from Spain and the Levant. It is made by burning to ashes different plants that grow on the sea-shore, chiefly of the genus *Salsola.* Many have referred it to the *Salsola kali*, of Linnæus; but various other plants, on being burned, are found to afford this alkali, and some in a greater proportion than this: these are,

1. The *Salsola sativa. Salsola sonda*, of Lofling. *Kali hispanicum supinum annuum sedi foliis brevibus. Kali d'Alicante.* This grows abundantly on that part of the Spanish coast which is washed by the Mediterranean Sea. This plant is deservedly first enumerated by Professor Murray, as it supplies all the best soda consumed in Europe, which by us is called Spanish or Alicant soda, and by the Spanish merchants Barilla de Alicante.

2. *Salsola soda. Kali majus cochleato semine. Le Salicor.* This species, which grows on the French Mediterranean coast, is much used in Languedoc for the preparation of this salt, which is usually exported to Sicily and Italy.

3. *Salsola tragus* affords an ordinary kind of soda, with which the French frequently mix that made in Languedoc. This adulteration is also practised by the Sicilians, who distinguish the plant by the term salvaggia.

4. *Salicornia herbacea* is common in salt marshes, and on the sea-shore all over Europe. Linnæus prefers the soda obtained from this plant to that of all the others; but, though the quantity of alkali which it yields is very considerable, it is mixed with much common salt.

5. *Salicornia Arabica*, and also the *Mesembryanthemum nodiflorum*, and *Plantago squarrosa.* All these, according to Alpinus, afford this alkali. It has also been procured from several of the fuci, especially *F. vesiculosus*, and distinguished here by the name of kelp. Various other marine plants might also be noticed as yielding an impure soda by combustion; but the principal are confined to the genus salsola, and that of salicornia. The salsola kali, on the authority of Rawolf, is the species from which the salt is usually obtained in eastern countries, which is brought to us in hard porous masses, of a speckled brown colour. Kelp, a still more impure alkali, made in this country by burning various sea-weeds, is sometimes called British barilla. The marine plants collected for the purpose of procuring barilla in this country, are the *Salsola kali, Salicornia europæa, Zostera maritima, Triglochen maritimum, Chenopodium maritimum, Atriplex portulacoides et littoralis, Plantago maritima, Tamarix Gallica, Eryngium maritimum, Sedum telephium, Dipsacus fullonum*, &c. &c.

It is to be regretted that the different kinds of soda which are brought to European markets have not been sufficiently analysed to enable us to ascertain with tolerable certainty the respective value of each; and, indeed, while the practice of adulterating this salt continues, any attempts of this kind are likely to prove fruitless. The best information on this subject is to be had from Jessica, Mascorelle, Cadet, Bolare, and Sestini. In those places where the preparation of soda forms a considerable branch of commerce, as on the coast of the Mediterranean, seeds of the salsola are regularly sown in a proper situation near the sea, which usually shoot above ground in the course of a fortnight. About the time the seeds become ripe, the plants are pulled up by the roots, and exposed in a suitable place to dry, where their seeds are collected; this being done, the plants are tied up in bundles, and burnt in an oven constructed for the purpose, where the ashes are then, while hot, continually stirred with long poles. The saline matter, on becoming cold, forms a hard solid mass, which is broken in pieces of a convenient size for exportation.

According to chemical analysis, the impure sodas of commerce generally contain a portion of vegetable alkali, and neutral salts, as muriate of soda, and sulphate of potash, and not unfrequently some portion of iron is contained in the mass; they are, therefore, to be considered as more or less a compound, and their goodness to be estimated accordingly. The Spanish soda, of the best sort, is in dark-coloured masses,

of a bluish tinge, very ponderous, sonorous, dry to the touch, and externally abounding with small cavities, without any offensive smell, and very salt to the taste; if long exposed to the air it undergoes a degree of spontaneous calcination. The best French soda is also dry, sonorous, brittle, and of a deep blue colour, approaching to black. The soda which is mixed with small stones, which gives out a fœtid smell on solution, and is white, soft, and deliquescent, is of the worst kind.

Soda powders. These are sold as an extemporaneous substitute for soda water, the purposes of which, however, they do not at all answer; since, when dissolved, they form a tartrate, not a carbonate of soda. They are put up in blue and white papers, the former containing half a drachm of carbonate of soda, and the latter twenty-five grains of tartaric acid. These are to be severally dissolved in water, and the solutions mixed and drunk while effervescing. They form a refreshing saline draught.

Soda water. This refreshing drink is formed by dissolving carbonate of soda in water, and super-saturating it with carbonic acid, under pressure. It affords a salutary stimulus to the stomach, and is useful in cases of debility of that organ, accompanied with acidity.

Soda, tartrate of. See *Sodæ potassio-tartras.*

Sodæ acetas. Acetate of soda. A salt formed of a combination of acetic acid with the soda. Its virtues are similar to those of the acetate of potash.

Sodæ biboras. *Sodæ boras.* Biborate of soda. Borate of soda. Borax. The obsolete synonyms are *Chrysocolla, Capistrum auri, Ancinar, Borax-trion, Acestis anucar, Antincar, Tincal, Amphitanc, Baurach, Nitrum factitium, Santerna, Nitrum nativum, Boras sodæ,* and *Subboras sodæ.*

It does not appear that borax was known to the ancients, their chrysocolla being a very different substance, composed of the rust of copper, triturated with urine. The word borax occurs for the first time in the works of Geber.

Borax is found in the East, and likewise in South America.

It is a biborate of soda. It was long purified, and the market supplied by the Venetians and Hollanders, who for a long time kept their processes a secret. Chaptal found, after trying all the processes in the large way, that the simplest method consists in boiling the borax strongly, and for a long time, with water. This solution being filtered, affords by evaporation crystals, which are somewhat foul, but may be purified by repeating the operation.

Purified borax, or biborate of soda, is white, transparent, rather greasy in its fracture, affecting the form of six-sided prisms, terminating in three-sided or six-sided pyramids. Its taste is styptic; it converts syrup of violets to a green; and when exposed to heat, it swells up, boils, loses its water of crystallisation, and becomes converted into a porous, white, opaque mass, commonly called calcined borax. A stronger heat brings it into a state of quiet fusion; but the glassy substance thus afforded, which is transparent, and of a greenish yellow colour, is soluble in water, and effloresces in the air. It requires about eighteen times its weight of water to dissolve it at the temperature of sixty degrees of Fahrenheit; but water at the boiling heat dissolves three times this quantity.

The biborate of soda is rarely used internally in modern practice; and, according to Murray, it does not appear to possess any activity, although it is supposed by some to be in doses of half a drachm or two scruples, diuretic and emmenagogue. It is occasionally given in cardialgia as an antacid. Its solution is in common use as a cooling gargle, in cases of apthæ. It may be used in the proportion of ʒj. to ʒij. to a pint of water. The officinal honey of borax is used in the same cases. See *Mel boracis.*

It is from this salt that the acid of borax is obtained. See *Boracic acid.*

Sodæ bicarbonas. A bicarbonate of soda may be formed by passing a stream of carbonic acid gas through a strong solution of the carbonate of soda. It is ordered in the Dublin Pharmacopœia. In its medicinal qualities it agrees with the sesqui-carbonate. It is made on a large scale in manufactories for the market. It may be prepared by saturating the solution of the preceding salt with carbonic acid gas, and then evaporating with a very gentle heat to dryness, when a white irregular saline mass is obtained. The London Pharmacopœia contains a formula for its preparation. Its constituents are 4 soda, + 5·50 carb. acid, + 1·125 water, = 10·625; or in 100 parts, 37·4 soda, + 52 acid, + 10·6 water.

Sodæ boras. See *Sodæ biboras.*

Sodæ carbonas. Carbonate of soda. Take of impure carbonate of soda, two pounds; distilled water, four pints. Boil the carbonate in the water, and strain the solution while still hot. Lastly, set it aside that crystals may form. This salt is in common use as an antacid in the dose of from grs. x. to ʒss.; combined with the resinous purgatives, it renders their action milder.

Sodæ carbonas exsiccata. Take of carbonate of soda, a pound. Expose it to a proper degree of heat in a vessel until it is dry. Then heat it to redness, and, lastly, rub it to powder. By the above process the carbonate of soda is deprived of its water of crystallisation, and, consequently, of its disposition to effloresce. Hence it can be given in the pill, which the hydrated carbonate cannot.

Sodæ chloras. See the *Supplement.*

Sodæ chlorinatæ liquor. Solution of chlorinated soda. Take of carbonate of soda, a pound; distilled water, forty-eight fluid ounces; chloride of sodium, four ounces; binoxide of manganese, three ounces; sulphuric acid, four ounces. Dissolve the carbonate of soda in two pints of water; then put the chloride of sodium and binoxide of manganese, rubbed to a powder, into a retort; and add to them the sulphuric acid, previously mixed with three fluid ounces of water, and cooled. Heat the mixture, and pass the chlorine first through five fluid ounces of water, and afterwards into the solution of carbonate of soda above directed.

The extrication of chlorine by the action of sulphuric acid upon a mixture of chloride of sodium and binoxide of manganese, has been already explained. In this case it is passed through a small quantity of water, which will combine with any hydrochloric acid that might otherwise pass into the solution of carbonate of soda.

The precise nature of this solution, usually called *Labarraque's soda disinfecting liquid*, has not been determined. When the quantity of chlorine gas liberated from the ingredients here directed is not exceeded, no carbonic acid is expelled from the carbonate of soda, and the compound form may be made to crystallise, and consists of chlorine and carbonate of soda; these crystals when re-dissolved re-produce the disinfecting liquid.

This solution is of a pale yellow colour; its taste is sharp, saline, and astringent; it first reddens and then bleaches turmeric paper. When exposed to the air it gradually evolves chlorine, and crystals of carbonate of soda are formed; its disinfecting property depends upon this gradual escape of the chlorine. — *Phillips.*

Sodæ hydriodas. See *Sodii iodidum.*

Sodæ liquor effervescens. Soda water is directed under this name in the last London Pharmacopœia. See *Soda water.*

Sodæ murias. See *Sodii chloridum.*

Sodæ phosphas. Phosphate of soda. Phosphorated soda. *Alkali minerale phosphoratum*, of Bergman. *Sal perlatum. Sal mirabile perlatum.* A compound of phosphoric acid and soda, obtained by saturating with carbonate of soda, the impure phosphoric acid separated from calcined bones by sulphuric acid, and then filtering the liquor, evaporating, and crystallising. The phosphate of soda is cathartic, and having little taste, has got the name of tasteless purging salt. The dose is from ℥ss. to ℥j.

Sodæ potassio-tartras. *Soda tartarizata.* Potassio-tartrate of soda. Tartarised soda; formerly known by the names of *sal rupellensis, sal polychrestum Seignetti*, and *natron tartarizatum.* Take of subcarbonate of soda, twenty ounces; supertartrate of potash, powdered, two pounds; boiling water, ten pints. Dissolve the subcarbonate of soda in the water, and add gradually the supertartrate of potash: filter the solution through paper, and evaporate it until a pellicle forms upon the surface; then set it by that crystals may form. Having poured away the water, dry these crystals upon bibulous paper. This salt consists of tartaric acid, soda, and potash, the soda only combining with the superabundant acid of the super salt: it is, therefore, a triple salt, and it has been judged by the London College more convenient to express this difference by the adjective *tartarizata*, than to introduce the three words necessary to its description. It possesses mildly cathartic, diuretic, and deobstruent virtues, and is administered in doses from one drachm to an ounce, as a cathartic, and in the dose of twenty to thirty grains in abdominal physconia, and torpidity of the kidneys.

Sodæ sesquicarbonas. *Sodæ carbonas.* Sesquicarbonate of soda. Take of carbonate of soda, seven pounds; distilled water, a gallon. Dissolve the carbonate of soda in the water, and strain; then pass carbonic acid into the solution to saturation, that the salt may subside. Dry this with a gentle heat, wrapped and pressed in cloth. The result of this process is a hydrated sesquicarbonate of soda, consisting, according to Mr. Phillips, of one equivalent and a half of carbonic acid, one of soda, and two of water. This salt is much less soluble in water than the carbonate, its taste is less alkaline and nauseous, and it does not cause a precipitate from a solution of sulphate of magnesia. When exposed to a strong heat, it loses carbonic acid and water, and becomes a dry carbonate. Its general medicinal qualities are the same as those of the carbonate.

Sodæ subboras. See *Sodæ biboras.*

Sodæ subcarbonas. See *Sodæ carbonas.*

Sodæ subcarbonas exsiccata. See *Sodæ carbonas exsiccata.*

Sodæ sulphas. Sulphate of soda. *Natron vitriolatum. Sal catharticus Glauberi.* Glauber's salt. Take of the salt which remains after the distillation of hydrochloric acid, two pounds; boiling water, two pints. Dissolve the salt in the water; then add gradually as much carbonate of soda as may be required to saturate the acid: boil the solution away until a pellicle forms upon the surface; and, after having strained it, set it by, that crystals may form. Having poured away the water, dry these crystals upon bibulous paper.

Scherer mentions another mode by Funcke, which is, making 8 parts of calcined sulphate of lime, 5 of clay, and 5 of common salt, into a paste with water; burning this in a kiln; and then powdering, lixiviating, and crystallising.

Sulphate of soda exists in large quantities under the surface of the earth in some countries, as Persia, Bohemia, and Switzerland; is found mixed with other substances in mineral springs and sea water; and sometimes effloresces on walls.

Sulphate of soda is bitter and saline to the taste. It is soluble in 2·85 parts of cold water, and 0·8 at a boiling heat. It crystallises in hexagonal prisms bevelled at the extremities, sometimes grooved longitudinally, and of very large size, when the quantity is great. These effloresce completely into a white powder if exposed to a dry air, or even if kept wrapped up in paper in a dry place; yet they retain sufficient water of crystallisation to undergo the aqueous fusion on exposure to heat, but, by

urging the fire, melt. Baryta and strontia take its acid from it entirely, and potash partially; the nitric and muriatic acids, though they have a weaker affinity for its base, combine with a part of it when digested on it. Heated with charcoal, its acid is decomposed; and it has been employed to furnish soda. Pajot des Charmes has made some experiments on it in fabricating glass: with sand alone it would not succeed; but equal parts of carbonate of lime, sand, and dried sulphate of soda, produced a clear, solid, pale yellow glass.

It is composed of 5 acid + 4 base + 11·25 water in crystals: when dry, the former two primes are its constituents.

It possesses cathartic and diuretic qualities, and is in high esteem as a mild cathartic. It is found in the mineral kingdom formed by nature, but that which is used medicinally is prepared by art. The dose is from one drachm to one ounce.

Sodii chloridum. Chloride of sodium. Muriate of soda. Common salt. This useful substance is very abundant in nature. It is found in large masses or rocks under the earth in this and other countries. In the solid form it is called *sal gemmæ* or *rock salt*. If it be pure and transparent, it may be immediately used in the state in which it is found; but if it contain any impure earthy particles, it should be previously freed from them. In some countries it is found in incredible quantities, and dug up like metals from the bowels of the earth. In this manner has this salt been dug out of the celebrated salt mines near Bochnia and Wieliczka, in Poland, ever since the middle of the 13th century, consequently, above these 500 years, in such amazing quantities, that sometimes there have been 20,000 tons ready for sale. In these mines, which are said to reach to the depth of several hundred fathoms, 500 men are constantly employed. The pure and transparent salt needs no other preparation than to be beaten to small pieces, or ground in a mill. But that which is more impure must be elutriated, purified, and boiled. That which is quite impure, and full of small stones, is sold under the name of rock salt, and is applied to ordinary uses. It may likewise be used for strengthening weak and poor brine-springs.

The waters of the ocean everywhere abound with common salt, though in different proportions. The water of the Baltic sea is said to contain one sixty-fourth of its weight of salt; that of the sea between England and Flanders contains one thirty-second part; that on the coast of Spain one sixteenth part; and between the tropics it is said, erroneously, to contain from an eleventh to an eighth part.

The water of the sea contains, besides the common salt, a considerable proportion of muriate of magnesia, and some sulphate of lime, of soda, and potash. The former is the chief ingredient of the remaining liquid which is left after the extraction of the common salt, and is called the mother water. Sea water, if taken up near the surface, contains also the putrid remains of animal substances, which render it nauseous, and in a long-continued calm cause the sea to stink.

The whole art of extracting salt from waters which contain it, consists in evaporating the water in the cheapest and most convenient manner. In England, a brine composed of sea water, with the addition of rock salt, is evaporated in large shallow iron boilers; and the crystals of salt are taken out in baskets. In Russia, and probably in other northern countries, the sea water is exposed to freeze; and the ice, which is almost entirely fresh, being taken out, the remaining brine is much stronger, and is evaporated by boiling. In the southern parts of Europe, the salt-makers take advantage of spontaneous evaporation. A flat piece of ground near the sea is chosen, and banked round, to prevent its being overflowed at high water. The space within the banks is divided by low walls into several compartments, which successively communicate with each other. At flood tide, the first of these is filled with sea water, which, by remaining a certain time, deposits its impurities, and loses part of its aqueous fluid. The residue is then suffered to run into the next compartment, and the former is again filled as before. From the second compartment, after a due time, the water is transferred into a third, which is lined with clay, well rammed and levelled. At this period, the evaporation is usually brought to that degree, that a crust of salt is formed on the surface of the water, which the workmen break, and it immediately falls to the bottom. They continue to do this until the quantity is sufficient to be raked out, and dried in heaps. This is called *bay salt*.

Besides its use in seasoning our food, and preserving meat both for domestic consumption and during the longest voyages, and in furnishing us with the muriatic acid and soda, salt forms a glaze for coarse pottery, by being thrown into the oven where it is baked; it improves the whiteness and clearness of glass; it gives greater hardness to soap; in melting metals it preserves their surface from calcination, by defending them from the air; and is employed with advantage in some assays; it is used as a mordant, and for improving certain colours, and enters more or less into many other processes of the arts.

Common salt was formerly regarded as a compound of muriatic acid and soda. It is now known to be a compound of chlorine and sodium. According to Dr. Ure's analysis, they are in the proportion 39·98 of sodium and 60·02 of chlorine, or one equivalent of each. Chloride of sodium, when dissolved in water, becomes hydrochlorate of soda. When sodium is heated in chlorine gas, it burns with a vivid flame; and chloride of sodium or common salt results. Muriate of soda possesses antiseptic, diuretic, cathartic, and resolvent qualities, and is frequently employed in form of clyster, fomentation, lotion, pediluvium, and bath, in obstipation, against worms, gangrene, scrofulous tumours, herpetic eruptions, arthritis, &c.

Sodii iod'idum. Hydriodate of soda. This possesses nearly the same medicinal properties as the iodide of potassium, but is little employed.

SO'DIUM. (*um, ii.* n.) The metallic base of soda. See *Soda*.

SOL. (*Sol, solis.* m.) The sun. Gold was so called by the older chemists.

SOLA'MEN. (*en, inis.* n. ; from *solor*, to comfort.) Consolation. Anise-seed has been named *solamen intestinorum*, from its carminative virtues.

SOLA'NEÆ. *Solanaceæ.* A natural family of plants, of which the genus *Solanum* is the type. It includes the deadly nightshade, henbane, belladonna, mandrake, tobacco, and many other plants.

SOLANINE. The narcotic principle of the solanum. See *Solanum dulcamara.*

SOLA'NUM. (*um, i.* n. ; from *solor*, to comfort: because it gives ease by its stupifying qualities.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria ;* Order, *Monogynia.*

2. The pharmacopœial name of the *Solanum nigrum.*

SOLANUM DULCAMARA. Bitter-sweet. Woody nightshade. *Dulcamara. Solanum scandens. Glycypicros, sive amaradulcis. Solanum lignosum.* Στρυχνος, of Theophrastus. *Solanum — caule inermi frutescente flexuosa ; foliis superioribus hastatis ; racemis cymosis*, of Linnæus. The roots and stalks of this nightshade, upon being chewed, first cause a sensation of bitterness, which is soon followed by a considerable degree of sweetness ; and hence the plant obtained the name of bitter-sweet. The berries have not yet been applied to medicinal use: they seem to act powerfully upon the primæ viæ, exciting violent vomiting and purging. Thirty of them were given to a dog, which soon became mad, and died in the space of three hours ; and, upon opening his stomach, the berries were discovered to have undergone no change by the powers of digestion. There can, therefore, be little doubt of the deleterious effects of these berries ; and as they are very common in the hedges, and may be easily mistaken, by children, for red currants, which they somewhat resemble, this circumstance is the more worthy of notice. The stipites, or younger branches, are directed for use in the pharmacopœia, and they may be employed either fresh or dried, making a proportionate allowance in the dose of the latter for some diminution of its powers by drying. In autumn, when the leaves are fallen, the sensible qualities of the plant are said to be the strongest ; and, on this account, it should be gathered in autumn rather than spring. Boiling water extracts all the active matter of the plant. M. Desfosses has found an alkaline substance in the berries of the dulcamara, which appears to be the narcotic principle of the plant. It is obtained by adding ammonia to the juice of the berries, drying the precipitate, which is thrown down, and digesting it in boiling alkohol : the alkaline substance called *solanine* is deposited from the alkohol on cooling. Another principle has been obtained from the stalks by Pfaff, and named *picroglycion* (bitter-sweet). Dulcamara does not manifest those strong narcotic qualities which are common to many of the nightshades : it is, however, very generally admitted to be a medicine of considerable efficacy. Murray says, it promotes all the secretions. Haller observes, that it partakes of the milder powers of the nightshade, joined to a resolvent and saponaceous quality ; and the opinion of Bergius seems to coincide with that of Murray : — " Virtus : pellens urinam, sudorem, menses, lochia, sputa ; mundificans." The diseases in which we find it recommended by different authors are extremely various ; but Bergius confines its use to rheumatisms, retentio mensium, et lochiorum. Dulcamara appears, also, by the experiments of Razoux and others, to have been used with advantage in some obstinate cutaneous affections. Dr. Cullen says, " We have employed only the stipites, or slender twigs of this shrub ; but, as we have collected them, they come out very unequal, some parcels of them being very mild and inert, and others of them considerably acrid. In the latter state, we have employed a decoction of them in the cure of rheumatism, sometimes with advantage, but at other times without any effect. Though the dulcamara is here inserted in the catalogue of diuretics, it has never appeared to us as powerful in this way ; for, in all the trials made here, it has hardly ever been observed to be in any measure diuretic." This plant is generally given in decoction, or infusion ; and, to prevent its exciting nausea, it is ordered to be diluted with milk, and to begin with small doses, as large doses have been found to produce very dangerous symptoms. Razoux directs the following : — R. Stipitum dulcam. rac. drac. ss ina quæ font. unc. 16 coquator ad unc. 8. This was taken in the dose of three or four drachms, diluted with an equal quantity of milk, every four hours. Linnæus directs two drachms, or half an ounce of the dried stipites, to be infused half an hour in boiling water, and then to be boiled ten minutes ; and of this decoction he gives two tea-cupfuls morning and evening. For the formula of a decoction of this plant, according to the London Pharmacopœia, see *Decoctum dulcamaræ.*

Solanum fœtidum. See *Datura stramonium.*

Solanum lethale. See *Atropa.*

Solanum lignosum. See *Solanum.*

SOLANUM LYCOPERSICUM. The love-apple plant. The fruit of this, called *Tomata*, and *love-apple*, is so much esteemed by the Portuguese and the Spaniards, that it is an ingredient in almost all their soups and sauces, and is by them considered cooling and nutritive.

SOLANUM MELONGENA. The systematic name of the mad-apple plant. Its oblong egg-shaped fruit is often boiled in the countries where it grows, in soups and sauces, the same as the love-apple ; is accounted very nutritive, and is much sought after by the votaries of Venus.

SOLANUM NIGRUM. The systematic name of the garden nightshade, which is highly deleterious, and very common in waste places, and by the road-sides.

SOLANUM SANCTUM. The systematic name of the Palestine nightshade ; the fruit of which is globular, and in Egypt much eaten by the inhabitants.

SOLANUM TUBEROSUM. The potato plant : called also, *Batatas, Solanum esculentum, Kippa, Kelengu, Papas Americanus, Pappus Americanus*

and *Convolvulus Indicus.* A native of Peru, first brought into Europe by Sir Francis Drake, 1486, and planted in London. The root of this plant is now in use all over Great Britain, and in most parts of Europe, as an article of diet, and is as generally eaten as bread.

Solanum vesicarium. See *Physalis alkekengi.*

SOLDANE'LLA. (*a, æ.* f.; *à solidando;* from its uses in healing fresh wounds.) The sea convolvulus. See *Convolvulus soldanella.*

Sole. See *Pleuronectes solea.*

SO'LEN. Σωλην. A tube or channel. A cradle for a broken limb.

SOLENA'RIUM. (Diminutive of σωλην, a tube.) A catheter.

SO'LEUS. (*us, i.* m.; from *solea*, a sole: from its shape being like the sole-fish.) See *Gastrocnemius internus.*

SOLIDA'GO. (*o, inis.* f.; from *solido*, to make firm: so called from its uses in consolidating wounds.) The name of a genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Polygamia superflua.* The herb comfrey.

SOLIDAGO VIRGAUREA. The golden rod. *Virga aurea. Herba dorea. Conyza coma aurea. Symphytum. Petræum. Elichrysum. Consolida saracenica* and *aurea.* Golden rod. The leaves and flowers of this plant are recommended as aperients and corroborants in urinary obstructions, ulcerations of the kidneys and bladder, and it is said by some to be particularly useful in stopping internal hæmorrhages.

SOLID. 1. In *Natural philosophy*, bodies, the particles of which cohere so firmly as not to be separated without some degree of force, are called *solids.*

2. In *Anatomy*, the solids are the bones, ligaments, membranes, muscles, nerves, and vessels.

SOLITA'RIUS. Solitary. Applied to leaves, stems, footstalks, worms in the body, &c. when either single on a plant, or only one in the same place.

SO'LIUM. (*um, ii.* n.; from *solus*, alone: so called because it infests the body singly.) A species of tape-worm. See *Tænia.*

SOLOMON'S ANTI-IMPETIGINES. A solution of corrosive sublimate.

SOLOMON'S BALM OF GILEAD. An aromatic tincture, of which brandy and cardamom seeds appear to be the principal ingredients. Some say it contains cantharides.

Solomon's seal. See *Convallaria.*

SOLSE'QUIUM. (*um, ii.* n.; from *sol*, the sun, and *sequor*, to follow: so called because it turns its flowers towards the sun.) See *Heliotropium.*

SOLUTIO SULPHATIS CUPRI COMPOSITA. *Aqua cupri vitriolati composita.* Compound solution of sulphate of copper. Take of sulphate of copper and sulphate of alumina, each, three ounces; water, two pounds; sulphuric acid, an ounce and a half. Boil the sulphates in the water that they may be dissolved; then filter through paper and add the acid. This is an Edinburgh formula. It is sometimes used as a styptic, and, when largely diluted, as an astringent collyrium.

SOLUTION. *Solutio.* An intimate commixture of solid bodies with fluids, into one seemingly homogeneous liquor. The dissolving fluid is called a menstruum or solvent.

SOLUTI'VUS. (From *solvo*, to loosen.) Laxative; gently purgative.

Solvent. See *Menstruum.*

SOMNA'MBULISM. This term is applied to sleep-walking, and also to a particular state induced by what is called animal magnetism. See *Sleep*, and *Magnetism, animal.*

SOMNI'FEROUS. (*Somniferus;* from *somnus*, sleep, and *fero*, to bring.) Having the power of inducing sleep.

SOMNOLE'NTIA. (*a, æ.* f.; from *somnus*, sleep.) Somnolency; sleepiness.

SO'MNUS. (*us, i.* m.) Sleep. See *Sleep.*

SO'NCHUS. (*us, i.* m. Παρα το σωον, χεειν; from its wholesome juice (?).) The name of a genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Polygamia æqualis.* The sow-thistle.

SONCHUS ARVENSIS. *Hieracium majus.* The greater hawkweed. A feebly astringent plant.

SONCHUS OLERACEUS. The systematic name of the sow-thistle. Most of the species of sonchus abound with a milky juice, which is very bitter, and said to possess diuretic virtues. It is sometimes employed with that intention. This plant, boiled, may be eaten as a substitute for cabbage.

Soot. See *Fuligo.*

SOPHI'A. (*a, æ.* f.; from σοφος, wise: so named from its great virtues in stopping fluxes.) See *Sisymbrium sophia.*

Sophia chirurgorum. See *Sisymbrium.*

SOPHISTICATION. *Sophisticatio.* The counterfeiting or adulterating any thing. See *Adulteration.*

SOPHO'RA. (*a, æ.* f.; a name of most whimsical origin. *Sophera* is, according to Prosper Alpinus, the Egyptian denomination of a species of cassia, the *Cassia sophera* of Linnæus, nearly related to this genus. Linnæus, spelling it *sophora*, calls it a *genus sophorum*, or of wise men; as teaching that separate stamens, in the papilionaceous family, if ever the limits of that family can be determined, afford so decisive a mark of discrimination, as almost to exclude the plants furnished with such from the same natural class, or order, with those the filaments of which are combined.) The name of a genus of plants. Class, *Decandria;* Order, *Monogynia.*

SOPHORA HEPTAPHYLLA. A shrub, the root and seeds of which are sometimes called *anticholerica:* they are both intensely bitter, and said to be useful in cholera, colic, and dysury.

SOPHRONISTE'RES. (From σωφρονιζω, to become wise: so called because they do not appear till after puberty.) The last of the grinding-teeth.

SO'PIENS. (From *sopio*, to make sleep.) Having the property of inducing sleep.

SO'POR. (*or, oris.* m.) Profound sleep.

SOPORI'FEROUS. (*Soporiferus;* from *sopor*, sleep, and *fero*, to bear.) Possessed of the power of inducing sleep.

SO'RA. (Arabic.) The nettle-rash.

SORBASTRE'LLA. (From *sorbeo*, to suck up: because it stops hæmorrhages.) See *Pimpinella saxifraga.*

SO'RBATE. (*Sorbas, atis.* f.) A compound of sorbic acid, with a base.

SORBIC ACID. (*Acidum sorbicum*; from *sorbus*, the mountain-ash, from the berries of which it is obtained.) The acid of apples, called malic, may be obtained most conveniently, and in greatest purity, from the berries of the mountain-ash, called *Sorbus*, or *Pyrus aucuparia*: and hence the present name, sorbic acid. This was supposed to be a new and peculiar acid by Donovan and Vauquelin, who wrote good dissertations upon it. But it now appears that the sorbic and *pure* malic acids are identical.

Bruise the ripe berries in a mortar, and then squeeze them in a linen bag. They yield nearly half their weight of juice, of the specific gravity of 1·077. This viscid juice, by remaining for about a fortnight in a warm temperature, experiences the vinous fermentation, and would yield a portion of alkohol. By this change it has become bright, clear, and passes easily through the filter, while the sorbic acid itself is not altered. Mix the clear juice with filtered solution of acetate of lead. Separate the precipitate on a filter, and wash it with cold water. A large quantity of boiling water is then to be poured upon the filter, and allowed to drain into glass jars. At the end of some hours, the solution deposits crystals of great lustre and beauty. Wash these with cold water, dissolve them in boiling water, filter, and crystallise. Collect the new crystals, and boil them for half an hour in 2·3 times their weight of sulphuric acid, specific gravity 1·090, supplying water as fast as it evaporates, and stirring the mixture diligently with a glass rod. The clear liquor is to be decanted into a tall narrow glass jar, and, while still hot, a stream of sulphuretted hydrogen is to be passed through it. When the lead has been all thrown down in a sulphuret, the liquor is to be filtered, and then boiled in an open vessel to dissipate the adhering sulphuretted hydrogen. It is now a solution of sorbic acid.

When it is evaporated to the consistence of a syrup, it forms mammalated masses of a crystalline structure. It still contains a considerable quantity of water, and deliquesces when exposed to the air. Its solution is transparent, colourless, void of smell, but powerfully acid to the taste. Lime and barytes waters are not precipitated by solution of the sorbic acid, although the sorbate of lime is nearly insoluble. One of the most characteristic properties of this acid is the precipitate which it gives with the acetate of lead, which is at first white and flocculent, but afterwards assumes a brilliant crystalline appearance. With potash, soda, and ammonia, it forms crystallisable salts, containing an excess of acid.

SO'RBUS. (*us, i.* f. and *um. i.* n.; from *sorbeo*, to suck up: because its fruit stops fluxes.) The name of a genus of plants in the Linnæan system. Class, *Icosandria*; Order, *Trigynia*. The service-tree.

Sorbus aucuparia. The wild service-tree. The berries of this plant are astringent, and, it is said, have been found serviceable in allaying the pain of calculous affections in the kidneys.

SO'RDES. (*es, is.* f.) When the matter discharged from ulcers is rather viscid, glutinous, of a brownish-red colour, somewhat resembling the grounds of coffee, or grumous blood mixed with water, it is thus named. Other fœtid excrementious substances are also called *sordes*, as the matter which forms round the teeth in fever, &c.

Sore, bay. The bay sore is an endemic disease at the bay of Honduras, which Dr. Mosely considers as a true cancer, commencing with an ulcer.

Sore-throat. See *Cynanche.*

Sorrel. See *Rumex acetosa.*

Sorrel, French. See *Rumex scutatus.*

Sorrel, round-leaved. See *Rumex scutatus.*

Sorrel, wood. See *Oxalis acetosella.*

SOUND. 1. An instrument which surgeons introduce through the urethra into the bladder, to discover whether there be a stone in this viscus or not.

2. The impression produced on the auditory nerve by certain vibrations. See *Auris.*

SOUNDING. *Searching.* The exploration of the bladder by means of the instrument called a sound.

Sour dock. See *Rumex acetosa.*

Southernwood. See *Artemisia abrotanum.*

Sow. See *Sus scrofa.*

Sow-bread. See *Cyclamen.*

SPA. 1. A general denomination for a mineral spring.

2. A town in France, in the department of the Ourte, famous for its mineral water, which is a very strongly acidulous chalybeate. What applies to the use of chalybeates in general will apply to this water.

SPA'DIX. (*ix, icis.* m.) An elongated receptacle or flower-bearing column, which emerges, mostly, from a spathe or sheath, as it does in *Arum maculatum*, *Calla Æthiopica*, and *palustris*; but the *Acorus calamus* has a spadix without any sheath.

The inflorescence of palms, and some other plants, is a *branched spadix*; as the *Chamærops humilis*, *Musa*, &c.

Spain, pellitory of. See *Anthemis pyrethrum.*

Spanish fly. See *Cantharis.*

Spanish liquorice. See *Glycyrrhiza.*

SPARGANO'SIS. (*is, is.* f.; from σπαργαω, to swell.) 1. A swelling.

2. A milk abscess. Dioscorides applied this term to phlegmon of the breast, and also, in a collective sense, to signify not only a milk abscess, but a variety of tumours and other diseases, supposed to depend upon an overflow, suppression, misdirection, or depraved secretion of milk.

SPA'RSUS. Dispersed; irregularly scattered. Frequently applied to eruptions, glands, leaves, flower-stalks.

SPA'RTIUM. (*um, ii.* n. Σπαρτιον, of Dioscorides: so called from σπαρτη, a rope; because of the use of the long, slender, tough branches, or bark, in making cordage.) The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria.*

Spartium junceum. The Spanish broom. Its medicinal properties resemble those of the common broom.

Spartium purgans. The leaves of this species are purgative, and the seeds strongly so.

Spartium scoparium. The systematic name of the common broom. *Genista.* The tops and leaves of this indigenous plant, *Spartium — foliis ternatis solitariisque, ramis inermibus angulatis,* of Linnæus, are the parts that are employed medicinally: they have a bitter taste, and are recommended for their purgative and diuretic qualities in hydropic cases.

SPA'SMA. (*a, atis.* n.; from σπαω, to draw.) That voluntary straining which takes place in any vehement exertion, contraction, or extension of a muscle, as in running, riding, or bearing heavy burdens. It differs from *spasmus,* which is an involuntary, and generally a morbid contraction of a muscle.

Spasmi. Spasmodic diseases. The third order of the class *Neuroses,* of Cullen; characterised by a morbid contraction or motion of muscular fibres.

SPASMO'DIC. *Spasmodicus.* Belonging to a spasm or convulsion.

Spasmodic asthma. See *Asthma.*

Spasmodic cholera. See *Cholera.*

Spasmodic colic. See *Colica.*

Spasmodic croup. See *Laryngismus stridulus.*

Spasmodic stricture. See *Strictura.*

SPASMO'LOGY. (*Spasmologia, æ.* f.; from σπασμος, a spasm, and λογος, a discourse.) A treatise on convulsions.

SPA'SMUS. (*us, i.* m.; from σπαω, to draw.) A cramp, spasm, or convulsion. An involuntary contraction of the muscular fibres, or that state of the contraction of muscles which is not spontaneously disposed to alternate with relaxation, is properly termed spasm. When the contractions alternate with relaxation, and are frequently and preternaturally repeated, they are called convulsions. Spasms are distinguished by authors into clonic and tonic spasms. In *clonic* spasms, which are the true convulsions, the contractions and relaxations are alternate, as in epilepsy; but in *tonic* spasms, the member remains rigid, as in locked-jaw. See *Convulsion, Tonic spasm,* and *Tetanus.*

Spasmus cynicus. *Risus caninus.* A convulsive affection of the muscles of the face and lips on one side, which involuntarily forces the muscles of those parts into a species of grinning distortion. The term is used by some authors synonymous with *risus Sardonicus.* When the masseter, buccinator, temporal, nasal, and labial muscles, are involuntarily excited to action, or contorted by contraction or relaxation, they give the expression of a malignant sneer. It sometimes arises from eating hemlock, or other acrid poisons, or succeeds to an apoplectic stroke.

SPA'THA. (*a, æ.* f.; from σπαθη, a ladle or spatula.) A sheath or covering of an immature flower, which bursts longitudinally, and is more or less remote from the flower. From the number of membranes, which are called valves, and of the flowers, and their duration, it is named, —

1. *Spatha univalvis,* having only one membraneous leaf; as in *Arum maculatum,* and *Crocus sativus.*

2. —— *bivalvis,* in *Stratiates aloides.*

3. —— *dimidiata,* or *lacera,* there being only one valve, and that covering the flower only partially; as in *Ixia uniflora,* and *Africana.*

4. *Spatha vaga,* the common sheath inclosing several partial ones; as in *Iris Germanica,* and *Helonica.*

5. —— *uniflora,* containing only one flower; as the *Narcissus poeticus, Pseudo-narcissus,* and *Amaryllis formosissima.*

6. —— *biflora,* with two; as in *Alpina racemosa,* and *Moræa virgata.*

7. —— *multiflora;* as in *Allium, Narcissus jonquilla,* and *Pancreatium carabeum.*

8. —— *persistens,* remaining with the fruit; as in *Heliconia bibai.*

9. —— *marcescens,* withering before or soon after the flowering; as in the *Allia,* and *Leucojum vernum.*

SPATHOME'LE. (From σπαθη, a sword, and μηλη, a probe.) An edged probe.

SPA'TULA. (Diminutive of *spatha,* a broad instrument.) An instrument for spreading salve.

SPATULA'TUS. Spatulate: battle-door-shaped. Applied to leaves, &c. of a roundish figure, tapering into an oblong base; as in *Silene otites.*

SPEAR. *Hasta.* A likeness to this instrument often gives a trivial name in *Natural History;* as spearmint, spearwort, &c.

Spearmint. See *Mentha viridis.*

Spear-shaped. See *Hastatus,* and *Lanceolatus.*

Spearwort, water. See *Ranunculus.*

SPECIES. (*es, ei.* f.) 1. Individual animals, plants, and minerals agreeing in their appearances or composition. Their similarity gives rise to the establishment of species. Individuals or species differing in circumstances arising from accident; in plants and animals, from soil and climate; in diseases, from constitution, &c.; in minerals from locality, are termed *varieties.* The circumstances which are common to one or more species give rise to a division, or the formation of a genus. See *Genus, Order, Class.*

2. An obsolete name for powders; as *species aromaticæ; species diambræ,* &c.

SPECIFIC. *Specificus.* Applied, 1. To that which acts on some particular organ more than on others; thus, ipecacuanha appears to have a *specific action* on *the respiratory* mucous membrane.

2. To a medicine possessed of sovereign efficacy in the cure of a particular disease; thus, sulphur may be considered as a specific for the itch, and bark for the ague.

Specific gravity. See *Gravity, specific.*

SPECI'LLUM. (*um. i.* n.; from *specio,* to examine.) A probe.

SPE'CULUM. (*um, i.* n.; from *specio,* to view.) An instrument for opening or obtaining a view of parts within each other; as *speculum oculi, speculum oris, speculum ani,* &c.

Speculum ani. An instrument for distending the anus, whilst an operation is performed upon the parts within.

Speculum matri'cis. An instrument to assist in any manual operation belonging to the womb.

Speculum oculi. An instrument by which the eyelids are kept open, and the eye fixed.

Speculum oris. An instrument to force open the mouth.

Speculum veneris. See *Achillea.*

Speech. See *Voice.*

Speechlessness. See *Aphonia.*

Speediman's pills. These consist of aloes, myrrh, rhubarb, extract of chamomile, and essential oil of chamomile.

Speedwell. See *Veronica.*

Speedwell, female. See *Antirrhinum.*

Speedwell, mountain. See *Veronica.*

Spermace'ti. (From σπερμα, seed, and κητος, the whale.) See *Physeter.*

SPERMA'TIC. (*Spermaticus*; from σπερμα, seed.) Belonging to the testicle and ovary; as the spermatic artery, chord, and veins.

Spermatic arteries. See *Testis.*

Spermatic veins. See *Testis.*

SPERMATOCE'LE. (*e, es.* f.; from σπερμα, seed, and κηλη, a tumour.) *Epididymis distensa.* A swelling of the testicle or epididymis from an accumulation of semen. In this case the swelling is accompanied by pain extending to the loins, without inflammation.

Spermatopoe'ticus. (From σπερμα, and ποιεω, to make.) Having the property of increasing the secretion of seed.

SPERMATORRHŒ'A. (*a, æ.* f.; from σπερμα, *semen*, and ρεω, *fluo.*) Seminal flux. See *Gonorrhœa.*

SPHACELI'SMUS. (*us, i.* m.; from σφακελιζω, to gangrene.) 1. A gangrene.

2. An inflammation of the brain.

SPHA'CELUS. (*us, i.* m.; from σφακω, to destroy.) Complete mortification. See *Mortification.*

Sphænoides. See *Sphenoides.*

SPHÆRO'MA. (*a, atis.* n.; from σφαιρα, a globe.) A fleshy globular protuberance.

Spheno-staphylinus. See *Levator palati.*

SPHE'NOID. (*Sphenoides*; from σφην, a wedge, and ειδος, a likeness: because it is fixed in the cranium like a wedge.) Wedge-like: applied to a bone of the skull. See *Sphenoides os.*

SPHENOIDAL. *Sphenoidalis.* Belonging to the sphenoid bone.

Sphenoidal suture. *Satura sphenoidalis.* The sphenoidal and ethmoidal sutures are those which surround the many irregular processes of these two bones, and join them to each other and to the rest.

Sphenoides os. This bone is also called, *Os cuneiforme, Os multiforme, Os azygos, Papillare os, Basilare os, Os polymorphos*, and *Pterygoideum.* The sphenoid bone is wedged in amidst the other bones of the head, and is of a more irregular figure than any other bone. It has been compared to a bat with its wings extended. This resemblance is but faint, but it would be difficult, perhaps, to find any thing it resembles more.

We distinguish in this bone its body or middle part, and its wings or sides, which are much more extensive than its body.

Each of its wings or lateral processes is divided into two parts. Of these the uppermost and most considerable portion, helping to form the deepest part of the temporal fossa on each side, is called the *temporal process.* The other portion makes a part of the orbit, and is therefore named the *orbitar process.* The back part of each wing, from its running out sharp to meet the os petrosum, has been called the *spinous process*; and the two processes, which stand out almost perpendicular to the basis of the skull, have been named *pterygoid* or *aliform* processes, though they may be said rather to resemble the legs than the wings of the bat. Each of these processes has two plates and a middle fossa facing backwards: of these plates the external one is the broadest, and the internal one the longest. The lower end of the internal plate forms a kind of hook, over which passes the round tendon of the *musculus circumflexus palati.* Besides these, we observe a sharp middle ridge, which stands out from the middle of the bone. The fore part of it, where it joins the nasal lamella of the ethmoidal bone, is thin and straight; the lower part of it is thicker, and is received into the vomer.

The cavities observable on the external surface of the bone, are where it helps to form the temporal, nasal, and orbitar fossæ.

It has likewise two fossæ in its pterygoid processes. Behind the edge, which separates these two fossæ, we observe a small groove, made by a branch of the superior maxillary nerve in its passage to the temporal muscle. Besides these, it has other depressions, which serve chiefly for the origin of muscles.

Its foramina are four on each side. The three first serve for the passage of the optic, superior maxillary, and inferior maxillary nerves; the fourth transmits the largest artery of the dura mater. On each side we observe a considerable fissure, which, from its situation, may be called the superior orbitar fissure. Through it pass the third and fourth pair of nerves, a branch of the fifth, and likewise the sixth pair. Lastly, at the basis of each pterygoid process, we observe a foramen which is named *pterygoidean*, and sometimes *Vidian*, from Vidius, who first described it. Through it passes a branch of the external carotid, to be distributed to the nose.

The os sphenoides on its internal surface affords three fossæ. Two of these are considerable ones: they are formed by the lateral processes, and make part of the lesser fossæ of the basis of the skull. The third, which is smaller, is on the top of the body of the bone, and is called *sella turcica*, from its resemblance to a Turkish saddle. In this the pituitary gland is placed. At each of its four angles is a process. They are called the *clinoid* processes, and are distinguished by their situation into anterior and posterior processes. The two latter are frequently united into one.

Within the substance of the os sphenoides, immediately under the sella turcica, we find two cavities, separated by a thin bony lamella. These are the sphenoidal sinuses. They are lined with the pituitary membrane, and, like the frontal sinuses, separate a mucus which passes into the nostrils. In some subjects there is only one cavity; in others, though more rarely, we find three,

In infants, the os sphenoides is composed of three pieces, one of which forms the body of the bone and its pterygoid processes, and the other two its lateral processes. The clinoid processes may even then be perceived in a cartilaginous state, though some writers have asserted the contrary; but we observe no appearance of any sinus.

This bone is connected with all the bones of the cranium, and likewise with the ossa maxillaria, ossa malarum, ossa palati, and vomer. Its uses may be collected from the description we have given of it.

SPHE'NO-MAX'ILLARY. *Spheno-maxillaris.* Relative to the sphenoid and maxillary bones.

SPHE'NO-MAX'ILLARY FISSURE. Inferior orbitary fissure. *Foramen lacerum inferius. Foramen spheno-maxillare.* A hole situated at the posterior part of the angle formed by the union of the internal and inferior parietes of the orbit. It is constituted, above, by the sphenoid bone; below, by the superior maxillary and palate bones; and before, by the malar bone; and forms a communication between the orbitar cavity and the zygomatic fossa.

SPHE'NO-MAX'ILLARY FOSSA. A depression at the union of the spheno-maxillary and pterygo-maxillary fissures.

SPHE'NO-PAL'ATINE. *Spheno-palatinus.* That which relates to the sphenoid and palate bones.

SPHE'NO-PAL'ATINE FORAMEN. A round aperture, formed by the vertical portion of the os palati and the sphenoid. It establishes a communication between the nasal fossæ and the zygomatic fossa.

SPHE'NO-PAL'ATINE AR'TERY. The termination of the internal maxillary. It enters at the posterior part of the superior meatus of the nose, through the spheno-palatine foramen, and ramifies on the pituitary membrane covering the septum, the cornua, and the meatus.

SPHE'NO-PAL'ATINE GAN'GLION. Ganglion of Meckel. A small or triangular ganglion, of variable size, situated without the foramen spheno-palatinum, in the pterygo-maxillary fissure. It seems suspended, by several nervous filaments, to the trunk of the superior maxillary nerve, and gives off *internal* or *spheno-palatine filaments, inferior* or *palatine filaments*, and a *posterior filament*, which is the *vidian* or *pterygoid nerve*.

SPHE'NO-PAL'ATINE NERVES. Lateral nasal nerves. These arise from the ganglion of Meckel, at its inner part, and enter the nasal fossæ by the spheno-palatine foramen. They are five or six in number, and distribute their filaments to the outer and inner parietes of the nasal fossæ. One of the most remarkable branches is the *Naso-palatine*.

SPHE'NO-PARI'ETAL. *Spheno-parietalis.* Belonging to the sphenoid and parietal bones.

SPHE'NO-PARI'ETAL SU'TURE. This is formed by the articulation of the extremity of the greater ala of the sphenoid with the anterior and inferior angle of the parietal bone.

SPHE'NO-TEM'PORAL. *Spheno-temporalis.* That which belongs to the sphenoid and temporal bones.

SPHE'NO-TEM'PORAL SU'TURE. The suture at the articulation of the great alæ of the sphenoid bone with the squamous portion of the temporal.

SPHINCTER. (*er, eris.* m.; from σφιγγω, to compress.) The name of several muscles, the office of which is to shut or close the aperture around which they are placed.

SPHINCTER ANI. *Sphincter externus*, of Albinus and Douglas. *Sphincter cutaneus*, of Winslow. A single muscle of the anus, which shuts the passage through the anus into the rectum, and pulls down the bulb of the urethra, by which it assists in ejecting the urine and semen. It arises from the skin and fat that surrounds the verge of the anus on both sides, near as far as the tuberosity of the ischium; the fibres are gradually collected into an oval form, and surround the extremity of the rectum. It is inserted by a narrow point into the perinæum, acceleratores urinæ, and transversi perinæi: and behind into the extremity of the os coccygis, by an acute termination.

Sphincter ani cutaneus. See *Sphincter ani.*

Sphincter ani externus. See *Sphincter ani.*

SPHINCTER ANI INTERNUS. Albinus and Douglas call the circular fibres of the muscular coat of the rectum, which surround its extremity, by this name.

Sphincter cutaneus. See *Sphincter ani.*

Sphincter externus. See *Sphincter ani.*

SPHINCTER GULÆ. The superior constrictor of the pharynx.

Sphincter labiorum. See *Orbicularis oris.*

Sphincter oris. See *Orbicularis oris.*

SPHINCTER VAGINÆ. *Constrictor cunni*, of Albinus. *Second muscle of the clitoris*, of Douglas. This muscle arises from the sphincter ani and from the posterior side of the vagina near the perinæum; from thence it runs up the side of the vagina, near its external orifice, opposite to the nymphæ, covers the corpus cavernosum, and is inserted into the crus and body or union of the crura clitoridis. Its use is to contract the mouth of the vagina.

SPHINGO'NTOS. (From σφιγγω, to bind.) Astringent.

SPHONDY'LIUM. (*um, ii.* n.; from σπονδυλος, a vertebra, so named from the shape of its root: or probably, because it was used against the bite of a serpent, called σπονδυλις.) 1. The Greek name of a plant, supposed by some to be the branckursine. See *Acanthus mollis.*

2. The specific name of a species of Heracleum. See *Heracleum sphondylium.*

Sphrongidium. See *Columnula.*

SPHY'GMICUS. Relating to the pulse.

SPHY'GMOS. (*os, i.* m.; from σφυξειν, to leap or rebound.) The pulse.

SPI'CA. (*a, æ.* f.) A spike. 1. A species of inflorescence, consisting of one common stalk bearing numerous flowers, all ranged along it, without any, or having very small partial stalks, as the flower-stalk of the greater plantain. From its figure, the situation of the flowers, and its vesture, it is said to be, —

1. *Cylindrical;* as in *Plantago media.*

2. *Ovate*, in *Sanguisorba officinalis.*

3. *Articulate*, with joints; as in *Salicornia herbacea*, and *Polygonum articulatum.*

4. *Conjugate*, two spikes going from the summit of the peduncle; as in *Heliotropium Europæum* and *parviflorum.*

5. *Ramose*, divided into branches; as in *Chenopodium bonus henricus*, and *Osmunda.*

6. *Imbricate*; as in *Salvia Hispanica.*

7. *Secundal*, the flowers leaning all to one side; as in *Anchusa officinalis.*

8. *Interrupted*, in separate groups; as in *Betonica officinalis.*

9. *Distichal*, or two-rowed, two series of spikes; as in *Gladiolus alopecuroides.*

10. *Terminal*; as in *Lavendula.*

11. *Axillary*; as in *Justitia spinosa.*

12. *Foliose*, leaflets between the flowers; as in *Agrimonia eupatoria.*

13. *Comose*, having a leafy bundle at the apex; as in *Lavendula stœchas.*

14. *Ciliate*, hairs between the flowers; as in *Nardus ciliaris.*

II. An ear of corn.

III. A bandage, the shape of which somewhat resembles that of an ear of corn.

Spica brevis. See *Alopecuris pratensis.*

Spica Celtica. See *Valeriana Celtica.*

SPICA FŒMINA. Common lavender.

Spica Indica. See *Nardus Indica.*

SPICA INGUINALIS. A bandage for ruptures in the groin.

SPICA DUPLEX. Double bandage.

SPICA MAS. Broad-leaved lavender.

Spica nardi. See *Nardus Indica.*

SPICA SIMPLEX. A common bandage.

SPI'CULA. (*a*, *æ*. f.; a diminutive of *spica.*) A spikelet or spiket. A term applied exclusively to grasses that have many florets on one calyx, such florets ranged on a little stalk constituting the spikelet, which is therefore a part of the flower itself, and not of the inflorescence; as in *Briza minor*, and *Poa aquatica.* *Locusta* means the same as *spicula.*

SPIGE'LIA. (*a*, *æ*. f.; so called by Linnæus in commemoration of an old botanist, Adrian Spigelius, who wrote *Isagoge in rem Herbariam*, in 1606.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia.*

2. The name in some pharmacopœias for the *Spigelia Marilandica.*

SPIGELIA ANTHELMIA. The systematic name of the spigelia of some pharmacopœias. It is directed as an anthelmintic: its virtues are very similar to those of the Indian pink. See *Spigelia Marilandica.*

Spigelia lonicera. See *Spigelia Marilandica.*

SPIGELIA MARILANDICA. Perennial worm-grass, or Indian pink. *Spigelia lonicera. Spigelio—caule tetragono, foliis omnibus oppositis*, of Linnæus. The whole of this plant, but most commonly the root, is employed as an anthelmintic by the Indians and inhabitants of America. Dr. Hope has written in favour of this plant, in continued and remitting low worm fevers. Besides its property of destroying the worms in the primæ viæ, it acts as a purgative.

Spigelian lobe. See *Liver.*

Spignel. See *Æthusa meum.*

Spikelet. See *Spicula.*

Spikenard. See *Nardus Indica.*

Spike-stalk. See *Rhachis.*

SPILA'NTHUS. (*us*, *i*. m.; from σπιλος, a spot, and ανθος, a flower: because of its dotted or speckled flowers.) The name of a genus of plants. Class, *Syngenesia*; Order, *Polygamia æqualis.*

SPILANTHUS ACMELLA. The balm-leaved spilanthus; called also, *Achmella* and *Achamella.* This plant possesses a glutinous bitter taste, and a fragrant smell. The herb and seed are said to be diuretic and emmenagogue, and useful in dropsies, jaundice, fluor albus, and calculous complaints, given in infusion.

SPILSBURY'S ANTISCORBUTIC DROPS. These consist of corrosive sublimate ʒij., prepared sulphuret of antimony ʒij., gentian root, orange peel, of each ʒij., shavings of red saunders ʒj.; digested with a pint of proof spirit, and strained.

SPI'LUS. (*us*, *i*. m.; from σπιλος, *macula.*) A spot or discolouration of the skin. A mother's mark has been so called when in the form of a mere spot.

SPI'NA. (*a*, *æ*. f.; *quasi spiculina*, diminutive of *spica.*) A thorn.

I. In *Anatomy.* 1. The back-bone: so called from the thorn-like processes of the vertebræ. See *Vertebræ.*

2. The shin-bone: so called on account of its sharp edge.

II. In *Botany*, a thorn of a plant. A prickly armature of plants, not easily removed by the finger, and proceeding from the woody part of the plant. It is either,

1. *Cauline*; as in *Prunus spinosa.*

2. *Terminal*, at the end of a branch; as in *Rhamnus catharticus.*

3. *Foliar*, on the surface of the leaf; as in *Carduus marianus.*

4. *Marginal*, on the margin of the leaf; as in *Ilex aquifolium.*

5. *Axillary*, going from the axilla of the leaf; as in *Gleditschia triacanthos.*

6. *Calycine*, on the calyx; as in *Carduus marianus.*

7. *Pericarpial*, on the pod; as in *Datura stramonium.*

8. *Stipular*, on the stipule; as in *Mimosa Nilotica*, and *horrida.*

9. *Straight*; as in *Mimosa nigra.*

10. *Recurve*; as in *Costus nobilis.*

11. *Decussate*; as in *Genista Lusitanica.*

12. *Setaceous*; as in *Cactus opuntia.*

13. *Subulate*; as in *Cactus tuna.*

14. *Inermous*, covered with soft and not prickly spines, also called *muricate*; as in *Convolvulus muricatus*, and *Mimosa muricata.*

15. *Simple*, when not divided; as *Genista anglica.*

16. *Germinal*; as in *Limonia trifoliata.*

17. *Ternate*; as in *Zanthium spinosum.*

18. *Ramose*; as in *Gleditschia horrida.*

Spina acida. See *Berberis.*

Spina ægyptiaca. See *Acacia vera.*

Spina bifida. See *Hydrorachis.*

Spina cervina. See *Rhamnus.*

Spina hirci. The *Astragalus tragacantha*.

Spina infectoria. See *Rhamnus catharticus.*

Spina purgatrix. See *Rhamnus catharticus.*

Spina solstitialis. See *Calcitrapa.*

Spina ventosa. (The term *spina* seems to have been applied to this disorder, because it occasions a prickling in the flesh like the puncture of thorns; and the *ventosa* is added, because, upon touching the tumour, it seems to be filled with wind, though this is not the cause of the distension.) A tumour arising from an internal caries of a bone. The term is a very vague one, and has been applied by some to abscess within a bone, by others to necrosis, and by others, again, to white swelling.

Spinacnia. See *Spinacia.*

SPINA'CIA. (*a, æ.* f.; derivation uncertain.) The name of a genus of plants. Class, *Diœcia;* Order, *Pentandria.* Spinage.

Spinacia oleracea. The systematic name of the spinach. Spinage. *Spinachia.* This plant has been employed for medicinal purposes in the cure of phthisical complaints: made into a poultice, by boiling the leaves and adding some oil, it forms an excellent emollient. As an article of food it may be considered as similar to cabbage and other oleraceous plants. It is, however, more digestible, and less apt to occasion flatulency.

Spinage. See *Spinacia.*

Spinæ ventositas. A caries of a bone.

SPINAL. *Spinalis.* Belonging to the spine of the back; as spinal nerves, spinal cord, spinal diseases, &c.

Spinal cord. *Medulla spinalis.* Spinal marrow. This is a continuation of the medulla oblongata. It begins directly behind the origin of the ninth pair of nerves, and obtains its name from being contained in the osseous canal of the spine. It is invested by the same membranes which cover the brain, and has an additional partial involucrum from the ligamentous membrane which lines the bodies of the vertebræ, and which has been already taken notice of in the description of the ligaments. On the inner side of the ligamentous lining, the dura mater is situated, which passes out of the cranium by the foramen magnum occipitis, and forms a cylindrical sheath, which loosely envelopes the spinal marrow, and extends as far as the os sacrum. It is more elastic than the dura mater of the brain, and thereby admits more readily of the different motions of the spine. At its egress from the cranium, it is intimately connected to the beginning of the above-mentioned common ligamentous lining, and is also united with the pericranium at the edge of the foramen magnum of the occipital bone. Below the first vertebra of the neck, this intimate connexion between the dura mater and inner ligament of the vertebræ is discontinued; a *cellular, fatty,* and *slimy substance,* which surrounds the dura mater throughout the rest of the canal, being interposed between that membrane and the ligament. The dura mater is only in contact with the tunica arachnoidea; and this, also, only in contact with the pia mater, and lying so loosely over the latter as to be separated from it with facility through the whole length of the spine, by making a puncture in it, and distending it with air. The spinal marrow, like the brain, consists of a cortical and medullary substance, but differs in this respect, that the cineritious matter is placed within the medullary. Upon the surface of the spinal marrow, while lying in its natural situation, many transverse wrinkles or folds are observed, which allow it to be extended in the motions of the vertebræ. It is a little flattened on its anterior and posterior surfaces, and is larger near the under part of the neck, and at the top of the loins, where the great nerves of the extremities are sent off, than in the other parts of the spine. It is divided into two lateral portions or cords, which are separated from each other externally by an anterior and posterior fissure continued from the medulla oblongata; and each of the lateral portions is in some measure subdivided by a superficial furrow, into a large anterior and small posterior cord. The lateral portions are firmly united together by fine cellular substance, but, without lacerating either, may be separated from each other, before as well as behind, to near their middle, where they are connected by a layer of cineritious matter, which passes from the one cord into the other. When the medulla spinalis is divided transversely, the cineritious substance is observed to have a cruciform appearance, corresponding with the cords of which it is composed. The body of the spinal marrow descends in the child to the twelfth dorsal, and in the adult as far as the second lumbar vertebra, and terminates there by a conical point, which is concealed by fasciculi of nerves. The spinal cord gives rise on each side to a number of nerves, the origin and distribution of which are described in the article *Nerve.*

The arteries of the spinal cord consist of anterior and posterior spinal arteries, and of many additional branches communicating with others from the adjacent vessels. The *anterior spinal arteries* arise, one on each side, from the vertebrals, near where these join to form the basilar artery. Upon the beginning of the spinal marrow, they generally unite into a common trunk, which descends in that depression on the anterior surface of the medulla, whereby it is distinguished into two lateral portions, and in this course is covered by the tunica arachnoidea. The artery continues nearly of the same size throughout, in consequence of additions it receives from the neighbouring arteries. In the neck it communicates with the vertebral, thyroid, and cervical arteries, by branches which pass through the same holes with the nerves. In the back it receives branches from the intercostal, and in the loins from the lumbar arteries; all of which go through the intervertebral holes. It terminates at the under end of the spinal marrow; the cauda equina being supplied by branches from the internal iliac artery, which enter through the anterior and posterior holes of the os sacrum. The *posterior spinal arteries* arise commonly from the inferior arteries of the cerebellum, and frequently from the trunks of the vertebral arteries within the cranium. They are equal in length to the former artery, but considerably inferior

to it in size, and continue separate through the whole of their course. They have constantly a serpentine appearance, and form frequent inosculations with each other, and with arteries, the branches of which communicate with the anterior spinal artery. The arteries of the spinal marrow are divided into minute branches, which are dispersed upon its substance, upon the membranes which inclose it, and also upon the origins of the nerves, and substance of the vertebræ. The *veins* of the spinal marrow accompany their arteries, and afterwards terminate in the sinus venosi of the spine. The *sinus venosi* consist of one on each side of the spinal marrow, which runs exterior to the dura mater; being chiefly lodged in the cellular substance, and in the ligamentous membrane which lines the fore and lateral parts of the vertebral canal. They extend from the foramen magnum of the occipital bone, to the under end of the os sacrum, and are so irregular on their surface, and so much divided and subdivided within by the openings of veins, as in many parts to have the appearance of cells. At the different vertebræ, they are joined by cross branches, which have a semilunar form, like the surface of the bones which surround them. They communicate at their superior extremity with the lateral sinuses, and with the occipital when present, and send numberless branches outwards, which open into the veins, the arteries of which anastomose with those of the spinal marrow. — *Fyfe.*

Spinal cord, diseases of the. The diseases of the spinal cord and its membranes, like those of the contents of the cranium, are so frequently consecutive on inflammation, of an acute or chronic kind, that an account of the phenomena and effects of this morbid action, when seated in the cord or its investing membranes, may suffice to give a general notion of their pathology.

1. *Acute inflammation of the spinal cord and its membranes.* The similarity of texture between the membranes of the cord and those of the brain would lead us to expect an analogy in their diseased states; and the same analogy might be expected with reference to the substance of the cord and that of the brain: accordingly, the changes of structure induced by inflammation in the parts themselves, are very analogous; but when we consider the diversity of function of these parts, we are prepared to meet with a very different train of symptoms, and very different effects on the economy. From the close proximity of the textures which form the spinal cord, inflammation seldom exists to any extent in one of them without spreading to the rest; so that the greater part of the cases which occur in practice are mixed cases; and hence there is a difficulty in determining what symptoms are diagnostic of inflammation of the membranes, and of that of the substance of the cord. It will be convenient, therefore, first to take a view of the phenomena of general inflammation of the contents of the spinal canal, and then to point out those diagnostic marks which have been supposed to indicate the particular texture implicated.

This affection is distinguished by pain, more or less acute, extending throughout the length of the spine, or confined to the cervical, dorsal, or lumbar region. It is much increased by every movement of the spine, and is said, by some authors, to be increased by external pressure on the spine, while others deny this. The pain lancinates from the origin of the spinal nerves, and extends to different parts, according to the portion of the cord affected. In many cases the pain is more or less intermittent. There is usually acute pain at the epigastrium, sometimes extending over the whole abdomen, and increased on pressure, while various parts of the surface of the body have their sensibility exalted, so that the patient shrinks from the slightest touch. The heart palpitates, and the patient has a sense of constriction and weight about the præcordia, with difficulty of breathing. The pulse is generally frequent, small, and hard; sometimes full; or small and weak. The sensorial functions are generally little disturbed. Portal says, that when delirium occurs in this affection, it is always from an extension of the inflammation to the brain. When we consider the great number of nerves, both of common sensation and of muscular motion, which have their origin from the spinal cord, we may be prepared to meet with a very Protean disease, exhibiting every conceivable variety of disordered sensation and motion.

When the commencement of the cord is chiefly affected, spasms of the pharynx occur, resembling those of hydrophobia; the jaw is locked and the voice extinct. According to Ollivier, when the tuber annulare and adjacent portion of the brain are inflamed, universal palsy ensues, followed by asphyxia and death. When the cervical portion of the cord is the seat of disease, the muscles of the neck and upper extremities, and the external muscles of respiration, are principally affected. Inflammation of the dorsal portion of the cord produces opisthotonos, and that of the lumbar portion, spasmodic or paralytic affections of the pelvic viscera; in both cases the lower limbs are generally paralysed or convulsed. When hemiplegia arises from inflammation of the spinal cord, it usually affects the side of the body corresponding with that half of the cord which is diseased. Portal, however, relates a case in which the palsy affected the left side of the body, but the right half of the cord was found on dissection to have been inflamed. The common sensibility of the surface and the sense of touch are variously exalted, abolished, or deranged; sometimes the limbs are perfectly insensible, at others the patient cannot bear to be touched; and Ollivier mentions a case in which cold water, applied to the limbs, produced a sensation of heat.

Where the inflammation is confined to the anterior or posterior columns of the cord, it may be expected that the sensibility or the power of voluntary motion will be influenced accordingly. In one case mentioned by Ollivier, in which voluntary motion was abolished, while sensibility was retained, the anterior portion of the cord was found in a state of ramolissement. The disorder of the functions,

of which a sketch has just been given, does not always exist: in a very acute case, related by Dr. Abercrombie, there was intolerable pain, but neither convulsions nor palsy.

Such are the general symptoms of acute inflammation of the contents of the spinal canal, without reference to any distinction between inflammation of the substance of the cord and that of its membranes. Such a distinction, however, doubtless exists; and the difficulty of establishing it arises from the fact, that in most cases the cord and its membranes are simultaneously affected. According to Ollivier, the sensibility of the surface is always exalted in spinal meningitis, while in inflammation of the substance of the cord it is generally diminished. On a comparison of the best marked cases, it would appear that *meningitis* is, on the whole, more frequently attended with general *tonic* spasm; while in *myelitis* the muscles of the back only are thus affected, and those of the limbs with paralysis or *clonic* spasm. In arachnitis, also, the bowels, though sometimes loose, are generally obstinately constipated, as in tetanus; while in myelitis, diarrhœa almost constantly prevails.

Inflammation of the spinal cord is liable to be mistaken for several other diseases. Thus, in acute inflammation of the membranes, all the more prominent symptoms of idiopathic tetanus are frequently present, — the trismus; the spasmodic affection of the muscles of deglutition; the constrictive pain at the epigastrium; and the universal tonic spasms. The two disorders may, however, be distinguished by the presence of fever in the one, and its absence in the other; and by the local pain which attends the inflammatory disease.

Inflammation of the *cervical* portion of the spinal cord approximates closely, in its symptoms, to *hydrophobia*; and if we conceive a person who has been bitten by a suspected dog, to be seized, from some other cause, with inflammation of the cervical portion of the spinal cord, with its accompanying spasms of the pharynx, and general clonic convulsions, it is evident that this case might not be easily distinguished from hydrophobia. The local pain, however, and the *trismus*, which very frequently occurs in the case under consideration, but very rarely, if ever, in hydrophobia, together with the different mode of accession of the two diseases, may generally suffice for their discrimination. It may be suspected, however, that certain cases of hydrophobia, reported to have been cured by *blood-letting*, may have been nothing more nor less than inflammation of the cervical portion of the spinal cord.

There are several other affections, especially *rheumatism*, with which inflammation of the spinal cord, in its acute or chronic form, may, by a possibility, be confounded; but these it is unnecessary to dwell on.

Chronic inflammation of the spinal cord and its membranes. This is generally attended with little local pain, and the chief symptoms consist in palsy, cramp, anæsthesia, disordered functions of the viscera, and rapid emaciation of the frame.

The principal causes of inflammation of the spinal cord and its membranes appear to be external injury, and exposure to cold and damp, as lying on wet grass. The chronic form seems sometimes to arise from venereal excesses, and other kinds of debauchery.

The changes of structure resulting from *spinal meningitis* are thickening and opacity of the membranes, effusions of serum, blood, or pus, and gelatinous or albuminous exudations. M. Magendie has shown that, in the healthy subject, the space between the dura mater and pia mater, within the spinal canal, contains a quantity of serum, which, therefore, must not be mistaken for the product of disease.

The substance of the cord is subject to a variety of lesions, resulting from inflammation; and these are generally similar to the morbid changes which take place in the substance of the brain. Such are, 1. *Softening*, either superficial or affecting the whole thickness of the cord. The softening is sometimes attended with *increase of volume* or hypertrophy. 2. *Induration*, which is attended with increase of volume. Softening of the cord appears to result from chronic, much more frequently than from acute inflammation; and induration of the cord seems to be always a result of chronic disease. 3. *Suppuration*, which may be more or less extensive. Dissolution of the substance of the cord into a matter resembling pus has been sometimes found to have occurred throughout the whole extent of the cord. 4. *Gangrene*, which resembles the same state as it occurs in the substance of the brain, and like it, also, is rare.

The different lesions of structure in the spinal cord are more frequently observed in the lumbar and cervical regions, than in the dorsal, which may probably arise from the larger proportion of cineritious matter in the lumbar and cervical portions, and the greater consequent vascularity.

Inflammation of the contents of the spinal canal is a highly dangerous disease, and the chronic more so than the acute.

The principles of treatment are the same with those already stated as applicable to inflammation of the brain and its membranes, with the exception of the local application of cold.

Spinal marrow. See *Spinal cord.*

Spinalis cervi'cis. This muscle, which is situated close to the vertebræ at the posterior part of the neck and upper part of the back, arises, by distinct tendons, from the transverse processes of the five or six uppermost vertebræ of the back, and ascending obliquely under the complexus, is inserted, by small tendons, into the spinous processes of the sixth, fifth, fourth, third, and second vertebræ of the neck. Its use is to extend the neck obliquely backwards.

Spinalis colli. See *Semi-spinalis colli.*

Spinalis dorsi. *Transversalis dorsi*, of Winslow. This is the name given by Albinus to a tendinous and fleshy mass, which is situated along the spinous processes of the back and the inner side of the longissimus dorsi.

It arises tendinous and fleshy from the spinous processes of the uppermost vertebræ of the

loins, and the lowermost ones of the back, and is inserted into the spinous processes of the nine uppermost vertebræ of the back.

Its use is to extend the vertebræ, and to assist in raising the spine.

Spindle-shaped. See *Fusiformis.*

Spine. See *Vertebræ.*

SPINE'SCENS. Spinescent: becoming hard and thorny. Applied to the leaf-stalk when it hardens into a thorn, and the leaf falls, as is the case in *Rhamnus catharticus*, and *Robinia spinosa;* and to the stipulæ of the *Robinia pseudacacia*, which also become thorns.

SPINO'SUS. Spinous. Applied in *Anatomy* and *Natural History* to any object resembling a spine or thorn, or beset with spines or thorns.

SPIRÆ'A. (*a*, *æ*. f.; from *spira*, a spire, so named from its spiral stalk.) The name of a genus of plants in the Linnæan system. Class, *Icosandria;* Order, *Pentagynia.*

Spiræa africana. A species of *Diosma*, most probably the *crenata.*

Spiræa filipendula. The systematic name of the officinal dropwort. *Filipendula. Saxifraga rubra.* The root of this plant, *Spiræa —foliis pennatis, foliolis uniformibus serratis; caule herbaceo; floribus corymbosis,* of Linnæus, possesses astringent, and, it is said, lithontriptic virtues. It is seldom used in the practice of the present day.

Spiræa ulmaria. The systematic name of the meadow-sweet. Meadow-sweet. Queen of the meadows. *Ulmaria. Regina prati. Barba capræ.* This is a beautiful and fragrant plant. The leaves are recommended as mild astringents. The flowers have a strong smell, resembling that of May: they are supposed to possess antispasmodic and diaphoretic virtues; and, as they are very rarely used in medicine, Linnæus suspects that the neglect of them has arisen from the plant being supposed to be possessed of some noxious qualities, which it seemed to betray by its being left untouched by cattle. It may be observed, however, that the cattle also refuse the Angelica and other herbs, whose innocence is apparent from daily experience.

SPIRAL. *Spiralis.* Twisted like a cork-screw.

Spiral bandage. The common roller which is wound spirally round a limb, and is the most commonly used of all bandages.

Spirit. See *Spiritus.*

SPI'RITUS. (*us*, *ûs*. m.; spirit.) This name was formerly given to all volatile substances collected by distillation. Three principal kinds were distinguished: inflammable or ardent spirits, acid spirits, and alkaline spirits. The word spirit is now almost exclusively confined to the various preparations of alkohol and ether.

Spiritus ætheris aromaticus. Take of cinnamon-bark bruised, three drachms; cardamon-seeds powdered, a drachm and a half; long pepper powdered, ginger-root sliced, each a drachm; spirit of sulphuric ether, a pint: macerate for fourteen days, in a closed glass vessel, and strain. An excellent stimulating and stomachic compound, which is administered in debility of the stomach and nervous affections.

Spiritus ætheris nitrici. *Spiritus ætheris nitrosi. Spiritus nitri dulcis.* Sweet spirit of nitre. Take of rectified spirits, three pounds; nitric acid, four ounces: add the acid gradually to the spirit, and mix them; then (with a gentle heat) distil thirty-two fluid ounces. An anodyne, antispasmodic, diaphoretic, and diuretic compound, mostly administered in febrile affections unattended with inflammation, in dropsy, and in dysuria. The ordinary dose is from twenty to thirty drops, but in typhoid cases it may often be given with advantage in much larger doses.

Spiritus ætheris sulphurici. *Spiritus vitrioli dulcis. Spiritus ætheris vitriolici.* Sweet spirit of vitriol. Take of sulphuric ether, half a pint; rectified spirit, a pint: mix them. This preparation has the same medicinal properties as sulphuric ether, but is less active. It is now omitted in the London Pharmacopœia, but is retained by the Edinburgh, under the name of *æther sulphuricus cum alkohole;* and by the Dublin, under that of *liquor æthereus sulphuricus.*

Spiritus ætheris sulphurici compositus. Take of sulphuric ether, eight fluid ounces; rectified spirit, sixteen fluid ounces; etherial oil, three fluid drachms: mix them. A stimulating anodyne, supposed to be similar to the celebrated *liquor mineralis anodynus*, of Hoffmann. It is exhibited in fevers, nervous affections, hysteria, &c.; and, in most cases of fever where medicines are rejected by the stomach, this is of infinite service. Dose from ʒ ss. to ʒ ij.

Spiritus ammoniæ. Spirit of ammonia. Formerly called *Spiritus salis ammoniaci dulcis;* and *Spiritus salis ammoniaci.* Take of muriate of ammonia, ten ounces; carbonate of potash, sixteen ounces; rectified spirit, water, of each three pints: mix them, and (with a gentle fire) distil three pints. A stimulating antispasmodic, occasionally exhibited in cases of asphyxia, asthenia, and in nervous diseases, but mostly used as an external stimulant against rheumatism, sprains, and bruises.

Spiritus ammoniæ aromaticus. Aromatic spirit of ammonia. Formerly known by the name of *Spiritus ammoniæ compositus; Spiritus volatilis aromaticus;* and *Spiritus salis volatilis oleosus.* Take of cinnamon-bark bruised, cloves bruised, each two drachms; lemon-peel, four ounces; carbonate of potash, eight ounces; muriate of ammonia, five ounces; rectified spirit, water, of each four pints: mix, and distil six pints. A stimulating antispasmodic and sudorific, in very general use to smell at in faintings and lowness of spirits. It is exhibited internally in nervous affections, hysteria, and weakness of the stomach. The dose is from half a drachm to a drachm.

Spiritus ammoniæ fœtidus. Fœtid spirit of ammonia. Formerly called *spiritus volatilis fœtidus.* Take of muriate of ammonia, ten ounces; carbonate of potash, sixteen ounces; rectified spirit, water, of each three pints; asafœtida, five ounces: mix; then, by a gentle fire, distil three pints. A stimulating antispasmodic, often

exhibited to children against convulsions, and to gouty and asthmatic and hysterical patients. The dose is from half to a whole fluid drachm.

Spiritus ammoniæ succinatus. Succinated spirit of ammonia. Formerly known by the names of *Eau de luce; Spiritus salis ammoniaci succinatus;* and *Liquor cornu cervi succinatus.* Take of mastich, three drachms; rectified spirit, nine fluid drachms; oil of lavender, fourteen minims; oil of amber, four minims; solution of ammonia, ten fluid ounces: macerate the mastich in the spirit, that it may dissolve, and pour off the clear tincture; to this add the remaining articles, and shake them together. This preparation is much esteemed as a stimulant and nervine medicine, and is employed internally and externally against spasms, hysteria, syncope, vertigo, and the stings of insects. The dose is from ten minims to half a fluid drachm.

Spiritus anisi. Spirit of aniseed. Formerly called *Spiritus anisi compositus;* and *Aqua seminum anisi composita.* Take of aniseed bruised, ten ounces; proof spirit, a gallon; water, two pints: mix, and distil a gallon by a gentle fire. A stimulating carminative and stomachic, calculated to relieve flatulency, borborygmus, colic, and spasmodic affections of the bowels. The dose is from half to a whole fluid drachm.

Spiritus armoraciæ compositus. Compound spirit of horse-radish. Formerly called *Spiritus raphani compositus;* and *Aqua raphani composita.* Take of horse-radish root fresh and sliced, dried orange-peel, of each twenty ounces; nutmegs bruised, five drachms; proof spirit, a gallon; water, two pints: mix, and distil a gallon by a gentle fire. A very warm stimulating compound, given in gouty, rheumatic, and spasmodic affections of the stomach, and in scorbutic disorders. The dose is from half a fluid drachm to half a fluid ounce.

Spiritus camphoræ. Spirit of camphire. Camphorated spirit of wine. Formerly known by the names of *Spiritus camphoratus; Spiritus vinosus camphoratus;* and *Spiritus vini camphoratus.* Take of camphire, four ounces; rectified spirit, two pints: mix, that the camphire may be dissolved. A stimulating medicine, used as an external application against chilblains, rheumatism, palsy, numbness, and gangrene.

Spiritus carui. Spirit of caraway. Formerly called *Aqua seminum carui.* Take of caraway-seeds bruised, twenty-two ounces; proof spirit, a gallon; water, two pints: mix, and distil a gallon by a gentle fire. The dose is from a fluid drachm to half a fluid ounce.

Spiritus cinnamomi. Spirit of cinnamon. Formerly called *Aqua cinnamomi spirituosa;* and *Aqua cinnamomi fortis.* Take of oil of cinnamon, two drachms; proof spirit, a gallon; water, a pint: mix, and distil a gallon by a gentle fire. Spirit of cinnamon is mostly used in conjunction with other carminatives to give a pleasant flavour: it may be exhibited alone as a carminative and stimulant. The dose is from a fluid drachm to half a fluid ounce.

Spiritus cornu cervi. See *Ammoniæ subcarbonas.*

Spiritus gallicus. Brandy.

Spiritus jamaicensis. Rum.

Spiritus juniperi compositus. Compound spirit of juniper. Formerly called *Aqua juniperi composita.* Take of juniper-berries bruised, fifteen ounces; caraway-seeds bruised, fennel-seeds bruised, of each two ounces; proof spirit, a gallon; water, two pints: mix, and distil a gallon by a gentle fire.

Spiritus lavendulæ. Spirit of lavender. Formerly called *Spiritus lavendulæ simplex.* Take of fresh lavender flowers, two pounds and a half; rectified spirit, a gallon; water, two pints: mix, and distil a gallon by a gentle fire. Though mostly used as a perfume, this spirit may be given internally as a stimulating nervine and antispasmodic. The dose is from a fluid drachm to half a fluid ounce.

Spiritus lavendulæ compositus. Compound spirit of lavender. Formerly called *Spiritus lavendulæ compositus matthiæ.* Take of spirit of lavender, three pints; spirit of rosemary, a pint; cinnamon bark bruised, nutmegs bruised, of each half an ounce; red saunders wood sliced, an ounce: macerate for fourteen days, and strain. An elegant and useful antispasmodic and stimulant, in very general use against nervous diseases, lowness of spirits, and weakness of the stomach, taken on a lump of sugar.

Spiritus lumbricorum. The spirit obtained by the distillation of the earth-worm is similar to hartshorn. It is therefore never obtained from this source in the present day.

Spiritus menthæ piperitæ. Spirit of peppermint. Formerly called *Spiritus menthæ piperitidis;* and *Aqua menthæ piperitidis spirituosa.* Take of oil of peppermint, three drachms; proof spirit, a gallon; water, a pint: mix, and distil a gallon by a gentle fire. This possesses all the properties of the peppermint, with the stimulating virtues of the spirit. The dose from one fluid drachm to a fluid ounce.

Spiritus menthæ pulegii. *Aqua pulegii spirituosa.* This is prepared in the same manner as the spirit of peppermint.

Spiritus menthæ viridis. Spirit of spearmint. Formerly called *Spiritus menthæ sativæ;* and *Aqua menthæ vulgaris spirituosa.* This also is prepared in the same manner.

Spiritus millepedarum. An obsolete preparation, the virtues of which are similar to hartshorn.

Spiritus mindereri. See *Ammoniæ acetatis liquor.*

Spiritus myristicæ. Spirit of nutmeg. Formerly called *Aqua nucis moschatæ.* Take of nutmegs bruised, two ounces and a half; proof spirit, a gallon; water, a pint: mix, and distil a gallon by a gentle fire. A stimulating and agreeable spirit, possessing the virtues of the nutmeg. The dose from one fluid drachm to a fluid ounce.

Spiritus nitri dulcis. See *Spiritus ætheris nitrici.*

Spiritus nitri duplex. See *Acidum nitrosum,* and *Nitric acid.*

Spiritus nitri fumans. See *Acidum nitrosum,* and *Nitric acid.*

Spiritus nitri glauberi. See *Acidum nitrosum,* and *Nitric acid.*

Spiritus nitri simplex. The dilute nitrous acid. See *Acidum nitricum dilutum.*

Spiritus nitri vulgaris. A very dilute nitric acid.

Spiritus pimentæ. Spirit of pimento. Formerly called *spiritus pimento*. This is prepared in the same manner as the *spiritus myristicæ*. A stimulating aromatic medicine, mostly employed with astringent and carminative medicines. The dose is from half a fluid drachm to half a fluid ounce.

Spiritus pulegii. See *Spiritus menthæ pulegii.*

Spiritus rector. Boerhaave, and other chemists, give this name to a very attenuated principle, in which the smell of odorant bodies peculiarly resides. It is now called *aroma.*

Spiritus rosmarini. Spirit of rosemary. Take of oil of rosemary, two drachms; proof spirit, a gallon; water, a pint: mix, and distil a gallon by a gentle fire. A very fragrant spirit, mostly employed for external purposes in conjunction with other resolvents.

Spiritus salis. Spirit of salt. Muriatic acid.

Spiritus salis ammoniaci aquosus. See *Ammoniæ subcarbonas.*

Spiritus salis ammoniaci dulcis. See *Spiritus ammoniæ.*

Spiritus salis ammoniaci simplex. See *Ammoniæ subcarbonas.*

Spiritus salis Glauberi. See *Hydrochloric.*

Spiritus salis marini. See *Hydrochloric.*

Spiritus vini rectificatus. See *Alkohol.*

Spiritus vini tenuior. Proof spirit, which is about half the strength of rectified, is much employed for preparing tinctures of resinous juices, barks, roots, &c.

Spiritus vitrioli. See *Sulphuric acid.*

Spiritus vitrioli dulcis. See *Spiritus ætheris sulphurici.*

Spiritus vitrioli tenuis. See *Acidum sulphuricum dilutum.*

Spiritus volatilis fœtidus. See *Spiritus ammoniæ fœtidus.*

Spiroid canal. The *Aquæductus Fallopii* is so named by Chaussier.

SPISSAME'NTUM. (*um*, *i.* n.: from *spisso*, to thicken.) A substance put into oils and ointments to make them thick.

Spitting of blood. See *Hæmoptysis.*

SPLA'NCHNIC. (*Splanchnicus*; from σπλαγχνον, an entrail.) Belonging to the entrails.

Splanchnic nerve. A branch of the great intercostal nerve. See *Intercostal nerve.*

SPLANCHNO'LOGY. (*Splanchnologia*, *æ.* f.; from σπλαγχνον, an entrail, and λογος, a discourse.) The doctrine of the viscera.

SPLEEN. (*Splen*, *enis.* m. Σπλην.) *Lien.* The spleen or milt is a spongy viscus of a livid colour, and so variable in form, situation, and magnitude, that it is hard to determine either. Nevertheless, in the normal condition, it is always placed on the left side, in the left hypochondrium, between the eleventh and twelfth false ribs. Its circumference is oblong and round, resembling an oval figure. It is larger, to speak generally, when the stomach is empty, and smaller when it is compressed, or evacuated by a full stomach.

It should particularly be remembered of this viscus, that it is convex towards the ribs, and concave internally: also, that it has an excavation, into which vessels are inserted.

It is connected with the following parts: — 1. With the stomach, by a ligament and short vessels. 2. With the omentum, and the left kidney. 3. With the diaphragm, by a portion of the peritonæum. 4. With the beginning of the pancreas, by vessels. 5. With the colon, by a ligament.

In man, the spleen is covered with one simple, firm membrane, arising from the peritonæum, which adheres to the spleen very firmly, by the intervention of cellular structure.

The internal structure of the spleen is, by some anatomists, considered as cellular, the cells communicating with each other and with the branches of the splenic vein: others deny the existence of true cells in the spleen. The mass of the spleen appears to be formed of a collection of reddish brown granules; though the red substance contains very small whitish bodies, first observed by Morgagni. They are distinct in some of the inferior animals; but, in the human subject, their existence is asserted by some anatomists and denied by others.

The vessels of the spleen are, the splenic artery, coming from the cœliac artery, which, considering the size of the spleen, is much larger than is requisite for the mere nutrition of it. This goes by serpentine movements, out of its course, over the pancreas, and behind the stomach, and, after having given off branches to the adjacent parts, it is inserted into the concave surface of the spleen. It is afterwards divided into smaller branches, which are again divided into others yet smaller, delivering their blood immediately to the veins, but emitting it nowhere else. The veins, at length, come together into one, called the splenic vein; and having received the larger coronary vein of the stomach, besides others, it constitutes the left principal branch of the vena portæ.

The nerves of the spleen are small; they surround the arteries with their branches; they come from a particular plexus, which is formed of the posterior branches of the eighth pair, and the great intercostal nerve.

Lymphatic vessels are sometimes seen on the surface of the human spleen.

The use of the spleen has not hitherto been determined. We merely know, says Professor Müller, that its importance in the economy is not great: the experiments of numerous observers have shown that it may be extirpated without any remarkable ill consequence. Dupuytren observed increased voracity in dogs after the operation; Mayer states that the lymphatic glands become enlarged, but this is certainly not a constant effect. It has by others been said that the secretion of urine becomes more abundant, but Tiedemann and Gmelin deny that such is always the case. Mead and Mayer had noticed signs of imperfect digestion after the removal of the spleen; and some writers have stated that the bile becomes very bitter and dark-coloured, both of which the Heidelberg professors likewise deny to be con-

stant phenomena. The refutation of the hypotheses proposed to explain the use of the spleen will not occupy us long; for they either rest on wholly incorrect premises, or they are such as can neither be proved nor disproved.

All the theories which regard the spleen as essentially connected in its function with the liver, can be shown to be fallacious. Doellinger supposes the spleen to be formed merely for the sake of symmetry, to be the fellow of the liver, — the rudimentary liver, as it were, of the left side. But the liver is originally symmetrical; and the spleen is, as we have already described, developed in the middle line. No greater value can be accorded to the circumstance that splenic veins join the vena portæ, and to the hypothesis, thence deduced, that the spleen prepares the blood for the secretion of the bile; for in this respect it does not differ from all the chylopoetic viscera, nor even from the inferior extremities in the lower vertebrata, and the generative organs and air-bladder of fishes.

Some physiologists imagine, without any reason, that the spleen may exert a de-oxidising effect on the blood; others, again, believe that it favours the secretion of the gastric juice, because it receives less blood (?) at the time that the stomach is full; while others, as Lieutaud and Moreschi, regard it as a reservoir of blood for the stomach, supposing that the stomach when distended with food may attract more blood to itself, or may press on the splenic artery so as to diminish the quantity of blood sent at that time to the spleen. Dobson's hypothesis is very similar: he stated that he has found the spleen to have its maximum volume at the time when the process of chymification is at an end, — namely, five hours after food is taken; and to be small and contain little blood seven hours later, no food having been taken in the interval: he hence inferred that the spleen is the receptacle for the increased quantity of blood which the system acquires from the food, and which cannot, without danger, be admitted into the blood vessels generally; and that it regains its previous dimensions after the volume of the circulating fluid has been reduced by secretion. The premises of this theory do not appear to me to be sufficiently proved. Dobson repeated Magendie's experiment of injecting fluids into the veins of an animal, and, he says, with the same result with regard to the spleen, namely, the increase of its size.

The assertion of Defermon, that, when certain substances are taken into the system, the spleen undergoes changes in volume, — that it becomes smaller under the influence of strychnine, camphor, and muriate of morphia, — appears to me likewise to require confirmation. Sir E. Home, resting on the statement that the spleen increases in size after fluids are taken into the stomach, imagined that the fluids found their way by some unknown canals from the stomach to the spleen, and thence to the kidneys; but he afterwards renounced this idea. The function of the spleen probably consists in the production of some change, of which the nature is unknown, in the blood which circulates through its tissue, and in thus contributing to the process of sanguification; or in the secretion of a lymph of peculiar nature, which, being mixed with the contents of the lymphatic and lacteal system coming from other parts, tends to perfect the formation of the chyle. There are no other ways than the lymphatics and veins, by which any animal matter, modified by the action of the spleen, can be conveyed away from it. Tiedemann believes that the lymphatics perform this office; but whether he is correct or not is quite uncertain, and the nature of the change which the animal matter is supposed to undergo is still less known.

The blood of the splenic vein, according to Tiedemann and Gmelin, does not differ from other venous blood; they saw it coagulate like the blood of other organs. The older physiologists, and more recently Autenrieth, maintain, however, that the blood has peculiar characters. Schultz, too, found the blood of the vena portæ of a darker blacker tint than other venous blood; and the dark colour was most evident in animals which were fasting. Neither neutral salts nor the action of the air had the effect of rendering it of a brighter red colour; its coagulum was less firm than that of other blood, and it contained less fibrine and albumen, but more fatty matter.

Mr. Hewson supposed that it was the office of the spleen, as well as of the lymphatic glands and thymus body, to secrete from arterial blood a fluid which, mixed with lymph, should give rise to red blood particles. This, however, cannot be true, for the red particles are formed equally well after the extirpation of the spleen. The reddish colour of the lymph of the spleen, observed by Hewson, Tiedemann, and Fohmann, is not constant.

Mayer has asserted that the spleen is reproduced after extirpation. He says, that after the lapse of some years, he has found in ruminating animals, in the place of the spleen, a body of the size of a lymphatic gland: this would be an interesting fact if it could be satisfactorily proved; but that is scarcely possible, for animals often have small accessory spleens (splenculi), and in the operation of extirpation a small portion of the organ might be left behind in the body. The presence or absence of the bunches of white corpuscules, above described, might aid in determining whether any substance be spleen or not. — *Müller's Physiology, Baly's translation.*

Spleenwort. See *Asplenium.*

SPLENA'LGIA. (*a, æ.* f.; from σπλην, the spleen, and αλγος, pain.) A pain in the spleen or its region.

SPLE'NETIC. (*Spleneticus;* from σπλην, the spleen.) Belonging to the spleen.

SPLENI'TIS. (*is, idis.* f.; from σπλην, the spleen.) Inflammation of the spleen. Characterised by fever, tension, heat, tumour, and pain in the left hypochondrium, increased by pressure. This disease, according to Juncker, comes on with a remarkable shivering, succeeded by a most intense heat, and very great thirst; a pain and tumour are perceived in the left hypochondrium, and the paroxysms for the most part assume a quartan form; when the patients

expose themselves for a little to the free air, their extremities immediately grow very cold. If an hæmorrhage happen, the blood flows out of the left nostril. The other symptoms are the same with those of the hepatitis. Like the liver, the spleen is also subject to a chronic inflammation, which often happens after agues, and is called the ague cake, though that name is also frequently given to a scirrhous tumour of the liver succeeding intermittents. The causes of this disease are, in general, the same with those of other inflammatory disorders; but those which determine the inflammation to that particular part more than another are very much unknown. It attacks persons of a very plethoric and sanguine habit of body rather than others.

During the acute stage of splenitis, we must follow the antiphlogistic plan, by general and topical bleedings, by purging frequently, and by the application of blisters near the part affected. If it should terminate in suppuration, we must endeavour to discharge the pus externally, by fomentations or poultices. When the organ is in an enlarged scirrhous state, mercury may be successful in preventing its farther progress, or even producing a diminution of the part; but proper caution is required in the use of it, lest the remedy do more harm than the disease.

Sple'nium. Spleen-wort. See *Asplenium*.

SPLE'NIUS. (*us, ii.* m.; from σπλην, the spleen: so named from its resemblance in shape to the spleen; or, according to some, it derives its name from *splenium*, a *ferula*, or splint, which surgeons apply to the sides of a fractured bone.) *Splenius capitis*, and *Splenius colli*, of Albinus. The splenius is a flat, broad, and oblong muscle, in part covered by the upper part of the trapezius, and obliquely situated between the back of the ear and the lower and posterior part of the neck.

It arises, tendinous, from the four or five superior spinous processes of the dorsal vertebræ; tendinous and fleshy from the last of the neck; and tendinous from the ligamentum colli; or, rather, the tendons of the two splenii unite here inseparably; but about the second or third vertebra of the neck they recede from each other, so that part of the complexus may be seen.

It is inserted, by two distinct tendons, into the transverse processes of the two first vertebræ of the neck, sending off some few fibres to the complexus and levator scapulæ; tendinous and fleshy into the upper and posterior part of the mastoid process, and into a ridge on the occipital bone, where it joins with the root of that process.

This muscle may be easily separated into two parts. Eustachius and Fallopius were aware of this; Winslow has distinguished them into the *superior* and *inferior* portions; and Albinus has described them as two distinct muscles, calling that part which is inserted into the mastoid process and os occipitis, *splenius capitis*, and that which is inserted into the vertebræ of the neck, *splenius colli*. We have here followed Douglas, and the generality of writers, in describing these two portions as one muscle, especially as they are intimately united near their origin.

When this muscle acts singly, it draws the head and upper vertebræ of the neck obliquely backwards; when both act, they pull the head directly backwards.

Splenius capitis. See *Splenius*.

Splenius colli. See *Splenius*.

Splenoce'le. (From σπλην, the spleen, and κηλη, a tumour.) A hernia of the spleen.

SPLINT. A long piece of wood, tin, or strong pasteboard, employed for preventing the ends of broken bones from moving, so as to interrupt the process by which fractures unite.

Splint bone. The fibula is so called.

SPLIT-CLOTH. *Scissum linteum*. A bandage which consists of a central portion and six or eight tails. It is used principally for the head.

SPO'DIUM. (*um, ii.* n. Σποδιον.) The *spodium* of Dioscorides and of Galen are now not known in the shops. It is said to have been produced by burning cadmia alone in the furnace; for, having thrown it in small pieces into the fire, near the nozzle of the bellows, they blow the most fine and subtle parts against the roof of the furnace; and what was reflected from thence was called *spodium*. It differed from the pompholyx in not being so pure, and in being more heavy. Pliny distinguishes several kinds of it, as that of copper, silver, gold, and lead.

Spodium abaisir. Burnt ashes. Metallic calces, and a composition of white lead and oil.

Spodium arabum. Burnt ivory, or ivory black.

Spodium græcorum. The white dung of dogs; called also, *Album græcum*.

Spolia'rium. A private room at the baths.

SPONDY'LIUM. (*um, ii,* n.; from σπονδυλος, a vertebra: so named from the shape of its root, or probably because it was used against the bite of a serpent called σπονδυλις.) See *Heracleum spondylium*.

SPO'NDYLUS. (*us, i.* m. Σπονδυλος, a vertebra.) The spine or back-bone.

Sponge-tent. See *Spongia præparata*.

SPO'NGIA. (*a, æ.* f. Σπογγος; σπογγια.) Sponge. A genus of marine productions, the nature of which is considered doubtful. It is a soft, light, very porous and compressible substance, readily imbibing water, and distending thereby. It is found adhering to rocks, particularly in the Mediterranean Sea, about the islands of the Archipelago. It was formerly supposed to be a vegetable production, but is now classed among the zoophytes. It contains *iodine*. Burnt sponge was some years since in great reputation for the cure of bronchocele, and scrofulous complaints. Any efficacy which it may possess must be owing to the iodine it contains. Sponge-tents are employed by surgeons to dilate fistulous ulcers, &c. *Spongia officinalis* is the species in ordinary use.

Spongia præparata. Prepared sponge. Sponge-tent. This is formed by dipping pieces of sponge in hot melted emplastrum ceræ compositum, and pressing them between two iron plates. As soon as cold, the substance thus formed may be cut into pieces of any shape. It was formerly used for dilating small open-

ings, for which it was well adapted, as, when the wax melted, the elasticity of the sponge made it expand and distend the opening in which it had been put.

Spongia usta. Burnt sponge. Cut the sponge into pieces, and beat it, that any extraneous matters may be separated; then burn it in a close iron vessel until it becomes black and friable; lastly, rub it to a very fine powder. This preparation is exhibited with bark in the cure of scrofulous complaints, and forms the basis of a lozenge, which has been known to cure the bronchocele in many instances. It contains a portion of *iodine*. The dose is from a scruple to a drachm.

Spongiosa ossa. *Ossa turbinata inferiora. Ossa convoluta.* These bones are situated in the under part of the side of the nose: they are of a triangular form and spongy appearance, resembling the os spongiosum superius: externally they are convex; internally they are concave; the convexity is placed towards the septum nasi, and the concavity outwards. The under edge of each bone is placed horizontally near the outer part of the nose, and ending in a sharp point behind. At the upper part of the bone are two processes, the anterior of which ascends and forms part of the lachrymal groove, and the posterior descends and forms a hook to make part of the maxillary sinus. The connection of this bone is to the os maxillare, os palati, and os unguis, by a distinct suture in the young subject; but in the adult, by a concretion of substance.

The ossa spongiosa afford a large surface for extending the organ of smell, by allowing the membrane of the nose to be expanded, upon which the olfactory nerves are dispersed.

In the fœtus these bones are almost complete.

Spongio'sum os. 1. The ethmoid bone.

2. See *Spongiosa ossa.*

SPONGY. *Spongiosus.* Applied very generally to express a texture resembling that of a sponge.

Spongoi'des. (Σπογγοειδης; from σπογγος, a sponge, and ειδος, *forma*, shape: so called because it is porous, like a sponge or sieve.) See *Ethmoid bone.*

SPORADIC. (*Sporadicus;* from σπειρω, to sow.) Diseases which are not epidemic, but occur here and there from causes affecting only the individual, are called sporadic diseases.

Spotted lungwort. See *Pulmonaria.*

Sprain. See *Subluxatio.*

Sprat. See *Clupea sprattus.*

Spreading. See *Diffusus.*

Sphrongidium. See *Columnula.*

SPRUCE. 1. A particular species of fir. See *Pinus abies.*

2. A fermented liquor, called spruce-beer, prepared from the spruce fir. From the quantity of carbonic acid it contains, it is found a useful antiscorbutic.

Spur. See *Calcar.*

Spurge-flax. See *Daphne gnidium.*

Spurge-laurel. See *Daphne laureola.*

Spurge-olive. See *Daphne mezereum.*

Spurious. See *Nothus.*

Spurred. See *Calcaratus.*

Sputamen. See *Sputum.*

SPU'TUM. (*um, i.* n.; from *spuo*, to spit.) *Sputamen.* Saliva. That which is cast out of the mouth merely by spitting or hawking, as the spittle, is properly the sputum: but it applies also to expectorated matter, or that which comes from within the chest and is spit out. For the varieties of sputa, see the *Supplement.*

SQUA'MA. (*a, æ.* f.) A scale. An opake and thickened lamina of the cuticle. See *Scale.*

Squamæ. An order of cutaneous diseases in Dr. Willan's arrangement. Scaly diseases are commonly produced by some degree of inflammation of the true skin, over which they are formed; but occasionally, as in the slighter forms of pityriasis, the cuticle alone, or with the rete mucosum, appears to be in a morbid condition. If the definition be carefully attended to, scales will not be confounded with the scabs succeeding confluent pustules and vesicles, or superficial ulcerations. The four genera of scaly diseases are, *Lepra, Psoriasis, Pityriasis,* and *Ichthyosis.*

SQUAMA'RIA. (From *squama*, a scale: so called from its scaly roots.) The great tooth-wort, or *Plumbago europæa.*

SQUAMA'TUS. Scaly: applied to the nectary of the *Ranunculus* genus, &c. See *Nectarium.*

SQUA'MOUS. (*Squamosus;* from *squama*, a scale: because the bones lie over each other like scales.) Scaly.

Squamous suture. The suture which unites the sqamose portion of the temporal bone with the parietal.

SQUARRO'SUS. (From *squarra*, rough.) Squarrose: rough, scabby, scurfy, scaly. Applied to plants, &c.; as *Juncus squarrosus.*

Squill. See *Scilla.*

Squilla. See *Scilla.*

Squills, vinegar of. See *Acetum scillæ.*

Squina'nthus. (From *squinanthia*, the quinsy: so named from its uses in the quinsy.) See *Andropogon schænanthus.*

Squinting. See *Strabismus.*

Squire's elixir.

STA'CHYS. (*ys, yos.* m. Σταχυς, a spike: so named from its spicated stalk and seed.) 1. The name of a genus of plants in the Linnæan system. Class, *Didynamia;* Order, *Gymnospermia.*

2. Some species of wild sage, and horehound, nettle, &c. were formerly so called.

Stachys fœtida. See *Ballote nigra.*

Stachys palustris. Clown's woundwort or all-heal. Fallen into disuse.

STA'CTE. (*e, es.* and *a, æ.* f. Σταχτη; from σταζω, to distil.) 1. That kind of myrrh which distils or falls in drops from the trees.

2. A more liquid kind of amber than what is commonly met with in the shops; whence in Scribonius Largus, Paulus Ægineta, and some others, we meet with a collyrium, and several other forms, wherein this was the chief ingredient, distinguished by the name of *Stactica.*

Sta'cticon. Instillation; also an eye-water.

Staff. A grooved steel instrument introduced through the urethra into the bladder, to guide the knife in the operation of lithotomy.

STA'GMA. (From σταζω, to distil.) 1. Any distilled liquor.

2. The vitriolic acid.

STAHLIANS. The followers of George Ernest Stahl, an eminent chemist and physiologist of the seventeenth century. The Stahlians are called also *Animists*, and their school is called the *Dynamic school*. See *Animists*, *Dynamic school*, and *Life*.

STALAGMI'TIS. (*is*, *is*. f.; from σταλαγμος, a dropping, or distillation, because the gum which it yields escapes in that manner.) The name of a genus of plants. Class, *Polygamia*; Order, *Monœcia*.

STALAGMITIS CAMBOGIOI'DES. This and several other species of stalagmitis yield a kind of gamboge: the true gamboge, however, is the produce of the *Garcinia cambogia*. See *Cambogia* in the Supplement.

STALA'GMUS. (*us*, *i*. m.; from σταλαζω, to distil.) Distillation.

Stalk. See *Scapus*.

STA'LTICUS. (From στελλω, to contract.) Healing: applied to medicines which were supposed to have that power.

STAMEN. (*en*, *inis*. n.) The male genital organ of plants, found generally within the corolla, near the pistil. Stamens were formerly called *chives*. They are various in number in different flowers, from one to some hundreds. This organ is essential to a plant, no one having yet been discovered, after the most careful research, that is destitute of it, either in the same flower with the pistils, or a separate one of the same species.

A stamen consists of three parts: —

1. The *filament*, the part which supports the anther.

2. The *anther*, placed on the filament, and the most essential part of all.

3. The *pollen*, or powder adhering to the anther.

II. Stamina. In *Physiology* and *Pathology*, applied to the degree of strength and vigour in the constitution.

STA'MINAL. *Staminalis*. Relating to the stamen.

STAMINI'FEROUS. *Staminiferus*. Stamen-bearing: applied to such flowers and florets as contain one or more stamens and no pistils. They are necessarily barren flowers.

Stammering. See *Blæsitas*.

Standard. See *Vexillum*.

STANNI PULVIS. Tin, finely divided, is exhibited internally as a vermifuge: it acts mechanically, and the fine filings are more effectual than the powder.

STANNIC ACID. *Acidum stannicum*. (*Stannicus*; from *stannum*, tin.) A name which has been given to the peroxide of tin, because it is soluble in alkalis.

STA'NNUM. (*um*, *i*. n.) See *Tin*.

Stapedis musculus. See *Stapedius*.

STAPE'DIUS. (From *stapes*, one of the bones of the ear.) *Musculus stapes*, of Cowper; and *pyramidal-stapedien*, of Dumas. A muscle of the internal ear. See *Auris*.

STA'PES. (*es*, *edis*. m.; *in quo pes stat*, a stirrup.) A bone of the internal ear, so called from its resemblance to a stirrup. See *Auris*.

STA'PHIS. (*is*, *idis*. f. Σταφις.) A grape, or a bunch of grapes; whence, from their likeness thereunto, it is applied to many other things, especially the glands of the body, whether in a natural or diseased state.

STAPHISA'GRIA. (*a*, *æ*. f. Σταφις αγρια, wild vine: from the resemblance of its leaves to those of the vine.) See *Delphinium staphisagria*.

STA'PHYLE. (Σταφυλη, a grape or raisin: so called from a supposed resemblance.) The uvula.

STAPHYLI'NOS. Σταφυλῖνος. A Greek name of the wild carrot.

STAPHYLI'NUS. (From σταφυλη, the uvula.) Applied, in *Anatomy*, to parts connected with the uvula.

Staphylinus externus. See *Circumflexus*.

STAPHYLO'MA. (*a*, *atis*. n.; from σταφυλη, a grape: so named from its being thought to resemble a grape.) A disease of the eyeball, in which the cornea loses its natural transparency, rises above the level of the eye, and successively even projects beyond the eyelids, in the form of an elongated, whitish, or pearl-coloured tumour, which is sometimes smooth, sometimes uneven, and is attended with a total loss of sight. The proximate cause is an effusion of thick humour between the lamellæ of the cornea, so that the internal and external superficies of the cornea very much protuberates. The remote causes are, an habitual ophthalmia, contusions, and frequently a deposition of the variolous humour in the small-pox.

This disease sometimes occupies the whole transparent cornea; the opake cornea projects, and, if in the form of a cone, increasing in magnitude, it has been known to push out and invert the lower eyelid; and sometimes the morbid cornea is so elongated as to lie on the cheek: in these instances, there are generally collections of pus or some analogous fluid.

Staphyloma requires the aid of surgery to remove all the adventitious growths, or collections of fluids, and the use of detergent lotions and such caustic application as can be with safety used.

Staphylosis. See *Staphyloma*.

Star grass. See *Aletris farinosa*.

Star-like. See *Stellatus*.

Star-shoot. See *Tremella nostoc*.

Star-thistle. See *Carlina acaulis*.

Starch. See *Amylum*.

STARKEY'S PILLS. The same as *Matthews's pills*.

Starkey's soap. See *Sapo terebinthinæ*.

STA'TICE. (*e*, *es*. f.; from στατιζω, to stop: so named from its supposed property of restraining fluxes.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Pentagynia*. The herb sea-thrift.

STATICE CAROLINIANA. Marsh rosemary. A plant used in the United States as an astringent in dysentery, and as a gargle in ulcerated sore throats.

STATICE LIMONIUM. The systematic name of the sea-thrift. Sea-lavender, or red behen.

Behen rubrum. Limonium. Limonium majus. Behen. The roots possess astringent and strengthening qualities, but not in a very remarkable degree.

STATIONA'RIA FEBRIS. A stationary fever. So Sydenham called those fevers which happen when there are certain general constitutions of the years, which owe their origin neither to heat, cold, dryness, nor moisture, but rather depend on a certain secret and inexplicable alteration in the bowels of the earth, whence the air becomes impregnated with such kinds of effluvia as subject the body to particular distempers, so long as that kind of constitution prevails, which, after a certain course of years, declines and gives way to another.

Stavesacre. See *Delphinium.*

STE'ARINE. (From στεαρ, fat.) See *Adeps.*

STEAROPTENE. *Stearoptenum.* A name given by Herberger to the concrete portion, or camphor of volatile oils. The term is altogether ill-formed, for the genitive of στεαρ is στεατος; and πτηνος does not mean volatile in the sense here intended, but *flying like a bird.*

STEATOCE'LE. (*e, es.* f.; from στεαρ, fat, and κηλη, a tumour.) A fatty tumour of the scrotum.

STEATO'MA. (*a, atis.* n.; from στεαρ, fat.) An encysted tumour, the contents of which are of a fatty consistence.

STEEL. *Chalybs.* The best, hardest, finest, and closest grained iron, combined with carbon by a particular process.

Steer's opodeldoc. See *Opodeldoc, Steer's.*

STE'LLA. (*a, æ.* f.; from στελλω, to appear a star.) A bandage with many crossings like a star.

STELLA'RIA. (*a, æ.* f.; from *stella*, a star: so named from the star-like appearance of its flowers.) The name of a genus of plants. Class, *Decandria;* Order, *Trigynia.* Stichwort.

STELLA'TÆ. The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of such as have stellate leaves, and quadrifid corollæ: mostly tetrandrous; as *Galium, Asperula, Rubia tinctorum,* &c.

STELLA'TUS. (From *stella*, a star.) Stellate: star-like. Applied to plants and parts of plants; as the nectary of the *Stapelia,* &c.

Stelochites. See *Osteocolla.*

Stem. See *Caulis,* and *Stipes.*

Stem-leaves. See *Caulinus.*

STE'MA. (From στημι, to stand.) The penis.

Stemless. See *Acaulis.*

Stemless milk-vetch. See *Astragalus excapus.*

Stenonis Ductus. See *Ductus stenonis.*

STENOTHO'RAX. (*ax, acis.* m.; from στενος, narrow, and θωραξ, the chest.) One who has a narrow chest.

STERCU'LIA. A genus of plants of the Class *Monodelphia;* and Order *Polyandria.*

STERCULIA URENS. This plant affords the Bassora gum. See *Bassora gum.*

STERILITY. (*Sterilitas, atis.* f.; from στειζος.) I. In *Physiology* and *Pathology,* sterility is the want of power to get or bear a child: hence it applies to both the male and female.

1. *Female sterility* is an inability to conceive offspring, — an imperfection or abolition of the conceptive power. In many instances this is a direct imbecility or want of tone, rather than a want of desire; and the common causes are, a life of intemperance of any kind, and especially of inordinate indulgence in sexual pleasures, a long continuance of the whites, or a paralytic affection of the generative organs. It has also been occasioned by injuries done to the loins or hypogastric region, and by over exertion in walking. The plan of treatment to be had recourse to, is similar to that recommended against sterility in males caused by debility.

Barrenness in females is often caused by organic derangement or structural defect, both natural and accidental. This may be of various kinds; for the vagina may be imperforate, and prohibit not only all intromission of semen, but an entrance of the penis itself. The ovaria may be defective, or even altogether wanting, or not duly developed, or destitute of ovula; or the fimbriæ may be defective, and incapable of grasping the ovum; or the Fallopian tube may be obstructed, or impervious, or wanting; in all which cases barrenness must necessarily ensue. These, however, are rare instances.

Barrenness is more frequently caused by a manifest retention, irregularity, or profusion of the menstrual secretion, producing the symptoms of chlorosis and amenorrhœa, or menorrhagia, which requires that the diseased state of the organs that form its seat should be removed. But there must also be a healthy degree of tone and energy in the conceptive organs, as well as of ease and quiet, in order that they should prove fruitful; and hence, whenever the menstrual flux is more frequently repeated than its natural course, or is thrown forth, even at its proper time, in great profusion, and, as is generally the case, intermixed with genuine blood, there is as little chance of conception as in difficult menstruation. The organs are too debilitated for the new process; and not unfrequently there is as little desire as there is elasticity. The cure of barrenness, under such circumstances, must depend on the cure of the particular kind of morbid affection that operates at the time, and lays the foundation for the disease.

Personal aversion, or want of appetency, also prohibit conception, though it is not altogether impossible that impregnation should take place from violence, rude or brutal force. Wherever there is a personal aversion, a coldness or reserve, instead of an appetency and pleasure — an irrespondence in the feelings of the female to those of the male, there is as little reason to hope for a parturient issue. There must be an orgastic shock or percussion sufficient to shock off an ovulum from its bed, and to urge the fine and irritable fimbriæ of the Fallopian tube to lay hold of it in the ovarium, and grasp it tight, by which alone a communication can be opened between this last organ and the ovarium, or the seed cannot reach home to its proper soil, and produce a harvest.

2. *Male sterility* is an inability to beget offspring. It is caused either by impotency, or by seminal misemission, or by copulative incongruity.

Impotency has often been called *anaphrodisia*, which, however, is variously used by medical writers, sometimes as importing a want of desire, sometimes inability, sometimes both, and sometimes a particular kind of inability resulting from weakness alone. Impotency is often the result of great weakness only, produced by excess of indulgence, long-continued gleet, or a paralytic affection of the generative organs; and it has resulted from injuries done to the loins and pelvis. Time, in these cases, often effects a cure, and tonics and stimulants are frequently useful, especially cold bathing; but when produced by a long life of debauchery, or by a paralytic condition of the nerves from accidents, the case is hopeless. Much has been written and said of aphrodisiacs, but there is no dependance to be placed on any one. Wine and vinous stimulants generally augment the state of which they were the original cause. Cantharides are frequently resorted to; but, like spirits and wine, they are now deservedly distrusted. Their effect, as a local stimulant, shows itself rather on the bladder and prostate gland than on the testes; and, as a general irritant, in increasing the heat and action of the whole system. Many of the verticillate plants, as mint and pennyroyal, have been tried in the concentrated state for the same purpose, but with different and even opposite effects in the hands of different practitioners. The best aphrodisiacs are warm and general tonics, as the stimulating bitters with chalybeates. Local stimulants, as blisters and electricity, have been found serviceable.

When impotency is caused by organic affection, the only chance of deriving benefit depends on the removal of the structural disease, or of any natural malformation.

Another cause of inability to beget offspring is what nosologists have termed *dyspermatismus*, or seminal misemission. Imperfection, or defective emission, is produced in several ways: from super-erection of the penis, or priapism, which, if caused by plethora or vascular fulness, is to be overcome by local bleedings, purgatives, and a slender diet; — by the incursion of an epileptic spasm, produced by sexual excitement during the intercourse; — by the discharge being ejected hastily, and without due adjustment, even before the vagina has been fairly entered, which, evincing great nervous irritability in a delicate habit, requires the use of tonics and chalybeates, a generous diet, and cold bathing; — by the discharge being unduly retarded, from hebitude of the genital organs, and hence not accomplished till the orgasm on the part of the female has subsided: this, which is called *bradyspermatismus*, requires tonics and local stimulants, especially electricity; — by the discharge being thrown back into the bladder before it reaches the extremity of the penis; which is called *dys-spermatismus refluus*. This is caused by some obstruction to the flow of the semen between the vesiculæ and glans, which is mostly a narrowing of the urethra, or stricture, and requires the removal of the cause of the obstruction.

II. In *Botany*. — See *Barren*.

STERNA'LGIA. (*a*, *æ*. f.; from στερνον, the sternum or chest, and αλγος, pain.) 1. Pain about the sternum, which is often very severe, and may arise from rheumatism, gout, dyspepsia, and other diseases.

2. A name of the pectoral angina. See *Angina pectoris*.

Sterno-cleido-hyoideus. See *Sterno-hyoideus*.

Sterno-cleido-mastoideus. *Sterno-mastoideus*, and *cleido-mastoideus*, of Albinus. *Mastoideus*, of Douglas and Cowper. A muscle, on the anterior and lateral part of the neck, which turns the head to one side, and bends it forward. It arises by two distinct origins: the anterior, tendinous and fleshy, from the top of the sternum near its junction with the clavicle; the posterior, fleshy, from the upper and anterior part of the clavicle. Both unite a little above the anterior articulation of the clavicle, to form one muscle, which runs obliquely upwards and outwards, to be inserted, by a thick strong tendon, into the mastoid process of the temporal bone, which it surrounds; and, gradually becoming thinner, is inserted as far back as the lambdoidal suture.

Sterno-costales. Vesalius considered these as forming a single muscle on each side, of a triangular shape; hence we find the name of *triangularis* adopted by Douglas and Albinus; but Verheyen, who first taught that they ought to be described as four or five distinct muscles, gave them the name of *sterno-costales*; and in this he is very properly followed by Winslow, Haller, and Lieutaud.

These muscles are situated at each side of the under surface of the sternum, upon the cartilages of the third, fourth, fifth, and sixth ribs. Their number varies in different subjects; very often there are only three, sometimes five, and even six, but most usually we find only four.

The lowermost of the sterno-costales, or what would be called the inferior portion of the triangularis, arises tendinous and fleshy from the edge and inner surface of the lower part of the cartilago ensiformis, where its fibres intermix with those of the diaphragm and transversalis abdominis. Its fibres run nearly in a transverse direction, and are inserted, by a broad thin tendon, into the inner surface of the cartilage of the sixth rib, and lower edge of that of the fifth.

The second and largest of the sterno-costales arises tendinous from the cartilago ensiformis and lower part of the sternum, laterally, and, running a little obliquely outwards, is inserted into the lower edge of the cartilage of the fifth, and sometimes of the fourth rib.

The third arises tendinous from the sides of the middle part of the sternum, near the cartilages of the fourth and fifth ribs, and, ascending obliquely outwards, is inserted into the cartilage of the third rib.

The fourth and uppermost, which is the most frequently wanting, arises tendinous from the beginning of the cartilage of the third rib and

the adjacent part of the sternum, and running almost perpendicularly upwards, is inserted by a thin tendon (which covers a part of the second internal intercostal) into the cartilage and beginning of the bony part of the second rib.

All these muscles are more or less intermixed with one another at their origin, and this probably occasioned them to be considered as one muscle. Fallopius informs us, that the plate Vesalius has given of them was taken from a dog, in which animal they are much larger than in man. Douglas has endeavoured to account for this difference, but his explanation is far from being satisfactory.

STE'RNO-HYOIDE'US. As this muscle arises from the clavicle, as well as from the sternum, Winslow calls it *sterno-cleido-hyoideus*. It is a long, flat, and thin muscle, situated obliquely between the sternum and os hyoides, behind the lower part of the mastoideus, and covering the *sterno-thyroideus* and the *hyo-thyroideus*. It arises, by very short tendinous fibres, from the cartilaginous part of the first rib, from the upper and inner part of the sternum, from the capsular ligament that connects that bone with the clavicle, and commonly from a small part of the clavicle itself; from thence, ascending along the anterior and lateral part of the neck, we see it united to its fellow, opposite to the inferior part of the larynx, by means of a thin membrane, which forms a kind of *linea alba*. After this the two muscles separate again, and each passing over the side of the thyroid cartilage, is inserted into the basis of the os hyoides, immediately behind the insertion of the last-described muscle.

Its use is to draw the os hyoides downwards.

Sterno-mastoideus. See *Sterno-cleido-mastoideus.*

STE'RNO-THYROIDE'US. This is flat and thin, like the sterno-hyoideus, but longer and broader. It is situated at the fore part of the neck, between the sternum and thyroid cartilage, and behind the sterno-hyoideus. It arises broad and fleshy from the upper and inner part of the sternum, between the cartilages of the first and second ribs, from each of which it receives some few fibres, as well as from the clavicle, where it joins with the sternum. From thence, growing somewhat narrower, it ascends, and, passing over the thyroid gland and the cricoid cartilage, is inserted tendinous into the lower and posterior edge of the rough line of the thyroid cartilage, immediately under the insertion of the sterno-hyoideus. Now and then a few of its fibres pass on to the os hyoides. Its use is to draw the thyroid cartilage, and consequently the larynx, downwards.

STE'RNUM. (*um, i.* n.) *Pectoris os.* The breast-bone. The sternum, os pectoris, or breast-bone, is the oblong, flat bone placed at the fore part of the thorax. The ossification of this bone in the fœtus beginning from many different points at the same time, we find it, in young subjects, composed of several bones, united by cartilages: but, as we advance in life, most of these cartilages ossify; and the sternum, in the adult state, is found to consist of three, and sometimes only of two pieces, the two lower portions being united into one; and very often, in old subjects, the whole is formed into one bone. But, even in the latter case, we may still observe the marks of its former divisions; so that, in describing the bone, we may very properly divide it into its upper, middle, and inferior portions.

The upper portion forms an irregular square, which, without much reason, has, by many writers, been compared to the figure of a heart as it is painted on cards. It is of considerable thickness, especially at its upper part. Its anterior surface is irregular, and slightly convex; posteriorly, it is somewhat concave. Its upper middle part is hollowed, to make way for the trachea. On each side, superiorly, we observe an oblong articulating surface, covered with cartilage in the recent subject, for receiving the ends of the clavicles. Immediately below this, on each side, the bone becomes thinner, and we observe a rough surface for receiving the cartilage of the first rib, and almost close to the inferior edge of this we find the half of such another surface, which, combined with a similar surface in the middle portion of the sternum, serves for the articulation of the cartilage of the second rib.

The middle portion is much longer, narrower, and thinner than the former; but is somewhat broader and thinner below than above, where it is connected with the upper portion. The whole of its anterior surface is slightly convex, and within it is slightly concave. Its edge, on each side, affords four articulating surfaces, for the third, fourth, fifth, and sixth ribs; and parts of articulating surfaces at its upper and lower parts, for the second and seventh ribs. About the middle of this portion of the sternum we sometimes find a considerable hole, large enough in some subjects to admit the end of the little finger. Sylvius seems to have been the first who described it. Riolanus and some others after him, have, without reason, supposed it to be more frequent in women than in men. In the recent subject it is closed by a cartilaginous substance; and, as it does not seem destined for the transmission of vessels, as some writers have asserted, we may, perhaps very properly, with Hunauld, consider it as an accidental circumstance, occasioned by an interruption of the ossification before the whole of this part of the bone is completely ossified.

The third and inferior portion of the sternum is separated from the former by a line, which is seldom altogether obliterated, even in the oldest subjects. It is smaller than the other parts of the bone, and descends between the ribs, so as to have been considered as an appendix to the rest of the sternum. From its shape, and it being constantly in a state of cartilage in young subjects, it has been commonly named *cartilago xiphoides, ensiformis*, or sword-like cartilage; though many of the ancients gave the name of xiphoides to the whole sternum, comparing the two first bones to the handle, and this appendix to the blade of the sword. The shape of this appendix varies in different subjects: in some it is longer and more pointed, in others shorter and more obtuse. Veslingius has seen it reaching as low as the navel, and incommoding the motion

of the trunk forwards. In general it terminates obtusely, or in a single point; sometimes, however, it is bifurcated; and Eustachius and Haller have seen it trifid. Very often we find it perforated, for the transmission of branches of the mammary artery. In the adult it is usually ossified and tipped with cartilage; but it very often continues cartilaginous through life, and Haller once found it in this state in a woman who died in her hundredth year.

The substance of the sternum, internally, is of a light, spongy texture, covered externally with a thin bony plate: hence it happens that this bone is easily fractured. From the description we have given of it, its uses may be easily understood. We have seen it serving for the articulation of seven true ribs on each side, and hence we shall find it of considerable use in respiration. We likewise observed, that it is articulated with each of the clavicles. It serves for the origin and insertion of several muscles; it supports the mediastinum; and, lastly, defends the heart and lungs; and it is observable, that we find a similar bone in almost all animals that have lungs, and even in such as have no ribs, of which latter we have an instance in the frog.

STERNUTAMENTO'RIA. (So called because the powdered flowers and roots have the property of exciting sneezing.) See *Achillea ptarmica*.

STERNUTAME'NTUM. (*um*, *i*. n.; from *sternuo*, to sneeze.) That which produces sneezing: snuff.

Sternutatio. See *Sneezing*.

STE'RTOR. (*or*, *oris*. m.) A snoring or snorting. A loud and deep sound produced in the larynx and fauces. In natural sleep snoring arises from the relaxation of the velum palati: in apoplexy it appears to arise chiefly from the accumulation of mucus in the air passages.

STE'THOSCOPE. (*Stethoscopus*, *i*. m.; from στῆθος, the chest, and σκοπεω, to explore.) An instrument invented by Läennec to aid auscultation. It is made of cedar wood, of a cylindrical form, about eleven inches long, and about an inch and a half in diameter. It has a cylindrical perforation throughout its whole length, and is divided into two parts, the only convenience of which is that of greater portability. The end of each part terminates in a funnel-shaped cavity, the one to receive the separate half of the instrument, and the other to receive the part acting as a stopper; which latter has a short pipe, made of brass, or silver, to enter the base of the cylinder. The instrument is used without the stopper, when employed to ascertain the state of respiration; and with it, either to examine the action of the heart, or the signs afforded by the voice, in certain states of disease affecting the lungs or pleural membrane. There are several modifications of the stethoscope, of which, perhaps the most convenient is one somewhat shorter than that above described, without any division in the middle, and furnished with rather a broad and very slightly concave ear-plate. In using this instrument, care is to be taken that it is kept perfectly flat upon the part to which it is applied, in order that the sound may not escape, nor air be admitted; for which purpose it is convenient to hold it at its lower part, while the other end (with the even surface) should be in close contact with the ear, so that the aperture of the instrument be in direct communication with the internal ear. Silk covering, as causing a cracking sort of noise, and thick dress, as obscuring the sound of respiration, should be avoided; but linen or flannel dress may remain on the person without disadvantage.

STHE'NIA. (*a*, *æ*. f.) A term employed by the followers of Dr. Brown, to denote that state of the body which disposes to inflammatory diseases, in opposition to those of debility, which arise from asthenia.

STHENIC. (From σθενος, strength.) A term applied by Brown to such diseases as he supposed to arise from accumulated excitability. See *Brunonian theory*.

STIBIA'LIS. (From *stibium*, antimony.) Antimonial: appertaining to antimony.

STI'BIC. (*Stibicus*; from *stibium* antimony.) Of or belonging to antimony.

STIBIC ACID. Berzelius's name for the yellow oxide of antimony.

STIBII ESSENTIA. Antimonial wine.

STI'BIOUS. *Stibiosus*. Antimonial.

STIBIOUS ACID. So Berzelius calls the white oxide of antimony.

STI'BIUM. (*um*. *ii*. n. *Stimmi*, στιμμι.) The ancient name of antimony. See *Antimony*.

STI'GMA. (*a*, *atis*. n. Στιγμα; from στιζω, to prick or to brand.) I. In *Pathology*, 1. A small red speck in the skin, occasioning no elevation of the cuticle. Stigmata are generally distinct, or apart from each other. They sometimes assume a livid colour, and are then termed *petechiæ* and *purpuræ*.

2. A natural mark or spot on the skin. See *Nævus maternus*.

II. In *Botany*, that part of the female organ of a plant which is placed at the summit of the style. It is an indispensable part of the fructification, and consists of a vast number of absorbing papillæ, rarely observable by the naked eye, but best seen in the *Mirabilis jalapa*. Botanists distinguish the following differences in the form of stigma: —

1. *Globose*; as in *Trachelium*.
2. *Capitate*, round, but flat below; as in *Sorbus* and *Vinca*.
3. *Acute*, ending in a point; as in *Piscidia*.
4. *Obtuse*; as in *Nigrina*.
5. *Clubbed*; as in *Genipi*.
6. *Emarginate*, cut; as in *Dentaria*.
7. *Peltate*; as in *Garcinia*.
8. *Uncinate*, acute and reflected; as in *Lantana*.
9. *Triangular*; as in *Linium candidum*.
10. *Trilobed*; as in *Tulipa Gesneriana*.
11. *Petaliform*; as in *Iris Germanica*.
12. *Convolute*; as in *Crocus*.
13. *Revolute*; as in *Leontodon*.
14. *Penicilliform*, resembling a pencil-brush; as in *Milium paspalium*.
15. *Perforate*; as in *Sloanea*.
16. *Concave*; as in *Viola*.
17. *Bifid*; as in *Menyanthes*.
18. *Trifid*; as in *Amaryllis*.
19. *Multifid*; as in *Cactus*.

20. *Striate;* as in *Papaver.*

21. *Plumose,* on each side like a hairy pen; as in grasses.

22. *Four-sided;* as in *Amyris.*

23. *Pubescent,* covered with hair; as in *Vicia.*

24. *Simple,* not differing from the style at its summit; as in *Galanthus* and *Hippuris.*

25. *Sessile,* on the germen: there being no style.

The stigma is always more or less moist with a peculiar viscid fluid, which in some plants is so conspicuous as to form a large drop, though never big enough to fall to the ground. This moisture is designed for the reception of the pollen, which explodes on meeting with it; and hence the seeds are rendered capable of ripening, which, though in many plants fully formed, they would not otherwise be.

STILBO'MA. (From στιλβω, to polish.) A cosmetic.

STILLICI'DIUM. (*um, ii.* n.; from *stillo,* to drop, and *cado,* to fall.) A strangury, or discharge of the urine, drop by drop. Also the pumping upon a part.

STI'MMI. Στιμμι. Antimony.

STIMULANT. (*Stimulans;* from *stimulo,* to stir up.) Possessed of the power of exciting the animal energy. Stimulants are divided into *general,* and *topical,* according as they affect the whole system or a particular part. Thus mercury taken internally is a general stimulant, mustard applied to the skin is a topical stimulant. Those general stimulants, the effect of which is very fugacious, are termed *diffusible* stimulants, as ether.

STI'MULUS. (*us, i.* m.; from στιγμος, *stigmulus,* per sync. *stimulus,* a sting or spur.) 1. In *Pathology* and *Physiology,* that which rouses the action or energy of a part.

2. In *Botany,* a sting, or a sharp-pointed substance, which conveys a poison into the part it penetrates; as that of the nettle.

Stinking lettuce. See *Lactuca virosa.*

STI'PES. (*es, itis.* m.; from the Greek, στυπος.) A stipe or stem of a fungus, fern, or palm.

STIPITA'TUS. Standing on a pillar or pedicle.

STI'PULA. (*a, æ.* f.) A leafy appendage to the proper leaves, or to their footstalks. In some instances they are so like unto leaves, that they are believed to be so, and can only be distinguished from leaves by their situation on the footstalk. Stipulæ are, —

1. *Solitary;* as in *Astragalus onobrychis.*

2. *In pairs;* as in *Lathyrus annuus.*

3. *Lateral,* on the side of the footstalk; as in *Lotus tetraphyllus.*

4. *Oppositifoliar,* in the side of the opposite leaves; as in *Trifolium pratense.*

5. *Extrafoliaceous,* external with respect to the leaf or footstalk; as in *Astragalus onobrychis.*

6. *Intrafoliaceous,* internal; as in *Morus nigra* and *alba.*

7. *Caducous,* falling off before the leaves are expanded; as in *Prunus avium.*

8. *Persistent,* remaining after the fall of the leaf; as in *Trifolium pratense.*

9. *Deciduous,* falling with the leaves; as in many stipulated plants.

10. *Spinescent,* thorny; as in *Robinia pseudacacia.*

11. *Sessile;* as in *Pisum sativum.*

12. *Adnate;* as in *Rosa canina.*

13. *Decurrent;* as in *Crotalaria sagittalis.*

14. *Sheathed;* as in *Hedysarum vaginale.*

15. *Lanceolate;* as in *Cistus helianthemum.*

16. *Subulate;* as in *Cassia glandulosa.*

17. *Sagittate;* as in *Pisum maritimum.*

18. *Lunate;* as in *Lathyrus tingitanus.*

19. *Ovate;* in *Ononis repens.*

20. *Cordate;* in *Ocymum sanctum.*

21. *Filiform;* in *Ononis mauritanica.*

22. *Foliaceous;* in *Sambucus ebulus.*

23. *Entire;* in *Vicia cracca.*

24. *Serrate;* in *Pisum sativum.*

25. *Ciliate;* in *Passiflora fœtida.*

26. *Toothed;* in *Orobus lathyroides.*

27. *Pinnatifid;* in *Viola tricolor.*

STIPULA'RIS. Stipular: belonging to the stipula of plants; as the *spina stipularis* of the *Mimosa nilotica* and *horrida.*

STITCH. A sharp spasmodic pain in the intercostal muscles, is vulgarly so called.

STŒ'CHAS. (*as, adis.* f.; from στοιχαδες, the islands on which it grew.) See *Lavendula.*

Stœchas arabica. See *Lavendula.*

Stœchas citrina. See *Gnaphalium.*

STO'LO. (*o, onis.* m.; a shoot, branch, or twig.) A sucker or scion. A runner which proceeds from the roots of some plants, and takes root in the earth. It is distinguished into a *supraterraneous,* which runs on the surface above ground, as in *Fragaria vesca* and *Potentilla reptans;* and *subterraneous,* which runs under the surface, as in *Triticum repens,* the stolos of which are erroneously taken for the roots.

STOLONI'FEROUS. *Stoloniferus.* Putting forth suckers.

STOMACA'CE. (*e, es.* f.; from στομα, the mouth, and κακος, evil.) *Cancrum oris. Gangrena oris.* Canker of the mouth. A fetor in the mouth, with a bloody discharge from the gums, which are ulcerated along their edges. The remedies for this disease are, acid gargles with myrrh, and the internal exhibition of mineral acids with bark or cascarilla; good food, especially a proper quantity of vegetables, and occasional purgatives; the cold bath, and walking exercise.

STO'MACH. (*Stomachus, i.* m.; στομαχος, from στομα, the mouth, and χεω, to pour.) *Ventriculus;* called also, *Anocœlia, Gaster,* and *Nedys.* A membraneous receptacle, situated in the epigastric region, which receives the food from the œsophagus. Its figure is somewhat oblong and round: it is largest on the left side, and gradually diminishes towards its lower orifice, where it is the least. Its superior orifice, where the œsophagus terminates, is called the *cardia;* the inferior orifice, where the intestine begins, the *pylorus.* The anterior surface is turned towards the abdominal muscles, and the posterior opposite the lumbar vertebræ. It has two curvatures: the first is called the great curvature of the stomach, and extends down

wards from one orifice to the other, having the omentum adhering to it; the second is the small curvature, which is also between both orifices, but superiorly and posteriorly. The stomach, like the intestinal canal, is composed of three coats or membranes: — 1. The *outermost*, which is very firm, and from the peritoneum. 2. The *muscular*, which is very thick, and composed of various muscular fibres; and, 3. The *innermost*, or *villous coat*, which is covered with exhaling and inhaling vessels, and mucus. These coats are connected together by cellular membrane. The glands of the stomach which separate the mucus are situated between the villous and muscular coat, in the cellular structure. The arteries of the stomach come chiefly from the cœliac artery, and are distinguished into the coronary, gastro-epiploic, and short arteries; they are accompanied by veins which have similar names, and which terminate in the vena portæ. The nerves of the stomach are very numerous, and come from the eighth pair and sympathetic nerve. The lymphatic vessels are distributed throughout the whole substance, and proceed immediately to the thoracic duct. The use of the stomach is to excite hunger and partly thirst, to receive the food from the œsophagus, and to retain it, till, by the motion of the stomach, the admixture of various fluids, and many other changes, it is rendered fit to pass the right orifice of the stomach, and be converted into chyle in the intestines.

Stomach, inflammation of. See *Inflammation of the stomach and intestines.*

STOMA'CHIC. (*Stomachicus*; from στομαχος, the stomach.) That which excites and strengthens the action of the stomach.

STOMA'CHICA PA'SSIO. A disorder in which there is an aversion to food; even the thought of it begets a nausea, anxiety, cardialgia, an effusion of saliva, and often a vomiting. Fasting is more tolerable than eating: if the patient be obliged to eat, a pain follows that is worse than hunger itself.

Stomachus. See *Stomach.*

Stone. See *Calculus.*

Stone-crop. See *Sedum acre.*

STONE-POCK. An acrid and hard pimple, which suppurates. The *acne indurata* of Bateman.

Storax. See *Styrax.*

Storax, liquid. See *Liquidambra.*

Storax liquida. See *Liquidambra.*

STORAX RUBRA OFFICINALIS. Cascarilla bark was formerly so called.

STORAX WHITE. The Peruvian balsam has been so called.

STOREY'S WORM CAKES. These consist of calomel and jalap made up into cakes, and coloured with vermilion.

Strabalismus. See *Strabismus.*

STRABI'SMUS. (*us, i.* m.; from στραβιζω, to squint.) Squinting. An affection of the eye, by which a person sees objects in an oblique manner, from the axis of vision being distorted. Dr. Cullen distinguishes three species: —

1. *Strabismus habitualis*, when from a custom of using only one eye.

2. *Strabismus commodus*, when one eye, in comparison with the other, from greater weakness, or mobility, cannot accommodate itself to the other.

3. *Strabismus necessarius*, when some change takes place in the situation or figure of the eye, or a part of it. The most likely way to overcome squinting, especially in children, is to blindfold the sound eye for a considerable part of the day, and thus force the affected eye into use, and a subserviency to the will.

Strabositas. See *Strabismus.*

STRA'MEN CAMELORUM. Camel's hay. See *Andropogon schænanthus.*

Strammonium. See *Stramonium.*

STRAMO'NIUM. (*um, ii.* n.; from *stramen*, straw: so called from its fibrous roots.) See *Datura stramonium.*

Stramonium officinale. See *Datura.*

Stramonium spinosum. See *Datura.*

STRA'NGALIS. (Στραγγαλις; from στραγγαλιζω, to strangle.) A hard, painful tumour in the breast, from obstruction of the flow of milk.

STRA'NGURY. (*Stranguria, æ.* f.; from στραγξ, a drop, and ουρον, urine.) A difficulty and pain in passing the urine, which is excreted by drops.

Strap-shaped. See *Ligulatus*, and *Linearis.*

STRATIOTES. (From στρατος, an army: so named from its supposed virtues in healing fresh wounds.) See *Achillea millefolium.*

Stratioticum. See *Achillea millefolium.*

Straw. See *Culmus.*

Strawberry. See *Fragaria.*

STREATHAM. A village in Surrey, where is a weak purging water, drunk to the amount of one, two, or more pints in a morning.

STRE'MMA. (*a, atis.* n. Στρεμμα; from στρεφω, to turn.) A strain or sprain of the parts about a joint.

STREPITOSUS MORBUS. A disease not uncommon among the Austrian Alps, in which emphysematous tumours arise on the neck, face, and arms, which, when not quite full of air, crepitate like a dry bladder. It is described by Paul de Sorbait. We do not hear of any such disease in the present day.

STRIA'TUS. Striate: scored. Applied to stems, seeds, &c.; as the stem of the *Œnanthe fistula*, and the seeds of the *Conium maculatum.*

STRI'CTURE. (*Strictura, æ.* f.) A diminution or contracted state of some tube or duct of the body; as the œsophagus, intestines, urethra, vagina, &c. It is either *organic*, that is, accompanied with actual thickening of the walls of the canal, or *spasmodic.*

STRI'CTUS. In botanical language, it means stiff and straight; as *Caulis strictus.*

STRIDOR DENTIUM. Grinding of the teeth. A common symptom during sleep in children affected with worms or other intestinal irritation. It occurs also in fevers, as a symptom of irritation of the brain.

STRI'GA. (*a, æ.* f.) A species of pubescence of plants, white, bristle-like, with broad bases, mostly decumbent; as in *Borago officinalis.*

STRI'GIL. *Strigilis.* An instrument to scrape

off the sweat during the gymnastic exercises of the ancients, and in their baths: *strigils* were made of metal, horn, or ivory, and were curved. Some were made of linen.

STRIGME'NTUM. The strigment, filth, or sordes scraped from the skin in baths and places of exercises.

STRIGO'SUS. Furnished with strigæ.

STROBILIFORM. *Strobiliformis.* In the form of a cone: applied to a spike.

STRO'BILUS. (*us, i.* m.) A cone. A species of pericarpium, or seed-vessel. A catkin hardened and enlarged into a seed-vessel: an example of which is in the *Pinus*, or fir. It is either *conic, cylindric, ovate, globose, squamose*, or *spurious*, consisting of membranaceous and not woody scales; as in *Origanum marjorana*.

STRO'NGYLUS. (*us, i.* m.) A genus of intestinal worms in Rudolphi's classification.

STRONGYLUS GIGAS. This species of worm is said to have been found in the human kidney.

STRO'NTIA. (*a, æ.* f.; so called because it was first found in a lead mine at Strontian, in Scotland.) A greyish white-coloured earth, found in combination with carbonic acid in the mineral called strontianite. It was discovered by Dr. Hope.

Pure strontia is of a greyish-white colour; a pungent, acrid taste; and, when powdered in a mortar, the dust that rises irritates the lungs and nostrils. Its specific gravity approaches that of barytes. It requires rather more than 160 parts of water at 60° to dissolve it; but of boiling water much less. On cooling, it crystallises in thin, transparent, quadrangular plates, generally parallelograms, seldom exceeding a quarter of an inch in length, and frequently adhering together. The edges are most frequently bevelled from each side. Sometimes they assume a cubic form. These crystals contain about ·68 of water; are soluble in 51·4 times their weight of water at 60°, and in little more than twice their weight of boiling water. They give a blood red colour to the flame of burning alkohol. The solution of strontia changes vegetable blues to a green. Strontia combines with sulphur either in the wet or dry way, and its sulphuret is soluble in water.

In its properties, strontia has a considerable affinity to baryta. It differs from it chiefly in being infusible, much less soluble, of a different form, weaker in its affinities, and not poisonous. Its saline compounds afford differences more marked.

The basis of strontia is *strontium*, a metal first procured by Sir H. Davy in 1808, precisely in the same manner as barium, to which it is very analogous, but has less lustre. It appeared fixed, difficultly fusible, and not volatile. It became converted into strontia by exposure to air, and, when thrown into water, decomposed it with great violence, producing hydrogen gas, and making the water a solution of strontia. By igniting the mineral strontianate intensely with charcoal powder, strontia is cheaply procured.

STRO'NTIUM. (*um, ii.* n.) The metallic base of strontia. See *Strontia*.

STROPHI'OLUM. (*um, i.* n.) A little curved gland-like part near the scar or base of some seeds, as that of *Asarum*; but especially in several papilionaceous genera, as *Ulex*, *Spartium*, &c.

STRO'PHOS. (From στρεφω, to twist.) Tormina, or griping pains of the bowels.

STRO'PHULUS. (*us, i.* m.) A papular eruption peculiar to infants, and exhibiting a variety of forms, which are described by Dr. Willan under the titles of *intertinctus, albidus, confertus, volaticus*, and *candidus*.

1. *Strophulus intertinctus*, usually called the *red gum*, and, by the French, *efflorescence benigne*. The papulæ characterising this affection rise sensibly above the level of the cuticle, are of a vivid red colour, and commonly distinct from each other. Their number and extent varies much in different cases. They appear most constantly on the cheeks, fore-arm, and back of the hand, but are sometimes diffused over the whole body. The papulæ are, in many places, intermixed with stigmata, and often with red patches of a larger size, which do not, however, occasion any elevation of the cuticle. A child's skin, thus variegated, somewhat resembles a piece of red printed linen; and hence this eruption was formerly called the *red gown*, a term which is still retained in several counties of England, and may be found in old dictionaries. Medical writers have changed the original word for one of a similar sound, but not more significant. The strophulus intertinctus has not, in general, any tendency to become pustular; a few small pustules, containing a straw-coloured, watery fluid, occasionally appear on the back of the hand, but scarcely merit attention, as the fluid is always reabsorbed in a short time, without breaking the cuticle. The eruption usually terminates in scurf, or exfoliation of the cuticle: its duration, however, is very uncertain: the papulæ and spots sometimes remain for a length of time, without an obvious alteration; sometimes disappear and come out again daily; but, for the most part, one eruption of them succeeds another, at longer intervals, and with more regularity. This complaint occurs chiefly within the two first months of lactation. It is not always accompanied with, or preceded by, any disorders of the constitution, but appears occasionally in the strongest and most healthy children. Some authors connect it with aphthous ulcerations common in children, supposing the latter to be a part of the same disease diffused along the internal surfaces of the mouth and intestines. The fact, however, seems to be, that the two affections alternate with each other: for those infants who have the papulous eruption on the skin are less liable to aphthæ; and, when the aphthæ take place to a considerable degree, the skin is generally pale and free from eruption. The strophulus intertinctus is, by most writers, said to originate from an acidity, or acrimonious quality of the milk taken into a child's stomach, communicated afterwards to the blood, and stimulating the cutaneous excretories. This opinion might, without difficulty, be proved to have little foundation. The predisposition to the complaint may be

deduced from the delicate and tender state of the skin, and from the strong determination of blood to the surface, which evidently takes place in infants. The papulous eruption is, in many cases, connected with a weak, irritable state of the alimentary canal, and consequent indigestion. For if it be by any means suddenly repelled from the surface, diarrhœa, vomiting, spasmodic affections of the bowels, and often general disturbance of the constitution, succeed; but as soon as it re-appears, those internal complaints are wholly suspended. Dr. Armstrong and others have particularly noted this reciprocation, which makes the red gum, at times, a disease of some importance, though in its usual form it is not thought to be in any respect dangerous. On their remarks a necessary caution is founded, not to expose infants to a stream of very cold air, nor to plunge them unseasonably in a cold bath. The most violent, and even fatal, symptoms have often been the consequence of such imprudent conduct.

2. The *Strophulus albidus*, by some termed the *white gum*, is merely a variety of strophulus intertinctus, but deserves some notice on account of the different appearance of its papulæ. In place of those described as characterising the red gum, there is a number of minute whitish specks, a little elevated, and sometimes, though not constantly, surrounded by a slight redness. These papulæ, when their tops are removed, do not discharge any fluid; it is, however, probable that they are originally formed by the deposition of a fluid, which afterwards concretes under the cuticle. They appear chiefly on the face, neck, and breast, and are more permanent than the papulæ of the red gum. In other respects, they have the same nature and tendency, and require a similar plan of treatment. Although a distinctive name has been applied to this eruption, when occurring alone, yet it is proper to observe, that, in a great number of cases, there are red papulæ and spots intermixed with it, which prove its connection with the strophulus intertinctus.

3. The *Strophulus confertus*. An eruption of numerous papillæ, varying in their size, appears on different parts of the body in infants, during dentition, and has thence been denominated the *tooth-rash*. It is sometimes also termed the *rank red gum*. About the fourth or fifth month after birth, an eruption of this kind usually takes place on the cheeks and sides of the nose, extending sometimes to the forehead and arms, but rarely to the trunk or body. The papulæ on the face are smaller, and set more closely together than in the red gum; their colour is not so vivid, but they are generally more permanent. They terminate at length with slight exfoliations of the cuticle, and often appear again in the same places, a short time afterwards. The papulæ which, in this complaint, occasionally appear on the back or loins, are much larger, and somewhat more distant from each other, than those on the face. They are often surrounded by an extensive circle of inflammation, and a few of them contain a semi-pellucid watery fluid, which is reabsorbed when the inflammation subsides. In the seventh or eighth month, the strophulus confertus assumes a somewhat different form; one or two large irregular patches appear on the arms, shoulder, or neck; in which the papulæ are hard, of a considerable size, and set so close together that the whole surface is of a high red colour. Most commonly the fore-arm is the seat of this eruption, the papulæ rising first on the back of the hand, and gradually extending upwards along the arm. Sometimes, however, the eruption commences at the elbow, and proceeds a little upwards and downwards on the outside of the arm. It arrives at its height in about a fortnight: the papulæ then begin to fade, and become flat at the top; afterwards the cuticle exfoliates from the part affected, which remains discoloured, rough, and irregular, for a week or two longer.

An obstinate and very painful modification of this disease takes place, though not often, on the lower extremities. The papulæ spread from the calves of the legs to the thighs, nates, loins, and round the body, as high as the navel: being very numerous and close together, they produce a continuous redness over all these parts.

The cuticle presently becomes shrivelled, cracks in various places, and finally separates from the skin in large pieces. During this process a new cuticle is formed, notwithstanding which the complaint recurs in a short time, and goes through the same course as before. In this manner successive eruptions take place, during the course of three or four months, and perhaps do not cease till the child is one year old, or somewhat more. Children necessarily suffer great uneasiness from the heat and irritation occasioned by so extensive an eruption; yet, while they are affected with it, they often remain free from any internal or febrile complaint. This appearance should be distinguished from the intertrigo of infants, which exhibits an uniform, red, smooth, shining surface, without papulæ; and which affects only the lower part of the nates and inside of the thighs, being produced by the stimulus of the urine, &c. with which the child's clothes are almost constantly wetted. The strophulus confertus, where the child is otherwise healthy, is generally ascribed to a state of indigestion, or some feverish complaint of the mother or nurse. Dr. Willan, however, asserts that he has more frequently seen the eruption when no such cause was evident. It may, with more probability, be considered as one of the numerous symptoms of irritation, arising from the inflamed and painful state of the gums in dentition: since it always occurs during that process, and disappears soon after the first teeth have cut the gums.

4. The *Strophulus volaticus* is characterised by an appearance of small circular patches, or clusters of papulæ, arising successively on different parts of the body. The number of papulæ in each cluster is from six to twelve. Both the papulæ and their interstices are of a high red colour. These patches continue red, with a little heat or itching, for about four days, when they turn brown, and begin to exfoliate.

As one patch declines, another appears at a small distance from it; and in this manner the complaint often spreads gradually over the face, body, and limbs, not terminating in less than three or four weeks. During that time the child has sometimes a quick pulse, a white tongue, and seems uneasy and fretful. In many cases, however, the eruption takes place without any symptoms of internal disorder. The above complaint has been by some writers denominated *ignis volaticus infantum*. Under this title Astruc and Lorry have described one of the forms of crusta lactea, in which a successive eruption of pustules takes place on the same spot, generally about the mouth or eyes, in children of different ages, and sometimes in adults. The *maculæ volaticæ infantum* mentioned by Wittichius, Sennertus, and Sebizeus, agree in some respects with the strophulus volaticus; but they are described by other German authors as a species of erysipelas, or as irregular efflorescences affecting the genitals of infants, and often proving fatal. The strophulus volaticus is a complaint by no means frequent. In most cases which have come under Dr. Willan's observation, it appeared between the third and sixth month; in one instance, however, it occurred about ten days after birth, and continued three weeks, being gradually diffused from the cheeks and forehead to the scalp, afterwards to the trunk of the body and to the extremities: when the patches exfoliated, a red surface was left, with a slight border of detached cuticle.

5. *Strophulus candidus.* In this form of strophulus, the papulæ are larger than in any of the foregoing species. They have no inflammation round their base; their surface is very smooth and shining, whence they appear to be of a lighter colour than the adjoining cuticle. They are diffused, at a considerable distance from each other, over the loins, shoulders, and upper parts of the arms: in any other situation they are seldom found.

This eruption affects infants about a year old, and most commonly succeeds some of the acute diseases to which they are liable. Dr. Willan has observed it on their recovery from a catarrhal fever, and after inflammation of the bowels or lungs. The papulæ continue hard and elevated for about a week, then gradually subside and disappear.

STROUGHTON'S ELIXIR. An aromatic tincture made with gentian, serpentaria, orange-peel, cardamoms, &c.

STRU'MA. (*a*, *æ*. f. Dr. Good thinks this word is most probably derived from *στρωμα*, congestion or coacervation, or from *struo*, to heap up, or *à struendo*, because they grow insensibly.) 1. Generally applied to scrofula. See *Scrofula*.

2. Bronchocele, or an induration of the thyroid gland.

STRU'MOUS. (*Strumosus*; from *struma*, scrofula.) Of the nature of scrofula.

STRUMUS. An obsolete name of the berry bearing chickweed, which was supposed to be efficacious in the cure of scrofula. See *Cucubalus bacciferus*.

STRU'THIUM. (*um*, *i*. n.; from *στρουθος*, a sparrow: so named from the resemblance of its flowers to an unfledged sparrow.) The masterwort. See *Imperatoria ostruthium*.

STRY'CHNIA. (*a*, *æ*. f.; so called, because it is obtained from the *Strychnos*.) Strychnine. An alkaline substance obtained from the bean of the *Strychnos nux vomica* by the following process: — The bean is rasped down as small as possible. It is then exposed to the action of nitric ether in a Papin's digester. The residue, thus deprived of a quantity of fatty matter, is digested in alkohol as long as that re-agent is capable of dissolving any thing. The alkoholic solutions are evaporated to dryness, and the residue redissolved in water. Caustic potash being dropped into the solution, a white crystalline precipitate falls, which is strychnia. It is purified by washing it in cold water, dissolving it in alkohol, and crystallising it. Strychnia is obtained likewise by boiling the infusion of the bean with magnesia, in the same manner as Robiquet had obtained morphia from the infusion of opium.

Strychnia exists in the St. Ignatius' bean nearly free from brucia: this bean, therefore, is the preferable source from which to obtain strychnia; but it is very rare in commerce.

The properties of strychnia, when in a state of purity, are as follows: —

It is crystallised in very small four-sided prisms, terminated by four-sided low pyramids. It has a white colour; its taste is intolerably bitter, leaving a metallic impression in the mouth. It is destitute of smell. It is not altered by exposure to the air. It is neither fusible nor volatile, except at temperatures at which it undergoes decomposition. It is very little soluble in cold water, 100,000 parts of that liquor dissolving only 15 parts of strychnia; but it dissolves in 2,500 times its weight of boiling water. A cold solution of strychnia in water may be diluted with 100 times its volume of that liquid without losing its bitter taste.

The action of strychnia on the animal economy is precisely analogous to that of the alkoholic extract of nux vomica, only much more powerful. Half a grain blown into the throat of a rabbit, has produced trismus in two minutes, and death in five: and the eighth of a grain taken into the stomach has proved fatal to a strong dog.

In exceedingly minute doses strychnia has been found a very useful medicine, especially in paralytic cases, and it appears preferable to the extract of nux vomica, as being of more uniform strength. Dr. Ryan, who has used it very extensively, speaks in high terms of its efficacy in a variety of nervous diseases. The dose is $\frac{1}{12}$ of a grain morning and evening, repeated more frequently as the patient gets accustomed to it. Dr. Ryan has met with few patients who would bear more than $\frac{5}{12}$ of a grain in the course of a day.

Strychnine. See *Strychnia*.

STRYCHNOMA'NIA. (*a*, *æ*. f.; from *στρυχνος*, nightshade, and *μανια*, madness.) So the ancients called the disorder produced by eating the deadly nightshade.

STRY'CHNOS. (*os*, *i.* m.; an ancient name which occurs in Pliny and Dioscorides, derived from *στρωννυμι*, to overthrow, and applied most probably from the overpowering narcotic quality of the plant to which it was assigned, *στρυχνος* of the Greeks being a kind of nightshade. Linnæus adopted this name for the present genus on account of the analogy of its narcotic properties with the plant of the ancients. Some derive it from *στρυχω*, to torment: from its properties of producing insanity.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia*.

This species affords the lignum colubrinum, or snake wood. It is poisonous. Its taste is very bitter. It has been esteemed as an anthelmintic, febrifuge, and astringent, but is not used in the practice of the present day.

STRYCHNOS NUX VOMICA. The systematic name of the tree the seed of which is called the poison-nut. *Nux vomica*. *Nux metella*. The *nux vomica*, *lignum colubrinum*, and *faba sancti Ignatii*, have long been known in the Materia Medica as narcotic poisons, brought from the East Indies, while the vegetables which produced them were unknown, or at least not botanically ascertained.

By the judicious discrimination of Linnæus, the nux vomica was found to be the fruit of the tree described and figured in the *Hortus malabaricus*, under the name of *Caniram cucurbitifera malabariensis*, of Plukenet, now called *Strychnos nux vomica*.

To this genus, also, but upon evidence less conclusive, he likewise justly referred the colubrinum. But the faba sancti Ignatii he merely conjectured might belong to this family, as appears by the query, *An Strychni species?* which subsequent discoveries have decided in the negative; for in the Supp. Plant. it constitutes the new genus *Ignatia*, which Loureiro has lately confirmed, changing the specific name *amara* to that of *philippinica*. The strychnos and ignatia are, however, nearly allied, and both rank under the order *Solanaceæ*. See *Ignatia amara*.

Dr. Woodville has inquired thus far into the botanical origin of these productions, from finding that, by medical writers, they are generally treated of under the same head, and in a very confused and indiscriminate manner. The seed of the fruit, or berry of this tree, *Strychnos nux vomica*, is the officinal nux vomica: it is flat, round, about an inch broad, and near a quarter of an inch thick; with a prominence in the middle on both sides, of a grey colour, covered with a kind of woolly matter; and internally hard and tough like horn. To the taste it is extremely bitter, but has no remarkable smell. It consists chiefly of a gummy matter, which is moderately bitter; the resinous part is very inconsiderable in quantity, but intensely bitter; hence rectified spirit has been considered as its best menstruum.

Nux vomica is one of the most powerful of the vegetable poisons, and is of the narcotico-acrid kind. It proves fatal to dogs in a very short time, as appears by various authorities. Hillefeld and others found that it also poisoned hares, foxes, wolves, cats, rabbits, and even some birds, as crows and ducks; and Loureiro relates, that a horse died in four hours after taking a drachm of the seed in a half roasted state.

The effects of this drug upon different animals, and even upon those of the same species, appear to be rather uncertain, and not always in proportion to the quantity of the poison given. With some animals it produces its effects almost instantaneously; with others, not till after several hours, when laborious respiration, followed by torpor, tremblings, coma, and convulsions, usually precede the fatal spasms, or tetanus, with which this drug commonly extinguishes life.

From four cases related of its mortal effects upon human subjects, we find the symptoms corresponded nearly with those which we have here mentioned of brutes. As no visible effect is produced on the stomach or intestines, except when the dose is very large, it appears that the nux vomica acts immediately upon the nervous system, and destroys life by the virulence of its narcotic influence.

The quantity of the seed necessary to produce this effect upon a strong dog, as appears by experiments, need not to be more than a scruple; a rabbit was killed by five, and a cat by four grains: and of the four persons to whom we have alluded, and who unfortunately perished by this deleterious drug, one was a girl ten years of age, to whom fifteen grains were exhibited at twice for the cure of an ague. Loss, however, tells us, that he took one or two grains of it in substance, without discovering any bad effect; and that a friend of his swallowed a whole seed without injury.

From the time of Gesner the nux vomica has been recommended by a succession of authors, as an antidote to the plague, as a febrifuge, as a vermifuge, and as a remedy in mania, hypochondriasis, hysteria, rheumatism, gout, and canine madness. In Sweden, it was successfully used in dysentery; but Bergius, who tried its effects in this disease, says, that it suppressed the flux for twelve hours, which afterwards returned again. A woman, who took a scruple of this drug night and morning, two successive days, is said to have been seized with convulsions and vertigo, notwithstanding which the dysenteric symptoms returned, and the disorder was cured by other medicines; but a pain in the stomach, the effect of the nux vomica, continued afterwards for a long time.

Bergius, therefore, thinks it should only be administered in the character of a tonic and anodyne, in small doses (from five to ten grains), and not till after proper laxatives have been employed. Loureiro recommends it as a valuable internal medicine in fluor albus; for which purpose he roasts it till it becomes perfectly black and friable, which renders its medicinal use safe, without impairing its efficacy. It is said to have been used successfully in the cure of agues, and has also been reckoned a specific in pyrosis, or water-brash. It is in different cases from the above, however, that the nux vomica maintains its reputation in the present day; namely, those of disordered innervation, and especially paralysis. The alcoholic extract is

the form in which it is most frequently given. The dose of this is from half a grain to a grain, given, at first, twice a day, and afterwards more frequently. The dose of the powdered nut is five grains, gradually increased to a scruple, or half a drachm. The nux vomica is now generally superseded by its active principle, the strychnia, which possesses all its virtues in a highly concentrated form. See *Strychnia*.

STRYCHNOS SANCTI IGNATII. The plant which produces the faba sancti Ignatii, now referred to the genus *Ignatia*. See *Ignatia amara*.

STRYCHNOS TIEUTE. This species produces the *upas tieuté*, one of the strong Java poisons. See *Upas*.

STRYCHNOS VOLUBILIS. This tree was supposed to afford the Jesuit's bean. See *Ignatia amara*.

Stupe. See *Stupha*.

STUPEFA'CIENT. (*Stupefaciens*; from *Stupefacio*, to stupify.) Of a stupifying quality.

STU'PHA. (*a*, *æ*. f.; στυππη; στυππειον.) *Stupa*. *Stuppa*. A stupe. A piece of cloth, or flax, soaked in a warm liquid and applied as a fomentation.

STU'POR. (*or*, *oris*. m.; from *stupeo*, to be senseless.) Insensibility.

Stuppa. See *Stupha*.

Sturgeon. See *Acipensor sturio*.

STUTTERING. A high degree of stammering, which is a nervousness, influencing the muscles of speech.

STY. (This vernacular term, or, as it is sometimes written, *stian*, is to be met with in the earlier writers, who derive it from the Saxons, in which *stihan* signifies a "rising, springing up, or ascent.") See *Hordeolum*.

STY'GIA. (From *Styx*, a name given by the poets to one of the rivers in hell.) A water made from sublimate, and directed in old dispensatories, was so called on account of its poisonous qualities. A name of the *aqua regia*, also, from its corrosive qualities.

STY'LIFORM. (*Styliformis*; from *stylus*, a bodkin, and *forma*, a likeness.) Shaped like a bodkin, or style. Applied to processes of bones, and parts of plants.

STYLI'SCUS. (From στυλος, a bodkin.) A tent made in the form of a bodkin.

STY'LO. Names compounded of this word belong to muscles which are attached to the styloid process of the temporal bone.

Stylo-cerato-hyoideus. See *Stylo-hyoideus*.

Stylo-chondro-hyoideus. See *Stylo-hyoideus*.

STYLO-GLOSSUS. A muscle situated between the lower jaw and os hyoides laterally, which draws the tongue aside and backwards. It arises, tendinous and fleshy, from the styloid process, and from the ligament which connects that process to the angle of the lower jaw, and is inserted into the root of the tongue, runs along its sides, and is insensibly lost near its tip.

STYLO-HYOIDEUS. A muscle situated between the lower jaw and os hyoides laterally, which pulls the os hyoides to one side, and a little upwards. It is a small, thin, fleshy muscle, situated between the styloid process, and os hyoides, under the posterior belly and middle tendon of the digastricus, near the upper edge of that muscle. It arises, by a long thin tendon, from the basis and posterior edge of the styloid process, and, descending in an oblique direction, is inserted into the lateral and anterior part of the os hyoides, near its horn. The fleshy belly of this muscle is usually perforated on one or both sides, for the passage of the middle tendon of the digastricus. Sometimes, though not always, we find another smaller muscle placed before the stylo-hyoideus, which, from its having nearly the same origin and insertion, and the same use, is called *stylo-hyoideus alter*. It seems to have been first known to Eustachius: so that Douglas was not aware of this circumstance when he placed it amongst the muscles discovered by himself. It arises from the apex of the styloid process, and sometimes by a broad and thin aponeurosis, from the inner and posterior part of the angle of the lower jaw, and is inserted into the appendix, or little horn of the os hyoides. The use of these muscles is to pull the os hyoides to one side, and a little upwards.

Stylo-hyoideus alter. See *Stylo-hyoideus*.

STYLO-MASTOID FORAMEN. *Foramen stylo-mastoideum*. A hole between the styloid and mastoid process of the temporal bone, through which the portio dura of the auditory nerve passes to the temples.

STYLO-PHARYNGEUS. A muscle situated between the lower jaw and os hyoides laterally which dilates and raises the pharynx and thyroid cartilage upwards. It arises, fleshy, from the root of the styloid process, and is inserted into the side of the pharynx and back part of the thyroid cartilage.

STY'LUS. (*us*, *i*. m.) I. A surgical instrument called a probe.

II. The style or shaft of a flower, which proceeds from the germen, and bears the stigma. It is, —

1. *Filiform*, in *Jasminum*, and *Zea mays*.
2. *Linear*, in *Orobus*.
3. *Subulate*, thicker below than towards the apex; as in *Geranium*.
4. *Clavate*, thicker at its summit than toward its base; as in *Leucojum vernum*.
5. *Triangular*, in *Pisum*.
6. *Bifid*, in *Polygonum persicaria*.
7. *Trifid*, in *Bryonia* and *Momordica*.
8. *Dichotomous*, divided into two, which again bifurcate; as in *Cordia*.
9. *Long*, much more so than the stamina; as in *Campanula* and *Dianthus*.
10. *Persistent*, not going off after the fecundation of the germen; as *Sinapis*.

STYMATO'SIS. (*is*, *is*. f.; from στυω, to have a priapism.) A violent erection of the penis, with a bloody discharge.

STYPTE'RIA. (From στυφω, to bind: so called from its astringent properties.) Alum.

STY'PTIC. (*Stypticus*; from στυφω, to constringe.) A term applied to those substances which possess the power of stopping hæmorrhages, such as turpentine, alum, &c.

STYPTICUM HELVETII. *Helvetius's styptic*. A preparation, an account of which was published by John Frederick Helvetius, the chemist. It consisted of iron filings and tarta made up to a proper consistence with Frenc

brandy. It long enjoyed reputation on the Continent, and was afterwards revived in England under the name of *Eaton's styptic*, which, however, is now generally made with the sulphate of iron. See *Eaton's styptic*.

STYRACI'FLUA. (From *styrax*, storax, and *fluo*, to flow.) See *Liquidambra*.

STY'RAX. (*ax*, *acis*. m. and f.; from στυραξ, a reed, in which it was used to be preserved.) 1. The name of a genus of plants in the Linnæan system. Class, *Decandria*; Order, *Monogynia*.

2. The pharmacopœial name of the *Styrax calamita*.

Styrax alba. See *Myroxylon peruiferum*.

STYRAX BENZOIN. The systematic name of the tree which affords the gum benzoin. This substance has received the following names: — *Benzoë*. *Benjoinum*. *Assa dulcis*. *Assa odorata*. *Liquor Cyreniacus*. *Balzoinum*. *Benzoin*. *Benjui*. *Benjuin*. It is classed, by modern chemists, among the balsams. There are two kinds of benzoin: *benzoe amygdaloides*, which is formed of white tears, resembling almonds, united together by a brown matter; and *common benzoin*, which is brown and without tears. The tree which affords this balsam, formerly called *Laurus benzoin*, *Benzoifera*, and *Arbor benenici*, is the *Styrax benzoin — foliis oblongis acuminatis, subtus tomentosis, racemis compositis longitudine foliorum*, of Dryander, from which it is obtained by incisions. The benzoin of the shops is usually in very large brittle masses. When chewed it imparts very little taste, except that it impresses on the palate a slight sweetness; its smell, especially when rubbed or heated, is extremely fragrant and agreeable. Gum benjamin was analysed by Brande. The products obtained by distillation were, from 100 grains, benzoic acid, 9 grains; acidulated water, 5·5: butyraceous and empyreumatic oil, 60; brittle coal, 22; and a mixture of carburetted hydrogen and carbonic acid gas, computed at 3·5. On treating the empyreumatic oil with water, however, 5 grains more of acid were extracted, making 14 in the whole.

From 1500 grains of benzoin, Bucholz obtained 1250 of resin; 187 benzoic acid; 25 of a substance similar to balsam of Peru; 8 of an aromatic substance soluble in water and alkohol; and 30 of woody fibres and impurities.

Ether, and sulphuric and acetic acids, dissolve benzoin; so do solutions of potash and soda. Nitric acid acts violently on it, and a portion of artificial tannin is formed. Ammonia dissolves it sparingly. Its preparations are much esteemed against inveterate coughs and pthisical complaints unattended with much fever; it has also been used as a cosmetic, and in the way of fumigation, for the resolution of indolent tumours. The acid of benzoin is employed in the *tinctura camphoræ composita*, and a tincture is directed to be made of the balsam. See *Benzoic acid*.

STYRAX CALAMI'TA. Storax in the cane: because it was formerly brought to us in reeds or canes. See *Styrax officinalis*.

STYRAX COLATA. Strained storax.

Styrax liquida. See *Liquidambra*.

STYRAX OFFICINALIS. The systematic name of the tree which affords the solid storax. Officinal storax. *Styrax officinalis — foliis ovatis, subtus villosis, racemis simplicibus, folio brevioribus*, of Linnæus. There are two kinds of storax to be found in the shops: the one is usually in irregular compact masses, free from impurities, of a reddish-brown appearance, and interspersed with whitish tears, somewhat like gum ammoniac, or benzoin; it is extremely fragrant, and, upon the application of heat, readily melts. This has been called *storax in lump*; *red storax*; and, when in separate tears, *storax in tears*. The other kind, which is called the *common storax*, is in large masses, very light, and bears no external resemblance whatever to the former storax, as it seems almost wholly composed of dirty saw-dust, caked together by resinous matter. Storax was formerly used in catarrhal complaints, coughs, asthmas, obstructions, &c. In the present practice it is almost totally disregarded, notwithstanding it is an efficacious remedy in nervous diseases.

STYRAX RUBRA. Red storax, or storax in the tear.

Subacetas cupri. See *Æruginis*.

Subacetate of copper. See *Æruginis*.

SUBALA'RIS VENA. The vein of the axilla.

Subcarbonas potassæ. See *Potassæ carbonas*.

Subcarbonas ferri. See *Ferri Sesquioxydum*.

Subcarbonas plumbi. See *Plumbum*.

SUBCA'RBONATE. *Subcarbonas*. A carbonate in which the base predominates.

SUBCARTILAGINOUS (*Subcartilaginosus*; from *sub*, under, and *cartilago*, a cartilage.) Of a structure approaching to that of cartilage.

SUBCLA'VIAN. (*Subclaviculus*; from *sub*, beneath, and *clavicula*, the clavicle.) That which is, or passes, under the clavicle.

SUBCLAVIAN ARTERY. The right subclavian arises from the arteria innominata, and proceeds under the clavicle to the axilla. The left subclavian arises from the arch of the aorta, and ascends under the left clavicle to the axilla. The subclavians in their course give off the internal mammary, the inferior thyroid, the vertebral, the cervicalis superficialis, the superior intercostal, and the suprascapular.

SUBCLAVIAN VEIN. This receives the blood from the veins of the arm, and runs into the vena cava superior.

SUBCLA'VIUS. (From *sub*, under, and *clavicula*, the collar-bone; as being situated under the clavicle or collar-bone.) *Subclavianus*. A muscle situated on the anterior part of the thorax, which pulls the clavicle downwards and forwards. It arises, tendinous, from the cartilage that joins the first rib to the sternum, is inserted, after becoming fleshy, into the inferior part of the clavicle, which it occupies from within an inch of the sternum as far outwards as to its connection, by a ligament, with the coracoid process of the scapula.

SUBCRURÆ'US. A name of two little muscular slips, sometimes found under the cruræus: they are inserted into the capsular ligament, which they pull up.

SUBCUTA'NEOUS. (*Subcutaneus*; from

sub, under, and *cutis*, the skin.) Under the skin; a name given to the platysma myoides muscle, and to some nerves, vessels, glands, &c. which are very superficial.

Subcutaneous glands. *Glandulæ subcutaneæ.* These are sebaceous glands lying under the skin, which they perforate by their excretory ducts.

Suber. Cork. See *Quercus suber.*

SUBE'RIC. (*Subericus*, from *suber*, cork.) Appertaining to cork.

Suberic acid. *Acidum subericum.* A white pulverulent acid, obtained from cork, by nitric acid. It is not used as a medicine.

Subintrans febris. Frank gives this name to what is usually called an anticipating quotidian. See *Anticipans.*

Sublimame'ntum. (From *sublimo*, to lift up.) The pendulous substance which floats in the middle of the urine.

SU'BLIMATE. 1. Any thing which is sublimed. See *Sublimation.*

2. The corrosive sublimate is sometimes simply called *sublimate.*

Sublimate, corrosive. See *Hydrargyri bichloridum.*

SUBLIMA'TION. (*Sublimatio, onis.* f.; from *sublimo*, to raise or sublime.) A process by which volatile substances are raised by heat, and again condensed in a solid form. This chemical process differs from evaporation only in being confined to solid substances. It is usually performed either for the purpose of purifying certain substances, and disengaging them from extraneous matters; or else to reduce into vapour, and combine, under that form, principles which would have united with greater difficulty if they had not been brought to that state of extreme division.

As all fluids are volatile by heat, and consequently capable of being separated, in most cases, from fixed matters, so various solid bodies are subjected to a similar treatment. Fluids are said to distil, and solids to sublime, though sometimes both are obtained in one and the same operation. If the subliming matter concretes into a solid hard mass, it is commonly called a sublimate; if into a powdery form, flowers.

The principal subjects of this operation are, volatile alkaline salts; neutral salts, composed of volatile alkali and acids, as sal ammoniac; the salt of amber, and flowers of benzoin, mercurial preparations, and sulphur. Bodies of themselves not volatile are frequently made to sublime by the mixture of volatile ones; thus iron is carried over by sal ammoniac in the preparation of the flores martiales, or ferrum ammoniatum.

The fumes of solid bodies in close vessels rise but a little way, and adhere to that part of the vessel where they concrete.

Sublimis. See *Flexor brevis digitorum pedis*, and *Flexor sublimis perforatus.*

SUBLINGUA'LIS. (From *sub*, under, and *lingua*, the tongue.) Sublingual. A name given to parts immediately under the tongue.

Sublingual glands. *Glandulæ sublingualas. G. Bartholinianæ. G. Rivinianæ.* The glands which are situated under the tongue, and secrete saliva. Their excretory ducts are called *Rivinian* from their discoverer *Rivinus.*

SUBLUXA'TIO. (*o, onis.* f.; from *sub*, diminutive, and *luxatio*, a dislocation.) A sprain. A sprain is an injury of a joint in which it has been twisted or strained, in any direction further than its natural range of motion allows, but without actual dislocation of the bones. In every sprain, the ligaments of the joint are preternaturally stretched, and in severe ones they are often partially torn. Hence follows inflammation of the ligaments and the soft parts surrounding the joint, and in bad cases of the capsular ligament itself. Sprains are a very troublesome class of injuries, and will often keep a patient confined much longer than fractures or even dislocations.

In the treatment of sprains, the first indication is to allay inflammation; and where this is considerable the copious and repeated application of leeches is often required, with purgatives, and an antiphlogistic regimen, and sometimes general bloodletting. The local applications may consist of cold lotions or hot fomentations, according to circumstances. When all danger of inflammation is past, the joint is to be strengthened by friction with stimulating liniments, the application of bandages, &c. While acute inflammation prevails, perfect rest of the joint must be insisted on; when weakness merely is present, gentle exercise is serviceable.

SUBMERSION. (*Submersio;* from *submergo*, to sink under water.) Drowning. See *Asphyxia.*

SUBME'RSUS. Under water: applied to leaves which are naturally under water, while others of the plants are above; as in *Ranunculus aquatilis.* See *Natans.*

SUBMU'RIAS. A submuriate, or muriate in which the base predominates.

Submurias hydrargyri. See *Hydrargyri chloridum.*

Suborbita'rius ne'rvus. The suborbitary nerve, a branch of the fifth pair, more usually called *infra-orbitary.*

SUBRAMO'SUS. A little branched.

SUBROTU'NDUS. Roundish; nearly globular: applied to several parts of plants. The leaf of the *Pyrola* is subrotund.

SUBSALT. A salt having an excess of base beyond what is requisite for saturating the acid, as *supersalt* is one with an excess of the acid. The *sulphate* of potash is the neutral compound of sulphuric acid and potash; *subsulphate* of potash, a compound of the same ingredients, in which there is an excess of base; *supersulphate* of potash, a compound of the same acid and the same base, in which there is an excess of acid.

SUBSCAPULA'RIS. (From *sub*, under, and *scapula*, the shoulder-blade.) *Infra-scapularis.* The name of this muscle sufficiently indicates its situation. It is composed of many fasciculi of tendinous and fleshy fibres, the marks of which we see imprinted on the under surface of the scapula. These fasciculi, which arise from all the basis of that bone internally, and likewise from its superior as well as from one half of its inferior costa, unite to form a considerable flat tendon which adheres to the capsular

ligament, and is inserted into the upper part of the lesser tuberosity at the head of the os humeri.

The principal use of this muscle is to roll the arm inwards. It likewise serves to bring it close to the ribs; and, from its adhesion to the capsular ligament, it prevents that membrane from being pinched.

SUBSULPHAS HYDRARGYRI FLAVUS. Yellow subsulphate of mercury. This preparation is directed to be made by the Edinburgh College in the following manner. Take of purified mercury two parts, sulphuric acid three parts. Put them into glass cucurbit, placed in a sand-bath and boil them to dryness. Reduce to powder the white mass which is left at the bottom of the vessel, and throw it into boiling water. It is immediately converted into a yellow powder which is to be repeatedly washed with warm water. This preparation is named *sulphuric oxide of mercury*, by the Dublin College, and is the substance long known under the name of turbeth mineral. When the sulphate of mercury, formed by the aid of heat, is thrown into water, that fluid by its strong affinity for sulphuric acid decomposes the salt, and precipitates the greater part of the oxide mercury. The acid which remains in the water, however, retains some of the oxide as a soluble super-sulphate, while the precipitated oxide takes with it a little of the acid, and remains in the form of an insoluble sulphate. The turbeth mineral acts as a powerful emetic in the dose of five grains. It has also the alterative properties of the other preparations of mercury. It is never used internally in the present day. It is a very useful errhine in cases of head-ache, amaurosis, &c. Ten grains of the subsulphate may be mixed with a drachm of sugar or powdered starch: a pinch, of this powder will produce a copious discharge of mucous from the nose.

SUBSU'LTUS TE'NDINUM. Weak convulsive motions or twitchings of the tendons. These twitchings or starts of the tendons are most common in the extreme stages of debility, produced by low nervous and typhus fevers, and are generally the harbingers of a fatal termination. They are, in these cases, weak convulsions, interruptedly undulating from one limb to another, too feeble to raise the limb itself, though sufficiently powerful to be felt in the belly of the muscle, and along its tendon: they affect the wrist and ankles the most. Twitchings of a limb or a set of muscles is often an habitual affection.

SUBTE'PIDUS. Lukewarm.

SUBU'BERES. (From *sub*, under, and *ubera*, the breasts.) This term has been used by some writers for those infants who yet suck, in distinction to those who are weaned, and then are called *exuberes*.

SUBULA'TUS. Subulate: awl-shaped. Applied, in *Botany*, to leaves, receptacles, &c. which are tapering from a thick base to a point like an awl; as the leaf of the *Salsola kali*, and receptacle of the *Scabiosa atropurpurea*.

SUCCA'GO. The rob of any fruit.

SUCCEDA'NEUM. (*um*, *i.* n.) A medicine substituted for another.

SUCCENTURIA'TI MU'SCULI. The pyramidal muscles of the belly.

SUCCENTURIATI RENES. Two glands lying above the kidneys. See *Renal gland*.

SU'CCI SCORBUTICI. The juice of English scurvy grass, &c.

SUCCINATE. (*Succinas, atis*, f.) A salt formed by the combination of the acid of amber, or succinic acid, with a salifiable base; as, *succinate of potash*, *succinate of copper*, &c.

SUCCI'NGENS MEMBRANA. The diaphragm.

SUCCI'NIC. (*succinicus*; from *succinum*, amber.) Of or belonging to amber.

SUCCINIC ACID. *Acidum succinicum*. *Sal succini*. It has long been known that amber, when exposed to distillation, affords a crystallised substance, which sublimes into the upper part of the vessel. Before its nature was understood, it was called *salt of amber*; but it is now known to be a peculiar acid, as Boyle first discovered. The crystals are at first contaminated with a little oil, which gives them a brownish colour; but they may be purified by solution and crystallisation, repeated as often as necessary, when they will become transparent and shining. Pott recommends to put on the filter, through which the solution is passed, a little cotton previously wetted with oil of amber. Their figure is that of a triangular prism. Their taste is acid; and they redden the blue colour of litmus, but not that of violets. They are soluble in less than two parts of boiling alkohol, in two parts of boiling water, and in twenty-five of cold water.

Planché of Paris observes, that a considerable quantity might be collected in making amber varnish, as it sublimes while the amber is melting for this purpose, and is wasted.

Several processes have been proposed for purifying this acid: that of Richter appears to be the best. The acid being dissolved in hot water, and filtered, is to be saturated with potash or soda, and boiled with charcoal, which absorbs the oily matter. The solution being filtered, nitrate of lead is added; whence results an insoluble succinate of lead, from which, by digestion in the equivalent quantity of sulphuric acid, pure succinic acid is separated. Nitrate or muriate of barytes will show whether any sulphuric acid remains mixed with the succinic solution; and if so, it may be withdrawn by digesting the liquid with a little more succinate of lead. Pure succinic acid may be obtained by evaporation, in white transparent prismatic crystals. Their taste is somewhat sharp, and they redden powerfully tincture of turnsole. Heat melts and partially decomposes succinic acid. Air has no effect upon it. It is soluble in both water and alkohol, and much more so when they are heated.

SU'CCINUM. (*um*, *i.* n.; from *succus*, juice: because it was thought to exude from a tree.) Amber. A beautiful bituminous substance, which takes a good polish, and, after a slight rubbing, becomes so electric as to attract straws and small bodies. It was called ηλεκτρον, *electrum*, by the ancients; and hence the word electricity. "Amber is a hard, brittle, tasteless substance, sometimes perfectly transparent,

but mostly semitransparent or opake, and of a glossy surface: it is found of all colours, but chiefly yellow or orange, and often contains leaves or insects: its specific gravity is from 1·065 to 1·100; its fracture is even, smooth, and glossy; it is capable of a fine polish, and becomes electric by friction; when rubbed or heated, it gives a peculiar agreeable smell, particularly when it melts, that is, at 550° of Fahrenheit, but it then loses its transparency; projected on burning coals, it burns with a whitish flame, and a whitish-yellow smoke, but gives very little soot, and leaves brownish ashes; it is insoluble in water and alkohol, though the latter, when highly rectified, extracts a reddish colour from it; but it is soluble in the sulphuric acid, which then acquires a reddish-purple colour, and is precipitable from it by water. No other acid dissolves it, nor is it soluble in essential or expressed oils without some decomposition and long digestion; but pure alkali dissolves it. By distillation it affords a small quantity of water, with a little acetous acid, an oil, and a peculiar acid. The oil rises at first colourless; but, as the heat increases, becomes brown, thick, and empyreumatic. The oil may be rectified by successive distillations, or it may be obtained very light and limpid at once, if it be put into a glass alembic with water, as the elder Rouelle directs, and distilled at a heat not greater than 212° Fahr. It requires to be kept in stone bottles, however, to retain this state; for in glass vessels it becomes brown by the action of light.

Amber is met with plentifully in regular mines in some parts of Prussia. The upper surface is composed of sand, under which is a stratum of loam, and under this a bed of wood, partly entire, but chiefly mouldered or changed into a bituminous substance. Under the wood is a stratum of sulphureous or rather aluminous mineral, in which the amber is found. Strong sulphureous exhalations are often perceived in the pits.

Detached pieces are also found occasionally on the sea-coast in various countries. It has been found in gravel beds near London. In the Royal Cabinet at Berlin there is a mass of 18lbs. weight, supposed to be the largest ever found. Jussieu asserts, that the delicate insects in amber, which prove the tranquillity of its formation, are not European. Haüy has pointed out the following distinctions between mellite and copal, the bodies which most closely resemble amber: — Mellite is infusible by heat. A bit of copal heated at the end of a knife takes fire, melting into drops, which flatten as they fall: whereas amber burns with spitting and frothing; and when its liquefied particles drop, they rebound from the plane which receives them.

The origin of amber is at present involved in perfect obscurity, though the rapid progress of vegetable chemistry promises soon to throw light on it.

Various frauds are practised with this substance. Neumann states as the common practices of workmen the two following: — The one consists in surrounding the amber with sand in an iron pot, and cementing it with a gradual fire for forty hours, some small pieces placed near the sides of the vessel being occasionally taken out for judging of the effect of the operation. The second method, which he says is that most generally practised, is by digesting and boiling the amber about twenty hours with rapeseed oil, by which it is rendered both clear and hard.

Werner has divided it into two subspecies, the white and the yellow; but there is little advantage in the distinction. Its ultimate constituents are the same with those of vegetable bodies in general; viz. carbon, hydrogen, and oxygen.

In the second volume of the Edinburgh Philosophical Journal, Dr. Brewster has given an account of some optical properties of amber, from which he considers it established beyond a doubt that amber is an *indurated vegetable juice*; and that the traces of a regular structure, indicated by its action upon polarised light, are not the effect of the ordinary laws of crystallisation by which *mellite* has been formed, but are produced by the same causes which influence the mechanical condition of gum arabic, and other gums which are known to be formed by the successive deposition and induration of vegetable fluids. See *Oleum succini*, and *Succinic acid*.

Succinum cinereum. See *Ambergris.*

Succinum griseum. See *Ambergris.*

Succinum oleum. See *Oleum succini.*

Succinum præparatum. See *Amber.*

SUCCI'SA. (*a*, *æ*. f.; from *succido*, to cut: so named from its being indented, and, as it were, cut in pieces.) Applied to a species of the genus *Scabiosa*.

Succory. See *Cichorium.*

SU'CCULENS. Succulent; juicy, rich. Applied to fruits, pods, soils, &c.

SUCCULE'NTÆ. The name of an order of Linnæus's Fragments of a Natural Method, containing those which have fleshy and succulent leaves; as *Cactus*, *Sedum*, *Sempervivum*, &c.

SUCCULE'NTUS. Juicy; full of juice. Applied to plants, pods, leaves, &c.

SU'CCUS. (*us*, *i*. m.) Juice.

SUCCUS COCHLEARIÆ COMPOSITUS. A warm aperient and diuretic, mostly exhibited in the cure of diseases of the skin arising from scurvy.

SUCCUS CYRENIACUS. Juice of laserwort.

Succus gastricus. See *Gastric juice.*

Succus heliotropii. See *Croton tinctorium.*

Succus indicus purgans. See *Gamboge.*

Succus liquoritiæ. See *Glycyrrhiza glabra.*

SUCCU'SSION. A mode of exploring the chest which consists in shaking the patient's body and listening to the sounds thereby produced.

Sucker. See *Stolo.*

SUDA'MEN. (*en*, *inis*. n.; from *sudo*, sweat.) *Sudamina* are vesicles resembling millet-seeds in form and magnitude, which appear suddenly, without fever, especially in the summer time, after much labour and sweating.

SUDA'TIO. (*o*, *onis*. f.; from *sudor*, sweat.) A sweating. See *Ephidrosis.*

SUDATORIA FEBRIS. The sweating sickness. See *Sudor anglicus.*

SUDATO'RIUS. Relating to perspiration.

SUDATO'RIUM. (From *sudo*, to sweat.) A sweating room. See *Balneum*.

SU'DOR. Sweat or perspiration.

SUDOR ANGLICUS. The sweating sickness. A very extraordinary epidemy, which made its first appearance in England in the year 1485, although it is, doubtless, an error to suppose that it originated in England. The celebrated Caius drew up an account of this disease from his own observation. Dr. Aiken, in his "Biographical Memoirs of Medicine in Great Britain," gives an abstract of Caius's work on the subject, with critical remarks, and to this we are indebted for what follows.

Caius being a witness, during his residence at Shrewsbury, in 1551, to the dreadful ravages made by this disease, hastily drew up an English treatise concerning it, designed for the use of the people at large. It was dedicated to William, Earl of Pembroke, and entitled, *A Boke or Conseill against the Disease commonly called the Sweat, or Sweating Sickness; made by John Caius, Doctor in Physic*, 1552, 12mo. This he sometime afterwards revised, enlarged, and put into a more scientific form, and the Latin language; and published it in the year 1556, under the title *De Ephemera Britannica*. The dedication, to Anthony Perrenot, bishop of Arras, is dated January 1555. It was correctly reprinted at London in 1721.

In this work we find the following account of the rise and appearance of this extraordinary disease.

It began in the army of the Earl of Richmond, afterwards King Henry VII., upon his landing at Milford-haven in 1485, and spread to London, where it raged from the beginning of August to the end of October. Dr. Friend, in his *History of Physick*, apparently transcribing his account of this disorder from Caius, says that it appeared first in 1483, yet adds the circumstance of its beginning in Henry's army at Milford. This he mentions as distinct from the visitation in 1485. That this learned writer has here fallen into a mistake, may be proved from our historians, who relate, that the Earl of Richmond did indeed approach the coast of Cornwall with a fleet in 1483; but, on advice that the insurrection of his friends had proved unsuccessful, sailed back without attempting to land. It appeared in England four times afterwards at unequal intervals; in the summer of 1506; in 1517, from July to the middle of December; in 1528, during the whole summer; and, lastly, in 1551, from April to the end of September. Its attack was extremely sudden. It generally began with the affection of some particular part, occasioning in some a sense of a hot vapour running through the limb. To this succeeded extreme internal heat, unquenchable thirst, and most profuse sweating. Anxiety, restlessness, sickness, violent pain of the head, delirium, and excessive drowsiness attended its progress; and frequently in one, two, three, four, or more hours from the eruption of the sweat, the patient was carried off. The violence of the attack was over in fifteen hours; yet the sick person was not in a state of security till the expiration of twenty-four hours; whence the disease is properly denominated by our author, an *Ephemera*. The persons most liable to the contagion were those in high health, of middle age, and of better rank and condition; children, poor and old people, were less subject to its influence. The numbers carried off by it were incredible. In the town of Salop 960 died in a few days (*pauculis diebus*); and our physician labours the description of this calamity with all the strong colouring of a Thucydides.

In his reasonings concerning it, he first accounts for its being an ephemera from the supposition that it attacked the more subtle spirits; whereas he conceives the plague and other fevers to attack the humours. He then proceeds to give his opinion concerning its origin and cause. He discusses the various sources of contagion; considering separately the effects of untimely seasons, of noxious effluvia peculiar to certain places, and other contaminations of the air, and of planetary conjunctions. The immediate origin of the sickness in his time he attributes to certain thick and stinking fogs rising from the low grounds near Shrewsbury, which, being wafted by the wind, were perceived to carry the contagion with them. This general cause was, he says, augmented in particular situations by other sources of corrupt air; such as close narrow streets, dunghills, privies, uncleansed drains, and the like. He strongly insists on the common notion of this distemper being in a manner peculiar to the English; asserting that it spared foreigners, even the Scotch, in England, and seized the English in foreign countries. This he imputes to the greater luxury in diet by which our countrymen were, it seems, even then distinguished from all other nations; and he confirms his conjecture by observing that the freest livers, and those of the most athletic habits, were attacked with the greatest violence.

The method of prevention he proposes is well suited to his ideas of the causes of the infection. It consists in more abstemious living, the use of acidulous fruits and sauces, great attention to cleanliness, and free exposure to the open air. He recommends the kindling of fires both round the house and within doors; looking upon fire as a great corrector of contagion, and adducing an observation to this purpose, that smiths and cooks were preserved by their fires from the distemper. He directs aromatics and sweet-scented herbs of all kinds to be burned in these fires, and also to be frequently applied to the nose. He speaks with some reserve concerning evacuations, recommending gentle purgatives and bleeding only to the plethoric, and in them not later than the spring; since he thinks they should meet the danger in summer with a body undisturbed and undebilitated by medicine.

The method of cure turns upon the sole idea that the sweat, from whence the disease is denominated, is critical, and therefore to be promoted in the greatest profuseness, till the danger is over. With this view, he directs the person seized to lie down immediately, in the clothes he happens to have on, and have the body completely covered (all but the face) with bedclothes; in which situation he is to remain per-

fectly still, not stirring a limb, if possible, nor putting a hand out of bed. He is to abstain from food the whole twenty-four hours; and even from drink the first five hours. Then a little ale or beer, or wine and water, is to be given in small portions, and sucked through a spout, the patient still lying in the same posture. At the expiration of about fourteen hours, the bed-clothes are gradually to be removed, and the sweating restrained; and after it is quite over, proper food is to be given to recruit the exhausted strength. This is the process when the sweat flows spontaneously. When this is not the case, attempts must be made to excite it; and the means here directed are dry and warm friction, draughts of generous wine with *theriaca*, or *mithridate*, or aromatics, vinegar whey, China root, and other sudorific medicines. By this method of practice, attentively pursued, and properly adapted to the circumstances, we are told that the disease, though so fatal when neglected or mismanaged, was got over with a tolerable certainty of success; so that, according to Lord Bacon's observation, it might be looked upon "rather as a surprise of nature, than obstinate to remedies."

Valuable as this treatise of our author is, not only as giving the fullest account of so singular a distemper, but as containing many judicious practical remarks, we must, however, acknowledge that it is far from a perfect piece of medical writing. It is not long, yet many digressions, foreign to the subject, are admitted; and trivial matters are dwelt upon more at length than those of capital importance. Under the head of diet, the author takes occasion to launch out into an enumeration of all the articles the tables of the luxurious at that time afforded. He employs several pages to describe the methods of making beer and ale, and the process of malting; and he concludes with a copious panegyric upon temperance, extracted from the ancients. What we have most to regret, is the little light he affords us with respect to the first rise of the disease; and there is little doubt that he is guided merely by vulgar prejudice in supposing it so peculiar to this country. Its first appearance seems to have been neither amongst Englishmen, nor in England; but among the foreign levies of the Earl of Richmond, who had either brought it with them, or, more probably, generated it in the crowded transport vessels on board of which they were embarked. This body of troops is described by a cotemporary historian (Philip de Comines) as the most wretched he had ever beheld; collected, we may suppose, from gaols and hospitals, and buried in filth. A highly malignant and contagious disease might readily be produced in such circumstances; but why it should appear under so new and singular a form, why this should be renewed so many times at irregular intervals, and should at length entirely cease, are questions perhaps impossible to be solved. That the climate of England was not essential to the existence of that disease, is rendered manifest by its raging with great violence in Germany and the Low Countries in 1529 and 1530; and that the persons of foreigners were not secure in England, appears from the death of Ammonius, a learned Italian, and a particular friend of Erasmus, in 1520 (in which year the sickness also prevailed in Calais); and from the death of another of that nation, related by Caius himself. On the supposition of its being a fever of the putrid and malignant kind, we shall scarcely be able to account for its prevailing most among the rich and well-fed, contrary to what we now observe of that class of disorders; and, indeed, the vast numbers related to be swept away by it, evidently prove its frequency among the lowest ranks of people.

If 960 persons were carried off by it at Shrewsbury in a few days, the greater part of whom were neither children nor old people, of what rank in life must the majority have been?

SUDORI'FIC. (*Sudorificus*; from *sudor*, sweat, and *facio*, to make.) A synonym of diaphoretic. See *Diaphoretic*.

SUFFIME'NTUM. (From *suffimen*, a perfume.) A perfume.

SUFFI'TUS. A fumigation.

SUFFOCA'TIO. (*o, onis.* f.) Suffocation.

Suffocatio hysterica. The *globus hystericus*; called also *suffocatio uterina*, from the supposed connection of hysteria with an affection of the uterus.

Suffocatio stridula. See *Croup*.

Suffru'tices plantæ. Under-shrubby plants. Vegetables which have stems that are somewhat ligneous, or of a nature intermediate between the shrubby and the herbaceous; as thyme, sage, hyssop, &c.

SUFFRUTICO'SUS. Somewhat woody; nearly shrubby; as *Lavendula*, *Salvia*, &c.

SUFFUMIGATION. (*Suffumigatio, onis.* f.; from *sub*, under, and *fumigo*, to smoke. The burning of odorous substances to remove an evil smell, or destroy miasma.

Suffusio auriginosa. The jaundice.

SUFFUSION. (*Suffusio, onis.* f.; from *suffundo*, to pour down: so called because the ancients supposed the opacity proceeded from something running under the crystalline humour.) 1. A cataract.

2. An extravasation of some humour, as the blood: thus we say, a suffusion of blood in the eye, when it is what is vulgarly called bloodshot.

Sugar. See *Saccharum*.

Sugar, maple. See *Acer*.

Sugar of lead. See *Plumbi acetas*.

Sugar of milk. See *Milk*.

SUGILLA'TION. (*Sugillatio*; from *sugillo*, to bruise.) A bruise. A spot or mark made by a leech or cupping-glass.

SULCA'TUS. Sulcate: furrowed; marked with deep lines running lengthways. Applied to stems, leaves, seeds, &c. of plants; and well seen in the seeds of the *Scandix odorata*.

SU'LCUS. A groove or furrow; generally applied to the bones.

SU'LPHAS. (*as, atis.* f.; from *sulphur*, brimstone.) A sulphate or salt formed by the union of the sulphuric acid with a salifiable base.

Those principally used in medicine are,—

1. Sulphate of alumina and potash. See *Alum*.
2. ——— copper. See *Cupri sulphas*.

3. ———— iron. See *Ferri sulphas.*
4. ———— magnesia. See *Magnesia sulphas.*
5. ———— potash. See *Potassæ sulphas.*
6. ———— soda. See *Sodæ sulphas.*
7. ———— zinc. See *Zinci sulphas.*
8. ———— quinine. See *Quinæ disulphas.*
9. ———— mercury. See *Subsulphas hydrargyri flavus.*

Sulphas aluminosus. See *Alumen.*

Sulphas ammoniæ. *Alkali volatile vitriolatum*, of Bergman. *Sal ammoniacum secretum*, of Glauber. *Vitriolum ammoniacale.* This salt has been found native in the neighbourhood of some volcanoes. It is esteemed diuretic and deobstruent, and exhibited in the same diseases as the muriate of ammonia.

Sulphas antimonii. Sulphate of antimony. *Vitriolum antimonii.* This is formed by boiling powdered antimony in sulphuric acid. A white saline mass results, which, when thrown into water, is resolved into a soluble *supersulphate* and an insoluble *subsulphate.*

Sulphas cupri. See *Cupri sulphas.*

Sulphas ferri. See *Ferri sulphas.*

Sulphas hydrargyri. See *Hydrargyrum vitriolatum.*

Sulphas magnesiæ. See *Magnesiæ sulphas.*

Sulphas potassæ. See *Potassæ sulphas.*

Sulphas quinæ. See *Quinæ disulphas.*

Sulphas sodæ. See *Sodæ sulphas.*

Sulphas zinci. See *Zinci sulphas.*

Sulphate of antimony. See *Sulphas antimonii.*

Sulphate of lime. This salt is commonly called *selenite*, *gypsum*, *plaster of Paris*, and sometimes *alabaster.* It forms extensive strata in various mountains. The *specular gypsum*, or *glacies Mariæ*, is a species of this salt, and affirmed by some French travellers to be employed in Russia, where it abounds, as a substitute for glass in windows. See *Gypsum.*

SU'LPHIS. A sulphite. A salt formed by the combination of a definite quantity of the sulphurous acid with a salifiable base; as *sulphite of potash*, *sulphite of ammonia*, &c.

Sulphite. See *Sulphis.*

Su'lpho-cya'nic acid. *Sulphuro-prussic acid. Sulphuretted chyazic acid.* Dissolve in water one part of sulphuret of potash, and boil it for a considerable time with three or four parts of powdered prussian blue, added at intervals. Sulphuret of iron is formed, and a colourless liquid containing the new acid combined with potash, mixed with hyposulphate and sulphate of potash. Render this liquid sensibly sour, by the addition of sulphuric acid. Continue the boiling for a little, and, when it cools, add a little peroxide of manganese in fine powder, which will give the liquid a fine crimson colour. To the filtered liquid add a solution containing persulphate of copper, and protosulphate of iron, in the proportion of two of the former salt to three of the latter, until the crimson colour disappears. Sulphuroprussiate of copper falls. Boil this with a solution of potash, which will separate the copper. Distil the liquid mixed with sulphuric acid in a glass retort, and the peculiar acid will come over. By saturation with carbonate of barytes, and then throwing down this by the equivalent quantity of sulphuric acid, the sulphuroprussic acid is obtained pure.

It is a transparent and colourless liquid, possessing a strong odour, somewhat resembling acetic acid. Its specific gravity is only 1·022. It dissolves a little sulphur at a boiling heat. It then blackens nitrate of silver; but the pure acid throws down the silver white. By repeated distillations sulphur is separated and the acid is decomposed. According to Berzelius it consists of

Carbon	20·30
Nitrogen	23·85
Hydrogen	1·68
Sulphur	54·17
	100·00

Su'lpho-naphtha'lic acid. Mr. Faraday communicated a paper to the Royal Society in 1826, to show that, during the mutual action of sulphuric acid and naphthaline, a compound of that acid with hydrocarbon is formed, differing from all known substances; and which, possessing acid properties, and combining with salifiable bases to produce a peculiar class of salts, is named sulpho-naphthalic acid.

Sulpho-salts. These are merely double sulphurets, in which Berzelius traces a close analogy to salts.

Sulphovi'nic acid. *Acidum sulphovinicum.* Œnothionic acid. A peculiar acid, generated during the process for obtaining sulphuric ether. See *Ether sulphuricus.*

SU'LPHUR. (*ur*, *uris.* n.) Sulphur. Brimstone. Its old names are, *Abric*, *Alcubrith*, *Anpater*, *Appebrioc*, *Aquala*, *Aquila*, *Chibur*, *Chybur*, and *Cibur.* It is the only simple combustible substance which nature offers pure and in abundance. It was the first known of them all. It is found in the earth, and exists externally in depositions, in sublimed incrustations, and on the surface of certain waters, principally near burning volcanoes. It is found combined with many metals.

Sulphur, in the mineral kingdom, is either in a loose powder or compact; and then either detached or in veins. It is found in the greatest plenty in the neighbourhood of volcanoes or pseudo-volcanoes, whether modern or extinct, as at Solfatara, &c. and is deposited as a crust on stones contiguous to them, either crystallised or amorphous. It is frequently met with in mineral waters, and in caverns adjacent to volcanoes; sometimes also in coal-mines. It is found in combination with most of the metals. When united to iron it forms the mineral called *martial pyrites*, or *iron pyrites.* All the ores known by the name of *pyrites*, of which there are a vast variety, are combinations of sulphur with different metals; and hence the names of copper, tin, arsenical, &c. pyrites. It exists likewise in combination with alumina and lime: it then constitutes different kinds of alum ore.

A prodigious quantity of pure sulphur is obtained from Solfatara in Italy.

From pyrites sulphur is extracted in the large way. In order to form it into rolls, it is melted and poured into cylindrical wooden moulds; in these it takes the form in which we usually see it in commerce, as roll sulphur.

Flowers of sulphur, as they are called, are formed by subliming purified sulphur with a gentle heat in close rooms, where the sublimed sulphur is collected, though the article met with in general under that name is nothing but sulphur finely powdered.

Properties. — Sulphur is a combustible, dry, and exceedingly brittle body, of a pale lemon-yellow colour. Its specific gravity is 1·990. It is destitute of odour, except when rubbed or heated. It is of a peculiar faint taste. It frequently crystallises in entire or truncated octahedra, or in needles. If a piece of sulphur, of a considerable size, be very gently heated, as, for example, by holding it in the hand and squeezing it firmly, it breaks to pieces with a crackling noise. It is a non-conductor of electricity, and hence it becomes electric by friction. When heated, it first softens before it melts, and its fusion commences at 218° Fahr.: it is capable of subliming at a lower temperature; and takes fire at 560°. In the beginning of fusion it is very fluid; but by continuing the heat it grows tough, and its colour changes to a reddish-brown. If in this condition it be poured into water, it remains as soft as wax, and yields to any impression. In time, however, it hardens again, and recovers its former consistence.

When a roll of sulphur is suddenly seized in a warm hand, it crackles, and sometimes falls in pieces. This is owing to the unequal action of heat on a body which conducts that power slowly, and which has little cohesion. If a mass of sulphur be melted in a crucible, and, after the surface begins to concrete, if the liquid matter below be allowed to run out, fine acicular crystals of sulphur will be obtained.

Sulphur is insoluble in water; but in small quantity in alkohol and ether, and more largely in oil.

Combinations of Sulphur. Sulphur combines with *oxygen* in four definite proportions, constituting an interesting series of acids. See *Sulphuric acid*, and *Sulphurous acid*.

Sulphur combines readily with *chlorine*.

Iodide of sulphur is easily formed by mixing the two ingredients in a glass tube, and exposing them to such a heat as melts the sulphur.

Sulphur and *hydrogen* combine, and form *sulphuretted hydrogen*. Their union may be effected, by causing sulphur to sublime in dry hydrogen in a retort.

The usual way of preparing sulphuretted hydrogen, is to pour a dilute sulphuric or muriatic acid on the black sulphuret of iron or antimony in a retort. For accurate experiments it should be collected over mercury. It takes fire when a lighted taper is brought in contact with it, and burns with a pale blue flame, depositing sulphur. Its smell is extremely fetid, resembling that of rotten eggs. Its taste is sour. It reddens vegetable blues. It is absorbable by water, which takes up more than an equal volume of the gas. Its sp. gr., according to Gay Lussac and Thénard, is to that of air as 1·1912 to 1·0.

Of all the gases, sulphuretted hydrogen is perhaps the most deleterious to animal life. A greenfinch, plunged into air which contains only $\frac{1}{1500}$ of its volume, perishes instantly. A dog of middle size is destroyed in air that contains $\frac{1}{800}$; and a horse would fall a victim to an atmosphere containing $\frac{1}{250}$.

Dr. Chaussier proves that to kill an animal, it is sufficient to make the sulphuretted hydrogen gas act on the surface of its body, when it is absorbed by the inhalants. He took a bladder having a stop-cock at one end, and at the other an opening, into which he introduced the body of a rabbit, leaving its head outside, and securing the bladder air-tight round the neck by adhesive plaster. He then sucked the air out of the bladder, and replaced it by sulphuretted hydrogen gas. A young animal in these circumstances usually perishes in 15 or 20 minutes. Old rabbits resist the poison much longer.

When potassium or sodium is heated merely to fusion, in contact with sulphuretted hydrogen, it becomes luminous, and burns with extrication of hydrogen, while a metallic sulphuret remains, combined with sulphuretted hydrogen, or a sulphuretted hydro-sulphuret.

Sulphuretted hydrogen combines with an equal volume of ammonia, and unites to alkalies and oxides, so that it has all the characters of an acid. These compounds are called *hydrosulphurets*.

All the *hydrosulphurets*, soluble in water have an acrid and bitter taste, and, when in the liquid state, the odour of rotten eggs. All those which are insoluble are, on the contrary, insipid, and without smell. Those which have been examined, are the hydrosulphurets of potash, soda, ammonia, barytes, strontites, lime and magnesia.

When we expose sulphur to the action of a solution of a hydrosulphuret, saturated with sulphuretted hydrogen, as much more sulphuretted hydrogen is evolved as the temperature is more elevated. But when the solution of hydrosulphuret, instead of being saturated, has a sufficient excess of alkali, it evolves no perceptible quantity of sulphuretted hydrogen even at a boiling heat; although it dissolves as much sulphur as in its state of saturation. It hence follows, 1st, That sulphuretted hydrogen, sulphur, and the alkalis have the property of forming very variable triple combinations; 2d, That all these combinations contain less sulphuretted hydrogen than the hydrosulphurets; and, 3d, That the quantity of sulphuretted hydrogen is inversely as the sulphur they contain and reciprocally. These compounds have been called, in general, sulphuretted hydrosulphurets and hydrogenated sulphurets.

Sulphur combines with *carbon*, forming an interesting compound, to which the name *sulphuret of carbon* is sometimes given.

Sulphur has been long an esteemed article in the Materia Medica. It stimulates the system

loosens the belly, and promotes the insensible perspiration. It pervades the whole habit, and manifestly transpires through the pores of the skin, as appears from the sulphureous smell of persons who have taken it, and from silver being stained in their pockets of a blackish colour. In the stomach it is probably combined with hydrogen. It is a celebrated remedy against cutaneous diseases, particularly psora, both given internally and applied externally. It has likewise been recommended in rheumatic pains, flying gout, rickets, atrophy, coughs, asthmas, and other disorders of the chest and lungs, and particularly in catarrhs of the chronic kind, also in colica pictonum, worm cases, and to lessen salivation.

In hæmorrhoidal affections it is almost specific; but in most of these cases it is advantageously combined with some cooling purgative, especially supertartrate of potash.

The preparations of sulphur in general use are the *Sulphur lotum*, *Sulphur præcipitatum*, and *Sulphur sublimatum*.

Sulphur antimonii præcipitatum. See *Antimonii sulphuretum præcipitatum.*

Sulphur auratum antimonii. See *Antimonii sulphuretum præcipitatum.*

Sulphur lotum. Washed sulphur. *Flores sulphuris loti.* Take of sublimed sulphur, a pound. Pour on boiling water, so that the acid, if there be any, may be entirely washed away: then dry it. The dose is from half a drachm to two drachms.

Sulphur, milk of. See *Sulphur præcipitatum.*

Sulphur præcipitatum. *Lac sulphuris.* Milk of sulphur. Take of sublimed sulphur, a pound; fresh lime, two pounds; water, four gallons: boil the sulphur and lime together in the water; then strain the solution through paper, and drop in as much muriatic acid as may be necessary to precipitate the sulphur; lastly, wash this by repeated affusions of water until it is tasteless. This preparation is mostly preferred to the flowers of sulphur, in consequence of its being freed from its impurities. The dose is from half a drachm to three drachms.

Sulphur, precipitated. See *Sulphur præcipitatum.*

Sulphur sublimatum. See *Sulphur.*

Sulphur vivum. Native sulphur.

Sulphur, washed. See *Sulphur lotum.*

Sulphur-wort. See *Peucedanum.*

SULPHU'REOUS. *Sulphureus.* 1. Of or belonging to sulphur.

2. Applied, in *Natural History*, to designate a bright pale yellow, without any orange tinge. See *Colour.*

Su'lphurous acid. *Acidum sulphurosum.* Sulphur, burned at a low temperature, absorbs less oxygen than it does when exposed to greater heat, and is consequently acidified in a slighter degree, so as to form sulphureous acid. This, in the ordinary state of the atmosphere, is a gas; but on reducing its temperature very low by artificial cold, and exposing it to strong compression, it becomes a liquid. To obtain it in the liquid state, however, for practical purposes, it is received into water, by which it is absorbed.

Water thus saturated is intensely acid to the taste, and has the smell of sulphur burning slowly. It destroys most vegetable colours, but the blues are reddened by it previously to their being discharged. A pleasing instance of its effect on colours may be exhibited by holding a red rose over the blue flame of a common match, by which the colour will be discharged wherever the sulphureous acid comes in contact with it, so as to render it beautifully variegated, or entirely white. If it be then dipped into water, the redness, after a time, will be restored.

Sulphurous acid is used in bleaching, particularly for silks. It likewise discharges vegetable stains and iron-moulds from linen.

In combination with the salifiable bases it forms sulphites, which differ from the sulphates in their properties.

Sulphuret of antimony. See *Antimonii sulphuretum.*

Sulphuret of carbon. This substance was discovered accidentally in the year 1796 by Professor Lampadius, who regarded it as a compound of sulphur and hydrogen, and termed it *alkohol of sulphur.* Clément and Desormes first declared it to be a sulphuret of carbon, and their statement was fully confirmed by the joint researches of Berzelius and the late Dr. Marcet. (Philos. Trans. for 1813.)

Sulphuret of carbon may be obtained by heating in close vessels native bisulphuret of iron (iron pyrites) with one fifth of its weight of well dried charcoal; or by transmitting the vapour of sulphur over fragments of charcoal heated to redness in a tube of porcelain. The compound, as it is formed, should be conducted by means of a glass tube into cold water, at the bottom of which it is collected. To free it from moisture and adhering sulphur, it should be distilled at a low temperature in contact with chloride of calcium.

Bisulphuret of carbon is a transparent colourless liquid, which is remarkable for its high refractive power. Its specific gravity is 1·272. It has an acid, pungent, and somewhat aromatic taste, and a very fœtid odour. It is exceedingly volatile;—its vapour at 63·5° F. supports a column of mercury 7·36 inches long; and at 110° F. it enters into brisk ebullition. From its great volatility it may be employed for producing intense cold.

Bisulphuret of carbon is very inflammable, and kindles in the open air at a temperature scarcely exceeding that at which mercury boils. It burns with a pale blue flame. Admitted into a vessel of oxygen gas, so much vapour rises as to form an explosive mixture; and when mixed in like manner with binoxide of nitrogen, it forms a combustible mixture, which is kindled on the approach of a lighted taper, and burns rapidly, with a large greenish white flame of dazzling brilliancy. It dissolves readily in alkohol and ether, and is precipitated from the solution by water. It dissolves sulphur, phosphorus, and iodine, and the solution of the latter has a beautiful pink colour. Chlorine decomposes it, with formation of chloride of sulphur. The pure acids have little action upon it. With the alkalies it unites slowly, forming compounds which Berzelius calls *carbo-*

sulphurets. It is converted by strong nitro-muriatic acid into a white crystalline substance like camphor, which Berzelius considers to be a compound of muriatic, carbonic, and sulphurous acid gases.

Xanthogen and hydro-xanthic acid. — M. Zeise, Professor of Chemistry at Copenhagen, has discovered some novel and interesting facts, relative to bisulphuret of carbon. When this fluid is agitated with a solution of pure potash in strong alkohol, the alkaline properties of the potash disappear entirely ; and on exposing the solution to a temperature of 32° F., numerous acicular crystals are deposited. M. Zeise attributes these phenomena to the formation of a new acid, the elements of which are derived, in his opinion, partly from the alkohol and partly from the bisulphuret of carbon. See *Hydro-xanthic acid.* — *Turner.*

Sulphuretted chyazic acid. See *Sulphocyanic acid.*

Sulphuretted hydrogen. See *Sulphur.*

Sulphuretted hydrogen gas. See *Sulphur.*

SULPHURE'TUM. (*um*, *i.* n.) Sulphuret. A combination of sulphur with an alkali, earth, or metal.

SULPHURETUM AMMONIÆ. *Hepar sulphuris volatile.* Boyle's or Beguine's fuming spirit. Sulphuret of ammonia is obtained in the form of a yellow fuming liquor, by the ammonia and sulphur uniting while in a state of gas during distillation. It excites the action of the absorbent system, and diminishes arterial action, and has been given internally in diseases arising from the use of mercury, phthisis, diseases of the skin, and phlegmasiæ: externally it is prescribed in the form of bath in paralysis, contractura, psora, and other cutaneous diseases.

Sulphuretum antimonii præcipitatum. See *Antimonii sulphuretum præcipitatum.*

SULPHURETUM CALCIS. Sulphuret of lime. Principally used to form a medicated bath for various diseases of the skin.

Sulphuretum hydrargyri nigrum. See *Hydrargyri sulphuretum nigrum.*

Sulphuretum hydrargyri rubrum. See *Hydrargyri sulphuretum rubrum.*

Sulphuretum potassæ. See *Potassii sulphuretum.*

Sulphuretum sodæ. See *Sulphuretum sodii.*

SULPHURETUM SODII. A combination of sodium and sulphur. It is improperly called sulphuret of soda. It is analogous to the sulphuret of potassium.

SULPHURETUM STIBII NATIVUM. *Sulphuretum stibii nigrum. Antimonium crudum.* Native sulphuret of antimony. It is from this ore that all our preparations of antimony are made. See *Antimony.*

SULPHURIC. *Sulphuricus.* Belonging to sulphur.

SULPHURIC ACID. *Acidum sulphuricum.* Oil of vitriol. Vitriolic acid. When sulphur is heated to 180° or 190° in an open vessel it melts, and soon afterwards emits a bluish flame, visible in the dark, but which, in open day-light, has the appearance of a white fume. This flame has a suffocating smell, and has so little heat that it will not set fire to flax, or even gunpowder, so that in this way the sulphur may be entirely consumed out of it. If the heat be still augmented, the sulphur boils, and suddenly bursts into a much more luminous flame, the same suffocating vapour still continuing to be emitted.

The suffocating vapour of sulphur is imbibed by water, with which it forms the fluid formerly called *volatile vitriolic*, now sulphureous acid. If this fluid be exposed for a time to the air, it loses the sulphureous smell it had at first, and the acid becomes more fixed. It is then the fluid which was formerly called *spirit of vitriol.* Much of the water may be driven off by heat, and the dense acid which remains is the sulphuric acid, commonly called *oil of vitriol;* a name which was probably given to it from the little noise it makes when poured out, and the unctuous feel it has when rubbed between the fingers, produced by its corroding and destroying the skin, with which it forms a soapy compound.

Sulphuric acid was formerly obtained in this country by distillation from sulphate of iron, as it still is in many parts abroad : the common green vitriol is made use of for this purpose, as it is to be met with at a low price, and the acid is most easily to be extracted from it.

That which is now made in Great Britain is produced by the combustion of sulphur. There are three conditions requisite in this operation : — oxygen must be present to maintain the combustion ; the vessel must be so close as to prevent the escape of the volatile matter which rises ; and water must be present to imbibe it. For these purposes, a mixture of eight parts of sulphur, with one of nitre, is placed in a proper vessel, enclosed within a chamber of considerable size, lined on all sides with lead, and covered at bottom with a shallow stratum of water. The mixture being set on fire, will burn for a considerable time by virtue of the supply of oxygen which nitre gives out when heated, and the water imbibing the sulphureous vapours, becomes gradually more and more acid, after repeated combustions, and the acid is afterwards concentrated by distillation.

Such was the account usually given of this operation, till Clement and Desormes showed its total inadequacy to account for the result. 100 parts of nitre, judiciously managed, will produce, with the requisite quantity of sulphur, 2000 parts of concentrated sulphuric acid.

The sulphuric acid strongly attracts water which it takes from the atmosphere very rapidly and in larger quantities if suffered to remain in an open vessel, imbibing one third of its weight in twenty-four hours, and more than six times its weight in a twelvemonth. If four parts by weight be mixed with one of water, at 50°, they produce an instantaneous heat of 300° F. ; and four parts raise one of ice to 212° ; on the contrary, four parts of ice, mixed with one of acid, sink the thermometer to 4° below 0. When pure it is colourless, and emits no fumes. It requires a great degree of cold to freeze it ; and if diluted with half a pint or more of water, unless the dilution be carried very far, it be

comes more and more difficult to congeal; yet at the specific gravity of 1·78, or a few hundredths above or below this, it may be frozen by surrounding it with melting snow. Its congelation forms regular prismatic crystals with six sides. Its boiling point, according to Bergman, is 540°; according to Dalton, 590°.

Pure sulphuric acid is without smell and colour, and of an oily consistence. Its action on litmus is so strong, that a single drop of acid will give to an immense quantity of water the power of reddening. It is a most violent caustic; and has sometimes been administered with the most criminal purposes. The person who unfortunately swallows it speedily dies in dreadful agonies and convulsions. Chalk, or common carbonate of magnesia, is the best antidote for this, as well as for the strong nitric and muriatic acids.

When transmitted through an ignited porcelain tube of one fifth of an inch diameter, it is resolved into two parts of sulphureous acid gas, and one of oxygen gas, with water. Voltaic electricity causes an evolution of sulphur at the negative pole; whilst a sulphate of the metallic wire is formed at the positive. Sulphuric acid has no action on oxygen gas or air. It merely abstracts their aqueous vapour.

All the simple combustibles decompose sulphuric acid, with the assistance of heat. About 400° Fahr. sulphur converts sulphuric into sulphureous acid. Several metals, at an elevated temperature, decompose this acid, with evolution of sulphureous acid gas, oxidisement of the metal, and combination of the oxide with the undecomposed portion of the acid.

The sulphuric acid is of very extensive use in the art of chemistry, as well as in metallurgy, bleaching, and some of the processes for dyeing: in medicine it is given as a tonic and stimulant, properly diluted, in the dose of from one to three drops, with cinchona and other medicines, in the cure of fevers and debilities; and it is often applied externally, as a caustic with oil, and, when very much diluted, against psora and some chronic affections of the skin. The combinations of this acid with the various bases are called *sulphates*, and most of them have long been known.

Sulphuric acid, oxygenated. If the oxygenised muriatic acid of Thénard be put in contact with the sulphate of silver, there is immediately formed insoluble chloride of silver, and oxygenised sulphuric acid. To obtain sulphuric acid in the highest degree of oxygenation, it is merely necessary to pour barytes water into the above oxygenised acid, so as to precipitate only a part of it, leaving the rest in union with the whole of the oxygen. [This, like the other supposed oxygenated, are in reality compounds of the acid with deutoxide of hydrogen. See *Hydrogen.*]

Sulphuris flores. See *Sulphur sublimatum.*

Sulphuris lac. See *Sulphur præcipitatum.*

Sulphuroprussic acid. See *Sulpho-cyanic acid.*

Sultan-flower. See *Centaurea moschata.*

Su'mach. (*Sumak*; from *samak*, to be red, Arabic: so called from its red berry.) See *Rhus coriaria.*

Sumach, elm-leaved. See *Rhus coriaria.*

Su'men. (Arabic.) The lower or fat part of the belly.

Sun-dew. See *Drosera rotundifolia.*

Superarse'nias potassæ. Superarseniate of potash. A compound of potash with excess of arsenic acid. It was called *Macquer's arsenical salt*, from its discoverer; and has been sometimes given in medicine, possessing similar properties to those of the white oxide of arsenic.

Superbus. See *Rectus superior oculi.*

SUPERCI'LIUM. (*um, ii.* n.; so called because it is *supra cilium.*) The eyebrow.

Supercilium veneris. See *Achillea millefolium.*

SUPE'RFLUUS. Superfluous: abounding; in excess. See *Polygamia.*

SUPERFŒTA'TION. (*Superfœtatio, onis.* f.; from *super*, above or upon, and *fœtus*, a fœtus.) The impregnation of a woman already pregnant. How far this is a possible case has for ages been a matter of controversy among physiologists and medical jurisconsults, and it remains so to the present time. Those who oppose the doctrine of superfœtation, regard all the apparent instances of it as in reality cases of twins, in which either one fœtus has died prematurely, but remained in utero along with the living one to the full period of gestation, or one ovum has been retarded in its descent into the uterus, and is hence less developed than the other, though both were impregnated by the same coition.

Supergemina'lis. (From *super*, above, and *gemini*, the testicles.) The epididymis, or body above the testicles.

Supergenua'lis. (From *super*, above, and *genu*, the knee.) The patella, or knee-pan.

Superimpregna'tio. (From *super*, above, and *impregnatio*, a conception.) See *Superfœtation.*

SUPE'RIOR. A term in general use as regards the relative situation of parts.

Superior auris. See *Attollens aurem.*

SUPERLI'GULA. (From *super*, above, and *ligula*, a little tongue.) The epiglottis.

Superpurga'tio. (From *super*, beyond, and *purgo*, to purge.) An excessive evacuation by stool.

Supersalt. See *Subsalt.*

SUPERSCAPULA'RIS. (From *super*, upon, and *scapula*, the shoulder-blade.) Two muscles are so called; the *super scapularis superior*, more commonly called *supra-spinatus*, and the *superscapularis inferior*, more commonly called *infra-spinatus.*

SU'PERUS. Above: applied to the perianthium of flowers when placed above the germen; as in roses, and the genus *Pyrus.*

SUPINA'TION. (*Supinatio, onis.* f.; from *supino*, to lay with the face upwards.) The act of turning the palm of the hand upwards, by rotating the radius upon the ulna.

SUPINA'TOR. (From *supino*, to lay with the face upwards.) A name given to those muscles which turn the hand upwards.

Supinator brevis. See *Supinator radii brevis.*

Supinator longus. See *Supinator radii longus.*

SUPINATOR RADII BREVIS. A supinator muscle of the hand, situated on the fore-arm. *Supinator brevis sive minor*, of Winslow. This small muscle, which is tendinous externally, is situated at the upper part of the fore-arm under the supinator longus, the extensor carpi radialis brevis, the extensor carpi ulnaris, the extensor digitorum communis, and the extensor minimi digiti.

It arises tendinous from the lower and anterior part of the outer condyle of the os humeri, and tendinous and fleshy from the outer edge and posterior surface of the ulna, adhering firmly to the ligament that joins the radius to that bone. From these origins its fibres descend forwards and inwards, and are inserted into the upper, inner, and anterior part of the radius around the cartilaginous surface upon which slides the tendon of the biceps, and likewise into a ridge that runs downwards and outwards below this surface. It assists in the supination of the hand by rolling the radius outwards.

SUPINATOR RADII LONGUS. *Supinator longus*, of Albinus. *Supinator longus sive major*, of Winslow. A long flat muscle covered by a very thin tendinous fascia, and situated immediately under the integuments along the outer convex surface of the radius. It arises, by very short tendinous fibres, from the anterior surface and outer ridge of the os humeri, about two or three inches above its external condyle, between the brachialis internus and the triceps brachii; and likewise from the anterior surface of the external intermuscular membrane, or ligament, as it is called. About the middle of the radius, its fleshy fibres terminate in a flat tendon, which is inserted into the inner side of the inferior extremity of the radius, near the root of its styloid process.

This muscle not only assists in rolling the radius outwards, and turning the palm of the hand upwards, on which account Riolanus first gave it the name of *supinator*, but it likewise assists in pronation, and in bending the fore-arm.

SUPPOSITO'RIUM. (*um*, *i.* n.; from *sub*, under, and *pono*, to put.) A suppository, *i. e.* a substance to put into the rectum, there to remain and dissolve gradually.

Suppressed menses. See *Amenorrhœa.*

SUPPRESSION. (*Suppressio*, *onis.* f.; from *supprimo*, to withhold.) The total defect or non-secretion of an excrementitious fluid, as a suppression of urine, in which the kidneys secrete none. The rapidly fatal effects of a total suppression of urine have been particularly pointed out by Sir Henry Halford. If the secretion be not restored, the patient dies in a state of coma within three days.

SUPPURA'TION. (*Suppuratio*, *onis.* f.; from *suppuro*, to suppurate.) The formation of pus. See *Inflammation*, *Abscess*, and *Pus.*

SU'PRA. Above. This word, affixed to the name of an object, denotes something situated above that object, as *supra-renal gland*, &c.

Supra-costales. See *Intercostal muscles.*

SUPRA-DECOMPO'SITUS. More than doubly compound: a botanical term, applied to leaves.

SUPRA-FOLIACEOUS. Situated above the leaf.

SUPRA-SPINA'TUS. *Supra-spinatus seu super-scapularis*, of Cowper. A muscle of the arm, first so named by Riolanus, from its situation. It is of considerable thickness, wider behind than before, and fills the whole of the cavity or fossa that is above the spine of the scapula. It arises fleshy from the whole of the base of the scapula that is above its spine, and likewise from the spine itself, and from the superior costa. Opposite to the basis of the coracoid process, it is found beginning to degenerate into a tendon, which is at first covered by fleshy fibres, and then passing under the acromion, adheres to the capsular ligament of the os humeri, and is inserted into the upper part of the large tuberosity at the head of the os humeri. This muscle is covered by a thin fascia which adheres to the upper edge and superior part of the basis, as well as to the upper edge of the spine of the scapula. The principal use of the supra-spinatus seems to be to assist in raising the arm upwards; at the same time, by drawing the capsular ligament upwards, it prevents it from being pinched between the head of the os humeri and that of the scapula. It may likewise serve to move the scapula upon the humerus.

SU'RA. (An Arabic word.) 1. The calf of the leg.

2. The fibula.

SU'RCULUS. (*us*, *i.* m.) A term applied by botanists to the stem of mosses, or the shoot which bears the leaves. It is *simple*, in *Polytrichum*; *branched*, in *Minium androgynum*; with *branches turned downward*, in *Sphagnum palustre*; *decumbent*, *creeping*, or *erect* in other mosses.

SU'RDITAS. Deafness. See *Aphonia*, and *Paracusis.*

SURFEIT. The consequence of excess in eating or drinking, or of something unwholesome or improper in the food. It consists in a heavy load or oppression of the stomach, with nausea, sickness, impeded perspiration, and, at times, eruptions on the skin.

Surgery. See *Chirurgia.*

Surmullet. See *Mullus.*

SUS. (*Sus*, *suis.* m. and f.) The name of a genus of animals. Class, *Mammalia*; Order *Pachyderma.* The hog.

SUS SCROFA. The systematic name of the hog, the fat of which is called lard. The flesh called pork, especially when young, is much used in most countries. It is generally easy of digestion, though it disagrees with some stomachs. Salted, it affords a harder food, still very nutritious to hard-working people, whose digestion is good.

Suspended animation. See *Asphyxia.*

SUSPENSION. *Suspensio.* Hanging. See *Asphyxia.*

SUSPENSO'RIUM. (*um*, *ii.* n.; from *suspendeo*, to hang.) A suspensory: a bag, or bandage to suspend any part.

SUSPENSORIUM HE'PATIS. The broad ligament of the liver.

Suspensorius testis. The cremaster muscle of the testicle.

SUSU'RRUS. (*us, i.* m.; from *susurro*, to murmur.) 1. A buzzing noise, like that of bees.

2. A whisper, or low tone of voice. See *Whisper.*

SUTU'RA. (*a, æ.* f.; from *suo*, to join together.) A suture. 1. In *Surgery*, this term signifies the uniting the lips of a wound by sewing. *Clavata commissura.* A number of a different kinds of sutures have been recommended by writers on surgery, but all of them are now reduced to two; namely, the *twisted*, and the *interrupted*, called also the *knotted suture.* The twisted suture is made in the following manner: — Having brought the divided parts nearly into contact, a pin is to be introduced from the outside inwards, and carried out through the opposite side to the same distance from the edge that it entered at on the former side; a firm wax ligature is then to be passed around it, making the figure of 8, by which the wounded parts are drawn gently into contact. The number of pins is to be determined by the extent of the wound: half an inch, or at most three quarters, is the proper distance between two pins. The interrupted suture is practised where a number of stitches is required, and the interruption is only the distance between the stitches.

2. In *Anatomy*, the word suture is applied to the union of bones by means of dentiform margins, as in the bones of the cranium. See *Temporal, sphenoidal, zygomatic, transverse, coronal, lamboidal*, and *sagittal sutures.*

3. In *Botany*, it is applied to that part of a capsule which is a kind of furrow on the external surface, in which the valves are united. See *Capsula.*

Swallow-wort. See *Hirundinaria.*

Swan. See *Cygnus.*

Swan, tame. See *Cygnus mutus*, and *Anas cygnus.*

Sweat. See *Perspiration.*

Sweet flag. See *Acorus calamus.*

Sweet marjoram. See *Origanum marjorana.*

Sweet navew. See *Brassica rapa.*

Sweet rush. See *Andropogon schænanthus.*

Sweet sultan. The *Centaurea moschata.*

Sweet willow. See *Myrica gale.*

SWIETE'NIA. (*a, æ.* f.; named after Van Swieten.) The name of a genus of plants. Class, *Decandria*; Order, *Monogynia.*

Swietenia febri'fuga. The red wood tree. The bark of this tree was proposed as a substitute for cinchona, and appears to have some febrifuge power, though not at all equal to that of the cinchona. Dr. Ainslie found, that when given to the extent of four or five drachms in the twenty-four hours, it occasioned vertigo and stupor. It is now never used in Europe. The timber of this tree is very hard and durable, and affords a red dye.

Swietenia maha'goni. The systematic name of the mahogany tree. The bark of the wood of this tree is of a red colour internally; has an astringent bitter taste; and yields its active matter to water. It has been proposed as a substitute for Peruvian bark, and has been used as such with advantage. Dose, half a drachm.

Swine-pox. See *Varicella.*

Swinging. See *Gestation.*

Sword-fish. See *Xiphias gladius.*

Sword-shaped. See *Lanceolatus*, and *Ensiformis.*

Sycamore. See *Sycomore.*

SYCO'MA. (From συκη, a fig.) *Sycosis.* A wart or excrescence resembling a fig, on the eyelid, about the anus, or any other part.

SYCOMORE. (*Sycomorus*; from συκον, a fig, and μωρον, a mulberry, because it belongs to the genus *ficus*, and has leaves like the mulberry tree.) It is a native of Egypt. The white sap has been esteemed laxative and vulnerary.

SYCO'SIS. (*is, is.* f.; from συκωσις, from συκον, a fig: and so called from the granulated and prominent surface of the ulceration which takes place in the disease.) A cutaneous disease which consists of an eruption of inflamed, but not very hard tubercles, occurring on the bearded portion of the face and on the scalp in adults, and usually clustering together in irregular patches. Celsus has correctly stated that some difference takes place in the appearance and the progress of the eruption, when it is seated in the chin and in the scalp; whence he divides it into two species.

1. In the *Sycosis menti*, the tubercles arise first on the under lip, or on the prominent part of the chin, in an irregularly circular cluster; but this is speedily followed by other clusters, and by distinct tubercles, which appear in succession, along the lower part of the cheeks up to the ears, and under the jaw towards the neck, as far as the beard grows. The tubercles are red and smooth, and of a conoidal form, and nearly equal to a pea in magnitude. Many of them continue in this condition for three or four weeks, or even longer, having attained their full size in seven or eight days; but others suppurate very slowly and partially, discharging a small quantity of thick matter, by which the hairs of the beard are matted together, so that shaving becomes impracticable, from the tender and irregular surface of the skin. This condition of the face, rendered rugged by tubercles from both ears round to the point of the chin, together with the partial ulceration and scabbing, and the matting together of the unshaven beard, occasions a considerable degree of deformity; and it is accompanied also with a very troublesome itching.

This form of the sycosis occurs, of course, chiefly in men; but women are not altogether exempt from it, though it is commonly slight when it appears in them. Its duration is very uncertain: it is commonly removed in about a fortnight: but sometimes the slow suppuration goes on for many weeks; and sometimes the suppurating turbercles heal, and again begin to discharge. Occasionally the disease disappears for a season, and breaks out again.

2. The *Sycosis capillitii*, is seated chiefly about the margin of the hairy scalp, in the occiput, or round the forehead and temples, and near the external ear, which is also liable to be included in the eruption. The tubercles rise in clusters, which affect the circular form: they are softer

and more acuminated than those on the chin; and they all pass into suppuration in the course of eight or ten days, becoming confluent, and producing an elevated, unequal, ulcerated surface, which often appears granulated, so as to afford some resemblance to the internal pulp of a fig. The ulceration, as Celsus states, is generally humid; for there is a considerable discharge of a thin ichorous fluid, which emits an unpleasant rancid odour.

The sycosis, under its first-mentioned form, may be distinguished from acne, by its seat being exclusively on the bearded part of the face, — by the softer, more numerous, and clustered turbercles, — and by the ulceration which they tend to produce. And, under its second form, in which it is somewhat assimilated to the eruption of favous pustules, or porrigo favosa, affecting the face and the borders of the hairy scalp, it may be discriminated by the turberculated and elevated base of the suppurating tumours; not to mention the adult age of the patient, and the absence of contagion.

The cure of sycosis is generally much more easily accomplished than that of porrigo favosa; but the method of treatment required for it is not very different. When the tubercles are numerous, inflamed, and confluent, and especially when the suppuration is either beginning or considerably advanced, the most speedy benefit is derived from the application of poultices, at night, of linseed meal, bread and milk, or other simple ingredients. In the less severe forms warm ablutions or fomentations may be substituted, when the inflammatory symptoms are reduced; and in cases where they are from the first moderate, the healing process is much promoted, and the discharge moderated and restrained, by the unguentum hydrargyri nitrati, or the unguentum hydrargyri præcipitati albi, reduced with common cerate. Ointments of zinc and acetate of lead are in some cases useful. At the same time attention must be paid to the constitution, which mostly requires tonics.

Sylphium. See *Silphium.*

Sylvius, digestive salt of. See *Sal digestivum sylvii.*

SYMBLE/PHARUM. (*um, i.* n.; from *συν*, with, and *βλεφαρον*, the eyelid.) A concretion of the eyelid to the globe of the eye. This chiefly happens in the superior, but very rarely in the inferior, palpebra. The causes of this concretion are a bad conformation of the parts, or from ulcers of the cornea, the membrana conjunctiva, or internal superficies of the palpebræ, or imprudent scarifications, or burns, especially if the eye remains long closed. There are two species, — the partial and total: in the former, the adhesion is partial; in the latter, the membrana conjunctiva and cornea are concreted to the eyelid.

Symbolo'gica. (From *συμβυλον*, a sign, and *λογος*, a discourse.) This term has been used by some writers synonymously with *symptomatology.*

SYMMETRY. (*Symmetria, æ.* f.; from *συν*, with, and *μετρον*, a measure.) The correspondence of parts in size and shape.

SYMMETRICAL. Endowed with symmetry. In *Anatomy*, organs are said to be symmetrical which are divided by the median line of the body into halves, which resemble each other more or less exactly. Thus the two hemispheres of the brain are symmetrical; the two sides of the pelvis are symmetrical. In the animal body the organs of relation only are symmetrical; those of organic life are not so; thus the parts of the liver are not symmetrical, nor those of the lungs. It is to be observed, however, that in the best formed body the symmetry of parts is not perfect: thus there are few individuals who have both sides of the face exactly of the same shape, or both hands exactly of the same size.

Sympa'sma. (*a, atis.* n.; from *συν*, and *παασσω*, to sprinkle.) A dry powder, which the ancients used to sprinkle over the body. See *Catapasma.*

SYMPATHETIC. *Sympatheticus.* Relating to sympathy.

Sympathetic ink. Among the amusing experiments of the art of chemistry, the exhibition of sympathetic inks holds a distinguished place. With these the writing is invisible, until some re-agent gives it opacity. We shall here mention a few, out of a great number, that a slight acquaintance with chemistry may suggest to the student. 1. If a weak infusion of galls be used, the writing will be invisible till the paper be moistened with a weak solution of sulphate of iron. It then becomes black, because these ingredients form ink. 2. If paper be soaked in a weak infusion of galls, and dried, a pen dipped in the solution of sulphate of iron will write black on that paper, but colourless on any other paper. 3. The diluted solutions of gold and silver remain colourless upon the paper until exposed to the sun's light, which gives a dark colour to the oxides, and renders them visible. 4. Most of the acids, or saline solutions, being diluted, and used to write with, become visible by heating before the fire, which concentrates them, and assists their action on the paper. 5. Diluted prussiate of potash affords blue letters when wetted with the solution of sulphate of iron. 6. The solution of cobalt in aqua regia, when diluted, affords an ink which becomes green when held to the fire, but disappears again when suffered to cool. This has been used in fanciful drawings of trees, the green leaves of which appear when warm, and vanish again by cold. If the heat be continued too long after the letters appear, it renders them permanent. 7. If oxide of cobalt be dissolved in acetic acid, and a little nitre added, the solution will exhibit a pale rose colour when heated, which disappears on cooling. 8. A solution of equal parts of sulphate of copper and muriate of ammonia gives a yellow colour when heated, that disappears when cold.

Sympathetic inks have been proposed as the instruments of secret correspondence; but they are of little use in this respect, because their properties change by a few days remaining on the paper; most of them have more or less of a tinge when thoroughly dry; and none of them resist the test of heating the paper till it begins to be scorched. — *Ure.*

Sympathetic nerve. See *Intercostal nerve.*

SYMPATHY. (*Sympathi'a, æ.* f. Συμπαθεια; from συν, with, and παθος, affection.) That relation of the organs and parts of the living body to each other whereby an action excited in one part induces a corresponding action in another part.

Baglivi attributed the sympathies to membranous connexion; Bordeu to the cellular tissue; Willis and Vieusens to the agency of the nerves; and Whitt and Broussais chiefly to the brain. Rega divided the sympathies into those of *sensibility* and those of *contractility* — a division which has much to recommend it. Bichât offered some very excellent observations on the relations subsisting between them and the different parts of the nervous system; but, although these observations were calculated to lead to a more correct arrangement of the sympathies than had been formerly offered, it has not come to our knowledge that any has appeared founded on a better basis than that indicated in the observations of Bichât.

The sympathies may be arranged into the *reflex* and the *direct;* the former arising through the instrumentality of the sensorium, the latter taking place independently of it, through the means of the ganglial nerves, and chiefly of those which are distributed to the blood-vessels, and which form communicating chords between the viscera.

With a view to the illustration of the latter class of sympathies, viz. those which are direct, and chiefly consist of the sympathetic actions of organic life, we shall offer a few remarks.

When it is considered, that the ganglial nerves alone supply the blood-vessels and the secreting organs and surfaces; that they accompany these vessels to the utmost limits of their ramifications; that they communicate very freely with each other, and with their chief centre, the semilunar ganglion; that they give rise to numerous plexuses, which render the connexion between them still more intimate; and that they hold a close relation with the rest of the nervous system, through means of communicating nerves; — the mutual dependence of action between the chief organs of the body, in health and in disease, may be easily explained. If, moreover, it be granted that the most important vital phenomena, as digestion, assimilation, circulation, secretion, animal heat, generation, &c.; in short, that life itself, with all those manifestations of it now particularised, and which have been usually called organic, results from the influence exerted by this part of the nervous system, through the instrumentality of the vessels upon the fluid they contain, and in some measure reciprocally by this fluid upon these nerves ramified in the parietes of the vessels, and upon the ganglia themselves, through which it must of course circulate, — the agency of this system in the production of the class of sympathies under consideration must be evident. From this view of the subject, and from taking into account the modifying operation of similar textures, the related action of various organs, and, under certain circumstances, the combined influence and reaction of the sensorium, the numerous relations and connexions of healthy function and of disordered action may be more satisfactorily traced.

When one organ or system of parts is excited to increased action, or when its operations are diminished or obstructed, we perceive all the other parts of the system which communicate with it through the medium of the ganglial system, experiencing a modification of their functions, — the action of one or more organs having always an evident relation to the kind and degree of action going on in the other. In these cases the relation is sufficiently manifest; but the kind and degree of it may vary very greatly between different organs. And the relations may be of the following sorts, as the vital energies distributed throughout the system are effected in degree or in kind, or in both ways at the same time.

I. *Organic sympathies, in which the vital energy of the system evinces various modifications in degree and distribution, but in which it is not changed in kind.*

1. Related actions may be characterised by a due proportion or a healthy degree of the vital forces of the whole system; but, owing to the application of an exciting cause to one organ or part, or to two or three organs, these forces may be greatly increased in them; as, however, the healthy or medium quantity of the vital forces of the body is not supposed to be exceeded, there consequently must be a diminution of these forces throughout the other parts of the system, in proportion to the increase in the excited organs.

When the natural functions of one organ are simply excited, without being diseased, the functions of other organs with which it holds communication, by means of the ganglial nerves, undergo a relative degree of change, — for the excitement of a viscus is merely an exaltation of its vitality; and, as we exalt the vital actions in one or more departments of the entire series, we diminish them throughout the rest in an equal proportion; the excitement being frequently greater or less in some parts, and the diminution more or less confined to others.

If, for the sake of illustration, we suppose the vital energies of the system to be equal to 50; and, through means of the organic or ganglial nerves to be distributed as follows, — to the stomach and intestines, 7; to the heart, vascular system, and lungs, 8; to the brain and voluntary nerves, 7; to the liver, spleen, and pancreas, 6; to the generative organs, 3; to the urinary apparatus, 4; to the surface of the body, 3; to the rest of the body, 11; we may consider that it is duly proportioned. But if, owing to the application of certain excitants to one or more organs, as to the stomach and intestines, we exalt the proportion bestowed on these to 13, we shall consequently find the brain and voluntary nerves possessing only 5; the heart, vessels, and lungs, 7; the urinary organs, 3; the surface of the body, 2; and the rest of the body experiencing the loss of the remaining one. If, again, we excite the vital

forces distributed to the heart and vascular system until they amount to 16, we shall have a febrile condition of the system in its simplest form, and all the other organs will suffer a diminution in proportion: the stomach will only equal 4, and so on in proportion. But the vital forces of the heart and blood-vessels may equal 16; and, owing to the arteries of the brain experiencing an undue proportion of this increase, this organ may at the same time equal 10; or, instead of this increase falling to the lot of the cerebral vessels, those of other viscera may be similarly augmented, whilst those of the remaining organs may be proportionally diminished: in such cases we have a less simple result; but, nevertheless, the increase of the circulating functions is followed by an equal diminution of the secreting. Viewing the sympathetic connexion of function in another direction, we shall suppose that the excited state of vital action takes place in secreting organs: in this case the nutritive and other animal operations are diminished in an equal degree. Or we shall suppose that the excitement commences in the capillaries of an organ, from the presence of an irritating cause; that, owing to these vessels being supplied with ramifications of the same order of nerves, which supply the heart and vascular system generally, the excitement extends more or less throughout this system; and that, in consequence of the continuity of this order of nerves, and their very frequent reticulations and inosculations, not only do the heart and arteries experience the excitement produced at a part of the extreme circumference, but the whole body suffers a relative degree of derangement, and hence evinces all the phenomena of sympathetic fever. Thus, the capillaries of a particular organ are excited; the excitement extends more or less generally throughout the vascular series, and the nutritive and secreting functions are diminished in proportion as the actions of the heart and arteries are increased. Many collateral views of this subject may be adduced, and many of its connexions traced, as well as various modifying influences, both in and out of the body, appreciated — all tending to establish the position, that it is chiefly to the ganglial nerves we ought to attribute the manifold phenomena of related action which we observe in the animal economy. At this place we have only considered one of the genera belonging to this class of sympathies, namely, that which comprehends the most simple of the related actions — those which supervene in the system without an increase or diminution of the whole amount of the vital energies with which the body is endowed. The other kinds of related function have been pointed out in the above arrangement of this class of sympathies, and we cannot farther allude to them here; indeed, it would be much beyond our limits to consider fully the different kinds of sympathy in their manifold relations; we have illustrated one more particularly, because of its importance, and of its having been very generally overlooked.

In this order of sympathies there are three relations to be observed, which actually more or less obtain and constitute the essence of the subject, or the actual condition of the animal functions under consideration: 1st, the relation may respect the increased actions subsisting in two or more organs; 2d, it may be viewed between the increased functions of one part and the diminished functions of another; and 3d, it may regard the diminished functions observed in those parts which do not participate in the excitement; the relation being most immediate in the first, and least so in the third of these forms.

2. The sympathetic or related actions may be attended with a diminution of the sum of the vital energies throughout the system. In this case the different relations pointed out above may nevertheless exist, or one or two of them only may be remarkable; the chief difference here being that the sympathies of this order are generally induced by agents, which while they diminish the entire sum of vital energy, act more decidedly upon particular organs or systems of parts.

3. The sympathetic operations may be characterised by a somewhat greater amount of the vital energies of the whole body. In this order of sympathies the three relations particularised above also subsist; for, although the entire sum of vital actions may be greater than what is usually bestowed on the system, it may be so much increased in some organs as to be greatly diminished in others. This condition of functional sympathy seldom continues long, until it subsides to the first, or, from exhaustion of the vital energies, to the second order just now particularised.

II. *Organic sympathies in which, in addition to various modifications in degree and distribution, the vital energy of the system suffers a change in its kind.*

1. Sympathetic actions in which the general amount of the vital forces is natural in degree but vitiated or modified in kind, the relation being evident — 1st, mutually between those functions which are increased; 2d, between the actions which are augmented and those which are diminished; and, 3d, between those only which are diminished.

2. Sympathies in which the entire sum of vital energy is both reduced in degree and modified in kind; the relation between its distribution in the various organs being the same as just now pointed out.

3. Sympathies in which the amount of the whole vital energy is both heightened in degree and modified in kind. In this order, the distribution and the relations to which such distribution gives rise are the same as already adduced.

The application of this classification, and the views which it embraces, to medicine, must appear evident. — *Copland.*

Dr. Burns, of Glasgow, in his excellent treatise on inflammation, a work less generally known than it deserves, has taken some original views of the subject of sympathy, of which the following is an abstract. All the body is sympathetically connected together, and dependent the one part upon the rest, constituting

general sympathy. But sometimes we find particular parts more intimately dependent upon each other than upon the rest of the body, constituting a particular sympathy. Action cannot be greatly increased in any one organ without being diminished in some other; but certain parts are more apt to be affected by the derangement of particular organs than others; and it was the observance of this fact which gave foundation to the old and well-known doctrine of sympathy, which was said to proceed "*tum ob communionem et similitudinem generis, tum ob viciniam.*" It may be thought that this position of action, being diminished in one organ by its increase either in the rest or in some other part, is contradicted by the existence of general diseases or actions affecting the whole system. But in them we find, in the first place, that there is always some part more affected than the rest. This local affection is sometimes the first symptom, and affects the constitution in a secondary way, either by the irritation which it produces, or by an extension of the specific action. At other times the local affection is coeval with the general disease, and is called sympathetic. It is observed in the second place, that, as there is some part which is always more affected than the rest, so also is there some organ which has its action, in consequence of this, diminished lower than that of the rest of the system, and most commonly lower than its natural standard. From the extensive sympathy of the stomach with almost every part of the body, we find that this most frequently suffers, and has its action diminished in every disease, whether general or local, provided that the diseased action arises to any considerable degree. There are also other organs which may, in like manner, suffer from their association or connexion with others which become diseased. Thus, for instance, we see, in the general disease called puerperal fever, that the action of the breasts is diminished by the increased inflammatory action of the uterus.

In consequence of this balance of action, or general connexion of the system, a sudden pain, consequent to violent action of any particular part, will so weaken the rest as to produce fainting, and occasionally death. But this dependence appears more evidently in what may be called the smaller systems of the body, or those parts which seem to be more intimately connected with each other than they are with the general system. Of this kind is the connexion of the breasts with the uterus of the female; of the urethra with the testicles of the male; of the stomach with the liver; and of the intestines with the stomach, and of this again with the brain; of the one extremity of the bone with the other; and of the body of the muscle with its insertion; of the skin with the parts below it.

These smaller systems, or circles, shall be treated regularly: but first it may be proper to observe, that these are not only intimately connected with themselves, but also with the general system, an universal sympathy being thus established.

That there is a very intimate connexion between the breasts and uterus has been long known; but it has not been very satisfactorily explained. Fallopius, and all the older authors, declare plainly that the sympathy is produced by an anastomosis of vessels; Bartholine adding that the child being born, the blood no longer goes to the uterus, but is directed to the breasts and changed into milk. But none of all those who talk of this derivation assign any reasonable cause which may produce it.

In pregnancy, and at the menstrual periods, the uterus is active; but, when the child is delivered, the action of the uterus subsides, whilst the breasts in their turn become active, and secrete milk. If, at this time, the uterus is again put into action, that of the breasts is diminished, and the secretion of milk is destroyed, as is well illustrated by the case of inflammation of the uterus, which is incident to lying-in women. When the uterus, at the cessation of the menses, ceases to be active, or to secrete, we often find that the breasts have an action excited in them, becoming slowly inflamed, and assuming a cancerous disposition. The uterus and breasts seem to be a set of glands balancing each other in the system, one only being naturally active, or secreting properly, at a time; and accordingly we seldom, if ever, find that when the uterus yields the menstrual discharge, the milk is secreted in perfection during the continuance of this discharge, nor do we ever find them both inflamed at the same time.

The uterus has not only this connexion with the breasts, but it has also a very particular sympathy with the stomach, which again sympathises with the brain; and thus we see how a disorder of the uterus may induce an extensive series of affections, each dependent on the other.

The organs of generation in the male form likewise a little system, in which all the parts exhibit this sympathy with each other. They likewise give us a very good instance of the association of action, or sympathy in the common acceptation of that word.

Sympathy is divided into, first, the sympathy of equilibrium, in which one part is weakened by the increased action of another; and, secondly, the sympathy of association, in which two parts act together at the same time.

The sympathy of association is produced suddenly, and for a short time. The sympathy of equilibrium is produced more slowly, and continues to operate for a much longer time.

It is curious enough that most, or at least many, of those organs, which seem to be connected by the sympathy of equilibrium, exhibit, likewise, more or less of the sympathy of association, when under the circumstances in which this can take place.

The sympathy of equilibrium is seen in the effects of inflammation of the end of the urethra or the testicle, which often diminishes its action, and produces a very disagreeable sensation of dulness; or, if this inflammation be suddenly diminished, the action of the testicle is as suddenly increased, and swelling takes place. The same is seen in the connexion of the urethra

with the bladder and prostate gland, as is mentioned in all the dissertations on gonorrhœa. These parts likewise affect the stomach greatly, increased action in them weakening that organ much. This is seen in the effects of swelled testicle, or excessive venery, or inflamed bladder, and in a stone; all which weaken the stomach, and produce dyspepsia. The same remark applies to the kidney; vomiting and flatulence being produced by nephritis.

The sympathy of association, or an instance of sympathy in the common acceptation of the word, is likewise seen in the connexion betwixt the glans and testicles in coition; but, for this purpose, the action in the glans must be sudden and of short duration; for, if continued long, weakness of the testicles, or diminished action, is induced. In those parts which exhibit this natural association of action, if the action of one part be suddenly and for a short time increased, the action of the sympathising part will likewise be increased; as we see in the instance already given of coition, and likewise in paroxysms of the stone, in which the glans penis, after making water, becomes very painful.

But if the action be more slowly induced, and continued for a long time, then this association is set aside, by a stronger and more general principle of the equilibrium of action, and the sympathising part is weakened. Hence violent inflammation of the end of the urethra produces a weakness and irritability of the bladder, dulness of the testicle, &c.

There is also an evident sympathy of equilibrium betwixt the stomach and lower tract of intestines; which two portions may be said, in general, to balance each other in the abdomen. When the action of the intestines is increased in diarrhœa, the stomach is often weakened, and the patient tormented with nausea. This will be cured, not so easily by medicines taken into the stomach, as by anodyne clysters, which will abate the action of the intestines. When the intestines are inflamed, as in strangulated hernia, vomiting is a never-failing attendant.

When, again, the stomach is inflamed, the intestines are affected, and obstinate costiveness takes place; even in hysterical affections of the stomach, the intestines are often deranged. Injections of cold water frequently relieve these affections of the stomach, by their action on the intestines.

The liver and stomach are also connected with one another. When the liver is inflamed, or has its action increased, the stomach is weakened, and dyspeptic symptoms take place. When the stomach is weakened, as, for instance, by intoxication, then the action of the liver is increased, and a greater quantity than usual of bile is secreted. The same takes place in warm climates, where the stomach is much debilitated.

If the liver has its action thus frequently increased, it assumes a species of inflammation, or becomes, as it is called, scirrhous. This is exemplified in the habitual dram-drinkers, and in those who stay long in warm countries and make free with their stomachs. The liver likewise sympathises with the brain; for when this organ is injured, and its action much impaired, as in compression, inflammation and suppuration have been often known to take place in the liver.

Besides this connexion of the stomach with the liver, it is also very intimately dependent on the brain, being weakened when the action of the brain is increased; as we see in an inflammation of that organ. The brain again is affected with pain when the stomach is weakened by intoxication, or other causes; and this pain will be often relieved by slowly renewing the action of the stomach by such stimuli as are natural to it, such as small quantities of soup frequently repeated. A slight increase of action in the stomach, at least if not of a morbid kind, affects the brain so as to produce sleep, diminishing its action. This we see in the effects of a full meal, and even of a draught of warm water. The stomach, likewise, sympathises with the throat, squeamishness, and anorexia being often produced by inflammation of the tonsils. This inflammation is frequently abated by restoring or increasing the action of the stomach. Hence the throat, in slight inflammation, is frequently easier after dinner: hence, likewise, the effects of emetics in cynanche.

The extremities of bones and muscles also sympathise in the same manner. When one end of a bone is inflamed, the action of the other is lessened, and pain is produced; for a painful sensation may result both from increased and diminished action. When the tendon of a muscle is inflamed, the body of that muscle often is pained, and *vice versâ*.

Lastly, the external skin sympathises with the parts below it. If it be inflamed, as in erysipelas, the parts immediately beneath are weakened, or have their natural action diminished. If this inflammation affect the face or scalp then the brain is injured; and headach, stupor or delirium supervene. If it attack the skin of the abdomen, then the abdominal viscera are affected, and we have vomiting and purging, or obstinate costiveness, according to circumstances. This is illustrated by the disease of children, which is called by the women the bowel-hive, in which the skin is inflamed, as they suppose, from some morbid matter within.

If the internal parts be inflamed, the action of the surface is diminished, and, by increasing this action, we can lessen or remove the disease below; as we see daily proved by the good effects of blisters. When the stomach, intestines, or kidney have been very irritable, a sinapism has been known to act like a charm; and, in the deep-seated inflammations of the breasts, bowels, or joints, no better remedy is known, after the use of the lancet, than blisters.

The utility of issues in diseases of the lungs, the liver, and the joints, is to be explained on the same principle. In these cases we find that issues do little good unless they be somewhat painful, or be in the state of healthy ulcers. An indolent flabby sore, however large the discharge (which is always thin, and accompanied with little action), does no good, but only adds to the misery of the patient. We may, how-

ever, err on the other hand, by making the issues too painful, or by keeping them active too long; for, after they have removed the inflammatory disease below, they will still operate on these parts, lessening their action, and preventing the healing process from going on properly. This is seen in cases of curvature of the spine, where, at first, the inflammation of the vertebra is diminished by the issues; but if they be kept long open after this be removed, they do harm. We often see the patient recover rapidly after his surgeon has healed the issue in despair, judging that it could do no farther service, but only increase the weakness of his patient.

It is a well-established fact that, when any particular action disappears suddenly from a part, it will often speedily affect that organ which sympathises most with the part that was originally diseased. This is best seen in the inflammatory action, which, as practical writers have well observed, occasionally disappears quickly from the part first affected, and then shows itself in some other.

From the united testimony of all these facts, Dr. Burns maintains the doctrine just delivered, and proposes to introduce it into pathological reasonings. In the whole of the animal economy we discover marks of the wisdom of the Creator, but perhaps in no part of it more than in this, of the existence of the sympathy of equilibrium; for, if a large part of the system were to have its action much increased, and all the other parts to continue acting in the same proportionate degree as formerly, the whole must be soon exhausted; for increased action would require for its support an increased quantity of energy.

But upon this principle, when action is much increased in one part, it is to a certain degree diminished in some other: the general sum or degree of action in the body is thus less than it otherwise would be, and consequently the system suffers less.

SY'MPHYSIS. (*is, is.* f.; from *συμφυω*, to grow together.) Mediate connexion. A genus of the connexion of bones, in which they are united by means of an intervening body. It comprehends four species; viz. synchondrosis, syssarcosis, synneurosis, and syndesmosis.

SY'MPHYTUM. (*um, i.* n.; from *συμφυω*, to unite: so called because it was supposed to unite the lips of wounds.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia*.

2. The pharmacopœial name of the comfrey. See *Symphytum officinale*.

Symphytum maculosum. See *Pulmonaria officinalis.*

Symphytum minus. See *Prunella vulgaris.*

SYMPHYTUM OFFICINALE. The comfrey. *Consolida major.* This plant, *Symphytum officinale —foliis ovatis lanceolatis decurrentibus,* is administered where the althæa cannot be obtained, its roots abounding with a viscid glutinous juice, whose virtues are similar to those of the althæa.

Symphytum petræum. See *Coris Monspeliensis.*

SYMPTOM. (*Symptoma, æ.* f.; from *συμπτωμα*, a coincidence, because the symptom is coincident with the disease. The sign of a disease, consisting in some deviation from the natural and healthy functions of the diseased part, or some other which sympathises with it.

The symptoms of diseases are very numerous, because most of the functions of the body undergo a change when disease takes place.

Symptoms, then, are the phenomena of diseases; and every symptom is a change of action, or an unhealthy action, or lesion of a visible quality of some part of the body.

Symptoms may be arranged under three divisions, or heads: —

I. *Impaired Functions.*

To this division belongs, —

a. *In the Animal Functions.*

1. Loss of speech.
2. Incoherent speech.
3. Deliriousness.
4. Impaired memory.
5. Delusion.
6. Unsound judgment.
7. Mental extravagance.
8. Fancied inspiration.
9. Fanaticism.
10. Sentimentalism.
11. Diminished sensibility of mind.
12. Absence of mind.
13. Wandering fancy.
14. Unnatural conscientiousness.
15. Inordinate energy of the passions of the mind.
16. Numbness, or diminished feeling of the skin.
17. Unnatural feeling.
18. Destruction of the feeling.
19. Want of taste.
20. Depraved taste.
21. Diminished smell.
22. Unnatural smell.
23. Diminished sight.
24. Lost sight.
25. Impaired sight.
26. Nearness of sight.
27. Diminished hearing.
28. Hearing destroyed.
29. False hearing.
30. Unnatural movement of the muscles.
31. Hoarseness.
32. Faulty articulation.
33. Want of sleep.
34. Unnatural sleep.

b. *In the Vital Functions.*

1. A frequent pulse.
2. A slow pulse.
3. A strong pulse.
4. A feeble pulse.
5. A hard pulse.
6. A soft pulse.
7. A contracted pulse.
8. An irregular pulse.
9. An intermitting pulse.
10. A rebounding pulse.
11. No pulse.
12. The action of the heart ceasing for a time.

13. A cough.
14. A difficulty of breathing.
15. Sighing.

c. *In the Natural Functions.*

1. Want of appetite.
2. A voracious appetite.
3. Sickness of stomach.
4. Depraved appetite.
5. Thirst.
6. Want of thirst.
7. A difficulty of swallowing.
8. Costiveness.
9. Relaxation of bowels.
10. Unnatural fæces.
11. Increased perspiration.
12. An expectoration.
13. An increased flow of saliva.
14. Unnatural urine.

d. *In the Sexual Functions.*

1. Unhealthy semen.
2. Unnatural emission of semen.
3. Obstructed emission of semen.
4. A want of erectile power in the penis.
5. Unnatural erection.
6. Impotence.
7. Discharge from the urethra.
8. Unnatural discharge from the vagina.
9. Suspension of menstrual discharge.
10. Painful menstruation.

II. *Change of Visible Qualities.*

To this division belongs, —

1. Pallor of the skin.
2. Preternatural redness.
3. Blueness.
4. Yellowness.
5. Tumefaction.
6. Crackling noise on pressure.
7. Fluctuation.
8. Grating of bone.
9. Grating of the teeth.
10. A sound when tapped.
11. Excess of cruor in the blood.
12. Excess of serum in the blood.
13. Too dark a colour of the blood.
14. Too florid a colour.
15. An albuminous surface of the cruor of the blood.
16. A yellow serum.
17. Dilatation of the pupil.
18. Contracted pupil.
19. A wasting of the body.
20. A wasting of a part.
21. An increased size of the body.
22. An increased size of a part.

III. *Uneasy Sensations.*

Under this division come, —

1. Pain, or uneasy feeling.
2. Anxiety.
3. Lassitude.
4. Coldness.
5. Horripilation.
6. Heat.
7. Giddiness.

According to the origin, the time of appearing, the situation, and the nature of symptoms, and other circumstances, writers have made the following distinctions: —

1. The true symptoms of the disease.
2. The symptoms of symptoms.
3. The epiginomic, or supervening symptoms.

The more trivial distinctions are divided into, —

1. Precedent.
2. Concomitant.
3. Consequent.
4. Proper.
5. Common.
6. Characteristic.
7. Primary.
8. Secondary.
9. Pathognomonic.

It is by arranging together diseases, t symptoms of which are similar, that nosologis form them into classes, orders, genera, speci and varieties.

Synanche. See *Cynanche.*

Syna'nchica. (From συναγχη, the quins so called from its uses in that disease.) Qui sey-wort, — the *Asperula cynanchica.* Not n used.

SYNARTHRO'SIS. (*is, is.* f.; from σ αρθροω, to articulate.) That mode of connexi of bones in which they do not admit of moti on each other. It has three species, viz. sutu harmony, and gomphosis.

Synastomosis. See *Anastomosis.*

SYNCHONDRO'SIS. (*is, is.* f.; fr συν, with, and χονδρος, a cartilage.) A spec of symphysis, in which one bone is united w another by means of an intervening cartila as the vertebræ and the bones of the pubes.

SYNCHONDROTO'MIA. (*a, æ.* f.; fr συνχονδρωσις, the symphysis of the pubes, τεμνω, to cut.) The operation of dividing symphysis of the pubes. See *Sigaultian ope tion,* in the *Supplement.*

Sy'nchysis. (Συγχυσις, from συγχυω, to c found.) 1. A confusion of the humours of eye from injury or other cause.

2. A dissolution of the vitreous humour. *Benedict.*

Synciput. See *Sinciput.*

SY'NCLONUS. (From συν, together, κλονος, agitation.) A genus in Good's n logy, including diseases characterised by trer lous, simultaneous, and clonic agitation of muscles, especially when excited by the will

Synclonus balli'smus. The name give the shaking palsy by Dr. Good, from whom following account of it is taken.

It is the *sclotyrbe festinans* of Professor Sauvages, and the *shaking palsy* of Mr. Par son. The genus Tantarismus of Baligvi se to hold an equal point between *ballismus chorea,* and the species usually arranged u it may be resolved into the one or the ot and are done so under the present arrangem

The term Ballismus (βαλλισμος) is not t in a medical sense by the Greek writers, occurs in Athenæus and various other auth in the literal sense of tripudiatio, or "t ping, capering, curvetting on the toes;" f βαλλιζω, "tripudio, pedibus plaudo;" an hence well designed to express the cha teristic feature of the patient's being thr involuntarily, when he attempts to walk, " the toes and fore-part of his feet," to em

the language of Mr. Parkinson, "and impelled, unwillingly, to adopt a running pace:" or as Dr. Cullen, who has indiscriminately blended this species with the preceding, expresses it, to "various fits of leaping and running."

Ballismus, however, though not found in the writings of the Greek physicians, has been long established as a technical term in the medical nomenclature of later times, in which it has been used, with little discrimination, to import almost all or any of the species that belong to the present genus.

Sauvages observes that while chorea, or scelotyrbe *Sancti Viti*, attacks the young, ballismus, or scelotyrbe *festinans*, attacks those in advanced life; and the remark is founded on a just distinction of the characters of the two diseases; though there are other features also peculiar to each, which entitle them to be considered as perfectly distinct maladies. Shaking palsy, as it is called by Mr. Parkinson, who has adopted the colloquial name, is by no means a correct designation; for though in the disease before us there is a weakness of muscular fibre, and a diminution of voluntary power in the parts affected, there is none of that diminution of sensation by which palsy is generally characterised. Mr. Parkinson's description of the disease, however, is the best we have hitherto had, and is as follows: —

So imperceptible is the approach of this malady that the precise period of its commencement is seldom recollected by the patient. A slight sense of weakness, with a proneness to trembling, sometimes in the head, but most commonly in the hands or arms, are the first symptoms noticed. These affections gradually increase, and at the period, perhaps, of twelve months from their first being observed, the patient, particularly while walking, bends himself forward. Soon after this his legs suffer similar agitations and loss of power with the hands and arms.

As the disease advances, the limbs become less and less capable of executing the dictates of the will, while the unhappy sufferer seldom experiences even a few minutes' suspension of tremulous agitation: and should it be stopped in one limb by a sudden change of posture, it soon makes its appearance in another. Walking, as it diverts his attention from unpleasant reflections, is a mode of exercise to which the patient is in general very partial. Of this temporary mitigation of suffering, however, he is now deprived. When he attempts to advance he is thrown on the toes and fore part of his feet, and impelled, unwillingly, to adopt a running pace, in danger of falling on his face at every step. In the more advanced stage of the disease the tremulous motions of the limbs occur during sleep, and augment in violence till they awaken the patient in much agitation and alarm. The power of conveying the food to the mouth is impeded, so that he must submit to be fed by others. The torpid bowels require stimulating medicines to excite them into action. Mechanical aid is often necessary to remove the fæces from the rectum. The trunk is permanently bowed; muscular power diminished; mastication and deglutition difficult; and the saliva constantly dribbles from the mouth. The agitation now becomes more vehement and constant; and when exhausted nature seizes a small portion of sleep, its violence is such as to shake the whole room. The chin is almost immoveably bent down upon the sternum; the power of articulation is lost; the urine and fæces are discharged involuntarily, and coma with slight delirium closes the scene.

The remote cause is involved in some obscurity. Long exposure to damp vapour, by lying from night to night on the bare earth, in a close unventilated prison, seems to have produced it; and possibly other causes of chronic rheumatism: and hence it has frequently supervened on chronic rheumatism itself. Long indulgence in spirituous potation has often given rise to it; and probably any thing that debilitates the nervous power.

And on this account miners, and others exposed to the daily exhalation of metallic vapours, and especially those of mercury, are frequent and severe sufferers; of which Hornung has adduced many interesting examples from the quarrymen in Carniola. It has also followed upon worms in the intestines; and in this case, has sometimes assumed a periodical type.

The part of the nervous organ more immediately affected has, also, afforded some ground for controversy. Bonet ascribes it to a diseased state of some portion of the cerebrum, and has given examples of its being found, on dissection, to contain, in various quarters, proofs of serum, sanies, and other morbid secretions. But the misfortune is here, as we have already observed in similar appearances after mania, that it is impossible for us to determine whether these diseased fluids give rise to the disease or the disease to them. And hence Mr. Parkinson seems to pay no attention to them, at least as a cause, and fixes the seat of the affection in the cervical part of the spinal marrow, from which he supposes it to shoot up by degrees to the medulla oblongata. We have already shown sufficiently in the physiological proem to the present class, that the nervous fibres which ramify over the extremities, whether sensific or motific, originate from the chain of the spinal marrow; and we have also shown, in discussing the diseases of trismus, tetanus, and lyssa, how acutely one extremity of a chain of any kind, and particularly of a continuous fibrous chain, sympathises with another: and there can be no difficulty, therefore, in conceiving that wherever the cutaneous ends of the nerves of motion are torpified, or otherwise affected by any of the causes just adverted to, the vertebral column must itself very seriously participate in the mischief, and consequently the upper or cervical part of this column: and that from this point the disease must ramify to the brain before the general functions of the system become affected, as in its latter stages.

The remedial process is not very plainly indicated. Vesicatories, and other stimulants, applied to the neck or even the dorsal vertebræ,

have appeared useful. A seton or caustic, and especially the actual cautery, as practised so generally in France, might possibly be of more avail, applied to different parts of the spine. Beyond this an active purgative system, as strongly recommended by Riedlin, has certainly been found efficacious; and the solution of arsenic bids as fair for a favourable result here as in the preceding species. Stark tried musk, and carried it to very large doses frequently repeated every day: but it does not seem to have produced any decisive success.

Friction of the affected extremities resolutely persevered in by a skilful rubber, with stimulant embrocations of camphor or ammonia, should also be tried in an early stage of the disease, and be alternated with the use of the voltaic trough. Here, too, we may expect to derive advantage from a free use of diaphoretic and alterant apozems, as the decoction of the woods, and especially where the disease is suspected to be of a rheumatic origin: to which may be added a regular course of bathing in the Bath springs.

SY'NCOPE. (*e, es.* f.; συγκοπη, from συγκοπτω, to strike or cut down.) Fainting or swooning. *Animi deliquium. Leipothymia. Defectio animi. Dissolutio. Exanimatio. Asphyxia. Virium lapsus. Apopsychia. Apsychia. Ecchysis.* A disease in which the respiration and action of the heart either cease, or become much weaker than usual, with paleness and coldness, arising from diminished energy of the brain, or from organic affections of the heart. Cullen's species are: —

1. *Syncope cardiaca*, the cardiac syncope, arising without a visible cause, and with violent palpitation of the heart during the intervals, and depending generally on some organic affection of the heart or neighbouring vessels.

2. *Syncope occasionalis*, the exciting cause being manifest. The disease is sometimes preceded by anxiety about the præcordia, a sense of fulness ascending from the stomach towards the head, vertigo, or confusion of ideas, dimness of sight, and coldness of the extremities. The attacks are frequently attended with or end in vomiting, and sometimes in epileptic or other convulsions. The causes are sudden and violent emotions of the mind, pungent or disagreeable odours, derangement of the primæ viæ, debility from preceding disorders, loss of blood, spontaneous or artificial, the operation of paracentesis, the kneeling position, &c. An ordinary fainting fit is a matter of little importance, and occurs frequently in persons who are in general perfectly healthy. The actions of the system will generally be spontaneously restored in a short time. This is accelerated by the horizontal position, which throws the blood on the brain, and thereby stimulates it to resume its wonted functions. Pungent volatile substances applied to the nostrils, cold water sprinkled on the face or chest, and the internal administration of gentle stimulants as soon as the patient can swallow, may also be resorted to. The more formidable kinds of syncope, which arise from diseases of the heart or great vessels, or from profuse hæmorrhage, need not be noticed here, as their consideratio belongs to the particular case in connexion wit which they occur.

Syncope angino'sa. Dr. Parry gives th name to the disease more commonly calle *angina pectoris.* See *Angina pectoris.*

SYNDESMOLO'GIA. (*a, æ.* f.; from συ δεσμος, a ligament, and λογος, a discourse.) Th doctrine of the ligaments.

Synde'smo-pharynge'us. See *Constrictor pha ryngis medius.*

SYNDESMO'SIS. (*is, is.* f.; from συνδε μος, a ligament.) That species of symphysi or mediate connexion of bones, in which the are united by ligament, as the radius with th ulna.

SYNDE'SMUS. (*us, i.* m. Συνδεσμος; fro συνδεω, to bind together.) A ligament.

SYNECHI'A. (*a, æ.* f. Συνεχεια, continuity. A concretion of the iris with the cornea, or wit the capsule of the crystalline lens. The remot causes are, a collapse of the cornea, a prolaps of the iris, a tumefied cataract, hypopium, c original malformation.

SYNGENE'SIA. (*a, æ.* f.; from συν, to gether, and γενεσις, generation.) The nam of a class of plants, in the sexual system c Linnæus, consisting of plants in which th anthers are united into a tube, the filaments o which they are supported being mostly separat and distinct. The flowers are compound. Th orders of the class *Syngenesia* have been erro neously placed in this dictionary, as those of th class *Polygamia*: — they are *Polygamia æquali Polygamia superflua, Polygamia frustranea, Poly gamia necessaria, Polygamia segregata.* For th orders of the class *Polygamia*, see *Polygamia* i the Supplement.

SYNIZE'SIS. (*is, is.* f.; from συνιζω *consido, coïo, coalesco*, to meet.) Closed pu pil. A perfect concretion and coarctation c the pupil. It is known by the absence of th pupil, and a total loss of vision. The specie are: —

1. *Native*, with which infants are sometime born.

2. *Simple*, the pupil being closed or obliterate from a gradual contraction, and, at length, coali tion, of the muscular fibres of the iris, unat tended by any other change or impairment o the eye.

3. *Accidental*, from an inflammation or exul ceration of the uvea or iris, or from a defect o the aqueous or vitreous humour.

4. *Complicate*, or that which is complicate with some other ocular disease. Medicines ar only serviceable in the simple species, in whic the tincture of belladonna often effects a cure and application, also, of stimulating solutions as sulphate of zinc, dilute alkohol, ether, &c When these are of no service, an artificial pupi may be made, either by excision, incision, o separation, according to the appearance of th closure.

SYNNEURO'SIS. (*is, is.* f.; from συν, with and νευρον, a nerve: the ancients include membranes, ligaments, and tendons under th head of nerves.) Synonymous with *Syndes mosis.*

SY'NOCHA. (*a*, *æ*. f.; from *συνεχω*, to continue.) See *Inflammatory fever.*

SY'NOCHUS. (*us*, *i*. m.; from *συνεχω*, to continue.) See *Mixed fever.*

SYNO'VIA. (*a*, *æ*. f.; a term of no radical meaning, coined by Paracelsus.) An unctuous fluid secreted from certain glands in the joint in which it is contained. Its use is to lubricate the cartilaginous surfaces of the articulatory bones, and to facilitate their motions.

According to Mr. Hatchett it consists of albumen and a small quantity of the phosphates of lime, soda, and ammonia. According to M. Margueron it consists of

Fibrous matter	11·86
Albumen.....	4·52
Muriate of soda	·71
Phosphate of lime	·70
Water	80·46
	100·00

SYNOVIAL. *Synovialis.* Of or belonging to the synovia, or fluid of the joints.

Synovial glands. *Glandulæ synoviales.* The fatty fimbriated structure found within the cavities of some joints.

Synovial membrane. The membrane which lines the cavities of the joints, and secretes the synovia. See *Texture.*

SYNTENO'SIS. (*is*, *is*. f.; from *συν*, with, and *τενων*, a tendon.) A species of articulation where the bones are connected together by tendons.

SYNTE'XIS. (From *συντηκω*, to dissolve.) A marasmus or wasting of the body.

SY'NTHESIS. (*is*, *is*. f.; from *συντιθημι*, to compose.) Combination. See *Analysis.*

Syntheti'smus. (From *συνθετιζω*, to place together.) The reduction of a fracture.

Synulo'ticus. (From *συνουλοω*, to cicatrise.) Conducive to the healing a wound. Having a healing property when applied to wounds.

SY'PHILIS. (The name of a shepherd, who fed the flocks of king Alcithous, who, proud of their number and beauty, insulted the sun; as a punishment for which, fable relates, that this disease was sent on earth; or from *σιφλος*, filthy.) Dr. Mason Good says that the term was probably invented by Fracastorio, from the Greek *συν* and *φιλεω*, importing "mutual love;" for such is the title by which he has designated his celebrated and very elegant poem on this very inelegant subject. The venereal disease, called *Lues venerea*, *Morbus Gallicus*, *Aphrodisius morbus*, *Morbus indicus*, *Morbus Neapolitanus*, and *Patursa*. By the "venereal disease" are usually signified certain morbid changes produced in various textures of the human body by the action of a specific morbid poison. Some writers, however, extend the meaning of the expression further; for they make it comprehend not only *syphilis*, or the *true venereal disease*, but also clap, or *gonorrhœa*, sores of different descriptions on the genitals, and numerous effects or accompaniments of the latter complaints. Such writers do not speak of the *venereal disease* in the singular but in the plural number, and offer a description not of one disorder, but of several, under the appellation of *venereal diseases*, the varieties of which are sometimes ascribed to the existence of different kinds of venereal poison, each capable of producing distinct and peculiar effects on the part and constitution.

Now, if it be inquired what we know about any venereal poison, and what proof we have of its existence, the answer is, that it has never been detected in a separate form, and nothing is known respecting its appearance, colour, consistence, or any of its general or chemical qualities. The only explanation that can perhaps be given of it is, perhaps, what Mr. Lawrence has suggested, namely, that it is that state of the secretion of a sore, which renders it capable of producing the disease in another person, or that state of the blood in the mother which renders it capable of communicating the disease to the *fœtus in utero*; but what that particular state is we are unable to describe; we are only able to observe its effects, and judge from them that a virus or poison is concerned.

It would not appear to be the nature of the venereal poison always and inevitably to excite inflammation, ulceration, or disease of the part to which it is applied in any shape; it cannot therefore be a very active and quickly penetrating agent; and though the proportion of cases in which the poison takes effect is considerable, experience proves, that many individuals, exposing themselves to the risk, come off with impunity. When the contrary happens, the poison, after the expiration of a variable space of time, which appears to be requisite for it to make an impression, produces changes not only in the part to which it is immediately applied, but, at a subsequent period, in a given number of examples, disease in other situations, in consequence of its absorption into the system.

Syphilis cannot be propagated from individual to individual through the medium of the breath, nor of the atmosphere, nor apparently through the medium of any of the ordinary natural secretions, and certainly never by one person merely touching the sound part of the skin of another individual labouring under the disorder. With the exception of what may happen between a syphilitic pregnant female and the child in her womb, only one way is positively known, in which the disease can be communicated, and that is through the medium of the specific poison, blended at the time of its application with pus, or some other morbid secretion. Such infectious matter begins its action by exciting inflammation, followed by a pimple, or pustule, which is gradually converted into an ulcer. Of course, such ulcer is almost always on the parts of generation; but, if a person accidentally prick himself with a lancet infectee with venereal matter, or, if such matter happen to come in contact with any abraded part of the skin, syphilis may then commence in other situations.

The symptoms or effects of the venereal disease are divided into the *primary* and *secondary*. The primary are those which arise from the direct application of the poison to the

part, namely, *ulceration* of that part, often followed by a *swelling of the absorbent glands*, to which the lymphatics of the ulcerated texture first direct their course; the sore receiving the name of *chancre*, and the glandular swelling that of *bubo*. The latter is deemed one of the primary effects, because excited not really by the poison after its entrance into the circulation (as all the secondary symptoms are believed to be), but by its directly irritating the gland or glands, as it is passing through this portion of the absorbent system into the blood.

It has been already stated, that the application of the poison does not invariably cause a chancre. It seems as if some individuals were less susceptible of the venereal disease than others, and, no doubt, those who are very attentive to ablution, after a suspicious connexion, much oftener avoid being infected than other parties who neglect this precaution. Nor does the poison, when it gives rise to a primary ulcer, or chancre, constantly lead to the formation of a bubo. In the majority of cases, the latter swelling is not produced, and this sometimes even when secondary symptoms follow, and the poison has found its way into the constitution.

The *secondary symptoms* are all those effects of the disease which take place from the introduction of the poison into the circulation, whether ulceration of the throat, cutaneous eruptions, ulcers, or excrescences on the surface of the body, inflammation of the iris, various affections of the nose, ears, testicles, or joints; and, in the osseous system, severe pains, nodes, caries, or necrosis. These secondary symptoms, which make the *constitutional form of the disease*, do not occur, however, with any regularity. In many cases, they never show themselves at all; while in others, they take place with great severity, though there may be no remarkable differences in the appearance of the primary ulcers, or the kind of treatment, to account for this diversity of consequences. In a given number of cases of primary symptoms, under any plan of treatment, secondary symptoms will occur only in a limited proportion of the patients.

With respect to the origin of venereal disease, it has been believed that it began in Europe towards the close of the fifteenth century, having been either brought to this quarter of the world from St. Domingo by the followers of Columbus, or having broken out from unknown causes in the French army then besieging Naples. Mr. S. Cooper says that the fullest consideration of the subject has led him to believe, that the venereal disease has existed from time immemorial; that it always has existed, and always will exist, in every populous country, where promiscuous sexual intercourse takes place. Those, who ascribe the origin of syphilis to the latter part of the fifteenth century, have been much influenced by one fact, which is, that down to that period no description of any disease, corresponding exactly to what we call syphilis, had been given by medical writers; and although ulcerations on the genitals, and buboes, had been commonly treated of, no mention was made of the secondary symptoms, no connexion was ever traced, or even suspected, between the primary effects, as they are called, and the sore throat, cutaneous affections, and the pain and swellings of the bones, which we denominate secondary ones. Perhaps, however, it is scarcely allowable to infer, that because no notice is taken of the secondary symptoms of the venereal disease in the old works on medicine and surgery, that such complaints were not in existence previously to the close of the fifteenth century. The relation of the primary and secondary symptoms to one another, might have been overlooked; it might never have been suspected when there had been a chancre on the penis, that the sore throat, cutaneous affection, or node, which came on subsequently, had any connexion with the sore. Certainly this will not seem incredible, when it is recollected that it was not until a very recent date, that some particular effects of the venereal disease were made out; and that, even at the present day, with all the advantages of a better system of pathology, our knowledge of many circumstances, relative to this extraordinary disease, is very obscure and uncertain. Thus, two or three hundred years hence, when it shall be recorded to posterity, that at as late a period as the year 1800, no account had been given of syphilitic iritis, and that the true character of gonorrhœal ophthalmia had not been described, it would not be correct to infer, that those affections had no existence until the time when they began to be discussed in works on surgery. Their not having prevailed, and their not having been described, are two different things.

Not only are diseases of the genitals acknowledged to have existed from time immemorial, but we have every ground for believing, that they were of a contagious nature. This seems proved by the precautions adopted by various governments, to prevent the extension of such disorders among the population. Thus, in the borough of Southwark, prior to the time sometimes fixed upon for the origin of syphilis, there were places called *stews*, where prostitutes were confined, and received the benefit of surgical assistance. They were taken up and put into these establishments, whether agreeable to them or not, by virtue of certain decrees, made expressly to protect the rest of the community from the risk of catching their complaints. At the same time, or even earlier, similar establishments were formed in Paris, Edinburgh, Avignon, and even in the holy city of Rome, under the Pope's nose, under the walls of the Vatican itself, with an abbess at the head of it.

The venereal disease is commonly believed to be communicable only through the medium of pus. The late Mr. Hey, of Leeds, was induced, however, to regard this doctrine as incorrect; and, from some cases which came under his observation, he suspected that the disease might sometimes be communicated, not only after all ulceration and suppuration had ceased, but even when the person, giving it to another, was to all appearance in perfect health; but whoever reads the cases on which Mr. Hey founded this extraordinary inference, will perceive how great was the possibility of his being

deceived by the patients, who gave him the histories of their cases. Some particulars involved the honour of the individuals themselves, and therefore they might have been ashamed of disclosing every secret relative to their cases. It is more rational, perhaps, to suppose that Mr. Hey had been deceived by the patients themselves, than that any such such mysterious sources of infection existed, as those implied by his view of their cases. The idea that syphilis can be communicated by a person so healthy, that he has no venereal matter formed upon any part of the surface of his body, or indeed any visible or palpable complaint whatsoever, is a problem, that every thing yet ascertained about the nature of syphilis tends to refute. As the venereal disease may be transmitted from the mother to the fœtus through the medium of her blood, many surgeons have been inclined to suspect, that it may be also communicable through the medium of the natural secretions, such as the saliva, the semen, the milk, &c. With respect to the fœtus, we may infer that it receives the infection by means of the circulating blood, in the same manner as the mother herself receives her secondary symptoms; but with regard to the saliva, semen, and milk, there is no evidence that these natural secretions will serve for the transmission of the disease. Mr. S. Cooper believes with Mr. Travers, that none of the common natural secretions of a contaminated individual can communicate the disease to other persons. The following statement in this gentleman's work is interesting; a man, who has syphilis in the secondary form, provided he be free from all affections of the genitals, will communicate no taint to his progeny, any more than to his wife; but a healthy wet nurse, getting a sore nipple in consequence of suckling a pocky child, and having secondary symptoms, will communicate the disease to the fœtus of which she may become pregnant. Now this is agreeable to the usually received opinions, that the blood will contaminate the embryo, though all genital sores may be absent, and though the party cohabiting with the woman is beyond the sphere of the influence of the disease in her. So far then as the present state of our knowledge reaches, we may conclude, that the disease is only communicable through the medium of purulent fluid, and not an ordinary natural secretion, with the exception of the mode of its transmission to the fœtus, which receives the infection through the circulation, and may be regarded as under the same circumstances, with respect to the secondary effects of the disorder, as the mother herself. There may also be an exception to the general principle in what happens between the pocky child and its nurse, provided the disease in the former is to be regarded as the constitutional modification of it, transmitted through the blood of the mother. Certain descriptions would tend to prove, however, that the ordinary secretions of the female organs are sometimes the medium or vehicle of infection.

The effects of the venereal disease are different in different individuals; two men may have connexion with the same woman; both may catch the disease, but one will have it severely, and the other only in a slight and mild form. One man has been known to give the disease to different women; some of whom have had it in a lenient shape, while the others have suffered most severely. Sometimes the same individual will have two or more sores of different kinds at the same time. In some examples, sores of the Hunterian character are seen on the glans penis, while sores of other descriptions are close by them. One of the most curious circumstances in the venereal disease is not unfrequently exemplified in the army: soldiers are sometimes gregarious in their amours: a party of six or eight will have connexion, one after another, with the same woman. In this manner, several men contract disease from the same source, and on one and the same occasion; yet they do not all suffer in the same manner. Some have sores of one kind; some of another; and some, various sorts of ulcers; while others will contract a discharge from the urethra. These facts are adverse to the opinion, that syphilis is owing to a plurality of poisons; for here are many different effects, apparently produced from the same source.

The venereal disease presents itself in a great variety of shapes, and is attended by apparently the most capricious irregularities, and this in relation both to the primary and the secondary symptoms: thus, we find that some persons will have only superficial ulcers without induration around and below them, but with elevated or raised margins; while others will have sores, characterised by a hard circumference, an indurated base, an indisposition to granulate, and, in a word, all the features belonging to, what is called, the Hunterian chancre. Again, others will have phagedenic sores, entirely different from either of the other kinds now described; and while one individual will have only one sore of one of the descriptions here pointed out, another will have not merely a sore, corresponding to one of those varieties, but also a bubo; and a third will have gonorrhœa, in addition to the chancre and bubo. With respect to the secondary symptoms, these also exhibit the most perplexing diversities: the primary symptoms are frequently followed by secondary ones, as varied as the former, and even more so; thus, with regard to the cutaneous eruption, the spots on the skin may either be a scaly eruption, a papular eruption, a pustular eruption, or a tubercular eruption. The sore throat also, which is a common secondary symptom, presents itself in a variety of forms. there may be a deep excavated ulcer on the tonsils, or only a superficial ulceration of them; or there may be an ulceration, extending to the upper part of the pharynx and soft palate, without affecting the tonsils. Then, in the affections of the osseous system, we notice the same indisposition in the disease to confine itself to any determinate shape: there may be only periostitis — a mere swelling or inflammation of the periosteum; or there may be true nodes, or a real enlargement of the osseous texture itself — an increased deposition of bony matter; or there may be merely pains in the bones, or swellings and

pains of the joints. Thus, we see in the outline of this singular disease, nothing but variety and irregularity, which it is difficult to solve by reference to any principles yet suggested by the many able men, who have exerted their talents in the investigation of this Protean disorder.

Mr. Carmichael attempted to explain some of the varieties of the venereal disease, by supposing a plurality of poisons; by the consideration that it is in truth not one, but several diseases, each depending on a specific poison of its own. His doctrine is, that, except in a few anomalous cases, every primary sore has its corresponding eruption; so that we may foretell by the appearance of the former what the latter will be, provided it come out at all; or if we see only the eruption, we may be able to pronounce from it what has been the character of the primary sore. When these views were first made known, they raised the most lively hopes, that a great step had been made in the knowledge of venereal complaints. But the disease in London is not found to have the same regularity and constancy in the relations between its primary and secondary symptoms, as Mr. Carmichael thought that he had noticed in Dublin. A primary sore of a determinate character will frequently communicate a sore of a different kind, and, what is still more inexplicable, frequently several sores, each of different kinds. Certain facts, recorded by Mr. Evans, prove, that a connexion with a common prostitute, in whom there are no ulcers at all, will sometimes give rise to venereal complaints, and then the disease seems indeed to have been communicated through the medium of the ordinary secretions of the genital organs, with which the poison was commixed. So far as the doctrine of Mr. Carmichael goes, which ascribes the origin of phagedenic ulcers to a particular venereal poison, the idea does not seem at all tenable. We have seen that the phagedenic character may occur as a complication of any kind of ulcers, whatever may have been their original nature, and that such unfavourable change often depends on constitutional causes, bad health, injudicious treatment, intemperance, disturbance of the part, and other very definite and manifest circumstances. It is true, that we see in hospital gangrene and phagedenic diseases from syphilis, which are believed to be analogous to, or identical with, hospital gangrene, disorders certainly capable of propagation by contagion; but this refers to the accidental application of the matter, by means of a sponge, &c., to the abraded surface, in another person. Without such abrasion there would have been no evil consequences. Then, how unlikely, how impossible we may say, it would be for a person afflicted with a phagedenic disease of the genitals, to have sexual intercourse, so as to give the complaint to another person. On the contrary, we have reason to believe, that some of the worst forms of phagedenic ulcers are communicated by women, who have but trivial complaints themselves. Every body has heard of the captivating Lisbon opera dancer, whose charms attracted so many of the officers of the British army into her embraces. If we are to credit the reports, many hundreds of our countrymen had connexion with her, no doubt civil also as well as military; and great numbers of them received, as a reward for their adoration of this irresistible goddess, the present of something more than a trifling clap. Many who had an acquaintance with this lady, contracted venereal complaints of a particularly obstinate and afflicting kind, such as are comprised under what is sometimes facetiously denominated the *black lion*, a phagedenic, rapidly spreading, almost incontrollable ulceration of the penis; yet this lady continued to dance every night for months and months together, as if she were right in every respect herself, whilst her unfortunate friends were suffering all the pains and penalties inflicted upon them through the power of so fascinating a goddess, whose poison, like that of the serpent, hurt not herself. Now it cannot be imagined, that she had phagedenic ulceration of the genitals, while she was discharging her duties so well, which consisted of dancing in the early part of the night, and of another sort of amusement in the latter part of it. It is impossible then to suppose, that these phagedenic sores could have arisen from a particular kind of poison, the product of any phagedenic sore. Mr. Carmichael's description of the venereal disease is excellent, so far as the symptoms are concerned; we daily recognise in practice the very forms and shapes of the disorder which he has described so well; yet we see various circumstances, which prevent us from coming to his conclusions respecting the diversities of venereal diseases. We cannot trace any uniform and mutual correspondence between the primary and the secondary symptoms; for the different effects, which he refers to different poisons, are found by us to be frequently too much blended together. One series of complaints is not so separate, so restricted to particular cases, as Mr. Carmichael's views would induce us to expect; for instance, we often meet with the scaly and pustular eruptions in the same patient. His account of the causes of phagedæna is totally incompatible with the facts revealed to us by experience. No doubt the Lisbon opera dancer had not any thing very serious the matter with her; probably her natural secretions were somewhat changed, or she might have had at most some gleety affection. Then we must recollect another fact, which agrees with this inference from the opera dancer's case; in the large towns in France, it is customary for the Cyprian corps to be inspected once a week by medical officers; although the frequency of disease does not appear to be diminished thereby. Mr. Evans, who was stationed in Valenciennes, attended several of these reviews, made under the direction of the police. The British garrison at Valenciennes, at that time, consisted of four or five thousand men, and many of them suffered severely from venereal complaints; there was at least the usual number of venereal cases among them: yet Mr. Evans informs us, that in the inspections referred to, where some hundreds of concubines were carefully examined, very little disease was found. Mr. Travers suggests one

peculiar mode by which the venereal disease may be communicated; he supposes that a woman may in some instances be the passive medium of infection, that is, when she has had connexion with an infected person, and immediately afterwards has connexion with another man who is sound, the last person may be contaminated, though she may escape the disease. This seems possible; but whether it frequently happens or not, it is difficult to say. At all events, it appears as if the natural secretions of the female organs were sometimes pregnant with infection, though no ulceration may exist on the surface of the genitals.

The symptoms of syphilis are divided into *primary* and *secondary*: the primary consists of various forms of ulceration on the genitals, or other parts to which the venereal matter may be applied, and specific inflammation of the glands called buboes; the secondary consist of a variety of constitutional diseases.

Primary symptoms. — Primary venereal sores are of several kinds. The most remarkable one is that which was so well described by Mr. Hunter, and is called accordingly the *Hunterian chancre*. It is characterised by a tendency to assume a circular form, its excavated surface, the tenacious and adherent quality of the matter produced on it, and by its hard cartilaginous base and margin. It generally begins as a pimple, or minute vesicle, which enlarges, and soon breaks and ulcerates. Generally speaking, venereal ulceration does not extend itself with great rapidity; neither is it the common character of the Hunterian chancre to make quick progress. Nevertheless, exceptions to this statement do occur, and these seem to depend on the state of the health; for when this is in an unfavourable condition, or certain forms of constitutional disturbance and irritability prevail, the ulceration will spread with greater quickness than usual. When the sore is situated on the prepuce, or the frænum, there is usually more inflammation present than when it is situated on the glans. When the ulcer is on the glans, it is less painful, but more disposed to give rise to hæmorrhage. What is termed *phymosis*, is an inflammation, a thickening, and a contraction of the extremity of the prepuce, rendering it impossible to draw it back so as to uncover the glans: this case is less frequently a consequence of the Hunterian chancre, than of some other primary sores on the penis. Mr. S. Cooper's experience does not incline him to adopt the opinion that the hard cartilaginous base of the Hunterian chancre is essential to a sore, that is capable of imparting to the system such effects, or secondary symptoms, as are exclusively regarded as syphilitic. All surgeons know, that the Hunterian chancre may, and often does, give rise to secondary symptoms; but there are other kinds of primary sores, which will produce similar complaints, so similar that they cannot be discriminated.

Another kind of primary sore is that which is generally called *the superficial ulcer with raised edges*; it is not accompanied by induration, but its margin is very high; it is often seen on the outside of the prepuce; and frequently is not a single sore, but is accompanied by others of the same nature, sometimes by two, three, four, or more. In many instances, we see them surrounding the orifice of the prepuce, producing a thickening of it and phymosis, which may continue long after the cure of the sores. Sometimes we notice some of these superficial ulcers on the corona glandis, and others under the prepuce, or around its orifice, or just on the outside of it. They are frequently very obstinate, and it may be long before any impression can be made upon them, whether mercury be given in full quantities, or merely in alterative doses. Sometimes, in five or six weeks, there will be very little change in them whatever is done, and what change does take place, may be for the worse. Mr. S. Cooper observes that, after five or six weeks, they generally yield to common treatment, to mild alterative plans, namely, to small doses of mercury, aperient medicines, and antimonials, and sometimes to tonics, bark, sarsaparilla, and the mineral acids. One common situation for such a sore is just at the side of the frænum, and then the frænum is generally destroyed. The black or yellow wash, and lotions of the sulphate of copper, or zinc, are the best applications.

Another description of primary sore is the *phagedenic*, as it is termed, — a corroding ulcer without granulations, corresponding to the description of phagedenic sores in general. It is destitute of any remarkable degree of surrounding induration, but its circumference is of a livid red colour. It is invariably rendered worse by mercury, a fact, which I deem to be as well established as anything yet made out, with regard to the treatment of venereal complaints. In this form of the disease, when the treatment is injudiciously conducted, the whole of the penis will frequently be destroyed in a very short time. Sometimes considerable hæmorrhage takes place, and a useful hint is afforded by it; for we commonly observe, that, after loss of blood, the extension of the ravages of the disease stops, or is suspended for a time; and hence we may infer that venesection will frequently be useful in the early stages of the disease, a truth fully confirmed by experience.

Another primary sore is called the *sloughing ulcer*. It appears first as a black spot, which increases, and is thrown off, leaving exposed to view a corroded or phagedenic surface. After the slough has separated, an ulcer remains of a painful character, with a dark blue, or livid crimson margin. In this manner the disease will go on alternately sloughing and ulcerating, sometimes till nearly all the external parts of generation are destroyed. With respect to the hypothesis, that phagedenic primary sores had their origin from a specific poison, various considerations oppose its adoption. The sore is not always phagedenic from the beginning, which we should naturally suppose would be the case, if it arose from a specific poison. The causes of phagedenic ulceration may frequently be traced very unequivocally to the condition of the individual's health; to his having neglected to restrict himself to proper regimen; to his having been guilty of excess, or to his having neglected some other kind of primary sore in its

commencement. It appears that any sore may assume the phagedenic or sloughing condition from the bad state of the constitution, or from neglect, or injudicious treatment.

With respect to primary venereal sores, we should be careful not to confound with them several common complaints which cannot even be suspected to be connected with, or to originate from, any kind of virus, as, for example, the disease called *herpes preputii*, which begins with heat and itching of the foreskin, and in one or two days is followed by red patches as large as a silver penny, on each of which may be remarked five or six small vesicles, which lose their transparency in a few days, and become filled with pus. They then burst, and the fluid oozing out of them, and drying, forms scabs. *Excoriations of the corona glandis* too, and of the prepuce, are common in individuals who are not cleanly, and who neglect to wash these parts occasionally. Under such circumstances, troublesome excoriations will be likely to be produced by the lodgment of the natural mucus, and its becoming acrid and irritating. These cases merely require cleanliness for their cure. Patients with such excoriations often ask our advice, and if we give them mercury, we give it unnecessarily; nothing is required but a weak solution of the sulphate of zinc, or a lotion of rose water and subcarbonate of potash. There are also cases in which there is a scaly appearance of the prepuce, a kind of *psoriasis*, which must not be mistaken for a venereal complaint.

The venereal poison, in its passage through the inguinal glands, frequently gives rise to inflammation and enlargement of them, which, in many instances, is followed by suppuration and ulceration. The swelling, abscess, or sore, thus produced, is termed a *bubo*, a name derived from a Greek word signifying *the groin*; though, if the patient happened to have a primary venereal sore on one of his fingers, he might have a bubo just above the elbow, near the inner edge of the biceps, or in the axilla; so that a bubo does not always imply a disease in the groin, as the etymology of the word would imply. But the poison of syphilis may make its way into the system, without exciting any inflammation in the absorbent glands of the groin, or other region of the body; no bubo at all may intervene between the occurrence of the primary sore and the commencement of secondary symptoms. In other terms, the latter are not invariably preceded by a bubo. On the whole, buboes form more frequently after a chancre on the prepuce, than after one on the glans; yet every inflammation of the glands of the groin must not be set down as venereal, for these parts are subject to various enlargements from other causes. Mr. Hunter observed, that when the venereal poison affected one of the absorbent glands, the gland that inflamed was one of the nearest to the primary ulcer. Such, indeed, is the fact; and we never find that the absorbent glands, situated in the course of the aorta or iliac vessels, are inflamed, and brought into the state of suppuration by the absorption of venereal matter. The glands of the groin, then, may inflame, suppurate, and ulcerate, but not those within the trunk. Mr. Hunter entertained a suspicion, that another criterion of a venereal bubo was the circumstance of its involving only one gland; but at the present day, this test is not relied on. Frequently, in venereal cases, several glands inflame; and sometimes in glandular swellings from irritation, only one gland is concerned. Also in a bubo arising from scrofula, there may be only one gland affected at first. Another character, assigned by Mr. Hunter to a venereal bubo, is the quickness with which it generally proceeds to suppuration, and the shortness of time which the matter requires to make its way to the surface. This test also appears not to be of much practical importance; for there is a great variety in venereal buboes in this respect; some are much more indolent than others. And it is far from being the invariable character of a venereal bubo to proceed rapidly to suppuration; for while some of them are very acute, corresponding more or less to Mr. Hunter's description, others are of a chronic character; and this frequently cannot be accounted for, either by the influence of scrofula or mercury, the two circumstances which Mr. Hunter believed would generally explain the greater slowness of certain varieties of bubo than of the generality of them.

The generality of buboes, not truly venereal, are preceded and accompanied by more or less disorder of the health; and under such circumstances, if there should be no chancre to account for the bubo, we should have reason for suspecting that the state of the health had brought on the glandular enlargement. It is one good rule when the patient will not admit that he has had a chancre, or we cannot discover any traces of one, always to inquire into the state of the nearest lower extremity, and to ascertain whether there is any inflammation, wound, boil, or sore, about the foot, leg, thigh, or nates; any bunnion on the great toe, or any inflamed bursa, or painful corn; for the inguinal glands are liable to inflammation and enlargement, in consequence of any of these causes.

Secondary symptoms. — Previously to the occurrence of *secondary symptoms*, the constitution may generally be observed to be somewhat disordered; there is more or less fever present, with accelerated pulse, headach, loss of appetite, pains in the limbs, and inability to sleep. Indeed, almost all patients are particularly restless for two or three days before the appearance of any secondary symptoms; that is, before they complain of a sore throat, or perceive any traces of cutaneous disease about them. According to the Hunterian doctrines, when secondary symptoms take place, they are more disposed to occur in some parts of the body than in others. On this account, Mr. Hunter divides the parts affected into two orders; the first order consisting of those in which the secondary symptoms usually first show themselves, namely, the throat and skin, with which parts the iris is also to be arranged; the second, including parts in which the disease produces its influence at a later period, as the periosteum and the bones, to which may be added the nose, in which ulcer-

ation of the mucous membrane, the ozæna syphilitica, with or without disease of the bones, is very common: in the second order of parts are likewise to be included the ear and the testicle, to which organs, however, the effects of syphilis less frequently extend than to the other parts here specified. Mr. Hunter's opinion, respecting the throat and skin, agrees pretty well with general experience, and modern surgeons are inclined to accede to his doctrine in relation to them; though pains in the bones and joints sometimes precede the sore throat and cutaneous eruption. Mr. S. Cooper has seen nodes follow a primary sore as the first secondary symptom, and this has also been noticed by others. Mr. Cooper once attended a medical gentleman, who had no sore throat, and no cutaneous eruption; yet he had nodes. It is generally considered, that the interval between the primary and the secondary symptoms is on an average from six to twelve weeks; but it may extend to several months, or, according to some reports, to one or two years. The earliest secondary symptoms generally commence within three months from the cure of the primary sore; but they may come on much more quickly, or even before the primary sore is healed. Almost every surgeon has had opportunities of seeing cases in which there were at the same time an uncured chancre, an unhealed bubo, a sore throat, an iritis, and so forth, all existing together.

The *cutaneous eruption* presents considerable varieties. A few years ago, it was considered that no eruption was venereal, unless it had a copper-coloured appearance, and was scaly. Mr. Hunter represents the skin as at first becoming mottled, and tells us that such appearance will come out, and fade away again repeatedly. Now, this observation must have been overlooked by former surgeons, who endeavoured to prove that, without mercury, syphilitic symptoms invariably proceed from bad to worse; for here we find it stated, by their own great authority, that the eruption spontaneously disappears and then returns; that the disease fluctuates; yet the doctrine, that Mr. Abernethy collected by his enquiries from all the most experienced surgeons in London was, that the symptoms of syphilis are continually progressive; and that when there is a true venereal sore, or eruption, it would always continue to get worse till mercury was given. One form of syphilitic eruption is characterised by being scaly, and of a copper or reddish-brown colour; small copper-coloured spots first shewing themselves, and the cuticle then peeling off. Some of these blotches conjoin, so as to form extensive batches; but others of the same colour, and decidedly syphilitic, are, on account of their diminutive size and particular figure, sometimes termed the *lenticular* syphilitic lepra. The venereal eruption, according to Mr. Hunter, consists of copper-coloured spots on the skin, accompanied by desquamation, which leaves the subjacent cuticle thicker and thicker as this process goes on, and of the same colour as the cuticle which peels off. If the disease advance further, scabs will form, suppuration will take place under them, and the result be a *secondary venereal ulcer*, which, when thus produced, affects principally such parts of the skin as are in contact with other portions of the cutis, like the fold of the nates, the angle between the scrotum and thigh, or in the armpit. In these situations, the eruption has a raised surface, from which a whitish matter frequently oozes. These copper-coloured scaly blotches generally first appear on the face, hands, and wrist, and afterwards on the breast and the extremities, where they are particularly numerous, and assume the form of *lepra* or *psoriasis*. There is another circumstance deserving of attention, namely, when the palm of the hand or the sole of the foot, where the cuticle is very thick, is affected, an appearance is produced, constituting what is often termed the *syphilitic lepra*, and *psoriasis of the hands and feet*. Mr. Carmichael, like Mr. Hunter, regarded the scaly copper-coloured eruption as characteristic of true syphilis; and though, says he, there are other eruptions which are venereal, or the consequence of venereal complaints, yet they are not truly syphilitic. He notices pustular, tubercular, and papular eruptions; but he does not consider these as consequences of a true Hunterian chancre, but refers them to primary sores of other descriptions. The syphilitic eruption, according to Mr. Carmichael, always consists of scaly blotches, in the form either of lepra or psoriasis, and unattended with fever; or it should rather be said, there is not so much fever present with these eruptions as with either of the others, namely, the papular, the tubercular, or pustular. As already noticed, Mr. Carmichael attaches so much importance to the form of the eruption, that he believes it possible to tell by the inspection of the cutaneous disease, what has been the character of the primary sore. In short, he divides the venereal disease into four species or varieties. The first of these is the *scaly venereal disease*, or that which is correspondent to the Hunterian description, the chancre having a hardened edge and base; and when the bones are affected, their shafts and harder parts chiefly suffering, the nodes being true ones, and the eruption scaly, in the form either of psoriasis or lepra. The second is the *papular*, so called from the character of its eruption, which consists of inflamed pimples, and may follow gonorrhœa, and what some surgeons call the *gonorrhœal ulcer* of the prepuce and corona glandis. The third is named the *tubercular*, as being attended with an eruption of this character: and the fourth is the *pustular* variety of the venereal disease, so called also from the appearance of the cutaneous affection. The projecting incrustations, which are conical, or in the form of limpet-shells, constitute the appearance known by the name of the *venereal rupia*, which may follow an eruption, originally either tubercular or pustular. One important fact to be remembered is, that papular and pustular eruptions, when they have reached a certain stage, may be attended with a scaly appearance, which is, therefore, not exclusively the feature of lepra and psoriasis. This circumstance may, perhaps, explain some cases in which the eruption seems to

consist of scaly spots, and pustules and pimples, more or less mixed together.

Secondary venereal ulceration of the skin is often preceded by an eruption, some part of which, after repeated desquamation and scabbing, is converted into sores; but, in other instances, chronic inflammation takes place, independently of any eruption, and ulceration follows; and occasionally inflammation, suppuration, and secondary venereal ulceration, will occur over nodes. Secondary venereal ulcers have not any regular and constant appearance; they are frequently of a round shape, more or less chronic, and with an irregular, foul, ash-coloured surface; while others evince the peculiarity of healing in the centre and extending at the circumference, the unhealed part being of a tawny colour, with sharp edges, and a foul bottom. No sooner does an experienced surgeon cast his eyes upon an ulcer of this kind, than he is led to suspect its venereal character; its tawny appearance, its shape, and its situation, will induce him to entertain a suspicion that it has been preceded by other venereal complaints. But we should never conclude, from the mere look of a sore, that it is certainly venereal; but always take into consideration the history of the case, before a positive opinion is delivered.

Besides these secondary symptoms presenting themselves as affections of the skin, we must not omit to specify the *ragged ulcerated fissures* and clefts seen on the nates, or about the anus (rhagades ani), and especially in the fold at the lower part of the nates, and between the perineum and the thigh, or sometimes even about the roots of the finger-nails. In the latter event, matter forms under the nail, which becomes detached, and the discharge is remarkable for its strong, fœtid, and peculiarly disagreeable smell. Such is the *venereal whitlow*, as it is sometimes named.

Some *excrescences* in venereal patients, taking place especially about the genitals, perineum, and anus, receive different names, according to their various shape and consistence; as *warts*, *condylomata*, *fici*, &c. They are frequently accompanied with ulceration, or purulent discharge from the urethra, or vagina; and they often grow from parts which have been ulcerated, though now healed. They are not essentially connected with syphilis; for we see precisely the same kind of growths in persons who appear never to have had the venereal disease. In women they are very common, and some of them do not appear to me to be materially different from particular kinds of hæmorrhoidal excrescences. Formerly it was the practice to salivate patients for the cure of these excrescences, and this sometimes more profusely than for a sore throat or a chancre; and it must be acknowledged, that when the system was thus brought and kept a long while under the influence of mercury, such growths generally dwindled away, and ultimately disappeared. The fact, however, that these excrescences could be as permanently and certainly cured by the knife, ligature, escharotics, and stimulating applications, as by mercury, was well known to some intelligent practitioners nearly half a century ago; and, what is still more to the point, it was known that the cure was radical. On what principle, then, could the severe measure of a long and profuse salivation be vindicated?

One of the most common secondary symptoms is *ulceration of the fauces, tonsils, and soft palate*, — in other words a *sore throat*. What has generally been considered as the most unequivocal specimen of syphilitic ulceration of the throat, is remarked to come on without much previous inflammation, to begin on the surface of the part affected, and to extend more and more deeply; so that, when situated on the tonsils, an appearance is produced, as if a portion of them had been scooped away. The sore has a sharp prominent margin, and its excavated surface is covered with yellow adhesive matter, that cannot readily be separated from it. It is not uncommonly believed, that a sore throat, corresponding to this description, is peculiar to true syphilis, or the scaly form of the venereal disease — that disease, all of whose symptoms are sometimes thought more particularly to require larger quantities of mercury for their cure, than other varieties of the venereal disease. On this point, however, it may be observed, that the doctrine to which allusion has here been made, is not so much insisted upon at the present day as it was some years ago. In fact, this kind of sore throat has frequently been cured by sarsaparilla; and it sometimes follows sores which have no kind of resemblance to the chancre with an indurated base and circumference. Mr. S. Cooper, however, is of opinion, that whenever this kind of sore throat is accompanied by a scaly eruption, or by pains in the shafts of the long bones, or by true nodes, it will be more benefited by mercury than by any other kind of medicine.

Besides this description of sore throat, there is another, consisting in superficial, but foul and wide-spreading ulcerations of the tonsils, velum pendulum palati, and upper portion of the pharynx, accompanied by considerable pain, restlessness, and fever. On account of its appearance, it is frequently called the *ulcerous excoriation of the throat*. Mr. Carmichael thought he had traced it to be an effect of what he terms the *papular venereal disease*, or that which he conceived to arise from the *simple primary sore*, patches of excoriation on the prepuce, or gonorrhœa virulenta.

In certain other cases, the *ulcers* of the throat have *a truly phagedenic character*, and are disposed, under improper treatment, to destroy the whole of the soft palate, and to extend their ravages to the pharynx, and even sometimes to the larynx, causing necrosis of its cartilages, and endangering life. With this form of sore throat, when the constitution is in an unfavourable state from the injudicious use of mercury, there is a tendency to the production of caries and necrosis in the bones of the palate, and even in the upper jaw-bone and the ossa spongiosa; but if the disease be properly treated, and the employment of too great a quantity of mercury be avoided, the patient will generally escape the serious mischief to which I have al-

luded. We must always be careful not to confound accidental inflammations of the throat from cold, and common abscesses, and chronic scrofulous enlargements of the tonsils, with venereal affections of them.

One species of *iritis*, or *inflammation of the iris*, is an affection ranking as a secondary symptom of syphilis. After the appearance of disease of the skin, or sore throat, the iris sometimes inflames; this affection, which may follow, or accompany, various kinds of syphilitic eruptions, and is usually attended with pains in the limbs and joints, is noticed in the article *Ophthalmitis*.

With regard to *venereal affections of the bones and joints*, if the swelling has come on suddenly, seems to be chiefly seated in the periosteum, and the pain is not remarkably aggravated at night, we may generally conclude that it is not a venereal affection. True syphilitic nodes are more indolent in their progress than the swellings just referred to; and the pain of them is always more severe at night than in the day. They are particularly disposed to occur on the central portions of the long cylindrical bones, and on such parts of the bones as are not covered by any great thickness of soft parts. Hence, the front surface of the tibia, the superficial part of the ulna, the sternum, the clavicle, and the cranium, are often the seat of nodes. The swellings, most likely to be mistaken for venereal nodes, are inflammations of the periosteum, and not of the bone itself, attended with pain in their very commencement, and even with redness of the skin; they arise suddenly, and frequently disappear in a short time without the use of mercury. They have, therefore, more of the inflammatory character about them, than usually belongs to venereal nodes. The best plan, in all doubtful cases, is to inquire particularly into their history; we should consider the other symptoms which may have previously existed; the order in which they have occurred; and the effect of any treatment that has been tried; and we must form our conclusion by connecting the present symptoms with all the other information which can be collected.

There is one curious circumstance in relation to nodes, namely, they are alleged to be rarely produced in syphilis, unless the patient has been using mercury; but in this as in other cases of venereal disease of the bones, it is probably the imprudent and excessive use of mercury that gives rise to them.

Treatment of syphilis. — Till of late years a very pernicious notion prevailed with respect to syphilis, namely, that it never underwent a spontaneous cure, but proceeded to destroy one texture after another till the patient fell a victim to its fury. This belief, in connexion with the absolute reliance on the specific and exclusive powers of mercury, frequently gave rise to a most destructive line of practice; the worse the disease became, the further the supposed remedy was pushed; and thus, between the disease and the doctor, thousands of patients were annually consigned to a premature grave. The error above alluded to, unfortunately derived strength from the weighty authority of John Hunter. In the year 1813, Mr. S. Cooper, in his *First Lines of the Practice of Surgery*, inferred, from statements of Mr. Pearson, the occasional curability of syphilis without mercury. The correctness of this view has since been amply established by subsequent experiments and observations. Those made in the hospital of the Coldstream Guards by the late Mr. Rose are the most important. The great question, as to the spontaneous curability of syphilis, was by him completely settled. It was proved, that the venereal disease might be cured, not only without mercury, but without any medicines whatever. As for the cure without mercury, that indeed may be said not to have been a new discovery: the spontaneous cure was the great point made out. Many practitioners of the sixteenth and seventeenth centuries treated the venereal disease with considerable success without mercury, that is to say, by means of guaiacum, sarsaparilla, and antimony, occasionally aided by venesection and purgatives. If it had been the character of the venereal disease always to grow progressively worse without mercury, no patient could ever have recovered prior to the epoch when that medicine began to be exhibited, which is contradicted by abundant evidence.

Mr. Rose had vast opportunities of bringing the question to a decision; for he could not only put his patients under particular treatment, but he had it in his power to enforce its strict adoption, and to watch his patients for the requisite period of time. Now, he cured without mercury all the ulcers on the parts of generation, sores of every kind, which he met with in the course of between two and three years in a regiment of soldiers, together with all the constitutional symptoms that followed them. It is not to be understood, that none of those who were cured of the primary sores without mercury had no secondary symptoms; a certain proportion of the men, so treated, had them; but, be it noticed, that Mr. Rose cured both the primary and the secondary symptoms too on the same plan. Some of these cases were probably not truly venereal; yet others must be admitted to have been venereal; for it cannot be imagined, that there were not many cases of true syphilis in a regiment of twelve or fifteen hundred men, who were continually having intercourse with the lowest prostitutes of the metropolis. In the treatment pursued by Mr. Rose, all ideas of specific remedies were renounced; his general practice was to confine the patient in bed; various local applications were used according to circumstances; aperient medicines, antimonials, bark, diluted sulphuric acid, and occasionally sarsaparilla, were administered; these were the chief means resorted to. From these, and other accounts corroborating them, there can be no doubt, that the venereal disease, both in its primary and secondary forms, may be cured without mercury; but this is not settling the question whether such practice is the right method or not. And the circumstance is only mentioned to prove that the old notions about the progressive nature of the venereal disease, till stopped by the imaginary specific

effects of mercury, were completely erroneous. The facts, established by Mr. Rose, are chiefly valuable on two accounts; first, as leading to more correct views of the diagnosis of the disease, inasmuch as they abolish the false doctrine, that all sores, healed without mercury, are necessarily not venereal, a maxim usually taught till within the last twenty years; and, secondly, Mr. Rose's facts are important, as encouraging us to withhold mercury when the patient's health is not in a safe or favourable state for its exhibition. Thirty or forty years ago, surgeons were actually frightened into the use of mercury, lest the disease should get progressively worse and worse, and the mischief advance till the patient had been destroyed.

It is now not only admitted by most enlightened practitioners, that syphilis may be cured without mercury, but that it is extremely doubtful whether that medicine possesses specific powers in any form of the disease. At the same time, all those who are not prejudiced in the antimercurial extreme, do not deny the great utility of mercury in the most common forms of the complaint; and the greater part actually employ it in the majority of cases. Several other substances besides mercury have enjoyed a transient reputation for their specific powers in syphilis, which is not to be wondered at when we know, what was not formerly known, that syphilis, like other diseases, has, in many instances, a tendency to a spontaneous cure. Of these substances, the principal are mezereon, guiac, sarsaparilla, nitric acid, and the preparations of gold. Some notice of the three former, in the capacity of antisyphilitics, will be found under the heads *Daphne mezeum* — *Guaiacum officinale* — and *Smilax sarsaparilla*, which see. Of the nitric acid, the effects are tonic and sedative; whence the appetite is increased, a greater rigidity or firmness is given to the living fibre, and a greater density to the coagulable lymph; the action of the bowels, and even of the bladder, being diminished. Besides these, it has a particular effect on the mouth, approaching to that of ptyalism; for the gums are rendered slightly sore, the mouth and tongue become moist, and in India and other warm climates, a real salivation is said to ensue. Under this change the syphilitic symptoms assume a better appearance, and especially those that belong to the primary set: but we have no decided case in which a perfect cure has been accomplished in our own country; though Dr. Scott affirms that in India this has been common. He was in the habit of employing the nitric and muriatic acids; and with the internal use of these he combined that of the acid bath. His object was to effect a cure without incurring any of the evils so frequent upon a mercurial course; and to this object the proposed plan has, in his opinion, given complete success. It would have been happy for the world if this success had been permanent and universal; but the plan has since fallen in its reputation, not much less in India than in Europe.

For the effects of gold in venereal diseases, see the article *Aurum*.

Taking for granted what is now established beyond doubt — that syphilis, although originating in a specific virus, is susceptible of cure by the natural efforts of the constitution, when vigorous, and exercised under favourable circumstances, and susceptible also of the influence of remedies quite independently of any specific effect, it becomes obvious that the disease should be treated, in a great measure, on general principles, the application of which must depend on the judgment of the practitioner in each individual case. The following general account of the mercurial treatment is taken from the excellent chapter on syphilis in Mr. S. Cooper's *First Lines of the Practice of Surgery*, the source from which the greater part of the present article is derived.

Whenever mercury is given, the wisest plan is to give it in moderation, and, above all things, to avoid the pernicious custom of putting the patient under a *course*, in which the mercury is given rapidly and profusely, and continued for an immoderate length of time. Experience has fully convinced me, that in no variety of chancre, nor in any other stage of the venereal disease, is it proper to give mercury so unmercifully, and for so long a period as was formerly done. At all events, violent and long salivations should be given up. This practice, as Mr. Cooper can state from his own observation in the foul wards of St. Bartholomew's Hospital, during a period of twelve years, instead of being more successful than the present methods, often led to the most dreadful of mutilations, and the number of those who lost their palates and noses, was infinitely greater than what is now observed. When these facts are considered, and joined with the treatment employed thirty or forty years ago, we cannot avoid concluding that a great deal of those ravages must have been produced not by the disease itself, but by the manner of treating it. At present, the practice of subjecting patients to long and immoderate courses of mercury is given up by all experienced and judicious surgeons. Common ulcerations are also more carefully discriminated from venereal ones; and when mercury is given, it is so administered as merely to produce a moderate affection of the gums and salivary glands, and not to occasion a total derangement of the whole economy.

Surgeons are also now no longer blinded by the pernicious fear, that unless mercury be given, the disease will continue to grow worse and worse till the patient is ultimately destroyed. In former days, directly a patient was brought to a hospital, however bad his health might be at the time, it was immediately considered necessary to cram him with mercury. But we are now aware, that the notion by which the old surgeons were terrified into such practice, was a mere ghost, nothing but a bugbear. When the patient's health is seriously impaired, as a general rule, mercury should be postponed till an amelioration in that respect has taken place. Even those practitioners who place the greatest reliance on mercury as a specific, and still maintain that it ought to be called so, qualify their assertions by admitting, that it

ought not to be given under every condition of the system; they candidly allow, that neither the condition of the parts, nor that of the constitution, is at all times such as will let mercury be given with impunity; they confess that its rash and unscientific employment will aggravate the symptoms; and they specify two cases in which its use is generally erroneous, namely, during excessive weakness of the system, and while the disease is complicated with excessive inflammation. Under these two conditions, the greatest advocates of mercury commonly admit, that its employment should be postponed. But these are not the only states in which it should usually be prohibited; it should not be given during any great derangement of the system from diarrhœa, or fever, or from what is termed *erythismus*, a peculiar state of constitution, in which the patient labours under excessive irritability, weakness, palpitation of the heart, and other evils from the mercury already given. There are some constitutions, in which this condition is liable also to be induced by a very slight quantity of mercury, and when it is present, the patient may die suddenly on making any trivial exertion.

Although mercury may not be absolutely essential to the cure of the venereal disease, yet so long as it shall continue to be a remedy of greater power for the prevention of secondary symptoms than any other known medicine, its reputation, as a means of curing this disorder, will always stand high. It is used either *topically*, that is, as a direct application to sores, nodes, and other local affections, or *constitutionally*, being introduced into the system either through the medium of the stomach or the skin.

Amongst *topical* mercurial preparations, the *black wash* is in very common use for venereal sores, both primary and secondary. It should vary in strength according to circumstances. Formerly the proportion of the ingredients in general use was a drachm of calomel to a pint of lime water; but now it is frequently made stronger, and sometimes as much as ten or fifteen grains of calomel are put into each ounce of lime water. With regard to the manner of using it: — if the sore or sores are on the outside of the prepuce, a piece of lint is dipped in the lotion and applied to them; but if the sores are under the prepuce, the introduction of lint into that situation would create too much irritation, and the lotion may therefore be occasionally injected under the prepuce with a small syringe. The *yellow wash*, used in the same manner, contains two grains of the oxymuriate of mercury in each ounce of lime water.

In general, *mercurial ointments* are not very good applications for venereal sores of any description; certainly they are not equal, in point of efficacy, to many other applications. Sometimes, however, the *unguentum hydrargyri nitratis*, blended with the unguentum cetaceum, or with zinc ointment, in various proportions, may be usefully employed.

Another manner of using mercury topically is that of *fumigation*. For this purpose we employ an apparatus that is furnished with an iron heater, and a copper tube, by which the fumes can be conveniently directed to the part affected; and in order to be able to do this better, we have both a straight tube and a curved one, the latter being particularly convenient for ulcers in the throat. The mercurial fumigating preparation in general use is *cinnabar*, or the *red sulphuret of mercury*, from which, when placed on the heater, a subtle grey powder is sublimed, which, lodging on the sore, is found in many instances to produce a very beneficial effect upon it. Mr. S. Cooper has seen sore throats, chancres, and other ulcerations, which had resisted for weeks and months every plan that could be devised, assume a healthy appearance, and heal up rapidly, after fumigation had been tried a few times. To know this truth is important; much more so than to be able to say exactly, how far the specific power of mercury is here concerned in the production of the good. The fumigation of a sore of moderate size is not likely to have much or any effect on the constitution; and it is probable that the method cannot generally operate on this principle. Perhaps, with the exception of fumigation, it may be said, as a general remark, that topical mercurial applications are not considered at all more useful than others which contain no mercury. The black, or calomel wash, is frequently made use of; but it is doubtful if it possesses more efficacy than several other astringent lotions which have not a particle of mercury in them.

With respect to the introduction of mercury into the system from the surface of the body, this can be accomplished either by rubbing mercurial ointment into the skin, or by mercurial fumigation of an extensive portion of the surface of the body. Friction with the ointment, the ordinary method, the most generally adopted, as requiring no machine for the purpose, is practised by the patient himself, who rubs some part of his body, which is frequently the inside of the thigh, for a quarter of an hour or twenty minutes before the fire, sometimes once a day and sometimes twice, with half a drachm or a drachm of the ointment. The quantity of ointment employed, however, varies in different cases, according to circumstances. Sometimes a scruple, sometimes half a drachm, and, in other instances, double this quantity, or even more, may be employed at a time. This is termed *rubbing in*, because a portion of the ointment seems as if it had been made to enter the pores of the skin by the friction; but, except where the patient is very easily affected, what remains on the surface of the skin should not be wiped away, the patient putting on a pair of flannel or other drawers over it. It should be mentioned, however, that sometimes friction and the rancidity of the ointment together (for we seldom meet with mercurial ointment perfectly free from rancidity), will bring out numerous pimples, and even erysipelatous inflammation, and then the patient should be directed to repeat the friction on another part, and not to leave any of the ointment on the skin. A few years ago, friction with mercurial ointment was commonly preferred in this country to all other plans of treating the venereal disease; first, because it was conceived to be the most efficient mode

of treatment, and the mercury in the ointment being combined with a very small proportion of oxygen, was usually given as one reason for the alleged fact; secondly, because it occasions less risk of disturbing the stomach and bowels than internal preparations; thirdly, because it is frequently considered to be the only certain way of getting a sufficient quantity of mercury into the system. Preparations of mercury, given by the mouth, are apt to disorder the stomach and bring on diarrhœa. Mr. Cooper suspected that the latter was the principal cause that rendered mercurial friction so favourite a practice; for, while the doctrine prevailed, that it was necessary for the cure of syphilis to fill the patient with mercury, to saturate him with it from head to foot, and to salivate him unmercifully, the stomach and bowels often revolted against the scheme, which absolutely could not be carried into execution in every instance by preparations designed for internal administration. It was then chiefly by means of mercurial friction that the old fiercely salivating practitioners were enabled to get into the system as much mercury as they wished; not that they did not also give internal preparations so far as they could. Mr. Cooper believes that the doctrine of the superior efficacy of mercurial friction is founded on prejudice, and that, unless the stomach and bowels be disordered, and the constitution cannot be affected with moderate doses of the blue pill, it is seldom indispensably necessary to have recourse to this uncleanly practice. In certain cases, we are indeed obliged to direct mercurial frictions, as when the stomach and bowels will not bear even a small quantity of mercury, which occasionally happens, or when it is necessary to resort to more plans than one, in order to bring the system under the influence of the mineral. Under these, and perhaps a few other circumstances, we may be called upon to prescribe frictions, as well as internal preparations.

Fumigating the surface of the body is not at present deemed so necessary and eligible a method of putting a patient under the influence of mercury, as some of its admirers once endeavoured to instil into the minds of the profession. It is attended with considerable trouble and inconvenience; it requires a particular machine, somewhat resembling a sedan-chair, in which the patient sits naked with his head out of an opening at the top of it. At the bottom of the machine is an iron heater, on which a preparation of mercury is thrown, which is sublimed and covers all the surface of the patient's body. The preparation of mercury employed for this purpose is the grey-oxide. Another mercurial powder, that was recommended and used by Mr. Abernethy, was calomel that had been put into liquor ammoniæ, and then dried. After having undergone the process, the patient puts on his shirt or flannel waistcoat, and goes to bed. The reasons formerly urged in favour of the practice were, that it is less fatiguing to a debilitated person than mercurial frictions, and that the system can be more quickly brought under the influence of mercury than by any other way whatsoever. This seems to have been Mr. Abernethy's opinion, who was once very zealous for fumigations; but afterwards relinquished them. With regard to the reasons given for the use of fumigations, that mercury may thus be employed, when the patient is in the weakest state, and that he may be mercurialised without the fatigue of friction, or the risk of disordering his stomach and bowels with internal preparations, the argument, though plausible, has not really much weight; because, when the health is seriously impaired, we are seldom justified in giving mercury at all; and, at all events, it should then never be introduced so rapidly into the system. But, if the plan deserves adoption in any particular instance, it may be useful to know, that it is not necessary for the patient to go into the machine at all; he may turn his flannel waistcoat and drawers inside out; and put them into the machine to be fumigated. They will become covered with the fine powder sublimed from the heater, and, on being worn afterwards, will salivate the patient as well as if he had gone into the machine himself.

Of the *internal preparations*, the *pilula hydrargyri*, or *common blue pill*, has the greatest reputation in this country; it is one of the mildest of all the internal preparations; the common dose of it is five grains; but frequently we are called upon to give a larger dose, and sometimes a smaller; from three to ten grains may be stated to be the ordinary average quantity proper to be given in the twenty-four hours. We may join it with other medicines, according to circumstances, as with the sulphate of quinine, the extract of conium, and various other medicines. We often combine the blue pill with a small quantity of opium, in order to lessen its tendency to affect the bowels.

The *hydrargyri submurias*, or *calomel*, is not very extensively employed in England for the cure of syphilitic complaints, though it is a favourite medicine for this purpose abroad, especially in Germany. Even in England, for one effect of the venereal disease, calomel is usually preferred, viz. syphilitic iritis. This preparation, like the blue pill, may be joined with other medicines, as with guaiacum and the sulphuret of antimony, as in the *compound calomel pill*, which is not unfrequently prescribed in venereal affections, but especially in those requiring merely slight alterative treatment.

The *oxymuriate of mercury*, or *corrosive sublimate*, is a very powerful medicine, and, if it be incautiously given, it may readily poison the individual. The dose is small, the average quantity, usually given, is one-eighth of a grain, twice or thrice a day. When mixed with distilled water, it dissolves more readily if a small proportion of the muriate of ammonia be added. There are instances, in which from half a grain to three quarters of a grain may be prescribed in divided doses to be taken in a day. The *liquor hydrargyri oxymuriatis* of the London Pharmacopœia, contains the eighth of a grain of the oxymuriate in two drachms. When it is wished to give it with bark, we may dissolve one grain of it in an ounce of the tinctura cinchonæ, of which a tea spoonful is the proper dose.

The *hydrargyrum cum cretâ* is the mildest preparation of mercury ever employed in this country, and, on this account, it is preferred in cases where we wish to exert a very slight mercurial influence on the constitution. It is deemed the best preparation of mercury for infants labouring under syphilis.

One caution is necessary in the employment of mercury; namely, to watch its effects very attentively; for it will act differently in different individuals. Some will be violently salivated by a few grains of blue pill, or a scruple of blue ointment; while others will use from one to three drachms of it daily for months together, with no manifest effect on the function of the salivary glands, bowels, or other organs. The doses of mercurial preparations must then be regulated by circumstances; indeed it is wholly impossible to give any precise rules on this head, on account of the different effects of the mineral on different individuals. The safest plan is always to begin with small quantities of mercury, watching the effects of the medicine, and being guided by them.

The action of mercury on the animal economy is very powerful; the nervous, the absorbent, and the sanguiferous systems are all considerably affected by it; an universal irritability is excited; there is a quickness of the pulse, and a feverish state of the whole constitution brought on by it; the secretions are all increased, especially those of the skin, kidneys, and salivary glands. *Salivation*, or an increased secretion of saliva, and a soreness and swelling of the gums and mouth, are the effects which surgeons have long been accustomed to observe with attention; for these are usually regarded as tests of the remedy having a sufficient influence on the system effectually to cure the complaint, for which it is given; not merely to cure the *primary symptoms*, but give the patient the best possible chance of escaping the *secondary ones*. In fact, this is the main object of giving mercury; we know that we can cure the primary symptoms without mercury; and were these alone abstractedly considered, perhaps, we should never be justified in salivating the patient at all. But the great and solid argument for the mercurial practice is, that, without it, the patients will be more likely to be attacked by secondary symptoms.

For the particulars of the local treatment of venereal sores, whether primary or secondary, we must refer to the treatises on surgery.

Syphilis Indica. See *Frambœsia.*

SY'PHILOID. (*Syphiloides*; from *syphilis*, and *εἶδος*, resemblance.) Like unto syphilis. The name of a disease which resembles syphilis. There are many diseases which have a close resemblance to the venereal in its primary and constitutional forms: these have all been called syphiloid. The principal of this family of diseases is the pseudo-syphilis, or bastard pox, of Hunter and Abernethy.

It mostly commences with local symptoms, though not always: but the local symptoms have a less resemblance to those of genuine syphilis than the constitutional by which they are succeeded. A few foul and highly irritable sores are unexpectedly discovered on the genitals, commonly larger than chancres, and less thickened than indurated, about the size of a sixpence, and frequently sprouting with fungous granulations. Rarely, but very rarely, they have the guise of a true chancre. These are sometimes succeeded by buboes, and sometimes not. And, where buboes take the lead, they run their course more rapidly, and with more violent inflammation, than in the true disease, and spread to a greater number of circumjacent glands. These often heal by the ordinary means without mercury, or constitutional symptoms of any kind But not unfrequently, in a few weeks or months, they are followed by a soreness and ulceration of the tonsils, copper-coloured spots over the body, and nodes or swellings of the periosteum in various bones; and sometimes these symptoms change their order of succession, or appear single.

In a few instances, the constitutional symptoms take the lead, and the local follow. In all these cases, the virus seems to be more active and irritating than that of genuine syphilis; but which, while it pursues, though with much irregularity, the same general path, runs through its course much quicker, and is more effectually coped with by the natural strength, or remedial instinct of the constitution. And hence, all that we are here called upon to do in the way of treatment is, to support the general vigour, and second the instinctive effort. This is best to be accomplished by tonics and gentle stimulants, and, where necessary, by sedatives. The mineral acids are the best means of supplying the first intention; camphire, the decoction of the woods, and the compound calomel pill, where small doses of mercury do not irritate, the second; and opium the third; though to this last it will rarely be necessary to have recourse at all.

The distinction between syphyloid affections and genuine syphilis is frequently difficult, but of importance: since, as a full use of mercury seldom seems to do good, and often does serious mischief in the former, such a plan has a chance of overwhelming the constitution with a second disorder instead of freeing it from a first.

SYRIÆ OLEUM. A fragrant essential oil, obtained by distilling the canary balsam plant, or moldavica.

Syrian herb mastich. See *Teucrium.*

SYRI'GMUS. (*Συριγμος*; from *συριζω*, to make a sound by blowing through a pipe.) This term has been applied to ringing in the ears. See *Tinnitus aurium.*

SYRINGO'TOMUM. (From *συριγξ*, a fistula, and *τεμνω*, to cut.) An instrument to cut fistulas.

SY'RINX. (*x, gis. f.* *Συριγξ*, from the Hebrew.) A pipe. A syringe. A fistula.

SYRMAI'SMUS. (*Συρμαισμος*; from *συρμαιζω*, to purge gently.) A gentle evacuation by vomit or stool. — *Hippocrates.*

SYROP. The French for a syrup.

SYROP DE CAPILLAIRE. *Syrupus capillorum veneris.* Syrup of capillaire. A syrup much used in France as a pectoral. It is made with maidenhair, liquorice water, and sugar.

Syrup. See *Syrupus.*

SYRU'PUS. (*us, i.* m. *Scrab*, a potion, Arabic.) The name syrup is given to sugar dissolved in water; and in the present Pharmacopœia this is termed simple syrup. See *Syrupus simplex.*

Syrups are generally made with the juice of vegetables or fruits, or by adding vegetable extracts or other substances. To keep syrups without fermenting, it is necessary that their temperature should be attended to, and kept as near 55° as possible. A good cellar will answer this purpose; for there are few summers in which the temperature of such a place rises to 60°.

SYRUPUS. The simple syrup is called merely *syrupus* in the London Pharmacopœia. See *Syrupus simplex.*

SYRUPUS ACETI. Sugar and vinegar. A refrigerating syrup. See *Oxymel.*

SYRUPUS ALTHÆÆ. Syrup of marshmallow. *Syrupus ex althæâ. Syrupus de althæâ.* Take of the fresh root of marshmallow, bruised, eight ounces; refined sugar, two pounds and a half; water, four quarts. Boil down the water with the marshmallow root to half, and press out the liquor when cold. Set it by for twenty-four hours, that the feculencies may subside; then pour off the liquor, and, having added the sugar, boil it down to a proper consistence. An emollient and demulcent, mostly given to allay tickling coughs, hoarseness, &c. in conjunction with other remedies.

SYRUPUS AURANTII. Syrup of orange. *Syrupus corticis aurantii. Syrupus è corticibus aurantiorum. Syrupus de cortice aurantiorum.* Take of fresh orange-peel, two ounces and a half; boiling water, a pint; refined sugar, three pounds. Macerate the orange-peel in the water for twelve hours in a covered vessel: then pour off the liquor, and add the sugar. A pleasant bitter and stomachic.

SYRUPUS CARYOPHYLLI RUBRI. Syrup of clove pinks. A warm and stimulating syrup.

SYRUPUS COLCHICI. An acrid and diuretic compound, given in dropsies.

Syrupus corticis aurantii. See *Syrupus aurantii.*

SYRUPUS CROCI. Syrup of saffron. Take of saffron, ten drachms; boiling water, a pint; refined sugar, three pounds. Macerate the saffron in the water for twelve hours, in a lightly covered vessel; then strain the liquor, and add the sugar. This imparts a beautiful colour to liquids, and is sometimes employed as a cordial. Among the vulgar, syrup of saffron is in high esteem in measles, small-pox, &c.

SYRUPUS LIMONUM. Syrup of lemon. *Syrupus succi limonis. Syrupus è succo limonum. Syrupus è succo citrorum.* Take of lemon-juice, strained, a pint; refined sugar, two pounds and a half. Dissolve the sugar in the lemon-juice in the manner directed for simple syrup. A very pleasant, cooling, and acid syrup, which may be exhibited with advantage in febrile and bilious affections.

SYRUPUS MORI. Syrup of mulberry. *Syrupus mororum.* Take of mulberry-juice, strained, a pint; refined sugar, two pounds and a half. Dissolve the sugar in the mulberry-juice in the manner directed for simple syrup. Syrup of mulberries is very grateful and aperient, and may be given with such intentions to children.

SYRUPUS PAPAVERIS. *Syrupus papaveris albi. Syrupus è meconio. Syrupus de meconio, sive diacodium.* Take of capsules of white poppy, three pounds; refined sugar, five pounds; boiling water, five gallons. Boil down the capsules in the water, to two gallons, and press out the liquor strongly. Boil down the liquor again, after being strained, to four pints, and strain it while hot. Set it by for twelve hours, that the feculencies may subside; then boil down the clear liquor to two pints, then add the sugar, and dissolve. It should be kept in stone bottles, and in a cellar. A useful anodyne preparation, which may be added with advantage to a vast variety of medicines against diseases of the bowels, coughs, &c.

Syrupus papaveris erratici. See *Syrupus rhœados.*

SYRUPUS RHAMNI. Syrup of buckthorn. Take of the fresh juice of buckthorn berries, four pints; ginger-root, sliced, allspice, powdered, of each six drachms; refined sugar, four pounds. Set by the juice for three days, that the feculencies may subside, and strain. To a pint of the clear juice add the ginger and allspice; then macerate in a gentle heat four hours, and strain; boil down what remains to one pint and a half; mix the liquors, add the sugar, and dissolve.

This preparation, in doses of three or four spoonfuls, operates as a brisk cathartic. The principal inconvenience attending it is, that it is very unpleasant, and occasions a thirst and dryness of the mouth and fauces, and sometimes violent gripes. These effects may be prevented by drinking liberally of water-gruel, or other warm liquids, during the operation.

SYRUPUS RHŒADOS. *Syrupus papaveris erratici. Syrupus de papavere erratico.* Syrup of red poppy. Take of red poppy petals, fresh, a pound; boiling water, a pint and a half; refined sugar, two pounds and a half. Having heated the water in a water-bath, add gradually the red poppy petals, frequently stirring them; then having removed the vessel, macerate for twelve hours; next press out the liquor, and set it by to settle; lastly, add the sugar, and dissolve. This is used merely as a colouring matter.

SYRUPUS RIBIS NIGRI. Syrup of black currants. Aperient and diuretic qualities are attributed to this preparation.

SYRUPUS ROSÆ. Syrup of roses. *Syrupus rosarum solutivus. Syrupus è rosis siccis.* Take of damask-rose petals, dried, seven ounces; refined sugar, six pounds; boiling water, three pints. Macerate the rose petals in the water for twelve hours, and strain; then evaporate the strained liquor, by means of a water-bath, to two pints; then add the sugar, and dissolve. A useful laxative for children. Dose from ʒj. to ʒss.

SYRUPUS RUBI IDÆI. Syrup of raspberry. A pleasant aperient syrup for children.

SYRUPUS SARZÆ. Syrup of sarsaparilla. Take of the sliced root of sarsaparilla, fifteen ounces;

boiling water, a gallon; sugar, fifteen ounces. Macerate the root in the water for twenty-four hours; then boil down to four pints, and strain the liquor while hot; then add the sugar, and evaporate to a proper consistence. This preparation has been introduced into the present London Pharmacopœia; but it is not so active as the extract. It is used chiefly as an adjunct to the decoction.

Syrupus scillæ. Syrup of squill. Used for the same purposes as the *Oxymel Scillæ*.

Syrupus sennæ. Syrup of senna. Take of senna-leaves, two ounces; fennel-seed bruised, an ounce; manna, three ounces; refined sugar, a pound; water, boiling, a pint. Macerate the senna-leaves and fennel-seeds in the water for an hour, with a gentle heat; strain the liquor, and mix with it the manna and sugar; then boil to the proper consistence. A useful purgative for children.

Syrupus simplex. *Syrupus.* Simple syrup. Take of refined sugar, ten pounds; water, three pints. Dissolve the sugar in the water with a gentle heat.

Syrupus tolutani. Syrup of Tolu. Take of balsam of Tolu, ten drachms; water, boiling, a pint; refined sugar, two pounds and a half. Boil the balsam in the water half an hour in a lightly covered vessel, occasionally stirring it: strain the liquor when it is cold; then add the sugar, and dissolve. An useful balsamic syrup, calculated to allay tickling coughs and hoarsenesses.

Syrupus vi'olæ. A pleasant laxative for young children.

Syrupus zingi'beris. Syrup of ginger. Take of ginger-root, sliced, two ounces; water, boiling, a pint; refined sugar, two pounds and a half. Macerate the ginger-root in the water for four hours, and strain; then add the sugar, and dissolve. A carminative and stomachic syrup. Dose from one to three drachms.

SYSPA'SIA. (*a, æ.* f.; from *συσπαω, contraho, convello.*) A spasm.

SYSSARCO'SIS. (*is, is.* f.; from *συν*, and *σαρξ*, flesh.) A species of union of bones, in which one bone is united to another by means of an intervening muscle. In this manner the os hyoides is connected with the sternum and other parts.

SYSTA'TICUS. (From *συνιστημι, congredior, consocio.*) Applied by Dr. Good to designate nervous diseases which affect several, or all, the sensorial powers simultaneously.

System, absorbent. See *Absorbent*, and *Lymphatic.*

System, genital. See *Generation, organs of.*

System, nervous. See *Nerve.*

System of plants. See *Classification.*

System, vascular. The arteries and veins.

SY'STOLE. (*e, es.* f.; from *συστελλω*, to contract.) The contraction of the heart.

SYSTRE'MMA. (*a, atis,* n.; from *συστρεφω, contorqueo*, to wind about, or twist.) The cramp.

T.

T-BANDAGE. A bandage so named from its figure. It is principally used for supporting the dressings, after the operation for fistula in ano, in diseases of the perinæum, and those of the groin, anus, &c.

TABA'CUM. (*um, i.* n.; so called from *Tobago*, the island whence it was first brought.) Tobacco. See *Nicotiana.*

TABASHEER. The silica found in the hollow stem of the bamboo cane is so called. Its optical properties are peculiar.

TABE'LLA. (*a, æ.* f.; diminutive of *tabula*, a table.) A lozenge.

TA'BES. (*es, is.* f.; a Latin word, of doubtful origin. The lexicographers, says Dr. Good, derive it from the Greek *τήκω, macero*, varied in the Doric dialect to *τάκω*, whence Scaliger makes a compound of *τακωδιος, macerans vitæ*, a consuming life, or life of consumption; and supposes that such a word existed formerly, and that *tabes* is a derivative from it. *Tab-eo, tab-es*, is most probably derived from the Hebrew תאב, *tab*, literally to *pine away*, or *consume*, which is the exact meaning of the Latin terms.) A wasting of the body; characterised by emaciation, weakness, and fever, but without any cough or spitting.

The distinction of modern nosologists between atrophy and tabes is, that the latter is accompanied by fever, which atrophy is not. The common causes of tabes are supposed to be an acrimony in the blood, either pus which is absorbed from an abscess, or some poisonous substance, as mercury or arsenic; or a scrofulous taint; or an excess of venereal indulgence: and from these causes Dr. Good institutes four species.

1. The *purulent tabes.*—An absorption of pus into the blood, acting upon a peculiarity of constitution, is here the exciting cause: but unless the latter be present, pus will rarely, if ever, be found to produce a tabid frame; for, if absorbed pus be capable, independently of idiosyncrasy, of inducing a decline in one instance, it ought to do so in every instance: yet this we know is not the case, since buboes, empyemas, and other abscesses of large size, have been removed by absorption, and yet no tabes has accompanied the process. It is said to occur more frequently where an abscess is open, in

consequence of pus becoming more acrimonious by the action of the air. But this supposition is altogether gratuitous; and, where hectic fever accompanies a sore or open abscess, it is more probably from increased irritation on the edges or internal surface of the cavity.

With respect to the treatment, every thing depends on the local disease; the proper remedies for which must be exhibited, and the strength maintained by a nutritious diet, pure air, and bark with mineral acids; and if stimulants be required, with a view of acting more directly on the morbid irritation, and changing its nature, they should be limited to the milder resins, as myrrh, or the mild terebinthinates.

2. The *tabes venenata* is that which is produced by a poisonous acrimony in the blood, which excites and maintains the hectic fever. This is a disease only met with amongst miners, mineralogists, and labourers in chemical laboratories, and the poison is probably taken in with the atmosphere, or by cutaneous absorption.

The first thing to be done in assisting the cure is to remove the patient from the deleterious scene into a salubrious atmosphere of fresh air, and then to purify the blood by a course of alkalies with sarsaparilla, mild bitters, and chalybeate mineral waters.

3. The *tabes scrofulosa*, corresponding with the *tabes mesenterica* of most writers. This Dr. Good considers as allied to scrofula; but it consists, beyond all doubt, in a real scrofulous affection of the mesenteric glands, which are the seat of a tubercular deposit similar to that which takes place in other scrofulous glands. Since, however, the disease is peculiarly connected with a morbid condition of one or more of the organs of nutrition, including those of digestion and assimilation, and is uniformly accompanied with emaciation, irritation, and some degree of hectic fever, it may, without impropriety, be considered in connexion with tabid diseases.

When the strumous taint is excited into action in infant life, it generally fixes upon the chylific or chyliferous glands, especially when they are in a weakly state: most commonly upon those of the mesentery. Scrofulous tabes begins with languor and want of appetite, pain in the back and loins, fulness, and, as the disease advances, pain and tenderness of the abdomen. The belly is enlarged, while the limbs are in a state of atrophy. These symptoms are accompanied or succeeded by a chalky appearance, and want of consistency in the alvine evacuations, as if the chyle were rejected by the absorbents, and left in the state of a milky fluid in the intestines, and the functions of the liver were at the same time impaired, the natural tinge of the bile being wanting. The evacuations are also sometimes mixed with mucus and blood; and are attended by pain, irritation, and tenesmus, somewhat resembling those which occur in a mild dysentery. Occasionally, also, there are symptoms of dropsy, and especially ascites; as if the absorption of the fluid, secreted into the cavity of the abdomen, were prevented by local obstacles: the absorbent glands, which are enlarged, being rendered impervious, and pressing also on the lacteals and lymphatics which enter them and pass by them. The appetite, in some cases, becomes ravenous, and worms are sometimes found in the fæces.

The treatment of this species of tabes is similar in every respect to that of the other forms of scrofula. Very small doses of the grey or black oxides of mercury, carefully guarding against relaxing the bowels and acting on the gums, may be beneficially employed, with mild tonic bitters, conium, and sarsaparilla; and, in most cases, benefit is derived from a steady perseverance in chalybeates.

4. The *tabes dorsalis*.—This, Dr. Good observes, is a disease of considerable antiquity; for we find traces of it in the oldest historical records that have reached our own day: and it is particularly described by Hippocrates under the name of φθισις νωτιας, literally "humid tabes," says the doctor, from the frequent and involuntary secretion of a gleety matter, or rather of a dilute and imperfect seminal fluid; but the term νωτιας evidently signifies "appertaining to the back," whence the translation of the name as *tabes dorsalis*. Hippocrates describes it as a disorder of the spinal marrow, incident to persons of a salacious disposition, or who are newly married, and have too largely indulged in conjugal pleasures. He represents the patient as complaining of a sense of formication, or a feeling like that of ants creeping from the upper part of his body, as his head, into the spine of his back; and tells us that when he discharges his urine or excrements there is at the same time a copious evacuation of semen, in consequence of which he is incapable of propagating his species, or answering the purpose of marriage. He is generally short breathed and weak, especially after exercise: he is sensible of a weight in his head, his memory is inconstant, and he is affected with a failure of sight and a ringing in his ears. Though without fever at first, he at length becomes severely feverish, and dies of that variety of remittent which the Greeks called leipyria, a sort of causus or ardent fever, attended with great coldness of the extremities, but with a burning fire and intolerable heat within, an insupportable anxiety and unconquerable dryness of the tongue. This description is fully confirmed by Professor Frank in his history of the miserable condition of two young men who had induced the same disease by a habit of self-pollution, one of whom, together with extreme emaciation, suffered excruciating pains in every limb from head to foot, was incapable of standing, and subject to epileptic fits; while the other, after a long career of acute suffering in various ways, was at length seized with a hemiplegia.

There is no reason to doubt the reality of the disease above described, but it is certainly not one of frequent occurrence, and has unquestionably been made a bugbear of by quacks to answer their own purposes.

The cure of this species is to be attempted, and often is effected, by attention to the mind; by avoiding the causes; by regular change of scene, and country air, with a nutritive and invigorating diet; cold bathing, especially in

the sea; and the moderate use of wine, with chalybeates, cinchona, and myrrh.

TABES COXARIA. A wasting of the thigh and leg from an abscess, or other cause, in the hip.

Tabes dorsalis. See *Tabes.*

Tabes pulmonalis. See *Phthisis.*

TACAMAHA'CA. (*a, æ.* f.; an Indian word.) A resinous substance of a yellowish-brown colour, slightly aromatic taste, and fragrant smell. Two kinds of it are generally found in commerce, namely, tacamahaca in the shell, which is the produce of the *Fagara octandra*, and *tacamahaca in the lump*, which is supposed to be the produce of the *Populus balsamifera*. Tacamahaca has had nervine, maturative, and other virtues attributed to it, but it is now hardly ever used.

Tact. See *Touch.*

TA'CTUS. (*us, ûs.* m.; from *tango*, to touch.) See *Touch.*

TÆ'DA. (*a, æ.* f. Δαιδα; from δαω, to burn.) A torch. A medicated torch for fumigations.

TÆ'NIA. (*a, æ.* f. Ταινια, a Greek word, signifying a fillet or tape.) 1. The tape-worm. A genus of intestinal worms, characterised by a long, flat, and jointed body. See *Entozoa.*

2. A name given by anatomists to two parts of the brain. See *Tænia hippocampi*, and *Tænia semicircularis.*

TÆNIA HIPPOCAMPI. *Corpus fimbriatum.* The plaited edge of the posterior crus of the fornix. See *Encephalos.*

TÆNIA SEMICIRCULARIS. *Tænia semicircularis Halleri.* A flattened white line, running in the groove between the optic thalamus and corpus striatum. See *Encephalos.*

Tail. See *Cauda.*

TALIACOTIAN OPERATION. In the year 1598, Caspar Taliacotius published a work entitled "Cheirurgia Nova de Narium, Aurium, Labiorumque Defectu, per insitionem cutis ex humero, arte hactenus omnibus ignotâ sarciendo." In this work several extraordinary cases are recorded of the restoration of noses and other parts by partially detaching a portion from the arm, moulding it to a proper shape, causing adhesion, and finally detaching it altogether from the arm, so that it remained in its new situation. Operations of this kind are called Taliacotian operations, from their discoverer, and *Rhinoplastic, cheiloplastic*, &c., according to the part restored. Of late years several successful operations for new noses have been performed, and this is now always done by turning down a flap of integument from the forehead.

TA'LPA. (*a, æ.* f.; from τυφλος, blind. ?) *Talparia.* 1. The mole. A small plantigrade animal. The cinders of this animal burnt, mixed with honey and white of egg, were formerly esteemed against gangrene, lepra, and scrofula. The blood was a remedy for alopecia.

2. Applied formerly to a kind of atheromatous tumour under the scalp, which sometimes produced caries and sinuses, burrowing under the scalp; whence its name.

TA'LUS. (*us, i.* m.; from *taxillus*, a small die.) 1. The ankle.

2. A bone of the ankle. See *Astragalus.*

Tamalapatra. See *Laurus cassia.*

TAMARI'NDUS. (*us, i.* m.; from *tamar*, or *tamarindi*, which is, in the Arabian language, a synonym of the dactylus or date. 1. The name of a genus of plants. Class, *Monadelphia*; Order, *Triandria.* The tamarind-tree and fruit.

2. The pharmacopœial name of the tamarind. See *Tamarindus indica.*

TAMARINDUS INDICA. The systematic name of the tamarind-tree: called also, *Oxyphœnicon, Siliqua arabica, Balampulli, Tamaræa zecla, Oxyphœnicia*, and *Acacia Indica.* This tree grows in hot climates, and is abundant in the West India islands. The preserve called in the shops tamarinds consists of a pulp, with the seeds connected together by numerous tough strings or fibres. According to Long, tamarinds are prepared for exportation, at Jamaica, in the following manner: — "The fruit or pods are gathered in June, July, and August, when full ripe, which is known by their fragility or easy breaking on small pressure between the finger and thumb. The fruit taken out of the pod, and cleared from the shelly fragments, is placed in layers in a cask, and boiling syrup, just before it begins to granulate, is poured in, till the cask is filled: the syrup pervades every part, quite down to the bottom, and when cool the cask is headed for sale." The tamarind is employed as a laxative, and for abating thirst or heat in various inflammatory complaints, and for correcting putrid disorders, especially of a bilious kind, in which the cathartic, antiseptic, and refrigerant qualities of the fruit have been found equally useful; with which intention they are mixed with barley-water, or any proper diluting fluid, and given as a drink. When intended merely as a laxative, it may be of advantage (Dr. Woodville observes) to join it with manna or purgatives of a sweet kind, by which its use is rendered safer and more effectual. Three drachms of the pulp are usually sufficient to open the body, but to prove moderately cathartic one or two ounces are required. It is an ingredient in the *confectio cassiæ*, and *confectio sennæ.*

TAMARI'SCUS. (*us, i.* m.) See *Tamarix.*

TA'MARIX. (*ix, icis.* f.; from *Tamarik*, abstersion, Heb.: named from its properties of cleansing and purifying the blood.) The name of a genus of plants. Class, *Pentandria*; Order, *Digynia.* The tamarisk-tree.

TAMARIX GALLICA. The systematic name of the tamarisk-tree: also named *Tamariscus.* Tamarisk. The bark, wood, and leaves of this tree were formerly employed medicinally, though seldom used at present: the former for its aperient and corroborant virtues in obstructions of the liver; the latter in icterus, hæmoptysis, and some affections of the skin.

Tame-poison. See *Asclepias.*

TANACE'TUM. (*um, i.* n.; corrupted from *tanasia, athanasia*, the old name for tansy.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia superflua.* Tansy.

2. The pharmacopœial name of the tansy. See *Tanacetum vulgare.*

TANACETUM BALSAMI'TA. The systematic name of the officinal costmary, or alecost: named also, *Balsamita mas*, *Balsamita major*, *Tanacetum hortense*, and *Costus hortorum*. The plant which bears this name in the pharmacopœias is the *Tanacetum balsamita — foliis ovatis, integris, serratis*, of Linnæus. An herb with a fragrant smell, somewhat like that of mint, formerly esteemed as a corroborant, carminative, and emmenagogue.

Tanacetum hortense. See *Tanacetum balsamita*.

TANACETUM VULGARE. The systematic name of the common tansy: called also, *Tanasia*, *Athanasia*, and *Parthenium mas*.

Tanacetum — foliis bipinnatis, incisis, serratis, of Linnæus. The leaves and flowers of tansy have a strong, not very disagreeable smell, and a bitter somewhat aromatic taste. The virtues of tansy are tonic, stomachic, anthelmintic, emmenagogue, and resolvent. It has been much used as a vermifuge; and testimonies of its efficacy are given by many respectable physicians. Not only the leaves, but the seeds have been employed with this intention, and substituted for those of santonicum. We are told by Dr. Clark, that in Scotland tansy was found to be of great service in various cases of gout; and Dr. Cullen, who afterwards was informed of the effect it produced upon those who had used the herb for this purpose, says, "I have known several who have taken it without any advantage, and some others who reported that they had been relieved from the frequency of their gout." Tansy is also recommended in the hysteria, especially when this disease is supposed to proceed from menstrual obstructions.

This plant may be given in powder to the quantity of a drachm or more for a dose; but it has been more commonly taken in infusion, or drank in tea.

Tanasia. See *Tanacetum*.

TANNIN. This, which is one of the immediate principles of vegetables, was first distinguished by Seguin from the gallic acid, with which it had been confounded under the name of the *astringent principle*. He gave it the name of tannin, from its use in the tanning of leather; which it affects by its characteristic property, that of forming with gelatine a tough insoluble matter.

It may be obtained from vegetables by macerating them in cold water; and precipitated from this solution, which contains likewise gallic acid and extractive matter, by hyperoxygenised muriate of tin. From this precipitate, immediately diffused in a large quantity of water, the oxide of tin may be separated by sulphuretted hydrogen gas, leaving the tannin in solution.

Professor Proust has since recommended another method, — the precipitation of a decoction of galls by powdered carbonate of potash, washing well the greenish-grey flakes that fall down with cold water, and drying them in a stove. The precipitate grows brown in the air, becomes brittle and shining like a resin, and yet remains soluble in hot water. The tannin in this state, he says, is very pure.

Sir H. Davy, after making several experiments on different methods of ascertaining the quantity of tannin in astringent infusions, prefers for this purpose the common process of precipitating the tannin by gelatine; but he remarks, that the tannin of different vegetables require different proportions of gelatine for its saturation; and that the quantity of precipitate obtained is influenced by the degree in which the solutions are concentrated.

Chenevix observed, that coffee-berries acquired by roasting the property of precipitating gelatine; and Hatchett has made a number of experiments, which show that an artificial tannin, or substance having its chief property, may be formed, by treating with nitric acid matters containing charcoal. It is remarkable that this tannin, when prepared from vegetable substances, as dry charcoal of wood, yields, on combustion, products analogous to those of animal matters. From his experiments it would seem that tannin is, in reality, carbonaceous matter combined with oxygen; and the difference in the proportion of oxygen may occasion the differences in the tannin procured from different substances, that from catechu appearing to contain most.

Bouillon Lagrange asserts that tannin, by absorbing oxygen, is converted into gallic acid.

It is not an unfrequent practice to administer medicines containing tannin in cases of debility, and at the same time to prescribe gelatinous food as nutritious. But this is evidently improper, as the tannin, from its chemical properties, must render the gelatine indigestible.

Tansy. See *Tanacetum*.

Tansy, maudlin. See *Achillea ageratum*.

Tansy, wild. See *Potentilla*.

TA'NTALUM. (*um*, *i.* n.) A metal at first supposed to be distinct, but now ascertained to be identical with columbium. See *Columbium*.

Taper. See *Acuminatus*, and *Attenuatus*.

Tape-worm. See *Entozoa*.

Tapioca. See *Jatropha manihot*.

Tapping. See *Paracentesis*.

TA'PSUS. (*us*, and *os*, *i.* f.) See *Verbascum nigrum*.

Tapsus barbatus. See *Verbascum*.

Tar. See *Pinus sylvestris*.

Tar, Barbadoes. See *Petroleum*.

TAR-WATER. A once celebrated remedy, but now neglected more than it deserves. It is made by infusing tar in water, stirring it from time to time, and, lastly, pouring off the clear liquor, now impregnated with the colour and virtues of the tar. It is drunk in many chronic affections, particularly of the lungs.

TARANTI'SMUS. (*us*, *i.* m.) The disease produced by the bite of the tarentula. See *Tarentula*.

Tarantula. See *Tarentula*.

TARA'XACUM. (*um*, *i.* n.; from ταρασσω, to alter or change: so called because it is said to alter the state of the blood.) See *Leontodon*.

TARA'XIS. (From ταρασσω, to disturb.) A slight inflammation of the eye. See *Ophthalmitis*.

Tarchon sylvestris. See *Achillea ptarmica*.

Tare. See *Ervum*.

TARE'NTULA. (*a*, *æ.* f.; from *Tarentum*,

now *Taranta*, in the kingdom of Naples, where the animal abounds. Such is the derivation generally given; but it appears more probable, that the word is from *terrantola*, a name given by the Italians to the *stellio* of the Romans, a reptile, to whose bite credulity ascribed the most extraordinary consequences, and which being afterwards confounded with the large spider in question, the same wonderful properties were transferred to the latter.) An animal of the class *Arachnida*, and order *Pulmonata*. The tarentula is a native of the south of Europe, and is one of the largest of European spiders. Wonderful stories have been told of the effects of its bite, which was said to produce a state of melancholy and stupor, attended with an extreme sensibility to music, and susceptible of relief only by dancing to the sound of the flute or other instrument, till the patient fell down quite exhausted. This affection was called *tarantism*, and once prevailed in Italy to such an extent as to constitute an epidemic mania, which, like St. Vitus dance, seems to have originated in morbid imagination, and to have been kept up by quackery. For a full and interesting account of tarantism, see Hecker, on the epidemics of the middle ages, lately translated by Dr. B. G. Babington. The real effects of the bite of the tarentula, as ascertained by modern experiment, are very similar to those of the common scorpion.

Target-shaped. See *Peltatus.*

Tarsi extensor minor. See *Plantaris.*

TA'RSUS. (*us, i.* m. Ταρσος.) 1. The instep, or that part of the foot which is between the leg and metatarsus: it is composed of seven bones, viz. the astragalus, os calcis, os naviculare, os cuboides, and three ossa cuneiformia.

2. The thin cartilage situated at the edges of the eyelids to preserve their firmness and shape.

TARTAR. (*Tartarum, i.* n.; from ταρταρος, infernal: because it is the sediment or dregs.) 1. The concretion which fixes to the inside of hogsheads containing wine. It is alloyed with much extractive and colouring matter, and in this impure or compounded state is called argal. It is either red or white, according to its colour. It is purified by decoction with argillaceous earths, by boiling its solution with $\frac{1}{20}$ of pipe-clay, and subsequent crystallisation. By this means it becomes perfectly white, and shoots out crystals, consisting of its peculiar acid called acid of tartar, imperfectly saturated with potash; it is therefore a super or bitartrate of that alkali which, when powdered, is the cream of tartar of the shops. See *Potassæ supertartras.*

2. A name heretofore given to many officinal preparations containing the acid of tartar, but, in consequence of recent changes in the chemical nomenclature, superseded by appellations more expressive of the respective compositions.

3. The human teeth are occasionally, after the age of puberty, and even before, and especially in advanced life, incrusted with an earthy-like substance, which is called tartar. It is deposited on them from the saliva, of which it is said to be a constituent. Berzelius says, that, when tartar first settles on the teeth, it is mere hardened mucus; and that, during the destruction of the mucus, phosphate of lime is traced on the enamel of the teeth, which in some cases increases to a great thickness, which, when analysed, is found to contain about one fifth of its weight of mucus. Rubbing the gums with earthy dentrifices is the best prophylactic against this unnatural condition; but rubbing alone is sufficient, if regularly resorted to.

TARTAR, CREAM OF. The popular name of the pulverised supertartrate of potash. See *Potassæ bitartras.*

Tartar, emetic. See *Antimonium tartarizatum.*

Tartar, oil of. See *Potassæ carbonatis liquor.*

Tartar, regenerated. See *Potassæ acetas.*

Tartar, salt of. See *Potassæ carbonas.*

Tartar, soluble. See *Potassæ tartras.*

TARTAR, SPIRIT OF. The *Pyrotartaric acid.*

Tartar, vitriolated. See *Potassæ sulphas.*

TARTA'RIC. (*Tartaricus*; from *tartar.*) Appertaining to tartar.

TARTARIC ACID. *Acidum tartaricum*; called also, *Sal essentiale tartari*, and *Acidum tartari essentiale*, and tartareous acid. The casks in which some kinds of wine are kept become incrusted with a hard substance, tinged with the colouring matter of the wine, and otherwise impure, which has long been known by the name of *argal*, or tartar, and distinguished into red and white according to its colour. See *Tartar.* This being purified by solution, filtration, and crystallisation, was termed *cream*, or *crystals of tartar.* It was afterwards discovered that it consisted of a peculiar acid combined with potash; and the supposition that it was formed during the fermentation of the wine, was disproved by Boerhaave, Newman, and others, who showed that it existed ready formed in the juice of the grape. It has likewise been found in other fruits, particularly before they are too ripe; and in the tamarind, sumach, balm, carduus benedictus, and the roots of rest-harrow, germander, and sage. The separation of tartaric acid from this acidulous salt, is the first discovery of Scheele that is known. He saturated the superfluous acid by adding chalk to a solution of the supertartrate in boiling water as long as any effervescence ensued, and expelled the acid from the precipitated tartrate of lime by means of the sulphuric. Or four parts of tartar may be boiled in twenty or twenty-four of water, and one part of sulphuric acid added gradually. By continuing the boiling the sulphate of potash will fall down. When the liquor is reduced to one half, it is to be filtered; and if any more sulphate be deposited by continuing the boiling, the filtering must be repeated. When no more is thrown down, the liquor is to be evaporated to the consistence of a syrup; and thus crystals of tartaric acid, equal to half the weight of the tartar employed, will be obtained. The following is given by Dr. Ure as the best formula for procuring tartaric acid:—Take of the supertartrate of potash, two pounds and a half; three gallons of boiling hot-water; one pound of prepared chalk; one pound of sulphuric acid. Boil the cream of tartar in two gallons of the water, and gradually throw in the chalk, until

all effervescence ceases: set the liquor aside that the tartrate of lime may subside; pour off the liquor, and wash the tartrate of lime repeatedly with distilled water until it is tasteless. Then pour on it the sulphuric acid, diluted with the remaining gallon of boiling water, and set the whole aside for twenty-four hours, stirring it well now and then. Strain the liquor, and evaporate in a water-bath until crystals form. The virtues of this acid are antiseptic, refrigerant, and diuretic. It is used in acute fevers, scurvy, and hæmorrhage.

The tartaric acid may be procured in needle-like or laminated crystals, by evaporating a solution of it. Its taste is very acid and agreeable, so that it may supply the place of lemon-juice. It is very soluble in water. Burnt in an open fire, it leaves a coaly residuum; in close vessels it gives out carbonic acid and carburetted hydrogen gas. By distilling nitric acid off the crystals, they may be converted into oxalic acid, and the nitric acid passes to the state of nitrous.

This acid combines with alkaline, earthy, and metallic bases, and form *tartrates*, all of which have been examined by chemists.

The tartrates of potash, soda, and ammonia, are not only susceptible of combining together, but also with the other tartrates, so as to form *double* or *triple salts*.

Tartrate of potash was formerly called *soluble tartar*, because much more so than the supertartrate. See *Potassæ tartras*.

The *supertartrate of potash* is much used in medicine, as well as in several chemical and pharmaceutical preparations. See *Potassæ supertartras*.

Mixed with an equal weight of nitre, and projected into a red-hot crucible, it detonates, and forms the *white flux*; treated in the same way with half its weight of nitre, it forms the *black flux*; and simply mixed with nitre in various proportions, it is called *raw flux*. It is likewise used in dyeing, in hat-making, in gilding, and in other arts.

By saturating the superfluous acid in the supertartrate with soda, a triple salt is formed which crystallises in larger regular prisms of eight nearly equal sides. See *Soda tartarizata*.

The *tartrate of soda* is much less soluble than this triple salt, and crystallises in slender needles or thin plates.

The *tartrate of ammonia* is a very soluble, bitter salt, and crystallises easily.

TA'RTARINE. The name given by Kirwan to the vegetable alkali.

Tartarum. See *Tartar*.

Tartarum emeticum. See *Antimonium tartarizatum*.

Tartarum regeneratum. See *Potassæ acetas*.

Tartarum solubile. See *Potassæ tartras*.

Tartarus ammoniæ. See *Tartras ammoniæ*.

Tartarus chalybeatus. See *Ferri potassio-tartras*.

TA'RTRAS. (*as, atis.* f.) A tartrate, or salt formed by the combination of tartaric acid with a salifiable base; as tartrate of soda, potash, &c.

Those used in medicine are,

1. The tartrate of ammonia.
2. ——— potash.
3. ——— potash and antimony.
4. ——— potash and soda.
5. ——— iron.
6. ——— soda.
7. The supertartrate of potash.

TARTRAS AMMONIÆ. Tartrate of ammonia; called also *Alkali volatile tartarizatum*, by Bergman; and *Sal ammoniacum tartareum*, and *Tartarus ammoniæ*. A salt composed of tartaric acid and ammonia. Its virtues are diaphoretic, diuretic, and deobstruent. It is prescribed in fevers, atonic exanthemata, catarrh, arthritic and rheumatic pains, hysteric spasms, &c.

Tartras potassæ. See *Potassæ tartras*.

TARTRAS POTASSÆ ACIDULUS. Acidulated tartrate of potash. See *Potassæ bitartras*.

TARTRAS POTASSÆ ACIDULUS FERRATUS. An old name of the *Ferri potassio-tartras* of the present London Pharmacopœia; formerly called also *Tartarus chalybeatus*, *Mars solubilis*, and *Ferrum potabile*. Its virtues are astringent. It used to be employed externally, in the form of fomentations or bath, in contusions, distortions, and luxations. See *Ferri potassio-tartras*.

Tartras potassæ acidulus stibiatus. See *Antimonium tartarizatum*.

Tartras sodæ. See *Sodæ potassio-tartras*.

TASTE. *Gustus*. Savours are only the impression of certain bodies upon the organ of taste. Bodies which produce it are called *sapid*.

It has been supposed that the degree of sapidity of a body could be determined by that of its solubility; but certain bodies, which are insoluble, have a very strong taste, whilst other bodies very soluble have scarcely any. The sapidity appears to bear relation to the chemical nature of bodies, and to the peculiar effects which they produce upon the animal economy.

Tastes are very numerous, and very variable. There have been numerous endeavours made to class them, though without complete success: they are better understood, however, than the odours, no doubt owing to the impressions received by the sense of taste being less fugitive than those received by the smell. Thus we are sufficiently understood when we speak of a body having a taste that is *bitter*, *acid*, *sour*, *sweet*, &c.

There is a distinction of taste which is sufficiently established, it being founded on the organisation: that of agreeable and disagreeable. Animals establish it instinctively. This is the most important distinction; for those things which have an agreeable taste are generally useful for nutrition, while those whose savour is disagreeable are, for the most part, hurtful.

Apparatus of Taste. — The tongue is the principal organ of taste: however, the lips, the internal surface of the cheeks, the palate, the teeth, the *velum pendulum palati*, the *pharynx*, *œsophagus*, and even the stomach, are susceptible of receiving impressions by the contact of sapid bodies.

The salivary glands, of which the *excretory ducts* open into the mouth; the follicles, which

pour into it the *mucus* which they secrete, have a powerful effect in forming the taste. Independently of the mucous follicles, that the superior surface of the tongue presents, and which form upon it *fungous papillæ*, there are also little inequalities seen, one sort of which, very numerous, are called *villous papillæ*; the others, less numerous, and disposed in two rows on the sides of the tongue, are called *conical papillæ*.

All the nerves with which those parts are provided that are intended to receive the impressions of sapid bodies may be considered as belonging to the apparatus of taste. Thus the inferior maxillary nerves, many branches of the superior, amongst which it is necessary to notice the threads which proceed from the *spheno-palatine* ganglion, particularly the *naso-palatine* nerve of Scarpa, the nerve of the ninth pair, *glosso-pharyngeus*, appear to be employed in the exercise of taste.

The lingual nerve of the fifth pair is that which anatomists consider the principal nerve of taste, and, as a reason, they say that its threads are continued into the *villous* and *conical papillæ* of the tongue.

Mechanism of Taste. — For the full exercise of taste, the mucous membrane which covers the organs of it must be perfectly uninjured; it must be covered with *mucous fluid*, and the saliva must flow freely in the mouth. When the mouth becomes dry, the powers of taste cannot be excited.

It is also necessary that these liquids undergo no change: for if the mucus become thick, yellow, and the saliva acid, bitter, &c., the taste will be exerted but very imperfectly.

Some authors have assured us that the *papillæ* of the tongue become really erect during the time that the taste is exerted. This assertion I believe to be entirely without foundation.

It is quite enough that a body be in contact with the organs of taste, for us to appreciate its savour immediately; but if it is solid, in most cases it is necessary to dissolve in the saliva to be tasted: this condition is not necessary for liquids and gases.

There appears to be a certain chemical action of sapid bodies upon the epidermis of the mucous membrane of the mouth: it is seen evidently, at least in some, as vinegar, the mineral acids, a great number of salts, &c. In these different cases, the colour of the epidermis is changed, and becomes white, yellow, &c. By the same causes, like effects are produced upon dead bodies. Perhaps to this sort of combination may be attributed the different kinds of impressions made by sapid bodies, as well as the variable duration of those impressions.

Hitherto no one has accounted for the faculty possessed by the teeth, of being strongly influenced by certain sapid bodies. According to the researches of Miel, a distinguished dentist of Paris, this effect ought to be attributed to imbibition. The researches of Miel prove that the teeth imbibe very quickly liquids with which they are placed in contact. Different parts of the mouth appear to possess different degrees of sensibility for sapid bodies: for they act sometimes on the tongue, on the gums, and on the teeth; at other times they have an exclusive action on the palate, on the pharynx, &c. Some bodies leave their taste a long time in the mouth: these are particularly the aromatic bodies. This *after-taste* is sometimes felt in the whole mouth, sometimes only in one part of it. Bitter bodies, for example, leave an impression in the pharynx; acids upon the lips and teeth: peppermint leaves an impression which exists both in the mouth and pharynx.

Tastes, to be completely known, ought to remain some time in the mouth: when they traverse it rapidly, they leave scarcely any impression. For this reason, we swallow quickly those bodies which are disagreeable to us; on the contrary, we allow those that have an agreeable savour to remain a long time in the mouth.

When we taste a body which has a very strong and pertinacious taste, such as a vegetable acid, we become insensible to others which are feeble. This observation has been found valuable in medicine, in administering disagreeable drugs to the sick. We are capable of distinguishing a number of tastes at the same time, as also their different degrees of intensity: this is used by chemists, tasters of wine, &c. By this means we arrive, sometimes, at a tolerably exact knowledge of the chemical nature of bodies; but such delicacy of taste is not acquired until after long practice.

Is the lingual nerve that which is essential to taste? Nothing is known which can make us attribute this property entirely to it.

The choice of food depends entirely on the taste: joined to smell, it enables us to distinguish between substances that are hurtful, and those that are useful. It is this sense which gives us the most correct knowledge of the composition of chemical bodies. — *Magendie.*

TA'XIS. (From ταττω, to put in order.) An operation, by which those parts which have quitted their natural situation are replaced by the hand without the assistance of instruments; as in reducing hernia, &c.

Tea. See *Thea.*

TEAR. *Lachryma.* The limpid fluid secreted by the lachrymal glands, and flowing on the surface of the eyes. See *Lachrymal apparatus.*

The tears have mixed with them an arterious roscid vapour, which exhales from the internal surface of the eyelids, and external of the tunica conjunctiva, into the eye. Perhaps the aqueous humour also transudes through the pores of the cornea on the surface of the eye. A certain part of this aqueous fluid is dissipated in the air; but the greatest part, after having performed its office, is propelled by the orbicular muscle, which so closely constringes the eyelid to the ball of the eye, as to leave no space between, unless in the internal angle, where the tears are collected. From this collection the tears are absorbed by the orifices of the puncta lachrymalia; from thence they are propelled, through the lachrymal canals, into the lachrymal sac, and flow through the ductus nasalis

into the cavity of the nostrils, under the inferior concha nasalis. The *lachrymal sac* appears to be formed of longitudinal and transverse muscular fibres; and its three orifices furnished with small sphincters, as the spasmodic constriction of the puncta lachrymalia proves, if examined with a probe.

The tears have no smell, but a saltish taste, as people who cry perceive. They are of a transparent colour and aqueous consistence.

The *quantity*, in its natural state, is just sufficient to moisten the surface of the eye and eyelids; but from sorrow, or any kind of stimulus applied to the surface of the eye, so great is the quantity of tears secreted, that the puncta lachrymalia are unable to absorb them. Thus the greatest part runs down from the internal angle of the eyelids, in the form of great and copious drops, upon the cheeks. A great quantity also descends, through the lachrymal passages, into the nostrils: hence those who cry have an increased discharge from the nose.

Use of the Tears. — 1. They continually moisten the surface of the eye and eyelids, to prevent the pellucid cornea from drying and becoming opake, or the eye from concreting, with the eyelids. 2. They prevent that pain which would otherwise arise from the friction of the eyelids against the bulb of the eye from continually winking. 3. They wash and clean away the dust of the atmosphere, or any thing acrid that has fallen into the eye. 4. Crying unloads the head of congestions.

TE'CTUS. Covered: applied as opposed to *nudus*, or naked; as to the seeds of the angiospermous plants.

TEETH. (*Dens*, a tooth; *quasi edens*, from *edo*, to eat.) Small bones fixed in the alveoli of the upper and under jaw. In early infancy, Nature designs us for the softest aliment, so that the gums alone are then sufficient for the purpose of manducation; but, as we advance in life, and require a different food, she wisely provides us with teeth. These are the hardest and whitest of our bones, and at full maturity, we usually find thirty-two in both jaws; viz. sixteen above, and as many below. Their number varies indeed in different subjects; but it is seldom seen to exceed thirty-two, and it will very rarely be found to be less than twenty-eight.

Each tooth may be divided into two parts; viz. its body, or that part which appears above the gums; and its fangs or root, which is fixed into the socket. The boundary between these two, close to the edge of the gum, where there is usually a small circular depression, is called the neck of the tooth. The teeth of each jaw are commonly divided into three classes; but, before each of these is treated of in particular, it will be right to say something of their general structure.

Every tooth is composed of its *cortex* or *enamel*, and its internal bony substances. The enamel, or, as it is sometimes called, the vitreous part of the tooth, is a very hard and compact substance, of a white colour, and peculiar to the teeth. It is found only upon the body of the tooth, covering the outside of the bony or internal substance. When broken it appears fibrous or striated; and all the striæ are directed from the circumference to the centre of the tooth. This enamel is thickest on the grinding surface, and on the cutting edges or points of the teeth, becoming gradually thinner as it approaches the neck, where it terminates insensibly. Some writers have described it as being vascular, but it is certain that no injection will ever reach this substance; that it receives no tinge from madder; and that it affords no appearance of a circulation of fluids. The bony part of a tooth resembles other bones in its structure, but is much harder than the most compact part of bones in general. It composes the inner part of the body and neck, and the whole of the root of the tooth. This part of a tooth when completely formed, does not, like the other bones, receive a tinge from madder, nor do the minutest injections penetrate into its substance, although many writers have asserted the contrary. Mr. Hunter has been therefore induced to deny its being vascular, although he is aware that the teeth, like other bones, are liable, to swellings, and that they are found anchylosed with their sockets. He supposes, however, that both these may be original formations; and, as the most convincing proof of their not being vascular, he reasons from the analogy between them and other bones. He observes, for instance, that, in a young animal that has been fed with madder, the parts of the teeth which were formed before it was put on madder diet will appear of their natural colour, but that such parts as were formed while the animal was taking the madder will be of a red colour: whereas, in other bones, the hardest parts are susceptible of the dye, though more slowly than the parts which are growing. Again he tells us, that if you leave off feeding the animal with madder a considerable time before you kill it, you will find the above appearances still subsisting, with this addition, that all the parts of the teeth which were formed after leaving off the madder will be white. This experiment proves, that a tooth once tinged does not lose its colour; whereas other bones do (though very slowly) return again to their natural appearance: and, as the dye in this case must be taken into the habit by absorbents, he is led to suspect that the teeth are without absorbents as well as other vessels. These arguments are very ingenious, but they are far from being satisfactory. The facts adduced by Mr. Hunter are capable of a different explanation from that which he has given them; and, when other facts are added relative to the same subject, it will appear that this bony part of a tooth has a circulation through its substance, and even lymphatics, although, from the hardness of its structure, we are unable to demonstrate its vessels. The facts which may be adduced are, 1st, We find that a tooth recently drawn and transplanted into another socket, becomes as firmly fixed, after a certain time, and preserves the same colour as the rest of the set; whereas a tooth that has been long drawn before it is transplanted, will never become fixed. Mr. Hunter, indeed, is aware of this

objection, and refers the success of the transplantation, in the first instance, to the living principle possessed by the tooth, and which, he thinks, may exist independent of a circulation. But however applicable such a doctrine may be to zoophytes, it is suspected that it will not hold good in man, and others of the more perfect animals: and there does not appear to be any doubt but that, in the case of a transplanted tooth, there is a real union by vessels. 2dly, The swellings of the fangs of a tooth, which, in many instances, are known to be the effects of disease, and which are analogous to the swelling of other bones, are a clear proof of a similarity of structure, especially as we find them invested with a periosteum. 3dly, It is a curious fact, though as yet perhaps not generally known, that, in cases of phthisis pulmonalis, the teeth become of a milky whiteness, and in some degree transparent. Does not this prove them to have absorbents?

Each tooth has an inner cavity, which, beginning by a small opening at the point of the fang, becomes larger, and terminates in the body of the tooth. This cavity is supplied with blood-vessels and nerves, which pass through the small hole in the root. In old people this hole sometimes closes, and the tooth becomes then insensible.

The teeth are invested with periosteum from their fangs to a little beyond their bony sockets, where it is attached to the gums. This membrane seems to be common to the tooth which it encloses, and to the sockets which it lines. The teeth are likewise secured in their sockets by a red substance called the *gums*, which every where covers the alveolar processes, and has as many perforations as there are teeth. The gums are exceedingly vascular, and have something like cartilaginous hardness and elasticity, but do not seem to have much sensibility. The gums of infants, which perform the offices of teeth, have a hard ridge extending through their whole length; but in old people, who have lost their teeth, this ridge is wanting. The three classes into which the teeth are commonly divided are, *incisores*, *canini*, and *molares*, or *grinders*.

The *incisores* are the four teeth in the forepart of each jaw: they derive their name from their use in dividing and cutting the food in the manner of a wedge, and have each of them two surfaces which meet in a sharp edge. Of these surfaces, the anterior one is convex, and the posterior one somewhat concave. In the upper jaw they are usually broader and thicker, especially the two middle ones, than those of the under jaw, over which they generally fall by being placed a little obliquely.

The *canini*, or *cuspidati*, are the longest of all the teeth, deriving their name from their resemblance to a dog's tusk. There is one of these teeth on each side of the incisores, so that there are two in each jaw. Their fangs differ from those of the incisores only in being much larger, and their shape may be easily described to be that of an incisor with its edge worn off, so as to end in a narrow point instead of a thin edge. The canini not being calculated for dividing like the incisores, or for grinding, seem to be intended for laying hold of substances. Mr. Hunter remarks of these teeth, that we may trace in them a similarity in shape, situation, and use, from the most imperfect carnivorous animal, which we believe to be the human species, to the lion, which is the most perfectly carnivorous.

The *molares*, or grinders, of which there are ten in each jaw, are so called, because from their size and figure they are calculated for grinding the food. The canini and incisores have only one fang, but the three last grinders in the under jaw have constantly two fangs, and the same teeth in the upper jaw three fangs. Sometimes these fangs are divided into two points near their base, and each of these points has, perhaps, been sometimes considered as a distinct fang. The grinders likewise differ from each other in their appearance. The two first on each side, which Mr. Hunter appears to have distinguished very properly by the name of *bicuspides*, seem to be a middle nature between the incisores and grinders; they have in general only one root, and the body of the tooth terminates in two points, of which the anterior one is the highest, so that the tooth has in some measure the appearance of one of the canini. The two grinders beyond these, on each side, are much larger. Their body forms almost a square with rounded angles; and their grinding surface has commonly five points or protuberances, two of which are on the inner, and three on the outer part of the tooth. The last grinder is shorter and smaller than the rest, and from its coming through the gums later than the rest, and sometimes not appearing till late in life, is called *dens sapientiæ*. The variation in the number of teeth usually depends on these dentes sapientiæ.

Having thus described the appearance of the teeth in the adult, the manner of their formation and growth in the fœtus is next to be considered. We shall find that the alveolar process, which begins to be formed at a very early period, appears, about the fourth month, only as a shallow longitudinal groove, divided by slight ridges into a number of intermediate depressions, which are to be the future alveoli or sockets. These depressions are, at first, filled with small pulpy substances, included in a vascular membrane; and these pulpy substances are the rudiments of the teeth. As these advance in their growth, the alveolar processes become gradually more completely formed. The surface of the pulp first begins to harden; the ossification, proceeding from one or more points, according to the kind of tooth that is to be formed. Thus, in the incisores and canini, it begins from one point; in the bicuspides, from two points, corresponding with the future shape of those teeth; and in the molares from four or five points. As the ossification advances, the whole of the pulp is gradually covered with bone, excepting its under surface, and then the fang begins to be formed. Soon after the formation of this bony part, the tooth begins to be encrusted with its enamel; but in what manner this is deposited we are, as yet, unable to ex-

plain. Perhaps the vascular membrane which encloses the pulp may serve to secrete it. It gradually crystallises upon the surface of the bony part, and continues to increase in thickness, especially at the points and basis of the tooth, till some time before the tooth begins to pass through the gum; and when this happens, the enamel seems to be as hard as it is afterwards, so that the air does not appear to have the least effect in hardening it, as has been sometimes supposed. While the enamel is thus forming, the lower part of the pulp is gradually lengthened out and ossified, so as to form the fang. In those teeth which are to have more than one fang, the ossification begins from different parts of the pulp at one and the same time. In this manner are formed the incisores, the canini, and two molares on each side, making in the whole twenty teeth, in both jaws, which are sufficient for the purposes of manducation early in life. As the fangs of the teeth are formed, their upper part is gradually pushed upwards, till at length, about the seventh, eighth, or ninth month after birth, the incisores, which are the first formed, begin to pass through the gum. The first that appears is generally in the lower jaw. The canini and molares not being formed so soon as the incisores, do not appear till about the twentieth or twenty-fourth month. Sometimes one of the canini, but more frequently one of the molares, appears first.

The danger to which children are exposed, during the time of dentition, arises from the pressure of the teeth in the gum, so as to irritate it, and excite pain and inflammation. The effect of this irritation is, that the gum wastes, and becomes gradually thinner at this part, till at length the tooth protrudes. In such cases, therefore, we may, with great propriety, assist nature by cutting the gum. These twenty teeth are called *temporary* or *milk* teeth, because they are all shed between the age of seven and fourteen, and are supplied by others of a firmer texture with large fangs, which remain till they become affected by disease, or fall out in old age, and are, therefore, called the *permanent* or *adult* teeth. The rudiments of these adult teeth begin to be formed at different periods. The pulp of the first adult incisor, and of the first adult grinder, may be perceived in a fœtus of seven or eight months, and the ossification begins in them about six months after birth. Soon after birth the second incisor, and canine tooth on each side, begin to be formed. About the fifth or sixth year the first bicuspis, and about the seventh the second bicuspis begins to ossify. These bicuspides are destined to replace the temporary grinders. All these permanent teeth are formed in a distinct set of alveoli; so that it is not by the growing of one tooth under another in the same socket, that the uppermost tooth is gradually pushed out, as is commonly imagined; but the temporary teeth, and those which are to succeed them, being placed in separate alveoli, the upper sockets gradually disappear, as the under ones increase in size, till at length the teeth they contain, having no longer any support, consequently fall out. But, besides these twenty teeth, which succeed the temporary ones, there are twelve others to be added, to make up the number thirty-two. These twelve are three grinders on each side in both jaws; and in order to make room for this addition, we find the jaws grow as the teeth grow, so that they appear as completely filled with twenty teeth as they are afterwards with thirty-two. Hence, in children, the face is flatter and rounder than in adults. The first adult grinder usually passes through the gum about the twelfth year; the second, which begins to be formed in the sixth or seventh year, cuts the gum about the seventeenth or eighteenth; and the third, or dens sapientiæ, which begins to be formed about the twelfth year, passes through the gum between the age of twenty and thirty. The dentes sapientiæ have, in some instances, been cut at the age of forty, fifty, sixty, and even eighty years; and it sometimes happens that they do not appear at all. Sometimes, likewise, it happens that a third set of teeth appear about the age of sixty or seventy. Diemerbroek tells us that he himself, at the age of fifty-six, had a fresh canine tooth, in the place of one he had lost several years before. M. Du Fay saw two incisores and two canini cut the gum in a man aged eighty-four. Mr. Hunter has seen two fore-teeth shoot up in the lower jaw of a very old person; and an account was lately published of a man who had a complete set of teeth at the age of sixty. Other instances of the same kind are to be met with in authors. The circumstance is curious; and, from the time of life at which it takes place, and the return of the catamenia, which sometimes happens to women at the same age, it has been very ingeniously supposed, that there is some effort in nature to renew the body at that period.

The teeth are subject to a variety of *accidents*. Sometimes the gums become so affected as to occasion them to fall out, and the teeth themselves are frequently rendered carious by causes which have not hitherto been satisfactorily explained. The disease usually begins on that side of the tooth which is not exposed to pressure, and gradually advances till an opening is made into the cavity: as soon as the cavity is exposed, the tooth becomes liable to considerable pain, from the air coming into contact with the nerve. Besides these accidental means by which the teeth are occasionally affected, old age seldom fails to bring with it sure and natural causes for their removal. The alveoli fill up, and the teeth consequently fall out. The gums then no longer meet in the fore-part of the mouth, the chin projects forwards, and the face being rendered much shorter, the whole physiognomy appears considerably altered. Having thus described the formation, structure, growth, and decay of the teeth, it remains to speak of their uses, the chief of which we know to be in mastication. And here we cannot help observing the great variety in the structure of the human teeth, which fits us for such a variety of food, and which, when compared with the teeth given to other animals, may, in some measure, enable us to explain the nature of the aliment for which man is intended by Nature. Thus, in ruminating animals, we find incisores only in the

lower jaw, for cutting the grass, and molares for grinding it; in graminivorous animals, we see molares alone; and in carnivorous animals, canine teeth for catching at their prey, and incisores and molares for cutting and dividing it. But, as man is not designed to catch and kill his prey with his teeth, we observe that our canini are shaped differently from the fangs of beasts of prey, in whom we find them either longer than the rest of the teeth, or curved. The incisores likewise are sharper in those animals than in man. Nor are the molares in the human subject similar to the molares of carnivorous animals; they are flatter in man than in these animals; and, in the latter, we likewise find them sharper at the edges, more calculated to cut and tear the food, and, by their greater strength, capable of breaking the bones of animals. From these circumstances, therefore, we may consider man as partaking of the nature of these different classes; as approaching more to the carnivorous than to the herbivorous tribe of animals; but, upon the whole, formed for a mixed aliment, and fitted equally to live upon flesh and upon vegetables. Those philosophers, therefore, who would confine a man wholly to vegetable food, do not seem to have studied nature. As the molares are the last teeth that are formed, so they are usually the first that fall out: this would seem to prove that we require the same kind of aliment in old age as in infancy. Besides the use of the teeth in mastication, they likewise serve a secondary purpose, by assisting in the articulation of the voice.

Teeth, tartar of. See *Tartar.*

Teething. See *Dentition.*

Teething, difficult. See *Dentition, difficult.*

Tegula hibernica. See *Lapis hibernicus.*

TE'GUMENTS. Under the term common teguments, or integuments, anatomists comprehend the cuticle, rete mucosum, skin, and adipose membrane, as being the covering of every part of the body except the nails. See *Cutis.*

TE'LA. (*a, æ.* f.; from *texo*, to weave.) A web of cloth. The cellular membrane is so called from its likeness to a fine web. See *Membrana.*

Tela cellulosa. See *Membrana.*

TELE'PHIUM. (*um, ii.* n.: because it heals old ulcers; such as that with which Telephus was afflicted from the wound inflicted by Achilles. See *Sedum telephium.*

TE'LLURETTED HY'DROGEN. A combination of tellurium and hydrogen. To make this compound, hydrate of potash and oxide of tellurium are ignited with charcoal, and the mixture acted on by dilute sulphuric acid, in a retort connected with a mercurial pneumatic apparatus. An elastic fluid is generated, consisting of hydrogen holding tellurium in solution. It is possessed of very singular properties. It is soluble in water, and forms a claret-coloured solution. It combines with the alkalies. It burns with a bluish flame, depositing oxide of tellurium. Its smell is very strong and peculiar, not unlike that of sulphuretted hydrogen. This elastic fluid was discovered by Sir. H. Davy, in 1809.

TELLU'RIC ACID. *Acidum telluricum.* The peroxide of tellurium, which combines with many of the metallic oxides, acting the part of an acid, and producing a class of compounds which have been called *tellurates.*

TELLU'RIUM. (*um, ii.* n.; from *tellus*, the earth.) The name given by Klaproth to a metal extracted from several Transylvanian ores. It is of a tin-white colour, verging to lead-grey, with a high metallic lustre, of a foliated fracture, and very brittle, so as to be easily pulverised. Tellurium is oxidised and dissolved by the principal acids. It has two oxides which have acid properties. See *Telluric acid*, and *Tellurous acid.* Fused with an equal weight of sulphur, in a gentle heat, it forms a lead-coloured, striated sulphuret. It does not easily amalgamate with quicksilver.

TELLUROUS ACID. The protoxide of tellurium, which, if precipitated from its solutions by the alkalis, carries down with it a portion of the precipitant.

TEMPERAME'NTUM. (*um, i.* n.; from *tempero*, to mix together.) In the ancient physiology, the different mixture of the four cardinal humours, and the predominance of one or the other, gave rise to four distinct *temperaments*, namely, the *sanguine*, the *choleric*, the *phlegmatic*, and the *melancholic.* The constitution of every individual was supposed to be conformed to some one of these temperaments, or to a mixture of several of them. See *Temperament*, in the *Supplement.*

TEMPERATURE. *Temperatura.* A definite degree of sensible heat, as measured by the thermometer. Thus, we say a high temperature and a low temperature, to denote a manifest intensity of heat or cold; the temperature of boiling water, or 212° Fahrenheit; and a range of temperature, to designate the intermediate points of heat between two distant terms of thermometric indication.

Temperature, morbid. See *Morbid temperature*, in the *Supplement.*

TEMPLE. (*Tempus, oris.* n.) The lateral and flat parts of the forehead: so called because the ravages of time are often first perceptible by the hair on the temples turning grey.

TE'MPORAL. (*Temporalis*; from *tempus.*) Belonging to the temple.

TEMPORAL ARTERY. *Arteria temporalis.* A branch of the external carotid, which runs on the temple, and gives off the frontal artery.

TEMPORAL BONE. *Os temporis.* Two bones situated one on each side of the head, of a very irregular figure. They are usually divided into two parts, one of which, from the manner of its connexion with the neighbouring bones, is called *os squamosum*, and the other, *os petrosum*, from its irregularity and hardness.

In both these parts there are processes and cavities to be described. Externally there are three processes: one anterior, called *zygomatic* process, which is stretched forwards to join with the os malæ, and thus forms the bony jugum, under which the temporal muscle passes; one posterior, called the *mastoid* or *mammillary* process, from its resemblance to a nipple; and one inferior, called the *styloid* process, from its shape, which is said to resemble that of the ancient *stylus scriptorius.* In young subjects,

this process is united with the bone by an intermediate cartilage, which sometimes, even in adults, is not completely ossified. Three muscles have their origin from this process, and borrow half of their names from it, viz. stylo-glossus, stylo-hyoideus, and stylo-pharyngeus. Round the root of this process there is a particular rising of the os petrosum, which some writers describe as a process, and, from its appearance with the styloid, have named it *vaginalis*. Others describe the semicircular ridge of the meatus auditorius externus as a fifth process, to which they give the name of *auditory*. The depressions and cavities are, 1. A large fossa, which serves for the articulation of the lower jaw: it is situated between the zygomatic auditory and vaginal processes, and is separated in its middle by a fissure, into which the ligament that secures the articulation of the lower jaw with this bone is fixed. The fore part of this cavity, which receives the condyle of the jaw, is covered with cartilage; the back part only with the periosteum. 2. A long fossa behind the mastoid process, where the digastric muscle has its origin. 3. The *meatus auditorius externus*, the name given to a large funnel-like canal that leads to the organ of hearing. 4. The *stylo-mastoid hole*, so called from its situation between the styloid and mastoid processes. It is likewise called the aqueduct of Fallopius, and affords a passage to the portio dura of the auditory, or seventh pair of nerves. 5. Below, and on the fore-part of the last foramen, we observe part of the jugular fossa, a thimble-like cavity, in which the beginning of the internal jugular vein is lodged. 6. Before, and a little above this fossa, is the orifice of a foramen, through which pass the internal carotid artery and two filaments of the intercostal nerve. This conduit runs first upward and then forward, forming a kind of elbow, and terminates at the end of the os petrosum. 7. At this part of the ossa temporum we observe the orifice of a canal which runs outwards and backwards in a horizontal direction, till it terminates in the cavity of the ear called tympanum. This canal, which in the recent subject is continued from the ear to the mouth, is called the *Eustachian tube*. 8. A small hole behind the mastoid process, which serves for the transmission of a vein to the lateral sinus. But this, like other foramina in the skull that serve only for the transmission of vessels, is neither uniform in its situation, nor to be met with in every subject. The internal surface of these bones may easily be divided into three parts. The first, uppermost, and largest, is the squamous part, which is slightly concave from the impression of the brain. Its semicircular edge is sloping, so that the external lamella of the bone advances farther than the internal, and thus rests more securely on the parietal bones. The second and middlemost, which is the petrous part of the bone, forms a hard, craggy, protuberance, nearly of a triangular shape. On its posterior side we observe a large foramen, which is the meatus auditorius internus; it receives the double nerve of the seventh pair, viz. the portio dura and portio mollis of that pair. About the middle of its anterior surface is a small foramen, which opens into the aqueduct of Fallopius, and receives a twig of the portio dura of the seventh pair of nerves. This foramen having been first described by Fallopius, and by him named *hiatus*, is sometimes called *hiatus Fallopii*. Besides these, we observe other smaller holes for the transmission of blood-vessels and nerves. Below this craggy protuberance is the third part, which, from its shape and connexion with the os occipitis by means of the lambdoidal suture, may be called the lambdoidal angle of the temporal bone. It is concave from the impression of the brain; it helps to form the posterior and inferior fossæ of the skull, and has a considerable furrow, in which is lodged part of the lateral sinus. The temporal bones differ a little in their structure from the other bones of the cranium. At their upper parts they are very thin, and almost without diploë, but below they have great strength and thickness. In the fœtus, the thin upper part and the lower craggy part are separated by a cartilaginous substance; there is no appearance either of the mastoid or styloid processes, and, instead of a long, funnel-like meatus auditorius externus, there is only a smooth bony ring, within which the membrana tympani is fastened. Within the petrous part of these bones there are several cavities, processes, and bones, which belong altogether to the ear, do not enter into the formation of the cranium, and are described under the article *Auris*. The ossa temporum are connected by suture with the ossa parietalia, the os occipitis, the ossa malarum, and the os sphenoides, and are articulated with the lower jaw.

TEMPORA'LIS. (From *tempus*, the temple.) Belonging to the temple.

Temporalis musculus. A muscle of the lower jaw, situated in the temple. *Crotaphites*, of Winslow. It arises fleshy from the lower, lateral, and anterior part of the parietal bone; from all the squamous portion of the temporal bone; from the lower and lateral part of the os frontis; from the posterior surface of the os malæ; from all the temporal process of the sphenoid bone; and sometimes from a ridge at the lower part of this process. This latter portion, however, is often common to this muscle and the pterygoideus externus. It is of a semicircular shape, and its radiated fibres converge, so as to form a strong middle tendon, which passes under the jugum, and is inserted into the coronoid process of the lower jaw, to which it adheres on every side, but more particularly at its fore-part, where the insertion is continued down to the body of the bone. This muscle is covered by a pretty strong fascia, which some writers have erroneously described as a part of the aponeurosis of the occipito-frontalis. This fascia adheres to the bones, round the whole circumference of the origin of the muscle, and, descending over it, is fixed below to the ridge where the zygomatic process begins, just above the meatus auditorius, to the upper edge of the zygomatic process itself, and anteriorly to the os malæ. This fascia serves as a defence to the muscle, and likewise gives origin to some of its fleshy fibres. The prin-

cipal use of the temporal muscle is to draw the lower jaw upwards, as in the action of biting; and as it passes a little forwards to its insertion, it may at the same time pull the condyle a little backwards, though not so much as it would have done if its fibres had passed in a direct line from their origin to their insertion, because the posterior and lower part of the muscle passes over the root of the zygomatic process, as over a pulley.

TENCH. This well known fish is the *Cyprinus tinca* of the Linnæan system. It inhabits streams of fresh water, is easy of digestion, and much esteemed by some.

TE'NDO. (*o, inis, vel onis.* m.; from *tendo*, to stretch out or extend.) The white and glistening extremity of a muscle. See *Muscle.*

Tendo Achillis. See *Achillis tendo.*

Tendon. See *Tendo.*

Tendril. See *Cirrus.*

TENE'SMUS. (*us, i.* m.; from τεινω, to constringe: so called from the perception of a continual constriction or bound state of the part.) A continual inclination to go to stool, without a discharge, accompanied by a straining.

The cause of this is an irritation of the muscles of the sphincter ani, produced generally by acrimonious substances, as bile, indurated fæces, gall-stones, extraneous bodies, aloetic medicines, &c. The disease is sometimes very violent, and the straining so great as to cause a protrusion of the bowel. Every time any attempt is made to pass the fæces, the irritation returns, and it is sometimes accompanied by painful micturition in men; and a burning painful feeling continues after the stool has passed, with more or less of an urgency to expel. It is often a symptomatic affection of diseases of the urinary bladder, uterus, prostate gland, piles, worms, and organic diseases of the rectum. The best remedies are opium, preparations of lead, and fomentations. A starch glyster, with laudanum, is perhaps the most effectual in allaying the irritation.

TE'NSOR. (*or, oris.* m.; from *tendo*, to stretch.) A muscle, the office of which is to extend the part to which it is fixed.

Tensor pala'ti. See *Circumflexus palati.*

TENSOR TY'MPANI. *Internus auris*, of Douglas and Cowper. *Internus malleus*, of Winslow. A muscle of the internal ear. See *Auris.*

TENSOR VAGINÆ FEMORIS. *Fascialis membranosus*, of Douglas. *Membraneus, vel fasciæ latæ*, of Cowper. *Musculus aponeurosis, vel fasciæ latæ*, of Winslow. A muscle situated on the outside of the thigh, which stretches the membraneous fascia of the thigh, assists in the abduction of the thigh, and somewhat in its rotation inwards. It arises by a narrow, tendinous, and fleshy beginning, from the external part of the anterior, superior, spinous process of the ilium, and is inserted a little below the great trochanter into the membraneous fascia.

TENT. A roll of lint, or piece of sponge, for dilating openings, sinuses, &c.

Tent-sponge. See *Spongia.*

Tent-wort. See *Asplenium murale.*

TENTA'CULUM. (*um, i.* n.; from *tento*, to feel.) A feeler. Tentacula are mobile appendages, destitute of joints, of various conformations, possessed by various invertebral animals, and which serve as organs of touch, or the means of attachment to foreign bodies.

TENTO'RIUM. (*um. ii.* n.; *à tendendo.*) A process of the dura mater, separating the cerebrum from the cerebellum. It extends from the internal horizontal spine of the occipital bone, directly forwards to the cella turcica of the sphenoid bone. See *Encephalos.*

TEREBE'LLA. (Diminutive of *terebra*, a piercer or gimblet.) A trepan or instrument for sawing out circular portions of the skull. A trephine.

TEREBI'NTHINA. (*a, æ.* f.; from τερεβινθος, the turpentine-tree.) Turpentine, the produce of pine-trees. See *Turpentine.*

TEREBINTHINA ARGENTORATENSIS. Strasburg turpentine. This species is generally more transparent and less tenacious than either the Venice or Chio turpentines. It is of a yellowish brown colour, and of a more agreeable smell than any of the turpentines, except the Chio. It is extracted in several parts of Germany, from the red and silver fir, by cutting out successively narrow strips of the bark. In some places a resinous juice, called *Lachryma abiegna*, and *Oleum abietinum*, is collected from under the bark.

TEREBINTHINA CANADENSIS. Canada turpentine. See *Pinus balsamea.*

Terebinthina Chia. See *Pistacia.*

Terebinthina communis. See *Pinus.*

Terebinthina Cypria. See *Pistacia.*

Terebinthina Vencta. See *Pinus.*

Terebinthina vulgaris. See *Pinus*, and *Turpentine.*

TEREBINTHINÆ OLEUM. Oil of turpentine. The oil distilled from the liquid resin of the *Pinus sylvestris.*

TE'RES. Round, cylindrical: applied to,

1. Some muscles and ligaments; as *teres major, ligamentum teres*, &c.

2. The *ascaris lumbricoides*, or round worm, which infests the intestines. See *Entozoa.*

3. Roots, stems, leaves, leafstalks, seeds, &c.

TERES LIGAMENTUM. The ligament at the bottom of the socket of the hip-joint.

TERES MAJOR. Riolanus, who was the first that distinguished this and the other muscles of the scapula by particular appellations, gave the name of *teres* to this and the following muscle, on account of their long and round shape. This muscle, which is longer and thicker than the teres minor, is situated along the inferior costa of the scapula, and is in part covered by the deltoides. It arises fleshy from the outer surface of the inferior angle of the scapula (where it covers some part of the infra-spinatus and teres minor, with both which its fibres intermix), and likewise from the lower and posterior half of the inferior costa of the scapula. Ascending obliquely towards the os humeri, it passes under the long head of the triceps brachii, and then becomes thinner and flatter, to form a thin tendon of about an inch in

breadth, and somewhat more in length, which runs immediately behind that of the latissimus dorsi, and is inserted along with it into the ridge at the inner side of the groove that lodges the long head of the biceps. These two tendons are included in a common capsula, besides which the tendon of this muscle adheres to the os humeri by two other capsulæ which we find placed one above the other.

This muscle assists in the rotatory motion of the arm, and likewise in drawing it downwards and backwards; so that we may consider it as the congener of the latissimus dorsi.

TERES MINOR. This muscle seems to have been first described by Fallopius. The teres minor is a thin fleshy muscle, situated along the inferior edge of the infra-spinatus, and is in part covered by the posterior part of the deltoides.

It arises fleshy from all the convex edge of the inferior costa of the scapula; from thence it ascends obliquely upwards and forwards, and terminates in a flat tendon, which adheres to the lower and posterior part of the capsular ligament of the joint, and is inserted into the lower part of the great tuberosity of the os humeri, a little below the termination of the infra-spinatus.

The tendinous membrane, which is continued from the infra-spinatus, and spread over the teres minor, likewise forms a thin septum between the two muscles. In some subjects, however, they are so closely united as to be with difficulty separated from each other. Some of the fibres of the teres minor are intermixed with those of the teres major and subscapularis.

The uses of this muscle are similar to those of the infra-spinatus.

TERETIU'SCULUS. Roundish. Applied in *Botany* to stems, &c.

TE'RETRUM. (*um*, *i.* n.; from τερεω, to pierce.) The trepan.

TERGE'MINUS. Doubly twin-forked: applied to a leaf-stalk, when it has two leaflets at the end of each, and two more at the division of the fork.

TERMINA'LIS. Terminal. In the language of *Botany*, opposed to lateral: applied to a flower-stalk when it terminates a stem or branch; as in *Centaurea scabiosa*.

TERMI'NTHUS. (*us*, *i.* m.; from τερμινθος, the turpentine-tree: so called from its resemblance to the fruit of the turpentine-tree.) A black ardent pustule, chiefly attacking the legs. It is not very clear what the disease was which the Greek writers describe under this name.

TE'RNARY. *Ternarius.* Relating to the number three. In the present day it is used only to express a particular mode of chemical combination. See *Combination, chemical.*

TERNA'TUS. Ternate: applied to a leaf which consists of three leaflets; as that of the trefoil.

TE'RNUS. Ternate: by threes. Applied to leaves, when there are three together; as in many of the plants of Chili and Peru, which seem particularly disposed to this arrangement, and in *Verbena triphylla*.

TE'RRA. (*a*, *æ.* f.) Earth. See *Earth.*

TERRA ABSORBENS. An absorbent earth, distinguishable from other earthy and stony substances by its solubility in acids; as chalk, crabs'-claws, oyster-shells, egg-shells, pearl, coral, &c.

Terra catechu. See *Acacia catechu.*

Terra damnata. See *Caput mortuum.*

Terra foliata tartari. See *Potassæ acetas.*

Terra japonica. See *Acacia catechu.*

Terra Lemnia. See *Bole.*

Terra Livonica. See *Bole.*

Terra marita. See *Curcuma longa.*

Terra mortua. See *Caput mortuum.*

Terra ponderosa. See *Baryta.*

TERRA PONDEROSA SALITA. The muriate of baryta.

Terra sigillata. See *Bole.*

Terræ oleum. See *Petroleum.*

TERRE'NUS. Terrene: belonging to the earth. Applied to plants which grow in the earth only, in opposition to those which live in water, and not in the earth.

Tertian ague. See *Ague.*

Tertiana. See *Ague.*

TERTIANA DUPLEX. A tertian fever that returns every day; but the paroxysms are unequal, every other fit being alike.

TERTIANA DUPLICATA. A tertian fever returning every other day; but there are two paroxysms in one day.

TERTIANA TRIPLEX. A tertian fever returning every day; every other day there are two paroxysms, and but one in the intermediate day.

TERTIANA'RIA. (*a*, *æ.* f.; from *tertiana*, a species of intermittent fever, which was said to be cured by this plant.) See *Scutellaria galericulata.*

TERTIUM SAL. (From *tertius*, third.) A neutral salt, as being the product of an acid and an alkali, making a third body different from either.

TESSELLA'TUS. (From *tessera*, a square.) Tesselated; chequered.

TE'SSERA. (From τεσσαρα, four.) The four-sided or cuboid bone.

TEST. Any reagent which, added to a substance, teaches us to discover its chemical nature or composition. See *Reagent.*

TE'STA. (*a*, *æ.* f.; *quasi tosta*; from *torreo*, to burn.) 1. The shell of a molluscous animal. See *Shell.*

2. In *Botany*, the term signifies the skin which contains all the parts of a seed, as the embryo, the lobes, the vitellus, and albumen, and which gives shape to the seed; for the skin is perfectly formed while they are but a homogeneous liquid. The testa differs in thickness and texture in different plants. It is sometimes single, but more frequently lined with a finer and very delicate film, called by Gærtner *membrana*, as may be seen in a walnut, and the kernel of a peach, almond, or plum. —*Smith.*

TESTA PROBA'TRIX. A cupel or test. A pot for separating baser metals from gold and silver.

TESTA'CEOUS. (*Testaceus*; from *testa*, a shell.) Having a shell, or of the nature of shell: thus, a testaceous animal is an animal

with a shell; a testaceous powder is a powder made of shells.

Testæ preparatæ. Prepared oyster-shells. Wash the shells, previously cleared of dirt with boiling water, then prepare them by repeated washings. This is merely carbonate of lime.

Testes cerebri. See *Tubercula quadrigemina.*

Testicle. See *Testis.*

Testicle, swelled. See *Orchitis.*

TESTI'CULUS. (*us, i.* m.; diminutive of *testis.*) 1. The testicle.

2. The *orchis* plant: so named from the resemblance of its roots to a testicle.

Testiculus caninus. See *Orchis mascula.*

TE'STIS. (*is, is.* m.; a witness: the *testes* being the witnesses of virility.) *Orchis.* The testicle. They are also called *didymi*, and by some *perin*. Two little oval bodies situated within the scrotum, and covered by a strong, white, and dense coat, called tunica albuginea. Each testicle is composed of small vessels, bent in a serpentine direction, arising from the spermatic artery, and convoluted into little heaps, separated from one another by cellular partitions. In each partition there is a duct receiving semen from the small vessels; and all the ducts constitute a net which is attached to the tunica albuginea. From this network twenty or more vessels arise, all of which are variously contorted, and being reflected, ascend to the posterior margin of the testis, where they unite into one common duct, bent into serpentine windings, and forming a hard body called the *epididymis*. The spermatic arteries are branches of the aorta. The spermatic veins empty themselves into the vena cava and emulgent vein. The nerves of the testicle are branches of the lumbar and great intercostal nerve. The use of the testicle is to secrete the semen.

TESTU'DO. (*o, inis.* f. A tortoise; from *testa*, a shell: because it is covered with a shell.) 1. The name of a genus of animals including the terrestrial species of the order *Chelonia*. The tortoise. See *Chelonia.*

2. A melicerous tumour of the scalp, of a flattened shape, has been so called from a fancied resemblance to a tortoise.

TETA'NIC. *Tetanicus.* Appertaining to tetanus — as *tetanic spasm.*

Tetano'ma. (From τετανοω, to smooth.) *Tetanothra.* A medicine which smoothes the skin, and removes wrinkles.

TE'TANUS. (*us, i.* m.; τετανος, from τεινω, to stretch.) Spasm with rigidity. *Convulsio Indica. Holotonicos. Rigor nervosus.* A disease characterised by a general spastic rigidity of the muscles. The varieties of tetanus are, 1. *Trismus*, the locked jaw. 2. *Opisthotonos*, where the body is thrown back by spasmodic contractions of the muscles. 3. *Emprosthotonos*, the body being bent forwards. 4. *Pleurothotonos*, where the body is bent to one side.

These affections arise more frequently in warm climates than in cold ones, and are very apt to occur when much rain or moisture quickly succeeds to extremely dry and sultry weather. They attack persons of all ages, sexes, temperaments, and complexions, but the male sex more frequently than the female, and those of a robust and vigorous constitution than those of a weak habit. An idea is entertained by many, Dr. Thomas observes, that negroes are more predisposed to attacks of tetanus than white people; they certainly are more frequently affected with it, but this circumstance does not arise from any constitutional predisposition, but from their being more exposed to punctures and wounds in the feet, by nails, splinters of wood, pieces of broken glass, &c., from usually going barefooted.

Tetanic affections are occasioned either by exposure to cold, or by some irritation of the nerves, in consequence of local injury by puncture, incision, or laceration: hence the distinction of tetanus into *idiopathic*, and *traumatic.* Lacerated wounds of tendinous parts prove, in warm climates, a never-failing source of these complaints. In cold climates, as well as in warm, the locked jaw frequently arises in consequence of the amputation of a limb.

Tetanus is also distinguished into *acute* and *chronic.*

When the disease has arisen in consequence of a puncture, or any other external injury, the symptoms show themselves generally about the eighth day; but when it proceeds from exposure to cold, they generally make their appearance much sooner.

In some instances it comes on suddenly, and with great violence; but it more usually makes its attack in a gradual manner; in which case, a slight stiffness is at first perceived in the back part of the neck, which, after a short time, becomes considerably increased, and at length renders the motion of the head both difficult and painful.

With the rigidity of the head there is likewise an uneasy sensation at the root of the tongue, together with some difficulty in swallowing, and a great tightness is perceived about the chest, with a pain at the extremity of the sternum, shooting into the back. A stiffness also takes place in the jaws, which soon increases to such a height that the teeth become so closely set together as not to admit of the smallest opening. This is what is termed the locked jaw, or *trismus.*

In some cases the spasmodic affection extends no further. In others, the spasms at this stage of the disease, returning with great frequency, become likewise more general, and now affect not only the muscles of the neck and jaws, but likewise those of the whole spine, so as to bend the trunk of the body very forcibly in some one direction. The *opisthotonos*, or bending backwards of the body, is the most common; the *emprosthotonos*, or bending forward, is very rare, and the *pleurothotonos*, or lateral distortion, still more so.

During the whole course of the disorder, the abdominal muscles are violently affected with spasm, so that the belly is strongly retracted, and feels very hard, most obstinate costiveness prevails, and both the flexor and extensor muscles of the lower extremities are commonly affected at the same time, so as to keep the limbs rigidly extended.

The flexors of the head and trunk become at length so strongly affected as to balance the

action of the extensors, and to keep the head and trunk so rigidly extended and straight, as to render it incapable of being moved in any direction. The arms, which were little affected before, are now likewise rigidly extended; the tongue also becomes affected with spasm, and, being convulsively darted out, is often much injured by the teeth at that moment snapping together. It is to this state of the disease that the term tetanus has been strictly applied.

The disorder continuing to advance, every organ of voluntary motion becomes affected: the eyes are rigid and immoveable; the countenance is hideously distorted, and expresses great distress; the strength is entirely exhausted; the pulse becomes irregular; and one universal spasm puts a period to a most miserable state of existence.

Attacks of tetanus are seldom attended with any fever, but always with violent pain, and the spasms do not continue for a constancy, but the muscles admit of some remission in their contraction, which is frequently renewed, especially if the patient makes the least attempt to speak, drink, or alter his position. The mind generally remains undisturbed to the last.

When tetanic affections arise in consequence of a wound or local injury, they are almost sure to prove fatal; but when the disease is idiopathic it may, in many cases, be removed by a timely use of proper remedies, although a considerable space will probably elapse before the patient will be able to recover his former strength. The chronic form of tetanus is much less fatal than the acute. The acute form usually destroys the patient within four days, though sometimes the fatal event is protracted to a much longer period; generally speaking, however, if the patient survives the fourth day, the symptoms begin to remit in their violence, and there is a fair chance of recovery. If the patient be alive, and the powers of the constitution keep up at the expiration of a week, there is great hope of a favourable issue: in this case the symptoms may gradually assume a chronic form, and wear themselves out in a period varying from some weeks to many months.

Morbid anatomy has hitherto thrown no light on the pathology of tetanus. In some cases there have been appearances of inflammation within the spinal canal, but in the greater part these have been absent. Inflammation and constriction of the pharynx, with a viscid reddish coloured secretion on the mucous membrane, and inflammation of different portions of the alimentary canal, have also been observed; but these, as well as some other morbid phenomena, seem to have been merely effects or incidental accompaniments of the disease. In many cases of traumatic tetanus, the nerve in the neighbourhood of the wound has been found inflamed and thickened, while in others nothing of the kind could be detected. Worms have often been found in the intestines, but so they have in many other cases besides tetanus. On the whole, it appears to be a purely nervous affection.

The diagnosis of tetanus is, generally speaking, very easy. The disease to which it has most affinity is hydrophobia; but the history of the case, the different period of accession of the two diseases, and the clonic character of the spasms which accompany hydrophobia, will amply suffice to discriminate them. Hysteria mimics almost all diseases, and tetanus among the rest; but its own characteristics are so marked, that a careful practitioner can hardly fail to recognise them. It is not to be forgotten that some or all of the phenomena of tetanus may ensue on inflammation of the spinal cord; but here the local pain, the inflammatory fever, the symptoms of paralysis and disordered sensation, and the different mode of accession, afford sufficient data for an accurate diagnosis.

The general indications of cure are, — 1. To remove any local irritation which may appear to have excited the disease. 2. To lessen the general irritability, and spasmodic tendency. 3. To restore the tone of the system. — If a thorn, or other extraneous substance, be lodged in any part, it must be extracted; any spicula of bone which may have brought on the disease after amputation should be removed; a punctured wound ought to be dilated, &c. Some have proposed dividing the nerve going to the part, or even amputating this, to cut off the irritation; others paralysing the nerves by powerful sedatives, or destroying them by caustics; others, again, exciting a new action in the part by active stimulants; but the efficacy, and even propriety, of such measures is doubtful. To fulfil the second indication, various means have been proposed. The abstraction of blood, recommended by Dr. Rush, might perhaps appear advisable in a vigorous plethoric habit in the beginning of the disease, but it has generally proved of little utility, or even hurtful, and is rather contra-indicated by the state of the blood. Purgatives are clearly indicated by the obstinate costiveness and vitiated state of the abdominal secretions, which are characteristic of the disease. They require to be given in very large, and often enormous doses, to produce any effect. It has been found, also, that a salivation, induced by mercury, has sometimes greatly relieved the disorder; but in other instances it has failed altogether. The remedy which has been oftenest employed, and with the most decided advantage, is opium, and sometimes prodigious quantities of it have been exhibited: indeed, small doses are useless, and even large ones have only a temporary effect, so that they must be repeated as the violence of the symptoms is renewed; and, where the patient cannot swallow, it may be tried in glyster, or freely rubbed into the skin. Large quantities of wine and ardent spirits have sometimes been administered with success, in conjunction with opium; and such is the singular state of the nervous system in this disease, that a quantity of ardent spirits, which would produce fatal intoxication in a healthy individual, will often produce no sensible effect whatever on one labouring under tetanus. Other sedative and antispasmodic remedies, besides, have been occasionally resorted to, as hemlock, tobacco, musk, camphire, &c., but for the most part with less satisfactory results. The warm bath has sometimes proved an useful auxiliary in

cold climates; and the cold bath has been much extolled, especially in the West Indies: the latter measure, however, has often proved worse than useless; and in one case, related by Mr. Morgan, it caused immediate death.

TETARTÆ'US. (Τεταρταιος, fourth.) Applied to a quartan fever. See *Ague*.

TETRADYNA'MIA. (*a*, *æ*. f.; from τεσσαρες, four, and δυναμις, power.) The name of a class of plants in the sexual system of Linnæus, containing hermaphrodite flowers, with six stamens, four of which are long, and two short.

TETRA'GONUS. Four-cornered; quadrangular; square. Applied to several parts of plants; as *caulis tetragonus*, *folium tetragonum*, &c.

TETRAGY'NIA. (*a*, *æ*. f.; from τεσσαρες, four, and γυνη, a wife.) The name of an order of plants in several of the classes of the sexual system of Linnæus, consisting of plants which, to the classic character, whatever it is, add the circumstance of having four pistils.

TETRAO. The name of a genus of birds, of the order *Gallinæ*.

TETRAO TETRIX. The black cock, or black grouse. A rare bird, much esteemed by game eaters. The flesh is nutritious, and easy of digestion.

TETRAMYRUM. (From τετρας, a quaternary, and μυρον, an ointment.) An ointment of four ingredients. See *Tetrapharmacum*.

TETRA'NDRIA. (*a*, *æ*. f.; from τετρας, a quaternary, and ανηρ, a husband.) The name of a class of plants in the sexual system of Linnæus. To it belong those which have hermaphrodite flowers, with four stamina of equal length.

TETRANGU'RIA. (From τετρας, a quaternary, and αγγος, a cup: so called because its fruit resembles a cup divided into four parts.) A species of citrul. Not now in use.

TETRAPE'TALOUS. *Tetrapetalus*. Four-petalled: applied to a flower that consists of four single petals or leaves placed around the pistil.

TETRAPHA'RMACUM. (*um*, *i*. n.; from τετρας, a quarternary, and φαρμακον, a drug.) A Greek ointment, composed of four ingredients, namely, wax, resin, pitch, and lard.

TETRAPHY'LLOUS. (*Tetraphyllus*; from τετρας, four, and φυλλον, a leaf.) Four-leaved.

TETRASPE'RMOUS. (*Tetraspermus*; from τετρας, a quarternary, and σπερμα, a seed.) Four-seeded.

Tetter. See *Psoriasis*.

Tetter, dry. See *Psoriasis*.

Tetter, humid. See *Impetigo*.

TEU'CRIUM. (*um*, *ii*. n.; from *Teucer*, who discovered it.) The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Gymnospermia*. The herb speedwell.

TEUCRIUM CAPITATUM. The systematic name of the poley mountain of Montpelier. *Polium montanum*. This plant bears the winter of our climate, and is generally substituted for the sandy species.

TEUCRIUM CHAMÆDRYS. The systematic name of the common germander. *Chamædrys. Chamædrys minor repens vulgaris. Quercula calamandrina. Trissago. Chamædrops*, of Paulus Ægineta, and Oribasius. This plant, called also creeping germander, small germander, and English treacle, *Teucrium — foliis cuneiformi-ovatis, incisis, crenatis, petiolatis; floribus ternis; caulibus procumbentibus, subpilosis*, of Linnæus, has a moderately bitter and somewhat aromatic taste. It was in high repute amongst the ancients in intermittent fevers, rheumatism, and gout; and where an aromatic bitter is wanting, germander may be administered with success. The best time for gathering this herb is when the seeds are formed, and the tops are then preferable to the leaves. When dry, the dose is from ʒss. to ʒj. Either water or spirit will extract their virtue; but the watery infusion is more bitter. This plant is an ingredient in the once celebrated powder named after the Duke of Portland.

TEUCRIUM CHAMÆPITYS. The systematic name of the common ground pine. *Chamæpitys. Arthetica. Arthretica. Ajuga. Abiga. Iva arthritica. Holocyron. Ionia. Sideritis.* This low hairy plant, *Teucrium — foliis trifidis, linearibus, integerrimis; floribus sessilibus, lateralibus, solitariis; caule diffuso*, of Linnæus, has a moderately bitter taste, and a resinous, not disagreeable smell, somewhat like that of the pine. The tops or leaves are recommended as aperients, and correborants of the nervous system, and are said to be particularly serviceable in uterine obstructions and paralytic disorders.

TEUCRIUM CRETICUM. The systematic name of the poley mountain of Candy. *Polium creticum*. The tops and whole herb enter the antiquated compounds *mithridate* and *theriaca*. The plant is obtained from the island of Candy; has a moderately aromatic smell, and a nauseous bitter taste. It is placed amongst the aperients and corroborants.

TEUCRIUM IVA. French ground-pine. *Chamæpitys moschata. Iva moschata Monspeliensium. Chamæpitys anthyllus*. It is weaker, but of similar virtues to chamæpitys.

TEUCRIUM MARUM. The systematic name of the Marum germander, or Syrian herb mastich. *Marum Syriacum. Marum Creticum. Majorana Syriaca. Marum verum. Marum cortusi. Chamedrys incana maritima*. This shrub is the *Teucrium — foliis integerrimis ovatis acutis petiolatis, subtus tomentosis; floribus racemosis secundis*, of Linnæus. It grows plentifully in Greece, Egypt, Crete, and Syria. The leaves and younger branches, when recent, on being rubbed betwixt the fingers, emit a volatile aromatic smell, which readily excites sneezing; to the taste they are bitterish, accompanied with a sensation of heat and acrimony. Judging from these sensible qualities of the plant, it may be supposed to possess very active powers. It is recommended as a stimulant, aromatic, and deobstruent; and Linnæus, Rosenstein, and Bergius speak highly of its utility. Dose, ten grains to half a drachm of the powdered leaves, given in wine. At present, however, marum is chiefly used as an errhine.

Teucrium montanum. The systematic name of the common poley mountain.

Teucrium polium. The systematic name of the golden poley mountain. Neither this nor the former are now used.

Teucrium scordium. The systematic name of the water germander. *Scordium. Trissago palustris. Chamædrys palustris. Allium redolens.* The leaves of this plant have a smell somewhat of the garlic kind, from which circumstance it is supposed to take its name: to the taste they are bitterish and slightly pungent. The plant was formerly in high estimation, but is now justly fallen into disuse, although recommended by some in antiseptic cataplasms and fomentations.

Teuthrum. See *Teucrium polium.*

TEXTURE. (*Textura*, from *texo*, to weave.) It is observed in the living body that there are certain common organised materials of which the different distinct parts are formed, and which are the same in appearance and properties in whatever part they are found. Such are cellular membrane, bone, muscular fibre, &c. These parts are called the *textures* of the body. They are also named, but improperly, *tissues.* A *texture* means any thing which is woven, and is therefore aptly enough applied metaphorically to various solids of the living body; a *tissue* means a piece of cloth interwoven with gold or silver, or embroidered.

However important the investigation of the common properties of the textures may now be considered, it was long before the attention of anatomists was directed to it.

The doctrine of the textures was first distinctly stated by Andrew Bonn, in a thesis *De Continuationibus Membranarum*, published in 1763. From this there is little doubt that Bichat originally derived the ideas which he afterwards gave to the world in his *Traité sur les Membranes*, in 1800.

The following is an enumeration of the textures according to Bichat.

1. Cellular
2. Nervous *animal*
3. Nervous *organic*
4. Arterial
5. Venous
6. Exhalant
7. Absorbent, with their glands
8. Osseous
9. Medullary
10. Cartilaginous
11. Fibrous
12. Fibro-cartilaginous
13. Muscular *animal*
14. Muscular *organic*
15. Mucous
16. Serous
17. Synovial
18. Glandular
19. Dermoid
20. Epidermoid
21. Pilous

} Systems.

The following table appended by the late Dr. Milligan to his translation of Magendie, gives a general view of the properties of the textures, many of which are more particularly described in this Dictionary under their respective heads.

Name, Division, Situation.	Characters.	Chemical Composition.	
		Animal.	Saline.
I. Cellular. Serous ..... Adipose ..... Situation. *Serous* every where, except brain: *Adipose* every where, except viscera, eyelids, nose, penis, scrotum.	Whitish semi-pellucid filaments, variously interwoven with interstices, communicating in *Serous*, not in *Adipose*; soft, extensible, contractile; insensible, rapidly inflaming; pours out serum, coagulable lymph, or suppurates.	Gelatine 100	Com. salts .....0·08 Water ..... ?
II. Nervous, of animal life. S. Brain, spinal marrow, their nerves.	Composed of white, slender, parallel filaments, united into bundles of a large size, arising in pairs from the brain and spinal cord; pain terribly when irritated.	Albumen .....7·0 White fat .....4·5 Red fat.....0·7 Osmazome .....1·1 Phosphorus.....1·5 14·8	Water .....80·0 Ph. lime Ph. soda Sulphur Ph. Am. ... 5·2 Vauq. 85·2
III. Nervous, of organic life. S. Sympathetic nerve, its ganglions.	System of nerves and ganglions, not connected with the cerebral mass, nor symmetrical; not connected with the brain; scarcely give pain on being irritated; scarcely influence their muscles.	Same as II.	
IV. Arterial.	Coats stronger, whiter — section patent; fibres of mid-	No fibrin? Berzelius.	

Name, Division, Situation.	Characters.	Chemical Composition.	
		Animal.	Saline.
S. Every where, except epidermis, &c. ?	dle coat transverse; internal without valves, readily ruptured, or ossified; not readily inflamed.	Fibrin? Magendie, p. 275. of first edition.	
V. Venous.	Coats thin, flesh-coloured; collapsing when cut; fibres of the middle coat longitudinal; cellular, dense, unalterable; internal tearing across — frequent valves — readily inflamed — not readily ossified.	.....	.....
S. Every where, except epidermis, &c.?			
VI. Exhalants.	Arise from arteries; carry no red blood; open on surfaces; exhale different fluids from different surfaces.		
S. Every where, on surfaces.			
VII. Absorbents and their glands.	Transparent, valvular, contractile; ramify and pass through glands; continue to act after death; easily inflamed; glands obovate, soft.	.....	.....
S. Every where, except the brain, eye, cartilages, serous membranes, placenta, bone, &c. ?			
VIII. Osseous.	White, partly soluble in acids, inflexible; hollow, insensible; pouring out callus when broken; fibrous; resists putrefaction.	Cartilage.....33·0 Oil? ..... Gelatine? ..... 33·0	Water ..... ? Phos. lime.....54·0 Carb. lime? ...10·0 Phos. magn.... 1·0 Fluate lime ... 2·0 Soda ..... 1·3 *Sulph. lime?* 1·0 Berzel. 70·0
S. Centre of limbs; walls of cavities; cavities.			
IX. Medullary.	In spongy bones, a vascular network, or *reticulum*, containing a peculiar oil; cells communicate; very subject to inflammation.	Pure med. oil 96·0 Albumen ... Gelatine..... Extractive.. Pecu. mat. 3·0 Water, membrane, and vessels..... 1·0 100	Phosp. lime..... ? Carb. lime..... ? Soda ..... ? Water..... 0 Berzel. ·0
Of spongy bones...			
Of long bones.....			
S. Internal cavities of bones.	In long bones, a membrane, contractile, sensible; rapidly suppurates, and destroys the bone.		
X. Cartilaginous.	Broader than thick, hard, elastic, whitish; apparently inorganic, but really constituted of fibres, which break when strongly bent. Cellular membrane and colourless vessels interposed. Insensible, almost imputrescible; no sympathies; tinges readily in jaundice; desquamates readily from inflammation. Ossifies in old age.	Coagulated albumen..... 98	Common salts 2·0 Water..... ?
S. Ends of bones; synchondroses; walls of cavities.			
XI. Fibrous.	Composed of a peculiarly hard, elastic, insensible, parallel or interlaced fibre, very strong; which ossifies slightly in old age. Without proper action, but is extensible.	Gelatine? 100	Water..... ? Com. salts? ...0·08
Membranous			
Fascicular			
S. Periosteum, dura mater, sclerotica, albuginea, membrane proper to kidney, spleen: capsular ligaments, tendinous sheaths, aponeuroses.			
Tendons, ligaments.			

Name, Division, Situation.	Characters.	Chemical Composition. Animal.	Saline.
XII. Fibro-Cartilaginous. Membranous ..... Articular ..... Tendinous sheaths S. Nose, trachea, palpebra, knee joint, lower jaw, articulation, periosteum, within tendinous sheaths.	Something between cartilage and ligament, having a base of parallel, or interlaced fibres, with cartilage interposed between them. Except the membranes, have no perichondrium; are rarely inflamed; elastic, pliable, insensible; reunite slowly; no sympathies; ossify slowly in old age.	Coag. albu.? 98·0	Com. salts .....2·0 Water..... ?
XIII. Muscular, of animal life. Long ..... Large ..... Short ..... S. Trunk and limbs, between skin and walls of cavities; or bones.	Red, massy, parallel, or diverging fibres; obedient to the will; contractile to a stimulus applied to themselves, to their *animal* nerves, or the brain; limited by antagonists; generally cross a joint; subject to fatigue; sympathise with one another; die with the lungs.	Fibrin ..... 17·7 Albumen ..... 2·2 Gelatine?..... Osmazome.... 0·15 19·24	Phosp. soda... 0·90 Phos. amm.? Phos. lime.... 0·08 Carb. lime? Mur. and lact. soda ..... 0·18 Water..... 77·77 Fourcr. 78·33
XIV. Muscular, of organic life. S. Within walls of cavities.	Occupy the cavities; fibres pale, curved, or irregularly interlaced; never attached to bone, nor to fibrous organs. Form, thin, flat membranes; rarely superimposed; not uniform; short; not obedient to the will; not symmetrical; not affected by stimulation of the nerves; receive their nerves chiefly from the sympathetic.	Same as XIII.	
XV. Mucous. Excreting ..... Non-excreting? or, *Gastro-pulmonary.* *Genito-urinary.* S. Lining imperfect cavities; eye, nose, throat, pulmonary, alimentary, genital, urinary passages. Facial sinuses, antrum, mammæ.	Soft, spongy, villous, equable membrane, furnished with follicles, glands, exhalants. Continuous with the skin, and lining all the cavities which open externally. Very sensible and irritable, though not contractile. Secretes mucus; pus, when inflamed; but very rarely coagulable lymph. Scarcely ever forms adhesions or ossifications.	Gelatine?.....100 Mucus?	Water ..... ? Com. salts .....0·08
XVI. Serous. Locomotive ..... Fixed?..... S. Lining imperfect cavities; thorax, abdomen, scrotum, head, labyrinth, eye, ovarium vesicle, blood and lymphatic vessels.	Dense, shining, semi-pellucid membrane, always forming a shut sac, and lining some shut cavity. Insensible, not contractile; exhaling an albuminous fluid, named serum. Never continuous with other tissues; easily inflamed, when it pours out coagulable lymph, and adheres to part of its own sac; frequently ossifies, or forms hydropic collections.	Gelatine? 100	Water ..... ? Com. salts .....0·08
XVII. Synovial. Articular ..... Tendinous ..... S. Lining joints.	Shut sac; structural characters resembling *serous tissue*, but exhales synovia, a widely different secretion. Not affected in general drop-	Gelatine? 100	Water..... ? Com. salts .....0·08

Name, Division, Situation.	Characters.	Chemical Composition.	
		Animal.	Saline.
Tendinous sheaths, or bursæ mucosæ.	sies, nor serous membranes in synovial dropsy; rarely and slowly adheres; of limited locomotion.		
XVIII. Glandular. Secreting ..... Aporous ..... S. Cavities, or the vicinity of cavities.	Insulated bodies, of indefinite form; rarely in pairs; of variable figure; easily torn; hardness increased; elasticity lost by boiling. — *Have excretory ducts*, a parenchyma of variously organised cellular membrane; insensible?	.....	.....
XIX. Dermoid. S. The surface of the body only.	Envelopes whole body; originates the mucous system. The *corium*, or true skin, consists of fibres variously interlaced in layers, superimposed to each other, so as to form areas, which transmit the exhalation of sweat, the sebaceous secretion, and the pilous system. Embrowned by light; contracts by cold; convex towards the epidermis by boiling, and passes into gelatine. Elastic; enjoys the sense of touch; unites when dead with tannin.	Gelatine? .....100 Albumen? ..... Mucus?	Water..... ? Com. salts.....0·08
XX. Epidermoid. Of skin ..... Of mucous membrane Of hairs? ..... S. Surface of the body, mucous cavities, hairs?	Transparent, furrowed externally; separates from the skin by heat, vesicatories, putrefaction. Tinged yellow by nitric acid; brown by chlorine. Without fibres, inelastic, insensible; impregnated by water, it becomes opake; not crispable by heat, but forms an oil during combustion; abraded, it reproduces itself.	Coag. album. 93·5 Mucus? ..... Gelatine?	Com. salts.....0·08 Water..... ?
XXI. Pilous. *Vibrissæ* ..... *Cirrhi* ..... *Lanugo*..... S. Head particularly, armpits, genitals, nose, caruncula, lacrymalis, ears, diseased ovaria.	*Conical* prolongations from bulbs under the true skin. Semi-transparent; resoluble into cuticle, corpus mucosum, and parallel but unequal fibres. (Flem. Zool.) Slightly crisped by heat, insensible? hollow? made lighter by maceration; black, by lunar caustic; yellow, by nitric acid; brown, by chlorine; depolarises light.	Coagu. album. 94 Mucus? ..... Gelatine? ..... White con. oil? Grey-green oil, sometimes red, or black } ? Vauq.	Sul. of lime. Lactic acid Lac. of pot. Pho. of pot. } 1·5 Mur. of pot. Magnesia ... Iron ..... Silica? ..... Sulphur..... Ph. & carb. lime ? Phos. of mag. ....? Water..... ?

THA'LAMUS. (*us*, *i.* m. Θαλαμος, a bed.) 1. In *Anatomy*, a part of the brain from which the optic nerve derives one of its origins. See *Encephalos*, and *Nerve*.

2. In *Botany*, the receptacle of the parts of fructification of plants. See *Receptaculum*.

Thalamus nervi optici. See *Encephalos*.

Thalasso'meli. (From θαλασσα, the sea, and μελι, honey.) A Greek cathartic medicine, made by exposing in a vessel lined with pitch, a mixture of equal parts of honey, sea water, and rain water.

THALI'CTRUM. (*um*, *i.* n.; from θαλλω, to flourish.) 1. The name of a genus of plants in the Linnæan system. Class, *Polyandria*; Order, *Polygynia*.

2. The pharmacopœial name of the poor man's rhubarb. See *Thalictrum flavum*.

THALICTRUM FLAVUM. The systematic name of the poor man's rhubarb. The root of this plant is said to be aperient and stomachic, and to come very near in its virtues to rhubarb. It is a common plant in this country, but seldom used medicinally.

THA'LLUS. (*us, i.* m.; from θαλλος, an olive bud, or green bough; from θαλλω, to be verdant, to shoot forth, or spread abroad.) A term applied by Acharius to the frond or foliage of a lichen, whether that part be of a leafy, fibrous, scaly, or crustaceous nature.

THA'PSIA. (*a, æ.* f.; from *Thapsus*, the island where it was found.) The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Digynia.*

THAPSIA ASCLEPIAS. The deadly carrot. The root operates violently both upwards and downwards, and is not used in the practice of the present day.

THA'PSUS. Θαψος. The great white mullein, or cows' lungwort. See *Verbascum thapsus.*

THE'A. (*a, æ.* f.) Tea. The dried leaves of the tea-tree, of which there are two species, viz.—1. The *Thea nigra,* bohea, or black tea; and, 2. The *viridis,* or green tea; both of which are natives of China or Japan, where they attain the height of five or six feet.

Great pains are taken in collecting the leaves *singly,* at three different times, viz. about the middle of February, in the beginning of March, and in April. Although some writers assert that they are first exposed to the steam of boiling water, and then dried on copper plates, yet it is now understood that such leaves are simply dried on *iron* plates, suspended over a fire, till they become dry and shrivelled: when cool, they are packed in tin boxes to exclude the air, and in that state exported to Europe.

Teas are divided in Britain into three kinds of *green,* and five of *bohea.* The former class includes,—

1. *Imperial* or *bloom tea,* having a large leaf, a faint smell, and being of a light green colour.

2. *Hyson,* which has small curled leaves, of a green shade inclining to blue.

3. *Singlo* tea, thus termed from the place where it is cultivated.

The boheas comprehend,—

1. *Souchong,* which, on infusion, imparts a yellowish-green colour.

2. *Camho,* a fine tea, emitting a fragrant violet smell, and yielding a pale shade; it receives its name from the province where it is reared.

3. *Pekoe tea,* which is known by the small white flowers that are mixed with it.

4. *Congo,* which has a larger leaf than the preceding variety, and yields a deeper tint to water; and,

5. *Common bohea,* the leaves of which are of an uniform green colour. There are besides other kinds of tea, sold under the names of *gunpowder tea,* &c., which differ from the preceding only in the minuteness of their leaves, and being dried with additional care.

The following interesting results of experiments on tea by Brande have been published by him in his Journal:—

One hundred parts of Tea.	Soluble in Water.	Soluble in Alkohol	Precipit. with Jelly.	Inert Residue.

Much has been said and written on the medicinal properties of tea. In its natural state it is a *narcotic* plant, on which account the Chinese refrain from its use till it has been divested of this property by keeping it at least for twelve months. If, however, good tea be drunk in moderate quantities, with sufficient milk and sugar, it invigorates the system and produces a temporary exhilaration; but when taken too copiously, it is apt to occasion weakness, tremor, palsies, and various other symptoms arising from narcotic plants, while it contributes to aggravate hysterical and hypochondriacal complaints. Tea has also been supposed to possess considerable diuretic and sudorific virtues, which, however, depend more on the *quantity* of warm water employed as a vehicle, than the quality of the tea itself. Lastly, as infusions of these leaves are the safest refreshment after undergoing great bodily fatigue or mental exertion, they afford an agreeable beverage to those who are exposed to cold weather; at the same time tending to support and promote perspiration, which is otherwise liable to be impeded.

THEA GERMANICA. The male speedwell. See *Veronica officinalis.*

THEBA'ICUS. (*A Thebaide regione;* from the country about the ancient city of Thebes in Egypt, where it flourished.) Theban: applied as a trivial name to articles which come from Thebes; as *Papaver Thebaicum,* the Egyptian poppy; *Confectio Thebaica,* the opiate confection, because it is prepared from that poppy, &c.

THEBE'SII FORA'MINA. The orifices of veins in the cavities of the heart. See *Heart.*

THE'CA. (*a, æ.* f.; from τιθημι, to place.) A case, sheath, or box. 1. The canal of the vertebral column. See *Spine.*

2. The capsule or dry fructification adhering to the apex of a frondose stem.

THECA VERTEBRALIS. The vertebral canal. See *Vertebra.*

THE'NAR. (*ar, aris.* n.) Θεναρ. The palm of the hand or sole of the foot.

THEOBRO'MA. (*a, æ.* f.; from θεος, a god, and βρωμα, food: so called from the deliciousness of its fruit.) 1. The name of a genus of plants. Class, *Polyadelphia;* Order, *Decandria.*

2. The name of a compound used as a food.

THEOBROMA CACA'O. The systematic name of the tree which affords cocoa and chocolate. Cocoa is the name given to the fruit, which is of the size of a kidney bean, and is enclosed in a thin shell. The shells are often ground and boiled for an article of diet; and the seed, ground down, is formed into cakes called chocolate. Both are highly nourishing when boiled

with milk; to which eggs are sometimes added. When the stomach can bear this food, it is admirably calculated for the sick, and especially the tabid. To those in health it is a luxury.

THEODO'RICUM. (From θεοι, the gods, and δωρον, a gift.) A pompous and obsolete name of some antidotes.

THERAPEI'A. (*a, æ.* f.; from θεραπευω, to heal.) *Therapia.* See *Therapeutics.*

THERAPEUTICS. (*Therapueticus;* from θεραπευω, to cure.) *Therapia. Methodus medendi.* Therapia, or therapeutice, is that division of pathology, or science, which considers the application of the remedies and means employed with a view to prevent and to cure diseases.

The cure of a disease depends on the removal of its proximate cause. This is effected either by the powers of nature alone, or conjointly with the assistance of art: so that the cure of a disease may said to be either natural or artificial.

The powers of nature, denominated the *vires medicatrices naturæ*, are inherent in the solids and fluids, and it is by their exertion that a stop is occasionally put to the progress of a disease, or that it is cured without the administration of medicine; and it is also by their co-operation that the medical art is so beneficial.

We are in ignorance, most probably, of the greater part of the healing powers of nature. Many diseases are cured by attention merely to the air we breathe, the food we eat, the state of the mind, the rest and exercise of the body; and many are naturally removed as life advances, and by alteration of habits, change of temperature, clothing, and climate, without the aid of medicines.

The assistance with which the medical art is enabled to attempt, and to effect, the cure of diseases is arranged under three heads; —

1. The *hygienal;* which embraces the diet and regimen.

2. The *medicinal;* which regards the administration of medicines, both external and internal.

3. The *surgical;* or the assistance of manual, fascial, and instrumental operations.

As some diseases admit of being prevented, some of being partially, and others of being wholly removed or cured, there is a natural distinction into, —

1. The *prophylactic.*

2. The *palliative.*

3. The *radical* cure.

The *methodus medendi*, or method of cure, is the plan which regulates all the circumstances, rules, regulations, &c. for the welfare of the diseased. It therefore not only embraces the knowledge of the remedy to be exhibited, but also the consideration of the state of the body, the knowledge of the nature of the disease, and the operation of the remedies; for when disease is going on the functions are not performed in a healthy manner, and one or more of the moving powers take on a particular change of action, in which change the disease consists. The removal, therefore, of the disease requires the return from morbid to healty action. This must, of course, be effected by bringing about certain alterations in the moving fibres. This being admitted, it follows that the application of the remedy must be so managed as to produce such alterations as are known by experience to diminish or destroy the diseased action; so that, to attempt the cure of a disease, we must first be acquainted with the alterations we wish to produce, and we must also know what means are capable of effecting the change we desire. Pathologists have arranged the consideration of these several circumstances under four heads: namely, the indicant, the indication, the thing indicated, and the contra-indication; and unless these are duly considered before we attempt either to palliate or cure a disease, the attempt will most probably be unsuccessful; at any rate it will be empirical.

1. The *indicant;* or diseased action from which the symptoms arise, and every thing that should not exist, is an indicant.

2. The *indication;* or that which is calculated to remove the indicant.

3. The *thing indicated;* or the remedy.

4. The *contra-indication;* or that about the patient or the disease which prevents the use or application of the usual remedies.

These several divisions are well illustrated in hysteria: the hysterical action of the nerves and muscles are the indicant or disease, the symptoms of which are the unnatural and peculiar movements of the muscles affected; the indication is to allay those unnatural and inordinate contractions; the thing indicated is opium, or æther, or camphire, or all in combination. It may happen that the smallest quantity of opium or æther would produce much after-inquietude; that peculiarity is a contra-indication to its use, and some other must be preferred.

THERI'ACA. (*a, æ.* f.; from θηρ, a venomous or ferocious animal.) 1. A name given to several confections, especially of an alexipharmic kind.

2. Treacle, or molasses. See *Saccharum officinale.*

Theriaca andromachi. See *Mithridatium.*

THERIACA CŒLESTIS. The tinctura opii.

Theriaca Damocratis. See *Mithridatium.*

Theriaca Edinensis. See *Confectio opii.*

THERIACA GERMANORUM. A rob of juniper berries.

THERIACA LONDINENSIS. A cataplasm of cummin seed, bay-berries, germander, snake-root, cloves, and honey.

Theriaca rusticorum. See *Allium.*

Theriaca Veneta. See *Mithridatium.*

THERIO'MA. (From θηριοω, to rage like a wild beast.) A malignant ulcer.

THE'RMA. (*a, æ.* f.; from θερμη, heat.) A warm bath or spring. See *Mineral waters*, and *Bath.*

THERMO'METER. (*Thermometrum, i.* n.; from θερμη, heat, and μετρον, a measure.) An instrument for measuring the degrees of heat. A thermometer is a hollow tube of glass, hermetically sealed, and blown at one end in the shape of a hollow globe. The bulb and part of the tube are filled with mercury, which is the only fluid which expands equally. When

we immerse the bulb of the thermometer in a hot body, the mercury expands, and of course *rises* in the tube; but when we plunge it into a cold body, the mercury contracts, and of course *falls* in the tube.

The rising of the mercury indicates, therefore, an increase of heat; its falling, a diminution of it; and the quantity which it rises or falls, denotes the proportion of increase or diminution. To facilitate observation, the tube is divided into a number of equal parts, called degrees.

Further, if we plunge a thermometer ever so often into melting snow or ice, it will always stand at the same point. Hence we learn that *snow* or *ice* always begins to melt at the same temperature.

If we plunge a thermometer repeatedly into water kept boiling, we find that the mercury rises up to a certain point. This is, therefore, the point at which water always boils, provided the pressure of the atmosphere be the same.

There are four different thermometers used at present in Europe, differing from each other in the number of degrees into which the space between the freezing and boiling points is divided. These are Fahrenheit's, Réaumur's, Celsius's, and Delisle's.

The thermometer uniformly used in Britain is Fahrenheit's: in this the freezing point is fixed at 32° — the boiling point, at 212° above 0° — or the part at which both the ascending and descending series of numbers commence.

In the thermometer which was first constructed by Réaumur, the scale is divided into a smaller number of degrees upon the same length, and contains not more than 80° between the freezing and the boiling points. The freezing point is fixed in this thermometer precisely at 0°, the term between the ascending and the descending series of numbers. Again, 100 is the number of the degrees between the freezing and the boiling points in the scale of Celsius, which has been introduced into France, under the name of the Centigrade thermometer; and the freezing point is in this, as in the thermometer of Réamur, fixed at 0°. One degree on the scale of Fahrenheit appears, from this account, to be equal to 4-9ths of a degree on that of Réamur, and to 5-9ths of a degree on that of Celsius.

The space in Delisle's thermometer between the freezing and boiling points is divided into 150°, but the graduation begins at the boiling point, and increases towards the freezing point. The boiling point is marked 0, the freezing point 150. Hence 180 F. = 150 D., or 6 F. = 5 D. To reduce the degrees of Delisle's thermometer *under* the boiling point to those of Fahrenheit, we have F. = 212 − 6-5 D.; to reduce those *above* the boiling point, F. = 212 + 6-5 D. Upon the knowledge of this proportion it is easy for the student to reduce the degrees of any of these thermometers into the degrees of any other of them.

Thieves'-vinegar. (So called after the four thieves, who by its use were said to have been preserved from the plague of Marseilles.) See *Acetum prophylacticum*.

Thigh. See *Femur*.

Thigh-bone. See *Femoris os*.

THIRST. *Sitis.* 1. In *Physiology*, the sensation by which we experience a desire to drink. It is variable according to individuals, and it is rarely uniform in the same person. Generally speaking, it consists of a feeling of dryness, of heat and constriction, which reigns in the back part of the mouth, the pharynx, œsophagus, and sometimes the stomach. Though thirst continue but for a short time, these parts swell and become red, the mucous secretion ceases almost entirely; that of the follicles changes, becomes thick and tenacious; the flowing of the saliva diminishes, and its viscosity is sensibly augmented. These phenomena are accompanied by a vague inquietude, by a general heat; the eyes become red, the mind is troubled, the motion of the blood is accelerated, the respiration becomes laborious, the mouth is frequently opened wide, in order to bring the external air into contact with the irritated parts, and thus to produce a momentary ease. For the most part the inclination to drink is developed, when by some cause, for example, heat and dryness of the atmosphere, the body has lost a great deal of fluid; but it appears under a great many different circumstances, such as having spoken long, having eaten certain sorts of food, or swallowed a substance which remains in the œsophagus, &c. The vicious habit of frequently drinking, and the desire of tasting some liquids, such as brandy, wine, &c., cause the development of a feeling which has the greatest analogy with thirst.

There are people who have never felt thirst, who drink from a sort of sympathy, but who could live a long time without thinking of it, or without suffering from the want of it; there are other persons in whom thirst is often renewed, and becomes so strong as to make them drink from forty to sixty pints of liquid in twenty-four hours: in this respect great individual differences are remarked. Thirst, then, is an internal sensation, an instinctive feeling: it belongs essentially to the organisation, and admits of no explanation.

II. In *Pathology*, this is frequently morbid, and in this state it is either in excess or deficient.

1. *Immoderate thirst* is accompanied by a sense of dryness in the mouth and throat, and a constant desire to drink. This, though a common symptom in most febrile diseases, occasionally exists as an idiopathic disease. Four hundred pints of wine and water are said to have been drank daily; and the most intolerable torture is often felt from thirst when the person is reluctantly compelled to a confession of guilt. Excessive thirst, when a disease, is best removed by mercurial purges.

2. *Thirstlessness.* — This is an unusual state. Sauvages, in his Nosology, mentions two instances of it; and the writer of this article knows at this time a gentleman who would never drink from a desire so to do. Absence of thirst is sometimes symptomatic of inflammation of the brain.

Thistle. See *Carduus*.

Thistle, carline. See *Carlina acaulis*.

Thistle, creeping. See *Serratula*.

Thistle, holy. See *Centaurea benedicta.*
Thistle, ladies'. See *Carduus marianus.*
Thistle, milk. See *Carduus.*
Thistle, pine. See *Carlina gummifera.*
Thistle, way. See *Serratula.*

THLA'SPI. (*pi.* n. indeclinable; from θλαω, to break: because its seed appears as if it were broken or bruised.) 1. The name of a genus of plants in the Linnæan system. Class, *Tetradynamia;* Order, *Siliculosa.*

2. The pharmacopœial name of the herb penny-cress. Two species of thlaspi are directed in some Pharmacopœias for medicinal uses, — the *Thlaspi arvense,* of Linnæus, or treacle mustard, and *Thlaspi campestre,* of Linnæus, or mithridate mustard. The seeds of both have an acrid biting taste, approaching to that of common mustard, with which they agree nearly in their pharmaceutic qualities. They have also an unpleasant flavour, somewhat of the garlic or onion kind.

THLASPI ARVENSE. The treacle mustard. See *Thlaspi.*

THLASPI CAMPESTRE. The mithridate mustard. See *Thlaspi.*

THORA'CIC. (*Thoracicus;* from *thorax,* the chest.) Belonging to the thorax or chest.

Thoracic aorta. See *Aorta, thoracic.*

THORACIC DUCT. *Ductus thoracicus. Ductus Pecquettii.* The trunk of the absorbents. It is of a serpentine form, and about the diameter of a crow-quill, and lies upon the dorsal vertebræ, between the aorta and vena azygos, extending from the posterior opening of the diaphragm to the angle formed by the union of the left subclavian and jugular veins, into which it opens and evacuates its contents. In this course the thoracic duct receives the absorbent vessels from almost every part of the body. See *Absorbent.*

THORACICI. An order of fishes in the Linnæan system, which have the ventral fins under the pectoral.

THO'RAX. (*ax, acis.* f.; from θορεω, to leap: because in it the heart leaps.) The chest, or that part of the body situated between the neck and the abdomen. The external parts of the thorax are, the common integuments, the breasts, various muscles, and the bones of the thorax. (See *Respiration.*) The parts within the cavity of the thorax are, the pleura and its productions, the lungs, heart, thymus gland, œsophagus, thoracic duct, arch of the aorta, part of the vena cava, the vena azygos, the eighth pair of nerves, and part of the great intercostal nerve. The chest, like the abdomen, is divided by imaginary lines into certain regions. These are, a right and left *humeral,* a right and left *subclavian,* a right and left *mammary,* a right and left *axillary,* a right and left *subaxillary,* a right and left *scapulary,* a right and left *intrascapulary,* and a right and left *subscapulary.*

THORI'NA. (*a, æ.* f.) An earth discovered in 1816 by Berzelius. He found it in small quantities in the gadolonite of Korarvet, and two new minerals, which he calls the deutofluate of cerium, and the double fluate of cerium and yttria. It resembles zirconia.

To obtain it from those minerals that contain protoxide of cerium and yttria, we must first separate the oxide of iron by succinate of ammonia. The new earth, indeed, may, when alone, be precipitated uy the succinates; but in the analytical experiments in which he has obtained it, it precipitated in so small a quantity along with iron, that he could not separate it from that oxide. The deutoxide of cerium is then precipitated by the sulphate of potash; after which the yttria and the new earth are precipitated together by caustic ammonia. Dissolve them in muriatic acid. Evaporate the solution to dryness, and pour boiling water on the residue, which will dissolve the greatest part of the yttria; but the undissolved residue still contains a portion of it. Dissolve it in muriatic or nitric acid, and evaporate it till it becomes as exactly neutral as possible. Then pour water upon it, and boil it for an instant. The new earth is precipitated, and the liquid contains disengaged acid. By saturating this liquid, and boiling it a second time, we obtain a new precipitate of the new earth.

This earth, when separated by the filter, has the appearance of a gelatinous, semi-transparent mass. When washed and dried, it becomes white, absorbs carbonic acid, and dissolves with effervescence in acids. Though calcined, it retains its white colour; and when the heat to which it has been exposed is only moderate, it dissolves readily in muriatic acid; but if the heat has been violent, it will not dissolve till it be digested in strong muriatic acid. This solution has a yellowish colour; but it becomes colourless when diluted with water, as is the case with glucina, yttria, and alumina. If it be mixed with yttria, it dissolves more readily after having been exposed to heat. The neutral solutions of this earth have a purely astringent taste, which is neither sweet, nor saline, nor bitter, nor metallic. In this property it differs from all other species of earths, except zirconia.

When dissolved in sulphuric acid with a slight excess of acid, and subjected to evaporation, it yields transparent crystals, which are not altered by exposure to the air, and which have a strong styptic taste.

This earth dissolves very easily in nitric acid; but after being heated to redness, it does not dissolve in it except by long boiling. The solution does not crystallise, but forms a mucilaginous mass, which becomes more liquid by exposure to the air, and which, when evaporated by a moderate heat, leaves a white opake mass, similar to enamel, in a great measure insoluble in water.

It dissolves in muriatic acid, in the same manner as in nitric acid. The solution does not crystallise. When evaporated by a moderate heat, it is converted into a syrupy mass, which does not deliquesce in the air, but dries, becomes white like enamel, and afterwards dissolves only in very small quantity in water, leaving a subsalt undissolved; so that by spontaneous evaporation it lets the portion of muriatic acid escape to which it owed its solubility.

This earth combines with avidity with carbonic acid. The precipitates produced by caus-

tic ammonia, or by boiling the neutral solutions of the earth in acids, absorb carbonic acid from the air in drying. The alkaline carbonates precipitate the earth combined with the whole of their carbonic acid.

The ferruginous prussiate of potash, poured into a solution of this earth, throws down a white precipitate, which is completely redissolved by muriatic acid.

Caustic potash and ammonia have no action on this earth newly precipitated, not even at a boiling temperature.

The solution of carbonate of potash, or carbonate of ammonia, dissolves a small quantity of it, which precipitates again when the liquid is supersaturated with an acid, and then neutralised by caustic ammonia; but this earth is much less soluble in the alkaline carbonates than any of the earths formerly known that dissolve in them.

Thorina differs from the other earths by the following properties: — From alumina, by its insolubility in hydrate of potash; from glucina, by the same property; from yttria, by its purely astringent taste, without any sweetness, and by the property which its solutions possess of being precipitated by boiling when they do not contain too great an excess of acid. It differs from zirconia by the following properties: — 1. After being heated to redness, it is still capable of being dissolved in acids. 2. Sulphate of potash does not precipitate it from its solutions, while it precipitates zirconia from solutions containing even a considerable excess of acid. 3. It is precipitated by oxalate of ammonia, which is not the case with zirconia. 4. Sulphate of thorina crystallises readily, while sulphate of zirconia, supposing it free from alkali, forms, when dried, a gelatinous transparent mass, without any trace of crystallisation.

THORI'NUM. The supposed metallic base of thorina.

Thorn. See *Spina.*

Thorn, Egyptian. See *Acacia vera.*

Thorn-apple. See *Datura.*

Thornback. See *Raia clavata.*

Thread. See *Filamentum.*

Thread-shaped. See *Filiformis.*

Three-edged. See *Trigonus.*

Three-fibred. See *Trinervus.*

Three-lobed. See *Trilobatus.*

THROMBO'SIS. (*is, is.* f.; from θρομβος.) The same as thrombus.

THRO'MBUS. (*us, i.* m.; from θρομβοω, to clot.) A small tumour which sometimes arises after bleeding, owing to the blood escaping from the vein into the cellular structure surrounding it.

Thrush. See *Aphthæ.*

THRY'PTICUS. (From θρυπτω, to break.) Synonymous with *lithontriptic.*

THU'RIS CO'RTEX. A name of the cascarilla bark. See *Croton.*

THUS. (*us, uris.* n.; from θυω, to sacrifice: so called from its great use in sacrifices.) Frankincense. See *Juniperus lycia.*

Thus judæorum. See *Thymiama.*

Thus masculum. See *Juniperus lycia.*

THUY'A. (*a, æ.* f.; from θυον, an aroma: so named from its fragrant smell.) *Thuja.* The name of a genus of plants. Class, *Monœcia;* Order, *Monadelphia.*

THUYA OCCIDENTALIS. The systematic name of the tree of life. *Arbor vitæ. Thuya — strobilis lævibus; squamis obtusis,* of Linnæus. The leaves and wood were formerly in high estimation as resolvents, sudorifics, and expectorants, and were given in phthisical affections, intermittent fevers, and dropsies.

THYLA'CION. (Θυλακιον. Θυλακος, a bag.) A word used by ancient writers to express the bag formed by the membranes of the fœtus at the orifice of the pudenda, before the birth.

THY'MBRA. (*a, æ.* f.; a name borrowed from Dioscorides, whose real θυμβρα, however, is a species of *Satureia.*) 1. The name of a genus of plants. Class, *Didynamia;* Order, *Gymnospermia.*

2. See *Satureia hortensis.*

THYMBRA HISPANICA. The name given by Tournefort to the common herb mastich. See *Thymus mastichina.*

Thyme. See *Thymus.*

Thyme, lemon. See *Thymus serpyllum.*

Thyme, mother of. See *Thymus serpyllum.*

THYMELŒ'A. (From θυμος, thyme, and ελαια, an olive; the first alluding to the leaf, and the latter to the shape and oiliness of the fruit.) See *Daphne gnidium.*

THYMIA'MA. (*a, atis.* n.; from θυμα, an odour: so called from its odoriferous smell.) Musk-wood. *Thus Judæorum.* A bark in small brownish-grey pieces, intermixed with bits of leaves, seeming as if the bark and leaves had been bruised and pressed together, brought from Syria, Cilicia, &c. and supposed to be the produce of the liquid storax tree. This bark has an agreeable balsamic smell, approaching to that of liquid storax, and a subacrid bitterish taste, accompanied with some slight astringency.

THYMIO'SIS. (From θυμος, an excrescence about the pudenda.) The name given by Swediaur to the yaws.

THYMI'TES. Wine impregnated with thyme.

THY'MIUM. (From θυμος, thyme; because it is of the colour of thyme.) A small wart upon the skin.

THYMOXA'LME. (From θυμος, thyme, οξυς, acid, and ἁλς, salt.) A medicine composed chiefly of thyme, vinegar, and salt.

THY'MUS. (*us, i.* m. Απο του θυμου, because it was used in faintings; or from θυμα, an odour, because of its fragrant smell.) 1. The name of a genus of plants in the Linnæan system. Class, *Didynamia;* Order, *Gymnospermia.* Thyme.

2. The pharmacopœial name of the common thyme. See *Thymus vulgaris.*

3. A small indolent fleshy tubercle like a wart, arising about the anus, or the pudenda, resembling the flowers of thyme, from which it takes its name.

THYMUS CITRA'TUS. Lemon thyme. See *Thymus serpyllum.*

Thymus creticus. See *Satureia capitata.*

THYMUS GLAND. Θυμος. A gland of considerable size in the fœtus, situated in the anterior duplicature or space of the mediastinum, under

the superior part of the sternum. An excretory duct has not yet been detected, but lymphatic vessels have been seen going from it to the thoracic duct. Its use is unknown.

THYMUS MASTICHINA. The systematic name of the common herb mastich. *Marum vulgare. Sampsuchus. Clinopodium mastichina Gallorum. Thymbra hispanica. Jaca indica.* A low shrubby plant, a native of Spain, which is employed as an errhine. It has a strong agreeable smell, like mastich. Its virtues are similar to those of the *Marum syriacum*, but less powerful.

THYMUS SERPYLLUM. The systematic name of the *Serpyllum. Serpillum. Gilarum. Serpyllum vulgare minus.* Wild thyme or mother of thyme. *Thymus—floribus capitatis, caulibus repentibus, foliis planis obtusis basi ciliatis*, of Linnæus. This plant has the same sensible qualities as those of the garden thyme, but has a milder and rather more grateful flavour. Lemon thyme, the *Serpyllum citratum*, is merely a variety of this plant. It is very pungent, and has a particularly grateful odour, approaching to that of lemons.

THYMUS VULGARIS. The systematic name of the common thyme. This herb, the *Thymus—erectus foliis revolutis ovatis, floribus verticillato spicatis*, of Linnæus, has an agreeable aromatic smell, and a warm pungent taste. Its virtues are said to be resolvent, emmenagogue, tonic, and stomachic; yet there is no disease mentioned in which its use is particularly recommended by any writer on the materia medica.

THY'RO-ARYTÆNOIDE'US. A muscle situated about the glottis, which pulls the arytenoid cartilage forwards nearer to the middle of the thyroid, and consequently shortens and relaxes the ligament of the larynx.

THY'RO-HYOIDE'US. A muscle situated between the os hyoides and trunk, which pulls the os hyoides downwards, and the thyroid cartilage upwards.

Thyro-pharyngeus. See *Constrictor pharyngis inferior.*

Thyro-pharyngo-staphilinus. See *Palato-pharyngeus.*

THY'RO-PHRA'XIA. (From θυρεος, a shield, and φραξις, obstruction.) An ill-devised name of goitre. See *Bronchocele.*

Thy'ro-staphili'nus. See *Palato-pharyngeus.*

THY'ROID. (*Thyroides*; from θυρεος, a shield, and ειδος, resemblance: from its supposed resemblance to a shield.) Resembling a shield.

THYROID CARTILAGE. *Cartilago thyroides. Cartilago scutiformis.* Scutiform cartilage. The cartilage which is placed perpendicular to the cricoid cartilages of the larynx, constituting the anterior, superior, and largest part of the larynx. It is harder and more prominent in men than in women, and forms what is called the *pomum Adami* in man.

THYROID GLAND. *Glandula thyroides.* A large glandiform body, situated upon the cricoid cartilage, trachea, and horns of the thyroid cartilage. The labours of anatomists have hitherto failed to discover any thing satisfactory, with regard to it. No excretory duct has been detected, and the use of the organ not yet known.

THYR'SUS. (*us, i.* m.; a young sprout.) In *Botany*, a dense and close panicle, bunch, or cluster, more or less of an ovate form. It is *oblong* in *Tussilago hybrida*, and *ovate* in *Tussilago petasites.*

TI'BIA. (*a, æ.* f.; the hautboy: qu. *tubia*, from *tuba*, a tube: so called from its pipe-like shape.) *Focile majus. Arundo major. Fosilus. Canna major. Canna-domestica cruris.* The largest bone of the leg. It is of a long, thick, and triangular shape, and is situated on the internal part of the leg. Its upper extremity is large, and flattened at its summit, where we observe two articulating surfaces, a little concave, and separated from each other by an intermediate irregular protuberance. Of these two cavities, the internal one is deepest, and of an oblong shape, while the external one is rounded, and more superficial. Each of these, in the recent subject, is covered by a cartilage, which extends to the intermediate protuberance, where it terminates. These two little cavities receive the condyles of the os femoris, and the eminence between them is admitted into the cavity which is seen between the two condyles of that bone; so that this articulation affords a specimen of the complete ginglymus. Behind the intermediate protuberance, or tubercle, is a pretty deep depression, which serves for the attachment of a ligament, and likewise to separate the two cavities from each other. Under the edge of the external cavity is a circular flat surface, covered with cartilage, which serves for the articulation of the fibula; and at the fore-part of the bone is a considerable tuberosity, of an inch and a half in length, to which the strong ligament of the rotula is fixed.

The body of the tibia is smaller than its extremities, and, being of a triangular shape, affords three surfaces. Of these, the external one is broad, and slightly hollowed by muscles above and below; the internal surface is broad and flat; and the posterior surface is narrower than the other two, and nearly cylindrical. This last has a slight ridge running obliquely across it, from the outer side of the upper end of the bone to about one third of its length downwards. A little below this we observe a passage for the medullary vessels, which is pretty considerable, and slants obliquely downwards. Of the three angles which separate these surfaces, the anterior one, from its sharpness, is called the *spine* or *shin.* This ridge is not straight, but describes a figure like an italic *f*, turning first inwards, then outwards, and lastly, inwards again. The external angle is more rounded, and serves for the attachment of the interosseous ligament; and the internal one is more rounded still by the pressure of muscles.

The tibia enlarges again a little at its lower extremity, and terminates in a pretty deep cavity, by which it is articulated with the uppermost bone of the foot. This cavity, in the recent subject, is lined with cartilage. Its internal side is formed into a considerable process, called *malleolus internus*, which, in its situation, resembles the styloid process of the radius. This

process is broad, and of considerable thickness. At its back part we find a groove, lined with a thin layer of cartilage, in which slide the tendons of the flexor digitorum longus, and of the tibialus posticus; and a little behind this is a smaller groove, for the tendon of the flexor longus pollicis. On the side opposite to the malleolus internus, the cavity is interrupted, and immediately above it is a rough triangular depression, which is furnished with cartilage, and receives the lower end of the fibula.

The whole of this lower extremity of the bone seems to be turned somewhat outwards, so that the malleolus internus is situated more forwards than the inner border of the upper extremity of the bone.

In the fœtus, both ends of the tibia are cartilaginous, and become afterwards epiphyses.

TI'BIAL. (*Tibialis*; from *tibia*, the bone of the leg so called.) Belonging to the tibia.

TIBIAL ARTERIES. *Arteriæ tibiales.* The two principal branches of the popliteal artery: the one proceeds forwards, and is called the *anterior tibial*; the other backwards, and is called the *posterior tibial*, of which the external tibial, the fibular, the external and internal plantar, and the plantar arch, are branches.

Tibialis. See *Tibial.*

TIBIA'LIS ANTI'CUS. A flexor muscle of the foot, situated on the leg, which bends the foot by drawing it upwards, and at the same time turns the toes inwards.

Tibialis gracilis. See *Plantaris.*

TIBIA'LIS POSTI'CUS. A flexor muscle of the foot, situated on the leg, which extends the foot, and turns the toes inwards.

TIC DOULOUREUX. A French term signifying a painful spasm. It is applied to facial neuralgia. See *Neuralgia.*

Tick. See *Acarus.*

Tick, domestic. See *Acarus domesticus.*

Tick, harvest. See *Acarus.*

Tick, itch. See *Acarus scabiei.*

TIFACOUM. Quicksilver. — *Ruland.*

Tiglia grana. See *Croton tiglium.*

TILBURY. A small town in Essex, celebrated for its fort. A mineral water is found at West Tilbury. It is aperient and chalybeate, but is now seldom used.

TI'LIA. (*a*, *æ*. f. Πτελεα, *ulmus*, the elm-tree.) 1. A genus of plants in the Linnæan system. Class, *Polyandria*; Order, *Monogynia.*

2. The pharmacopœial name of the lime, or linden-tree. See *Tilia europæa.*

TILIA EUROPÆA. The systematic name of the lime-tree. The flowers of this tree are supposed to possess anodyne and antispasmodic virtues. They have a moderately strong smell, in which their virtue seems to consist, and abound with a strong mucilage. They are in high esteem in France. See *Tilia.*

Tilli grana. See *Croton tiglium.*

TI'LMUS. (From τιλλω, to pluck.) Floccilation, or picking of bed-clothes. See *Carphologia.*

TIMAC. The name of a root imported from the East Indies, which is said to possess diuretic virtues, and therefore exhibited in dropsies. The plant is thought to be the *Cissampelos caapeba.* See *Cissampelos caapeba.*

TIN. *Stannum. Jupiter* of the alchemists. It has been much doubted whether this metal is found native. The *native oxide of tin*, or *tin stone*, occurs both massive and crystallised. The *wood tin ore* is a variety of the native oxide, termed so from its fibrous texture. This variety has hitherto been found only in Cornwall. Tin is also found mineralised by sulphur, associated always with a portion of copper, and often of iron. This ore is called *tin pyrites.* Its colour is yellowish grey. It has a metallic lustre, and a fibrous or lamellated texture: sometimes it exhibits prismatic colours. Tin is comparatively a rare metal, as it is not found in great quantity any where but in Cornwall or Devonshire; though it is likewise met with in the mines of Bohemia, Saxony, the island of Banca, the peninsula of Malacca, and in the East Indies.

Tin is a metal of a yellowish white colour, considerably harder than lead, scarcely at all sonorous, very malleable, though not very tenacious. Under the hammer it is extended into leaves, called tinfoil, which are about one thousandth of an inch thick, and might easily be beaten to less than half that thickness, if the purposes of trade required it. Its specific gravity is 7·29. It melts at about the 442° of Fahrenheit's thermometer; and by a continuance of the heat it is slowly converted into a white powder by oxidation. Like lead, it is brittle when heated almost to fusion, and exhibits a grained or fibrous texture, if broken by the blow of a hammer. It may also be granulated by agitation at the time of its transition from the fluid to the solid state. The oxide of tin resists fusion more strongly than that of any other metal; from which property it is useful to form an opake white enamel when mixed with pure glass in fusion. The brightness of its surface, when scraped, soon goes off by exposure to the air; but it is not subject to rust or corrosion by exposure to the weather.

To obtain pure tin, the metal should be boiled in nitric acid, and the oxide which falls down reduced by heat, in contact with charcoal, in a covered crucible.

There are three definite combinations of tin and oxygen: —

1. The *protoxide*, which is grey.

2. The *sesquioxide*, distinguishable from the protoxide by its solubility in ammonia, and from the peroxide by its giving a purple precipitate with perchloride of gold.

3. The *peroxide*, which is white.

There are two *chlorides* and three *sulphurets* of tin.

The sulphuric, nitric, muriatic acids, and aqua regia, consisting of two parts nitric and one muriatic acid, all act on this metal; the acetic scarcely at all. The operation of other acids upon this metal has been little inquired into.

If small pieces of phosphorus be thrown on tin in fusion, it will take up from fifteen to twenty per cent., and form a silvery white phosphuret.

Tin unites with bismuth by fusion, and becomes harder and more brittle in proportion to the quantity of that metal added. With nickel

it forms a white brilliant mass. It cannot easily be united in the direct way with arsenic, on account of the volatility of this metal. Cobalt unites with tin by fusion, and forms a grained mixture of a colour slightly inclining to violet. Zinc unites very well with tin, increasing its hardness, and diminishing its ductility, in proportion as the quantity of zinc is greater. This is one of the principal additions used in making pewter, which consists for the most part of tin.

Antimony forms a very brittle hard mixture with tin. Tungsten, fused with twice its weight of tin, affords a brown spongy mass, which is somewhat ductile.

The uses of tin are very numerous. It is seldom used in the cure of diseases: the filings, however, have been used as a vermifuge.

TI'NCA. (*a*, *æ*. f.; *quasi tincta:* so called because it appears as if it were dyed.) The tench. See *Tench*.

Tincæ os. (So called from its resemblance to a tench's mouth.) The mouth of the uterus.

TINCAL. Crude borax, as it is imported from the East Indies in yellow greasy crystals. See *Sodæ biboras*.

Tinckling, metallic. See *Metallic tinckling*, in the *Supplement*.

TINCTO'RIUS. (From *tingo*, to dye.) Appertaining to the art of the dyer. Applied as a trivial name to plants, as *genista tinctoria*.

TINCTU'RA. (*a*, *æ*. f.; from *tingo*, to dye.) A tincture. A solution of any substance in spirit of wine. Rectified spirit of wine is the direct menstruum of the resins, and essential oils of vegetables, and totally extracts these active principles from several vegetable matters, which yield them to water not at all, or only in part. It dissolves likewise the sweet saccharine matter of vegetables, and generally those parts of animal bodies in which their peculiar smell and taste reside.

The virtues of many vegetables are extracted almost equally by water and rectified spirit; but in the watery and spirituous tinctures of them there is this difference, that the active parts in the watery extractions are blended with a large proportion of inert gummy matter, on which their solubility in this menstruum in a great measure depends, while rectified spirit extracts them almost pure from gum. Hence, when the spirituous tinctures are mixed with watery liquors, a part of what the spirit had taken up from the subject generally separates and subsides, on account of its having been freed from that matter, which, being blended with it in the original vegetable, made it soluble in water. This, however, is not universal, for the active parts of some vegetables, when extracted by rectified spirits, are not precipitated by water, being almost soluble in both menstrua.

Rectified spirit may be tinged by vegetables of all colours, except blue. The leaves of plants, in general, will give out little of their natural colour to watery liquors, but communicate to spirit the whole of their green tincture, which for the most part proves elegant, though not very durable.

Fixed alkaline salts deepen the colour of spirituous tinctures; and hence they have been supposed to promote the dissolving power of the menstruum, though this does not appear from experience. In the trials which have been made, no more was found to be taken up in the deep-coloured tinctures than in the paler ones, and often not so much. If the alkali be added after the extraction of the tincture, it will heighten the colour as much as when mixed with the ingredients at first. The addition of these salts in making tinctures is not only needless but prejudicial, as they generally injure the flavour of aromatics, and superadd a quality sometimes contrary to the intention of the medicine.

Volatile alkaline salts, in many cases, promote the action of the spirits. Acids generally weaken it; unless when the acid has been previously combined with the vinous spirit into a compound of new qualities, called dulcified spirit.

Tinctura aloes. Tincture of aloes. Take of aloes powdered, an ounce; extract of liquorice, three ounces; distilled water, a pint and a half; rectified spirit, half a pint: macerate for fourteen days, and strain. This preparation possesses stomachic and purgative qualities, but should never be given where there is a tendency to hæmorrhoids. In chlorotic cases, and amenorrhœa, it is preferred to other purges. The dose is from half to a whole fluid ounce.

Tinctura aloes composita. Compound tincture of aloes; formerly callad *elixir aloes*, and *elixir proprietatis*. Take of aloes powdered, four ounces; saffron, two ounces; tincture of myrrh, two pints: macerate for fourteen days, and strain. A more stimulating compound than the former. It is a useful application to old indolent ulcers. The dose is from half a fluid drachm to two.

Tinctura aloes vitriolata. With the bitter infusion, a drachm or two of this elegant tincture is extremely serviceable against gouty and rheumatic affections of the stomach and bowels, and also in the weaknesses of those organs which frequently attend old age.

Tinctura ammoniæ composita. Take of mastich, two drachms; rectified spirit, nine fluid drachms; oil of lavender, fourteen minims; oil of amber, four minims; strong solution of ammonia, a pint: macerate the mastich in the spirit, that it may be dissolved, and pour off the defecated tincture, then add the other ingredients and shake them altogether. This preparation of the present London Pharmacopœia corresponds nearly with the *spiritus ammoniæ succinatus* of the former one.

Tinctura assafœtidæ. Tincture of assafœtida; formerly known by the name of *tinctura fœtida*. Take of assafœtida, five ounces; rectified spirit, two pints: macerate for fourteen days, and strain. Diluted with water, this is mostly given in all kinds of fits by the vulgar. It is a useful preparation as an antispasmodic, especially in conjunction with sulphate of zinc. The dose is from half a fluid drachm to two drachms.

Tinctura aurantii. Tincture of orange-peel; formerly *tinctura corticis aurantii*. Take

of fresh orange-peel, three ounces and a half; proof spirit, two pints: macerate for fourteen days, and strain. A mild and pleasant stomachic bitter.

Tinctura balsami tolutani. Tincture of balsam of tolu. Take of balsam of tolu, an ounce and a half; rectified spirit, a pound: digest until the balsam be dissolved, and strain. This is used chiefly for making the syrup of tolu.

Tinctura benzoini composita. *Tinctura benzoes composita, Balsamum traumaticum.* Compound tincture of benzoin. Friars' balsam. Take of benzoin, three ounces and a half; storax balsam, strained, two ounces and a half; balsam of tolu, ten drachms; aloes, five drachms, rectified spirit, two pints: macerate for fourteen days, and strain. This tincture is more generally applied externally to ulcers and wounds than given internally, though possessing expectorant, antispasmodic, and stimulating powers. Against coughs, spasmodic affections of the stomach and bowels, and diarrhœa, produced by ulcerations of those parts, it is a very excellent medicine. The dose, when given internally, is from half a fluid drachm to two.

Tinctura calumbæ. *Tinctura columbæ.* Tincture of calumba. Take of calumba root, sliced, three ounces, proof spirit, two pints: macerate for fourteen days, and strain. This tincture contains the active part of the root, and is generally given with the infusion of it, as a stomachic and astringent. The dose is from one to three drachms.

Tinctura camphoræ. This is the *spiritus camphoræ* of the former London Pharmacopœia.

Tinctura camphoræ composita. Compound tincture of camphire; formerly called *tinctura opii camphorata*, and *elixir paregoricum*. Take of camphire, two scruples and a half; opium, dried and powdered, benzoic acid, of each seventy-two grains; oil of anise, a fluid drachm; proof spirit, two pints: macerate for fourteen days, and strain. This is a useful diaphoretic anodyne, and is much used in catarrhal affections. The dose is from a drachm to half an ounce.

Tinctura cantharidis. Tincture of blistering fly: formerly called *tinctura lyttæ*, and *tinctura cantharidum*. Take of blistering flies, bruised, four drachms; proof spirit, two pints: macerate for fourteen days, and strain. This is a very acrid, diuretic, and stimulating preparation, which should always be administered with great caution. For its properties, see *Cantharis vesicatories*.

Tinctura capsici. Tincture of capsicum. Take of capsicum, bruised, ten drachms; proof spirit, two pints: macerate for fourteen days, and strain. See *Capsicum annuum*.

Tinctura cardamomi. Tincture of cardamom. Take of cardamom seeds, bruised, three ounces and a half; proof spirit, two pints: macerate for fourteen days, and strain. A powerful stimulating carminative. In spasm of the stomach an ounce, with some other diluted stimulant, is given with advantage. The dose may vary according to circumstances, from half a drachm to an ounce and upwards.

Tinctura cardamomi composita. Compound tincture of cardamom; formerly called *tinctura stomachica*. Take of cardamom seeds, caraway seeds, of each, powdered, two drachms and a half; cochineal, powdered, a drachm; cinnamon bark, bruised, five drachms; raisins, stoned, five ounces; proof spirit, two pints: macerate for fourteen days, and strain. A useful and elegant carminative and cordial. The dose from half a fluid drachm to half a fluid ounce.

Tinctura cascarillæ. Tincture of cascarilla. Take of cascarilla bark, powdered, five ounces; proof spirit, two pints: macerate for fourteen days, and strain. A stimulating aromatic tonic, that may be exhibited in debility of the bowels and stomach, and in those cases of fever in which the Peruvian bark proves purgative. The dose from half a drachm to two drachms.

Tinctura castorei. Tincture of castor. Take of castor, powdered, two ounces and a half; rectified spirit, two pints: macerate for seven days, and strain. A powerful stimulant and antispasmodic, mostly exhibited in hysterical affections in a dilute form. The dose is from half a fluid drachm to two.

Tinctura catechu. Tincture of catechu; formerly known by the name *tinctura japonica*. Take of extract of catechu, three ounces and a half; cinnamon bark, bruised, two ounces and a half; proof spirit, two pints: macerate for fourteen days, and strain. An aromatic astringent, mostly given in protracted diarrhœa. The dose is from half a fluid drachm to two.

Tinctura cinchonæ. Tincture of cinchona; formerly known by the name of *tinctura corticis peruviani simplex*. Take of heart-leaved cinchona bark, powdered, eight ounces; proof spirit, two pints: macerate for fourteen days, and strain. The dose is from a fluid drachm to half a fluid ounce. For its virtues, see *Cinchona*.

Tinctura cinchonæ ammoniata. Ammoniated tincture of cinchona. Volatile tincture of bark. Take of lance-leaved cinchona bark, powdered, four ounces; aromatic spirit of ammonia, two pints: macerate for ten days, and strain.

Tinctura cinchonæ composita. Compound tincture of cinchona. Take of lance-leaved cinchona bark, powdered, four ounces: orange-peel, dried, three ounces; serpentary root, bruised, six drachms; saffron, two drachms; cochineal, a drachm; proof spirit, two pints: macerate for fourteen days, and strain. The dose is from one fluid drachm to half a fluid ounce. For its virtues, see *Cinchona*.

Tinctura cinnamomi. Tincture of cinnamon; formerly called *aqua cinnamomi fortis*. Take of cinnamon bark, bruised, three ounces and a half; proof spirit, two pints: macerate for fourteen days, and strain. The dose is from a fluid drachm to three or more.

Tinctura cinnamomi composita. Compound tincture of cinnamon; formerly called *tinctura aromatica*. Take of cinnamon bark, bruised, an ounce; cardamon seeds, bruised, half an ounce; long pepper, powdered, ginger root, sliced, of each two drachms and a half; proof spirit, two pints: macerate for fourteen days, and strain.

The dose is from half a fluid drachm to two or more.

Tinctura colchici. Tincture of colchicum. Take of the seeds of colchicum, five ounces; proof spirit, two pints: macerate for fourteen days, and strain. The virtues of this preparation are similar to those of the wine of colchicum. Dose from ♏ xx. to ʒ j.

Tinctura colchici composita. *Spiritus colchici ammoniatus* of the last London Pharmacopœia. Compound tincture of colchicum. Take of colchicum seeds, bruised, five ounces; aromatic spirit of ammonia, two pints: macerate for fourteen days, and strain. By this preparation the action of the colchicum is determined to the kidneys, and a diuretic effect combined with its ordinary operation. Dose half a drachm to a drachm.

Tinctura conii. Tincture of hemlock. Take of the dried leaves of hemlock, five ounces; cardamom seeds, bruised, an ounce; proof spirit, two pints. Digest for fourteen days, and strain. This tincture possesses all the active properties of the hemlock. Dose from half a drachm to a drachm.

Tinctura cubebæ. Tincture of cubebs. Take of cubebs, bruised, five ounces; rectified spirit, two pints: macerate for fourteen days, and strain. A weak tincture, which to produce any effect, should be given in full doses, as two or three drachms.

Tinctura digitalis. Tincture of fox-glove. Take of fox-glove leaves, dried, four ounces; proof spirit, two pints: macerate for fourteen days, and strain. This tincture possesses the properties of the plant in a convenient, uniform, and permanent form. It is a saturated tincture, and in the same proportions has been long used in general practice. The dose is from ten to forty minims. For its virtues, see *Digitalis*.

Tinctura ferri acetatis. This preparation is directed in the Dublin Pharmacopœia, with acetate of potash, two parts; sulphate of iron, one part; and rectified spirit, twenty-six parts. It is a mild chalybeate. Dose from ♏ x. to ʒ j.

Tinctura ferri ammoniati. See *Tinctura ferri ammonio-chloridi.*

Tinctura ferri ammonio-chloridi. Tincture of ammonio-chloride of iron; formerly called *tinctura ferri ammoniati*, *tinctura ferri ammoniacalis*, *tinctura florum martialium*, and *tinctura martis Mynsichti*. Take of ammonio-chloride of iron, four ounces; proof spirit, a pint: digest and strain. This is a most excellent chalybeate in all atonic affections, and may be given with cinchona in the cure of dropsical and other cachectic diseases. The dose is from half a fluid drachm to two.

Tinctura ferri muriatis. See *Tinctura ferri ammonio-chloridi.*

Tinctura ferri sesqui-chloridi. Tincture of muriate of iron: formerly called *tinctura ferri muriatis*, *tinctura martis in spiritu salis*, and *tinctura martis cum spiritu salis*; and lately known by the name of *tinctura ferri muriati*. Take of sesquioxide of iron, six ounces; muriatic acid, a pint; rectified spirit, three pints. Pour the acid upon the subcarbonate of iron in a glass vessel, and shake it occasionally for three days; then add the spirit, and strain. Cline strongly recommends this in ischuria, and many diseases of the kidneys and urinary passages. The dose is from ten to twenty drops. It is a good chalybeate, and serviceable against most diseases of debility without fever.

Tinctura gallæ. Tincture of galls. Take of galls, powdered, five ounces; proof spirit, two pints: macerate for fourteen days, and strain. This tincture contains all the virtues of the galls. Dose from ʒ ss. to ʒ ij. See *Quercus*.

Tinctura gentianæ composita. Compound tincture of gentian; formerly called *tinctura amara*. Take of gentian root, sliced, two ounces and a half; orange-peel, dried, ten drachms; cardamom seeds, bruised, five drachms; proof spirit, two pints: macerate for fourteen days, with a gentle heat, and strain. The dose is from one fluid drachm to two. For its virtues, see *Gentiana*.

Tinctura guai'aci. Tincture of guaiacum. Take of guaiacum resin, powdered, seven ounces; rectified spirit, two pints: macerate for fourteen days, and strain. This tincture possesses all the active properties of guaiacum. The dose is from one fluid drachm to two. For its virtues, see *Guaiacum*.

Tinctura guaiaci composita. *Tinctura guaiaci ammoniata*. Ammoniated tincture of guaiacum; formerly called *tinctura guaiacina volatilis*. Take of guaiacum resin, powdered, seven ounces; aromatic spirit of ammonia, two pints: macerate for fourteen days, and strain. The dose is from one fluid drachm to two.

Tinctura helle'bori. *Tinctura hellebori nigri*. Tincture of black hellebore; formerly called *tinctura melampodii*. Take of black hellebore root, sliced, five ounces; proof spirit, two pints: macerate for fourteen days, and strain. The dose is from half to a whole fluid drachm. For its virtues, see *Helleborus niger*.

Tinctura humuli. See *Tinctura lupuli.*

Tinctura hyoscy'ami. Tincture of henbane. Take of henbane leaves, dried, five ounces; proof spirit, two pints: macerate for fourteen days, and strain. That the henbane itself is narcotic is abundantly proved; that the same power is also found in its tincture is also certain; but to produce the same effects requires a much larger dose, as from one to two drachms or more. For the virtues, see *Hyoscyamus niger*.

Tinctura iodi'nii composita. Compound tincture of iodine. Take of iodine, an ounce; iodide of potassium, two ounces; rectified spirit, two pints: macerate until they are dissolved, and strain. A convenient formula for administering iodine. Dose ten minims, gradually increased to sixty.

Tinctura jalapæ. Tincture of jalap; formerly called *tinctura jalapii*. Take of jalap root, powdered, ten ounces; proof spirit, two pints: macerate for fourteen days, with a gentle heat, and strain. The dose is from one fluid drachm to half a fluid ounce. For its virtues, see *Convolvulus jalapa*.

Tinctura kino. Tincture of kino. Take of kino, powdered, three ounces and a half;

proof spirit, two pints: macerate for fourteen days, and strain. All the astringency of kino is possessed by this preparation. The dose is from half a fluid drachm to two. See *Kino.*

Tinctura lupuli. *Tinctura humuli.* Tincture of hops. Take of hops, six ounces; proof spirit, two pints: macerate for fourteen days, and strain. Dose ʒj. to ʒij. or more. For its virtues, see *Humulus lupulus.*

Tinctura lyttæ. See *Tinctura cantharidis.*

Tinctura myrrhæ. Tincture of myrrh. Take of myrrh, bruised, three ounces; rectified spirit, two pints: macerate for fourteen days, and strain. The dose is from half to a whole fluid drachm. For its virtues, see *Myrrha.*

Tinctura opii. Tincture of opium. Laudanum. Take of hard opium, powdered, three ounces; proof spirit, two pints: macerate for fourteen days, and strain. This is the most common form in which opium is administered, and possesses all the active properties of the drug.

The tincture of opium of the London Pharmacopœia of 1836 is considerably stronger than that of its predecessor. Of the present preparation nineteen drops are equal to about a grain of opium. Such unnecessary and whimsical changes in the constitution of very active medicines in common use cannot be too strongly reprobated. The ordinary dose of tincture of opium is from ♏ x. to l.

Tinctura rhei. Tincture of rhubarb; formerly known by the names of *tinctura rhabarbari*, and *tinctura rhabarbari spirituosa.* Take of rhubarb root, sliced, two ounces; cardamom seeds, bruised, half an ounce; saffron, two drachms; proof spirit, two pints: macerate for fourteen days, with a gentle heat, and strain. The dose is from half a fluid ounce to one and a half. For its virtues, see *Rheum.*

Tinctura rhei composita. Compound tincture of rhubarb; formerly called *tinctura rhabarbari composita.* Take of rhubarb root, sliced, two ounces and a half; liquorice root, bruised, six drachms; ginger root, sliced, saffron, of each three drachms; proof spirit, two pints: macerate for fourteen days, with a gentle heat, and strain. This is a mild stomachic aperient. The dose is from half a fluid ounce to one and a half.

Tinctura scillæ. Tincture of squill. Take of squill root, fresh dried, five ounces; proof spirit, two pints: macerate for fourteen days, and strain. The virtues of the squill reside in the tincture, which is administered in doses of from ten drops to a fluid drachm. See *Scilla.*

Tinctura sennæ composita. *Tinctura sennæ.* Tincture of senna; formerly called *elixir salutis.* Take of senna leaves, three ounces and a half; caraway seeds, bruised, three drachms and a half; cardamom seeds, bruised, a drachm; raisins, stoned, five ounces; proof spirit, two pints: macerate for fourteen days, and strain. A carminative, aperient, and purgative, in doses from two fluid drachms to a fluid ounce. See *Senna.*

Tinctura serpentariæ. Tincture of serpentary; formerly called *tinctura serpentariæ virginianæ.* Take of serpentary root, three ounces and a half; proof spirit, two pints: macerate for fourteen days, and strain. This tincture possesses, in addition to the virtues of the spirit, those of the serpentaria. The dose is from half a fluid drachm to two. See *Aristolochia serpentaria.*

Tinctura valerianæ. Tincture of valerian; formerly called *tinctura valerianæ simplex.* Take of valerian root, five ounces; proof spirit, two pints: macerate for fourteen days, and strain. A useful antispasmodic in conjunction with others. The dose from half a fluid drachm to two. See *Valeriana.*

Tinctura valerianæ composita. *Tinctura valeriana ammoniata.* Ammoniated tincture of valerian; formerly called *tinctura valerianæ volatilis.* Take of valerian root five ounces; aromatic spirit of ammonia, two pints: macerate for fourteen days, and strain. A strong antispasmodic and stimulating tincture. The dose is from half a fluid drachm to two.

Tinctura vera'tri. A very active alterative, recommended in the cure of epilepsy and cutaneous eruptions. Its administration requires great caution, the white hellebore being a powerful poison.

Tinctura zingiberis. Tincture of ginger. Take of ginger-root, sliced, two ounces and a half; proof spirit, two pints: macerate for fourteen days, and strain. A stimulating carminative. The dose is from a fluid drachm to three.

Tincture. See *Tinctura.*

Ti'nea. (*a*, *æ*. f.; from *teneo*, to hold.) *Tinea capitis.* The scald-head. See *Porrigo.*

Tinnitus aurium. Ringing in the ears. A common symptom in many diseases.

TISSUE. A term introduced by the French anatomists to express the textures which compose the different organs of animals. The word has been improperly adopted into our own language.

TITA'NIC. (*Titanicus*; from *titanium*, its base.) Appertaining to titanium.

Titanic acid. *Acidum titanicum.* The peroxide of titanium, which acts on alkalis as an acid.

TITA'NIUM. (*um*, *ii*. n.) The name of a metal which exists in the state of an oxide in the minerals called *tetanite* and *menachanite.* In *tetanite*, the oxide is nearly pure; in *menachanite*, so called, because it is found in the bed of a stream at Menachan, in Cornwall, the oxide of turanium is blended with oxide of iron. It exists also in several other minerals. There appear to be two oxides of this metal, a *protoxide* and a *peroxide*; the constitution of the former is yet imperfectly known; the latter has acid properties.

Tithy'malus. (*us*, *i*. m.; from τιθος, a dug, and μαλος, tender; so called from its smooth leaves and milky juice.) Cypress spurge. Poor man's rhubarb. Once in use as a purgative. See *Euphorbia cyparissias.*

Tithymalus cyparissius. See *Euphorbia cyparissias.*

Tithymalus paralios. See *Euphorbia paralias.*

Tithymelæa. See *Daphne.*

Titi'llicum. (*um*, *i*. n.; from *titillo*, to tickle: so called from its being easily tickled.) The arm-pit.

Titubа'tio. (*o*, *onis*, f.; from *titubo*, to stagger

or waver.) Restlessness, with an inclination to constant change of position. The fidgets.

Toad-flax. See *Antirrhinum.*

Tobacco. See *Nicotiana.*

Tobacco, English. See *Nicotiana rustica.*

Tobacco, Virginian. See *Nicotiana.*

TOE. *Digitus pedis.* The toes are terminated by nails, are covered by the common integuments, under which the vessels and tendons run, protected by their ligaments, which extend or bend them, to be inserted into their respective phalanges. Each toe consists of three distinct bones disposed in rows, called phalanges, or ranks of the toes. The great toe has but two phalanges; the others have three ranks of bones, which have nothing particular, only the joints are made round and free, formed by a round head on one bone, and by a pretty deep hollow for receiving it, in the one above it.

Toffania aqua. See *Aquetta.*

Tolu balsam. See *Toluifera balsamum.*

TOLUI'FERA. (*a*, *æ.* f.; so called because it produces the balsam of Peru.) A genus of plants in the Linnæan system. Class, *Decandria;* Order, *Monogynia.*

TOLUIFERA BALSAMUM. The systematic name of the tree which affords the Tolu balsam. *Balsamum Tolutanum.* Balsam of Tolu. It grows in South America, in the province of Tolu, behind Carthagena, whence we are supplied with the balsam, which is brought to us in little gourd-shells. The balsam is obtained by making incisions into the bark of the tree, and is collected in spoons, which are made of black wax, from which it is poured into proper vessels. It thickens, and in time becomes concrete: it has a fragrant odour, and a warm sweetish taste. It dissolves entirely in alkohol, and communicates its odour and taste to water by boiling. It contains acid of benzoin. This is the mildest of all the balsams. It has been used as an expectorant; but its powers are very inconsiderable, and it is at present employed principally on account of its flavour, somewhat resembling that of lemons. It is directed by the pharmacopœias, in the *syrupus tolutanus*, and *tinctura tolutana.*

Tolutanum balsamum. See *Toluifera balsamum.*

TOMA'TUM. (*um*, *i.* n.) The tomato or love-apple. See *Solanum lycopersicum.*

TOMBAC. A white alloy of copper with arsenic.

TOMEI'UM. (From τεμνω, to cut.) An incision-knife.

TOMENTO'SUS. Downy; woolly; cottony. Applied to stems, leaves, &c.; as the stem of the *Geranium rotundifolium.*

TOME'NTUM. (*um*, *i.* n.; a flock of wool.) 1. In *Anatomy*, applied to the small vessels on the surface of the brain, which appear like wool.

2. In *Botany*, a species of pubescence, very soft to the touch, of a white or ferruginous colour, giving the surface a downy appearance, and so thick that they cannot be seen separately.

TOMENTUM CEREBRI. The small vessels that penetrate the cortical substance of the brain from the pia mater, which, when separated from the brain, and adhering to the pia mater, give it a flocky appearance.

TONGUE. *Lingua.* A soft fleshy viscus, very moveable in every direction, situated inferiorly in the cavity of the mouth, and constituting the organ of taste. It is divided into a base, body, and back, a superior and inferior surface, and two lateral parts. It is composed of muscular fibres, covered by a nervous membrane, on which are a great number of nervous papillæ, particularly at the apex and lateral parts; the rete mucosum, and epidermis. About a quarter of an inch from its base is a little round pit, called *foramen cæcum*, which seems to form a sort of reservoir for the contiguous mucous follicles. The papillæ of the tongue are distinguished into *lenticulares*, which are from ten to fifteen in number, and are situated near the base of the tongue; *capitatæ* or *fungiformes*, smaller and more numerous than the preceding, and situated towards the edges and tip of the tongue; *conicæ* or pyramidales, which are very numerous, and dispersed over the whole upper surface of the tongue; *filiformes*, which are few in number, and situated close to the tip of the tongue. The arteries of the tongue are branches of the ranine and labial. The veins empty themselves into the great linguals, which proceed to the external jugular. The nerves come from the eighth, ninth, and fifth pair. The use of this organ is for chewing, swallowing, sucking, and tasting. See also *Taste.*

Tongue-shaped. See *Lingulatus.*

TONE. (Τονος, from τεινω, to extend.) The natural and healthy tension of the muscular fibre.

TO'NIC. (*Tonicus.* Τονικος; from τεινω, to pull or draw.) A rigid contraction of the muscles, which lasts for some time without relaxation, is called a *tonic spasm.*

TO'NIC. (From τονοω, to strengthen.) Applied to that which increases the tone of the muscular fibre, and imparts vigour to the whole system. Tonics are divided into *mineral* and *vegetable.* The principal mineral tonics are iron, zinc, copper, arsenic, silver, bismuth, mercury, and the mineral acids. The vegetable tonics consist chiefly of the bitters: the aromatics also have a degree of tonic power.

TONI'CITY. The elasticity of living parts is so named by some writers.

TO'NSIL. (*Tonsilla*, *æ.* f.) *Amygdala. Tola. Toles. Tolles.* An oblong, sub-oval gland, situated on each side of the fauces, and opening into the cavity of the mouth by twelve or more large excretory ducts.

TONSILLI'TIS. (*is*, *idis.* f.; from *tonsilla*, the seat of the disease, and *itis*, which signifies inflammation.) This is described by Dr. Cullen, and other writers, as a species of sore throat, under the name of cynanche tonsillaris, and cynanche maligna. There are, therefore, two species of inflammation of the tonsils: the one is phlegmonoid, the other erythematous or erysipelatous: they are perfectly distinct diseases.

1. *Tonsillitis phlegmonoides.* This is the common quinsey, or inflammation of the cellular tissue of or about the tonsils. The com-

mon quinsey, or inflammatory sore throat, of most writers. It begins with a soreness or stiffness about one side of the throat; the swallowing becomes impeded; the mouth is clammy; and when the jaw is moved, or there is any attempt to swallow, there is a pain extending from the throat to the ear. As these symptoms come on, there is an accession of fever; a shivering often announces the disease: the pulse becomes frequent, the face flushed, and exacerbations of fever are established of an inflammatory character. As the local disease advances, the fever increases; deglutition becomes more difficult; the speech is obstructed; a great secretion of saliva or a salivation supervenes; and, if the inflammation be not resolved, which it seldom is, the part becomes more tumid, deglutition more impeded, the febrile symptoms exacerbate more violently: a tumour is felt in the gland, if the mouth can be opened so as to permit the finger to reach the gland; suppuration soon follows, and, though the patient be in the greatest misery from the symptoms already mentioned, the abscess bursts, and he is instantly relieved. In eight or ten cases suppuration results, and all inconvenience is soon removed: but it sometimes happens, that no sooner is one abscess burst, before the state of the opposite gland tells us that the same symptoms are to be encountered from inflammation there; which, in its turn, suppurates also. The suppuration occasionally extends round the pharynx, and a large quantity of pus evacuated, either by spontaneous rupture or by an opening from the lancet. This species of tonsillitis is produced by cold, and is a common disease in spring and autumn, and seldom attended with any danger.

The chief danger arising from this species of quinsey is, the inflammation occupying both tonsils, and proceeding to such a degree as to prevent a sufficient quantity of nourishment for the support of nature from being taken, or to occasion suffocation; but this seldom happens, and its usual termination is either in resolution or suppuration. It is never contagious, and mostly attacks the young and sanguine. It is apt to produce a disposition to return from slight causes.

At the very commencement, the inflammation is occasionally, though not often, resolved: to effect this, blood is seldom taken from the arm; but if the febrile and local symptoms are strongly marked, and the patient is young and robust, and there is no reason why blood should not be abstracted, recourse should be had to the lancet: leeches externally are proper. A purgative and antiphlogistic diet are required, with iced acidulated gargles, and such antifebrile remedies as are recommended against inflammation. Very many quinseys are resolved by the following: —

℞. Antimonii tartarisati, gr. vj.; sacchari purificati, ʒiij. Optimè in pulverem contere; dein divide in partes duodecim æquales: sumat unam in horas.

The patient is to be directed to put one of these powders into his mouth, and to let it dissolve in his saliva, and to swallow it; and to continue through the day, every hour or every two hours, keeping up a constant nausea or vomiting during that time.

It is during the inflammatory stage of quinsy that blisters are useful, and particularly so when there is external as well as internal swelling: blisters do no good when suppurative action has commenced. Writers mention danger of suffocation in some cases, and recourse to tracheotomy. There is occasionally danger of suffocation; but the surgeon is to open the abscess, and not the trachea.

When the abscess has burst, or the pus is evacuated, the after-treatment is very little required: detergent gargles and nourishment soon put all right again.

2. *Tonsillitis maligna.* This is the ulcerated, specky, malignant, putrid, gangrenous sore throat of authors. It is also called *angina maligna*, and *cynanche maligna.* Malignant sore throat prevailed as a very destructive epidemic in Spain and Italy at the beginning of the last century, and was described by some authors of those nations. In 1754 an excellent account of it was published in England by Dr. Fothergill, and another appeared soon after by Dr. Huxham. The inflammation is usually superficial on the membrane which covers the tonsils, and does not affect the cellular tissue beneath. No sooner does the inflammation take place, than it passes immediately into small ulcers, which have a varied appearance; being whitish, cineritious, brown, or black; of smaller or larger extent, sometimes the size of a lentil or pea, and sometimes much larger, mostly spreading so as to extend over the pharynx and the whole fauces, into the nostrils, and even around the glottis, and down the œsophagus. As these ulcerations increase, they have a sloughing appearance; and the membrane of the fauces is occasionally separated in large sloughs. The local affection is attended from its commencement with typhoid fever; the pulse is small, and rapid; the heat considerable; the prostration of strength great; and there is mostly some disturbance of the sensorium. The disease is highly contagious, and usually epidemic; and according to the nature of the epidemic, the character of the fever, and other circumstances, the danger is to be appreciated. A very frequent concomitant of the malignant, ulcerated sore throat is a scarlet eruption over the body, in a simple form, or with blotches of a scarlet colour, or petechiæ, or vibices. This mostly increases the danger, though very many fall victims to the malignant form of tonsillitis without any eruption on the skin. When attended with an eruption, malignant tonsillitis appears entirely similar to scarlet fever of a bad type; and, after much controversy, it is now generally agreed that malignant sore throat and scarlet fever are merely modifications of the same disease. See *Scarlatina.* Malignant tonsillitis is generally produced by a particular state of the atmosphere; hence it is mostly epidemic. The system under its influence generates more contagion; so that when it attacks one of a family, scarcely any escape its ravages.

When the local symptoms are mild, the fever

is seldom great, and the danger comparatively little: but when the ulcerations assume a sloughing character, spread rapidly, and the fever is high, with delirium, and more especially if, in addition to this, there be purple spots or gangrene, the danger is great indeed. The known nature of the disease, when epidemic, is also to be borne in mind: many are carried off, especially children, without any apparent malignancy of the symptoms; and in other epidemics the malignancy is obvious, and yet, under proper management, most recover.

In conducting the cure, cleanliness, pure air, and a free ventilation are here of the utmost importance, and especially the removing of all the excretions and cleansings of the fauces, which contain the contagion in its most active form. The remedies are similar to those recommended against typhus, which the fever of malignant tonsillitis is, and against gangrene. Many are fond of emetics in the beginning; but they more frequently increase the debility and disturb the sensorium than produce any good effect. The nitro-muriatic acid is here an excellent remedy, and possesses great advantages with children and youth, who cannot, perhaps, be prevailed on to take the other less palatable medicines.

R. Aquæ cinnamomi, f. ʒx.
Acidi muriatici,
Acidi nitrici, singulorum, ♏j.

Misce pro haustu, tertia, vel quarta, vel quinta quaque hora sumendo.

This is the dose for an adult.

All the acids are proper: the sulphuric, in the infusum rosæ compositum, is an excellent drink when more diluted; the citric acid is grateful in lemonade; and the tartaric in the drink called imperial. The subacid fruits, in their season, are also good assistants.

The antiseptic tonics are more powerful in destroying the fever and the disease than the former medicines, and in the more malignant forms are not to be forgotten. Cinchona, cascarilla, and columba are the best: their infusions and decoctions, and the sulphate of the first, may be made into mixtures, and acidulated with either of the acids.

When these are required, port wine is also, and is to be given freely, as being, perhaps, more efficacious. When wine, from any circumstance, does not agree, brandy should be substituted in a dilute form.

If the bowels, from the free use of acids, become loose, aromatics and astringents are proper, with spiced wine and cordials.

The local treatment consists in the use of stimulating gargles, especially of port wine, capsicum, or the mineral acids. In administration of these, the best rule is to proportion them to the effect they produce: their biting or stimulating the part is necessary; and, in some cases, half a fluid drachm of the tincture of Cayenne pepper will produce as much effect, in half a pint of dilute port wine or compound infusion of roses, as three times that quantity in others. The diet should consist of arrow-root, sago, gruel, and the like, with wine or brandy. Bottled porter, that gives off its carbonic acid gas freely, is a good medicine.

Tooth. See *Teeth.*

Tooth-ache. See *Odontalgia.*

Tooth-rash. See *Strophulus.*

Tooth-shape. See *Dentatus.*

TO'PHUS. (*us, i.* m. *Toph*, Hebrew.) 1. A toph, or soft swelling on a bone.
2. A concretion in the joints.
3. Gravel.

TO'PICAL. (*Topicus;* from τοπος, a place.) Medicines applied to a particular part are called *topical.*

TOPINA'RIA. A species of tumour under the scalp; the same as *talpa.*

TO'RCULAR. (From *torqueo*, to twist.) A press for wine, oil, or cider. The tourniquet. See *Tourniquet.*

TORCULAR HERO'PHILI. *Lechenon. Lenos.* The press of Herophilus. So named after Herophilus, who described it. The fourth sinus of the dura mater.

TORDY'LIUM. (*um, ii.* n.; *quasi tortilium;* from *torqueo*, to twist: so named from its tortuous branches, or from the neat orbicular figure of its seeds, which seem as if artificially wrought or turned.) A genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Digynia.*

TORDYLIUM OFFICINALE. The officinal *seseli creticum.* The seeds are said to be diuretic.

Tormentil. See *Tormentilla.*

TORMENTI'LLA. (*a, æ,* f.; from *tormentum*, pain: because it was supposed to relieve pain in the teeth.) 1. The name of a genus of plants in the Linnæan system. Class, *Icosandria;* Order, *Monogynia.*

2. The pharmacopœial name of the upright septfoil. See *Tormentilla erecta.*

TORMENTILLA ERECTA. The systematic name of the upright septfoil. *Heptaphyllum. Consolida rubra. Tormentilla—caule erecti usculo, foliis sessilibus,* of Linnæus. The root is the only part of the plant which is used medicinally: it has a strong styptic taste, but imparts no peculiar sapid flavour: it has been long held in estimation as a powerful astringent; and, as a proof of its efficacy in this way, it has been substituted for oak bark in the tanning of skins for leather. Tormentil is ordered in the *Pulvis cretæ compositus,* of the London Pharmacopœia.

TORME'NTUM. The ileac passion was so called from its severely painful nature. See *Ileac passion.*

TO'RMINA. (*Tormen, inis.* n.) Severe griping pains in the bowels.

TORO'SUS. Protuberant: applied to seed-vessels enlarged by the swelling of the enclosed seeds; as in the pods of the *Sinapis.*

Torpe'do. See *Raia torpedo.*

TO'RPOR. A numbness, or deficient sensation.

Torsk. See *Gadus ciliaris* and *brosme.*

TORTICO'LLIS. (*is, is.* m.; from *torqueo*, to twist, and *collum*, the neck.) The wry-neck. See *Wry-neck.*

TO'RTILIS. Twisted. Applied in *Natural History.*

TORTUO'SUS. Tortuous: twisted. Applied in *Natural History.*

Tortu'ra oris. A wry-mouth.

TORULO'SUS. Torulous. Bulged out at intervals, like a cord with several knots in it. Applied in *Botany* and *Zoology:* thus, the *Sinapis alba*, white mustard, has a torulous pod.

Tota bona. See *Chenopodium*.

TOUCH. *Tactus*. The sense by which we are enabled to know the properties of bodies; and as it is less subject to deception than the other senses, enabling us in certain cases to clear up errors into which the others have led us, it has been considered the first, and the most excellent of all the senses; but several of the advantages which have been attributed to it by physiologists and metaphysicians should be considerably limited.

Tact should be distinguished from touch. *Tact* is, with some few exceptions, generally diffused through all our organs, and particularly over the cutaneous and mucous surfaces. It exists in all animals; whilst touch is exerted evidently only by parts that are intended particularly for this use. It does not exist in all animals, and it is nothing else but *tact* united to muscular contractions directed by the will.

In the exercise of *tact*, we may be considered as passive, whilst we are essentially active in the exercise of *touch*.

Physical properties of bodies which employ the action of touch. — Almost all the physical properties of bodies are susceptible of acting upon the organs of touch: form, dimensions, different degrees of consistence, weight, temperature, locomotion, vibration, &c., are all so many circumstances that are exactly appreciated by the touch.

The organs destined to touch do not alone exercise this function; so that in this respect the touch differs much from the other senses. As in most cases it is the skin which receives the tactile impressions produced by the bodies which surround us, it is necessary to say something of its structure.

The skin forms the envelope of the body: it is lost in the mucous membranes at the entrance of all the cavities; but it is improper to say that these membranes are a continuation of it.

The skin is formed principally by the *cutis vera*, a fibrous layer of various thickness, according to the part which it covers: it adheres by a cellular tissue, more or less firm; at other times by fibrous attachments. The *cutis* is almost always separated from the subjacent parts by a layer of a greater or less thickness, which is of use in the exercise of touch.

The external side of the *cutis vera* is covered by the epidermis, a solid matter secreted by the skin. We ought not to consider the epidermis as a membrane: it is a homogeneous layer, adherent by its internal face to the *chorion*, and full of a great number of holes, of which the one sort are for the passage of the air, and the other for that of cutaneous perspiration: they serve at the same time for the absorption which takes place by the skin. These last are called the pores of the skin.

It is necessary to notice, with regard to the epidermis, that it is void of feeling; that it possesses none of the properties of life; that it is not subject to putrefaction; that it wears and is renewed continually; that its thickness augments or lessens as it may be necessary: it is even said to be proof to the action of the digestive organs.

The connexion of the epidermis to the *cutis vera* is very close; and yet it cannot be doubted that there is a particular layer between these two parts, in which certain particular phenomena take place. The organisation of this layer is yet little known. Malpighi believed it to be formed of a particular mucus, the existence of which has been long admitted, and which bore the name of the corpus mucosum of Malpighi. Other authors have considered it, more justly, as a vascular network. Gall makes it similar to the grey matter which is seen in many parts of the brain.

Gautier, in examining attentively the external surface of the true skin, has noticed some small reddish projections, disposed in pairs: they are easily perceived when the skin is laid bare by a blister. These little bodies are regularly disposed upon the palm of the hand, and on the sole of the foot. They are sensible, and are reproduced when they have been torn out. They appear to be essentially vascular. These bodies, without being understood, have been long called the *papillæ* of the skin. The epidermis is pierced by little holes, opposite their tops, through which small drops of sweat are seen to issue, when the skin is exposed to an elevated temperature. The skin contains a great number of sebaceous follicles: it receives a great number of vessels and nerves, particularly at the points where the sense of touch is more immediately exercised. The mode in which the nerves are terminated in the skin is totally unknown: all that has been said of the cutaneous nervous papillæ is entirely hypothetical.

The exercise of tact and of touch is facilitated by the thinness of the *cutis vera*, by a gentle elevation of temperature, by an abundant cutaneous perspiration, as well as by a certain thickness and flexibility of the epidermis: when the contrary dispositions exist, the tact and the touch are always more or less imperfect.

Mechanism of Tact. — The mechanism of tact is extremely simple: it is sufficient that bodies be in contact with the skin to furnish us with *data*, more or less exact, of their tactile properties. By tact we judge particularly of the temperature. When bodies deprive us of caloric, we call them cold; when they yield it to us, we say they are hot; and according to the quantity of caloric which they give or take, we determine their different degrees of heat or cold. The notions that we have of temperature are, nevertheless, far from being exactly in relation to the quantity of caloric that bodies yield to us, or take from us; we join with it unawares a comparison with the temperature of the atmosphere, in such a manner that a body colder than ours, but hotter than the atmosphere, appears hot, though it really deprive us of caloric when we touch it. On this account, places which have a uniform temperature, such as cellars or wells, appear cold in summer, and hot in winter. The

capacity also of bodies for caloric has a great influence upon us with regard to temperature: as an example of this we have only to notice the great difference of sensation produced by iron and wood, though the temperature of both be the same.

A body which is sufficiently hot to cause a chemical decomposition of our organs, produces the sensation of burning. A body whose temperature is so low as to absorb quickly a great portion of the caloric of any part, produces a sensation of the same sort nearly: this may be proved in touching frozen mercury.

The bodies which have a chemical action upon the epidermis, those that dissolve it, as the caustic alkalies, and concentrated acids, produce an impression which is easy to be recognised, and by which these bodies may be known.

Every part of the skin is not endowed with the same sensibility; so that the same body applied to different points of the skin in succession, will produce a series of different impressions.

The mucous membranes possess great delicacy of tact. Every one knows the great sensibility of the lips, the tongue, of the conjunctiva, the pituitary membrane, of the mucous membrane, of the trachea, of the urethra, of the vagina, &c. The first contact of bodies, which are not destined naturally to touch these membranes, is painful at first, but this soon wears off.

Mechanism of Touch. — In man the hand is the principal organ of touch: all the most suitable circumstances are united in it. The epidermis is thin, smooth, flexible; the cutaneous perspiration abundant, as well as the oily secretion. The vascular eminences are more numerous there than any where else. The *cutis vera* has but little thickness; it receives a great number of vessels and nerves; it adheres to the subjacent *aponeuroses* by fibrous adhesions; and it is sustained by a highly elastic cellular tissue. The extremities of the fingers possess all these properties in the highest degree: the motions of the hand are very numerous, and performed with facility, and it may be applied with ease to any body of whatsoever form.

As long as the hand remains immoveable at the surface of a body, it acts only as an organ of *tact*. To exercise *touch*, it must move, either by passing over the surface, to examine form, dimensions, &c., or it must press for the purpose of determining its consistence, elasticity, &c.

We use the whole hand to touch a body of considerable dimensions: if, on the contrary, a body is very small, we employ only the points of the fingers. This delicacy of touch in the fingers has given man a great advantage over the animals. His touch is so delicate, that it has been considered the source of his intelligence.

From the highest antiquity the touch has been considered of more importance than any of the other senses: it has been supposed the cause of human reason. This idea has continued to our times: it has been even remarkably extended in the writings of Condillac, of Buffon, and other modern physiologists. Buffon, in particular, gave such an importance to the touch, that he thought one man had little more ability than another, but only in so far as he had been in the habit of making use of his hands. He said it would be well to allow children the free use of their hands, from the moment of their birth.

The touch does not really possess any prerogative over the other senses; and if in certain cases it assists the eye or the ear, it receives aid from them in others, and there is no reason to believe that it excites ideas in the brain of a higher order than those which are produced by the action of the other senses.

Of internal sensations. — All the organs, as well as the skin, possess the faculty of transmitting impressions to the brain, when they are touched by exterior bodies, or when they are compressed, bruised, &c. It may be said, that they generally possess *tact*. There must be an exception made of the bones, the tendons, the aponeuroses, the ligaments, &c., which in a healthy state are insensible, and may be cut, burned, or torn without any thing being felt by the brain.

This important fact was not known to the ancients: they considered all the white parts as nervous, and attributed to them all those properties which we now know belong only to the nerves. These useful results, which have had a great influence upon the recent progress of surgery, we owe to Haller and his disciples.

All the organs are capable of transmitting spontaneously a great number of impressions to the brain without the intervention of any external cause. They are of three sorts. The first kind take place when it is necessary for the organs to act: they are called *wants, instinctive desires.* Such are hunger, thirst; the necessity of making water, of respiration; the venereal impulse, &c. The second sort take place during the action of the organs; they are frequently obscure, sometimes very violent. The impressions which accompany the different excretions, as of the semen, the urine, are of this number.

Such are also the impressions which inform us of our motions, of the periods of digestion: even thought seems to belong to this kind of impression.

The third kind of internal sensations are developed when the organs have acted. To this kind belongs the feeling of fatigue, which is variable in the different sorts of functions.

The impressions which are felt in sickness ought to be added to these three sorts: these are much more numerous than the others. The study of them is absolutely necessary to the physician.

All those sensations which proceed from within, and which have no dependence upon the action of exterior bodies, have been collectively denominated *internal sensations*, or *feelings*. — *Magendie's Physiology.*

Touch-me-not. See *Noli me tangere.*

Touchwood. See *Agaricus.*

TOU'RNIQUET. (French; from *tourner*, to turn.) An instrument used for stopping the flow of blood into a limb by compressing the main artery. The tourniquet is used to stop

hæmorrhage till some more permanent means can be put in effect, as during the amputation of a limb. It is unnecessary to describe the tourniquet, which is in constant use among surgeons.

TOXICA'RIA MACASSARIE'NSIS. A name of the *bohun upas*. See *Upas*.

TOXICODE'NDRUM. (*um, i.* n.; from τοξικον, a poison, and δενδρον, a tree.) The poison oak. See *Rhus toxicodendron*.

TOXICO'LOGY. (*Toxicologia, æ.* f.; from τοξικον, a poison, and λογος, a discourse.) The study of poisons. See *Poison*.

TO'XICUM. (*um, i.* n.; τοξικον, from τοξον, a bow or a quiver of arrows; because arrows are sometimes poisoned.) A poison. See *Poison*.

TOXITE'SIA. The artemisia or mugwort.

TRABE'CULA. (*a, æ.* f.; a small beam.) This word is mostly applied by anatomists to the thread-like processes in the longitudinal sinus of the dura mater, and to the small medullary fibres of the brain, which constitute the commissures.

TRACHE'A. (*a, æ.* f. Τραχεια, from its roughness; from τραχυς, rough.) *Trachelos*. The windpipe. The trachea is a cartilaginous and membraneous canal, through which the air passes into the lungs. Its upper part, which is called the larynx, is composed of five cartilages. The uppermost and smallest of these cartilages is placed over the glottis or mouth of the larynx, and is called epiglottis, as closing the passage to the lungs in the act of swallowing. The sides of the larynx are composed of the two arytenoid cartilages, which are of a very complex figure, not easy to be described. The anterior and larger part of the larynx is made up of two cartilages, one of which is called *thyroides* or *scutiformis*, from its being shaped like a buckler; and the other *cricoides* or *annularis*, from its resembling a ring. Both these cartilages may be felt immediately under the skin, at the fore-part of the thorax; and the thyroides, by its convexity, forms an eminence called the pomum adami, which is usually more considerable in the male than in the female subject.

All these cartilages are united to each other by means of very elastic ligamentous fibres; and are enabled, by the assistance of their several muscles, to dilate or contract the passage of the larynx, and to perform that variety of motion which seems to point out the larynx as the principal organ of the voice; for when the air passes through a wound in the trachea, it produces little or no sound.

These cartilages are moistened by a mucus, which seems to be secreted by minute glands situated near them. The upper part of the trachea, and the cricoid and thyroid cartilages, are in some measure covered anteriorly by a considerable body, which is supposed to be of a glandular structure, and from its situation is called the thyroid gland, though its excretory duct has not yet been discovered, or its real use ascertained. The glottis is entirely covered by a very fine membrane, which is moistened by a constant supply of a watery fluid. From the larynx the canal begins to take the name of trachea, or aspera arteria, and extends from thence as far down as the fourth or fifth vertebræ of the back, where it divides into two branches, which are the right and left bronchial tube. Each of these bronchia ramifies through the substance of that lobe of the lungs, to which it is distributed by an infinite number of branches, which are formed of cartilages, separated from each other like those of the trachea, by an intervening membraneous and ligamentary substance. Each of these cartilages is of an annular figure; and as they become gradually less and less in their diameter, the lower ones are in some measure received into those above them, when the lungs, after being inflated, gradually collapse by the air being pushed out from them in expiration. As the branches of the bronchia become more minute, their cartilages become more and more annular and membraneous, till at length they become perfectly membraneous, and at last become invisible. The trachea is furnished with fleshy or muscular fibres, some of which pass through its whole extent longitudinally, while the others are carried round it in a circular direction, so that, by the contraction or relaxation of these fibres, it is enabled to shorten or lengthen itself, and likewise to dilate or contract the diameter of its passage. The trachea and its branches, in all their ramifications, are furnished with a great number of small glands, which are lodged in their cellular substance, and discharge a mucous fluid on the inner surface of these tubes.

The cartilages of the trachea, by keeping it constantly open, afford a free passage to the air which we are obliged to be incessantly respiring; and its membraneous part, by being capable of contraction or dilatation, enables us to receive and expel the air in a greater or less quantity, and with more or less velocity, as may be required in singing and declamation. This membraneous structure of the trachea posteriorly seems likewise to assist in the descent of the food, by preventing that impediment to its passage down the œsophagus, which might be expected if the cartilages were complete rings. The trachea receives its arteries from the carotid and subclavian arteries, and its veins pass into the jugulars. Its nerves arise from the recurrent branch of the eighth pair, and from the cervical plexus.

TRACHE'LAGRA. (*a, æ.* f.; from τραχηλος, the throat, and αγρα, a seizure.) The gout or rheumatism in the neck.

TRACHE'LIUM. (*um, ii.* n.; from τραχηλος, the throat: so called from its efficacy in diseases of the throat.) The herb throat-wort, *Campanula trachelium*; now disused.

TRACHELOCE'LE. (*e, es.* f.; from τραχηλος, the throat, and κηλη, a tumour.) A bronchocele. See *Bronchocele*.

TRACHE'LO-MASTOIDE'US. A muscle situated on the neck, which assists the complexus, but pulls the head more to one side. It is the *complexus minor seu mastoideus lateralis*, of Winslow. It arises from the transverse processes of the five inferior cervical vertebræ, where it is connected with the transversalis cer-

vicis, and of the three superior dorsal, and it is inserted into the middle of the posterior part of the mastoid process.

TRACHELO'PHYMA. (*a, atis.* n.; from τραχηλος, the throat, and φυμα, a tumour.) A bronchocele.

TRACHEO'TOMY. (*Tracheotomia, æ.* f.; from τραχεια, the trachea, and τεμνω, to cut.) See *Bronchotomy.*

TRACHI'TIS. (*is, idis.* f.; from τραχεια, the windpipe, and *itis*, the terminal, which denotes inflammation.) Inflammation of the trachea. See *Croup.*

TRACHO'MA. (*a, atis.* n.; from τραχυς, rough.) An asperity in the internal superficies of the eyelid. The effects are a violent ophthalmia, and a severe pain, as often as the eyelid moves. It may be produced from sand falling between the eye and the eyelid of persons travelling, blown by a high wind: this happens chiefly in sandy situations, and may be prevented by spectacles for the purpose, or by guarding against the flights of sand by covering the eyes. It also arises from caruncles, or fleshy warts, growing in the internal superficies of the eyelid, and by hard pustules in the internal superficies of the eyelids.

TRACTUS OPTICUS. The elongation of the optic thalamus, which is continued on each side to form the optic nerve, is termed *tractus opticus.*

Tragacanth. See *Astragalus tragacantha.*

TRAGACA'NTHA. (*a, æ.* f.; from τραγος, a goat, and ακανθα, a thorn: so called on account of its hirsute or woolly boughs.) See *Astragalus tragacantha.*

TRA'GICUS. A proper muscle of the ear, which pulls the point of the tragus a little forward.

TRA'GIUM. (*um, ii.* n.; from τραγος, a goat, so named from its filthy smell.) 1. The name of a genus of plants. Class, *Pentandria;* Order, *Digynia.*

2. The bastard dittany, or *Dictamnus albus.*

TRAGO'CERUS. (From τραγος, a goat, and κερας, a horn: so named from the supposed resemblance of its leaves to the horn of a goat.) The aloe plant.

TRAGOPO'GON. (*on, onis.* m.; from τραγος, a goat, and πωγων, a beard: so called because its downy seed, while enclosed in the calyx, resembles a goat's beard.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Polygamia.*

2. The pharmacopœial name of the goat's beard. See *Tragopogon pratense.*

TRAGOPOGON PRATENSE. The common goat's beard. The young stems of this plant are eaten like asparagus, and are a pleasant and wholesome food. The root is also excellent, and was formerly used medicinally as a diuretic.

TRAGO'PYRUM. (*um, i.* n.; from τραγος, a goat, and πυρον, wheat: so named from its beard.) Buck-wheat, the *Polygonum fagopyrum,* of Linnæus.

TRAGO'RCHIS. (*is, is.* m.; from τραγος, a goat, and ορχις, a testicle: so named from the supposed resemblance of its roots to the testicles of a goat.) One or more of the orchis tribe have received this name.

TRAGORI'GANUM. (*um, i.* n.; from τραγος, a goat, and οριγανον, marjoram: so called because goats are fond of it.) Applied formerly to several species of origanum.

TRAGOSELI'NUM. (*um, i.* n.; from τραγος, a goat, and σελινον, parsley: named from its hairy coat like the beard of a goat.) The burnet saxifrage. See *Pimpinella saxifraga.*

TRA'GUS. (*us, i.* m. Τραγος, a goat: so called from its being furnished, in some persons, with a tuft of hair like a goat's beard.) 1. In *Anatomy,* a small cartilaginous eminence of the external ear. See *Auris.*

2. In *Botany,* this name has been variously applied, by Dioscorides, to meal or flour, and to a maritime shrub.

Trailing. See *Procumbens.*

TRA'MIS. Τραμις. The line which divides the scrotum, and runs on to the anus. See *Raphe.*

Trance. See *Catalepsy.*

Transcendental anatomy. See the *Supplement.*

TRANSFORMATION. In *Pathology,* a morbid change in a part, which consists in the conversion of its texture into one which is natural to some other part; as when soft parts are converted into cartilage or bone.

TRANSFUSION. (*Transfusio, onis.* f.; from *transfundo,* to pour from one vessel into another.) The transmission of blood from one living animal to another by means of a canula. Harvey was thirty years before he could get his discovery admitted, though the most evident proofs of it were every where perceptible; but as soon as the circulation was acknowledged, people's minds were seized with a sort of delirium: it was thought that the means of curing all diseases was found, and even of rendering man immortal. The cause of all our evils was attributed to the blood: in order to cure them, nothing more was necessary but to remove the bad blood, and to replace it by pure blood, drawn from a sound animal.

The first attempts were made upon animals, and they had complete success. A dog having lost a great part of its blood, received, by transfusion, that of a sheep, and it became well. Another dog, old and deaf, regained, by this means, the use of hearing, and seemed to recover its youth. A horse of twenty-six years, having received in his veins the blood of four lambs, recovered his strength.

Transfusion was soon attempted upon man. Denys and Emerez, the one a physician, the other a surgeon, of Paris, were the first who ventured to try it. They introduced into the veins of a young man, an idiot, the blood of a calf, in greater quantity than that which had been drawn from them, and he appeared to recover his reason. A case of lepra and one of quartan ague, were also cured by this means; and several other transfusions were made upon healthy persons without any disagreeable result.

However, some sad events happened to calm the general enthusiasm caused by these repeated successes. The young idiot we mentioned fell into a state of madness a short time after the

experiment. He was submitted a second time to the transfusion; and he was immediately seized with a *Hæmaturia*, and died in a state of sleepiness and torpor. A young prince of the blood royal was also the victim of it. The parliament of Paris prohibited transfusion. A short time after, G. Riva having, in Italy, performed the transfusion upon two individuals, who died of it, the Pope prohibited it also.

In 1785, Dr. Harwood, of Cambridge, made some experiments on transfusion, from which he inferred that the blood of a herbivorous animal may be substituted for a carnivorous, or *vice versâ*, without danger or inconvenience to the animal.

The recent experiments of MM. Prevost and Dumas tend to an opposite conclusion.

The most important experiments on transfusion which have lately been performed, are those of Dr. Blundell, who has established both the safety and utility of replenishing the vessels of persons sinking from the effects of hæmorrhage, from the veins of another healthy human being. In the opinion of Dr. Blundell, a very moderate quantity of fresh blood is sufficient to turn the balance wavering between life and death: he considers half a pint or a pint as an ample supply. The operation of transfusion must be performed with a well-adjusted apparatus, and with the utmost caution, that no air be injected from the syringe along with the blood — an accident the fatal consequences of which are well known. For further information on the subject of transfusion, the reader is referred to Dr. Blundell's tract, appended to *Ashwell on Parturition*, London, 8vo. 1828, and to the article by Dr. Kay in the Cyclopædia of Practical Medicine.

TRANSPIRA'TION. (*Transpiratio, onis.* f.; from *trans*, through, and *spiro*, to breathe.) See *Perspiration.*

TRANSUDA'TION. *Transudatio.* The passing through the cells or pores of any thing. The term should be distinguished from perspiration, which implies a function by which the perspired fluid is secreted from the blood, whereas by transudation the blood or other fluid merely oozes through unaltered.

TRANSVERSA'LIS. Transverse. Applied very generally in the several departments of nature, especially in *Anatomy*, to muscles, vessels, &c. which have a transverse direction.

TRANSVERSALIS ABDOMINIS. A muscle situated on the anterior part of the abdomen: so named from its direction. It arises internally or posteriorly from the cartilages of the seven lower ribs, being there connected with the intercostals and diaphragm; also from the transverse process of the last vertebra of the back, from those of the four upper vertebræ of the loins, from the inner edge of the crista ilii, and from part of Poupart's ligament; and it is inserted into the inferior bone of the sternum, and almost all the length of the linea alba. Its use is to support and compress the abdominal viscera.

Transversalis anticus primus. See *Rectus capitis lateralis.*

Transversalis cervicis. See *Longissimus dorsi.*

TRANSVERSALIS COLLI. A muscle, situated on the posterior part of the neck, which turns the neck obliquely backwards, and a little to one side.

Transversalis dorsi. See *Multifidus spinæ.*

Transversalis major colli. See *Longissimus dorsi.*

TRANSVERSALIS PEDIS. A muscle of the foot, which it contracts, by bringing the great toe and the two outermost toes nearer each other.

TRANSVERSE SUTURE. *Sutura transversalis.* This suture runs across the face, and sinks down into the orbits, joining the bones of the skull to the bones of the face; but with so many irregularities and interruptions, that it can scarcely be recognised as a suture.

Transversospinalis. See *Multifidus spinæ.*

TRANSVE'RSUS. Transverse: placed across.

TRANSVERSUS AURIS. A muscle of the external ear, which draws the upper part of the concha towards the helix.

TRANSVERSUS PERINÆI. A muscle of the organs of generation, which dilates the bulb of the urethra, and assists the action of the levator ani.

TRANSVERSUS PERINÆI ALTER. *Prostaticus inferior*, of Winslow. A small muscle occasionally found accompanying the former.

TRA'PA. (*a, æ.* f.; a name given by Linnæus, whose idea is certainly taken from the warlike instrument called caltrop, the tribulus of the ancients, which consisted of four iron radiated spikes, so placed that one of them must always stand upwards, in order to wound the feet of the passengers. Such is the figure of the singular fruit of this genus; hence named by Tournefort *Tribuloides*. *Calcitrapa*, an old botanical term of similar meaning to *tribulus*, is compounded, perhaps, of *calco*, to tread or kick, and τρεπω, to turn; because the caltrops are continually kicked over if they fail of their intended mischief: here we have the immediate origin of *trapa*.) The name of a genus of plants. Class, *Tetrandria*; Order, *Monogynia*.

TRAPA NATANS. The systematic name of the plant which affords the *nux aquatica*. *Tribulus aquaticus*. Caltrops. The fruit is of a quadrangular and somewhat oval shape, including a nut of a sweet farinaceous flavour, somewhat like that of the chesnut, which is apt to constipate the bowels, and produce disease: however, it is said to be nutritious and demulcent, and to be useful in diarrhœas from abraded bowels, and against calculus. Likewise a poultice of these nuts is said to be efficacious in resolving hard and indolent tumours.

TRAPE'ZIFORM. *Trapeziformis.* Of the shape of a trapezium.

TRAPE'ZIUM. (*um, ii.* n.; a geometrical figure.) The first bone of the second row of the carpus, so called from its shape.

TRAPE'ZIUS. (*us, ii.* m.; from τραπεζιον, the name of a geometrical figure: so named from its shape.) *Cucullaris.* A muscle situated immediately under the integuments of the posterior part of the neck and back. It arises by a thick, round, and short tendon from the lower part of a protuberance in the middle of

the occipital bone backwards, and from the rough line that is extended from thence towards the mastoid process of the os temporis, and by a thin membranous tendon, which covers part of the complexus and splenius. It then runs downwards along the nape of the neck, and rises tendinous from the spinous processes of the two lowermost vertebræ of the neck, and from the spinous processes of all the vertebræ of the back, being inseparably united to its fellow, the whole length of its origin, by tendinous fibres, which, in the nape of the neck, form what is called *ligamentum colli*, or the cervical ligament. It is inserted fleshy into the broad and posterior half of the clavicle, tendinous and fleshy into one half of the acromion, and into almost all the spine of the scapula.

This muscle serves to move the scapula in different directions. Its upper descending fibres pull it obliquely upwards; its middle transverse ones pull it directly backwards; its inferior fibres, which ascend obliquely upwards, draw it obliquely downwards and backwards.

The upper part of the muscle acts upon the neck and head, the latter of which it draws backwards, and turns upon its axis. It likewise concurs with other muscles in counteracting the flexion of the head forwards.

TRAPEZOI'DES OS. (From τραπεζιος, the trapezium, and ειδος, resemblance.) The second bone of the second row of the carpus.

TRAUMA'TIC. (*Traumaticus*; from τραυμα, a wound.) Relating to a wound.

Traveller's joy. See *Clematis.*

Treacle. See *Saccharum officinale.*

Treacle, mustard. See *Thlaspi.*

Treacle, Venice. See *Mithridatum.*

Tree liver-wort. See *Lichen olivarius.*

Trefoil. See *Trifolium.*

TREFOIL, ACACIA. The *Spartium spinosum*, of Linnæus.

Trefoil, marsh. See *Menyanthes.*

Trefoil, water. See *Menyanthes trifoliata.*

TREME'LLA. (*a, æ.* f.; from *tremo*, to tremble or quake: and so called because of its gelatinous, tender, and tremulous substance.) The name of a genus of plants, of the Class *Cryptogamia*; Order, *Algæ.*

TREMELLA NOSTOC. *Nostoc commune.* An indigenous greenish jelly, which is edible.

TRE'MOR. (*or, oris.* m.) Trembling.

TREPA'N. (*Trepanum, i.* n.; from τρυπαω, to perforate.) A surgical instrument bearing much resemblance to a wimble, and worked in the same manner. It is used for sawing a circular portion of bone out of the skull. On the Continent the trepan is generally used; in England it is superseded by the trephine.

TREPHINE. An instrument generally used by English surgeons instead of the trepan. It consists of a cylindrical saw, with a handle placed transversely, like that of a gimlet, and has a perforator or centre pin, which is fixed into the skull, and forms an axis on which the circular edge of the saw rotates, and which is removed as soon as the teeth of the saw have made a groove in which they can work steadily.

TRIA'NDRIA. (*a, æ.* f.; from τρεις, three, and ανηρ, a man.) 1. The name of the third class in the sexual arrangement of Linnæus's system. It embraces hermaphrodite plants which have three distinct stamens. It has three orders, — Monogynia, Digynia, and Trigynia.

2. The name of several orders of the Linnæan system; as the first of the Monadelphia, the third of the Gynandria, the third of the Monœcia, and the third of Dicœcia.

TRIANGULA'RIS. Triangular: a term very generally applied, in the different departments of science, to parts of animals, vegetables, minerals, &c., from their form. See *Caulis, Folium*, &c.

Triangularis sterni. See *Sternocostales.*

TRI'BULUS. (*us. i.* m. Τριβολος; from τριβω, to tear or injure: an instrument of war to be thrown in the way to annoy the enemy's horse: hence the name of an herb from its resemblance to this instrument.) 1. The name of a genus of plants. Class, *Decandria*; Order, *Monogynia.*

2. See *Trapa natans.*

Tribulus aquaticus. See *Trapa.*

TRI'CA. (*a, æ.* f.; from θριξ, τριχος, a hair: because they seem composed of a horse-hair rolled, or partly folded, into a little round black head.) A term applied by Dr. Acharius to the black filaments, resembling a curled horse-hair, in the *Gyrophora* and *Umbilicaria*, of Hoffmann.

TRICAUDA'LIS. (From *tres*, three, and *cauda*, a tail.) Having three tails.

TRI'CEPS. (*eps, ipitis.*, sc. *musculus*; from *tres*, three, and *caput*, a head.) Three-headed.

TRICEPS ADDUCTOR FEMORIS. Under this appellation are comprehended three distinct muscles. See *Adductor brevis, longus*, and *magnus femoris.*

Triceps auris. See *Retrahens auris.*

TRICEPS EXTENSOR CUBITI. This muscle occupies all the posterior part of the os humeri, and is described as two distinct muscles by Douglas, and as three by Winslow. The upper part of its long head is covered by the deltoides: the rest of the muscle is situated immediately under the integuments.

It arises, as its name indicates, by three heads. The first, or long head (the long head of the *biceps externus*, of Douglas; *anconeus major*, of Winslow, as it is called) springs, by a flat tendon of an inch in breadth, from the anterior extremity of the inferior costa of the scapula, near its neck, and below the origin of the teres minor. The second head (the short head of the *biceps externus*, of Douglas; *anconeus externus*, of Winslow) arises by an acute, tendinous, and fleshy beginning from the upper and outer part of the os humeri, at the bottom of its great tuberosity. The third head (*brachialis externus*, of Douglas; *anconeus internus*, of Winslow), which is the shortest of the three, originates by an acute fleshy beginning, from the back part of the os humeri, behind the flat tendon of the latissimus dorsi. These three portions unite about the middle of the arm, so as to form one thick and powerful muscle,

which adheres to the os humeri to within an inch of the elbow, where it begins to form a broad tendon, which, after adhering to the capsular ligament of the elbow, is inserted into the upper and outer part of the olecranon, and sends off a great number of fibres, which help to form the fascia on the outer part of the fore-arm. The use of this muscle is to extend the fore-arm.

TRI'CHIA. (*a, æ.* f.; from θριξ, a hair.) The same as *Trichiasis.*

TRICHI'ASIS. (From θριξ, a hair.) 1. A disease of the eyelashes, in which they are turned in towards the bulb of the eye.

2. A disease of the hair. See *Plica.*

TRICHI'SMUS. (*us, i.* m.; from θριξ, a hair.) A species of fracture which appears like a hair, and is almost imperceptible.

TRICHOCE'PHALUS. (*us. i.* m.; from θριξ, hair, and κεφαλη, the head.) The hair-headed worm. See *Entozoa.*

Trichocephalus dispar. See *Entozoa.*

TRICHO'MA. (*a, atis.* n.; from θριξ, a hair.) The plaited hair. See *Plica.*

TRICHO'MANES. (*es, is.* m.; from τριχες, hair, and μανος, thin, lax: so called because it resembles fine hair.) The trivial name of a plant. See *Asplenium trichomanes.*

TRICHO'SIS. (Τριχωσις, *pilare malum;* from θριξ, a hair.) Under this name Good arranges a genus, which embraces most of the diseases of the hair.

TRICHO'TOMOUS. *Trichotomus.* Divided by threes. Applied in *Natural History.*

TRICHU'RIS. (*is, idis.* f.; from θριξ, a hair.) The long hair-worm. See *Entozoa.*

TRICO'CCÆ. The name of an order in Linnæus's Fragments of a Natural Method, consisting of those which have a triangular capsule with three seeds.

TRICO'CCUS. (From τρεις, three, and κοκκος, a grain.) Three-seeded.

TRICU'SPID. (*Tricuspis, tricuspidatus;* from *tres,* three, and *cuspis,* a point.) Three pointed.

TRICUSPID VALVE. The valve situated between the auricle and ventricle on the right side of the heart. See *Heart.*

Tricuspidatus. See *Tricuspid.*

TRIFACIAL NERVE. The fifth nerve is so called from its division into three great branches, and distribution to the face.

TRI'FIDUS. (From *tres,* three, and *findo,* to cut.) Three-cleft.

TRIFO'LIUM. (*um, ii.* n.; from *tres,* three, and *folium,* a leaf: so called because it has three leaves on each stalk.) The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Monogynia.* Trefoil.

Trifolium acetosum. See *Oxalis.*

Trifolium aquaticum. See *Menyanthes.*

TRIFOLIUM ARVENSE. The hare's foot trefoil: not now used.

TRIFOLIUM AUREUM. The *Anemone hepatica,* of Linnæus.

Trifolium caballinum. See *Trifolium melilotus officinalis.*

TRIFOLIUM CÆRULEUM. Sweet trefoil.

Trifolium falcatum. See *Hieracium.*

Trifolium fibrinum. See *Menyanthes.*

Trifolium hepaticum. See *Anemone.*

TRIFOLIUM MELILOTUS OFFICINALIS. The systematic name of the officinal melilot; called in the shops *Melilotus,* and formerly *Lotus sylvestris, Serratula campana, Trifolium caballinum, Corona regia,* and *Trifolium odoratum.* This plant has been said to be resolvent, emollient, anodyne, and to participate of the virtues of chamomile. Its taste is unpleasant, subacrid, subsaline, but not bitter; when fresh it has scarcely any smell; in drying it acquires a pretty strong one of the aromatic kind, but not agreeable. The principal use of melilot has been in clysters, fomentations, and other external applications.

Trifolium odoratum. See *Trifolium melilotus officinalis.*

Trifolium paludosum. See *Menyanthes.*

TRIGE'MINI. (*Trigeminus;* from *tres,* three, and *geminus,* double: three-fold.) *Nervi innominati.* The fifth pair of nerves. See *Nerve.*

TRIGONE'LLA. (*a, æ.* f.; a diminutive of *trigona,* three-sided, alluding to its little triangular flower.) The name of a genus of plants. Class, *Diadelphia;* Order, *Decandria.*

TRIGONELLA FŒNUM GRÆCUM. The systematic name of the fœnugreek; called also, *Fœnum græcum, Buceras,* and *Ægoceras.*

Trigonella — leguminibus sessilibus strictis erectiusculis subfalcatis acuminatis, caule erecto, of Linnæus. A native of Montpellier. The seeds are brought to us from the southern parts of France and Germany: they have a strong disagreeable smell, and an unctuous farinaceous taste, accompanied with a slight bitterness. They are esteemed as assisting the formation of pus, in inflammatory tumours; and the meal, with that intention, is made into a poultice with milk.

TRIGO'NUS. (From τρεις, three, and γωνια, an angle.) Trigonal, or three-cornered.

TRIGY'NIA. (*a, æ.* f.; from τρεις, three, and γυνη, a female.) The name of an order in many of Linnæus's classes of the sexual system of plants, distinguished by the flowers having three pistils.

TRIHILA'TÆ. The name of a class of plants in Linnæus's Fragments of a Natural Method, consisting of plants the seeds of which have the *hilum* or scar well marked; the style has three stigmas.

TRIHILA'TUS. (From *tres,* three, and *hilum,* the scar or external mark on the seed.) Having three *hila* or scars.

Trilobatus. See *Trilobus.*

TRI'LOBUS. *Trilobatus.* Trilobate: three-lobed. Applied to parts of animals and plants which are so shaped.

TRILO'CULAR. *Trilocularis.* Three-celled.

TRINE'RVIS. Three-nerved. Three-ribbed; as applied to leaves, &c.

Trinitatis herba, See *Anemone.*

Trinity-herb. See *Anemone.*

TRIPARTI'TUS. Tripartite: divided into three. Applied to parts of animals and vegetables.

TRIPA'STRUM APE'LLIDIS. *Tripastrum Archimedis.* A surgical instrument for extending fractured limbs: so named because it resembled

a machine invented by Apellides or Archimedes, for launching of ships, and because it was worked with three cords.

TRIPHY'LLUS. (From τρεις, three, and φυλλον, a leaf.) Triphyllous: three-leaved.

TRIPI'NNATE. (*Tripinnatus*; from τρεις, three, and πινναι, a wing.) *Triplicato-pinnatus.* Triply pinnate. Applied to a pinnated leaf, of which the secondary petioles produce tertiary petioles on which the leaflets are implanted.

TRIPLINE'RVIS. Triply-ribbed: applied to a leaf which has a pair of large ribs branching off from a main one above the base, which is the case in every species of sunflower, and the *Blakea triplinervis.*

TRIPLO'PIA. (*a, æ.* f.; from τρεις, three, and οπτομαι, to see.) *Visus triplicatus.* A species of disordered vision, in which objects are seen triple.

TRIQUE'TRA OSSI'CULA. *Ossicula Wormiana.* The triangular-shaped bones which are found mostly in the course of the lambdoidal suture of the skull.

TRIQUE'TRUM. (*um, i.* n.) A triangle.

TRIQUE'TRUS. (From *tres.*) Three-sided. Applied to some parts of animals, plants, &c.; as bones, stems, flowerstalks, leaves, seeds, &c.

TRI'SMUS. (*us, i.* m.; from τριζω, to gnash.) Locked jaw. Spastic rigidity of the under jaw. There are two species: — 1. *Trismus nascentium*, attacking infants during the two first weeks from their birth. 2. *Trismus traumaticus*, attacking persons of all ages, and arising from cold or a wound. See *Tetanus.*

TRI'SSAGO. (*o, inis.* f.; *quasi tristago*, from *tristis*, sad: because it dispels sadness.) See *Teucrium chamædrys.*

Trissago palustris. See *Teucrium.*

TRITÆO'PHYA. (*a, æ.* f.; from τριταιος, tertian, and φυω, to arise.) A fever much of a nature with a tertian, and taking its rise from it.

TRITÆOPHYA CAUSUS. The fever called *causus* by Hippocrates.

TRITÆ'US. Tertian. See *Ague.*

TRITERNA'TUS. *Triplicato-ternatus.* The term applied to a leaf when the divisions of a triple leafstalk are again subdivided into threes, and there are three leaflets at the end of each subdivision.

TRI'TICUM. (*um, i.* n.; from *tero*, to thresh from the husk.) The name of a genus of plants. Class, *Triandria*; Order, *Digynia.* See *Wheat.*

TRITICUM REPENS. *Gramen caninum. Gramen Dioscoridis. Gramen repens. Loliaceum radice repente.* Dog's-grass. Couch-grass. A very common grass, the roots of which are agreeably sweet, and possess aperient properties. The expressed juice is recommended to be given largely.

TRITO'RIUM. (From *tritus*, beat small.) 1. A mortar.

2. A glass for separating the oil from the water in distilling.

TRITURA'TION. (*Trituratio, onis.* f.; from *tero*, to rub or grind.) *Tritura. Tritus.* The act of reducing a solid body into a subtile powder; as woods, barks, &c. It is performed mostly by the rotatory motion of a pestle in metallic, glass, or wedgewood mortars.

TRI'VIAL. In *Botany*, the *trivial* name means the same as the *specific*: it is that which is added to the generic name for the more ready discrimination of the species of the same genus: thus, in *Plantago*, the name of a genus, the trivial names are, *major, lanceolata, coronopus*, &c.

TROCA'R. (Corrupted from *un trois quart*, French, *a three quarters*; from the three sides with which the point is made. The name of an instrument used in tapping for the dropsy.

TROCHA'NTER. (*er, ri.* m.; from τροχαζω, to run: because the muscles inserted into them perform the office of running.) The name of two processes of the thigh-bone, which are distinguished into the greater and lesser. See *Femur.*

TROCHI'SCUS. (*us, i.* m.; diminutive of τροχος, a wheel.) A troch or round tablet. Troches and lozenges are composed of powders made up with glutinous substances into little cakes, and afterwards dried. This form is principally used for the more commodious exhibition of certain medicines, by fitting them to dissolve slowly in the mouth, so as to pass by degrees into the stomach; and hence these preparations have generally a considerable portion of sugar or other materials grateful to the palate. Some powders have likewise been reduced into troches, with a view to their preparation, though possibly for no very good reasons: for the moistening them, and afterwards drying them in the air, must on this account be of greater injury than any advantage accruing from this form can counterbalance.

General rules for making troches: —

1. If the mass proves so glutinous as to stick to the fingers in making up, the hands may be anointed with any sweet or aromatic oil; or else sprinkled with starch, or liquorice powder, or with flour.

2. In order to thoroughly dry the troches, put them on an inverted sieve, in a shady airy place, and frequently turn them.

3. Troches are to be kept in glass vessels, or in earthen ones well glazed.

TRO'CHLEA. (*a, æ.* f. Τροχλεα, a pulley; from τρεχω, to run.) A kind of cartilaginous pulley, through which the tendon of one of the muscles of the eye passes.

TROCHLEA'RIS. A muscle so called because its tendon passes through a pulley. See *Obliquus superior oculi.*

TROCHLEA'TOR. A nerve: so called because it supplies the musculus trochlearis of the eye. See *Pathetici.*

TROCHOI'DES. (From τροχος, a wheel, and ειδος, resemblance.) *Axea commissura.* A species of movable connexion of bones, in which one bone rotates upon another; as the first cervical vertebra upon the odontoid process of the second.

TROPÆ'OLUM. (*um, i.* n.; a diminutive of *tropæum*, or τρωπαιον, a warlike trophy. This fanciful but elegant name was chosen by Linnæus for this singular and striking genus, because he conceived the shield-like

leaves and the brilliant flowers, shaped like golden helmets, pierced through and through, and stained with blood, might well justify such an allusion.) The name of a genus of plants. Class, *Octandria*; Order, *Monogynia*.

TROPÆOLUM MAJUS. The systematic name of the Indian cress. Greater Indian cress or Nasturtium. *Nasturtium indicum. Acriviola. Flos sanguineus monardi. Nasturtium Peruvianum. Cardaminum minus.* This plant is a native of Peru: it was first brought to France in 1684, and there called *Le grande capucine*. In its recent state this plant, and more especially its flowers, have a smell and taste resembling those of water-cress; and the leaves, on being bruised in a mortar, emit a pungent odour, somewhat like that of horse-radish. By distillation with water they impregnate the fluid in a considerable degree with the smell and flavour of the plant. Hence the antiscorbutic character of the nasturtium seems to be well founded, at least as far as we are able to judge from its sensible qualities: therefore, in all those cases where the warm and antiscorbutic vegetables are recommended, this plant may be occasionally adopted as a pleasant and effectual variety. Patients, to whom the nauseous taste of scurvy-grass is intolerable, may find a grateful substitute in the nasturtium. The flowers are frequently used in salads, and the capsules are by many highly esteemed as a pickle. The flowers, in the warm summer months, about the time of sunset, have been observed to emit sparks like those of the electrical kind.

TROPHIS AMERICANA. Red-fruited bucephalon. The fruit of the plant is a rough red berry, which is eaten in Jamaica, though not very pleasant.

Trough, pneumatic. See *Apparatus, pneumatic.*

Trowel-shaped. See *Deltoides.*

TRUE. *Verus.* Formerly applied to designate diseases, when they were really what the name implied, and in opposition to those which only simulated them: hence *peripneumonia vera* and *notha.*

Truffle. See *Lycoperdon tuber.*

Truffle, Piedmont. See *Lycoperdon tuber.*

TRUNCA'TUS. Truncate: lopped; appearing as if cut off with a pair of scissors. A truncate leaf is one which has the extremity cut off, as it were, by a transverse line; as in *Liriodendrum tulipifera*, and the petals of *Hura crepitans.*

TRU'NCUS. (*us, i.* m.) The trunk.

I. In *Anatomy*, applied to the body strictly so called. It is divided into the *thorax*, or chest, the *abdomen*, or belly, and the *pelvis*. See *Body.*

II. In *Botany*, that part of a plant which emerges from the root, and sustains all other parts. The genera of trunks are, —

1. *Truncus:* applied to trees and shrubs which are thick and woody.

2. *Caulis:* the stem of herbs.

3. *Culmus:* the stem of grasses.

4. *Stipes:* the trunk of funguses, ferns, and palms.

5. *Scapus:* which is not a trunk, but a flower-stalk, emerging from the root.

TRUSS. (From the French *trousse. Brachierium.*) A bandage for a hernia.

TU'BA. (*a, æ.* f.; from *tubus*, any hollow vessel.) A tube. 1. In *Anatomy*, applied to several canals; as the Eustachian tube, Fallopian tube, &c.

2. In *Botany*, the inferior part of a monopetalous coral. It is the cylindrical part which is enclosed in the calyx of the primrose. See *Corolla.*

8. In *Surgery*, applied to hollow instruments.

TUBA EUSTACHIA'NA. (So called because it was first described by Eustachius.) *Tuba Aristotelica. Aquæductus. Aquæ ductus Fallopii. Meatus siccus. Palatinus ductus. Ductus auris palatinus.* The Eustachian tube. A tube which forms a communication between the cavity of the tympanum and the posterior nares. See *Auris.*

TUBA FALLOPIA'NA. (So called because it was first described by Fallopius.) The Fallopian tube. A canal which arises at each side of the fundus of the uterus, and ends at the ovarium. See *Uterus.*

Tube. See *Tuba.*

TU'BER. (*er, eris.* n.; from *tumeo*, to swell.) An old name for an excrescence. 1. In *Anatomy*, applied to some parts which are rounded; as *tuber, annulare*, &c.

2. In *Surgery*, a knot or swelling in any part.

3. In *Botany*, applied to a kind of round turgid root, as a turnip: hence these are called tuberose roots.

4. The name of a genus of plants in the Linnæan system. Class, *Cryptogamia*; Order, *Fungi.*

Tuber album. See *Lycoperdon.*

TUBER ANNULARE. *Tuberculum annulare.* See *Pons varolii.*

Tuber cibarum. See *Lycoperdon tuber.*

Tuber griseum. See *Lycoperdon.*

Tuber moschatum. See *Lycoperdon.*

Tuber rufum. See *Lycoperdon.*

TU'BERCLE. (*Tuberculum, i.* n.; diminutive of *tuber.*) A tubercle. 1. In *Anatomy*, applied to several elevations.

2. In *Pathology*, a peculiar morbid product occurring in various textures of the body, in connexion with the scrofulous, or, as it is now frequently termed, the tubercular diathesis. It occurs in isolated roundish masses, or infiltrated in the texture of organs. The matter which forms tubercles is unorganised, of a dull whitish yellow, or yellowish-gray colour, opake, and varying in form and consistence according to the stage of development of the tubercle, and the texture of the part in which it is formed.

According to Laennec, tubercular matter, in whatever form it presents itself, is at first gray and semi-transparent, which, by degrees, becomes yellow, opake, and very dense; lastly, it undergoes a softening process, and is converted into a matter resembling pus. Isolated tubercles of the lungs are described by this distinguished pathologist as making their first appearance as gray semi-transparent grains resembling millet seeds; and hence named *miliary.* After a while, a yellowish-white opake

spot is seen in the centre of each tubercle, and gradually pervades the whole, and the tubercle is then said to be in the *crude* state. A number of these crude tubercles coalesce, undergo the softening process, and form a vomica. Tubercle is thus regarded by Laennec as an *organised* product, which undergoes changes by virtue of actions carried on within itself. This opinion, however, is now generally considered erroneous, and tubercular matter is regarded as a mere unorganised deposit. The softening process does not arise from any action carried on by the tubercle itself, but from the action of the surrounding living parts. Laennec, in supposing that it commenced in the centre of the tubercle, appears to have been misled by an anatomical deception which has been pointed out by Dr. Carswell. The softening generally commences at the circumference, and is always caused by the admixture of fluid secreted by the vessels of the surrounding texture, which are irritated by the presence of the tubercle, acting as a foreign body.

According to the analysis of M. Thenard, as given by M. Andral, crude pulmonary tubercle consisted of

Animal matter	98·15
Muriate of soda, Phosphate of lime, Carbonate of lime	1·185
	100·00

It is the general opinion of pathological anatomists, that there is scarcely any texture of the body which may not occasionally become the seat of tubercle. It has been found on the surface of mucous and serous membranes, within mucous follicles, within lymphatic vessels, in the cellular membrane, and in the blood, especially in that contained in the cells of the spleen. Dr. Carswell regards the mucous and serous surfaces, and the blood, as the exclusive seats of the tubercular deposition, which, according to him, is never to be found in the molecular structure of organs. The same able pathologist contends that the free surface of the mucous membrane is the most frequent seat of tubercle, and has adduced strong arguments in favour of this position. The cellular tissue has hitherto been regarded as most subject to tubercular disease.

The presence of tubercles gives rise to many severe and incurable diseases, as well as to the less formidable glandular affections which infest the scrofulous constitution, especially in early life. See *Phthisis*, *Scrofula*, *Tabes*, &c.

3. In *Botany*, applied to the hemispherical projections; as in the fruit of the *Lichen caninus*.

TUBE'RCULA. The name of an order in Dr. Willan's Cutaneous Diseases, defined small, hard, superficial tumours, circumscribed and permanent, or suppurating partially. It comprehends nine genera; viz. *phyma*, *verruca*, *molluscum*, *virtiligo*, *acne*, *sycosis*, *lupus*, *elephantiasis*, and *frambœsia*.

TUBERCULA QUADRIGE'MINA. *Corpora quadrigemina. Eminentiæ quadrigeminæ. Natulæ. Nates cerebri.* Four white oval tubercles of the brain, two of which are situated on each side, at the posterior part of the third ventricle and over the aqueduct of Sylvius. The ancients called them nates and testes, from their resemblance in shape to those parts. See *Encephalos.*

TUBE'RCULAR. *Tuberculatus.* Tuberculate: tubercled; having small warts or tubercles.

Tuberculum annulare. See *Tuber annulare.*

TUBERCULUM LOWERI. An eminence in the right auricle of the heart where the two venæ cavæ meet: so called from Lower, who first described it. See *Heart.*

TU'BEROSE. *Tuberosus.* Tuberous: knobbed. Applied to parts of plants. The root so called is of many kinds. The most genuine consists of fleshy knobs, various in form, connected by common stalks or fibres; as the potato and Jerusalem artichoke.

TU'BULAR. *Tubularis.* Tube-like.

TU'BULATED. *Tubulatus.* 1. Synonymous with *tubulous.*

2. A retort which has a small tubular production at its upper and back part, with a stopper adapted to it, is called a *tubulated retort.*

TU'BULI LACTI'FERI. The ducts or tubes in the nipple through which the milk passes.

TU'BULOUS. *Tubulosus.* Tubular: a leaf is so called which is hollow within, as that of the common onion.

The florets of a compound flower are called *tubulosi*, tubular or cylindrical, to distinguish them from such as are ligulate, or riband-like.

TU'BULUS. A small tube or duct.

Tuft. See *Capitulum*, and *Cyma.*

TUMOUR. (*Tumor, oris.* m.; from *tumeo*, to swell.) In a wide acceptation, a tumour means a swelling of any part of whatever kind, and from whatever cause. The term, however, is usually restricted to a permanent swelling, while the swelling which arises from inflammation, and ceases along with the cause, is more generally called *tumefaction.* Tumours are commonly distinguished into *Sarcomatous*, firm and of a fleshy consistence; and *Encysted*, consisting of a sac containing matter more or less pulpy, or fluid.

I. *Sarcomatous tumours.* These are divided by Abernethy into, —

1. *Common vascular*, or *organised sarcoma*, including tumours which appear to be composed of the lymph of the blood, rendered more or less vascular by the growth of vessels through it.

2. *Adipose sarcoma*, including fatty tumours which are originally formed like the preceding, and afterwards become fat owing to a particular action of their vessels.

3. *Pancreatic sarcoma*, so called from the resemblance of its structure to that of the pancreas.

4. The *Mastoid*, or *Mammary sarcoma*, so called from the resemblance of its structure to that of the mammary gland.

5. The *Tuberculated sarcoma*, composed of numerous small firm roundish tumours of various sizes and colours, connected with each other by cellular membrane.

6. *Medullary sarcoma*, so called from its resembling the medullary matter of the brain. It is the *fungus hæmatodes* of other writers.

7. The *Carcinomatous sarcoma*, or cancerous tumour. Of these different kinds of tumours,

the *common vascular*, the *adipose*, and the *pancreatic*, are considered as devoid of any malignity; the *tuberculated*, *medullary*, and *carcinomatous*, are highly malignant: the *mammary* sarcoma is placed by Mr. Abernethy between the two.

II. *Encysted tumours.* These are distinguished into, —

1. *Steatomatous*, or those containing a fatty matter.

2. *Melicerous*, containing matter somewhat resembling honey.

3. *Atheromatous*, containing a pap-like matter.

TUNBRIDGE. Tunbridge Wells is a populous village in the county of Kent, which contains many chalybeate springs, all of which resemble each other very closely in their chemical properties. Two of these are chiefly used, which yield about a gallon in a minute, and therefore afford an abundant supply for the numerous invalids who yearly resort thither. The Tunbridge waters derive their characteristic properties from a strong impregnation of iron and carbonic acid. The saline ingredients are similar to those of spring waters in general. The general operation of this chalybeate water is to increase the power of the secretory system in a gradual, uniform manner, and to impart tone and strength to all the functions: hence it is asserted to be of eminent service in irregular digestion; flatulency; in the incipient stages of those chronic disorders which are attended with great debility; in chlorosis; and numerous other complaints incident to the female sex. The prescribed method of using the Tunbridge water, observes Dr. Saunders, is judicious. The whole of the quantity daily used is taken at about two or three intervals, beginning at eight o'clock in the morning, and finishing about noon. The dose at each time varies from about one to three quarters of a pint, according to the age, sex, and general constitution of the patient, and especially the duration of the course; for it is found that these waters lose much of their effect by long habit.

TU'NGSTATE. *Tungstas.* A salt formed by the combination of the tungstic acid with a salifiable base.

TU'NGSTEN. (*Tungstenum*, *i.* n.) This name, signifying heavy stone, was given by the Swedes to a mineral, which Scheele found to contain a peculiar metal, as he supposed, in the state of an acid, united with lime. The same metallic substance was afterwards found by the Don d'Elhuyarts united with iron and manganese in wolfram.

From the first of these the oxide may be obtained by digesting its powder in thrice its weight of nitric acid; washing the yellow powder that remains, and digesting it in ammonia, by which a portion of it is dissolved. These alternate digestions are to be repeated, and the tungstic oxide precipitated from the ammoniacal solutions by nitric acid. The precipitate is to be washed with water, and exposed to a moderate heat, to expel any ammonia that may adhere to it. Or the mixture may be evaporated to a dry mass, which is to be calcined under a muffle, to dissipate the nitrate of ammonia. From wolfram it may be obtained by the same process, after the iron and manganese have been dissolved by muriatic acid.

The Spanish chemists reduced the oxide of tungsten to the metallic state, by exposing it, moistened with oil, in a crucible lined with charcoal, to an intense heat. After two hours a piece of metal weighing 40 grains, but slightly agglutinated, was found at the bottom of the crucible. Some have attempted its reduction in vain, but Guyton, Ruprecht, and Messrs. Aikin and Allen, have been more successful. The latter gentlemen produced it from the ammoniuret. From 240 grains of this substance, in acicular crystals, exposed for two hours to a powerful wind-furnace, in a crucible lined with charcoal, they obtained a slightly cohering mass of roundish grains, about the size of a pin's head, with a very brilliant metallic lustre, and weighing in the whole 161 grains.

Tungsten is said to be of a greyish-white or iron colour, with considerable brilliancy, very hard and brittle. Its specific gravity Don d'Elhuyarts found to be 17.6; Messrs. Aikin and Allen, above 17.22.

There are two oxides of tungstenum, the brown, and the yellow or tungstic acid.

The brown oxide is formed by transmitting hydrogen gas over tungstic acid in an ignited glass tube. It has a flea-brown colour, and when heated in the air it takes fire and burns like tinder, passing into *tungstic acid;* which see.

The brown oxide consists of

Tungstenum,	100	
Oxygen,	16.6. — *Berzelius.*	

Hence, if we regard it as composed of 2 primes oxygen + 1 metal, its composition will be

Tungstenum,	12.05	100
Oxygen,	2.00	16.6

Hence the acid prime ought probably to be 12.05 + 3 = 15.05 or 15; and that of the metal 12.

But from Berzelius's experiments, tungstate of lime seems to consist of

Tungstic acid,	100	14.50
Lime,	24.12	3.50

The difference indeed is not great.

Sir H. Davy found that tungstenum burns with a deep red light when heated in chlorine, and forms an orange-coloured volatile substance, which affords the yellow oxide of tungstenum, and muriatic acid, when decomposed by water.

Scheele supposed the white powder obtained by digesting the ore in an acid, adding ammonia to the residuum, and neutralising it by nitric acid, to be pure acid of tungsten. In fact it has a sour taste, reddens litmus, forms neutral crystallisable salts, with alkalies, and is soluble in 20 parts of boiling water. It appears, however, to be a triple salt, composed of nitric acid, ammonia, and oxide of tungsten; from which the oxide may be obtained in a yellow powder, by boiling with a pure concentrated acid. In this state it contains about 20 per cent. of oxygen; part of which may be expelled by a red heat, when it assumes a green colour.

Tungsten is insoluble in the acids; and its oxide is nearly the same. It appears to be

capable of uniting with most other metals, but not with sulphur. Guyton found that the oxide gives great permanence to vegetable colours.

M. Wöhler has written a memoir on tungsten and its combination in the *Annales de Chimie*, xxix. 43. Oxide of tungsten inflames in the air, and becomes tungstic acid. 100 of the former absorb 8 of oxygen; while 100 of metallic tungsten absorb 25 in becoming tungstic acid. M. Wöhler describes three chlorides of tungsten.

TUNGSTIC ACID. *Acidum tungsticum.* See *Tungsten.*

TUNGSTOUS ACID. What has been thus called appears to be merely an oxide of tungsten.

TUNGSTEN OF BASTNAS. *False tungsten.* Cerium has been so called. See *Cerium.*

TU'NIC. (*Tunica, æ.* f.; a coat, *à tuendo corpore*, because it defends the body.) A membrane or covering; as the coats of the eye, &c.

Tunic of a seed. See *Arillus.*

Tunica aciniformis. See *Iris.*

Tunica albuginea oculi. See *Adnata tunica.*

Tunica albuginea testis. See *Albuginea testis.*

Tunica Arachnoides. See *Arachnoid.*

TUNICA CELLULOSA RUYSCHII. The cellular coat of the intestines.

Tunica choroides. See *Choroid.*

Tunica conjunctiva. See *Conjunctive.*

Tunica cornea. See *Cornea.*

TUNICA FILAMENTOSA. The false or spongy chorion. See *Chorion.*

Tunica retina. See *Retina.*

Tunica vaginalis testis. See *Testis.*

TUNICA VILLOSA. The villous, or inner coat of the intestines.

TUNICA'TUS. Coated.

Turbeth mineral. See *Subsulphas hydrargyri flavus.*

Turbeth root. See *Convolvulus turpethum.*

TU'RBINATE. (*Turbinatus*; from *turbo*, a top.) Shaped like a top.

TURBINATED BONES. The superior spongy portion of the ethmoid bone, and the inferior spongy bones, are so called by some writers. See *Spongiosa ossa.*

TURBINA'TUM. The pineal gland.

TURBINA'TUS. Turbinate, top-shaped. Applied in *Zoology* and *Botany.*

Turbith. See *Convolvulus turpethum.*

Turbith mineral. See *Subsulphas hydrargyri flavus.*

TURBITH, MONTPELLIER. The *Globularia alypum.*

Turbot. See *Pleuronectes maximus.*

TURGID. *Turgidus.* Swollen; turgid.

Turkey. See *Meleagris gallipova.*

Turkey rhubarb. See *Rheum.*

TU'RIO. (*o, nis.* m.; from *tyro.*) A young unexpanded shoot, as that of the asparagus in the state it is gathered for eating.

Turmeric. See *Curcuma.*

TURNER'S CERATE. The *Ceratum calaminæ* of the London Pharmacopœia.

Turnip. See *Brassica rapa.*

Turnip, French. See *Brassica rapa.*

Turnsole. See *Heliotropium.*

TURPENTINE. *Terebinthina.* There are many kinds of turpentine. Those employed medicinally are,—

1. The Chian or Cyprus turpentine. See *Pistacia terebinthus.*

2. The common turpentine. See *Pinus sylvestris.*

3. The Strasburg turpentine. See *Pinus picea.*

4. The Venice turpentine. See *Pinus larix.*

All these have been considered as hot, stimulating corroborants and detergents,—qualities which they possess in common. They stimulate the primæ viæ, and prove laxative; when carried into the blood-vessels they excite the whole system, and thus prove serviceable in chronic rheumatism and paralysis. Turpentine readily passes off by urine, which it imbues with a peculiar odour; also by perspiration, and by exhalation from the lungs; and to these respective effects are ascribed the virtues it possesses in gravelly complaints, scurvy, and pulmonic disorders. Turpentine is much used in gleets and fluor albus, and in general with much success. The essential oil, in which the virtues of turpentine reside, is not only preferred for external use, as a rubefacient, but also internally as a diuretic and styptic; the latter of which qualities it possesses in a very high degree. Turpentine is a powerful local stimulant and detersive. It is much used by some surgeons as an application to burns. See *Ambustio.*

Turpeth mineral. See *Subsulphas hydrargyri flavus.*

TURPE'THUM. (*um, i.* n.; from *Turpeth*, an Indian word.) See *Convolvulus turpethum.*

Turpethum minerale. See *Subsulphas hydrargyri flavus.*

TURU'NDA. (*a, æ.* f.; *à terendo*, from its being rolled up.) A tent, or suppository.

TUSSILA'GO. (*o, inis.* f.; from *tussis*, a cough: because it relieves coughs. 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia superflua.*

2. The pharmacopœial name of the coltsfoot. See *Tussilago farfara.*

TUSSILAGO FA'RFARA. The systematic name of the *Bechium. Bechion. Calceum equinum. Chamæleuce. Filius ante patrem. Farfarella. Farfara. Tussilago vulgaris. Farfara bechium. Ungula caballina.* Coltsfoot. *Tussilago farfara — scapo unifloro imbricato, foliis subcordatis angulatis denticulatis.* The sensible qualities of this plant are very inconsiderable: it has a rough mucilaginous taste, but no remarkable smell. The leaves have always been esteemed as possessing demulcent and pectoral virtues; and hence they have been exhibited in pulmonary consumptions, coughs, asthmas, and catarrhal affections. It is used as tea, or given in the way of infusion with liquorice-root or honey. Fuller thought well of it in the cure of scrofula, which induced Dr. Cullen to try it. He gave the expressed juice and the decoction in large quantities, which induced the scrofulous sores, he tells us, to heal. It has fallen into disuse.

TUSSILAGO PETASITES. The systematic name of the butter-bur. *Petasites.* Pestilent-wort. The roots of this plant are recommended as aperient and alexipharmic, and promise, though

now forgotten, to be of considerable activity. They have a strong smell, and a bitterish acrid taste, of the aromatic kind, but not agreeable.

TU'SSIS. (*is, is.* f.; from the Hebrew word for sneezing.) A cough. See *Cough.*

Tussis convulsiva. See *Pertussis.*

Tussis ferina. See *Pertussis.*

TUTE'NAG. 1. A name given in India to zinc.

2. A metallic compound brought from China, and called *Pakfong* or Chinese copper. See *Pakfong.*

TU'TIA. (*a, æ.* f.; Persian.) *Pompholyx. Cadmia. Cadmia factitia. Cadmia fornacum.* Tutty. A grey oxide of zinc. It is generally formed by fusing brass or copper, mixed with blende, when it is incrusted in the chimneys of the furnace.

TUTIA PRÆPARATA. Mixed with any common cerate, or diffused in distilled water, it was formerly in common use to apply to the eye, in debilitated states of the conjunctive membrane.

TUTSAN. (A corruption of the French *tout-sain*, which means all heal.) See *Hypericum androsæmum.*

Tutty. See *Tutia.*

Twining. See *Volubilis.*

Twinforked. See *Bigeminus.*

TYLO'SIS. (From τυλος, a callus.) *Tyloma.* An induration of the margin of the eyelids.

Tympani membrana. See *Membrana tympani.*

TYMPANI'TES. (*es, æ.* m.; from τυμπανον, a drum: so called because the belly is distended with wind, and sounds like a drum when struck.) Tympany. Drum-belly. An elastic distension of the abdomen, which sounds like a drum when struck, with costiveness and atrophy, but no fluctuation. Species: — 1. *Tympanites intestinalis*, a lodgment of wind in the intestines, known by the discharge of wind giving relief.

2. *Tympanites abdominalis*, when the wind is in the cavity of the abdomen.

The intestinal species of tympanites is seldom an idiopathic disease, but mostly dependant on some other—as indigestion, colic, &c.; in which case it is removed by those remedies which are proper against dyspepsia, colic, &c. There is, however, a species of intestinal tympanites which is idiopathic, and that is when the arteries of the stomach and intestines secrete a gaseous fluid. This now and then occurs, and to a great extent, so as to inflate the abdomen to an enormous size. Warm and, as they are called, carminative medicines are to be exhibited with purgatives, as aloes, rhubarb, and the like, unless the bowels are purged; and, in this case, astringents are to be combined with the carminatives; spirituous, camphorated, and other cordials are calculated to give tone to the bowels, the loss of which mostly exists in intestinal flatulency.

The tympanites abdominalis is a very rare disease indeed: in it the gas is collected within the cavity of the peritonæum. When it exists, it mostly supervenes other diseases, and is then called *meteorismus.* Ulcerated bowels, strangulated hernia, gangrene of the intestines, produce it, when the parietes of the bowels burst. It may also be caused by abscesses bursting into the abdomen, and by gangrene of any of its viscera. Tapping the belly has been resorted to, but without effecting a cure. The disease is generally fatal.

TY'MPANUM. (*um, i.* n. Τυμπανον, a drum.) The drum or barrel of the ear. See *Auris.*

TY'PHA. (*a, æ.* f. Τυφη of the ancient Greeks; from τιφος, a bog or marsh: because it grows in marshy places.) The name of a genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Triandria.* The cat's-tail, or reed-mace.

Typha aromatica. See *Acorus calamus.*

TYPHA LATIFOLIA. The broad-leaved cat's-tail, or reed-mace. The young shoots, cut before they reach the surface of the water, eat like asparagus when boiled, and are equally nourishing.

TYPHOMA'NIA. (*a, æ.* f.; from τυφος, stupor, and μανια, madness.) The low muttering delirium which accompanies typhoid fevers.

TY'PHUS. (*us, i.* m.; derived according to some etymologists from τυφω, to smoulder, or to burn and smoke without vent; a term applied to this genus, in opposition to a *cauma* or inflammatory fever, because it burns, not in open violence as a cauma does, but with a sort of concealed and smothered flame. According to others, the term is derived from τυφος, stupor.) A form of continued fever characterised by extreme depression of the nervous powers, and imperfect reaction of the vascular system, giving rise to changes in the circulating fluids, and remarkable disorder of all the secretions.

It has already been stated in the article *febris*, that there is much reason to believe that all the varieties of continued fever are modifications of a disease essentially the same.

Any of the ordinary causes of fever may give rise to typhus; for the typhoid form is often dependant upon the state of the constitution on which the cause is acting, as evincing a great deficiency of sensorial power: and hence cold, mental agitation, excess of muscular labour, and intemperance, which, in strong and sanguineous habits, might generate an inflammatory fever, will often in a debilitated and nervous constitution, and especially when the debility depends primarily upon the state of the nervous system, give a typhous complexion to the disease from the first. But the most common cause by far is contagion, or a febrile miasm, the activity of which is much increased by the crowding of a number of individuals in close and ill-ventilated places, filth, insufficient nutriment, and other causes which tend to depress the vital power. When any of the remote causes of fever act on the system of those whose vital power is in a very depressed state from any cause, typhus is far more likely to take place than any other form of fever: but when the effluvium from the bodies of those labouring under the disease co-operates with the other causes, it is almost impossible for an individual to escape; for the contagion thus generated has a specific power

—a power beyond all other febrile causes whatever — of lowering still farther the vital energy as soon as it impresses the system, and thus of confirming any previous tendency to this fever. The contagion of typhus, as of other diseases propagable in the same way, is much more active at one time than another, from causes which are not understood, hence it sometimes prevails as a most alarming epidemic, and the healthiest individuals using every precaution against it, fall victims to its violence, while in sporadic cases, however severely the individual may be affected, the disorder has little tendency to spread. The contagion of typhus, like that of the plague and several other diseases, sometimes adheres with great tenacity to porous bodies, as woollen or linen cloths, feathers, &c. Some speculative writers utterly deny that typhus is ever contagious—an opinion, however, which very few practical men will be found to adopt.

As typhous fever originates from different causes, and all these causes are modified in their action by collateral circumstances, it follows that it must be accompanied by different symptoms, and appear under different degrees of severity. Hence a general distinction of typhus into *typhus mitior*, mild typhus or nervous fever; and *typhus gravior*, severe or malignant typhus.

I. *Typhus mitior. Nervous fever. Slow fever.*— Characterised by slight shiverings; heavy or vertiginous headach; great oppression about the præcordia; nausea; frequent sighing; despondency; whey-like urine; with the ordinary heat of skin, thirst, and febrile symptoms, which exacerbate once or twice a day, and are accompanied in many cases by low muttering delirium.

There is seldom any thing alarming in the commencement. The first symptoms are slight: the tongue exhibits little change, and the pulse is only a little quickened, and somewhat smaller than usual; at the same time, however, there is great anxiety and depression of mind; so that the symptoms do not much differ from a mild and comparatively insignificant fever of any kind operating on a nervous temperament. But as the disease advances, all the symptoms of sensorial debility become severer; the skin, which has hitherto been mostly dry, will now be covered with profuse, clammy, weakening sweats, while the heat is still inconsiderable, and the countenance pale and sunk. The perspiration is often offensive to the smell, and has a sour odour. About the tenth day, the weakness greatly increases; all the limbs become tremulous; and the tremors soon become convulsive, with a despondency and alienation of mind, at first observable only in the night, but soon continuing with little intermission. This delirium is of the mildest form. The disease often runs on to the twenty-first day, and occasionally to a much longer period. It very seldom vanishes under an obvious crisis, but gradually becomes more aggravated in its symptoms, till it reaches a fatal termination; or, by a gradual subsidence of the severity of the symptoms, it slowly advances to convalescence, indicated by a disposition to natural sleep; more steadiness, and firmness of pulse; a more favourable countenance; a tongue more florid at its edges; a firmer and more collected mind; and a returning desire for food.

Where the patient is of a sound constitution, and not debilitated by age, nervous fever is seldom fatal. In some instances, however, it is protracted without any obvious cause, and continues till the vital powers are completely exhausted, and the patient sinks. Nervous fever, when characterised by slight symptoms, but an unusually lengthened and tedious course, forms what is more especially called *slow fever:* the case is a very intractable one, and very little under the control of art.

II. *Typhus gravior. Malignant typhus. Putrid fever. Pestilential fever. Petechial fever. Spotted fever. Jail fever. Camp fever. Hospital fever.* — At the onset of this form of fever, the patient is seized with great languor and dejection of spirits, extreme depression and loss of muscular strength, universal weariness and soreness, pains in the head, back, and extremities, and rigors; the eyes appear full, heavy, yellowish, and often a little inflamed; the temporal arteries throb; the tongue is covered with a brownish-coloured mucus, and soon becomes dry and parched; the proper taste is lost; the respiration is commonly laborious, and interrupted with deep sighing; the breath is offensive and hot; the body costive; the urine very natural, or pale; the pulse is frequent, small, hard, and fluttering, a trifling circumstance causing it to become very rapid, and unequal. There is sometimes a great load, feeling of heat, and oppression of the stomach, and not uncommonly bilious vomiting, when the disease is called *typhus biliosus.* As the disease advances, the pulse generally increases in frequency, but is, in many cases, not above the healthy standard, and in some cases below it, not being more than forty or sixty in the minute. Great debility is now present, and great heat and dryness of the skin; oppression of the heart, with anxiety, sighing, and moaning; the thirst is usually moderate, and the tongue, gums, teeth, mouth, and lips are covered with a brown or blackish tenacious fur; the speech becomes inarticulate, scarcely intelligible; the patient consequently mutters, and is mostly very delirious. The fever continuing to increase still more in violence, symptoms of an altered state of fluids occur, which were referred by the older writers to *putrefaction;* but real putrefaction never happens in the living body, and modern pathologists are therefore content to admit that a change takes place, the nature of which is not understood. The breath becomes highly offensive; the urine deposits a black and fœtid sediment; the stools are dark, offensive, and pass off insensibly; hæmorrhages issue from the gums, nostrils, mouth, and other parts of the body; petechiæ, and sometimes vibices, appear on the surface; the pulse intermits and sinks; the extremities grow cold; and hiccough ensues, followed by death. In the older writers we find cases described in which a dissolved state of the fluids, with large livid blotches on the skin, and

copious passive hæmorrhages from the mucous surfaces, seem to indicate a combination of the worst form of fever with scurvy. M. Andral aptly calls this state *un scorbut aigu*, an acute scurvy. Such cases are rarely if ever to be met with in the practice of the present day, nor are we able to account for this diversity of character in the febrile epidemics of different ages: they ought, however, to impress upon us the Protean character of fever, and to teach us to be careful how we fix upon this or that particular condition as a permanent and essential characteristic of the disease. See *Febris*.

When typhus does not terminate fatally, it generally begins, in temperate and cold climates, to diminish about the fourteenth day, or beginning of the third week, and goes off gradually without any evident crisis; it is not uncommon, however, for sleep and perspiration to announce the favourable change. In warm climates, the fever seldom lasts so long, but mostly terminates in five or eight days.

Our opinion as to the event is to be formed from the degree of violence of the symptoms, particularly from the strength of the heart's action, the state of the nervous power, the tendency to a dissolved state of the fluids and the local complications, bearing in mind that recoveries have taken place under the most unpromising appearances, and that, in many epidemics of this disease, some have fallen victims to it without any apparent malignancy of the symptoms. An abatement of febrile heat and thirst; a gentle moisture diffused equally over the whole surface of the body; loose bilious stools; deposition of lateritious sediment in the urine; more strength in the pulse; and the abscence of stupor and delirium; are always to be regarded as favourable. On the contrary, a fœtid odour from the body, effusions of blood under the skin, dark, highly offensive, and dysenteric evacuations from the bowels; involuntary discharges by urine and stool; hæmorrhages, hiccough, continued delirium and stupor, denote the almost certain dissolution of the patient.

The appearances, on dissection, are very varied: traces of subacute inflammation are generally to be found in some of the great cavities; but these do not occur in any one organ with sufficient uniformity to warrant us in regarding any one of them as a constant concomitant, much less as the proximate cause of typhus: the remarks which have been already made on the morbid anatomy of continued fever in general, are equally applicable to that of typhus. See *Febris*.

The division of typhus by Dr. Armstrong into *simple*, *inflammatory*, and *congestive*, is of little value in a pathological point of view, because every case is more or less congestive at its commencement, and any case may become complicated with local inflammation during its progress. This distinction, however, is a very useful one in relation to the treatment.

In simple typhus, that is, where the disease is characterised by its general symptoms, with a moderate reaction of the arterial system, and without marked symptoms of local inflammation, the efforts of art should be directed to sustaining the vital powers by a proper regulation of the diet, to keeping the bowels regular, and to obviating the disordered state of the secretions, rather than to any more active contest with the disease, which will generally run its course and terminate favourably. The diet should be light and moderately nutritious, consisting of farinaceous substances; the bowels, if torpid, should be stimulated by gentle purgatives; the disordered state of the abdominal secretions obviated by occasional doses of calomel; diarrhœa, if excessive, restrained by the cretaceous mixture, combined, if necessary, with small doses of opium; the hot and dry state of the skin obviated by saline diaphoretics, with minute doses of antimony, and by sponging the surface with tepid vinegar and water. Thirst is to be allayed by the free use of acidulated drinks.

In the advanced stages of the disease, if there be much nervous irritation, opiates combined with diaphoretics are highly serviceable; and, if great debility prevail, wine in moderate quantities may be given with advantage, but it is seldom required.

In the *inflammatory* form of typhus, or that in which the disease is complicated with membranous or visceral inflammation, the means available for the subjugation of ordinary inflammation are indicated, in conjunction with the treatment of simple fever; but these means are to be used under strict limitations. In this case there are two circumstances which should never be lost sight of: the one is, that the inflammation which accompanies fever differs entirely from ordinary idiopathic inflammation, and is much less under the control of bloodletting and other antiphlogistic measures; the other is, that this inflammation occurs in connexion with a protracted and debilitating disorder of the whole system, which forbids our drawing too largely on the vital powers. It sometimes, though very rarely, happens that the local affection may be subdued at the commencement, and the case converted into one of simple fever; but it much more frequently happens that the local inflammation cannot be entirely subdued, and the object of the practitioner should then be so to moderate it as to prevent its terminating in organic lesion. It is here that rash antiphlogistic practice is so pernicious, and the bad effect of certain exclusive pathological views so conspicuous.

The practitioner who, having detected inflammation of an important organ in a case of fever, makes up his mind that the essence of the disease consists therein — that such inflammation must at all events be entirely subdued — and that depletion must be persevered in till this end be attained — will generally fail in his immediate object, will find that the inflammation cannot be entirely subdued, and, what is worse, will too often sink the vital powers of the patient into an irrecoverable state of exhaustion. The practitioner who regards fever as simple inflammation of the brain, bowels, or any other part, and acts implicitly on this sup-

position, will destroy many patients who, if left to nature, would have recovered. A moderate general bleeding at the beginning of inflammatory typhus is often beneficial; and still more frequently the occasional application of leeches in the early stage of the disease. By such treatment the local affection is kept below the point of disorganisation, the fever runs its course, and the patient recovers.

The treatment of inflammation accompanying adynamic fever often severely taxes the judgment of the practitioner: it may happen on the one hand, that local inflammation continues so acute as to endanger disorganisation of a vital part, and on the other hand, that antiphlogistic means have been pushed as far as prudence will admit; under these circumstances mercury is sometimes a valuable auxiliary, enabling us to arrest the local inflammation and to save the patient. Much more extensive utility has been ascribed to mercury in fever, and a specific power of arresting the disease has been claimed for it; but the validity of such a claim is subverted by the numerous instances in which patients have died of fever while the mouth was sore from the effect of mercury. It is true, also, that patients labouring under continued fever have a peculiar insusceptibility of the action of mercury, and that in many cases no effect whatever is produced by its fullest administration.

In the advanced stages of typhus, complicated with local inflammation, the vital power, if severely depressed, must be supported by stimulants, even though the inflammatory action still continue. The case is one which, in a great measure, baffles our art; we have two opposite evils to contend against, and we must choose the less: if the patient can be kept alive for a certain time, there is a hope that the local affection may subside as the fever approaches the termination of its natural course; while, if we persevere in an antiphlogistic regimen, the powers of life will almost inevitably sink. Wine is the best stimulant in typhus, and is most effectual when given in moderate quantities frequently repeated. Opium, in small and repeated doses, is also a valuable medicine, and camphor may be usefully combined with it. Sulphate of quinine is much relied on by some practitioners, but it generally does more harm than good where there is local inflammation. Blisters afford a means of combating inflammation after bloodletting is inadmissible, but they often increase the general irritation and distress: their effect seems to be more beneficial where the seat of the inflammatory action is within the cranium, than when it is in the thorax or abdomen.

In the *congestive* form of typhus, either the morbid cause is so concentrated, or the powers of the system so inadequate to contend against it, that arterial reaction is overpowered, or very insufficiently established: hence the pulse is extremely feeble, the surface cold, and the countenance collapsed. The first indication, therefore, is, if possible, to rouse the arterial system, and thus to convert the disease into one or other of its more tractable forms — the simple or the inflammatory. For this purpose there is perhaps no more effectual means than to excite strong vomiting, by which a salutary reaction is often established. A full dose of ipecacuanha will generally be the most eligible emetic, as it has little tendency to irritate the gastro-enteric membrane: tartrate of antimony is to be avoided, as it has that tendency in a high degree. In addition to full vomiting, the warm bath and gentle stimulants will be found serviceable. If reaction cannot be set up, the case will be speedily fatal. It is from this cause that fever, in its more formidable epidemic visitations, is, in a few instances, so rapidly fatal. Dr. Fordyce gives the following description of this overwhelming invasion of fever. "When the attack is fatal, it sometimes kills in five minutes, sometimes it requires half an hour, seldom longer than that time. While the patient is yet sensible, violent headach, with great sense of chilliness, take place; the extremities become very cold and perfectly insensible; there is great prostration of strength, so that the patient is incapable of supporting himself in an erect posture; he becomes pale, his skin of a dirty brown, and he is soon insensible to external objects; the eyes are half open, the cornea somewhat contracted. If the patient goes off very soon, the pulse is diminished and at last lost, without frequency taking place; but if it be long before he dies, the pulse becomes excessively small and frequent, all the appearances of life gradually subside, and the patient is carried off."

If we succeed in establishing reaction, which is generally the case, the disease assumes a simple or inflammatory form, more frequently the latter, and is to be treated on the principles already explained.

We have hitherto said nothing of the several means which have been proposed for arresting fever *in limine*, or *cutting it short*, as it is called. This is sometimes spoken of in books as if it were a frequent occurrence; but we venture to assert that it is in reality extremely rare, and not generally to be looked for. The means which have been principally used with this intention are, —

1. *Venesection.* This, as before observed, is often useful, when prudently employed, in checking inflammation at the commencement of fever; but when it is had recourse to simply as a means of cutting short the fever, it is not only, in most cases, entirely ineffectual, but is injurious, in as much as it diminishes the vital power.

2. The *cold affusion.* This has already been treated of under the head *Affusion.* All that need be said of it here is, that its inutility has nearly banished it from practice.

3. *An emetic of tartrate of antimony.* This is, for the most part, as ineffectual as the means already noticed, and is often extremely injurious by setting up inflammation of the gastro-enteric mucous membrane.

It is not to be inferred from the distinctions just laid down, that the two severer forms of

typhus are exclusively inflammatory or congestive; for a low insidious form of inflammation is frequently going on in the gastro-enteric or bronchial membrane, or in the membranes of the brain, while the general character of the disease is that of deficient arterial action. In these cases all that we have to do is to support nature, for assuredly art can do very little.

From the brief survey we have just taken of the treatment of typhous fever, three prominent general indications may be deduced:

1. To assist arterial reaction when deficient.

2. To subdue local inflammation, or, if we cannot do so (which happens in a great majority of cases), to keep it below the point of disorganisation.

3. To sustain the vital powers by a proper regulation of the diet, and the judicious use of stimulants when required.

Typhus ca'rcerum. The gaol fever.

Typhus castrensis. The camp fever.

Typhus gravior. The more malignant species of typhus.

Typhus ictero'des. The yellow fever. See *Remittent fever.*

Typhus mitior. The milder form of typhus or *nervous fever.*

Typhus nervosus. The nervous fever.

Typhus petechialis. Typhus with purple spots.

Tyrannis. Τυραννις. An antidote mentioned by Galen, consisting of an immense number of aromatics, gums, balsams, &c., and the flesh of the lizard called *skink.* It was esteemed lithontriptic, antipodagric, alexiphamic, &c.

Tyri'asis. A corruption of *satyriasis.* An old name of the tubercular elephantiasis, on account of the morbid salacity which has been alleged to attend the disease.

Tyrium emplastrum. A plaster described by Aëtius, and so named from its purple colour. It consisted of litharge, oxide, and scales of copper, verdigris, galbanum, wax, pitch, and oil. It was esteemed vulnerary, discutient, &c.

Tyrrhenicum emplastrum. *Emplastrum Persicum. Pampathes.* A plaster to which Aëtius ascribes the most extraordinary virtues in a variety of cases. It consisted of various metallic ingredients, the magnet, gums, aromatics, &c.

U.

Ulcer. (*Ulcus, eris.* n.; from the Greek ἑλκος.) A purulent solution of continuity of the soft parts of an animal body. Ulcers may arise from a variety of causes, as all those which produce inflammation, from wounds, specific irritations of the absorbents, from scurvy, cancer, the venereal or scrofulous virus, &c. The proximate or immediate cause is an increased action of the absorbents, and a specific action of the arteries, by which a fluid is separated from the blood upon the ulcerated surface. They are variously denominated: the following is the most frequent division: —

1. The *simple ulcer*, which takes place generally from a superficial wound.

2. The *sinuous*, that runs under the integuments, and the orifice of which is narrow, but not callous.

3. The *fistulous ulcer*, or *fistula*, a deep ulcer with a narrow and callous orifice.

4. The *fungous ulcer*, the surface of which is covered with fungous flesh.

5. The *gangrenous*, which is livid, fœtid, and gangrenous.

6. The *scorbutic*, which depends on a scorbutic acrimony.

7. The *venereal*, arising from the venereal disease.

8. The *cancerous ulcer*, or open cancer. See *Cancer.*

9. The *carious ulcer*, depending upon a carious bone.

10. The *inveterate ulcer*, which is of long continuance, and resists the ordinary applications.

11. The *scrofulous ulcer*, known by its having arisen from indolent tumours, its discharging a viscid, glairy matter, and its indolent nature.

Ulcera serpentia oris. See *Aphtha.*

Ulcerated sore throat. See *Cynanche.*

Ulma'ria. (*a, æ.* f.; from *ulmus*, the elm: so named because it has leaves like the elm.) See *Spiræa ulmaria.*

U'lmine. A peculiar vegetable principle. It exuded spontaneously from the trunk of a species of elm, which Klaproth conjectures to be the *Ulmus nigra*, and was sent to him from Palermo in 1802. In its external characters it resembles gum. It is solid, hard, of a black colour, and has considerable lustre. Its powder is brown. It dissolves readily in the mouth, and is insipid.

U'lmus. (*us, i.* f.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia.*

2. The pharmacopœial name of the common elm. See *Ulmus campestris.*

Ulmus campestris. The systematic name of the common elm. *Ulmus — foliis duplicato-serratis, basis inæqualibus,* of Linnæus. The

inner tough bark of this tree, which is directed for use by the pharmacopœias, has no remarkable smell, but a bitterish taste, and abounds with a slimy juice, which has been recommended in nephritic cases, and externally as an useful application to burns. It is also highly recommended in some cutaneous affections allied to herpes and lepra. It is mostly exhibited in the form of decoction, by boiling four ounces in four pints of water to two pints; of which from four to eight ounces are given two or three times a day.

U'LNA. (*a*, *æ*. f.; from ωλενη, the ulna, or cubit.) *Cubitus*. The larger bone of the fore-arm. It is smaller and shorter than the os humeri, and becomes gradually smaller as it descends to the wrist. We may divide it into its upper and lower extremities, and its body, or middle part. At its upper extremity are two considerable processes, of which the posterior one and largest is named *olecranon*, and the smaller and interior one the *coronoid* process. Between these two processes, the extremity of the bone is formed into a deep articulating cavity, which, from its semicircular shape, is called the *greater sigmoid cavity*, to distinguish it from another, which has been named the *lesser sigmoid cavity*. The *olecranon*, called also the *anconoid* process, begins by a considerable tuberosity, which is rough, and serves for the insertion of muscles, and terminates in a kind of hook, the concave surface of which moves upon the pulley of the os humeri. This process forms the point of the elbow. The *coronoid process* is sharper at its extremity than the olecranon, but is much smaller, and does not reach so high. In bending the arm, it is received into the fossa at the fore part of the pulley. At the external side of the coronoid process is the lesser sigmoid cavity, which is a small, semilunar, articulating surface, lined with cartilage, on which the round head of the radius plays. At the fore part of the coronoid process we observe a small tuberosity, into which the tendon of the brachialis internus is inserted. The greater sigmoid cavity, the situation of which we just now mentioned, is divided into four surfaces by a prominent line, which is intersected by a small sinuosity that serves for the lodgment of mucilaginous glands. The whole of this cavity is covered with cartilage. The body or middle part of the ulna is of a prismatic or triangular shape, so as to afford three surfaces and as many angles. The external and internal surfaces are flat and broad, especially the external one, and are separated by a sharp angle, which, from its situation, may be termed the internal angle. This internal angle, which is turned towards the radius, serves for the attachment of the ligament that connects the two bones, and which is, therefore, called the *interosseous* ligament. The posterior surface is convex, and corresponds with the olecranon. The borders or angles, which separate it from the other two surfaces, are somewhat rounded. At about a third of the length of this bone from the top, in its fore part, we observe a channel for the passage of vessels. The lower extremity is smaller as it descends, nearly cylindrical, and slightly curved forwards and outwards. Just before it terminates, it contracts so as to form a neck to the small head with which it ends. On the outside of this little head, answering to the olecranon, a small process, called the *styloid* process, stands out, from which a strong ligament is stretched to the wrist. The head has a rounded articulating surface on its internal side, which is covered with cartilage, and received into a semi-lunar cavity formed at the lower end of the radius. Between it and the os cuneiforme a moveable cartilage is interposed, which is continued from the cartilage that covers the lower end of the radius, and is connected by ligamentous fibres to the styloid process of the ulna. The ulna is articulated above with the lower end of the os humeri. This articulation is of the species called ginglymus: it is articulated also both above and below to the radius, and to the carpus at its lowest extremity. Its chief use seems to be to support and regulate the motions of the radius. In children, both extremities of this bone are first cartilaginous, and afterwards epiphyses, before they are completely united to the rest of the bone.

U'LNAR. (*Ulnaris*; from *ulna*, the bone, so named.) Belonging to the ulna.

Ulnar artery. One of the branches into which the brachial artery divides it, bend of the arm. It passes down the inner side of the fore-arm, gives off the ulnar recurrent, the anterior and posterior interosseous, and terminates by forming the superficial palmar arch.

Ulnar nerve. See *Nerve*.

Ulnaris externus. See *Extensor carpi ulnaris*.

Ulnaris internus. See *Flexor carpi ulnaris*.

U'LVA. (*a*, *æ*. f.; from *uligo*, moisture, ooziness.) The name of a genus in the Linnæan system of plants. Class, *Cryptogamia*; Order, *Algæ*. Laver.

Ulva lactu'ca. *Lichen marinus*. Oyster-green laver. It is refrigerant and nutritive, and was probably first used in an anti-scrofulous diet, but is now introduced as a luxury.

Ulva umbilicalis. Shield laver. This is said to be eatable and nourishing when well baked.

U'mbel. See *Umbella*.

UMBE'LLA. (*a*, *æ*. f.; a little shade or umbrella.) An umbel. The *rundle* of some authors. A species of inflorescence, in which several flower-stalks, nearly equal in length, spread from one common centre, their summits forming a level, convex, or even globose surface; more rarely a concave one, as hemlock, carrot, cow-parsnip, &c.

From the *insertion* of the umbel, it is distinguished into *pedunculate* and *sessile*. The former implies that the flower-stalks come from one common peduncle; and the latter, that the stalklets come, not from a common peduncle, but from the stem or branch of the plant; as in *Sium nodiflorum*, and *Prunus avium*.

From the *division* of the umbel, it is, —

1. *Simple*, when single-flowered; as in *Allium ursinum*.

2. *Compound*, when each ray or stalk bears an *umbellula*, or partial umbel; as in the *Anethum fœniculum*.

The *umbella involucrata* is supplied with involucra.

UMBELLI'FEROUS. Plants are so called which have umbels. The *umbelliferæ* form an important natural order.

UMBE'LLULA. A partial or little umbel. The flower-stalks or spokes, which compose an umbel, are often divided at the top into several smaller ones; and these smaller sets of flowers are called umbellules. See *Umbella*.

Umbellule. See *Umbellula.*

UMBILICAL. (*Umbilicalis;* from *umbilicus*, the navel.) Of or belonging to the navel.

Umbilical cord. *Funis umbilicalis. Funiculus umbilicalis.* The navel-string. A cord-like substance, of an intestinal form, about half a yard in length, that proceeds from the navel of the fœtus to the centre of the placenta. It is composed of a cutaneous sheath, cellular substance, one umbilical vein, and two umbilical arteries: the former conveys the blood to the fœtus from the placenta, and the latter return it from the fœtus to the placenta.

Umbilical hernia. See *Hernia umbilicalis.*

Umbilical region. See *Abdomen.*

UMBILICA'TUS. Having a cavity or dimple resembling a navel. Applied in *Natural History*, and in *Botany*, to leaves, fruits, stigmata, &c.

UMBILI'CUS. The navel.

Umbilicus marinus. *Cotyledon marina. Androsace. Acetabulum marinum. Androsace Matthioli. Fungus petræus marinus.* A submarine production, found on rocks and the shells of fishes, about the coast of Montpellier, &c. It is said to be, in the form of powder, a useful anthelmintic and diuretic.

U'MBO. (The boss of a shield.) The knob or more prominent part in the centre of the hat or pilus of the fungus tribe.

U'NCIFORM. (*Unciformis;* from *uncus*, a hook, and *forma*, a likeness.) Hook-like: applied to bones, &c.

Unciform bone. The last bone of the second row of the carpus, or wrist: so named from its hook-like process, which projects towards the palm of the hand, and gives origin to the great ligament by which the tendons of the wrist are bound down.

Unciform processes. See *Sphenoides os.*

UNCINA'TUS. (From *uncus*, a hook.) Uncinate, or hooked at the end: applied to the stigma of the *Lantana*.

UNDULA'TUS. Undulated: waved. Applied to a leaf when the disk near the margin is waved obtusely up and down, as in *Reseda lutea*.

Unedo papyracea. See *Arbutus unedo.*

Unequal. See *Inequalis.*

UNGUE'NTUM. (*um*, *i.* n.; from *ungo*, to anoint.) An ointment. The usual consistence of ointments is about that of butter.

Unguentum apostolorum. *Dodecapharmicum.* The apostles' ointment: so called because it consisted of twelve ingredients, exclusive of a little vinegar. These ingredients were, turpentine, resin, yellow wax, aristolochia longa, frankincense, bdellium, myrrh, galbanum, opopanax, verdigris, litharge, and oil. It was formerly used as a detergent.

Unguentum arma'rium. A celebrated sympathetic ointment, which it was believed would cure wounds if the weapon which inflicted them were smeared with it, without any application to the wound itself. It consisted of the usnea of the human skull, human fat, of each two ounces; mummy, human blood, of each half an ounce; linseed oil, turpentine, Armenian bole, of each an ounce. A present of the prescription for this mess was made by Paracelsus to the Emperor Maximilian, who esteemed it a great treasure. Much was written at one time for and against the efficacy of such applications. It is singular, it never occurred to the wise men, that wounds heal of themselves if there be nothing particular to prevent it.

Unguentum cantha'ridis. *Unguentum lyttæ.* Ointment of the blistering-fly. Take of the blistering-fly, rubbed to a very fine powder, an ounce; distilled water, four fluid ounces; resin cerate, four ounces. Boil the water with the blistering-fly to one half, and strain: mix the cerate with the liquor, and then let it evaporate to the proper consistence. This is sometimes used to keep a blister open; but the savine cerate is to be preferred.

Unguentum ceta'cei. Spermaceti ointment; formerly called *linimentum album*, and *unguentum spermaceti.* Take of spermaceti, six drachms; white wax, two drachms; olive oil, three fluid ounces. Having melted them together over a slow fire, constantly stir the mixture until it gets cold. A simple emollient ointment.

Unguentum cicu'tæ. Hemlock ointment. Take of the fresh leaves of hemlock, and prepared hog's lard, of each four ounces. The hemlock is to be bruised in a marble mortar, after which the lard is to be added, and the two ingredients thoroughly incorporated by beating. They are then to be gently melted over the fire; and after being strained through a cloth, and the fibrous parts of the hemlock well pressed, the ointment is to be stirred till quite cold. It is applied to cancerous, scrofulous, and other ill-conditioned sores.

Unguentum creaso'ti. Take of creasote, half a fluid drachm; lard, an ounce. Rub them together till they are mixed. A stimulant ointment. It has been used in porrigo.

Unguentum e'lemi. *Unguentum elemi compositum*, ointment of elemi; formerly called *linimentum arcæi*, and *unguentum è gummi elemi.* Take of elemi, a pound; common turpentine, ten ounces; prepared suet, two pounds; olive oil, two fluid ounces: melt the elemi with the suet, then remove it from the fire, and immediately mix in the turpentine and oil; then strain through a linen cloth. Applied to indolent ulcers, chilblains, chronic ulcers after burns, and indolent tumours.

Unguentum gallæ compositum. Take of galls very finely powdered, two drachms; lard, two ounces; hard opium powdered, half a

drachm. Mix them. An astringent and anodyne ointment, applied chiefly to hæmorrhoidal tumours.

Unguentum hydrargyri ammonio-chloridi. *Unguentum hydrargyri precipitati albi. Unguentum calcis hydrargyri albæ. Unguentum mercurio-precipitati.* Take of ammonio-chloride of mercury, a drachm; lard, an ounce and a half. Dissolve the lard with a gentle heat, then add the ammonio-chloride of mercury, and mix. A mild detergent ointment. It is little used.

Unguentum hydrargyri fortius. Strong mercurial ointment; formerly called *unguentum cæruleum fortius.* Blue ointment. Take of purified mercury, two pounds; prepared lard, twenty-three ounces; prepared suet, an ounce: first rub the mercury with the suet and a little of the lard, until the globules disappear; then add the remainder of the lard, and mix. In very general use for mercurial frictions.

Unguentum hydrargyri mitius. Mild mercurial ointment; formerly called *unguentum cæruleum mitius.* Take of strong mercurial ointment, a pound; prepared lard, two pounds: mix. Weaker than the former.

Unguentum hydrargyri nitratis. *Unguentum hydrargyri nitrati.* Ointment of nitrate of mercury. Take of purified mercury, an ounce; nitric acid, eleven fluid drachms; prepared lard, six ounces; olive oil, four fluid ounces; first dissolve the mercury in the acid; then, while the liquor is hot, mix it with the lard and oil melted together. A stimulating and detergent ointment. Tinea capitis, psorophthalmia, indolent tumours on the margin of the eyelid, and ulcers in the urethra, are cured by its application.

Unguentum hydrargyri nitratis mitius. Weaker than the preceding.

Unguentum hydrargyri nitrico-oxidi. Ointment of nitric oxide of mercury. Take of nitric oxide of mercury, an ounce; white wax, two ounces; prepared lard, six ounces: having melted together the wax and lard, add thereto the nitric oxide of mercury in very fine powder, and mix. A most excellent stimulating and escharotic ointment.

Unguentum hydrargyri præcipitati albi. Ointment of white precipitate of mercury; formerly called *unguentum è mercurio præcipitato albo;* and latterly, *unguentum calcis hydrargyri albæ.* Take of white precipitate of mercury, a drachm; prepared lard, an ounce and a half: having melted the lard over a slow fire, add the precipitated mercury, and mix. A useful ointment to destroy vermin in the head, and to assist in the removal of scald-head, venereal ulcers of children, and cutaneous eruptions.

Unguentum hydrargyri biniodidi. Prepared in a similar manner to the *unguentum hydrargyri nitrico-oxidi.*

Unguentum hydrargyri iodidi. Prepared in a similar manner with the preceding.

Unguentum iodinii compositum. Compound ointment of iodine. Take of iodine, half a drachm; iodide of potassium, a drachm; rectified spirit, a fluid drachm; lard, two ounces. Rub down the iodine and the iodide of potassium with the spirit, and then mix them with the lard. Applied by way of friction to goitre, scrofulous tumours, &c.

Unguentum lyttæ. See *Unguentum cantharidis.*

Unguentum ophthalmicum. Ophthalmic ointment of Janin. Take of prepared hog's lard, half an ounce; prepared tutty, Armenian bole, of each two drachms; white precipitate, one drachm: mix. This celebrated ointment may be used for the same diseases of the eye and eyelid as the ung. hydrarg. nitratis. It must be at first weakened with about twice its quantity of hog's lard.

Unguentum picis aridæ. See *Unguentum resinæ nigræ.*

Unguentum picis liquidæ. Tar ointment; formerly called *unguentum picis,* and *unguentum è pice.* Take of tar, prepared suet, of each a pound: melt them together, and strain the mixture through a linen cloth. This is applicable to cases of tinea capitis, and some eruptive complaints; also to some kinds of irritable sores.

Unguentum plumbi compositum. Compound ointment of lead. Take of prepared chalk, eight ounces; distilled vinegar, six fluid ounces; plaster of lead, three pounds; olive oil, a pint. Melt the plaster in the oil with a slow fire; then gradually add the chalk separately mixed with the vinegar, the effervescence being finished, and stir constantly until they are cooled. Used as a dressing for indolent ulcers.

Unguentum plumbi iodidi. Ointment of iodide of lead. Take of iodide of lead, an ounce; lard, eight ounces. Rub together, and mix. Employed by way of friction in chronic enlargement of the joints, and indolent scrofulous tumours.

Unguentum resinæ flavæ. Yellow basilicon is in general use as a stimulant and detersive; it is an elegant and useful form of applying the resin.

Unguentum resinæ nigræ. *Unguentum picis aridæ.* Pitch ointment; formerly called *unguentum basilicum nigrum,* vel *tetrapharmacum.* Take of pitch, yellow wax, yellow resin, of each nine ounces; olive oil, a pint: melt them together, and strain the mixture through a linen cloth. This is useful for the same purposes as the tar ointment.

Unguentum sambuci. Elder ointment; formerly called *unguentum sambucinum.* Take of elder flowers, two pounds; prepared lard, two pounds: boil the elder flowers in the lard until they become crisp; then strain the ointment through a linen cloth. A cooling and emollient preparation.

Unguentum sulphuris. Sulphur ointment; formerly called *unguentum è sulphure.* Take of sublimed sulphur, three ounces; prepared lard, half a pound: mix. The most effectual preparation to destroy the itch. It is also serviceable in the cure of other cutaneous eruptions.

Unguentum sulphuris compositum. Compound sulphur ointment. Take of sublimed sulphur, half a pound; white hellebore-root, powdered, two ounces; nitrate of potash, a

drachm; soft soap, half a pound; prepared lard, a pound and a half: mix. This preparation was introduced into the London Pharmacopœia, as a more efficacious remedy for itch than common sulphur ointment. In the army, where it is generally used, the sulphur vivum, or native admixture of sulphur, with various heterogeneous matters, is used instead of sublimed sulphur.

Unguentum vera'tri. White hellebore ointment; formerly called *unguentum hellebori albi*. Take of white hellebore-root, powdered, two ounces; prepared lard, eight ounces; oil of lemons, twenty minims: mix.

Unguentum zinci. Zinc ointment. Take of the oxide of zinc, an ounce; prepared lard, six ounces: mix. A very useful application in chronic ophthalmia and relaxed ulcers.

U'NGUIS. (*is, is.* m.; from *ονυξ*, a hook.) 1. In *Anatomy*, the nail. The nails are horny laminæ situated at the extremities of the fingers and toes; composed of coagulated albumen, and a little phosphate of lime. The lachrymal bone is named *os unguis*, from its resemblance to a nail of the finger.

2. In *Surgery*, an abscess or collection of pus between the lamellæ of the cornea transparens of the eye: so called from its resemblance to the lunated portion of the nail of the finger.

3. In *Botany*, the claw: applied to the thin part of the petal of a polypetalous corolla.

Ungula caballina. See *Tussilago*.

UNGULA'TUS. Hoof-shaped.

U'NICUS. Single.

UNIFLO'RUS. Bearing one flower.

Uniform. See *Æqualis*.

UNILA'TERAL. *Unilateralis*. On one side only.

UNILO'CULAR. *Unilocularis*. One-celled.

U'NIO. (*o, onis.* m.) A pearl. See *Margarita*.

Union by the First Intention. This phrase is applied by surgeons to the healing of wounds by adhesion, without suppuration or granulation. See *Inflammation*, and *Wounds*.

United. See *Connatus*.

U'NIVALVE. One-valved.

U'PAS. The name given in Java to several deadly poisons, of which the *Bohun upas* and *upas tieuté* are the most remarkable. They belong to different genera, and owe their poisonous properties to different principles.

1. The *Bohun upas*. This is a bitter gum resin, which exudes from incisions in the bark of a large tree which grows in Java and the neighbouring islands, and is called *antiar*, or *antshar*, by the Javanese. It is the *Antiaris toxicaria*, or *Ipo toxicaria*, of botanists. The *Bohun upas* is a deadly and rapid poison, which, if excluded from the air, retains its activity for an unlimited time. MM. Pelletier and Caventou attribute its deleterious powers to a new alkali not hitherto obtained in a separate state. Wonderful stories have been told of the blighting effect of the upas tree, which was said to make a complete desert of the country for ten or twelve miles round it, in which space no animal or vegetable could live. The poison was said to be fetched from the tree by condemned malefactors, who sometimes succeeded, by the greatest precautions, in procuring some of the poison, and returning in safety, in which case they were pardoned. All these marvels were believed on the credit of a tract published in Dutch by a surgeon named Foërsch. This all turns out to be mere romance. The tree grows in the most fertile places, and twining plants grow around it.

Some persons, however, on approaching it nearly, have experienced unpleasant sensations analogous to those caused by the exhalation from the manchineel and some other plants. The production of M. Foërsch is supposed by some to have originated in a confusion of the *upas tree* and the *upas valley* in Java, an interesting account of which has been published by Mr. Barrow in the Philosophical Transactions, from the notes of Mr. Loudon: these materials are thought to have been worked up by a talent for invention into the monstrous fable above alluded to. According to Mr. D'Israeli, however, the hoax was still more complex. The account was published in English, in the London Magazine, but it has no existence in the Dutch work, from which it professes to be translated. The lying Dutchman, therefore, is as fictitious as the tree he is made to describe. Mr. D'Israeli believes the whole affair to have been a fabrication of that mischievous individual George Stevens, whose principal delight was in literary impostures. See *Curiosities of Literature, Second Series*, vol. iii. p. 39.

2. The *Upas tieuté*. This poison is the produce of the *strychnos tieuté*, and owes its deadly power to *strychnia*.

Both of the above poisons are used, by the natives of the islands where they grow, to poison arrows.

Upright. See *Erectus*.

U'RACHUS. (*us, i.* m.; *ουρακος*, from *ουρον*, urine.) *Urinaculum*. The ligamentous cord that arises from the basis of the urinary bladder, which it runs along, and terminates in the umbilical cord. In the fœtuses of brute animals, which the ancients mostly dissected, it is a hollow tube, and conveys the urine to the allantoid membrane.

Ura'gium. (From *ουραγος*, the leader of the last band of an army.) The apex or extreme point of the heart.

Urani'scus. (From *ουρανος*, the firmament: so called from its arch.) The palate.

Uranite. See *Uranium*.

URA'NIUM. (*um, ii.* n.) Uranite. This metal was discovered by Klaproth in the year 1789. It exists combined with sulphur, and a portion of iron, lead, and silex, in the mineral termed *pechblende*, or *oxide of uranium*. Combined with carbonic acid it forms the *chalcolite*, or *green mica*; and mixed with oxide of iron, it constitutes the *uranitic ochre*. It is always found in the state of an oxide, with a greater or smaller portion of iron, or mineralised with sulphur and copper. The ores of uranium are of a blackish colour, inclining to a dark iron

grey, and of a moderate splendour: they are of a close texture, and when broken present a somewhat uneven, and, in the smallest particles, a conchoidal surface. They are found in the mines of Saxony.

Properties of Uranium. — Uranium exhibits a mass of small metallic globules, agglutinated together. Its colour is a deep grey on the outside, in the inside it is a pale brown. It is very porous, and is so soft that it may be scraped with a knife. It has but little lustre. Its specific gravity is between eight and nine. It is more difficult to be fused than even manganese. When intensely heated with phosphate of soda and ammonia, or glacial phosphoric acid, it fuses with them into a grass-green glass. With soda or borax it melts only into a grey, opake, scoriaceous bead. It is soluble in sulphuric, nitric, and muriatic acids. It combines with sulphur and phosphorus, and alloys with mercury. It has not yet been combined with other combustible bodies. It decomposes the nitric acid, and becomes converted into a yellow oxide. The action of uranium alone upon water, &c. is still unknown, probably on account of its extreme scarcity.

Method of obtaining Uranium. — In order to obtain uranium, the *pechblende* is first freed from sulphur by heat, and cleared from the adhering impurities as carefully as possible. It is then digested to nitric acid: the metallic matter that it contains is thus completely dissolved, while part of the sulphur remains undissolved, and part of it is dissipated under the form of sulphuretted hydrogen gas. The solution is then precipitated by a carbonated alkali. The precipitate has a lemon-yellow colour when it is pure. This yellow carbonate is made into a paste with oil, and exposed to a violent heat, bedded in a crucible well lined with charcoal.

Klaproth obtained a metallic globule 28 grains in weight, by forming a ball of 50 grains of the yellow carbonate with a little wax, and by exposing this ball in a crucible lined with charcoal to a heat equal to 170° of Wedgwood's pyrometer. Richter obtained in a single experiment 100 grains of this metal, which seemed to be free from all admixture. There are probably but two oxides of uranium, the *protoxide*, which is a greyish black, and the *peroxide*, which is yellow.

U'RATE. (*Uras, atis.* f.) A compound of uric or lithic acid with a salifiable base.

URCE'OLA. (*a, æ.* f.; from *urceolus*, a small pitcher: so named from its uses in scouring glazed vessels.) The *Parietaria officinalis* of Linnæus.

URCEOLA'TUS. Urceolate or pitcher-shaped: swelling or bellying out like a common jug. Applied in *Botany* to calyces, &c.

URE'A. (*a, æ.* f.; from *urina.*) A constituent of urine. The best process for preparing it is to evaporate urine to the consistence of syrup, taking care to regulate the heat towards the end of the evaporation; to add very gradually to the syrup its volume of nitric acid; to stir the mixture, and immerse it in a bath of iced water; to harden the crystals of the acidulous nitrate of urea which precipitate; to wash these crystals with ice-cold water, to drain them, and press them between the folds of blotting paper. When the adhering heterogeneous matter is thus separated, redissolve the crystals in water, and add to them a sufficient quantity of carbonate of potash to neutralise the nitric acid. Then evaporate the new liquor at a gentle heat, almost to dryness, and treat the residuum with a very pure alkohol, which dissolves only the urea. On concentrating the alkoholic solution, the urea crystallises.

The preceding is Thénard's process, which Dr. Prout has improved. He separates the nitrate of potash by crystallisation, makes the liquid urea into a paste with animal charcoal, digests this with cold water, filters, concentrates, then dissolves the new colourless urea in alkohol, and lastly crystallises.

Urea crystallises in four-sided prisms, which are transparent and colourless, with a slight pearly lustre. It has a peculiar, but not urinous odour; it does not affect litmus or turmeric papers; it undergoes no change from the atmosphere, except a slight deliquescence in very damp weather. In a strong heat it melts, and is partly decomposed and partly sublimed without change. The specific gravity of the crystals is about 1·35. It is very soluble in water. Alkohol, at the temperature of the atmosphere, dissolves about 20 per cent.; and, when boiling, considerably more than its own weight, from which the urea separates, on cooling, in its crystalline form. The fixed alkalis and alkaline earths decompose it. It unites with most of the metallic oxides, and forms crystalline compounds with the nitric and oxalic acids.

Urea has been recently analysed by Dr. Prout and Berard. The following are its constituents: —

	PER CENT.	PER CENT.	PER ATOM.
Hydrogen,	10·80	6·66	2 = 2·5
Carbon,	19·40	19·99	1 = 7·5
Oxygen,	26·40	26·66	1 = 10·0
Azote,	43·40	46·66	1 = 17·5
	100·00	100·00	37·5

Uric, or lithic acid, is a substance quite distinct from urea in its composition. This fact, according to Dr. Prout, explains why an excess of urea generally accompanies the phosphoric diathesis, and not the lithic. He has several times seen urea as abundant in the urine of a person, where the phosporic diathesis prevailed, as to crystallise spontaneously on the addition of nitric acid, without being concentrated by evaporation.

As urea and uric acid, says Berard, are the most azotised of all animal substances, the secretion of urine appears to have for its object the separation of the excess of azote from the blood, as respiration separates from it the excess of carbon. "The relation," says Dr. Prout, "which exists between urea and sugar, seems to explain, in a satisfactory manner, the phænomena of diabetes, which may be considered as a depraved secretion of sugar. The weight of the atom of sugar is just half that of the weight of the atom of urea; the absolute quantity of hydrogen in a given weight of both, is equal; while

the absolute quantities of carbon and oxygen in a given weight of sugar, are precisely twice those of urea."

The constituents of these two bodies and lithic acid, are thus expressed by that ingenious philosopher: —

Elements.	Urea.			Sugar.			Lithic acid.		
	No.	Per Atom.	Per Cent.	No.	Per Atom.	Per Cent.	No.	Per Atom.	Per Cent.
Hydrogen .	2	2·5	6·66	1	1·25	6·66	1	1·25	2·85
Carbon . .	1	7·5	19·99	1	7·50	39·99	2	15·00	34·28
Oxygen . .	1	10·0	26·66	1	10·00	53·33	1	10·00	22·85
Azote . . .	1	17·5	46·6				1	17·50	40·00
	5	37·5	100·00	3	18·75	100·00	5	43·75	100·00

The above compounds appear to be formed by the union of more simple compounds: as sugar, of carbon and water; urea, of carburetted hydrogen and nitrous oxide; lithic acid, of cyanogen and water, &c.: whence it is inferred, that their artificial formation falls within the limits of chemical operations.

URE'DO. (From *uro*, to burn.) An itching or burning sensation of the skin, which accompanies many diseases. The nettle-rash is also so called.

URE'TER. (*er, eris.* m.; from *ουρον*, urine). The membraneous canal which conveys the urine from the kidney to the urinary bladder. At its superior part it is considerably the largest, occupying the greatest portion of the pelvis of the kidney; it then contracts to the size of a goose-quill, and descends over the psoas magnus muscle and large crural vessels into the pelvis, in which it perforates the urinary bladder very obliquely. Its internal surface is lubricated with mucus to defend it from the irritation of the urine in passing.

URETERI'TIS. (*is, idis.* f.; from *ουρητηρ*, the ureter.) Inflammation of the ureter. Its symptoms and treatment are the same as those of inflammation of the kidney and urinary bladder.

URE'THRA. (*a, æ.* f.; from *ουρον*, the urine: because it is the canal through which the urine passes.) A membranous canal, which in the male runs from the neck of the bladder, through the inferior part of the penis, to the extremity of the glans penis, in which it opens by a longitudinal orifice, called *meatus urinarius*. In this course, it first passes through the prostate gland, and is there distinguished by the name of the *prostatic urethra*; it then becomes much dilated, and is known by the name of the *bulbous part*, in which is situated a small round eminence, called the *caput gallinaginis*, or *verumontanum*, around which are ten or twelve orifices of the excretory ducts of the prostate gland, and two of the spermatic vessels. The remaining part of the urethra contains a number of triangular mouths, which are the *lacunæ*, or openings of the excretory ducts of the mucous glands of the urethra. In the female the urethra is much shorter and straighter than in the male. It is about an inch and a half long, and appears a little below the clitoris.

URETHRI'TIS. (*is, idis.* f.; from *ουρηθρα*, the urethra.) An inflammation in the urethra. Inflammation may take place on this membrane, as on other mucous membranes, and from the same causes; but it is, however, generally excited by calculous and gouty complaints, and most commonly by the venereal poison, which gives rise to the

Urethritis venerea. This is the proper term to be applied to that form of the venereal disease which consists of a discharge or running of a more or less puriform fluid from the urethra of men, and the vagina and urethra of women. Many names have been given to it by nosologists. Dr. Cullen arranges it in his genus gonorrhœa, under the trivial name of *impura*, *maligna*, *syphilitica*; but it is not a flow or emission of semen, and therefore should not be called a gonorrhœa. Dr. Good and Dr. Swediaur call it blennorrhœa; but this term is equally applicable to a discharge of mucus from any other part. The poison, which is the exciting cause of it, produces a specific inflammation of the membrane it acts on, whether it be the urethra, the vagina, or the nose, or the eye. Inflammation, therefore, is the disease; and the proper term for it is *urethritis venerea*, when the urethra is the seat of it. It has been called *elytritis venerea*, when occurring in the female vagina; but the term *elytritis* is not well derived. See *Elytritis*.

In Germany, the disorder is named *tripper*, from dripping; and in French, *chaudpisse*, from the heat and scalding in making water.

It has been long a disputed point, whether the morbid poison which gives rise to urethritis venerea, be identical or not with that of syphilis, nor can the question be considered as yet settled; but the general impression is, that they are different.

No certain rule can be laid down with regard to the time that a clap will take before it makes its appearance, after infection has been conveyed. With some persons it will show itself in the course of three or four days; while, with others, there will not be the least appearance of it before the expiration of some weeks. It most usually is perceptible, however, in the space of from six to fourteen days, and, in a male, begins with an uneasiness about the parts of generation, such as an itching in the glans penis, and a soreness and tingling sensation along the whole course of the urethra; soon after which, the person perceives an appearance of whitish

matter at its orifice, and also some degree of pungency upon making water.

In the course of a few days, the discharge of matter will increase considerably; will assume, most probably, a greenish or yellowish hue; and will become thinner, and lose its adhesiveness: the parts will also be occupied with some degree of redness and inflammation, in consequence of which the glans will put on the appearance of a ripe cherry; the stream of urine will be smaller than usual, owing to the canal being made narrower by the inflamed state of its internal membrane; and a considerable degree of pain and scalding heat will be experienced on every attempt to make water. Sometimes, though rarely, the poison acts on the mucous membrane behind and all around the glans penis, and a similar discharge of vitiated mucus takes place to that which escapes from the urethra.

Where the inflammation prevails in a very high degree, it prevents the extension of the urethra, on the taking place of any erection, so that the penis is, at that time, curved downwards, with great pain, which is much increased if an attempt be made to straighten the penis, and the stimulus occasions it often to be erected, particularly when the patient is warm in bed, and so deprives him of sleep, producing, in some cases, an involuntary emission of semen. This is called a *chordee*.

In consequence of the inflammation, it sometimes happens that, at the time of making water, owing to the rupture of some small blood-vessel, a slight hæmorrhage ensues, and a small quantity of blood is voided. In consequence of inflammation, the prepuce likewise becomes often so swelled at the end that it cannot be drawn back, which symptom is called a *phimosis;* or that, being drawn behind the glans, it cannot be returned, which is known by the name of *paraphimosis*. Now and then, from the same cause, little hard swellings arise on the lower surface of the penis, along the course of the urethra, and these perhaps suppurate and form into fistulous sores.

The adjacent parts sympathising with those already affected, the bladder becomes irritable and incapable of retaining the urine for any length of time, which gives the patient a frequent inclination to make water, and he feels an uneasiness about the scrotum, perinæum, and fundament. Moreover, the glans of the groins grow indurated and enlarged, or perhaps the testicles become swelled and inflamed, in consequence of which he experiences excruciating pains, extending from the seat of the complaint up into the small of the back: he gets hot and restless, and a small symptomatic fever arises.

Where the parts are not occupied by much inflammation, few or none of the last-mentioned symptoms will arise, and only a discharge with a slight heat or scalding in making water will prevail.

If the disease be neither irritated by any irregularity of the patient, nor prolonged by the want of timely and proper assistance, then, in the course of about a fortnight or three weeks, the discharge, from having been thin and discoloured at first, will become thick, white, and of a ropy consistence; and, from having gradually begun to diminish in quantity, will at last cease entirely, together with every inflammatory symptom whatever: whereas, on the contrary, if the patient has led a life of intemperance and sensuality, has partaken freely of the bottle and high-seasoned meats, and has, at the same time, neglected to pursue the necessary means, it may then continue for many weeks or months; and, on going off, may leave a weakness or gleet behind it, besides being accompanied with the risk of giving rise, at some distant period, to a constitutional affection, especially if there has been a neglect of proper cleanliness; for where venereal matter has been suffered to lodge between the prepuce and glans penis for any time, so as to have occasioned either excoriation or ulceration, there will be more danger of its having been absorbed.

Another risk, arising from the long continuance of a clap, especially if it has been attended with inflammatory symptoms, or has been of frequent recurrence, is the taking place of one or more strictures in the urethra. These are sure to occasion a considerable degree of difficulty, as well as pain, in making water, and, instead of its being discharged in a free and uninterrupted stream, it splits into two, or perhaps is voided drop by drop. Such affections become, from neglect, of a most serious and dangerous nature, as they not unfrequently block up the urethra, so as to induce a total retention of urine.

Where the disease has been of long standing, warty excrescences are likewise apt to arise about the parts of generation, owing to the matter falling and lodging thereon; and they not unfrequently prove both numerous and troublesome.

Having noticed every symptom which usually attends this disease in the male, it will only be necessary to observe, that the same heat and soreness in making water, and the same discharge of discoloured mucus, together with a slight pain in walking, and an uneasiness in sitting, take place in females as in the former; but as the parts in women which are most apt to be affected by the venereal poison are less complex in their nature and fewer in number than in men, so of course the former are not liable to many of the symptoms which the latter are, and from the urinary canal being much shorter and of a more simple form in them than in men, they are seldom, if ever, incommoded by the taking place of strictures.

With women it, indeed, often happens, that all the symptoms of the disease are so very slight, that they experience no other inconvenience than the discharge, except perhaps immediately after menstruation, at which period it is no uncommon occurrence for them to perceive some degree of aggravation in the symptoms.

Women of a relaxed habit, and such as have had frequent miscarriages, are apt to be afflicted with a disease known by the name of fluor albus, which it is often difficult to distinguish from a

clap, as the matter discharged in both is, in many cases, of the same colour and consistence. The surest way of forming a just conclusion, in instances of this nature, will be to draw it from an accurate investigation, both of the symptoms which are present, and those which have preceded the discharge; as, likewise, from the concurring circumstances, such as the character and mode of life of the person, and the probability there may be of her having had venereal infection conveyed to her by any connection in which she may be engaged.

It was once generally supposed, that the discharge depended always upon ulcers in the urethra, producing a discharge of purulent matter; and such ulcers do, indeed, occur in consequence of a high degree of inflammation and suppuration: but many dissections of persons, who have died whilst labouring under a clap, have clearly shown that the disease exists without any ulceration in the urethra, so that the discharge which appears is a puriform secretion, such as often takes place from the surface of other mucous membranes. On opening this canal, in recent cases, it usually appears red and inflamed: its mucous glands are somewhat enlarged, and its cavity is filled with matter to within a small distance from its extremity. Where the disease has been of long continuance, its surface all along, even to the bladder, is generally found pale and relaxed, without any erosion.

The cure of this disease is, in the present day, very simple; for the poison appears to have lost very much of its virulence, by passing from one constitution to another, which it evinced on its first detection. Rest, diluent drinks, and an antiphlogistic regimen, will often effect a cure alone; but it may be expedited by cooling laxatives and topical applications.

The remedies employed are of two kinds, and very opposite characters, — stimulant and sedative. Both also are used generally and locally: with a view of taking off the irritation directly, by exciting a new action; or indirectly, by rendering the parts affected torpid to the existing action, and thus allowing it to die away of its own accord. Many of these remedies, indeed, as well the local as the general, were at one time supposed to be natural antidotes, and to cure by a specific power, — an idea, however, which has been long banished from the minds of most practitioners.

The general sedatives that have hitherto been principally employed, are opium, conium, hyosciamus, papaver, nitrate of potash, oily emulsions, and mucilages. The first has often succeeded, but with considerable and very unnecessary inconvenience to the constitution: the others are not much to be depended on. They may have co-operated with a rigidly reducent diet, but have seldom answered alone. Employed locally, some of them, and particularly opium, have proved far more beneficial. The best form of this last is that of an injection. Practitioners usually direct it mixed with some oil or mucilage, both of which have a greater chance of acting as demulcents, and sheathing or inviscating the acrimonious corpuscles in this case, than in the irritable surface of the lungs in catarrh and asthma when given by the lungs. Two drachms of powder of gum acacia, five grains of powdered opium, and half a pint of distilled water, form a good injection; also, six fluid drachms of almond oil, half an ounce of powdered gum acacia, ten grains of powdered opium, and seven fluid ounces of distilled water, made into an emulsion: also, ten grains of powdered opium, and half a pint of decoction of marshmallows, or decoction of barley. The quantity of opium, and of the mucilaginous material, may be increased or diminished according to circumstances; and it is necessary, in the preparation of all these, to dissolve the opium first in the water, which should be distilled, or the purest soft water that can be obtained; then to filter or strain it through the finest gauze or lint before the mucilage is added. The chill should be taken off before the injection is used. The compound powder of ipecacuanha, the pilula opii, the extractum conii, the extractum hyosciami, and extractum papaveris, are the best forms of sedatives for internal use, and the dose must be accommodated to the effect which is required. To that which is selected, it is a good practice to add two or three grains of the piluia hydrargyri at bedtime, which has the beneficial effect of inducing an action under which the mucus is secreted of a less virulent nature, and the inflammation is more speedily removed.

The stimulant process has, however, been found to answer so much more rapidly, and more effectually, that it has almost superseded the use of sedatives in modern practice. Formerly this process was also employed generally; and it was supposed, and in many cases sufficiently ascertained, that by strongly irritating some other part, the morbid excitement of the urethra would subside, and the organ have time to recover its natural action: hence the intestines were daily stimulated by cathartics, as the neutral salts, mercury, and colocynth, which last was at one time regarded as a specific; or terebinthinates, as copaiba, camphire, and turpentine itself.

The stimulating plan is still continued with another remedy, imported from the East. In Bengal and Java, the common remedy is cubebs, the *Piper cubeba* of Linnæus. This pepper, well pounded, is exhibited in a little water, five or six times a day, in the quantity of a dessert spoonful, or about three drachms, during which time all heating aliments are to be carefully abstained from. The cure, we are told, is entirely completed in two or three days, the heat in making water first ceasing, and the discharge becoming viscid. A slight diarrhœa is sometimes produced, with a flushing in the face, and a sense of heat in the palms of the hands and the soles of the feet. There is no necessity, however, for subjecting the constitution to so severe a discipline; for the stimulant process, and particularly that of astringent stimulants, when employed locally, succeeds ordinarily in a few days without any trouble. These consist chiefly of the metallic salts in solution; as the oxymuriate, the submuriate of mercury, the sulphate and the acetate of zinc, the acetate of

lead, the sulphate of copper, and ammoniacal copper.

℞. Liquoris hydrargyri oxymuriatis, f. ℥j.; aquæ distillatæ, f. ℥ vij.: misce.

℞. Liquoris oxymuriatis hydrargyri, f. ℥j.; aquæ distillatæ, f. ℥ vij.; extracti hyosciami, gr. x.: misce et cola.

℞. Liquoris hydrargyri oxymuriatis, f. ℥j.; pulveris acaciæ, ℥ ss.; aquæ distillatæ, f. ℥ vij.: misce.

℞. Liquoris hydrargyri oxymuriatis, f. ℥j.; tinctura opii, f. ℥j.; pulveris acaciæ, ℥ ss.; aquæ distillatæ, f. ℥ vij.: misce.

℞. Liquoris hydrargyri oxymuriatis, f. ℥jss.; aquæ distillatæ, f. ℥ vjss.: misce.

℞. Hydrargyri submuriatis, ℈j.; liquoris calcis, f. ℥ iij.; aquæ distillatæ, f. ℥ iv.: misce.

After these have been mixed and occasionally shaken during one hour, pour off the clear liquor from the sediment.

℞. Hydrargyri submuriatis, ℈j.; liquoris calcis, f. ℥ iij.; tincturæ opii, f. ℥j.; aquæ distillatæ f. ℥ v.: misce.

℞. Zinci sulphatis, gr. v.; aquæ distillatæ, f. ℥ viij.: misce.

℞. Zinci sulphatis, gr. x.; aquæ distillatæ, f. ℥ viij.: misce.

℞. Zinci acetatis, ℈ ss.; aquæ distillatæ, f. ℥ viij.: misce.

℞. Plumbi acetatis, gr. iv.; spiritus tenuioris, f. ℥j.; aquæ distillatæ, f. ℥ vij.: misce.

The sulphate of copper and the ammoniacal copper require much more caution in their use: they are to be ordered in a very weak solution, which should be tasted before it is used; and if the tongue be sensible of their taste, the solution must be still further diluted, until the taste is scarcely perceptible.

These injections should be applied three times a day, with a proper instrument, and should be retained about a minute. The ill effect of them is a sudden stoppage of the discharge, from which swelled testicle, inflammation of the prostate gland and bladder, occasionally result; but the most frequent of all the sequels of the use of astringent injections, during the organic inflammation of the mucous membrane of the urethra, is stricture, which, though it seldom places the patient's life in any danger, proves a constant source of distress and anxiety, requires the long-continued use of bougies, and the attendance of the surgeon. Where the complaint, however, has been improperly treated with stimulating, and particularly stimulating-astringent injections, or where it has continued too long before application for medical assistance, the whole range of the urethra, or some particular parts of it, are apt to become so irritable as to excite spasmodic contractions, which commonly pass under the name of strictures, without being so in reality; and this irritation sometimes extends to the bladder. The most sensible parts of fibrous structures and canals are their extremities; and hence the portions of the urethra which suffer most from irritation, are the interior membrane of the glans and prostate, particularly the latter, in consequence of its direct connection with the bladder as well as the urethra. On this account, when a patient once labours under *spasmodic contractions*, or strictures, as they are called, from clap, whatever other parts these may exist in, the introduction of a bougie will be almost sure to prove that there is also a constriction at the prostatical portion. Generally speaking, it will be found to originate here, and to occur in other parts of the canal from sympathy. But the case will often be reversed; and while the irritation originates in some other part, or in the bladder, it is by sympathy with these that the prostate itself is affected. Mr. Abernethy has pointed out this double source of spasmodic constriction in the prostate, in the clearest manner possible, in his surgical observations on diseases of the urethra; and the remarks he has there offered upon the propriety of employing or withholding the bougie, as an instrument of cure, cannot be too deeply imprinted on every student's mind. It is almost unnecessary to add, that the utmost cleanliness, by frequent washing, should be maintained from the first appearance of the disease.

When urethritis is a secondary disease, or produced by accidents, operations, &c., it requires the same local treatment as inflammation of other mucous membranes; viz. leeches, cold lotions, and aperients. The view taken of the treatment of gonorrhœa in the preceding article is that which prevailed a few years back. The treatment of the inflammatory stage is now generally conducted on very different principles See the *Supplement*, art. *Urethritis venerea*.

Ure'ticus. (From *ουρον*, urine.) Applied to that which promotes a discharge of urine.

U'rias. (From *ουρον*, urine.) The urethra.

URIC. *Uricus.* Appertaining to urine.

Uric acid. See *Lithic acid.*

Urina'culum. See *Urachus.*

Uri'næ ardor. See *Dysuria.*

Urina'ria. (*a, æ.* f.; from *urina*, urine: so named from its diuretic qualities.) See *Leontodon taraxacum.*

U'RINARY. (*Urinarius*; from *urina*, urine.) Appertaining to urine.

Urinary bladder. *Vesica urinaria.* The bladder is a membraneous pouch, capable of dilatation and contraction, situated in the lower part of the abdomen, immediately behind the symphysis pubis, and opposite to the beginning of the rectum. Its figure is nearly that of a short oval. It is broader on the fore and back than on the lateral parts; rounder above than below, when empty; and broader below than above, when full. It is divided into the body, neck, and fundus, or upper part; the neck is a portion of the lower part, which is contracted by a sphincter muscle. This organ is made up of several coats; the upper, posterior, and lateral parts are covered by a reflection of the peritonæum, which is connected by cellular substance to the muscular coat. This is composed of several strata of fibres, the outermost of which are mostly longitudinal, the interior becoming gradually more transverse, connected together by reticular membrane. Under this is the cellular coat, which is nearly of the same structure with the tunica nervosa of the stomach. Winslow describes the internal or villous coat as somewhat granulated and glandular; but this

has been disputed by subsequent anatomists. However, a mucous fluid is poured out continually from it, which defends it from the acrimony of the urine. Sometimes the internal surface is found very irregular, and full of rugæ, which appear to be occasioned merely by the strong contraction of the muscular fibres, and may be removed by distending it. The sphincter does not seem to be a distinct muscle, but merely formed by the transverse fibres being closely arranged about the neck. The urine is received from the ureters, which enter the posterior part of the bladder obliquely; and when a certain degree of distension has occurred, the muscular fibres are voluntarily exerted to expel it.

Urinary calculus. See *Calculus, urinary.*

URINE. (*Urina, æ.* f. Ουρον; from ορουω, to rush out.) The saline liquid secreted in the kidneys, and dropping down from them, *guttatim*, through the ureters, into the cavity of the urinary bladder. *The secretory organ* is composed of the arterious vessels of the cortical substance of the kidneys, from which the urine passes through the uriniferous tubuli and renal papillæ, into the renal pelvis, whence it flows, drop by drop, through the ureters into the cavity of the urinary bladder, where it is detained some hours, and at length, when *abundant*, eliminated through the urethra.

Few of the apparatus of secretion are so complicated as that of the urine: it is composed of the two kidneys, of the *ureters*, of the bladder, and the *urethra;* besides the abdominal muscles contribute to the action of these different parts, amongst which the kidneys alone form urine: the others serve in its transportation and expulsion.

Situated in the abdomen, upon the sides of the vertebral column, before the last false ribs and the *quadratus lumborum*, the kidneys are of small volume relatively to the quantity of fluid they secrete. They are generally surrounded with a great deal of fat. Their parenchyma is composed of two substances: the one exterior, vascular, or *cortical;* the other called *tubular*, disposed in a certain number of cones, the base of which corresponds to the surface of the organ, and their summits unite in the membranous cavity called *pelvis*. Its cones appear formed by a great number of small hollow fibres, which are excretory canals of a particular kind, and which are generally filled with urine.

In respect of its volume, no organ receives so much blood as the kidney. The artery which is directed there is large, short, and proceeds immediately from the aorta: it has easy communication with the veins and the tubulous substance, as may be easily ascertained by means of the most coarse injections, which, being thrown into the renal artery, pass into the veins and into the pelvis, after having filled the cortical substance.

The filaments of the great sympathetic alone are distributed to the kidneys. The *calices*, pelvis, and ureter, form together a canal which commences in the kidneys, where it embraces the top of the mamillary processes; and, placed at the sides of the vertebral column, it goes in the bottom of the pelvis to the bladder, where it terminates. This last organ is an extensible and contractile sac, intended to hold the fluid secreted by the kidneys, and which communicates with the exterior by a canal of considerable length in man, but very short in woman, called *urethra*.

The posterior extremity of the urethra is only in man, surrounded by the *prostate* gland, which is considered by certain anatomists as a collection of mucous follicles. Two small glands placed before the anus pour a particular fluid into this canal. Two muscles which descend from the pubis towards the rectum, pass upon the sides of the part of the bladder which ends in the urethra, approach one another behind, and form a small arc which surrounds the neck of the bladder, and carries it more or less upwards.

If the pelvis is cut open in a living animal, the urine is seen to pass out slowly by the summits of the excretory cones. This liquid is deposited in the pelvis of the kidney, and then by little and little it enters into the *ureter*, through the whole length of which it passes. It thus arrives at the bladder, into which it penetrates by a constant exudation or dribbling.

A slight compression upon the uriniferous cones makes the urine pass out in considerable quantity; but, instead of being limpid, as when it passes out naturally, it is muddy and thick. It appears, then, to be filtered by the hollow fibres of the tubular substance.

Neither the *pelvis* nor the *ureter* being contractile, probably the power which produces the motion of the urine is, on one hand, that by which it is poured into the *pelvis;* and, on the other, the pressure of the abdominal muscles; to which may be added, when we stand upright, the weight of the liquid.

Under the influence of these causes, the urine passes into the bladder, and slowly distends this organ, sometimes to a considerable degree; this accumulation being permitted by the extensibility of different organs.

How does the urine accumulate in the bladder? Why does it not flow immediately by the urethra? and why does it not flow back into the ureter? The answer is easy: for the ureters. These conduits pass a considerable distance into the sides of the bladder. In proportion as the urine distends this organ, it flattens the ureters, and shuts them so much more firmly as it is more abundant. This takes place in the dead body as well as in the living; also, a liquid, or even air, injected into the bladder by the urethra, never enters the ureters. It is then, by a mechanism analogous to that of certain valves, that the urine does not return towards the kidneys.

It is not so easy to explain why the urine does not flow by the urethra. Several causes appear to contribute to this. The sides of this canal, particularly towards the bladder, have a continual tendency to contract, and to lessen the cavity; but this cause alone would be insufficient to resist the efforts of the urine to escape, when the bladder is full. In the dead body, in which the canal contracts nearly in the

same manner, it has but a very weak resistance, and does not prevent the passage of the liquid outwards, though the bladder may be very little compressed.

The angle of the bladder with the urethra, when it is strongly distended, may also present an obstacle to the passage of the urine; but the principal cause, most probably, is the contraction of the elevating muscles of the anus, which, either by the disposition to contraction of the muscular fibres, or by their contraction under the influence of the brain, press the urethra upwards, compress its sides with more or less force against each other, and thus shut its posterior orifice.

Excretion of Urine. — As soon as there is a certain quantity of urine in the bladder, we feel an inclination to discharge it. The mechanism of this expulsion deserves particular attention, and has not always been well understood.

If the urine is not always expelled, this ought not to be attributed to the want of contraction in the bladder — for this organ always tends to contract; but, by the influence of the causes that we have noticed, the internal orifice of the urethra resists with a force that the contraction of the bladder cannot surmount. The will produces this expulsion: — 1st, By adding the contraction of the abdominal muscles to that of the bladder; 2dly, By relaxing the *levatores ani*, which shut the urethra. The resistance of this canal being once overcome, the contraction of the bladder is sufficient for the complete expulsion of the urine it contained; but the action of the abdominal muscles may be added, and then the urine passes out with much greater force. We may also stop the flowing of the urine all at once, by contracting the levators of the anus.

The contraction of the bladder is not voluntary, though, by acting on the abdominal muscles, and the levators of the anus, we may cause it to contract when we choose.

The urine that remains in the urethra after the bladder is empty, is expelled by the contraction of the muscles of the perinæum, and particularly by that of the *acceleratores urinæ*.

Though the quantity of urine is very copious, and though it contains several proximate principles which are not found in the blood, and consequently a chemical action takes place in the kidneys, the secretion of the urine is nevertheless very rapid.

The physical properties of urine are subject to great variations. If rhubarb or madder has been used it becomes of a deep yellow, or blood-red; if one has breathed an air charged with vapours of oil or turpentine, or if a little rosin has been swallowed, it takes a violet colour. The disagreeable odour that it takes by the use of asparagus is well known.

Its chemical composition is not less variable. The more use that is made of watery beverages, the more considerable the total quantity and proportion of water becomes. If one drinks little, the contrary happens.

The uric acid becomes more abundant when the regimen is very substantial, and the exercise trifling. This acid diminishes, and may even disappear altogether, by the constant and exclusive use of unazotised food, such as sugar, gum, butter, oil, &c. Certain salts, carried into the stomach, even in small quantity, are found in a short time in the urine.

The extreme rapidity with which this translation takes place, has made it be supposed there is a direct communication between the stomach and the bladder. Even now there are considerable numbers of partisans in favour of this opinion.

It is not yet long since a direct canal from the stomach to the bladder was supposed to exist; but this passage has no existence. Others have supposed, without giving any proof, that the passage took place by the cellular tissue, by the anastomoses of the lymphatic vessels, &c.

Darwin having given to a friend several grains of nitrate of potash, in half an hour he had him bled, and collected his urine. The salt was found in the urine, but not in the blood. Brande made similar observations with prussiate of potash. He concluded from it, that the circulation is not the only means of communication between the stomach and the urinary organs, but without giving any explanation of the existing means. Sir Everard Home is also of this opinion.

Professor Magendie made experiments in order to clear up this important question; and found, 1st, That whenever prussiate of potash is injected into the veins, or absorbed in the intestinal canal, or by a serous membrane, it very soon passes into the bladder, where it is easily recognised amongst the urine. 2dly, That if the quantity of prussiate injected is considerable, the tests can discover it in the blood; but if the quantity is small, its presence cannot be recognised by the usual means. 3dly, That the same result takes place by mixing the prussiate and blood together in a vessel. 4thly, That the same salt is recognised in all proportions in the urine. It is not extraordinary, then, that Darwin and Brande did not find in the blood the substance that they distinctly perceived in the urine.

With regard to the organs that transport the liquids of the stomach and intestines into the circulating system, it is evident, according to what we have said, in speaking of the chyliferous vessels, and the absorption of the veins, that these liquids are directly absorbed by the veins, and transported by them to the liver and the heart; so that the direction which these liquids follow, in order to reach the veins, is much shorter than is generally admitted, viz. by the lymphatic vessels, the mesenteric glands, and the thoracic duct. — *Magendie.*

The urine of a healthy man is divided in general into, —

1. *Crude*, or that which is emitted one or two hours after eating. This is for the most part aqueous, and often vitiated by some kinds of food.

2. *Cocted*, which is eliminated some hours after the digestion of the food, as that which is emitted in the morning after sleeping. This is generally in smaller quantity, thicker, more

coloured, more acrid, than at any other time. Of such cocted urine, the *colour* is usually citrine.

The *degree of heat* agrees with that of the blood. Hence in atmospheric air it is warmer, as is perceived if the hand be washed with urine. The *specific gravity* is greater than that of water; and that emitted in the morning is always heavier than at any other time. The *smell* of fresh urine is not disagreeable. The *taste* is saltish and nauseous. The *consistence* is somewhat thicker than water. The *quantity* depends on that of the liquid drank, its diuretic nature, and the temperature of the air.

Changes of urine in the air. — Preserved in an open vessel, it remains pellucid for some time, and at length there is perceived at the bottom a *nubecula*, or little cloud, consolidated, as it were, from the gluten. This nubecula increases by degrees, occupies all the urine, and renders it opake. The natural smell is changed into a putrid *cadaverous* one; and the surface is now generally covered with a *cuticle*, composed of very minute crystals. At length the urine regains its transparency, and the *colour* is changed from a yellow to a brown; the cadaverous smell passes into an *alkaline;* and a brown, grumous *sediment* falls to the bottom, filled with white particles, deliquescing in the air, and so conglutinated as to form, as it were, little soft calculi.

Thus *two sediments* are distinguishable in the urine: the *one* white and gelatinous, and separated in the beginning; the *other* brown and grumous, deposited by the urine when putrid.

Spontaneous degeneration. — Of all the fluids of the body, the urine first putrefies. In summer, after a few hours, it becomes turbid, and sordidly black; then deposits a copious sediment, and exhales a fœtor like that of putrid cancers, which at length becomes cadaverous. Putrid urine effervesces with acids; and, if distilled, gives off, before water, an urinous volatile spirit.

The properties of healthy urine are, —

1. It reddens paper stained with turnsole and with the juice of radishes, and therefore contains an acid. This acid has been generally considered as the phosphoric, but Thénard has shown that, in reality, it is the *acetic*.

2. If a solution of ammonia be poured into fresh urine, a white powder precipitates, which has the properties of *phosphate of lime*.

3. If the phosphate of lime precipitated from urine be examined, a little magnesia will be found mixed with it. Fourcroy and Vauquelin have ascertained that this is owing to a little *phosphate of magnesia* which urine contains, and which is decomposed by the alkali employed to precipitate the phosphate of lime.

4. Proust informs us that *carbonic acid* exists in urine, and that its separation occasions the froth which appears during the evaporation of urine.

5. Proust has observed, that urine kept in new casks deposits small crystals, which effloresce in the air, and fall to powder. These crystals possess the properties of the *carbonate of lime*.

6. When fresh urine cools, it often lets fall a brick-coloured precipitate, which Scheele first ascertained to be crystals of *uric acid*. All urine contains this acid, even when no sensible precipitate appears when it cools.

7. During intermitting fevers, and especially during diseases of the liver, a copious sediment of a brick-red colour is deposited from urine. This sediment contains the *rosacic acid* of Proust.

8. If fresh urine be evaporated to the consistence of a syrup, and muriatic acid be then poured into it, a precipitate appears which possesses the properties of *benzoic acid*.

9. When an infusion of tannin is dropped into urine, a white precipitate appears, having the properties of the combination of tannin and *albumen*, or gelatine. Their quantity in healthy urine is very small, often indeed not sensible. Cruickshank found that the precipitate afforded by tannin in healthy urine amounted to 1-240th part of the weight of the urine.

10. If urine be evaporated, by a slow fire, to the consistence of a thick syrup, it assumes a deep brown colour, and exhales a fœtid ammoniacal odour. When allowed to cool, it concretes into a mass of crystals, composed of all the component parts of urine. If four times its weight of alkohol be poured into this mass at intervals, and a slight heat be applied, the greatest part is dissolved. The alkohol which has acquired a brown colour is to be decanted off, and distilled in a retort in a sand heat till the mixture has boiled for some time, and acquired the consistence of a syrup. By this time the whole of the alkohol has passed off, and the matter, on cooling, crystallises in quadrangular plates, which intersect each other. This substance is *urea*, which composes 9-20ths of the urine, provided the watery part be excluded. It is this substance which characterises urine, and constitutes it what it is, and to which the greater part of the very singular phenomena of urine are to be described.

11. According to Fourcroy and Vauquelin, the colour of urine depends upon the urea: the greater the proportion of urea the deeper the colour. But Proust has detected a *resinous matter* in urine, similar to the resin of bile, and to this substance he ascribes the colour of urine.

12. If urine be slowly evaporated to the consistence of a syrup, a number of crystals make their appearance on its surface: these possess the properties of the *muriate of soda*.

13. The saline residuum which remains after the separation of urea from crystallised urine by means of alkohol, has been long known by the names of *fusible salt of urine*, and *microcosmic salt*. When these salts are examined, they are found to have the properties of phosphates. The rhomboidal prisms consist of *phosphate of ammonia* united to a little *phosphate of soda*. The rectangular tables, on the contrary, are phosphate of soda united to a small quantity of phosphate of ammonia. Urine, then, contains *phosphate of soda*, and *phosphate of ammonia*.

14. When urine is cautiously evaporated, a few cubic crystals are often deposited among

the other salts: these crystals have the properties of *muriate of ammonia*.

15. When urine is boiled in a silver basin, it blackens it; and if the quantity of urine be large, small crusts of sulphuret of silver may be detached. Hence we see that urine contains *sulphur*.

Urine, then, contains the following substances: —

1. Water.
2. Acetic acid.
3. Phosphate of lime.
4. Phosphate of magnesia.
5. Carbonic acid.
6. Carbonate of lime.
7. Uric acid.
8. Rosacic acid.
9. Benzoic acid.
10. Albumen.
11. Urea.
12. Resin.
13. Muriate of soda.
14. Phosphate of soda.
15. Phosphate of ammonia.
16. Muriate of ammonia.
17. Sulphur.

According to Berzelius, healthy human urine is composed of water, 933; urea, 30·10; sulphate of potash, 3·71; sulphate of soda, 3·16; phosphate of soda, 2·94; muriate of soda, 4·45; phosphate of ammonia, 1·65; muriate of ammonia, 1·50; free acetic acid, with lactate of ammonia, animal matter soluble in alkohol, urea adhering to the preceding, altogether 17·14; earthy phosphates with a trace of fluate of lime, 1·0; uric acid, 1; mucus of the bladder, 0·32; silica, 0·03; in 1000·0.

No liquor in the human body, however, is so variable, in respect to *quantity* and *quality*, as the urine; for it varies,

1. *In respect to age.*—In the *fœtus* it is inodorous, insipid, and almost aqueous; but as the *infant* grows, it becomes more acrid and fœtid; and in *old age* more particularly so.

2. *In respect to drink.*— It is secreted in greater quantity, and of a more pale colour, from cold and copious draughts. It becomes green from an infusion of Chinese tea.

3. *In respect to food.*—From eating the heads of asparagus, or olives, it contracts a peculiar smell; from the fruit of the opuntia, it becomes red; and from fasting, turbid.

4. *In respect to medicines.*—From the exhibition of rhubarb root it becomes yellow; from cassia pulp, green; and from turpentine it acquires a violet odour.

5. *In respect to the time of the year.*—In the winter the urine is more copious and aqueous; but in the summer, from the increased transpiration, it is more sparing, higher coloured, and so acrid that it sometimes occasions strangury. The climate induces the same difference.

6. *In respect of the muscular motion of the body.*—It is secreted more sparingly, and concentrated by motion; and is more copiously diluted, and rendered more crude by rest.

7. *In respect of the affections of the mind.*—Thus fright makes the urine pale.

Use.—The urine is an excrementitious fluid, like lixivium, by which the human body is not only liberated from the superfluous water, but also from the superfluous salts and animal earth, and is defended from corruption.

Lastly, the vis medicatrix naturæ sometimes eliminates many morbid and acrid substances with the urine; as may be observed in fevers, dropsies, &c.

Urine, retention of. See *Retention*.

Urine, suppression of. See *Ischuria*.

UROCRI'SIA. (*a*, *æ*. f.; from *ουρον*, and *κρινω*, to judge.) The judgment formed of diseases by the inspection of urine.

UROPLA'NIA. (From *ουρον*, urine, and *πλαναω*, to wander.) Erratic urine. A translation of the urine to some part of the body where its presence is unnatural, as to the skin, the ventricles of the brain, &c.

UROSCO'PIA. (*a*, *æ*. f.; from *ουρον*, the urine, and *σκοπεω*, to inspect.) Inspection of urine, that a judgment of diseases may be made from its appearance.

URSI'NA RADIX. The root of the plant called baldmoney. See *Æthusa meum*.

URTI'CA. (*a*, *æ*. f.; *ab urendo*: because it excites a painful heat like that of a burn.) 1. The name of a genus of plants in the Linnæan system. Class, *Monœcia*; Order, *Tetrandria*. The nettle.

2. The pharmacopœial name of the common nettle. See *Urtica dioica*.

URTICA DIOICA. The systematic name of the common stinging nettle. This plant is well known, and though generally despised as a noxious weed, has been long used for medical, culinary, and economical purposes. The young shoots in the spring possess diuretic and antiscorbutic properties, and are with these intentions boiled and eaten like cabbage or other greens.

Urtica mortua. See *Lamium album*.

URTICA PILULIFERA. The systematic name of the pill-bearing nettle. *Urtica romana*. The seed was formerly given against diseases of the chest, but is now deservedly forgotten. To raise an irritation in paralytic limbs, the fresh plant may be employed, as producing a more permanent sting than the common nettle.

Urtica romana. See *Urtica pilulifera*.

URTICA URENS. The systematic name of a lesser nettle than the dioica, and possessing similar virtues.

URTICA'RIA. (*a*, *æ*. f.; from *urtica*, a nettle.) The nettle-rash; called also, *Febris urticata*, *Uredo*, *Purpura urticata*, and *Scarlatina urtica*. An eruption on the skin like the wheals caused by the sting of a nettle. The little elevations, called the nettle-rash, often appear instantaneously, especially if the skin be rubbed or scratched, and seldom stay many hours in the same place, and sometimes not many minutes. No part of the body is exempt from them; and where many of them rise together, and continue an hour or two, the parts are often considerably swelled, which particularly happens in the arms, face, and hands. These eruptions will continue to infest the skin, sometimes in one place, and sometimes in another, for one or two hours together, two or three times a day, or perhaps for the greatest part of twenty-four hours. In some constitutions they last only a few days, in others many months.

Urticaria is sometimes attended with fever and sometimes not. Bateman describes six varieties of this disease, viz. *Urticaria febrilis*, *U. evanida*, *U. perstans*, *U. conferta*, *U. subcutanea*, *U. tuberosa*.

All that is required in the treatment of this disease is gentle aperients, and not keeping the body too warm, but cool and lightly covered. The best application to allay the itching is dilute vinegar, or camphire water and vinegar. The decoction of Virginian snake-root is particularly useful in removing chronic urticaria.

URTICA'TIO. (*o, onis.* f.; from *urtica*, a nettle.) The whipping a paralytic or benumbed limb with nettles, in order to restore its feeling.

U'SNEA. (*a, æ.* f. An Arabic word.) A moss or lichen. More especially that which is found adhering to the skull when exposed to the air in damp places. It is the *Lichen saxatilis* of Linnæus. Extraordinary antiepileptic and antihæmorrhagic virtues were ascribed to the *usnea cranii humani*. It was an ingredient in the celebrated *unguentum armarium*.

USQUEBAUGH. (The Irish for *mad water*.) Originally the pure spirit called *whiskey*, which term is corrupted from usquebaugh. The usquebaugh of the present day is a strong rich compound spirit, chiefly taken as a dram, and made of cinnamon, coriander, nutmeg, mace, aniseed, citron, thyme, balm, savory, mint, rosemary, Spanish liquorice, sugar-candy, raisins, currants, and dates, infused in brandy.

USSAC. A name given by Serapion the Arabian to the gum ammoniacum of the Greek writers, which does not appear to be the same as that so called by us.

U'TERINE. *Uterinus.* Appertaining to the womb.

Uterine fury. See *Nymphomania.*

Uterine gestation. See *Pregnancy.*

U'TERUS. (*us, i.* m. Ὑστερα.) *Matrix. Ager naturæ. Hystera. Metra. Utriculus.* The womb. A spongy receptacle of the shape of a compressed pear, situated in the cavity of the pelvis, above the vagina, and between the urinary bladder and rectum.

The form of the uterus resembles that of an oblong pear flattened, with the depressed sides placed towards the ossa pubis and sacrum; but, in the impregnated state, it becomes more oval, according to the degree of its distension. For the convenience of description, and for some practical purposes, the uterus is distinguished into three parts, — the fundus, the body, and the cervix. The upper part is called the fundus, the lower the cervix; the space between them, the extent of which is undefined, the body. The uterus is about three inches in length, about two in breadth at the fundus, and one at the cervix. Its thickness is different at the fundus and cervix, being at the former usually rather less than half an inch, and at the latter somewhat more; and this thickness is preserved throughout pregnancy, chiefly by the enlargement of the veins and lymphatics, there being a smaller change in the size of the arteries. But there is so great a variety in the size and dimensions of the uterus in different women, independently of the states of virginity, marriage, or pregnancy, as to prevent any very accurate mensuration. The cavity of the uterus corresponds with the external form: that of the cervix leads from the os uteri, where it is very small, in a straight direction, to the fundus, where it is expanded into a triangular form, with two of the angles opposed to the entrance into the Fallopian tubes; and at the place of junction between the cervix and the body of the uterus, the cavity is smaller than it is in any other part. The angles above mentioned are called *cornua uteri*. There is a swell or fulness of all the parts towards the cavity, which is sometimes distinguished by a prominent line running longitudinally through its middle. The villous coat of the vagina is reflected over the os uteri, and is continued into the membrane which lines the cavity of the uterus. The internal surface of the uterus is corrugated in a beautiful manner, but the rugæ, or wrinkles, which are longitudinal, lessen as they advance into the uterus, the fundus of which is smooth. In the intervals between the rugæ are small orifices, like those in the vagina, which discharge a mucus, serving, besides other purposes, that of closing the os uteri very curiously and perfectly during pregnancy. The substance of the uterus, which is very firm, is composed of arteries, veins, lymphatics, nerves, and muscular fibres, curiously interwoven and connected together by cellular membrane. The muscular fibres are of a pale colour, and appear also in their texture somewhat different from muscular fibres in other parts of the body. The arteries of the uterus are the spermatic and hypogastric. The spermatic arteries arise from the anterior part of the aorta, a little below, and sometimes from the emulgents. They pass over the psoæ muscles behind the peritonæum, enter between the two laminæ or duplicatures of the peritonæum which form the broad ligaments of the uterus, and proceed to the uterus, near the fundus of which they insinuate themselves, giving branches in their passage to the ovaria and Fallopian tubes. The hypogastric arteries are on each side a considerable branch of the internal iliacs. They pass to the sides of the body of the uterus, sending off a number of smaller branches, which dip into its substance. Some branches also are reflected upwards to the fundus uteri, which anastomose with the spermatic arteries, and others are reflected downwards, supplying the vagina. The veins which reconduct the blood from the uterus are very numerous, and their size in the unimpregnated state is proportioned to that of the arteries; but their enlargement during pregnancy is such, that the orifices of some of them, when divided, will admit even of the end of a small finger. The veins anastomose in the manner of the arteries which they accompany out of the uterus, and then, having the same names with the arteries, spermatic and hypogastric, the former proceeds to the vena cava on the right side, and on the left to the emulgent vein; and the latter to the internal iliac.

From the substance and surfaces of the uterus an infinite number of lymphatics arise, which follow the course of the hypogastric and spermatic blood-vessels. The first pass into the gland of the internal iliac plexus, and the other into the glands which are situated near the origin of the spermatic arteries. Of these Nuck first gave a delineation.

The uterus is supplied with nerves from the lower mesocolic plexus, and from two small flat circular ganglions, which are situated behind the rectum. These ganglions are joined by a number of small branches from the third and fourth sacral nerves. The ovaria derive their nerves from the renal plexus. By the great number of nerves, these parts are rendered very irritable; but it is by those branches which the uterus receives from the intercostal, that the intimate consent between it and various other parts is chiefly preserved. The muscular fibres of the uterus have been described in a very different manner by anatomists, some of whom have asserted that its substance was chiefly muscular, with fibres running in transverse, orbicular, or reticulated order, whilst others have contended that there were no muscular fibres whatever in the uterus. In the unimpregnated uterus, when boiled for the purpose of a more perfect examination, the former seems to be a true representation, and when the uterus is distended towards the latter part of pregnancy, these fibres are very thinly scattered; but they may be discovered in a circular direction, at the junction between the body and the cervix of the uterus, and surrounding the entrance of each Fallopian tube in a similar order. Yet it does not seem reasonable to attribute the time of labour to its muscular fibres only, if we are to judge of the power of a muscle by the number of fibres of which it is composed, unless it is presumed that those of the uterus are stronger than in common muscles. With respect to the glands of the uterus, none are discoverable dispersed through its substance upon the inner surface of the cervix: between the rugæ there are lacunæ which secrete mucus, and there are small follicles at the edge of the os uteri. These last are only observable in a state of pregnancy, when they are much enlarged. From the angles at the fundus of the uterus, two processes of an irregular round form originate, called, from the name of the first describer, the *Fallopian tubes*. They are about three inches in length, and, becoming smaller in their progress from the uterus, have an uneven, fringed termination, called the fimbriæ. The canal which passes through these tubes is extremely small at their origin, but it is gradually enlarged, and terminates with a patulous orifice, the diameter of which is about one third of an inch, surrounded by the fimbriæ. It is also lined by a very fine vascular membrane, formed into serpentine plicæ. Through this canal the communication between the uterus and ovaria is preserved. The Fallopian tubes are wrapped in duplicatures of the peritonæum, which are called the broad ligaments of the uterus; but a portion of their extremities, thus folded, hangs loose on each side of the pelvis. From each lateral angle of the uterus, a little before and below the Fallopian tubes, the *round ligaments* arise, which are composed of arteries, veins, lymphatics, nerves, and a fibrous structure. These are connected together by cellular membrane, and the whole is much enlarged during pregnancy. They receive their outward covering from the peritonæum, and pass out of the pelvis through the ring of the external oblique muscle to the groin, where the vessels subdivide into small branches, and terminate at the mons veneris and contiguous parts. From the insertion of these ligaments into the groin, the reason appears why that part generally suffers in all the diseases and affections of the uterus, and why the inguinal glands are in women so often found in a morbid or enlarged state. The duplicatures of the peritonæum, in which the Fallopian tubes and ovaria are involved, are called the *broad ligaments* of the uterus. These prevent the entanglement of the parts, and are conductors of the vessels and nerves, as the mesentery is of those of the intestines. Both the round and broad ligaments alter their position during pregnancy, appearing to rise lower and more forward than in the unimpregnated state. Their use is supposed to be that of preventing the descent of the uterus, and to regulate its direction when it ascends into the cavity of the abdomen; but whether they answer these purposes may be much doubted. The use of the womb is for menstruation, conception, nutrition of the fœtus, and parturition. The uterus is liable to many diseases, the principal of which are retroversion and its falling down, hydatids, dropsy of the uterus, moles, polypes, ulceration, cancer, &c.

Uterus, inversion of. This is mostly produced by unskilfully and violently pulling away the placenta after delivery, and is only to be remedied by a restoration of the uterus to its proper state before it contracts; without which, perpetual barrenness must necessarily ensue, and the person be subject for life to a difficulty of walking, and other maladies.

Uterus, retroversion of. By the term retroversion such a change of the position of the uterus is understood, that the fundus is turned backwards and downwards upon its cervix, between the vagina and rectum, and the os uteri is turned forwards to the pubis, and upwards, in proportion to the descent of the fundus, so that, by an examination *per vaginam*, it cannot be felt, or not without difficulty, when the uterus is retroverted. By the same examination there may also be perceived a large round tumour, occupying the inferior part of the cavity of the pelvis, and pressing the vagina towards the pubes. By an examination *per anum*, the same tumour may be felt, pressing the rectum to the hollow of the sacrum; and if both these examinations are made at the same time, we may readily discover that the tumour is confined within the vagina and rectum. Besides the knowledge of the retroversion which may be gained by these examinations, it is found to be accompanied with other very distinguishing symptoms. There is in every case, together with extreme pain, a suppression of urine; and by the continuance of this distension of the bladder, the tumour formed by it in the abdomen often equals in size, and resembles in shape, the uterus in the sixth or seventh months of pregnancy: but it is necessary to observe, that the suppression of urine is frequently absolute only before the retroversion of the uterus, or during the time it is retroverted; for when

the retroversion is completed, there is often a discharge of urine, so as to prevent an increase of the distension of the bladder, though not in a sufficient quantity to remove it. There is also an obstinate constipation of the bowels, produced by the pressure of the retroverted uterus upon the rectum, which renders the injection of a clyster very difficult, or even impossible. But it appears that all the painful symptoms are chiefly in consequence of the suppression of urine; for none of those parts which are apt to sympathise in affections or diseases of the uterus are disturbed by its retroversion. The retroversion of the uterus has generally occurred about the third month of pregnancy, and sometimes after delivery it may likewise happen, where the uterus is, from any cause, enlarged to the size it acquires about the third month of pregnancy, but not with such facility as in the pregnant state, because the enlargement is then chiefly at the fundus. If the uterus is but little enlarged, or if it be enlarged beyond a certain time, it cannot well be retroverted: for, in the first case, should the cause of a retroversion exist, the weight at the fnndus would be wanting to produce it; and, in the latter, the uterus would be raised above the projection of the sacrum, and supported by the spine.

UTRI'CULUS. (Dim. of *uter*, a bottle: so called from its shape.) 1. The womb.

2. A little bag, bladder, or hollow vesicle. Applied by botanists to a species of capsule, which varies in thickness, never opens by any valve, and falls off with the seed. Sir J. Smith believes it never contains more than one seed, of which it is most commodiously, in botanical language, called an external coat, rather than a capsule. Gærtner applies it to *Chenopodium* and *Clematis:* in the former it seems to be pellicula; in the latter, testa. — *Smith.*

U'VA. (*a*, *æ*. f.; *quasi uvida*, from its juice.) 1. An unripe grape.

2. A tumour resembling a grape.

Uva gruina. See *Vaccinium.*

Uva passa major. See *Vitis.*

Uva passa minor. See *Vitis.*

Uva ursi. See *Arbutus uva ursi.*

U'VEA. (*a*, *æ*. f.; from *uva*, an unripe grape: so called because, in beasts, which the ancients chiefly dissected, it is like an unripe grape.) The black pigment on the back part of the iris. See *Oculus.*

U'VULA. (*a*, *æ*. f.; dim. of *uva*, a grape.) *Columella. Cion. Gargareon. Columna oris. Gurgulio. Interseptum.* The small conical fleshy substance hanging in the middle of the *velum pendulum palati*, over the root of the tongue. It is composed of the common membrane of the mouth, and a small muscle resembling a worm, which arises from the union of the palatine bone, and descends to the tip of the uvula. It was called *Palato-staphilinus*, by Douglas, and *Staphilinus epistaphilinus*, by Winslow. By its contraction, the uvula is raised up.

U'VULA VESI'CÆ. A small eminence in the neck of the bladder, which constitutes the apex of the triangle at the fore-part of the bladder, of which the openings of the ureters indicate the posterior angles.

UVULA'RIA. (*a*, *æ*. f.; from *uvula:* because it cured diseases of the uvula.) See *Ruscus hypoglossum.*

V.

VA'CCA. The cow. See *Bos taurus.*

VACCINATION. The insertion of the matter to produce cow-pox. See *Cow-pox.*

Vaccinia. See *Cow-pox.*

VACCI'NIUM. (*um*, *ii*. n.; *quasi baccinium*, from its berry.) The name of a genus of plants in the Linnæan system. Class, *Octandria;* Order, *Monogynia.*

VACCINIUM MYRTILLUS. The systematic name of the myrtle-berry. The berries, which are directed in the pharmacopœias by the name of *baccæ myrtillorum*, are the fruit of this plant. Prepared with vinegar they are esteemed as antiscorbutics, and when dry possess astringent virtues.

VACCINIUM OXYCOCCOS. The systematic name of the cranberry-plant. *Oxycoccus palustris. Vaccinia palustris. Uva gruina. Vitis idæa palustris.* Moor-berry. Cranberry. These berries are directed in some pharmacopœias. They are about the size of our haws, and are pleasantly acid and cooling, with which intention they are used medicinally in Sweden. In this country they are mostly preserved and made into tarts.

VACCINIUM VITIS IDÆA. The systematic name of the red whortle-berry. *Vitis idæa.* The leaves of this plant, *vaccinium vitis idæa*, of Linnæus, are so astringent as to be used in some places for tanning. They are said to mitigate the pain attendant on calculous diseases when given internally in the form of decoction. The ripe berries abound with a grateful acid juice; and are esteemed in Sweden as aperient, antiseptic, and refrigerant, and often given in typhoid diseases.

VAGI'NA. (*a*, *æ*. f.) *Vagina uteri.* The canal which leads from the external orifice of the female pudendum to the uterus. It is somewhat of a conical form, with the narrowest part downwards, and is described as being five or six inches in length, and about two in diameter. But it would be more proper to say, that it is capable of being extended to those

dimensions; for, in its common state, the os uteri is seldom found to be more than three inches from the external orifice, and the vagina is contracted as well as shortened. The vagina is composed of *two coats*, the first or innermost of which is villous, interspersed with many excretory ducts, and contracted into plicæ, or small transverse folds, particularly at the fore and back part; but, by child-bearing, these are lessened or obliterated. The second coat is composed of a firm membrane, in which muscular fibres are not distinctly observable, but which are endowed, to a certain degree, with contractile powers like a muscle. This is surrounded by cellular membrane, which connects it to the neighbouring parts. A portion of the upper and posterior part of the vagina is also covered by the peritonæum. The entrance of the vagina is constricted by muscular fibres originating from the rami of the pubis, which run on each side of the pudendum, surrounding the posterior part, and executing an equivalent office, though they cannot be said to form a true sphincter.

The upper part of the vagina is connected to the circumference of the os uteri, but not in a straight line, so as to render the cavity of the uterus a continuation of that of the vagina; for the latter stretches beyond the former, and being joined to the cervix, is reflected over the os uteri, which, by this mode of union, is suspended with protuberant lips in the vagina, and permitted to change its position in various ways and directions. When, therefore, these parts are distended and unfolded at the time of labour, they are continued into each other, and there is no part which can be considered as the precise beginning of the uterus or termination of the vagina.

The diseases of the vagina are, first, such an abbreviation and contraction as render it unfit for the uses for which it was designed; secondly, a cohesion of the sides in consequence of preceding ulceration; thirdly, cicatrices after an ulceration of the parts; fourthly, excrescences; fifthly, fluor albus. The abbreviation and contraction of the vagina, which usually accompany each other, are produced by original defective formation, and they are seldom discovered before the time of marriage, the consummation of which they sometimes prevent. The curative means are to relax the parts by the use of emollient applications, and to dilate them to their proper size by sponge or other tents, or, which are more effectual, by bougies gradually enlarged. But the circumstances which attend this disorder are sometimes such as might lead us to form an erroneous opinion of the disease. A case of this kind, which was under Dr. Denman's care, from the strangury, from the heat of the parts, and the profuse and inflammatory discharge, was suspected to proceed from venereal infection; and with that opinion the patient had been put upon a course of medicine composed of quicksilver, for several weeks, without relief. When she applied to the doctor, he prevailed upon her to submit to an examination, and found the vagina rigid, so much contracted as not to exceed half an inch in diameter, nor more than one inch and a half in length. The repeated, though fruitless attempts which had been made to complete the act of coition had occasioned a considerable inflammation upon the parts, and all the suspicious appearances before mentioned. To remove the inflammation she was bled, took some gentle purgative medicines, used an emollient fomentation, and afterwards some unctuous applications; she was also advised to live separate from her husband for some time. The inflammation being gone, tents of various sizes were introduced into the vagina, by which it was distended, though not very amply. She then returned to her husband, and in a few months became pregnant. Her labour, though slow, was not attended with any extraordinary difficulty. She was delivered of a full-sized child, and afterwards suffered no inconvenience. Another kind of constriction of the external parts sometimes occurs, and which seems to be a mere spasm. By the violence or long continuance of a labour, by the morbid state of the constitution, or by the negligent and improper use of instruments, an inflammation of the external parts, or vagina, is sometimes produced in such a degree as to endanger a mortification. By careful management this consequence is usually prevented: but in some cases, when the constitution of the patient was prone to disease, the external parts have sloughed away; and in others, equal injury has been done to the vagina. But the effect of the inflammation is usually confined to the internal or villous coat, which is sometimes cast off wholly or partially. An ulcerated surface being thus left, when the disposition to heal has taken place, cicatrices have been formed of different kinds, according to the depth and extent of the ulceration, and there being no counteraction to the contractile state of the parts, the dimensions of the vagina become much reduced; or, if the ulceration should not be healed, and the contractibility of the parts continue to operate, the ulcerated surfaces being brought together may cohere, and the canal of the vagina be perfectly closed.

Cicatrices in the vagina very seldom become an impediment to the connection between the sexes: when they do, the same kind of assistance is required as was recommended in the natural contraction or abbreviation of the part: they always give way to the pressure of the head of the child in the time of labour, though in many cases with great difficulty. Sometimes the appearances may mislead the judgment; for the above author was called to a woman in labour who was thought to have become pregnant though the hymen remained unbroken; but, on making very particular enquiry, he discovered that this was her second labour, and that the part, which, from its form and situation was supposed to be the hymen, with a small aperture, was a cicatrice, or unnatural contraction of the entrance into the vagina, consequent on an ulceration of the part after her former labour. Fungous excrescences, arising from any part of the vagina or uterus, have been distinguished, though not very properly, by the general term polypus. See *Polypus*.

VAGI'NAL. *Vaginalis.* 1. In *Anatomy*, of or belonging to the vagina.

2. In *Botany*, a sheath formed by a part of a leaf. It is a distinct thing from what is termed the spatha or sheath, which is a species of calyx. The vagina is very frequent in the grasses.

Vaginalis tunica. See *Tunica vaginalis testis.*

VAGINANS. Sheathing; applied to parts of animals and plants; especially to leaves which sheathe the stem, or each other, as in grasses; and to the leafstalk of the *Canna indica*, which surrounds the stem like a sheath; hence *petiolus vaginans.*

VAGINA'TUS. Sheathed.

Valerian. See *Valeriana.*

Valerian, celtic. See *Valeriana celtica.*

Valerian, garden. See *Valeriana major.*

Valerian, great. See *Valeriana major.*

Valerian, lesser. See *Valeriana officinalis.*

VALERIA'NA. (*a*, *æ*. f.; from *Valerius*, who first particularly described it.) 1. The name of a genus of plants in the Linnæan system. Class, *Triandria*; Order, *Monogynia.* Valerian.

2. The pharmacopœial name of the wild valerian. See *Valeriana officinalis.*

VALERIANA CELTICA. The Celtic nard. *Nardus celtica. Spica celtica Dioscoridis.* The root of this plant, a native of the Alps, has been recommended as a stomachic, carminative, and diuretic. At present it is only used in this country in the theriaca and mithridate, though its sensible qualities promise some considerable medicinal powers. It has a moderately strong smell, and a warm, bitterish, subacrid taste.

VALERIANA LOCUSTA. *Valerianella olitoria. Album olus.* Corn salad. This is cultivated in our gardens for an early salad. It is a wholesome esculent plant, gently aperient and antiscorbutic. This plant is now generally referred to another genus, under the name of *Fœdia olitoria.*

Valeriana major. See *Valeriana phu.*

Valeriana minor. See *Valeriana officinalis.*

VALERIANA OFFICINALIS. The systematic name of the *Valeriana minor*, *Valeriana sylvestris*, and *Leucho lachanum.* Officinal valerian. Wild valerian. *Valeriana — floribus triandris, foliis omnibus pinnatis*, of Linnæus. The root of this plant has been long extolled as an efficacious remedy in epilepsy, which caused it to be exhibited in a variety of other complaints termed nervous, in which it has been found highly serviceable. It is also in very general use as an antispasmodic, and is exhibited in convulsive and hysterical diseases. A simple and volatile tincture are directed in the pharmacopœias. The extract is not a good preparation, and is seldom used. The dose of the powder is from grs. x. to ʒ i. three times a day or oftener.

VALERIANA PHU. The systematic name of the garden valerian. *Valeriana major.* The root of this plant is said to be efficacious in removing rheumatism, especially sciatica; and also inveterate epilepsies.

Valeriana sylvestris. See *Valeriana officinalis.*

Valerianella olitoria. See *Valeriana locusta.*

VA'LGUS. Bandy-legged; having the legs bent outwards.

VALIGA. An old name for an alkoholic tincture of jalap, coloured with saffron.

VA'LLUM. (From *vallus*, a rampart with palisades.) The eye-brow.

VALS. A town in the department of Ardèche, which has mineral waters containing carbonic acid and sulphates of iron and alumen.

VALVE. (*Valvæ*, folding-doors.) In *Anatomy*, a membranous elongation in canals which prevents the reflux of fluids: applied to the valve of the colon, and to thin and transparent membranes situated within arteries, veins, and absorbents.

Valve of the colon. See *Intestine.*

Valve, semilunar. See *Semilunar valves.*

Valve, tricuspid. See *Tricuspid valves.*

Valve, triglochin. See *Tricuspid valves.*

VA'LVULA. (*a*, *æ*. f.; from *valva*, a valve, of which it is a diminutive.) A little valve. I. Applied to the valves of the venous and lymphatic system of animals.

II. In *Botany*, applied to several parts: thus, 1. A capsule is composed of valves: the fruit of the *Datura stramonium* has four valves; a siliqua has two valves, as the pea tribe, &c.

2. The petals and calyxes which constitute the flowers of grasses are called valves: in the common meadow-grass, for example, the cup is a dry, chaffy husk, composed of two valves, and the blossom is formed of two others.

3. The mouth of the tube of a blossom is frequently closed by several projecting substances; thus, in the flower of the *Borago officinalis*, the tube is closed by five of the substances called valves.

Valvula coli. See *Intestine.*

VALVULA EUSTA'CHII. A membraneous semilunar valve, situated at the mouth of the inferior vena cava, first described by Eustachius. See *Heart.*

Valvula mitralis. See *Mitral valve.*

Valvula semilunaris. See *Semilunar valves.*

Valvula triglochin. See *Tricuspid valves.*

Valvula tulpii. See *Intestine.*

VALVULÆ CONNIVENTES. The semilunar folds formed of the villous coat of the small intestines. They are most numerous in the *jejunum*, and gradually disappear in the *ileum.* Their use appears to be to increase the internal surface of the intestines.

Vane-like. See *Versatilis.*

Vanelloe. See *Epidendrum vanilla.*

Vanilla. See *Epidendrum vanilla.*

VAPORA'RIUM. (From *vapor*, vapour.) A vapour-bath.

VARRE'CULÆ. The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of such as are, and have a monophyllous calyx, like a coloured corolla.

Vareni. See *Flatus furiosus.*

VARICE'LLA. (Diminutive of *variola*, the small-pox.) The chicken-pox; called also, the *water-pox.* The eruption in this disease consists of vesicles scattered over the body: they are mostly smooth and transparent, lentil-shaped, or irregularly circular, flattened at the

top; the fluid at first pellucid, then whitish, afterwards straw-coloured; and this kind is called the *chicken-pox*. Sometimes the vesicles are pointed, and the fluid clear throughout the disease; and this is termed the *swine-pox*. In other cases, the vesicles are very large and globular, and the fluid, at first whey-coloured, is afterwards yellow; this form is denominated the *Hives*. In these several forms the eruption, though very generally distinct, is confluent; and when so, there is considerable fever and derangement of the system, which is not the case when the eruption is distinct and few. About the third or fourth day the vesicles burst, and concrete into puckered scabs, which fall off, and leave no cicatrices or marks.

The eruption of varicella does not come out all nearly together, but one crop after another, for several days.

Several of the varieties of this disease are sometimes intermixed, and the fluid, about three days after the eruption, occasionally becomes thickish, as well as yellowish, in the first and third variety, and possesses a purulent appearance; whence, in various instances, they have been mistaken for the small-pox. The eruptive fever in varicella is sometimes considerable, which has also led many to favour the opinion of its being small-pox. Varicella is now ascertained to originate from a specific contagion; and the characters by which it is sufficiently distinguished from small-pox are that its fluid, except in a few anomalous cases, is limpid throughout; and that, as early as the third or fourth day from the eruption, it concretes into crusts, which are thrown off without indenting the cutis: while, in small-pox, the fluid consists of pus as soon as formed, and does not concrete into crusts till the eleventh day, and often much later. Like the small-pox, it does not attack the same person a second time, excepting in a few anomalous constitutions.

This disease merely requires that the bowels be kept open, and that mild antiphlogistic or saline medicines be administered, if there be fever.

VARICOCE'LE. (*e, es.* f.: from *varix*, a distended vein, and κηλη, a tumour.) A swelling of the veins of the scrotum, or spermatic cord: hence it is divided into the *scrotal varicocele*, which is known by the appearance of livid and tumid veins on the scrotum; and *varicocele of the spermatic cord*, known by feeling hard vermiform vessels in the course of the spermatic cord. Varicocele mostly arises from excessive walking, running, jumping, wearing of trusses, and the like, producing at first a slight uneasiness in the part, which, if not remedied, continues advancing towards the loins.

VARICIFO'RMES PARA'STATÆ. This name has been given by some authors to the vasa deferentia at their commencement.

VARICIFO'RMIS. Variciform. Resembling a varix.

VARICO'MPHALUS. (From *varix*, and ομφαλος, the navel.) A varicose tumour of the navel.

VARI'CULA. (Diminutive of *varix*.) Varicose enlargement of the veins of the conjunctiva. — *M. A. Severinus.*

VARIEGA'TUS. Variegated: applied to an intermixture of colours; as in the leaves of some plants, *Mentha rotundifolia*, &c.

VARIETY. *Varietas.* In *Botany*, applied to such individual plants as differ in some circumstances from others of the same species, but not so essentially or permanently as to induce us to reckon them distinct species.

VARI'OLA. (*a, æ.* f.; from *varius*, changing colour: because it disfigures the skin.) The small-pox. A disease distinguished by acute fever, eruption of red pimples on the third day, which on the eighth contain pus, and afterwards drying, fall off in crusts. It is of a very contagious nature, supposed to have been introduced into Europe from the East. The first account we have of it is from Rhazes, the Arabian. No trace of it is to be found in the writings of the Greeks or Romans. For a long time the small-pox and the measles were supposed to be varieties of the same disease. This error prevailed as late as the days of Sydenham, who was the first to establish a decided distinction between them. It makes its attack on people of all ages, but the young of both sexes are more liable to it than those who are much advanced in life; and it may prevail at all seasons of the year, but is most prevalent in the spring and summer.

The small-pox is distinguished into the *distinct* and *confluent*; implying that, in the former, the eruptions are perfectly separate from each other; and that, in the latter, they run much into one another.

Both species are produced either by breathing air impregnated with the effluvia arising from the bodies of those who labour under the disease, or by the introduction of a small quantity of the variolous matter into the habit by inoculation; and it is probable that the difference of the small-pox is not owing to any difference in the contagion, but depends on the state of the person to whom it is applied, or on certain circumstances concurring with the application of it.

A variety of opinions have been entertained respecting the effect of the variolous infection on the fœtus in utero; a sufficient number of instances, however, have been recorded to ascertain that the disease may be communicated from the mother to the child. In some cases, the body of the child at its birth has been covered with pustules, and the nature of the disease has been most satisfactorily ascertained by inoculating with matter taken from the pustules. In other cases, there has been no appearance of the disease at the birth, but an eruption and other symptoms of the disease have appeared so early, as to ascertain that the infection must have been received previously to the removal of the child from the uterus.

Four different states, or stages, are to be observed in the small-pox: first, the febrile; second, the eruptive; third, the maturative; and fourth, that of the declination or scabbing. When the disease has arisen naturally, and is of the distinct kind, the eruption is commonly pre-

ceded by a redness in the eyes, soreness in the throat, pains in the head, back, and loins, weariness and faintness, alternate fits of chilliness and heat, thirst, nausea, inclination to vomit, and a quick pulse.

In some instances these symptoms prevail in a high degree, and in others they are very moderate. In very young children, startings and convulsions are apt to take place a short time previous to the appearance of the eruption, always giving great alarm to those not conversant with the frequency of the occurrence.

About the third or fourth day from the first seizure, the eruption shows itself in little red spots on the face, neck, and breast, and these continue to increase in number and size for three or four days longer; at the end of which time they are to be observed dispersed over several parts of the body.

If the pustules are not very numerous, the febrile symptoms will generally go off on the appearance of the eruption, or then will become very moderate. It sometimes happens, that a number of little spots, of an erysipelatous nature, are interspersed amongst the pustules; but these generally go in again, as soon as the suppuration commences, which is usually about the fifth or sixth day, at which period a small vesicle, containing an almost colourless fluid, may be observed upon the top of each pimple. Should the pustules be perfectly distinct and separate from each other, the suppuration will probably be completed about the eighth or ninth day, and they will then be filled with a thick yellow matter; but should they run much into each other, it will not be completed till some days later.

When the pustules are very thick and numerous on the face, it is apt, about this time, to become much swelled, and the eyelids to be closed up; previous to which there usually arises a hoarseness, and difficulty of swallowing, accompanied with a considerable discharge of viscid saliva. About the eleventh day, the swelling of the face usually subsides, together with the affection of the fauces, and is succeeded by the same in the hands and feet, after which the pustules break and discharge their contents; and then becoming dry, they fall in crusts, leaving the skin which they covered of a brown red colour, which appearance continues for many days. In those cases where the pustules are large, and are late in becoming dry and falling off, they are very apt to leave pits behind them; but where they are small, suppurate quickly, and are few in number, they neither leave any marks behind them, nor do they occasion much affection of the system.

In the confluent small-pox, the fever which precedes the eruption is much more violent than in the distinct, being attended usually with great anxiety, heat, thirst, nausea, vomiting, and a frequent and contracted pulse, and often with coma or delirium. In infants, convulsive fits are apt to occur, which either prove fatal before any eruption appears, or they usher in a malignant species of the disease.

The eruption usually makes its appearance about the third day, being frequently preceded or attended with a rosy efflorescence, similar to what takes place in the measles; but the fever, although it suffers some slight remission on the coming out of the eruption, does not go off as in the distinct kind; on the contrary, it becomes increased after the fifth or sixth day, and continues considerable throughout the remainder of the disease.

As the eruption advances, the face, being thickly beset with pustules, becomes very much swelled, the eyelids are closed up, so as to deprive the patient of sight, and a gentle salivation ensues, which, towards the eleventh day, is so viscid as to be spit up with great difficulty. In children, a diarrhœa usually attends this stage of the disease instead of a salivation, which is to be met with only in adults. The vesicles on the top of the pimples are to be perceived sooner in the confluent small-pox than in the distinct; but they never rise to an eminence, being usually flattened in; neither do they arrive to proper suppuration, as the fluid contained in them, instead of becoming yellow, turns to a brown colour.

About the tenth or eleventh day the swelling of the face usually subsides, and then the hands and feet begin to puff up and swell, and about the same time the vesicles break, and pour out a liquor that forms into brown or black crusts, which, upon falling off, leave deep pits behind them that continue for life; and where the pustules have run much into each other, they then disfigure and scar the face very considerably.

Sometimes it happens that a dissolved state of the fluids takes place at an early period of the disease, and shows itself in livid spots, interspersed among the pustules, and by a discharge of blood by urine, stool, and from various parts of the body.

In the confluent small-pox, the fever, which, perhaps, had suffered some slight remission from the time the eruption made its appearance to that of maturation, is often renewed with considerable violence at this last-mentioned period, which is what is called the secondary fever; and this is the most dangerous state of the disease. It has been observed, even amongst the vulgar, that the small-pox is apt to appear immediately before or after the prevalence of the measles. Another curious observation has been made relating to the symptoms of these complaints; namely, that if, while a patient labours under the small-pox, he is seized with the measles, the course of the former is retarded till the eruption of the measles is finished. The measles appear, for instance, on the second day of the eruption of small-pox; the progress of this ceases till the measles terminate by desquamation, and then it goes on in the usual way. Several cases are, however, recorded in the Medical and Physical Journal, as likewise in the third volume of the Medical Commentaries, in which a concurrence of the small-pox and measles took place without the progress of the former being retarded. The distinct small-pox is not attended with danger, except when it attacks pregnant women, or approaches nearly in its nature to that of the confluent; but this

last is always accompanied with considerable risk, the degree of which is ever in proportion to the violence and permanence of the fever, the number of pustules on the face, and the disposition to putrescency which prevails.

When there is a great tendency this way, the disease usually proves fatal between the eighth and eleventh day, but, in some cases, death is protracted till the fourteenth or sixteenth. The confluent small-pox, although it may not prove immediately mortal, is very apt to induce various morbid affections.

Both kinds of small-pox leave behind them a predisposition to inflammatory complaints, particularly to ophthalmia and visceral inflammations, but more especially of the thorax; and they do not unfrequently excite scrofula into action which might otherwise have lain dormant in the system.

The regular swelling of the hands and feet upon that of the face subsiding, and its continuance for the due time, may be regarded in a favourable light.

The dissections which have been made of confluent small-pox, have never discovered any pustules in the substance of the viscera. From them it also appears that variolous pustules never attack the cavities of the body, except those to which the air has free access; as the nose, mouth, trachea, the larger branches of the bronchia, and the outermost part of the meatus auditorius. In cases of prolapsus ani, they likewise frequently attack that part of the gut which is exposed to the air. Visceral inflammation and all its results may, and do occur, in small-pox as in ordinary fever, but these never present any indications of the effects of small-pox.

The treatment of small-pox will differ materially according to the species of the disease. In the distinct, ushered in by synochal pyrexia, it may be occasionally proper, in persons of a middle age, good constitution, and plethoric habit, to begin by taking away a moderate quantity of blood; the exhibition of an emetic will be generally advisable, provided there be no material tenderness of the stomach; the bowels must then be cleared, antimonial and other diaphoretics employed, and the antiphlogistic regimen strictly enforced. It is particularly useful in this disease during the eruptive fever to expose the patient freely to cold air, as taught by the celebrated Sydenham; and sponging the surface with cold water may be proper, where there is much heat and redness of the skin, unless the lungs be weak. After the eruption has come out, the symptoms are usually so much mitigated that little medical interference is necessary. But the confluent small-pox requires more management: after evacuating the primæ viæ, and employing other means to moderate the fever in the beginning, the several remedies adapted to support the strength and counteract the septic tendency must be resorted to, as the disease advances, such as have been enumerated under typhus. The chief points of difference are, that bark may be more freely given to promote the process of suppuration, and opium to relieve the irritation in the skin: when the eruption has come out, it will be generally proper to direct a full dose of this remedy every night, to procure rest, using proper precautions to obviate its confining the bowels, or determining to the head. Where alarming convulsions occur also, opium is the medicine chiefly to be relied upon, taking care subsequently to remove any source of irritation from the primæ viæ. Sometimes the tepid bath may be useful under these circumstances, and favour the appearance of the eruption, where the skin is pale and cold, the pulse weak, &c. Where, at a more advanced period, the pustules flatten, and alarming symptoms follow, the most powerful cordial and antispasmodic remedies must be tried, as the confectio opii, ether, wine, &c. For the relief of the brain, and other important part particularly affected, local means may be used, as in typhus. To prevent the eyes being injured, a cooling lotion may be applied, and blisters behind the ears, or leeches to the temples.

Variola vaccina. See *Cow-pox.*

VARIUM OS. The cuboid bone was formerly called *os varium*, from its irregular shape.

VARI'OLOID. This term has been applied to diseases resembling the small-pox.

VA'RIX. (*ix, icis.* m.; from *varus*, i. e. *obtortus.*) A dilatation of a vein. A disease, known by a soft tumour on a vein which does not pulsate. Varicose veins mostly become serpentine, and often form a plexus of knots, especially in the groins and scrotum. This disease is relieved by cold applications, pressure from bandages, and by ligature.

VA'RUS. This term has been applied, *adjectively*, to one who has the legs bent inwards; *substantively*, to pimples on the face, and to misplaced gout.

VARUS PUNCTATUS. The maggot pimple, so common in the skin of the face, especially of young persons.

VA'RVICITE. An oxide of manganese, which is found native, but has not hitherto been imitated by art. It appears to be a mixture of the peroxide and sesquioxide, but its exact constitution is not yet known.

VAS. (*Vas, vasis.* n.; from *vasum*: hence in the plural, *vasa, orum; à vescendo*, because it conveys drink.) A vessel: applied to arteries, veins, ducts, &c.

VAS DE'FERENS. A duct which arises from the epididymis, and passes through the inguinal ring, as part of the spermatic cord, into the cavity of the pelvis, and terminates in the vesicula seminalis. Its use is to convey the semen secreted in the testicle, and brought to it by the epididymis, into the vesicula seminalis.

VASA BREVIA. The arteries which come from the spleen, and run along the large arch of the stomach to the diaphragm.

VASA DEFERENTIA MULIEBRIA. The Fallopian tubes.

VASA EFFERENTIA. The absorbent vessels, as they pass out of a lymphatic gland, are so called.

VASA INFERENTIA. The absorbent vessels which pass into a lymphatic gland.

VASA PRÆPARANTIA. A name given by the old anatomists to the spermatic vessels.

Vasa vasorum. The very minute vessels which supply the tunics of the arteries and veins.

Vasa vortico'sa. The contorted vessels of the choroid membrane of the eye.

VA'STUS. (So called from its size.) A name given to certain muscles.

Vastus externus. A large, thick, and fleshy muscle, situated on the outer side of the thigh: it arises, by a broad thick tendon, from the lower and anterior part of the great trochanter, and upper part of the linea aspera; it likewise adheres, by fleshy fibres, to the whole outer edge of that rough line. Its fibres descend obliquely forwards, and after it has run four or five inches downwards, we find it adhering to the anterior surface and outer side of the cruræus, with which it continues to be connected to the lower part of the thigh, where we see it terminating in a broad tendon, which is inserted into the upper part of the patella laterally, and it sends off an aponeurosis that adheres to the head of the tibia, and is continued down the leg.

Vastus internus. This muscle, which is less considerable than the vastus externus, is situated at the inner side of the thigh, being separated from the preceding by the rectus.

It arises, tendinous and fleshy, from between the fore-part of the os femoris and the root of the lesser trochanter, below the insertion of the psoas magnus, and the iliacus internus; and from all the inner side of the linea aspera. Like the vastus externus it is connected with the cruræus, but it continues longer fleshy than that muscle. A little above the knee we see its outer edge uniting with the inner edge of the rectus, after which it is inserted tendinous into the upper part and inner side of the patella, sending off an aponeurosis which adheres to the upper part of the tibia.

Vaulted. See *Forniciformis.*

Vectis. A lever. See *Lever.*

VEGETABLE. *Vegetabilis.* A living body, distinguished from an animal by a number of characteristics, no one of which can be fixed on as absolute and definitive, but the aggregate of which, except in a few instances, abundantly suffice for their discrimination. The most general distinction between animals and vegetables consists in the mode and materials of their nutrition. Animals are nourished only by aliment which has undergone a process of digestion, and this process takes place in a canal contained within the body of the animal; vegetables are nourished by aliments already prepared for them, and which they absorb by tubes opening externally. Other distinctions will be found in the article *Body.*

Vegetables, like animals, are composed of *textures*, which, however, are much fewer than in animals. In the most simple or acotyledonous vegetables, the texture is uniform throughout, and consists of rounded or oblong cells, containing liquids, or a granular substance: these are called *cellular vegetables.* In the monocotyledonous and dicotyledonous plants, we find, in addition to the cellular, a vascular and cuticular texture: these are called *vascular plants.* We find the transition from the simple cellular to the vascular plants, in the ferns and allied cryptogamous genera, in which the heterogeneous textures of the higher vegetables begin to be perceived. The tubular or vascular texture of the higher plants exhibits two kinds of vessels, the *spiral* and the *nutritious.* The spiral vessels compose the greater part of the wood, and are found in the root, trunk, branches, flower-stalks, and leaf-stalks, spreading into the nerves of the leaves, into the veins of the petals, the filaments of the stamen, into the pistil, and into the joint: there is no trace of them in the bark. The spiral vessels contain the *sap* or liquid which rises from the root to different parts of the plant, especially in the spring season. The nutritive vessels are less obvious than the spiral, and very delicate in their texture. In herbaceous plants, they are found distributed in a fascicular manner along the spiral vessels of the leaves, stalks, and petals; in ligneous plants they are found in the soft internal layer of the bark, or in the cortical substance, whence they extend into the wood and cellular texture. These vessels contain the *cambium* or nutritive juice of the plant, analogous to the blood of animals. It is believed that the sap carried up from the root to the leaves undergoes, in the latter organs, certain changes by the influence of the air and light, analogous to those effected by *respiration* in the blood of animals, and is then distributed throughout the plant by the nutritive vessels. The cellular texture surrounds both the spiral and nutritious vessels, and it forms the basis of the pith in the centre of the wood. In the pith of many plants are hollows in the cellular tissue containing air; and in the bark and wood of some plants, it leaves hollow oblong spaces or reservoirs, containing resinous, oily, mucilaginous, or gummy matters. Plants afford an infinite variety of secretions, the uses of which, in the vegetable economy, are very obscure, while the uses of many of them to man are very familiar, as in the examples of sugar and gum.

The different parts and organs of plants, as the wood, bark, flowers, fruits, seed vessels, &c. are described under their respective heads.

The nutrition or support of plants appears to require water, earth, light, and air. Various experiments have been instituted to show that water is the only aliment which the root draws from the earth. Van Helmont planted a willow, weighing fifty pounds, in a certain quantity of earth covered with sheet-lead: he watered it for five years with distilled water; and at the end of that time the tree weighed one hundred and sixty-nine pounds three ounces, and the earth in which it had vegetated was found to have suffered a loss of no more than three ounces. Boyle repeated the same experiment upon a plant, which at the end of two years weighed fourteen pounds more, without the earth in which it had vegetated having lost any perceptible portion of its weight.

Duhamel and Bonnet supported plants with moss, and fed them with mere water: they observed, that the vegetation was of the most

vigorous kind; and the naturalist of Geneva observes, that the flowers were more odoriferous, and the fruit of a higher flavour. Care was taken to change the supports before they could suffer any alteration. Tillet has likewise raised plants, more especially of the gramineous kind, in a similar manner, with this difference only, that his supports were pounded glass, or quartz in powder. Hales has observed, that a plant, which weighed three pounds, gained three ounces after a heavy dew. Do we not every day observe hyacinths and other bulbous plants, as well as gramineous plants, raised in saucers or bottles containing mere water? Braconnot, also, has found mustard-seed to germinate, grow, and produce plants, that came to maturity, flowered, and ripened their seed, in litharge, flowers of sulphur, and very small unglazed shot. The last appeared least favourable to the growth of the plants, apparently because their roots could not penetrate between it so easily.

All plants do not demand the same quantity of water; and Nature has varied the organs of the several individuals conformably to the necessity of their being supplied with this food. Plants which transpire little, such as the mosses and the lichens, have no need of a considerable quantity of this fluid; and accordingly they are fixed upon dry rocks, and have scarcely any roots; but plants which require a larger quantity have roots which extend to a great distance, and absorb humidity throughout their whole surface.

The leaves of plants have likewise the property of absorbing water, and of extracting from the atmosphere the same principle which the root draws from the earth. But plants which live in the water, and as it were swim in the element which serves them for food, have no need of roots; they receive the fluid at all their pores; and we accordingly find that the fucus, the ulva, &c. have no roots whatever.

The dung which is mixed with earths, and decomposed, not only affords the alimentary principles we have spoken of, but likewise favours the growth of the plant by that constant and steady heat which its ulterior decomposition produces. Thus it is that Fabroni affirms his having observed the development of leaves and flowers in that part of a tree only which was in the vicinity of a heap of dung.

From the preceding circumstances it appears, that the influence of the earth in vegetation is almost totally confined to the conveyance of water, and probably the elastic products from putrefying substances, to the plant.

Vegetables cannot live without air. From the experiments of Priestley, Ingenhouz, and Sennebier, it is ascertained, that plants absorb the azotic part of the atmosphere; and this principle appears to be the cause of the fertility which arises from the use of putrefying matters in the form of manure. The carbonic acid is likewise absorbed by vegetables, when its quantity is small. If in large quantity, it is fatal to them.

Chaptal has observed, that carbonic acid predominates in the fungus, and other subterraneous plants. But, by causing these vegetables, together with the body upon which they were fixed, to pass, by imperceptible gradations, from an almost absolute darkness, into the light, the acid very nearly disappeared; the vegetable fibres being proportionally increased, at the same time that the resin and colouring principles were developed, which he ascribes to the oxygen of the same acid. Sennebier has observed, that the plants which he watered with water impregnated with carbonic acid transpired an extraordinary quantity of oxygen, which likewise indicates a decomposition of the acid.

Light is almost absolutely necessary to plants. In the dark they grow pale, languish, and die. The tendency of plants towards the light is remarkably seen in such vegetation as is effected in a chamber or place where the light is admitted on one side; for the plant never fails to grow in that direction. Whether the matter of light be condensed into the substance of plants, or whether it act merely as a stimulus or agent, without which the other requisite chemical processes cannot be effected, is uncertain.

It is ascertained, that the processes in plants serve, like those in animals, to produce a more equable temperature, which is for the most part above that of the atmosphere. Dr. Hunter, quoted by Chaptal, observed, by keeping a thermometer plunged in a hole made in a sound tree, that it constantly indicated a temperature several degrees above that of the atmosphere, when it was below the fifty-sixth division of Fahrenheit; whereas the vegetable heat, in hotter weather, was always several degrees below that of the atmosphere. The same philosopher has likewise observed, that the sap which, out of the tree, would freeze at 32°, did not freeze in the tree unless the cold were augmented 15° more.

The vegetable heat may increase or diminish by several causes, of the nature of disease; and it may even become perceptible to the touch in very cold weather, according to Buffon.

The principles of which vegetables are composed, if we pursue their analysis as far as our means have hitherto allowed, are chiefly carbon, hydrogen, and oxygen. Nitrogen is a constituent principal of several, but for the most part in small quantity. Potash, soda, lime, magnesia, silex, alumina, sulphur, phosphorus, iron, manganese, and muriatic acid, have likewise been reckoned in the number; but some of these occur only occasionally, and chiefly in very small quantities; and are scarcely more entitled to be considered as belonging to them than gold or some other substances, that have been occasionally procured from their decomposition.

The following are the principal products of vegetation: —

1. Sugar.
2. Sarcocol.
3. Asparagin.
4. Gum.
5. Ulmin.
6. Inulin.
7. Starch.
8. Indigo.
9. Gluten.
10. Albumen.
11. Fibrin.
12. Gelatine.
13. Bitter principle.
14. Extractive.
15. Tannin.
16. Fixed oil.
17. Wax.
18. Volatile oil.

19. Camphire.
20. Birdlime.
21. Resins.
22. Guaiacum.
23. Balsam.
24. Caoutchouc.
25. Gum resins.
26. Cotton.
27. Suber.
28. Wood.
29. Emetine.
30. Fungine.
31. Hematine.
32. Nicotine.
33. Pollenine.
34. Aconite.
35. Atropia.
36. Brucia.
37. Cicuta.
38. Datura.
39. Delphia.
40. Hyosciama.
41. Morphia.
42. Picotroxia.
43. Quina, cinchonia.
44. Strychnia.
45. Veratria.
46. The vegetable acids.

VEGETABLE KINGDOM. That department of nature which embraces the various organised bodies called vegetables or plants. The natural history of this department is called *Botany*, which embraces the anatomy, physiology, chemical composition, economical uses, and scientific classification of plants; see *Botany*, and *Vegetable*. The classification of plants, or systematic botany, is a science of modern origin. It commenced under the auspices of Conrad Gesner and Cæsalpinus, who, without any knowledge of each others plan, both conceived the idea of a classification founded upon the parts of fructification. Of the ideas of Gesner only scattered notices appear in his posthumous letters. Cæsalpinus, however, published his system in 1583. The primary division in this system was into trees and herbs. The subdivisions depended on the position of the embryo at the summit or base of the seed — on the superior or inferior position of the germen — on the number of the seeds, and that of the seed-vessels. Ray also formed a classification founded on the fruit, but different from that of Cæsalpinus. Several other systems have also been founded on the fruit.

Subsequently, the form of the corolla became a basis of classification, and was adopted as such by Rivinus, Ruppius, Ludwig, and the celebrated Tournefort.

The classification of Tournefort was the first that had any pretensions to be considered as at all complete. The sexual system of Linnæus immediately threw all former ones into the shade; and it may be fairly asserted that, as an *exclusive* one, it is to the present day by far the best, although it is incomplete by itself, and the greatest advantage is derived from the study of the more recent natural classifications along with it. The natural system of Jussieu gained high and deserved reputation; and has, since its original publication, been improved upon both by Decandolle and by Jussieu himself.

We proceed to give a view of the classifications of Tournefort, Linnæus, Decandolle, and Jussieu.

System of Tournefort.

First Division. — *Herbs.*

I. *Herbs with petalous flowers.*

A. *Herbs with simple petalous flowers.*

a. Corolla monopetalous and regular.

Class 1. *Campanulatæ.*—Bell-shaped flowers; as the *campanula.*

Class 2. *Infundibuliformes.* — Funnel-shaped flowers.

This class is divided into,

1. *Infundibuliformes, properly so called;* as the *hyoscyamus.*

2. *Hypocrateriformes.*—Salver-shaped; as the *primrose.*

3. *Infundibuliformes, with the limb of the corolla wheel-shaped;* as in the *veronica.*

b. Corolla monopetalous and irregular.

Class 3. *Personatæ.* — Flowers having some resemblance to a mask, or the muzzle of an animal; as in the *foxglove.*

Class 4. *Labiatæ.* — The limb of the corolla divided into an upper and lower lip; as in the *sage.*

c. Corolla polypetalous and regular.

Class 5. *Cruciformes.* — Flowers in the shape of a cross; as in *sinapis.*

Class 6. *Rosaceæ.* — Rose-shaped flowers; as the *strawberry.*

Class 7. *Umbelliferæ.* — Bearing umbels; as the *hemlock.*

Class 8. *Caryophylleæ.* — Clove-shaped flowers, having five petals with a long claw contained in a monophyllous calyx; as the *pink.*

Class 9. *Liliaceæ.* — Lily-like plants, having a corolla, or calyx resembling a corolla, divided into six petals; as the *lily, tulip,* &c.

d. Corolla polypetalous and irregular.

Class 10. *Papilionaceæ.* — Papilionaceous or butterfly-shaped flowers; as the *sweet pea.*

Class 11. *Anomalæ.* — Anomalous. Flowers composed of dissimilar and irregular shaped petals; as the *violet.*

B. *Herbs with compound petalous flowers.*

Class 12. *Flosculosæ.* — Having florets with a regular tubular corolla, with the limb divided into five segments; as the *artichoke.*

Class 13. *Semiflosculosæ.* — Composed of tubular florets terminating in a little tongue; as the *dandelion.*

Class 14. *Radiatæ.* — Flowers of a radiated shape, with entire florets in the centre, and demi-florets at the circumference; as the *sunflower.*

II. *Apetalous herbs.*

Class 15. *Staminous apetalous herbs,* in which the stamens are contained in a calyx; as in *atriplex.*

Class 16. *Apetalous herbs without flowers, but with visible grains;* as *lichens.*

Class 17. *Apetalous herbs without flowers or grains;* as *mosses.*

Second Division—. *Trees and shrubs.*

I. *Apetalous Trees.*

Class 18. Apetalous trees having flowers provided with a calyx, and not in a catkin; as the *ash.*

Class 19. Apetalous trees with flowers in a catkin; as the *poplar.*

II. *Petalous Trees.*

Class 20. *Petalous trees with a monopetalous corolla;* as the *lilac.*

Class 21. *Petalous trees with a regular polypetalous corolla;* as the *cherry.*

Class 22. *Petalous trees with an irregular polypetalous or papilionaceous corolla;* as the *laburnum.*

The sexual system of Linnæus, founded on the parts of fructification, is of all others best adapted to the purposes of practical botany, and the student who meets with a plant unknown to him, may discover what it is by a reference to the Linnæan system, with infinitely greater facility than by the use of any other. The following is a view of the Linnæan system, as given by Sir James Smith.

The *Classes* of the Linnæan system are 24, and their distinctions are founded on the number, situation, or proportion of the stamens. The orders are founded either on the number of the pistils, or on some other character equally obvious.

The first eleven classes are characterised solely by the number of the stamens, and distinguished by names, of Greek derivation, expressive of the number of these organs.

1. *Monandria* (a small class), stamen 1.
2. *Diandria*, stamens 2.
3. *Triandria*, stamens 3.
4. *Tetrandria*, stamens 4.
5. *Pentandria* (a numerous class), stamens 5.
6. *Hexandria*, stamens 6.
7. *Heptandria* (a very small class), stamens 7.
8. *Octandria*, stamens 8.
9. *Enneandria* (a small class), stamens 9.
10. *Decandria*, stamens 10.
11. *Dodecandria*, stamens 12 to 19.
12. *Icosandria*, stamens 20 or more, *inserted into the calyx*. Here we first find the *situation* of the stamens taken into consideration. They grow out of the sides of the calyx, often from a sort of ring, as in the strawberry. This is truly a natural class, as are several of the following ones; so that in these instances the Linnæan method of arrangement performs more than it promises. The character of this class is the more important, as such a mode of insertion indicates the pulpy fruits which accompany it to be infallibly wholesome, and this holds good, not only when the stamens are numerous, but in all other cases. Thus *ribes*, the currant and gooseberry genus, whose five stamens grow out of the calyx, stands in the fifth class, a wholesome fruit, among many poisonous berries. No traveller in the most unknown wilderness need scruple to eat any fruit whose stamens are thus situated; while, on the other hand, he will do well to be cautious of feeding on any other parts of the plant.
13. *Polyandria*. — Stamens numerous, commonly more so than in the last class, and *inserted into the receptacle*, or base of the flower, as in the poppy, anemone, &c. The plants of this fine and numerous class are very distinct in nature, as well as character, from those of the *icosandria*.
14. *Didynamia*. — Stamens two long and two short. Here *proportion* comes to our assistance. This is a natural class, and contains most of the labiate, ringent, or personate flowers, as the dead-nettle, snap-dragon, fox-glove, &c.
15. *Tetradynamia*. — Stamens four long and two short. A very natural class, comprehending all the cruciform flowers, as the wall-flower, stock, radish, mustard, &c. *Cleome* only does not properly belong to the rest.
16. *Monadelphia*. — Stamens united by their filaments, more or less extensively, into one tube, as the mallow tribe, in which such union is very remarkable; and the geranium family, in which it is less evident.
17. *Diadelphia*. — Stamens united into two parcels, both sometimes cohering together at the base. This class consists of papilionaceous flowers, and is therefore natural, except that some such genera, having distinct stamens, are excluded, and referred to the tenth class, in consideration of their number solely; as some ringent flowers with only two stamens are necessarily placed, not in the fourteenth class, but the second.
18. *Polyadelphia*. — Stamens united into more than two parcels, as in St. John's-wort. A small class, in some points related to *Icosandria*.
19. *Syngenesia*. — Stamens united by their anthers into a tube, rarely by their filaments also; and the flowers compound. A very natural and extremely numerous class. Examples of it are the dandelion, daisy, sunflower, &c.
20. *Gynandria*. — Stamens united with, or growing out of, the pistil; either proceeding from the germen, as in *aristolochia*, or from the style, as in the orchis family. The passion-flower is wrongly put by Linnæus and others into this class, as its stamens merely grow out of an elongated receptacle or column supporting the germen.
21. *Monoecia*. — Stamens and pistils in separate flowers, but both growing on the same plant, or, as the name expresses, dwelling in one house, as the oak, hazel, and fir.
22. *Dioecia*. — Stamens and pistils not only in separate flowers, but those flowers situated on two separate plants, as in the willow, hop, yew, &c.

These two last classes are natural when the barren flowers have, besides the difference in their essential organs, a different structure from the fertile ones in other respects; but not so when they have the same structure, because then both organs are liable to meet in the same flower. In some plants, as *rhodiola*, each flower has always the rudiments of the other organ, though generally inefficient.

23. *Polygamia*. — Stamens and pistils separate in some flowers, united in others, either on the same plant, or on two or three different ones.

This class is natural only when the several flowers have a different structure, as those of *atriplex*; but in this genus the pistil of the united flower scarcely produces seed. If, with Linnæus, we admit into *Polygamia* every plant on which some separated barren or fertile flowers may be found among the united ones, while all agree in general structure, the class will be overwhelmed, especially with Indian trees. I have therefore proposed that regard should be had to their general structure, which removes all such inconvenience, and renders the class much more natural.

24. *Cryptogamia*. — Stamens and pistils either not well ascertained, or not to be numbered with any certainty, insomuch that the plants cannot be referred to any of the foregoing classes. Of

this, ferns, lichens, sea-weeds, and mushrooms, are examples.

Appendix.—*Palmæ*, palm-trees, a magnificent tribe of plants, chiefly tropical, whose flowers were too little known, when Linnæus wrote, to serve the purposes of classification; but they are daily clearing up, and the palms are found generally to belong to the classes *Monoecia*, *Dioecia*, or *Hexandria*.

The orders of the Linnæan system are, in the first thirteen classes, founded on the number of the styles, or on that of the stigmas when the styles are wanting, which occurs in *viburnum*. Such orders are accordingly named —

Monogynia, style, or sessile stigma, 1.
Digynia, styles, or sessile stigmas, 2.
Trigynia, styles, or sessile stigmas, 3.
Tetragynia, styles, or sessile stigmas, 4.
Pentagynia, styles, or sessile stigmas, 5.
Hexagynia (of very rare occurrence), styles, or sessile stigmas, 6.
Heptagynia (still more unusual), styles, or sessile stigmas, 7.
Octagynia (scarcely occurs at all), styles, or sessile stigmas, 8.
Enneagynia (of which there is hardly an instance), styles, or sessile stigmas, 9.
Decagynia, styles, or sessile stigmas, 10.
Dodecagynia, styles, or sessile stigmas, about 12.
Polygynia, styles, or sessile stigmas, many.

The two orders of the fourteenth class, *Didynamia*, both natural, are characterised by the fruit, as follows: —

1. *Gymnospermia*. —Seeds naked, almost universally four, never more.

2. *Angiospermia*. — Seeds in a capsule, numerous.

The two orders of the fifteenth class, *Tetradynamia*, both very natural, are distinguished by the form of the fruit, thus:

1. *Siliculosa*.—Fruit a *silicula*, pouch, or roundish pod.

2. *Siliquosa*. — Fruit a *siliqua*, or long pod.

The orders of the sixteenth, seventeeth, and eighteenth classes, *Monadelphia*, *Diadelphia*, and *Polyadelphia*, are founded on the number of the stamens, that is, on the characters of the first thirteen classes.

The orders of the great natural nineteenth class, *Syngenesia*, are marked by the united or separated, barren, fertile, or abortive, nature of the florets.

1. *Polygamia æqualis*. — Florets all perfect or united, that is, each furnished with perfect stamens, a pistil, and one seed.

2. *Polygamia superflua*. — Florets of the disk with stamens and pistil; those of the radius with pistil only, but each, of both kinds, forming perfect seed.

3. *Polygamia frustranea*. — Florets of the disk as in the last; those of the radius with merely an abortive pistil, or with not even the rudiments of any. Sir J. Smith considers this a bad order, and proposes to abolish it.

4. *Polygamia necessaria*. — Florets of the disk with stamens only, those of the radius with pistils only.

5. *Polygamia segregata*.—Several flowers, either simple or compound, but with united anthers, and with a proper calyx, included in one common calyx.

Linnæus has a sixth order in this class, named *Monogamia*, consisting of simple flowers with united anthers; but this has been suppressed by Sir J. Smith, because the union of the anthers is not constant throughout the species of each genus referred to it, witness *lobelia* and *viola*, while, on the contrary, several detached species in other classes have united anthers, as in *gentiana*. These reasons, which show the connexion of the anthers of a simple flower to be neither important in nature, nor constant as an artificial character, are confirmed by the plants of this whole Linnæan order being natural allies of others in the fifth class, and totally discordant, in every point, from the compound syngenesious flowers.

The orders of the twentieth, twenty-first, and twenty-second classes are distinguished by the characters of some of the classes themselves which precede them, that is, almost entirely by the number of their stamens; for the union of the anthers in some of them is, for the reasons just given, of no moment.

The orders of the twenty-third class, *Polygamia*, are, according to the beautiful uniformity of plan which runs through this ingenious system, distinguished upon the principles of the classes immediately preceding.

1. *Monoecia* has flowers with stamens and pistils on the same plant with others that have only pistils, or only stamens; or perhaps all these three kinds of blossoms occur; but whatever the different kinds may be, they are confined to one plant.

2. *Dioecia* has the two or three kinds of flowers on two separate plants.

3. *Trioecia* has them on three separate plants, of which the fig is the only real example, and in that the structure of the flowers is alike in all.

The Orders of the twenty-fourth class, *Cryptogamia*, are professedly natural. They are four in Linnæus, but we now reckon five.

1. *Filices*.—Ferns, whose fructification is obscure, and grows either on the back, summit, or near the base of the leaf, thence denominated a frond.

2. *Musci*. — Mosses, which have real separate leaves, and often a stem; a hood-like corolla, or *calyptra*, bearing the style, and concealing the capsule, which at length rises on a stalk with the *calyptra*, and opens by a lid.

3. *Hepaticæ*. — Liverworts, whose herb is a frond, being leaf and stem united, and whose capsules do not open with a lid. Linnæus comprehends this order under the following.

4. *Algæ*. — Flags, whose herb is likewise a frond, and whose seeds are imbedded, either in its very substance, or in the disk of some appropriate receptacle.

5. *Fungi*.—Mushrooms, destitute of herbage, bearing their fructification in a fleshy substance.

Natural System of Decandolle.

It is to be observed, that in this and other natural systems, the names of the orders are taken from that of some genus which is considered as typical of the order; thus the *ranun-*

culaceæ are plants which more or less resemble the *ranunculus;* or, the names are from some still more general character; as *umbelliferæ*, plants bearing umbels.

Sect. I.—Vascular, or cotyledonous plants; plants the embryo of which is furnished with one or more cotyledons.

A. *Exogenæ*, or *Dicotyledones.*

1. *With a double perigonium, or with the corolla and calyx distinct.*

a. *With a polypetalous corolla.*

a. With hypogynous petals, that is, petals not adhering to the calyx.

1. Ranunculaceæ.
2. Dilleniaceæ.
3. Chlenaceæ.
4. Magnoliaceæ.
5. Annonaceæ.
6. Malvaceæ.
7. Sterculiaceæ.
8. Tiliaceæ.
9. Elæocarpeæ.
10. Marcgraviaceæ.
11. Ochnaceæ.
12. Simaroubiaceæ.
13. Rutaceæ.
14. Caryophylleæ,—
    Dianthineæ.
    Alsineæ.
15. Linnæeæ.
16. Cistineæ.
17. Violaceæ.
18. Passifloreæ.
19. Camellieæ.
20. Hesperidiæ.
21. Meliaceæ.
22. Geraniaceæ.
23. Sarmentaceæ.
24. Guttiferæ.
25. Hypericineæ.
26. Hippocraticiæ.
27. Malpighiaceæ.
28. Acerineæ.
29. Sapindaceæ.
30. Droseraceæ.
31. Resedaceæ.
32. Capparideæ.
33. Cruciferæ.
34. Papaveraceæ,—
    Fumarieæ,
    Papaveraceæ.
35. Nymphæaceæ.
36. Menispermeæ.
37. Berberideæ.

b. With perigynous petals, that is, petals inserted into the calyx.

38. Frangulaceæ.
39. Samydeæ.
40. Xanthoxyleæ.
41. Juglandeæ.
42. Terebinthaceæ.
43. Polygaleæ.
44. Leguminosæ.
45. Rosaceæ,—
    Drupaceæ,
    Prockieæ,
    Spiræeæ,
    Dryadeæ,
    Agrimonieæ,
    Roses,
    Pomaceæ.
46. Salicariæ.
47. Melastomeæ.
48. Myrtineæ.
49. Combretaceæ.
50. Loaseæ.
51. Onagræ.
52. Ficoides.
53. Portulaceæ.
54. Nopaleæ.
55. Gooseberries.
56. Crassulaceæ.
57. Saxifragiæ.
58. Umbelliferæ.
59. Araliaceæ.

b. With a monopetalous corolla.

b. With a perigynous corolla, or one attached to the calyx.

60. Caprifolieæ.
61. Loranthieæ.
62. Rubiaceæ,—
    Guettardaceæ,
    Cinchoniaceæ,
    Coffeaceæ,
    Stellatæ.
63. Operculatæ.
64. Valerianeæ.
65. Dipsaceæ.
66. Compositæ,—
    Corymbiferæ,
    Cynarocephaleæ,
    Labiatiflores,
    Cichoriaceæ.
67. Campanulaceæ.
68. Lobeliaceæ.
69. Cucurbitaceæ.
70. Gesnerieæ.
71. Vaccinieæ.
72. Ericineæ,—
    Ericineæ,
    Epacrideæ,
    Rhodoraceæ.
73. Aquifoliaceæ.

c. With an hypogynous corolla, or one not attached to the calyx.

74. Myrsineæ.
75. Sapoteæ.
76. Ebenaceæ.
77. Oleineæ.
78. Jasmineæ.
79. Pedalineæ.
80. Strychneæ.
81. Apocyneæ,—
    Rauvolfieæ,
    Apocyneæ,
    Asclepiadeæ.
82. Gentianeæ.
83. Bignoniaceæ.
84. Polemonideæ.
85. Convolvulaceæ.
86. Borragineæ,—
    Borragineæ,
    Sebestens.
87. Solanaceæ.
88. Personatæ,—
    Antirrhineæ,
    Rhinanthaceæ.
89. Labiatæ.
90. Myoporineæ.
91. Pyrenaceæ.
92. Acanthaceæ.
93. Lentibulareæ.
94. Primulaceæ.
95. Globulariæ.

2. *With a simple perigonum, or the calyx and corolla united.*

96. Plumbagineæ.
97. Plantagineæ.
98. Nyctagineæ.
99. Amaranthaceæ.
100. Chenopodeæ.
101. Polygoneæ.
102. Laurineæ.
103. Myristiceæ.
104. Proteaceæ.
105. Thymeleæ.
106. Santalaceæ.
107. Elæagneæ.
108. Aristolochiæ.
109. Euphorbiaceæ.
110. Monimieæ.
111. Urticeæ,—
    Urticeæ,
    Piperiteæ,
    Artocarpeæ.
112. Amentaceæ.
113. Coniferæ.

B. *Endogenous plants, or Monocotyledones.*

1. Phanerogamic plants, or those in which the fructification is visible and regular.

114. Cycadeæ.
115. Hydrocharideæ.
116. Alismaceæ.
117. Pandaneæ.
118. Aroides.
119. Orchideæ.
120. Drymyrrhizeæ.
121. Musaceæ.
122. Irideæ.
123. Hæmodorhaceæ.
124. Amaryllideæ.
125. Hemerocallideæ.
126. Dioscoreæ.
127. Smilaceæ.
128. Liliaceæ,—
    Asparageæ,
    Trilliaceæ,
    Asphodelieæ,
    Bromelieæ,
    Tulipaceæ.
129. Colchicaceæ.
130. Commelineæ.
131. Palms.
132. Junceæ.
133. Typhaceæ.
134. Cyperaceæ.
135. Gramineæ.

2. Cryptogamic plants, or those in which the fructification is concealed, unknown, or irregular.

136. Equisetaceæ.
137. Marsileaceæ.
138. Lycopodineæ.
139. Ferns.

Sect. II.— *Cellular* or *Acotyledonous* vegetables; composed of cellular substance, destitute of vessels, and the embryo of which is without cotyledons.

1. *Foliaceous; having leaves.*

140. Mosses.
141. Liver worts.

2. *Leafless.*

142. Lichens.
143. Hypoxyla.
144. Funguses.
145. Flags.

The following table exhibits Jussieu's classification, as modified in the latest edition of his work. It is founded principally on the number of the cotyledons, and the insertion of the stamina.

Class I. *Acotyledonia:* plants without cotyledons.

Families.	
Flags.	Lichens.
Mushrooms.	Liverworts.
Hypoxyleæ.	Mosses.

Lycopodiaceæ. Equisetaceæ.
Ferns. Salvinieæ.
Characeæ.

Class II. *Monohypogynia:* monocotyledonous with hypogynous stamina, that is, stamina inserted below the pistil.

Families.

Fluviales. Typhineæ.
Saurureæ. Cyperaceæ.
Aroides. Gramineæ.
Piperiteæ.

Class III. *Monoperigynia:* monocotyledonous plants with peryginous stamina, that is, stamina inserted into the calyx around the pistil.

Families.

Palms. Butomeæ.
Asparagineæ. Juncagineæ.
Restiaceæ. Colchiceæ.
Junceæ. Liliaceæ.
Commelineæ. Bromeliaceæ.
Alismaceæ. Asphodeliæ.

Class IV. *Monæpigynia:* monocotyledonous plants with epigynous stamina.

Families.

Narcisseæ. Musaceæ.
Irideæ. Orchideæ.
Dioscoriæ. Nympheaceæ.
Amomieæ. Hydrocharideæ.
Hæmodoraceæ. Balanophoriæ.

Class V. *Epistaminia:* dicotyledonous apetalous plants, with epigynous stamina.

Family.

Aristolochiæ.

Class VI. *Peristaminia:* dicotyledonous apetalous plants, with peryginous stamina.

Families.

Osyrideæ. Laurineæ.
Myrobalaneæ. Polygoneæ.
Eleagneæ. Begoniaceæ.
Thymeleæ. Atripliceæ.
Proteaceæ.

Class VII. *Hypostaminia:* dicotyledonous apetalous plants, with hypogynous stamina.

Families.

Amaranthaceæ. Nyctagineæ.
Plantagineæ. Plumbagineæ.

Class VIII. *Hypocorollia:* dicotyledonous monopetalous plants, with hypogynous stamina.

Families.

Primulaceæ. Personatæ.
Utriculineæ. Solaneæ.
Rhinantheæ. Borragineæ.
Orobancheæ. Convolvulaceæ.
Acanthaceæ. Polemoniaceæ.
Jasmineæ. Bignonieæ.
Pedalineæ. Gentianeæ.
Verbenaceæ. Apocyneæ.
Myroporineæ. Sapoteæ.
Labiatæ. Ardisiaceæ.

Class IX. *Pericorollia:* dicotyledonous monopetalous plants with peryginous stamina.

Families.

Ebenaceæ. Campanulaceæ.
Klenaceæ. Lobeliaceæ.
Rhodoraceæ. Gesneriaceæ.
Epacrideæ. Stylidieæ.
Ericineæ. Goodenovieæ.

Class X. *Epicorollia, Synantheria:* dicotyledonous, monopetalous, and epigynous plants, with the anthers united.

Families.

Cichoreaceæ. Calycereæ.
Cinarocephaliæ. Corymbiferæ.

Class XI. *Epicorollia, Corysantheria:* dicotyledonous, monopetalous, and epigynous plants, with the anthers distinct.

Families.

Dipsaceæ. Caprifoliaceæ.
Valerianeæ. Lorantheæ.
Rubiaceæ.

Class XII. *Epipetalia:* plants dicotyledonous, polypetalous, and epigynous.

Families.

Araleaceæ. Umbelliferæ.

Class XIII. *Hypopetalia:* plants dicotyledonous, polypetalous, and hypogynous.

Families.

Ranunculaceæ. Buttneriaceæ.
Papaveraceæ. Magnoliaceæ.
Fumariaceæ. Dilleniaceæ.
Cruciferæ. Ochnaceæ.
Capparideæ. Simaroubeæ.
Sapindeæ. Anoniæ.
Acerineæ. Menispermeæ.
Hippocrateæ. Berberidiæ.
Malpighiaceæ. Hermanniæ.
Hypericeæ. Tiliaceæ.
Guttiferæ. Cisteæ.
Olacineæ. Violeæ.
Aurantiaceæ. Polygaleæ.
Ternstromieæ. Diosmeæ.
Theaceæ. Rutaceæ.
Meliaceæ. Caryophylleæ.
Viniferæ. Tremandreæ.
Geraniaceæ. Linaceæ.
Malvaceæ. Tamariscineæ.

Class XIV. *Peripetalia:* plants dicotyledonous, polypetalous, and perigynous.

Families.

Paronychieæ. Melastomeæ.
Portulaceæ. Lythrarieæ.
Saxifrageæ. Rosaceæ.
Cunoniaceæ. Amygdaleæ.
Crassuleæ. Spireaceæ.
Opuntiaceæ. Pomaceæ.
Ribesieæ. Sanguisorbeæ.
Loaseæ. Leguminosæ.
Ficoïdeæ. Terebinthaceæ.
Cercodeæ. Pittosporeæ.
Onagræ. Rhamneæ.
Myrteæ.

Class XV. *Diclinia:* dicotyledonous apetalous plants, which are *diclinic*, that is, each individual bearing flowers of one sex only.

Families.

Euphorbiaceæ. Quercineæ.
Cucurbitaceæ. Salicineæ.
Passifloreæ. Betulaceæ.
Myristiceæ. Ulmaceæ.
Urticeæ. Cycadeæ.
Monimieæ. Coniferæ.

VEGETATION. (*Vegetatio, onis*, f.; from *vegeo*, to flourish.) 1. The state of a living vegetable.

2. The increase or extension of metallic veins in the earth was called the vegetation of metals by the alchemists.

Veil. See *Calyptra.*

VEIN. (*Vena, æ.* f.) A long membraneous canal, which continually becomes wider, does not pulsate, and returns the blood from the arteries to the heart. All veins originate from the extremities of arteries, or, more properly speaking, from the capillary vessels which connect the arteries and veins, and terminate in the auricles of the heart; *e. g.* the venæ cavæ in the right, and the pulmonary veins in the left auricle. They are composed, like arteries, of three tunics or coats, which are much more slender than in the arteries, and are supplied internally with semilunar membranes, or folds, called valves. Their use is to return the blood to the heart.

The blood is returned from every part of the body, except the lungs, into the right auricle, from three sources: —

1. The *vena cava superior*, which brings it from the head, neck, thorax, and superior extremities.

2. The *vena cava inferior*, from the abdomen and inferior extremities.

3. The *coronary vein* receives it from the coronary arteries of the heart.

1. The *vena cava superior.* This vein terminates in the superior part of the right auricle, into which it evacuates the blood from the *right* and *left subclavian vein*, and the *vena azygos.* The right and left subclavian veins receive the blood from the head and upper extremities, in the following manner: — The veins of the fingers, called *digitals* receive the blood from the digital arteries, and empty it into —

The *cephalic of the thumb*, which runs on the back of the hand along the thumb, and evacuates itself into the external radial.

The *salvatella*, which runs along the little finger, unites with the former, and empties its blood into the internal and external cubital veins. At the end of the fore-arm are three veins, called the great cephalic, the basilic, and the median.

The *great cephalic* runs along the superior part of the fore-arm, and receives the blood from the external radial.

The *basilic* ascends on the under side, and receives the blood from the *external* and *internal cubital veins*, and some branches which accompany the brachial artery, called *venæ satellites.*

The *median* is situated in the middle of the fore-arm, and arises from the union of several branches. These three veins all unite above the bend of the arm, and form

The *brachial vein*, which receives all their blood, and is continued into the axilla, where it is called, —

The *axillary vein.* This receives also the blood from the scapula, and superior and inferior parts of the chest, by the *superior* and *inferior thoracic vein*, the *vena muscularis*, and the *scapularis.*

The axillary vein then passes under the clavicle, where it is called the *subclavian*, which unites with the external and internal jugular veins, and the vertebral vein, which brings the blood from the vertebral sinuses; it receives also the blood from the *mediastinal, pericardiac, diaphragmatic, thymic, internal mammary*, and *laryngeal veins*, and then unites with its fellow, to form the vena cava superior, or, as it is sometimes called, *vena cava descendens.*

The blood from the external and internal parts of the head and face is returned, in the following manner, into the external and internal jugulars, which terminate in the sub-clavians: —

The *frontal, angular, temporal, auricular, sublingual*, and *occipital* veins receive the blood from the parts after which they are named; these all converge to each side of the neck, and form a trunk, called the *external jugular vein.*

The blood from the brain, cerebellum, medulla oblongata, and membranes of these parts, is received into the lateral sinuses, or veins of the dura mater, one of which empties its blood through the foramen lacerum in basii cranii on each side into the *internal jugular*, which descends in the neck by the carotid arteries, receives the blood from the *thyroideal* and *internal maxillary veins*, and empties itself into the subclavians within the thorax.

The vena azygos receives the blood from the *bronchial, superior, æsophageal, vertebral*, and *intercostal veins*, and empties it into the superior cava.

2. *Vena cava inferior.* The vena cava inferior is the trunk of all the abdominal veins, and those of the lower extremities, from which parts the blood is returned in the following manner. The veins of the toes, called the *digital veins*, receive the blood from the digital arteries, and form on the back of the foot three branches, one on the great toe, called the *cephalic*, another which runs along the little toe, called the *vena saphena*, and a third on the back of the foot, *vena dorsalis pedis;* and those on the sole of the foot evacuate themselves into the *plantar veins.*

The three veins on the upper part of the foot coming together above the ankle, form the *anterior tibial;* and the plantar veins, with a branch from the calf of the leg, called the *sural vein*, form the *posterior tibial;* a branch also ascends in the direction of the fibula, called the *peroneal vein.* These three branches unite before the ham into one branch, the *subpopliteal vein*, which ascends through the ham, carrying all the blood from the foot: it then proceeds upon the anterior part of the thigh, where it is termed the *crural* or *femoral vein*, receives several muscular branches, and passes under Poupart's ligament into the cavity of the pelvis, where it is called the *external iliac.*

The arteries which are distributed about the pelvis evacuate their blood into the *external hæmorrhoidal veins*, the *hypogastric veins*, the *internal pudendal*, the *vena magna ipsius penis*, and *obturatory veins*, all of which unite in the pelvis, and form the *internal iliac vein.*

The external iliac vein receives the blood from the external pudendal veins, and then unites with the internal iliac at the last vertebra of the loins, forming the *common iliac;* the two common iliacs then form the *vena cava inferior*, or *ascendens*, which ascends on the right side of the

spine, receiving the blood from the *sacral, lumbar, emulgent, right spermatic veins*, and the *vena cava hepatica;* and, having arrived at the diaphragm, it passes through the right foramen, and enters the right auricle of the heart, into which it evacuates all the blood from the abdominal viscera and lower extremities.

Vena cava hepatica. This vein ramifies in the substance of the liver, and brings the blood into the vena cava inferior from the branches of the *vena portæ*, a great vein which carries the blood from the abdominal viscera into the substance of the liver. The trunk of the vena portæ, about the fissure of the liver, in which it is situated, is *divided* into the hepatic and abdominal portions. The *abdominal portion* is composed of the *splenic, meseraic*, and *internal hæmorrhoidal veins*. These three venous branches carry all the blood from the stomach, spleen, pancreas, omentum, mesentery, gall-bladder, and the small and large intestines, into the *sinus* of the vena portæ. The *hepatic portion* of the vena portæ enters the substance of the liver, divides into innumerable ramifications, which secrete the bile, and the superfluous blood passes into corresponding branches of the *vena cava hepatica*.

The *action of the veins.* Veins do not pulsate: the blood which they receive from the arteries flows through them very slowly, and is conveyed to the right auricle of the heart, by the contractility of their coats, the pressure of the blood from the arteries, called the *vis à tergo*, the contraction of the muscles, and respiration; and it is prevented from going backwards in the vein by the valves, of which there are a great number.

Veinless leaf. See *Avenius.*

Veiny leaf. See *Venosus.*

VELAME'NTUM BOMBYCI'NUM. The interior soft membrane of the intestines.

VELNO'S VEGETABLE SYRUP. An old nostrum, the composition of which has been kept very secret. It has generally been supposed to consist of corrosive sublimate, rubbed up with honey and mucilage. Swediaur says, that it contains volatile alkali. Dr. Paris received from Sir B. Brodie, a formula by which a medicine, perfectly analogous to this syrup in its sensible properties, might be prepared, and the effects of which appear, also, to be in every respect similar. It is as follows. Take of burdock root, young, and fresh, sliced, ℥ij., dandelion root, ℥i., fresh spearmint, senna leaves, coriander seeds, bruised liquorice root fresh, of each, ʒiss., water, a pint and a half: boil gently down to a pint; then strain, and when cold, add a pound of lump sugar: boil it to the consistence of a syrup, and add a small proportion of oxymuriate of mercury.

VE'LUM, (*um, i.* n.) A veil.

VELUM PENDULUM PALATI. *Velum. Velum palatinum.* The soft palate. The soft part of the palate, which forms two arches, affixed laterally to the tongue and pharynx.

Velum pupillæ. See *Membrana pupillaris.*

VE'NA. (*a, æ.* f.; from *venio*, to come: because the blood comes through it.) A vein. See *Vein.*

Vena azygos. See *Azygos vena.*

Vena medinensis. See *Medinensis vena.*

VENA PORTÆ. *Vena portarum.* The great vein, situated at the entrance of the liver, which receives the blood from the abdominal viscera, and carries it into the substance of the liver. It is distinguished into the *hepatic* and *abdominal* portion: the former is ramified through the substance of the liver, and carries the blood destined for the formation of the bile, which is returned by branches to the trunk of the vena cava; the latter is composed of three branches; viz. the splenic, mesenteric, and internal hæmorrhoidal veins. See *Liver.*

VENÆ LACTEÆ. The lacteal absorbents were formerly so called. See *Lacteals.*

VENÆSE'CTION. (*Venæsectio, onis.* f.; from *vena*, a vein, and *sicco*, to cut.) The opening of a vein. By modern surgeons this operation is performed only on the veins, at the bend of the arm, and the external jugular. The ancients practised it on various veins, with a view to a more immediate effect on the diseased part; but this seems to be of very little consequence.

VENE'NUM. (*um, i.* n.) A poison. See *Poison.*

VENE'REAL. (*Venereus;* from *Venus*, because it belongs to acts of venery.) Of or belonging to sexual intercourse.

Venereal disease. See *Syphilis* and *Urethritis venerea.*

Venice turpentine. See *Pinus larynx.*

VENISON. (From *venaison*, French; from *venatio*, hunting.) The flesh of the deer kind, as the buck, the doe, the hart, the hind, &c. Venison that is well fed, and killed at a proper season, is a very wholesome meat, tenderer than mutton, and more easy of digestion. It is esteemed a great delicacy, and, like other game, is preferred by connoisseurs when it is *high;* that is, in a state of incipient putrefaction. See *Cervus.*

VENO'SUS. Veiny; veined: applied by botanists to a leaf which has the vessels, by which it is nourished, branched, subdivided, and more or less prominent, forming a net-work over either or both its surfaces; as in *Cratægus, Pyrolus terminalis*, &c.

VE'NTER. The belly. Old writers apply this term to the abdomen, *venter infimus;* the chest, *venter medius;* and the head, *venter supremus.*

VE'NTRICLE. (*Ventriculus;* from *venter.*) A term applied by anatomists to the cavities of the brain and heart. See *Cerebrum*, and *Heart.*

VENTRICO'SUS. (From *venter*, the belly.) Ventricose: distended; bellying. Applied, in *Botany;* as to the cup of the rose, or the under part of the blossom of the foxglove.

VENTRI'CULUS PULMONA'RIS. The right ventricle of the heart.

VENTRICULUS SUCCENTURIATUS. That portion of the duodenum which is surrounded by the peritonæum is sometimes so large as to resemble a second stomach, and is so called by some writers.

VENTRI'LOQUISM. (*Ventriloquismus;*

from *venter*, the belly, and *loquor*, to speak: because the voice seems to come from the belly.) Gastroloquism. The formation of the voice within the mouth in such a way as to imitate other voices than that which is natural to the person, and so as not to be seen to move the lips. Nothing is more easy to man than to imitate the different sounds he hears: this, in fact, he performs in many circumstances. Mimics imitate perfectly the voice and pronunciation of others. Hunters imitate the different cries of the game, and thus succeed in decoying it into their nets. This faculty of imitating the different sounds has given rise to the art called ventriloquism and gastroloquism. The persons who exercise this art are called ventriloquists, gastroloquists, and engastrimythists. They have no organisation different from that of other men: they require only to have the organs of voice and speech very perfect, in order that they may readily produce the necessary sounds.

The basis of this art is easily understood. We have found by experience, instinctively, that sounds are changed by many causes; for example, that they become feeble, less distinct, and that their expression changes, according as they are more distant from us: a man who is at the bottom of a well wishes to speak to persons who are at the top; but his voice will not reach their ears until it has received certain modifications, which depend upon the distance and the form of the tube through which it passes.

If a person remark these modifications with care, and endeavour to imitate them, he will produce acoustic illusions, which would be equally deceiving to the ear as the observation of objects through a magnifying glass is to the eye. The error will be complete if he employ those deceptions which are necessary to distract the attention.

These illusions will be numerous in proportion to the talents of the performer; but we must not imagine that a ventriloquist produces vocal sounds, and articulates, differently from other people. His voice is formed in the ordinary manner; only he is capable of modifying, according to his pleasure, the volume, the expression, &c. of it; and with regard to the words that he pronounces without moving his lips, he takes care to choose those into which no labial consonants enter, otherwise he would be obliged to move them. This art is, in certain respects, for the ear what painting is for the eye.

VE'NUS. Copper was formerly so called by the chemists.

VERA'TRIA. (*a*, *æ*. f.; so called because obtained from veratrum.) Veratrine. A new vegetable alkali, discovered lately by Pelletier and Caventou, in the *veratrum sabadilla*, or cevadilla, the *veratrum album*, or white hellebore, and the *colchicum autumnale*, or meadow-saffron.

The seeds of cevadilla, after being freed from an unctuous and acrid matter by ether, were digested in boiling alkohol. As this infusion cooled, a little wax was deposited; and the liquid being evaporated to an extract, redissolved in water, and again concentrated by evaporation, parted with its colouring matter. Acetate of lead was now poured into the solution, and an abundant yellow precipitate fell, leaving the fluid nearly colourless. The excess of lead was thrown down by sulphuretted hydrogen, and the filtered liquor being concentrated by evaporation, was treated with magnesia, and again filtered. The precipitate, boiled in alkohol, gave a solution, which on evaporation left a pulverulent matter, extremely bitter, and decidedly with alkaline characters. It was at first yellow, but by solution in alkohol, and precipitation by water, was obtained as a fine white powder.

The precipitate by the acetate of lead gave, on examination, gallic acid; and hence it is concluded, that the new alkali existed in the seed as a gallate.

Veratria was found in the other plants above mentioned. It is white, pulverulent, has no odour, but excites violent sneezing. It is very acrid, but not bitter. It produced violent vomiting in very small doses, and, according to some experiments, a few grains may cause death. It is very little soluble in cold water. Boiling water dissolves about $\frac{1}{1000}$ part, and becomes acrid to the taste. It is very soluble in alkohol, and rather less soluble in ether.

The London College of physicians in the last edition of their pharmacopœia, have given a process for the preparation of veratria. This substance, taken internally, is a drastic purgative, resembling elaterium in its operation: the dose is $\frac{1}{12}$ of a grain. It is hardly ever used internally, but has come into vogue lately as a topical stimulant in neuralgic, rheumatic, and other painful diseases. M. Magendie has used it successfully, and Dr. Turnbull has been lavish in his encomiums of it. It is applied in the form of liniment made with from six to twelve grains to an ounce of alkohol, or in that of an ointment consisting of ℥ss. of the veratria mixed with ℥i. of olive oil, and ℥j. of lard. Veratria has been considered as identical with the alkali of the colchicum, but this has lately been called in question. See *Colchicia* in the *Supplement*.

Veratrine. See *Veratria*.

VERA'TRUM. (*um*, *i*. n.; probably derived from *verè atrum*, truly black: because the root is externally of that colour.) 1. The name of a genus of plants in the Linnæan system. Class. *Polygamia*; Order, *Monœcia*.

2. The pharmacopœial name of white hellebore. See *Veratrum album*.

VERATRUM ALBUM. White hellebore, or veratrum: called also, *Helleborus albus*, and *Elleborum album*.

Veratrum — racemo supra-decomposito, corollis erectis, of Linnæus. This plant is a native of Italy, Switzerland, Austria, and Russia. Every part of the plant is extremely acrid and poisonous. The dried root has no particular smell, but a durable, nauseous, and bitter taste, burning the mouth and fauces: when powdered, and applied to issues or ulcers, it produces griping and purging; if snuffed up the nose, it proves a violent sternutatory. Gesner made

an infusion of half an ounce of this root with two ounces of water: of this he took two drachms, which produced great heat about the scapulæ and in the face and head, as well as the tongue and throat, followed by singultus, which continued till vomiting was excited. Bergius also experienced very distressing symptoms, upon tasting this infusion. The root, taken in large doses, discovers such acrimony, and operates by the stomach and rectum with such violence, that blood is usually discharged: it likewise acts very powerfully upon the nervous system, producing great anxiety, tremors, vertigo, syncope, aphonia, interrupted respiration, sinking of the pulse, convulsions, spasms, and death. Upon opening those who have died of the effects of this poison, the stomach discovered marks of inflammation, with corrosions of its internal coat. The ancients exhibited this active medicine in maniacal cases, and, it is said, with success. The experience of Greding is somewhat similar: out of twenty-eight cases, in which he exhibited the bark of the root collected in the spring, five were cured. In almost every case that he relates, the medicine acted more or less upon all the excretions; vomiting and purging were very generally produced, and the matter thrown off the stomach was constantly mixed with bile; a florid redness frequently appeared on the face, and various cutaneous efflorescences upon the body; and, in some, pleuritic symptoms, with fever, supervened, so as to require bleeding; nor were the more alarming affections of spasms and convulsions unfrequent. Critical evacuations were also very evident; many sweating profusely, in some the urine was considerably increased, in others the saliva and mucous discharges: the uterine obstructions, of long duration, were often removed by its use. Veratrum has likewise been found useful in epilepsy, and other convulsive complaints: but the diseases in which its efficacy seems least equivocal are those of the skin, as itch, and different prurient eruptions, herpes, morbus pediculosus, lepra, and other scaly diseases: in many of these it has been successfully employed both internally and externally. As a powerful stimulant and irritating medicine, its use has been resorted to in desperate cases only, and even then it ought first to be exhibited in very small doses, as a grain, and in a diluted state, and to be gradually increased, according to the effects, which are generally of an alarming nature. The active ingredient of this plant is an alkali lately detected. See *Veratria*.

Veratrum nigrum. See *Helleborus niger*.

Veratrum sabadilla. Indian caustic barley. Called also, *Cevadilla Hispanorum; Sevadilla; Sabadilla; Hordeum causticum;* and *Canis interfector*. The plant, the seeds of which are thus denominated, is a species of *veratrum*: they are powerfully caustic, and are administered with very great success as a vermifuge. They are also diuretic and emetic. The dose to a child, from two to four years old, is two grains; from hence to eight, five grains; from eight to twelve, ten grains. A new alkali has been detected in the seeds of this plant. See *Veratria*.

VERBA'SCUM. (*um, i.* n.; *quasi barbascum*, from its hairy coat.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Monogynia*.

2. The pharmacopœial name of the yellow and black mullein.

Verbascum blatta'ria. Moth mullein. This possesses demulcent properties, but is not used in the practice of the present day.

Verbascum nigrum. The systematic name of the black mullein: called also, *Candela regia, Tapsus barbatus, Candelaria*, and *Lanaria*. The *Verbascum nigrum* and *Verbascum thapsus*, appear to be ordered indifferently by this name in the pharmacopœias. The flowers, leaves, and roots, are used occasionally as mild astringents. The leaves possess a roughish taste, and promise to be of service in diarrhœas and other debilitated states of the intestines.

Verbascum thapsus. The systematic name of the yellow mullein. See *Verbascum nigrum*.

VERBE'NA. (*a, æ.* f.; *quasi herbena*, a name of distinction for all herbs used in sacred rites.) Vervain. 1. The name of a genus of plants in the Linnæan system. Class, *Decandria;* Order, *Monogynia*.

2. The pharmacopœial name of the vervain. See *Verbena officinalis*.

Verbena fœmina. The hedge mustard is sometimes so called. See *Erysimum alliaria*.

Verbena officinalis. Vervain. The systematic name of *Verbenaca, Peristerium, Hierobotane*, and *Herba sacra*. This plant is destitute of odour, and to the taste manifests but a slight degree of bitterness and astringency. In former times the verbena seems to have been held sacred, and was employed in celebrating the sacrificial rites; and with a view to this, more than the natural power of the plant, it was worn suspended about the neck as an amulet. This practice, thus founded on superstition, was, however, in process of time, adopted in medicine; and therefore, to obtain its virtues more effectually, the vervain was directed to be bruised before it was appended to the neck; and of its good effects thus used for inveterate headaches, Forestus relates a remarkable instance. In still later times it has been employed in the way of cataplasm, by which we are told the most severe and obstinate cases of cephalalgia have been cured, for which we have the authorities of Etmuller, Hartman, and more especially De Haën. Notwithstanding these testimonies in favour of vervain, it has deservedly fallen into disuse in Britain; nor has the pamphlet of Mr. Morley, written professedly to recommend its use in scrofulous affections, had the effect of restoring its medical character. This gentleman directed the root of vervain to be tied with a yard of white satin riband round the neck, where it was to remain till the patient recovered. He also had recourse to infusions and ointments prepared from the leaves of the plant, and occasionally called in aid the most active medicines of the Materia Medica.

Verdigris. See *Æruginis æris*.

Verjuice. An acid liquor prepared from grapes or apples that are unfit to be converted

into wine or cyder. It is also made from crab-apples. It is principally used in sauces and ragouts, though it sometimes forms an ingredient in medicinal compositions.

VERMICULA'RIS. (From *vermis*, a worm.) Vermicular: shaped like or having the properties of a worm: applied very generally in natural history.

VE'RMIFORM. (*Vermiformis*; from *vermis*, a worm, and *forma*, resemblance.) Worm-like.

Vermiform process. *Processus* and *Protuberantia vermiformis*. The substance which unites the two hemispheres of the cerebellum like a ring, forming a process, so called from its resemblance to an earth-worm rolled up.

VE'RMIFUGE. (*Vermifugus*; from *vermis*, a worm, and *fugo*, to drive away.) See *Anthelmintic*.

Vermilion. See *Cinnabar*.

VE'RMIS. (*is, is.* m.; *à vertendo*: because it twists itself about.) A worm. The name generally given to the parasitical animals that infest the animal body. See *Entozoa*, and *Invermination*.

Vermis cerebri. Brain-worm. This name has been given to the Hungarian camp fever.

Vermis mordicans. *Vermis repens*. A species of herpetic eruption on the skin.

Vermis terrestris. See *Lumbricus*.

VERNA'TIO. (From *ver*, the spring.) This term is applied to the manner in which the leaves are folded or wrapped up, and expand in the spring. See *Germ*.

VERO'NICA. 1. The name of a genus of plants in the Linnæan system. Class, *Diandria*; Order, *Monogynia*. Speedwell.

2. The pharmacopœial name of the male veronica. See *Veronica officinalis*.

Veronica beccabunga. The water-pimpernel and brooklime: called also, *Berula*, *Beccabunga*, *Anagallis aquatica*, *Laver germanicum*, *Veronica aquatica*, and *Cepæa*. The plant which bears these names is the *Veronica — racemis lateralibus, foliis ovatis planis, caule repente*, of Linnæus. It was formerly considered of much use in several diseases, and was applied externally to wounds and ulcers: but if it have any peculiar efficacy, it is to be derived from its antiscorbutic virtue. As a mild refrigerant juice, it is preferred where an acrimonious state of the fluids prevails, indicated by purulent eruptions upon the skin, or in what has been called the hot scurvy. To derive much advantage from it, the juice ought to be taken in large quantities, or the fresh plant eaten as food.

Veronica officinalis. The systematic name of the plant which is called in the phamacopœias *Veronica mas; Thea germanica: Betonica, pauli; Chamædrys spuria. Veronica — spicis lateralibus pedunculatis; foliis oppositis; caule procumbente*, of Linnæus, is not unfrequent on dry barren grounds and heaths, as that of Hampstead, flowering in June and July. This plant was formerly used as a pectoral against coughs and asthmatic affections, but it is now justly forgotten.

VE'RRES. (*es, is.* m.) The boar. See *Sus, scrofa*.

Verricula'ris tu'nica. (*Vericularis*, from *vericulum*, a drag-net.) The retina of the eye.

VERRU'CA. (*a, æ.* f.) 1. A wart, or thickening and induration of the cuticle, which is raised up in different forms, mostly the size of a lentil or flat pea.

2. In *Botany*, applied to a small round prominence on the inferior surface of funguses.

VERRUCA'RIA. (*a, æ.* f.; from *verruca*, a wart: because it was supposed to destroy warts.) The *Heliotropium europæum*, or turnsole.

VERRUCO'SUS. Warty; applied to smal rough tubercles on vegetables, as on the stem of the *Euonymus verrucosus*; and the seed-vessel of the *Cucurbita verrucosa*.

VERSA'TILIS. Versatile: vane-like; turning about like a vane or weathercock: applied to the anthers of the *Geranium Imperatoria*, &c.

VE'RTEBRA. (*a, æ.* f.; from *verto*, to turn.) The spine is a long bony column, which extends from the head to the lower part of the trunk, and is composed of irregular bones, which are called vertebræ.

The spine may be considered as being composed of two irregular pyramids, which are united to each other in that part of the loins where the last of the lumbar vertebræ is united to the os sacrum.

The vertebræ which form the upper and longest pyramid are called true vertebræ; and those which compose the lower pyramid, or the os sacrum and coccyx, are termed false vertebræ, because they do not in every thing resemble the others, and particularly because in the adult state, they become perfectly immoveable, while the upper ones continue to be capable of motion: for it is upon the bones of the spine that the body turns; and their name has its derivation from the Latin verb *verto*, to turn, as observed above.

The true vertebræ, from their situations with respect to the neck, back, and loins, are divided into three classes, — of cervical, dorsal, and lumbar vertebræ. We will first consider the general structure of all these, and then separately describe their different classes.

In each of the vertebræ, as in other bones, we may remark the body of the bone, its processes and cavities. The body may be compared to part of a cylinder cut off transversely: convex before, and concave behind, where it makes part of the cavity of the spine.

Each vertebra has commonly seven processes. The first of these is the *spinous* process, which is placed at the back part of the vertebra, and gives the name of spine to the whole of this bony canal. Two others are called *transverse* processes, from their situation with respect to the spine, and are placed on each side of the spinous process. The four others, which are called *oblique* processes, are much smaller than the other three. There are two of these on the upper and two on the lower part of each vertebra, rising from near the basis of the transverse processes. They are sometimes called *articular* processes, because they are articulated with each other; that is, the two superior pro-

cesses of one vertebra are articulated with the two inferior processes of the vertebra above it; and they are called oblique processes, from their situation with respect to the processes with which they are articulated. These oblique processes are articulated to each other by a species of ginglymus, and each process is covered at its articulation with cartilage.

There is in every vertebra, between its body and apophyses, a foramen, large enough to admit a finger. These foramina correspond with each other through all the vertebræ, and form a long bony conduit, for the lodgment of the spinal marrow.

Besides this great hole, there are four notches on each side of every vertebra, between the oblique processes and the body of the vertebra. Two of these notches are at the upper, and two at the lower part of the bone. Each of the inferior notches, meeting with one of the superior notches of the vertebra below it, forms a foramen; whilst the superior notches do the same with the inferior notches of the vertebra above it. These four foramina form passages for blood-vessels, and for the nerves that pass out of the spine.

The vertebræ are united together by means of a substance, compressible like cork, which forms a kind of partition between the several vertebræ. This intervertebral substance seems, in the fœtus, to approach nearly to the nature of ligament: in the adult it has a great resemblance to cartilage. When cut horizontally, it appears to consist of concentrical curved fibres: externally it is firmest and hardest; internally it becomes thinner and softer, till at length, in the centre, we find it in the form of a mucous substance, which facilitates the motions of the spine.

Genga, an Italian anatomist, long ago observed, that the change which takes place in these intervertebral cartilages (as they are usually called), in advanced life, occasions the decrease in stature, and the stooping forwards, which are usually to be observed in old people. The cartilages then become shrivelled, and consequently lose, in a great measure, their elasticity. But, besides this gradual effect of old age, these cartilages are subject to a temporary diminution, from the weight of the body in an erect posture; so that people who have been long standing, or who have carried a considerable weight, are found to be shorter than when they have been long in bed. Hence we are taller in the morning than at night. This fact, though seemingly obvious, was not ascertained till of late years. The difference in such cases depends on the age and size of the subject: in tall, young people, it will be nearly an inch; but in older, or shorter persons, it will be less considerable.

Besides the connection of the several vertebræ, by means of these cartilages, there are likewise many strong ligaments, which unite the bones of the spine to each other. Some of these ligaments are external, and others internal. Among the external ligaments, we observe one which is common to all the vertebræ, extending, in a longitudinal direction, from the fore part of the body, or the second vertebra of the neck, over all the other vertebræ, and becoming broader as it descends towards the os sacrum, where it becomes thinner, and gradually disappears. This external longitudinal ligament, if we may so call it, is strengthened by other shorter ligamentous fibres, which pass from one vertebra to another, throughout the whole spine. The internal ligament, the fibres of which, like the external one, are spread in a longitudinal direction, is extended over the back part of the bodies of the vertebræ, where they help to form the cavity of the spine, and reaches from the foramen of the occipital bone to the os sacrum.

We may venture to remark, that all the vertebræ diminish in density and firmness of texture, in proportion as they increase in size; so that the lower vertebræ, though larger, are not so heavy in proportion as those above them. In consequence of this mode of structure, the size of the vertebræ is increased without adding to their weight; and this is an object of no little importance in a part of the body, which, besides flexibility and suppleness, seems to require lightness as one of its essential properties.

In the fœtus, at the ordinary time of birth, each vertebra is found to be composed of three bony pieces, connected by cartilages which afterwards ossify. One of these pieces is the body of the bone; the other two are the posterior and lateral portions, which form the foramen for the medulla spinalis. The oblique processes are at that time complete, and the transverse processes beginning to be formed, but the spinous processes are totally wanting.

The cervical vertebræ are seven in number; their bodies are smaller, and of a firmer texture, than the other bones of the spine. The transverse processes of these vertebræ are short, and forked for the lodgment of muscles; and, at the bottom of each of these processes, there is a foramen, for the passage of the cervical artery and vein. The spinous process of each of these vertebræ is likewise shorter than the other vertebræ, and forked at its extremity; by which means it allows a more convenient insertion to the muscles of the neck. Their oblique processes are more deserving of that name than either those of the dorsal or lumbar vertebræ. The uppermost of these processes are slightly concave, and the lowermost slightly convex. This may suffice for a general description of these vertebræ; but the first, second, and seventh deserve to be spoken of more particularly. The first, which is called *atlas*, from its supporting the head, differs from all the other vertebræ of the spine. It forms a kind of bony ring, which may be divided into its anterior and posterior arches, and its lateral portions. Of these, the anterior arch is the smallest and flattest: at the middle of its convex fore-part we observe a small tubercle, which is here what the body is in the other vertebræ. To this tubercle a ligament is attached, which helps to strengthen the articulation of the spine with the os occipitis. The back part of this anterior portion is concave, and covered with cartilage, where it receives the odontoid process of the second vertebra. The posterior portion of the vertebra, or,

more properly speaking, the posterior arch, is larger than the anterior one. Instead of a spinous process, we observe a rising, or tubercle, larger than that which we have just now described on the fore-part of the bone. The lateral portions of the vertebra project, so as to form what are called the transverse processes, one on each side, which are longer and larger than the transverse processes of the other vertebræ. They terminate in a roundish tubercle, the end of which has a slight bend downwards. Like the other transverse processes, they are perforated at their basis, for the passage of the cervical artery. But, besides these transverse processes, we observe, both on the superior and inferior surface of these lateral portions of the first vertebra, an articulating surface, covered with cartilage, answering to the oblique processes in the other vertebræ. The uppermost of these are oblong, and slightly concave, and their external edges rise somewhat higher than their internal brims. They receive the condyloid processes of the os occipitis, with which they are articulated by a species of ginglymus. The lowermost articulating surfaces, or the inferior oblique processes, as they are called, are large, concave, and circular, and are formed for receiving the superior oblique processes of the second vertebra; so that the atlas differs from the rest of the cervical vertebræ in receiving the bones, with which it is articulated both above and below. In the fœtus we find this vertebra composed of five, instead of three pieces, as in the other vertebræ. One of these is the anterior arch; the other four are the posterior arch and the sides, each of the latter being composed of two pieces. The transverse process, on each side, remains long in a state of epiphysis with respect to the rest of the bone.

The second vertebra is called *dentata*, from the process on the upper part of its body, which has been, though perhaps improperly, compared to a tooth. This process, which is the most remarkable part of the vertebra, is of a cylindrical shape, slightly flattened, however, behind and before. Anteriorly it has a convex, smooth, articulating surface, where it is received by the atlas, as we observed in our description of that vertebra. It is by means of this articulation that the rotatory motion of the head is performed; the articulation of the os occipitis with the superior oblique processes of the first vertebra, allowing only a certain degree of motion backwards and forwards, so that when we turn the face either to the right or left, the atlas moves upon this odontoid process of the second vertebra. But as the face cannot turn a quarter of a circle, that is, to the shoulder, upon this vertebra alone, without being liable to injure the medulla spinalis, we find that all the cervical vertebræ concur in this rotatory motion, when it is in any considerable degree; and indeed we see many strong ligamentous fibres arising from the sides of the odontoid process, and passing over the first vertebra, to the os occipitis, which not only strengthen the articulation of these bones with each other, but serve to regulate and limit their motion. It is on this account that the name of *moderators* has sometimes been given to these ligaments. The transverse processes of the vertebra *dentata* are short, inclined downwards, and forked at their extremities. Its spinous process is short and thick. Its superior oblique processes are slightly convex, and somewhat larger than the articulating surfaces of the first vertebra, by which mechanism the motion of that bone upon this second vertebra is performed with greater safety. Its inferior oblique processes have nothing singular in their structure.

The seventh vertebra of the neck differs from the rest chiefly in having its spinous process of a greater length, so that, upon this account, it has been sometimes called *vertebra prominens*.

The dorsal vertebræ, which are twelve in number, are of a middle size, between the cervical and lumbar vertebræ; the upper ones gradually losing their resemblance to those of the neck, and the lower ones coming nearer to those of the loins. The bodies of these vertebræ are more flattened at their sides, more convex before, and more concave behind, than the other bones of the spine. Their upper and lower surfaces are horizontal. At their sides we observe two depressions, one at their upper, and the other at their lower edge, which, united with similar depressions in the vertebræ above and below, form articulating surfaces, covered with cartilage, in which the heads of the ribs are received. These depressions, however, are not exactly alike in all the dorsal vertebræ; for we find the head of the first rib articulated solely with the first of these vertebræ, which has therefore the whole of the superior articulating surface within itself, independently of the vertebra above it. We may likewise observe a similarity in this respect in the eleventh and twelfth of the dorsal vertebræ, with which the eleventh and twelfth ribs are articulated separately. Their spinous processes are long, flattened at the sides, divided at their upper and back part into two surfaces by a middle ridge, which is received by a small groove in the inner part of the spinous process immediately above it, and connected to it by a ligament. These spinous processes are terminated by a kind of round tubercle, which slopes considerably downwards, except in the three lowermost vertebræ, where they are shorter and more erect. Their transverse processes are of considerable length and thickness, and are turned obliquely backwards. Anteriorly they have an articulating surface, for receiving the tuberosity of the ribs, except in the eleventh and twelfth of the dorsal vertebræ, to which the ribs are articulated by their heads only. In the last of these vertebræ the transverse processes are very short and thick, because otherwise they would be apt to strike against the lowermost ribs, when we bend the body to either side.

The *lumbar vertebræ*, the lowest of the true vertebræ, are five in number. They are larger than the dorsal vertebræ. Their bodies are extremely prominent, and nearly of a circular form at their fore part; posteriorly they are concave. Their intermediate cartilages are of considerable thickness, especially anteriorly, by which means

the curvature of the spine forwards, towards the abdomen, in this part, is greatly assisted. Their spinous processes are short and thick, of considerable breadth, erect, and terminated by a kind of tuberosity. Their oblique processes are of considerable thickness: the superior ones are concave, and turned inwards; the inferior ones convex, and turned outwards. Their transverse processes are thin and long, except in the first and last vertebræ, where they are much shorter, that the lateral motions of the trunk might not be impeded. The inferior surface of all these vertebræ is slightly oblique, so that the fore part of the body of each is somewhat thicker than its hind part; but this is more particularly observable in the lowermost vertebra, which is connected with the os sacrum. Many anatomists describe the os sacrum and the os coccygis when considering the bones of the spine, whilst others regard them as belonging more properly to the pelvis. These bones the reader may consult. It now remains to notice the uses, of the spine. We find the spinal marrow lodged in this bony canal, secure from external injury. It defends the thoracic and abdominal viscera, and forms a pillar which supports the head, and gives a general firmness to the whole trunk.

To give it a firm basis, we find the bodies of the vertebræ gradually increasing in breadth as they descend; and to fit it for a variety of motion, it is composed of a great number of joints, with an intermediate elastic substance, so that to great firmness there is added a perfect flexibility.

We have already observed, that the lowermost and largest vertebræ are not so heavy in proportion as those above them; their bodies being more spongy excepting at their circumference, where they are more immediately exposed to pressure; so that nature seems every where endeavouring to relieve us of an unnecessary weight of bone. But behind, where the spinal marrow is more exposed to injury, we find the processes composed of very hard bone; and the spinous processes are in general placed over each other in a slanting direction, so that a pointed instrument cannot easily get between them, excepting in the neck, where they are almost perpendicular, and leave a greater space between them. Hence, in some countries, it is usual to kill cattle by thrusting a pointed instrument between the occiput and the atlas, or between the atlas and the second vertebra. Besides these uses of the vertebræ in defending the spinal marrow, and in articulating the several vertebræ, as is the case with the oblique processes, we shall find that they all serve to form a greater surface for the lodgment of muscles, and to enable the latter to act more powerfully on the trunk, by affording them a lever of considerable length.

In the neck, we see the spine projecting somewhat forward, to support the head, which, without this assistance, would require a greater number of muscles. Through the whole length of the thorax it is carried in a curved direction backwards, and thus adds considerably to the cavity of the chest, and consequently affords more room to the lungs, heart, and large blood-vessels. In the loins, the spine again projects forwards, in a direction with the centre of gravity, by which means the body is easily kept in an erect posture; for otherwise we should be liable to fall forwards. But, at its inferior part, it again recedes backwards, and helps to form a cavity called the pelvis, in which the urinary bladder, intestinum rectum, and other viscera are placed.

In a part of the body that is composed of so great a number of bones, and constructed for such a variety of motion, as the spine is, luxation is more to be expected than fracture; and this is very wisely guarded against in every direction, by the many processes that are to be found in each vertebra, and by the cartilages, ligaments, and other means of connection, which we have described as uniting them together.

VE'RTEBRAL. *Vertebralis.* Appertaining to the vertebræ, or bones of the spine.

VERTEBRAL ARTERY. *Arteria vertebralis.* A branch of the subclavian, proceeding through the vertebræ to within the cranium, where, with its fellow, it forms the basillary artery, the internal auditory, and the posterior artery of the dura mater.

Vertebral sinuses. See *Sinuses vertebral.*

VE'RTEX. (*ex, icis.* m.; from *verto.*) The crown of the head. The os verticis is the parietal bone.

VE'RTICAL. *Verticalis.* Perpendicular: applied to leaves which have both sides at right angles with the horizon; as in *Lactuca scariola.*

Verticalia ossa. See *Parietal bone.*

VERTICI'LLUS. A whorl. The botanical name of a species of inflorescence, in which the flowers surround the stem in a sort of ring.

From the *insertion* of the flowers, the *vesture,* and *distance* of the verticillus, it is called,

1. *Pedunculatus;* as in *Melissa officinalis.*
2. *Sessilis,* in *Mentha arvensis.*
3. *Dimidiatus,* going half round; as in *Ballota disticha.*
4. *Nudus,* without floral or other leaf; as in *Salvia verticellata.*
5. *Bracteatus,* in *Ballota nigra.*
6. *Distans,* in *Salvia indica.*
7. *Confertus,* when crowded together.

Verticis os. See *Parietal bone.*

VERTI'GO. (*o, inis.* f.; from *verto, à vertendo.*) Giddiness or swimming of the head. This carries its own meaning, but there are some varieties of it. It is, in the generality of cases, a dizziness, with a fear of falling, and more or less of mental confusion. Objects appear to be moving horizontally or perpendicularly, and not unfrequently the person thinks he is also moving. In many cases, the person hears whispering sounds, ringing of bells, or sounds like the beating of drums. This affection takes place whether the person be in the dark or light, whether the eyes be closed or open. In some cases the representations of objects are very numerous and rapid, and in others far less so; and as the affection advances the representations are confused, indistinct, and more rapid in succession, often conjoined with a sense of dimness or darkness, forming the *scotodinus* of Hippocrates and the Greek writers.

The predisposing causes of this affection are such as produce debility or exhaustion of the nervous power; and the exciting causes are, whatever has a tendency to disturb the uniformity with which the nervous power is supplied through the whole of its channels, and from one fibre to another. Hence they are the most subject to vertiginous affections whose nervous systems are constitutionally weak, or have become so by disease or accident: dyspeptic persons are peculiarly subject to them; as are those who are faint from sudden and violent evacuations, want of food, or a long course of labour: indulgence in the pleasures of the table and sexual intercourse produce vertigo in the same way; and hence also it is so frequently symptomatic of fevers, inflammations, and many other diseases.

In attempting the removal of vertiginous states, the attention must be directed to the removal of determination or congestion of blood to the head; the clearing the stomach and bowels, which done, ammoniated and camphorated remedies will generally allay the nervous agitation: but if, on the other hand, it proceeds from emptiness of the stomach, hæmorrhage, or the like debilitating causes, food and stimulants are the immediate restoratives.

Vervain. See *Verbena officinalis.*

Vervain, female. See *Erysimum alliaria.*

VESA'NIÆ. (The plural of *vesania*, madness.) The fourth order in the Class *Neuroses* of Cullen's nosological arrangement; comprehending diseases in which the judgment is impaired, without either coma or pyrexia.

VESI'CA. (*a*, *æ*. f.; a diminutive of *vas*, a vessel.) A bladder.

Vesica fellis. The gall-bladder. See *Gall-bladder.*

Vesica natato'ria. The air bladder of fishes. A pneumatic apparatus situated immediately under the spine, which, by its contraction or dilatation, renders the animal specifically heavier or lighter, and enables it to rise or sink in the water. It exists in a great number of fishes, but not in all. According to M. Biot and others, fish that inhabit the deep waters have their air bladders filled with a mixture of oxygen and nitrogen, in which the former greatly preponderates; while fish which swim nearer the surface have their air bladders filled chiefly or entirely with nitrogen.

Vesica urinaria. The urinary bladder. See *Urinary bladder.*

VESICATO'RIUS. (From *vesica*, a bladder: because it raises a bladder.) Having the property when applied to the skin of raising a bladder, by causing a fluid to collect between the cuticle and cutis. Various substances produce this effect on the skin: but the powder of the *cantharis*, or blistering fly, is what operates with most certainty and expedition, and is now invariably made use of for the purpose.

It is a principle sufficiently established with regard to the living system, that where a morbid action exists, it may often be removed by inducing an action of a different kind in the same or a neighbouring part. On this principle is explained the utility of blisters in local inflammation and spasmodic action, and it regulates their application in pneumonia, gastritis, hepatitis, phrenitis, angina, rheumatism, colic, and spasmodic affections of the stomach; diseases in which they are employed with the most marked advantage. A similar principle exists with respect to pain; exciting one pain often relieves another. Hence blisters often give relief in toothache, and some other painful affections. Lastly, blisters, by their operation, communicate a stimulus to the whole system, and raise the vigour of the circulation. Hence, in part, their utility in fevers of the typhoid kind, though in such cases they are used with still more advantage to obviate or remove local inflammation.

When it is not wished to maintain a discharge from the blistered part, it is sufficient to make a puncture in the cuticle to let out the fluid; but when the case requires keeping up a secretion of pus, the surgeon must remove the whole of the detached cuticle with a pair of scissars, and dress the excoriated surface in a particular manner. Practitioners used formerly to mix powder of cantharides with an ointment, and dress the part with this composition. But such a dressing not unfrequently occasioned very painful affections of the bladder, a scalding sensation in making of water, and very afflicting stranguries. The treatment of such complaints consists in removing every particle of the fly from the blistered part, and making the patient drink abundantly of mucilaginous drinks. According to some practitioners, camphor has a specific effect in removing this kind of strangury; but it has failed in the hands of others.

These objections to the employment of salves containing the lytta, for dressing blistered surfaces, led to the use of mezereon, euphorbium, and other irritating substances, which, when incorporated with ointment, form very proper compositions for keeping blisters open, which they do without the inconvenience of irritating the bladder, like the blistering fly. The favourite application, however, for keeping open blisters, is the savine cerate, which was brought into notice by Mr. Crowther, in his book on white swellings. (See *Ceratum sabinæ.*) On the use of the savine cerate, immediately after the cuticle raised by the blister is removed, says Mr. Crowther, it should be observed that experience has proved the advantage of using the application lowered by half or two thirds of the unguentum ceræ. An attention to this direction will produce less irritation and more discharge than if the savine cerate were used in its full strength. Mr. Crowther says also, that he has found fomenting the part with flannel, wrung out of warm water, a more easy and preferable way of keeping the blistered surface clean, and fit for the impression of the ointment, than scraping the part, as has been directed by others. An occasional dressing of unguentum resinæ flavæ, he has found a very useful application for rendering the sore free from an appearance of slough, or rather dense lymph, which has sometimes been so firm in its texture as to be separated by the probe, with as much readiness as the cuticle is detached after blistering. As the

discharge diminishes, the strength of the savine dressing should be proportionably increased. The ceratum sabinæ must be used in a stronger or weaker degree, in proportion to the excitement produced on the patient's skin.

VE'SICLE. (*Vesicula*, *æ*. f.; a diminutive of *vesica*, a bladder.) An elevation of the cuticle or bladder-like tumour in any part, containing a transparent watery fluid.

VESICULA FELLIS. The gall-bladder.

VESICULÆ DIVÆ BARBARÆ. The confluent small-pox.

VESICULÆ GINGIVARUM. The thrush.

VESICULÆ GRAAFIANÆ. Graafian vesicles. The vesicles contained in the ovarium, named after De Graaf. See *Ovarium*.

VESICULÆ NABOTHI. Vesicles of Naboth. The follicles in the interior of the cervix uteri.

VESICULÆ PULMONALES. The air-cells of the lungs. See *Pulmo*.

VESICULÆ SEMINALES. Two membraneous receptacles, situated on the back part of the bladder, above its neck. The excretory ducts are called ejaculatory ducts. They proceed to the urethra, into which they open by a peculiar office at the top of the verumontanum. They have vessels and nerves from the neighbouring parts, and are well supplied with absorbent vessels, which proceed to the lymphatic glands about the loins. The use of the vesiculæ seminales is to receive the semen brought into them by the vasa deferentia, to retain, somewhat inspissate, and to excern it *sub coitu* into the urethra, from whence it is propelled into the vagina uteri.

Vesicular fever. See *Pemphigus*.

VE'SPA. (*a*, *æ*. f.) The name of a genus of insects, of the order *Hymenoptera*. The wasp.

VESPA CRABRO. The hornet. The sting of this insect is very severe, and the effect best allayed by dilute subcarbonate of ammonia.

VESPA VULGARIS. The common wasp, the sting of which produces much irritation. The best application is diluted ammonia, alone or with oil.

VESTI'BULUM. (*um*, *i*. n.) A cavity of the internal ear, between the cochlea and semicircular canals. See *Auris*.

Vetonica cordi. See *Betonica*.

VEXI'LLUM. (*um*, *i*. n.; a banner or standard.) The standard, or large uppermost petal at the back of a papilionaceous flower.

VI'A. (*a*, *æ*. f.) A way or passage. Used in anatomy. See *Primæ viæ*.

VIABILITY. The state of a child which is *viable*. See *Viable*.

VIABLE. A term adopted from the French, and applied to a new-born child, to express its capability of sustaining extrauterine and independent life. If a fœtus be properly organised and sufficiently developed to live, it is said to be *viable*.

VI'BEX. (*ex*, *icis*.; plu. *Vibices*.) A large purple spot which appears under the skin in certain malignant fevers.

VIBRI'SSÆ. (*æ*, *arum*. f.) The hairs growing inside the nostrils. See *Capillus*.

VIBU'RNUM. (*um*, *i*. n.; from *vieo*, to bind.) The name of a genus of plants. Class, *Pentandria*; Order, *Trigynia*.

VIBURNUM LANTANA. *Liburnum*. The pliant mealy tree. The berries are considered as astringent.

VICHY. A small town in the department of Allier, in France, where there are seven mineral springs, known by the names of *source de grande Grille*, *des Bains*, *de l'Hôpital*, *le petit Puits*, or *source Chomel*, *les Celestins*, *les Acacias*, or *source des Galeux*, and the *source Lucas*.

Most of the springs are thermal. These waters contain variable proportions of carbonic acid, subcarbonate of soda, subcarbonates of lime, magnesia, and iron, sulphate and muriate of soda, silica, and a green vegeto-animal matter, which abounds particularly in the source *de l'Hôpital*. These waters are both taken internally and used as a bath. They are particularly recommended in chronic obstructions of the liver and spleen, rheumatism, and gout.

VI'CIA. (*a*, *æ*. f.; an old Latin name, derived by some etymologists from *vincio*, to bind together; as the various species of this genus twine, with their tendrils, round other plants.) The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria*.

VICIA FABA. The systematic name of the common bean plant. It is a native of Egypt. There are many varieties. Beans are very wholesome and nutritious to those whose stomachs are strong, and accustomed to the coarser modes of living. In delicate stomachs they produce flatulency, dyspepsia, cardialgia, &c., especially when old.

Victorialis longa. See *Allium*.

VIGILANCE. *Pervigilium*. Continued wakefulness. This, when attended by anxiety, pain in the head, loss of appetite, and diminution of strength, is by Sauvages and Sagar considered as a genus of disease, and is called *Agrypnia*.

VILLO'SUS. Villous, shaggy: applied, in *Anatomy*, to a velvet-like arrangement of fibres or vessels, as the villous coat of the intestines; and, in *Botany*, to stems, as that of *Cineraria integrifolia*, and to other parts of plants; as the receptacle of the *Artemisia absinthium*.

VI'LLUS. (*us*, *i*. m.) A species of hairy pubescence of plants, consisting of soft, slender, upright, short, scarcely conspicuous, and for the most part white hair-like filaments.

VI'MEN. (*en*, *inis*. n.; from *vieo*, to bind.) A slender and flexible twig.

VI'NCA. (From *vincio*, to bind: because of its usefulness in making bands.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia*.

VINCA MINOR. The systematic name of the lesser periwinkle. *Vinca pervinca*. *Clematis daphnoides major*. It possesses bitter and astringent virtues, and is said to be efficacious in stopping nasal hæmorrhages when bruised and put into the nose. Boiled, it forms a useful astringent gargle in common sore throat, and it is given by some in phthisical complaints.

Vinca pervinca. See *Vinca minor*.

VINCETO'XICUM. (*um*, *i*. n.; from *vinco*, to overcome, and *toxicum*, poison: so named from

its supposed virtue of resisting and expelling poison.) See *Asclepias vincetoxicum.*

Vine. See *Vitis.*

Vine, white. See *Bryonia alba.*

Vine, wild. See *Bryonia alba.*

Vinegar. See *Acetum.*

Vinegar, aromatic. See *Acetum aromaticum.*

Vinegar, distilled. See *Acetum.*

Vinegar of squills. See *Acetum scillæ.*

Vinegar, radical. See *Acetum radicale.*

Vinegar, spirits of. See *Acetum.*

Vinegar, thieves'. See *Acetum prophylacticum.*

Vinum. See *Wine.*

VINUM ALOES. Wine of aloes. Formerly known by the names of *Tinctura hieræ*, and *Tinctura sacra.* Take of extract of aloe, two ounces; canella-bark, four drachms; sherry wine, two pints. Macerate for fourteen days, occasionally shaking the mixture, and afterwards strain. A stomachic purgative, calculated for the aged and phlegmatic, who are not troubled with the piles. The dose is from a half to a whole fluid ounce.

VINUM ANTIMONII POTASSIO-TARTRATIS. The antimonial wine is so named in the London Pharmacopœia of 1836. See *Antimonii tartarizati liquor.*

Vinum antimonii tartarizati. See *Antimonium tartarizatum.*

VINUM CO'LCHICI. Wine of colchicum. Take of the cormus of colchicum, dried and sliced, eight ounces; sherry wine, two pints. Macerate for fourteen days, shaking occasionally, and strain. For its virtues, see *Colchicum.*

VINUM FERRI. Wine of iron; formerly called *Vinum chalybeatum.* Take of iron filings, two ounces; wine, two pints: mix, and set the mixture by for a month, occasionally shaking it; then filter it through paper. For its virtues, see *Ferrum tartarizatum.*

VINUM IPECACUANHÆ. Wine of ipecacuanha. Take of ipecacuanha root, bruised, two ounces and a half; sherry wine two pints: macerate for fourteen days, and strain. The dose, when used as an emetic, is from two fluid drachms to half a fluid ounce. As a diaphoretic the dose is about half a drachm, and it produces an expectorant effect in the dose of ten or fifteen drops several times a day.

VINUM OPII. Wine of opium; formerly known by the names of *Laudanum liquidum Sydenhami*, and *Tinctura thebaica.* Take of purified extract of opium, two ounces and a half; cinnamon-bark, bruised, cloves, bruised, of each two drachms and a half; sherry wine, two pints: macerate for eight days, and strain. This preparation, as an internal medicine, agrees nearly in its virtues with tincture of opium, but it is hardly ever given internally. It is very useful in chronic opthalmia, two or three drops being introduced into the eye every day. This practice was introduced by Mr. Ware.

VINUM VERA'TRI. Wine of white hellebore. Take of white hellebore-root, sliced, eight ounces; sherry wine, two pints and a half: macerate for fourteen days, and strain. See *Veratrum.*

VI'OLA. (From Ιον: because it was first found in Ionia.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Monogynia.* The violet.

2. The pharmacopœial name of the sweet violet. See *Viola odorata.*

VIOLA CALCEOLARIA. One of the emetic species of violet. It affords a kind of ipecacuanha.

VIOLA CANINA. The dog violet. The root of this plant excites vomiting and purging; with which intention a scruple of the dried root must be exhibited. It appears, though neglected in this country, worthy the attention of physicians.

VIOLA IPECACUANHA. This plant affords a species of ipecacuanha-root. See *Ipecacuanha.*

Viola lutea. See *Cheiranthus cheiri.*

VIOLA ODORATA. The systematic name of the sweet violet. *Viola — acaulis, foliis cordatis, stolonibus repentibus*, of Linnæus. The recent flowers of this plant are received into the catalogues of the Materia Medica. They have an agreeable sweet smell, and a mucilaginous bitterish taste. Their virtues are purgative or laxative, and by some they are said to possess an anodyne and pectoral quality. The officinal preparation of this flower is a syrup, which, to young children, answers the purpose of a purgative; it has also been used as a test in chemical experiments, to detect an acid or an alkali; the former changing the blue colour to a red, and the latter to a green.

Viola palustris. See *Pinguicula.*

VIOLA PARVIFLO'RA. This plant affords a kind of ipecacuanha.

VIOLA TRI'COLOR. Heart's-ease. Pansy. This well-known beautiful little plant grows in corn-fields, and in waste and cultivated grounds, flowering all the summer months. It varies much by cultivation; and by the vivid colouring of its flowers often becomes extremely beautiful in gardens, where it is distinguished by various names. To the taste, this plant in its recent state is extremely glutinous, or mucilaginous, accompanied with the common herbaceous flavour and roughness. By distillation with water, according to Haase, it affords a small quantity of odorous essential oil, of a somewhat acrid taste. The dried herb yields about half its weight of watery extract, the fresh plant about one eighth. Though many of the old writers on the Materia Medica represent this plant as a powerful medicine in epilepsy, asthma, ulcers, scabies, and cutaneous complaints, yet the viola tricolor owes its modern character as a medicine to the authorities of Stoerck, Metzger, Haase, and other writers, especially as a remedy for the crusta lactea. For this purpose, a handful of the fresh herb, or half a drachm of it dried, boiled two hours in milk, is to be strained, and taken night and morning. Bread, with this decoction, is also to be formed into a poultice, and applied to the part. By this treatment, it has been observed, that the eruption, during the first eight days, increases, and that the urine, when the medicine succeeds, has an odour similar to that of cats; but on continuing the use of the plant a sufficient time, this smell goes off, the scabs disappear, and the skin recovers its natural

purity. Instances of the successful exhibition of this medicine, as cited by these authors, are very numerous; indeed, this remedy, under their management, seems rarely, if ever, to have failed. It appears, however, that Mursinna, Akermann, and Henning were less fortunate in the employment of this plant; the last of whom declares, that in the different cutaneous disorders in which he used it, no benefit was derived. Haase, who administered this species of violet in various forms, and large doses, extended its use to many chronic disorders; and, from the great number of cases in which it proved successful, it has as good a claim to further trial as many other medicines.

It is remarkable that Bergius speaks of this plant as a useful mucilaginous purgative, and takes no notice of its efficacy in the crustea lactea, or in any other disease.

VIOLA'CEOUS. *Violaceus.* 1. Applied to a deep bluish purple or violet colour.

2. Applied to a smell like that of the *Viola odorata*, or sweet-smelling violet.

Viola'ria. See *Viola.*

Violet. See *Viola odorata.*

Violet dog. See *Viola canina.*

VI'OLINE. The emetic principle of the ipecacuhan violets, similar to emetine.

Viper. See *Vipera.*

Viper-glass. See *Scorzonera.*

VI'PERA. (*Quod vi pariat;* because it was thought that its young eat through the mother's bowels.) The viper or adder. See *Coluber berus.*

Viperaria. See *Aristolochia serpentaria.*

VIPERI'NA. (From *vipera*, a snake: so called from the serpentine appearance of its roots.) See *Aristolochia serpentaria.*

Viperina virginiana. See *Aristolochia.*

Virga aurea. See *Solidago virga aurea.*

VIRGA'TA SUTURA. The sagittal suture of the skull.

VIRGA'TUS. Rodshaped.

Virgin's bower. See *Clematis.*

Virgin's milk. See *Lac virgineum*, in the *Supplement.*

VIRGINA'LE CLAUSTRUM. The hymen.

Virginian snake-root. See *Aristolochia.*

Virginian tobacco. See *Nicotiana.*

VI'RUS. A poison. In the language of pathology, any matter which is the product of a disease, and is capable of producing that disease in a healthy individual by inoculation or absorption through the cuticle, is called the virus of that disease: thus we speak of the *virus of small-pox*, of the *venereal virus*, &c.

VIS. (*Vis, viris.* f.) Power. In *Physiology*, applied to the vital power and its effects: hence *vis vitæ*, *vis insita*, *vis irritabilis*, *vis nervea*, &c.

VIS A TERGO. Any moving power acting from behind.

Vis conservatrix. See *Vis medicatrix.*

VIS ELASTICA. Elasticity.

VIS I'NSITA. This property is defined by Haller to be that power by which a muscle, when wounded, touched, or irritated, contracts, independently of the will of the animal that is the object of the experiment, and without its feeling pain. See *Irritability.*

VIS MEDICATRIX NATURÆ. *Vis conservatrix.* A term employed by physicians to express that healing power in an animated body, by which, when diseased, the body is enabled to regain its healthy actions.

VIS MORTUA. That property by which a muscle, after the death of the animal, or immediately after having been cut out from a living body, contracts.

Vis nervea. See *Vis nervosa.*

VIS NERVOSA. *Vis nervea.* The power of the muscles by which they act when excited by the nerves, as opposed to the *vis insita*, or *irritabilis.*

VIS PLASTICA. The formative energy which spontaneously operates in animals.

VIS VITÆ. The vital power or energy. See *Life.*

VISCID. *Viscidus.* 1. Of the nature of ropy pulp of the *viscum*, or misletoe. In general use to imply viscidity in fluids, &c.

2. See *Lentor.*

VISCIDITY. (*Visciditas;* from *viscus.*) Viscosity: glutinous, sticky, like the bird-lime.

VISCOSITY. *Viscositas.* Viscidity: clamminess.

VIS'CUM. (*um*, *i.* n.; and *us*, *i.* m. Derived from the Greek, ἰξος, altered by the Æolians into βισκος.) 1. The fruit of the misletoe. See *Viscum album.*

2. The name of a genus of parasitical plants in the Linnæan system. Class, *Diœcia;* Order, *Tetandria.*

VISCUM ALBUM. *Viscus quercinus.* Misletoe. This singular parasitical plant most commonly grows on apple-trees, also on the pear, hawthorn, service, oak, hazel, mapel, ash, lime-tree, willow, elm, horn-bean, &c. It is supposed to be propagated by birds, especially by the fieldfare and thrush, which feed upon its berries, the seeds of which pass through the bowels unchanged, and, along with the excrement, adhere to the branches of trees, where they vegetate.

The misletoe of the oak has, from the times of the ancient Druids, been always preferred to that produced on other trees; but it is now well known that the *viscus quercinus* differs in no respect from others.

This plant is the ἰξ of the Greeks, and was in former times thought to possess many medicinal virtues; however, we learn but little concerning its efficacy from the ancient writers on the Materia Medica, nor will it be deemed necessary to state the extraordinary powers ascribed to the misletoe by the crafty designs of druidical knavery. Both the leaves and branches of the plant have very little smell, and a very weak taste of the nauseous kind. In distillation they impregnate water with their faint unpleasant smell, but yield no essential oil. Extracts, made from them by water, are bitterish, roughish, and subsaline. The spirituous extract of the wood has the greatest austerity, and that of the leaves the greatest bitterness. The berries abound with an extremely tenacious and sweet mucilage.

The *viscus quercinus* obtained great reputation for the cure of epilepsy; and a case of this disease, in a lady of quality, in which it proved remarkably successful, is mentioned by Boyle.

Some years afterwards its use was strongly recommended in various convulsive disorders by Colbach, who has related several instances of its good effects. He administered it in substance, in doses of half a drachm or a drachm of the wood or leaves, or in the form of infusion. This author was followed by others, who have not only given testimony of the efficacy of the misletoe in different convulsive affections, but also in those complaints denominated nervous, in which it was supposed to act in the character of a tonic. But all that has been written in favour of this remedy, has not prevented it from falling into general neglect; and the British colleges of physicians have, perhaps not without reason, expunged it from their catalogues of the Materia Medica.

VISCUS. (*us, eris.* n.; plural, *viscera.*) 1. A bowel. The organs contained in any of the three great cavities, especially of the thorax and abdomen, are called *viscera.*

2. (*Viscus, i.* m.) The name of the misletoe. See *Viscum album.*

VISION. (*Visus, ûs.* m.) The function which enables us to perceive the magnitude, figure, colour, distance, &c., of bodies. The organs which compose the apparatus of vision enter into action under the influence of a particular excitant, or stimulus, called *light.*

We perceive bodies, we take cognisance of many of their properties, though they are often at a great distance; — there must then be between them and our eye some intermediate agent; this intermediate substance we denominate *light.* Light is an excessively subtle fluid, which emanates from those bodies called *luminous;* as the sun, the fixed stars, bodies in a state of ignition, phosphorescence, &c. Light is composed of atoms, which move with a prodigious rapidity, since they pass through about eighty thousand leagues of space in a second.

A series of atoms, or particles, which succeed each other in a right line without interruption, are denominated a *ray of light.* The atoms which compose every ray of light are separated by intervals, that are considerable in proportion to their mass; which circumstance permits many rays to cross each other in the same point, without their particles coming in contact.

The light that proceeds from luminous bodies forms diverging cones, which would prolong themselves indefinitely, did they meet with no obstacles. Philosophers have from thence concluded, that the intensity of light in any place is always in an inverse ratio to the square of the distance of the luminous bodies from which it proceeds. The cones that are formed by the light in passing from luminous bodies are, in general, called pencils of light, or pencils of rays; and the bodies through which the light moves are designated by the name of *media.*

When light happens to come in contact with certain bodies that are called opake, it is repulsed, and its direction is modified according to the disposition of those bodies. — The change that light suffers in its course is, in this case, called *reflection.* The study of reflection constitutes that part of physics which is named *catoptrics.*

Certain bodies allow the light to pass through them; for instance, glass: they are said to be *transparent.* In passing through these bodies, light suffers a certain change, which is called *refraction.* As the mechanism of vision rests entirely upon the principles of refraction, the examination of these becomes, therefore, a matter of importance.

The point where a ray of light enters into a medium is called the point of immersion; and that where it goes out is called the point of emergence.

If the ray comes in contact with a medium in a line perpendicular to its surface, the ray then continues its direction without any change; but if its direction is oblique to the surface of the medium, the ray is then turned out of its course, and appears broken at the point of immersion.

The *angle of incidence* is that which the incident ray makes with a perpendicular line drawn over the point of immersion upon the surface of the medium, and the *angle of refraction* is that which the broken ray makes with the perpendicular.

If the ray of light pass from a rare medium into one more dense, it inclines towards the perpendicular at the point of contact; but it declines from it if it pass from a dense medium into one that is rarer. The same phænomenon takes place, but in a contrary direction, when the ray enters into the first medium: this takes place in such a manner, that if the two surfaces of the medium traversed by the ray are parallel to each other, the ray, in passing into the surrounding medium, will take a direction parallel to that of the incident ray.

Bodies refract the light in proportion to their density and combustibility. Thus, of two bodies of equal density, one of which being composed of more combustible elements than the other, the refractive power of the first will be greater than that of the second.

All transparent bodies refract at the same time that they reflect the light. On account of this property, these bodies are capable of being used as a sort of mirror. When their density is very inconsiderable, such as that of the air, they are not visible unless their mass be considerable.

The form of a refractive body has no influence upon its refractive power; but it modifies the disposition of the refracted rays in respect to each other. In fact, the perpendiculars to the surfaces of the body approaching or receding according to the form of the body, the refracting rays should at the same time approach or recede.

When, by the effort of a refractive body, the rays tend towards each other, the point where they unite is called *the focus of the refractive body.* Bodies of a lenticular form are those which present principally this phænomenon.

A refractive body, with parallel surfaces, does not change the direction of the rays, but it inclines them towards its axis by a sort of *transportation.* A refractive body of two convex sides does not possess a greater refractive power than a body convex on one side, and plane on

the other; but the point behind it, in which the rays are united, is much nearer.

The discovery of the action of refractive bodies upon light has not been an object of simple curiosity; it has led to the construction of ingenious instruments, by means of which the sphere of human vision has been extended to an extraordinary degree.

Apparatus of Vision. — The apparatus of vision is composed of three distinct parts.

The *first* modifies the light.

The *second* receives the impression of that fluid.

The *third* transmits this impression to the brain.

The apparatus of vision is of an extremely delicate texture, capable of being deranged by the least accident. Nature has also placed before this apparatus a series of organs, the use of which is to protect and maintain it in those conditions necessary to the perfect exercise of its functions. Those protecting parts are the eyebrows, the eyelids, and the *secreting* and *excreting* apparatus of the tears.

The eyebrows, which are peculiar to man, are formed, —

1. By *hair*, of a variable colour.
2. By the *skin*.
3. By *sebaceous follicles* placed at the root of every hair.
4. By *muscles* destined for their various motions; viz. the frontal portion of the occipito-frontalis, the superior edge of the orbicularis palpebrarum, the supercilium.
5. Numerous *vessels*.
6. *Nerves*.

The eye is composed of parts which have very different uses in the production of vision. They may be distinguished into refractive, and non-refractive.

The refractive parts are, —

A. The *transparent cornea*, a refractive body, convex and concave, which, in its transparency, its form, and its insertions, pretty much resembles the glass that is placed before the face of a watch.

B. The *aqueous humour* which fills the chambers of the eye; a liquid which is not purely aqueous, as its name indicates, but is essentially composed of water, and of a little albumen.

C. The *crystalline humour*, which is improperly compared to a lens. The comparison would be exact, were it merely for the form; but it is defective in regard to structure. The crystalline is composed of concentric layers, the hardness of which increases from the surface to the centre, and which probably possess different refractive powers. The crystalline is, besides, surrounded by a membrane, which has a great effect upon vision, as experience teaches us. A lens is homogeneous in all its parts; at its surface, as in every point of its substance; it possesses every where the same refractive power. However, it is necessary to remark, that the curve of the anterior surface of the crystalline is very far from being similar to that of the posterior aspect. This last belongs to a sphere, of which the diameter is much less than that of the sphere to which the curve of the anterior surface belongs. Until lately it has been understood that the crystalline was composed mostly of albumen; but, according to a new analysis of Berzelius, it does not contain any: it is formed almost entirely of water, and of a peculiar matter, that has a great analogy, in its chemical properties, to the colouring matter of the blood.

D. Behind the crystalline is the *vitreous humour*, so called because of its resemblance to melted glass.

Each of the parts which we have noticed is enveloped by a very thin membrane, which is transparent like the part that it covers: thus, before the cornea is the conjunctiva; behind it is the membrane of the aqueous humour, which lines all the anterior chamber of the eye; that is, the anterior surface of the iris, and the posterior surface of the cornea.

The crystalline is surrounded by the crystalline capsule, which adheres by its circumference to the membrane that covers the vitreous humour. This, in passing from the circumference of the crystalline upon the anterior and posterior surfaces, leaves between an interval, which has been called the *canal goudronné*.

The vitreous humour is contained in the innumerable cells of a membrane called the *hyaloid*, which also surrounds the whole. The details of anatomy, with regard to the disposition of the cells, have not hitherto added any thing to what is known of the use of the vitreous humour.

The eye is not only composed of parts that are refractive, but it is composed also of membranes which have each a particular use; these are, —

a. The *sclerotic*, the exterior envelope of the eye, which is a membrane of a fibrous nature; it is thick and resisting, and its use is evidently to protect the interior parts of the organ; it serves besides as a point of insertion for many muscles that move the eye.

b. The *choroid*, a vascular and nervous membrane, formed by two distinct plates; it is impregnated with a dark matter which is very important to vision.

c. The *iris*, which is seen behind the transparent cornea, is differently coloured in different individuals; it is pierced in the centre by an opening called the *pupil*, which dilates or contracts according to certain circumstances which we shall notice. The iris adheres outwardly, and by its circumference, to the sclerotic, by a cellular tissue of a particular nature, which is called the *ciliary*, or *iridian* ligament. There are behind the iris a great number of white lines, arranged in the manner of rays, which would unite at the centre of the iris, if they were sufficiently prolonged: these are the *ciliary processes*.

Neither the use nor the structure of these bodies have been properly determined: they are believed by some to be nervous, by others to be muscular; whilst others think them glandular, or vascular. The truth is, their real structure is not understood.

The colour of the iris depends on its structure, which is variable, and on that of the dark layer of its posterior surface, the colour of

which shines through the iris. For instance, the tissue of the iris is nearly white in blue eyes; in this case the dark colour behind appears almost alone, and determines the colour of the eyes.

Anatomists differ about the nature of the tissue of the iris: some think it entirely like that of the choroid, essentially composed of vessels and of nerves; others have imagined they saw a great many muscular fibres in it; others consider this membrane a tissue *sui generis;* and others confound it with the *erectile* structure. Edwards has shown that the iris is formed by four layers very easy to be distinguished, two of which are a continuation of the laminæ of the choroid; a third belongs to the membrane of the aqueous humour; and a fourth forms the proper tissue of the iris.

Between the choroid and the hyaloid there exists a membrane essentially nervous. This membrane, known by the name of the *retina*, is almost transparent; it presents a slight opacity, and a tint feebly inclining to *lilac;* it is composed of the expansion of the threads which compose the optic nerve.

The eye receives a great number of vessels, the *ciliary arteries* and *veins*, and many nerves, the greater part of which come from the *ophthalmic ganglion*.

The *optic nerve* preserves the communication between the brain and the eye.

Mechanism of Vision. — In order the better to explain the action of light in the eye, let us suppose a luminous cone commencing in a point placed in the prolongation of the *anterior posterior axis* of the eye. We see that only the light which falls upon the cornea can be useful for vision; that which falls on the white of the eye, the eyelids, and eyelashes, contributes nothing: it is reflected by those parts differently according to their colour. The cornea itself does not receive the light on its whole extent; for it is generally covered in part by the border of the eyelids.

The cornea having a fine polish on its surface, as soon as the light reaches it, part of it is reflected, which contributes to form the brilliancy of the eye. The same reflected light forms the images which one sees behind the cornea. In this case the cornea acts as a convex mirror. The form of the cornea indicates the influence it should have upon the light which enters the eye: on account of its thickness, it only causes the rays to converge a little towards the axis of the pencil; in other words, it increases the intensity of the light which penetrates into the anterior chamber.

The rays, in traversing the cornea, pass from a more rare to a denser medium: consequently they ought to converge from the perpendicular towards the point of contact. If, on entering into the anterior chamber, they passed out again, they would diverge as much from the perpendicular as they had converged before; and would, therefore, assume their former divergence: but as they enter into the aqueous humour, which is a medium more refractive than air, they incline less from the perpendicular, and consequently diverge less than if they had passed back into the air.

Of all the light transmitted to the anterior chamber, only that which passes the pupil can be of use to vision; all that which falls upon the iris is reflected, returns through the cornea, and exhibits the colour of the iris.

In traversing the posterior chamber the light undergoes no new modification, as it proceeds always in the same medium (the aqueous humour).

It is in traversing the crystalline that light undergoes the most important modification. Philosophers compare the action of this body to that of a lens, the use of which would be to assemble all the rays of any cone of light upon a certain point of the retina. But as the crystalline is very far from being like a lens, we merely mention this opinion, which is generally received, to remark that it merits a fresh investigation. Every thing positive which can be said on the subject is, that the crystalline ought to increase the intensity of the light which is directed towards the bottom of the eye, with an energy proportionate to the convexity of its posterior surface. It may be added, that the light which passes near the circumference of the crystalline is probably reflected in a different manner from that which passes through the centre; and that, therefore, the contraction and dilatation of the pupil ought to possess an influence upon the mechanism of vision, which deserves the attention of philosophers.

The whole of the light which arrives at the anterior surface of the crystalline does not penetrate into the vitreous body; it is partly reflected. One part of this reflected light traverses the aqueous humour and the cornea, and contributes to form the brilliancy of the eye; another falls upon the posterior surface of the iris, and is absorbed by the dark matter found there.

It is probable that something of this sort happens at every one of the strata or layers which forms the crystalline.

The vitreous body possesses a less refractive power than the crystalline: consequently the rays of light which, after having passed the crystalline, penetrate into the vitreous body, diverge from the perpendicular at the point of contact. Its use then, with regard to the direction of the rays in the eye, is to increase their convergence. It might be said, that, in order to produce the same result, Nature had only to render the crystalline a little more refractive; but the vitreous humour has another most essential use, which is, to give a larger extent to the retina, and thus to increase the field of vision.

What we said about a cone of light, commencing in a point placed in the prolongation of the anterio-posterior axis of the eye, must be repeated for every luminous cone commencing in other points, and directed towards the eye; with this difference, that, in the first case, the light tends to unite at the centre of the retina; whilst the light of the other cones tend to unite in different points, according to that form which they commence. Thus the lumi-

nous cones commencing from below, unite at the upper parts of the retina; whilst those that come from above, unite at the lower part of this membrane. The other rays follow a direction analogous; so that there will be formed at the bottom of the eye an exact representation of every body placed before it, with this difference, that the images will be inverted, or in a position contrary to that of the objects they represent.

This result is ascertained by different means. For this purpose, eyes, constructed artificially of glass, which represent the transparent cornea, and the crystalline; and of water, which represent the aqueous and vitreous humours, have long been employed.

Motions of the Iris. — Some say that the pupil varies its dimensions according to the distance of the object. This fact has not been sufficiently demonstrated: hitherto the influence of the intensity of light is the only thing that has been correctly observed.

The choroid is of use to vision, principally by the dark matter with which it is impregnated, and which absorbs the light immediately after it has traversed the retina. One may consider as a confirmation of this opinion what happens to some individuals, in whom some parts of this membrane become *varicose*: the dilated vessels throw off the dark matter which covered them, and every time that the image of the object falls upon the point of the retina corresponding to these vessels, the object appears spotted with red.

The state of vision in Albino men and animals, in which the choroid and the iris are not coloured black, supports still more this assertion; vision is extremely imperfect in them: during the day, they can scarcely see sufficiently to go about. Mariotte, Lecat, and others have allowed to the choroid the faculty of perceiving light. This idea is completely without proof.

We know very little, that is certain, of the ciliary processes. They are generally supposed *contractile*; but some think that they are destined to the motions of the iris, whilst others imagine they are intended to bring forward the crystalline.

The rays of light have now reached the retina, which receives the impression of light when it is within certain limits of intensity. A very feeble light is not felt by the retina; too strong a light hurts it, and renders it unfit for action.

When the retina receives too strong a light, the impression is called *dazzling*; the retina is then incapable for some time of feeling the presence of the light. This happens when one looks at the sun. After having been long in the dark, even a very feeble light produces dazzling. — When the light is exceedingly weak, and the eye made to observe objects narrowly, the retina becomes fatigued, there follows a painful feeling in the orbit, and also in the head.

A light, of which the intensity is not very strong, but which acts for a certain time upon a determined point of the retina, renders it at last insensible in this point. When we look for some time at a white spot upon a black ground, and afterwards carry the eye to a white ground, we seem to perceive a black spot; this happens because the retina has become insensible in the point which was formerly fatigued by the white light. In the same manner, after the retina has been some time without acting in one of its points whilst the others have acted, the point which has been in repose becomes of an extreme sensibility, and on this account objects seem as if they were spotted. In this manner it is explained, why, after having looked a long time at a red spot, white bodies appear as if spotted with green: in this case, the retina has become insensible to the red rays; and we know that a ray of white light, from which the red is subtracted, produces the sensation of green.

The same sort of phenomena happens when we have looked long at a red body, or one of any other colour, and afterwards look at white or differently coloured bodies. — We perceive with facility the *direction* of the light received by the retina. We believe instinctively that light proceeds in a right line, and that this line is the prolongation of that according to which the light penetrated into the cornea. Therefore, whenever the light has been modified in its direction, before reaching the eye, the retina gives us nothing certain. Optical illusions proceed principally from this cause.

The retina can receive at the same time impressions in every point of its extent, but the sensations which result from them are then incorrect. It may be affected by the image of one or two objects only, though a much greater number be impressed on it; the vision is then much more defined.

The central part of the membrane appears to possess much more sensibility than the rest of its extent; we therefore make the image fall on this part when we wish to examine an object with attention.

Does the light act upon the retina by simple contact only, or must it traverse this membrane? The presence of the choroid in the eye, or rather the dark matter which covers it, renders this second opinion the most probable.

That part of the retina which corresponds with the centre of the optic nerve, has been said to be insensible to the impression of light. No experiment has hitherto directly proved this assertion.

There is no doubt that the optic nerve transmits to the brain, in an instant, the impression that the light makes on the retina; but by what mechanism we are entirely ignorant. The manner in which the two optic nerves are confounded upon the *sphenoid bone*, ought, doubtless, to have a considerable influence upon the transmission of the impressions received by the eyes; — but this is also a point upon which it is difficult to form any probable conjecture.

Notwithstanding what has been said at different periods, as well as the late efforts of Gall, to prove that we see with only one eye at a time, there seems sufficient proof not only that the two eyes concur at the same time in the production of vision, but that it is absolutely necessary this should be so, for certain most important operations of this function.

There are, however, certain cases in which it is more convenient to employ only one eye; for instance, when it is necessary to understand perfectly the *direction* of the light, or the *situation* of any body relative to us. Thus we shut one eye to take aim with a gun, or to place a number of bodies upon a level in a right line.

Another case in which it is advantageous to employ only one eye is, when the two organs are unequal, either in refractive power or in sensibility. For the same reason we shut one eye when we employ a telescope. But, except in these particular cases, it is of the utmost importance to employ both eyes at once. The following experiment proves that both eyes see the same object at the same time.

Receive the image of the sun upon a plane in a dark chamber; put before your eyes two thick glasses, each of which presents one of the prismatic colours. If your eyes are good, and both equally strong, the image of the sun will appear of a dirty white, whatever be the colour of the glasses employed. If one of your eyes is much stronger than the other, the image of the sun will be seen of the same colour as the glass which is before the strongest eye.

One object produces, then, really two impressions, while the brain perceives only one. To produce this the motions of the two eyes must be in unison. If, after a disease, the movements of the eyes are no longer regular, we receive two impressions from the same object, which constitutes *strabismus*, or squinting. We may also, at pleasure, receive two impressions from one body; for that purpose, it is only necessary to derange the harmony of the two eyes.

Estimation of the Distance of Objects. — Vision is produced essentially by the action of light upon the retina, and yet we always consider the bodies from which light proceeds as being the cause of it, though they are often placed at a considerable distance. This result can be produced only by an intellectual operation.

We judge differently of the distance of bodies according to the degree of that distance; we judge correctly when they are near us, but it is not the same when they are at a short distance; our judgment is then often incorrect: but when they are at a great distance, we are constantly deceived. The united action of the two eyes is absolutely necessary to determine exactly the distance, as the following experiment proves: —

Suspend a ring by a thread, and fix a hook to the end of a long rod, of a size that will easily pass the ring; stand at a convenient distance, and try to introduce the hook: in using both eyes, you may succeed with ease in every attempt you make; but if you shut one eye, and then endeavour to pass the hook through, you will not succeed any longer; the hook will go either too far or else not far enough, and it will only be after trying repeatedly that it will be got through. Those persons whose eyes are very unequal in their power, are sure to fail in this experiment, even when they use them both.

When a person loses an eye by accident, it is sometimes a whole year before he can judge correctly of the distance of a body placed near him. Those who have only one eye, determine distance, for the most part, very incorrectly. The size of the object, the intensity of the light that proceeds from it, the presence of intermediate bodies, &c. have a great influence upon our just estimation of distance.

We judge most correctly of objects that are placed upon a level with our bodies. Thus, when we look from the top of a tower at the objects below, they appear much less than they would if they were placed at the same distance on the same plane with ourselves. Hence the necessity of giving a considerable volume to objects that are intended to be placed on the tops of buildings, and which are to be seen from a distance. The smaller the dimensions of an object are, the nearer it ought to be to the eye, in order to be distinctly seen. What is called the distinct point of view, is also very variable. A horse is seen very distinctly at six yards, but a bird could not be distinctly seen at the same distance. If we wish to examine the hair or the feathers of those animals, the eye requires to be much nearer. However, the same object may be seen distinctly at different distances; for example, it is quite the same to many persons whether they place the book that they are reading at one or two feet of distance from the eye. The intensity of the light which illuminates an object, has a considerable effect upon the distance at which it can be distinctly seen.

Estimation of the Size of Bodies. — The manner in which we arrive at a just determination of the size of bodies depends, more upon knowledge and habit than upon the action of the apparatus of vision. We form our judgment relative to the dimensions of bodies, from the size of the image which is formed in the eye, from the intensity of the light which proceeds from the object, from the distance at which we think it is placed, and, above all, from the habit of seeing such objects. We therefore judge with difficulty of the size of a body that we see for the first time, when we cannot appreciate the distance. A mountain which we see at a distance for the first time, appears generally much less than it really is; we think it is near us when it is very far away.

Beyond a distance somewhat considerable we are so completely deceived, that judgment is unable to correct us. Objects appear to us infinitely less than they really are: as happens with the celestial bodies.

Estimation of the Motion of Bodies. — We judge of the motion of a body by that of its image upon the retina, by the variations of the size of this image, or, which is the same thing, by the change of the direction of the light which arrives at the eye.

In order that we may be able to follow the motion of a body, it ought not to be displaced too rapidly, for we could not then perceive it; this happens with bodies projected by the force of gunpowder, particularly when they pass near us. When they move at a distance from us, the light comes from them to the eye for a much longer space of time, because the field of view

is much greater, and we can see them with more facility. We ought to be ourselves at rest, in order to judge correctly of the motions of bodies.

When bodies are at a considerable distance from us, we cannot easily perceive their motions to or from us. In this case, we judge of the motion of the body only by the variation of the size of its image. Now this variation being infinitely small, because the body is at a great distance, it is very difficult, and frequently impossible, for us to estimate its motion. Generally we perceive with great difficulty, sometimes we cannot perceive at all, the motion of a body which moves extremely slow: this may be on account of the slowness of its own motion, as in the case of the hand of a watch; or it may be the result of the slow motion of the image, which happens with the stars, and objects very far from us.

Of Optical Illusions. — After what we have just said, of the manner in which we estimate the distance, the size, and the motion of bodies, we may easily see that we are often deceived by sight. These deceptions are known in *Physics*, and in *Physiology*, by the name of optical illusions. Generally we judge pretty well of bodies placed near us; but we are most commonly deceived with regard to those that are distant. Those illusions which happen to us with regard to objects that are near us, are the result, sometimes of the reflection, sometimes of the refraction, of light before it reaches the eye; and sometimes of the law that we establish instinctively; namely, that light proceeds always in right lines.

We must refer to this cause those illusions occasioned by mirrors: objects are seen in plane mirrors at the same distance behind them, as the mirrors are distant from the eye. To this cause may be attributed also the apparent increase or diminution of bodies seen through a glass. If the glass make the rays converge, the body will appear greater; if it cause them to diverge, the body will appear less. These glasses produce still another illusion: objects appear surrounded by the colours of the solar spectrum, because their surfaces not being parallel, they decompose light in the manner of the prism.

We are constantly deceived by objects at a distance, in a manner that we cannot prevent, because those deceptions result from certain laws which govern the animal economy. An object seems near us in proportion as its image occupies a greater space upon the retina; or in proportion to the intensity of the light which proceeds from it.

Of two objects of a different volume, equally illuminated and placed at the same distance, the greatest will appear the nearest, should circumstances be such as to admit of the distance being justly estimated. Of two objects of equal volume, placed at an equal distance from the eye, but unequally illuminated, the brightest will appear the nearest; it would be the same if the objects were at unequal distances, as can be easily seen in looking at a string of lamps: if there happen to be one of them brighter than the rest, it will appear the nearest, whilst that which is really the nearest will appear the farthest if it is the least bright. An object seen without any intermedium always appears nearer than when there happens to be between it and the eye some body that may have an influence upon the estimation that we make of its distance.

When a bright object strikes the eye whilst all the objects around it are obscured, it appears much nearer than it really is; a light in the night produces this effect.

Objects appear always small in proportion as they are distant; thus, the trees in a long alley appear so much smaller, and so much nearer together, in proportion as they are farther from us. It is by observing these illusions, and the laws of the animal economy, upon which they are founded, that art has been enabled to imitate them. The art of painting, in certain cases, merely transfers to the canvass those optical errors into which we most habitually fall.

The construction of optical instruments is also founded upon these principles: some of them augment the intensity of the light, which proceeds from the objects observed; others cause it to diverge, or converge, in order to increase or diminish their apparent volume, &c.

By the constant exercise of the sense of sight, we are enabled to get over many optical illusions, as will be proved by the curious history of the blind youth, spoken of by Cheselden. This celebrated surgeon, by a surgical operation, generally said to be that for cataract, but, more probably, it was a division of the *membrana pupillaris*, procured sight to a very intelligent person who was born blind: and he observed the manner in which this sense was developed in this young man. "When he saw the light for the first time, he knew so little how to judge of distances, that he believed the objects which he saw touched his eyes (and this was his expression), as the things which he felt touched his skin. The objects which were most pleasant to him were those whose form was regular and smooth, though he had no idea of their form, nor could he tell why they pleased him better than the others. During the time of his blindness he had such an imperfect idea of colours, that he was then able to distinguish, by a very strong light, that they had not left an impression sufficient by which he could again recognise them. Indeed, when he saw them, he said the colours he then saw were not the same as those he had seen formerly; he did not know the form of any object; nor could he distinguish one object from another, however different their figure or size might be; when objects were shown to him which he had known formerly by the touch, he looked at them with attention, and observed them carefully in order to know them again; but as he had too many objects to retain at once, he forgot the greater part of them; and when he first learned, as he said, to see and to know objects, he forgot a thousand for one that he recollected. It was two months before he discovered that pictures represent solid bodies; until that time he had considered them as planes and surfaces differently coloured, and diversified by a variety of shades: but when he began to conceive that these pictures represented solid

bodies, in touching the canvass of a picture with his hand he expected to find in reality something solid upon it, and he was much astonished when, upon touching those parts which seemed round and unequal, he found them flat, and smooth like the rest; he asked, which was the sense that deceived him, — the sight or the touch? There was shown to him a little portrait of his father, which was in the case of his mother's watch: he said, that he knew very well it was the resemblance of his father; but he asked, with great astonishment, how it was possible for so large a visage to be kept in so small a space, as that appeared to him as impossible as that a bushel should be contained in a pint. He could not support much light at first, and every object seemed very large to him; but after he had seen larger things he considered the first smaller: he thought there was nothing beyond the limits of his sight. The same operation was performed on the other eye about a year after the first, and it succeeded equally well. At first he saw objects with his second eye much larger than with the other, but not so large, however, as he had seen them with the first eye; and when he looked at the same object with both eyes at once, he said that it appeared twice as large as with the first eye; but he did not see double, at least it could not be ascertained that he saw objects double, after he had got the sight of the second eye."

This observation is not singular; there exists a number of others, and they have all given results nearly alike. The conclusion that may be drawn from it is, that the exact manner in which we determine the distance, size, and form of objects, is the result of habit, or, which is the same thing, of the education of the sense of sight.

Vision, defective. See *Dysopia.*

Vision, lateral. See *Dysopia.*

Visus. See *Vision.*

VITE'LLINE. (*Vitellinus*, from *vitellus*, the yolk of an egg.) Of a colour which is yellow, verging to orange.

VITE'LLUS. (*us, i.* m.; from *vita*, life: because the life of the chick is in it.) 1. The yolk of an egg. See *Ovum.*

2. In *Botany*, applied, by Gærtner, to that part of a seed which is very firmly and inseparably connected with the embryo, yet never rising out of the integuments of the seed in germination, but absorbed, like the albumen, for the nourishment of the embryo. If the albumen be present, the vitellus is always situated between it and the embryo, and yet is constantly distinct from the former. It is esteemed, by Gærtner, to compose the bulk of the seed in the fusci, mosses, and ferns. In the natural order of grasses, the vitellus forms a scale between the embryo and the albumen. Sir J. Smith thinks the vitellus is nothing else than a subterraneous cotyledon. See *Albumen.*

VI'TEX. (*ex, icis.* f.; from *vieo*, to bind.) The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Angiospermia.*

VITEX AGNUS CASTUS. The systematic name of the *Agnus castus.* *Elæagnon.* The chaste tree. *Vitex — foliis digitatis, serratis, spicis verticillatis*, of Linnæus. The seeds are the medicinal part, which have, when fresh, a fragrant smell, and an acrid, aromatic taste. Formerly they were celebrated as antiphrodisiacs; but experience does not discover in them any degree of such virtue, and some have ascribed to them an opposite one. They are now fallen into disuse.

Viti saltus. See *Chorea.*

VITILI'GO. (*o, inis.* f.; from *vitulus*, a calf: the white and glistening appearance of the skin in this disease bearing some resemblance to the flesh of calves.) Veal skin. Celsus includes the three varieties of lepra, the *alphos, melas*, and *leuce* under the name vitiligo. Dr. Willan applies the name to a tubercular disease which is somewhat rare, and perhaps but little known. It is characterised by the appearance of smooth, white, shining tubercles, which rise on the skin, sometimes in particular parts, as about the ears, neck, and face, and sometimes over nearly the whole body, intermixed with shining papulæ. They vary much in their course and progress: in some cases they reach their full size in the space of a week (attaining the magnitude of a large wart), and then begin to subside, becoming flattened to the level of the cuticle in about ten days; in other instances, they advance less rapidly, and the elevation which they acquire is less considerable; in fact, they are less distinctly tubercular. But in these cases they are more permanent; and, as they gradually subside to the level of the surface, they creep along in one direction, as, for example, across the face or along the limbs, checkering the whole superfices with a veal-skin appearance. All the hairs drop out where the disease passes, and never re-sprout; a smooth shining surface, as if polished, being left, and the morbid whiteness remaining through life. The eruption never goes on to ulceration.

There is no considerable constitutional disorder combined with this affection; but it has proved exceedingly unmanageable under the use of both internal and external medicines. The mineral acids internally, and the application of diluted caustic and spirituous substances externally, have been chiefly employed, but with little obvious effect.

VI'TIS. 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia.*

2. The pharmacopœial name of the grape. See *Vitis vinifera.*

Vitis alba. See *Bryonia alba.*

VITIS CORINTHIACA. The dried fruit of this tree is the kind of raisin called *Passa corinthiaca.* See *Vitis vinifera.*

Vitis idæa. See *Vaccinium.*

Vitis marina. See *Fucus natans.*

VITIS SYLVESTRIS. White bryony.

VITIS VINI'FERA. The sytematic name of the grape-tree. *Vitis — foliis lobatis sinuatis nudis,* of Linnæus. Vine-leaves and the tendrils have an astringent taste, and were formerly used in diarrhœas, hæmorrhages, and other disorders requiring refrigerant and styptic medicines. The juice or sap of the vine, called lachryma, has been recommended in calculous disorders: and it is said to be an excellent application to weak eyes and specks of the cornea. The unripe fruit has a harsh, rough, sour taste: its expressed juice, called verjuice, was formerly much esteemed, but is now superseded by the juice of lemons; for external use, however, particularly in bruises and pains, verjuice is still employed and considered to be a very useful application. The dried fruit is termed *Uva passa major. Passula major,* the raisin. Raisins are prepared by immersing the fresh fruit into a solution of alkaline salt and soap-ley, made boiling hot, to which is added some olive oil, and a small quantity of common salt, and afterwards drying them in the shade. They are used as agreeable, lubricating, acescent sweets, in pectoral decoctions, and for obtunding the acrimony in other medicines, and rendering them grateful to the palate and stomach. They are directed in the *decoctum hordei compositum, tinctura sennæ,* and *tinctura cardamomi composita.* See also *Wine,* and *Acetum.*

VITRA'RIA. The pellitory of the wall. See *Parietaria officinalis.*

VITREOUS. (*Vitreus;* from *vitrum,* glass: so named from its transparency.) Glassy: applied to parts of the body.

Vitreous body. See *Vitreous humour.*

VITREOUS HUMOUR. *Humor vitreus. Corpus vitreum.* Vitreous body. The pellucid body which fills the whole bulb of the eye behind the crystalline lens. See *Oculus.*

VITRIFICATION. The conversion of any subtance into a glass.

Vitriol. See *Vitriolum.*

Vitriol, acid of. See *Sulphuric acid.*

Vitriol, blue. See *Cupri sulphas.*

Vitriol, green. See *Ferri sulphas.*

VITRIOL, OIL OF. The sulphuric acid was so called because it was obtained from green vitriol, and because, when rubbed between the fingers, it combines with the skin, and has an unctuous, soapy feel.

Vitriol, Roman. See *Cupri sulphas.*

Vitriol, sweet spirit of. See *Spiritus ætheris sulphurici.*

Vitriol, white. See *Zinci sulphas.*

Vitriolated kali. See *Potassæ sulphas.*

VITRI'OLUM. (*um, i.* n.; from *vitrum,* glass: so called from its likeness to glass. Hollandus says this word is fictitious, and composed from the initials of the following sentence: *Vade in terram rimando, invenies optimum lapidem, veram medicinam.*) *Calcadinum. Colcothar. Calcotar. Calcanthos. Calcanthum. Calcitea.* Vitriol, or sulphate of iron. See *Ferri sulphas.*

Vitriolum album. See *Zinci sulphas.*

Vitriolum cæruleum. See *Cupri sulphas.*

Vitriolum romanum. See *Cupri sulphas.*

Vitriolum viride. See *Ferri sulphas.*

VI'TRUM. (*um, i.* n.) See *Glass.*

VITRUM ANTIMONII. Glass of antimony. See *antimonii vitrum.*

VITRUM ANTIMONII CERATUM. A diaphoretic compound, made of powdered glass of antimony and yellow wax melted together and pulverised when cold. Once employed in the cure of dysenteries arising from checked perspiration.

VITRUM HYPOCLEPTICUM. A funnel to separate oil from water.

Vitulus. See *Bos taurus.*

VIVE'RRA. (*a, æ.* f.) The name of a genus of digitigradous quadrupeds.

VIVERRA CIVETTA. The systematic name of the ash-coloured weazel, which, with the following species, affords the perfume called civet. See *Zibethum.*

VIVERRA ZIBE'THA. The systematic name of the civet-cat. See *Civetta.*

VIVI'PAROUS. *Viviparus.* 1. In *Zoology,* an animal which brings forth its young alive and perfect, is styled *viviparous,* in opposition to one which is *oviparous,* or lays eggs.

2. In *Botany,* it is applied to stems or stalks, producing bulbs, that are capable of vegetation. In *Dentaria,* these bulbs are found at the basis of the leaves; in some species of *Allium,* at the origin of the umbel.

VI'VUS. Living: variously applied: to mercury, because it moves about as if it were alive; hence *argentum vivum:* to lime, because, when moisture is added, it cracks and swells, as if alive.

VOCAL CHORDS. *Chordæ vocales.* Vocal ligaments. Two ligaments which pass, one on each side, from the base of the arytenoid cartilage, and are inserted into the thyroid cartilage. They are supposed to be particularly connected with the formation of the voice. See *Voice.*

VOICE. *Vox.* By *voice,* we understand the sound which is produced in the larynx, at the instant when the air traverses this organ, either to enter or go out of the *trachea.*

In order to understand the mechanism by which the voice is produced and modified, we must say something of the manner in which sound is produced, in which it is propagated and modified in wind instruments, particularly those that have most analogy with the organ of voice.

A wind instrument is generally formed of a tube, either straight or bent, in which, by various processes, the air is made to vibrate.

Wind instruments are of two sorts: the one sort are called *mouth* instruments, the other sort *reed* instruments.

In the mouth instruments (the horn, trumpet, *trombone,* flageolet, flute, organ), the column of air contained in the tube is the sonorous body. The air must be caused to vibrate in it in order to produce sounds. For this purpose, the means

employed are variable, according to the sort of instrument. The length, the width, the form of the tube, the openings in its sides, or its extremities, the power of the vibrations, and the manner in which they are excited, are the causes of the various sounds of this sort of instruments. The nature of the matter which forms the sounds has no influence but upon the tone.

The reed instruments are the most necessary to be known, for the organ of the voice is of this kind. Their theory is, unfortunately, much more imperfect than that of the other sort. In this sort of instruments (the clarionet, hautboy, bassoon, voice organ, &c.), we ought to distinguish between the reed, or *anche*, and the body of the tube. Their mechanism is essentially different.

A reed is always formed of one, and sometimes of two, thin plates, susceptible of a rapid motion, the alternate vibrations of which are intended to intercept and permit, *by turns*, the passage of a current of air. For this reason, the sounds which they produce do not follow the same laws as the sounds formed by elastic plates, with one end fixed and the other free, which produce sonorous undulations in the open air. In the reed instruments, the reed alone produces and modifies the sound. If the plate is long, the motions are long, slow, and, consequently, the sounds are grave. On the contrary, a short plate produces acute sounds, because the alternations of transmission and interception of the current of air are more rapid.

When a number of different sounds are intended to be produced by a reed, it is necessary to vary the length of the plate. The bassoon and clarionet players do this when they wish to produce different sounds on the same instrument. We add, as an important circumstance, that the greater or less elevation of sound produced by the instrument, partly depends on the elasticity, the weight, and the form of the little tongue, or plate, and on the force of the current of air. If all these elements are not the same, the length being invariable, the tone will be different.

A reed is never employed alone; it is always fitted to a tube through which the wind passes that has been blown into the reed, and which ought, on this account, to be open at the two extremities. The tube has no influence upon the tone of the music; it acts only upon the intensity, the *timbre*, and upon the power of making the reed *speak*.

Apparatus of Voice. — The larynx ought properly to be considered as the organ of voice.

The size of the larynx varies according to age and sex. It is placed at the anterior part of the neck, where a small projection is seen, between the tongue and the trachea. It is small in children and women, greater in young men, and still larger in adult age.

The larynx not only produces the voice, but it is also the agent of its principal modifications; on which account, a knowledge of the anatomy of this organ is indispensably necessary in order to be well acquainted with the mechanism of voice. As we cannot enter here into all the details of the structure of the larynx, we will only touch upon such as are most necessary to be known, many of which are not yet well understood.

Four cartilages and three fibro-cartilages enter into the composition of the larynx, and form the skeleton of it. The cartilages are the *cricoid*, the *thyroid*, and the two *arytænoid*. The *thyroid* joins with the *cricoid* by the extremity of its two inferior *horns*. In the living state, the *thyroid* is fixed with respect to the *cricoid*, which is contrary to what is generally supposed. Every *arytænoid* cartilage is articulated with the *cricoid* by means of a surface, which is oblong, and concave in a transverse direction. The *cricoid* presents a surface which is similarly disposed to that of the *arytænoid*, with this difference, that it is convex in the same direction in which the other is concave. Round the articulation there is a *synovial capsule*, firm before and behind, and moveable without and within. Before the articulation is the *thyro-arytænoid* ligament; behind is a strong ligamentous band, that might be called *crico-arytænoid*, on account of the manner in which it is fixed.

Thus disposed, the articulation admits only of lateral movements of the *arytænoid* upon the *cricoid cartilage*. No movement forward or backward can take place, nor a certain movement up and down, mentioned in anatomical books, which none of the muscles is so disposed as to produce. This articulation ought to be considered as a simple lateral *ginglymus*. The fibro-cartilages of the larynx are the *epiglottis*, and two small bodies that are found above the top of the *arytænoid* cartilages, and that have been called by Santorini, *capitula cartilaginum arytænoidearum*.

There are a great many muscles attached to the larynx. These muscles are called external: they are intended to move the whole organ, either in carrying it up or down, backward or forward, &c. The larynx has also other muscles, whose use is to give a movement to the different parts in respect of each other. These muscles have been called internal. They are,

1st, The *crico-thyroid*, the use of which is not, as has hitherto been believed, to lower the thyroid upon the cricoid cartilage, but, on the contrary, to raise the cricoid towards the thyroid cartilage, or in making it pass a little below its inferior edge.

2d, The muscles *crico-arytænoideus posterior*, and the *crico-arytænoideus lateralis*, the use of which is to draw outwards the arytænoid cartilages, in separating them from one another.

3d, The *arytænoid* muscle, which draws the arytænoid cartilages together.

4th, The *thyro-arytænoideus*, a knowledge of which is more important than that of all the muscles of the larynx, because its vibrations produce the vocal sound. This muscle forms the lips of the *glottis*, and the inferior, superior, and lateral sides of the ventricles of the larynx.

5th, Lastly, the muscles of the *epiglottis*, which are the *thyro-epiglottideus*, the *arytæno-epiglottideus*, and some fibres that may be considered

as the vestige of the *glosso-epiglottidæus* muscle that exists in some animals, whose contraction has an influence upon the position of the *epiglottis*.

The larynx is covered within by a *mucous membrane*. This membrane, in passing from the epiglottis to the arytænoid and thyroid cartilages, forms two folds, called lateral ligaments of the epiglottis. They concur in the formation of the superior and inferior ligaments of the glottis.

In the substance of the epiglottis, and behind it, are found a great number of *mucous follicles*, and some *mucous glands*. Within the mass of the ligaments of the epiglottis, there exists a collection of those bodies that have been very improperly called *arytænoid glands*.

Between the epiglottis behind, and the os hyoides and thyroid cartilage before, there is seen a considerable quantity of the adipose *cellular tissue*, which is very elastic, and similar to that which exists near certain articulations. There has been no use assigned to this body. Dr. Magendie believes it serves to facilitate the frequent movements of the thyroid cartilage upon the posterior face of the os hyoides, and to keep the epiglottis separated from the upper part of this bone, whilst, at the same time, it provides it with a very elastic support, favourable to the action of the *fibro-cartilages* in the production of the voice, or in deglutition.

The *vessels* of the larynx present nothing remarkable. It is not so with the nerves of this organ. Their distribution merits a careful examination. There are four of these nerves, the *superior laryngeal* and the *inferior*.

The *recurrent nerve* is distributed to the posterior crico-arytænoid, to the lateral crico-arytænoid, and thyro-arytænoid. None of the ramifications of this nerve go to the arytænoid, or to the crico-thyroid, muscles. On the contrary, the superior nerve of the larynx goes to the arytænoid muscle, which it provides with a considerable branch; and to the crico-thyroid, to which it gives a small filament, more remarkable for the distance it proceeds than for its size. In certain cases this filament does not exist. The external branch of the nerve of the larynx is then of a larger size. The remainder of the filaments of the laryngeal nerves are distributed to the epiglottis, and to the mucous membrane which covers the entrance of the larynx. This part possesses an extraordinary sensibility.

The interval which separates the thyro-arytænoid muscles, and the arytænoid cartilages, is called *glottis*. In the dead body, the glottis presents the appearance of a longitudinal slit of about eight or ten lines long, and two or three wide: it is wider behind than before. Here the two sides meet at the point of their insertion into the *thyroid* cartilage. The posterior extremity of the glottis is formed by the *arytænoid* muscles.

If the arytænoid cartilages are brought together so as to touch on their internal faces, the glottis is diminished nearly a third of its length. It then presents a slit which is from five to six inches long, and from half a line to a line long. The sides of this slit are called the *lips of the glottis*. They present a sharp edge, turned upward and inward. They are essentially formed by the arytænoid muscle, and by the ligament of the same name, which, as an *aponeurosis*, covers the muscle to which it adheres strongly, and which, being itself covered by the mucous membrane, forms the thinnest parts or edge of the *lip*. These lips of the glottis vibrate in the production of the voice; they might be called the *human reed*. Above the inferior ligaments of the glottis are the *ventricles of the larynx*, the cavity of which is larger than it seems at first sight. The superior, inferior, and external sides of it are formed by the thyro-arytænoid muscle, turned upon itself. The extremity, or anterior side, is formed by the thyroid cartilage. By means of these ventricles, the lips of the glottis are completely isolated upon their upper side.

Above the opening of the ventricles we see two bodies, which, in their manner of being disposed, have a great deal of analogy with the vocal chords, and which form a sort of second glottis above the first. These bodies are called the *superior ligaments of the glottis*. They are formed by the superior edge of the thyro-arytænoid muscle, a little adipose cellular tissue, and the mucous membrane of the larynx, which covers them before penetrating into the ventricles. These observations are easily made upon the larynx of dead bodies. The glottis of a living person has never been examined, at least there has been nothing written on this subject; but when those of animals, as of dogs, are examined, they contract and enlarge alternately. The arytænoid cartilages are directed outwards when the air penetrates into the lungs; and in the instant when the air passes out, they come close together.

Mechanism of the Production of Voice. — If we take the trachea and the larynx of an animal or of a man, and blow air strongly into the trachea, directing it towards the larynx, there is no sound produced, but only a slight noise, resulting from the pressure of the air against the sides of the larynx. If, in blowing, we bring together the arytænoid cartilages, so that they may touch upon their internal face, a sound will be produced, something like the voice of the animal to which the larynx used in the experiment belongs.

The sound will be dull or sharp, according as the cartilages are pressed more or less forcibly together: its intensity will be more or less, according to the intensity of the air. It is easily seen, in this experiment, that the sound is produced by the vibrations of the inferior ligament of the glottis.

Both man and the animals are deprived of voice by making an opening below the larynx. The voice is reproduced if the opening is closed mechanically. Dr. Magendie knows a person who has been in this situation for four years. He cannot speak without pressing a cravat strongly against a fistulous opening in the larynx. The same thing takes place when the larynx is opened below the inferior ligaments of the glottis.

But if a wound exist above the glottis, if the

epiglottis and its muscles are affected, if the superior ligament of the glottis, even if the superior aspect of the *arytænoid* cartilages are injured, the voice continues.

Lastly, the glottis of an animal being laid bare in the instant that it cries, shows very well that voice is produced by the vibrations of the vocal chords, or lips of the glottis. This is enough to prove, beyond all doubt, that the voice is formed in the glottis by the motion of its inferior ligaments.

This fact being established, is it possible, on physical principles, to account for the formation of the voice? The following explanation appears the most probable: —

The air being pressed from the lungs, proceeds in a pipe of a considerable size. This pipe very soon becomes contracted, and the air is forced to pass through a narrow slit, the two sides of which are vibrating plates, which permit and intercept the air, like the plates of reeds, and which ought, in the same manner, by these alternations, to produce sonorous undulations in the transmitted current of air.

But, in blowing into the trachea of a dead body, why does it not produce a sound like that of the human voice? Why is the palsied state of the internal muscles of this organ followed by the loss of the voice? Why, in a word, is an act of the will necessary to produce the vocal sound? The answer to this is not difficult. The ligaments of the glottis have not the faculty of vibrating like the plates of reeds, except the thyro-arytænoid muscles are contracted; and, therefore, in every case in which the muscles are not contracted the voice will not be produced.

Experiments performed on animals are perfectly in unison with this doctrine. Divide the two recurrent nerves, and the voice will cease. If only one is cut, the voice will be only half lost.

Dr. Magendie, however, has seen a number of animals, in which the two recurrent nerves had been cut, cry very loud when they suffered severe pain. These sounds were very similar to the sounds that would be produced mechanically with the larynx of the animal when dead, by blowing into the trachea, and bringing together the arytænoid cartilages. This phænomenon is easily understood by the distribution of the nerves of the larynx. The recurrents being cut, the thyro-arytænoid muscles do not contract, and thence results the loss of voice; but the arytænoid muscle, that receives its nerves from the superior laryngeal, contracts, and brings together, in the instant of a strong expiration, the arytænoid cartilages, and the slit of the glottis becomes sufficiently narrow for the air to throw the thyro-arytænoid muscles, though they are not contracted, into vibration.

Intensity or Volume of the Voice. — The intensity of the voice, like that of all other sounds, depends upon the extent of the vibrations.

The vibrations of the *vocal chords* will be in proportion to the force with which the air is expelled from the breast; and the longer the chords are, — that is, the more voluminous the larynx is, — the more considerable will be the extent of the vibrations. A strong person, with a large chest, and a larynx of large dimensions, presents the most advantageous condition for the intensity of the voice. If such a person becomes sick, his voice, on account of his weakness, loses much of its intensity, because it is no longer expelled with the same force from the chest.

Children, women, and eunuchs, whose larynx is proportionably less than that of a man in adult age, have also much less intensity of voice.

In the ordinary production of the voice, it results from the simultaneous motions of the two sides of the glottis. Were one of these sides to lose the faculty of causing the air to vibrate, the voice would lose, necessarily, half its intensity, the force of expiration being the same. This may be proved in cutting one of the recurrent nerves of a dog, or in paying attention to the voice of a person who has had a complete attack of *hemiplegia*.

Tone of the Voice. — Every individual has a particular tone of voice by which he is known: there is also a particular tone which belongs to the different sexes and ages. The tone of the voice presents an infinite number of modifications. Upon what circumstances do these depend? This is unknown. The feminine tone, however, which is found in children and eunuchs, generally agrees with the state of the cartilages of the larynx. On the contrary, the masculine tone which women sometimes possess appears to be connected with the state of these cartilages, and particularly with that of the thyroid. Tone is a modification of sound, of which philosophers have by no means given an exact explanation.

Of the Extent of the Voice. — The sounds which the human larynx is capable of producing are very numerous. Many celebrated authors have endeavoured to explain the manner of their formation; but they have rather given us comparisons than explanations.

We have examined the reed of the organ of voice; we shall now consider the tube that the vocal sound traverses after having been produced. In proceeding from below upwards, the tube is composed, 1st, of the interval between the epiglottis before, its lateral ligaments upon the sides, and of the posterior side of the pharynx; 2dly, of the pharynx behind, and laterally, and of the most posterior part of the base of the tongue before; 3dly, sometimes of the mouth, and sometimes of the nasal cavities; at other times of these two cavities together.

This tube, capable of being prolonged or shortened, of being made wider or narrower; being susceptible of assuming an infinite variety of forms, ought to be very capable of performing all the functions of the body of a reed instrument; — that is, to be capable of harmonising with the larynx, and of thus favouring the production of the numerous tones of which the voice is susceptible; of increasing the intensity of the vocal sound, by taking a conical form, with the base outwards; of giving a roundness and agreeableness to the sound, by suitably dis-

posing its exterior opening, or by almost entirely shutting it, &c.

Until the influence of the tube of reed instruments has been determined with precision, it is evident that we can form only probable conjectures respecting the influence of the tube of the organ of voice. In this respect we can make only a small number of observations, which relate particularly to the most apparent phænomena.

A. The larynx is raised in the production of acute sounds; it is lowered, on the contrary, in the formation of those that are grave: consequently the vocal tube is shortened in the first case, and lengthened in the second.

We suppose that a short tube is more favourable to the transmission of acute sounds, whilst a long one is more so for those that are grave. The tube changes its length at the same time that it changes its breadth; and this is remarkable, as we have seen above that the breadth of the tube has a great influence upon its facility of transmitting sounds.

When the larynx descends, that is, when the vocal tube is prolonged, the thyroid cartilage descends, and removes from the os hyoides the whole height of the thyro-hyoid membrane. By this separation the gland of the epiglottis is carried forward, and places itself in the cavity of the posterior aspect of the os hyoides; this gland draws after it the epiglottis: from this results a considerable enlargement of the inferior part of the vocal tube.

The contrary phenomenon happens when the larynx is raised. The thyroid cartilage then rises, and becomes engaged behind the os hyoides, by displacing and pushing backward the epiglotted gland; this pushes the epiglottis, and the vocal tube is much contracted. By imitating the motion upon the dead body, we may easily ascertain that the narrowing may proceed to five sixths of the breadth of the tube. Now, we adapt a large tube to a reed for the purpose of producing grave sounds; on the contrary, it is a narrow tube which is generally employed for the purpose of transmitting acute sounds. We can then, to a certain degree, account for the utility of the changes of breadth which take place in the inferior part of the vocal tube.

B. The presence of the ventricles of the larynx immediately above the inferior ligaments of the glottis, appears intended to isolate those ligaments, so that they may vibrate freely in the air. When foreign bodies enter the ventricles, or when a false membrane or mucosities are formed, the voice is generally extinguished, or much weakened.

C. From its form, its position, its elasticity, — from the motions which its muscles impress upon it, the epiglottis appears to belong essentially to the apparatus of the voice; but what are its uses? We have already seen that it contributes powerfully to the narrowing of the vocal tube; it may be supposed that it has a more important function.

D. The vocal tube has visibly an influence upon the intensity of the voice. The most intense sounds which the voice can produce cause the mouth to be opened very wide, the tongue to be drawn a little back, and the velum of the palate raised into a horizontal position, and to become elastic, closing all communication with the nostrils.

In this case the pharynx and the mouth evidently perform the office of a speaking trumpet; that is to say, they represent very exactly a tube with a reed, which increases in wideness outwards, the effect of which is to augment the intensity of the sound produced by the reed. If the mouth is in part closed, the lips carried forward and turned towards each other, the sound will acquire rotundity, and an agreeable expression; but it will lose part of its intensity: this result is easily explained after what we have said of the influence of the form of tubes in reed instruments.

For the same reasons, whenever the vocal sound passes into the nose, it will become dull; for the form of the cavities of the nose is well fitted for diminishing the intensity of sounds. If the mouth and nose are shut at the same time, no sound can be produced.

E. We have seen, in considering the production of voice, that a great number of modifications relative to expression arise from changes of the thickness and of the elasticity of the lips of the glottis. The tube may produce a number of others, according to its different degrees of length or breadth; according to its form, the contraction of the pharynx, the position of the tongue, or of the velum of the palate; according as the sound passes wholly or in part through the mouth or the nose, or both together; according to the individual disposition of the mouth or nose, the existence or non-existence of teeth, the size of the tongue, &c.: the expression of the voice is continually modified according to all these circumstances. For example, whenever the sound traverses the nasal cavities, it becomes disagreeably nasal.

Those persons are mistaken who think that the intensity of vocal sound may be augmented by repercussion, in passing through the nasal cavities; these cavities produce quite a contrary effect. Whenever the voice is introduced into them, from whatever cause, it becomes dull.

F. Besides the numerous modifications which the tube of the vocal organ causes in the intensity and the expression of the voice, in alternately permitting or intercepting its productions, there is another very important kind of modification produced by it. By means of this the vocal sound is divided into very small portions, each possessing a distinct character, because each of them is produced by a distinct motion of the tube. This sort of influence of the vocal tube is called the *faculty of articulating*, which presents, besides, an infinite variety of individual differences suitable to the peculiar organisation of the vocal tube.

We have hitherto treated of the human voice in a general manner; we now proceed to speak of its principal modifications: namely, the cry or native voice; the voice properly so called, or acquired voice; speech, or articulate voice; singing, or *appreciable* voice.

The Cry, or Native Voice. — The cry is a sound which cannot be appreciated: it is, like all those sounds produced by the larynx, susceptible of variation in tone, intensity, and expression. The cry is easily distinguished from all other vocal sounds; but as its character depends upon the expression, it is impossible to account physically for the difference between it and the latter. Whatever is the condition of man, or whatever his age, he is capable of crying. The new-born child, the idiot, the person deaf from birth, the savage, the civilised, the decrepit old man, all are capable of producing cries. We ought, then, to consider the cry as particularly attached to organisation; indeed we may be convinced of this in examining its uses.

By the cry we express vivid sensations, whether they proceed from without or within; whether they are agreeable or painful: — there are cries of pleasure and of pain. By the cry we express our most simple instinctive wants, the natural passions. There is a cry of fury, another of fear, &c.

The social wants and passions, not being an indispensable consequence of organisation, and the state of civilisation being necessary for their development, they have no peculiar cry. The cry comprehends, generally, the most intense sounds that the organ of voice can produce: its expression has often something in it which offends the ear, and it has a strong action upon those who are near it.

By means of the cry, important relations are established among mankind. The cry of joy inclines to joy; the cry of pain excites pity; the cry produced by terror causes fear, even in those at a distance, &c. This sort of language is found in most animals; it is almost the only language which has been given them; the song of birds ought to be considered as a modification of their cry.

Acquired Voice, or Voice properly so called. — In the usual state of man, — that is, when he lives in society, and when he is possessed of the faculty of hearing, — he knows, from earliest youth, that mankind utters sounds which are not cries; he very soon finds that he can produce the same sort of sounds with his larynx, and immediately what is called *acquired voice* is developed in him, by the effect of imitation, and the advantages he derives from it. A deaf child cannot make any remark with regard to sound, and therefore he never acquires it. There seems to be no difference between the voice and the cry, except in intensity and expression; for it is likewise formed of inappreciable sounds, or of sounds whose intervals are not exactly distinguished by the ear.

Since the voice is the consequence of hearing, and of an intellectual process, it cannot be developed if those circumstances by which it is produced do not exist. In fact, children born deaf, who have never had any idea of sound; idiots, that establish no relation between the sounds which they hear and those which their larynx can produce, have no voice, though the vocal apparatus of both may be fit to form and modify sounds as well as that of individuals perfectly formed.

For the same reason, those whom we improperly term *savages*, because they have been found wandering in forests since their infancy, can have no voice; the understanding not being developed in a solitary state, but only in social life.

The expression, the intensity, the tone of the voice, are susceptible of numerous modifications on the part of the larynx; the vocal tube also exerts a powerful influence upon the voice: speech and singing are only modifications of the social voice.

Modifications of the Voice by Age. — The larynx is in proportion very small in the fœtus and the new-born infant: its small volume forms a contrast with that of the os hyoides, with the tongue and other organs of deglutition, which are already much developed. Besides, it is round, and the thyroid cartilage forms no projection in the neck.

The lips of the glottis, the ventricles, the superior ligaments, are very short in proportion to what they become afterwards; for the thyroid cartilage not being much developed, they consequently occupy a small space. The cartilages are flexible, and have not near the solidity which they possess afterwards.

The larynx preserves these characters almost till puberty; at this period a general revolution takes place in the economy. The development of the genital organs determines a sudden increase in the nutrition of many of the organs, of which that of the voice is one.

The greatest activity of nutrition is first remarked in the muscles, afterwards, but more slowly, it is seen in the cartilages: the general form of the larynx is then modified; the thyroid cartilage becomes developed in its anterior part, it forms a projection in the neck, but greater in the male than in the female. From this circumstance results a considerable prolongation of the lips of the glottis, or thyro-arythænoid muscles; and this phenomenon is much more worthy of remark than the general increase of the glottis which happens at the same time.

Though these changes in the larynx are rapid, they do not happen all at once; sometimes it is six or eight months before they terminate.

After puberty the larynx does not suffer any other remarkable changes; its volume and the projection of the thyroid cartilage continue to increase, and become more strongly marked. The cartilages become partially ossified in manhood.

In old age the ossification of the cartilages continues, and becomes almost complete; the epiglottic gland diminishes considerably, and the internal muscles, but those particularly that form the lips of the glottis, diminish in volume, assume a colour less deep, and lose their elasticity; in a word, they take the same modifications as the muscular system in general.

The production of voice, as it supposes the passage of air to and from the lungs to take place, cannot exist in the fœtus, plunged as it is in the *liquor amnii*; but the child is capable of producing very acute sounds at the instant of birth.

Vagitus is the name that is given to this voice, or cry of children, by which they express their wants and feelings. We must recollect that this is the object of the cry.

Towards the end of the first year the child begins to form sounds that are easily distinguished from the vagitus. These sounds, at first vague and irregular, very soon become more distinct and connected; nurses then begin to make them pronounce the most simple words, and afterwards those that are more complicated.

The pronunciation of children has very little resemblance to that of adults; but there is also a great difference between them. In children, the teeth have not yet quitted their alveoli; the tongue is comparatively very large; when the lips are closed they are larger than is necessary for covering anteriorly the gums; the nasal cavities are not much developed, &c.

Children advance only by degrees, and in proportion as their organs of pronunciation approach those of the adult, to articulate exactly the different combinations of letters. They are not capable of forming appreciable sounds, or of singing, until long after they have acquired the faculty of speech. This sort of sounds is the voice properly so called or acquired: they could not exist in the child were it deaf. They ought not to be considered as a modification of the vagitus.

Until the period of puberty, the larynx remains proportionably very small, as well as the lips of the glottis: the voice is also composed entirely of acute sounds. It is physically impossible that the larynx should produce grave ones.

At puberty, particularly in males, the voice undergoes a remarkable modification: it acquires in a few days, often all at once, a gravity, and a dull or deaf expression, that it was far from having before.

It sinks in general about an octave. The voice of a young man is said to *moult*, according to the common expression. In certain cases the voice is almost entirely lost for some weeks; it frequently contracts a marked hoarseness. Sometimes it happens that the young man produces, involuntarily, a very acute sound when he wishes to produce a grave one: it is then scarcely possible for him to produce uniform sounds, or to sing true.

This state of things continues sometimes nearly a year, after which the voice becomes more clear, and remains so during life: but some individuals lose entirely, during the *moulting*, of the voice, the faculty of singing; others, who had a fine and extensive voice before the *moulting*, have afterwards only a very ordinary one.

The gravity that the voice acquires depends evidently upon the development of the larynx, and particularly on the prolongation of the lips of the glottis. As these parts cannot stretch backwards, they come forward: it is also at this time that the larynx projects in the neck, and the *pomum Adami* appears. In the female, the lips of the glottis do not present at puberty this increase in breadth; the voice also generally remains acute.

The voice generally preserves the same characters until after adult age; at least, the modifications that it undergoes in the interval are but inconsiderable, and effect principally the expression and the volume. Towards the beginning of old age, the voice changes anew, its expression alters, and its extent diminishes: singing is more difficult, the sounds become noisy, and their production painful and fatiguing. The organs of pronunciation being changed by the effect of age, the teeth become shorter, and frequently being lost, the pronunciation is sensibly changed. All these phænomena are more noted in confirmed old age. The voice is weak, shaken, and broken; singing has the same characters, which depend on impaired muscular contraction. Speech also undergoes remarkable modifications; the slowness of the motions of the tongue, the want of the teeth, the lips proportionally longer, &c., necessarily influence the pronunciation. — *Magendie's Physiology.*

VOLATILE. (*Volatilis;* from *volo*, to fly.) Substances the particles of which have a tendency to evaporate, or diffuse themselves through the air at ordinary temperatures, are called *volatile* substances: such are ether, ammonia, &c.

Volatile alkali. See *Ammonia.*

VOLATILITY. The property of bodies by which they are disposed to evaporate, or diffuse themselves through the air.

VOLSELLA. A probang. See *Probang.*

Voltaic pill. See *Galvanism.*

Voltaism. See *Galvanism.*

VOLU'BILIS. (Easy to be rolled or wound.) Twining. Botanists apply it to stems which twine round other plants by their own spiral form, either from left to right, supposing the observer in the centre; (or, in other words, according to the apparent motions of the sun;) as in *Tamus communis* and the honey-suckle: or from right to left, contrary to the sun; as with *Convolvulus sæpium*, the French bean, &c.

VOLUME. The apparent space occupied by a body. The less the density of a body the greater is its volume.

VOLUNTARY. Relating to the will. Those muscles which are thown into action in obedience to the will are called *voluntary muscles*, in opposition to the *involuntary*, those which act independently of it. Motions affected by the action of the voluntary muscles are termed *voluntary motions.*

Voluntary motions. See *Voluntary.*

Voluntary muscles. See *Voluntary.*

VO'LVA. (*a*, *æ*. f.; from *valva.*) The curtain, wrapper, or covering of the fungous tribe, of a membranous texture, concealing their parts of fructification, and in due time bursting all around, forming a ring upon the stalk; as in *Agaricus campestris.* Such is the original meaning of this term, as explained by Linnæus; but it has become more generally used by Linnæus himself for the fleshy external covering of some other fungi, which is scarcely raised out of the ground, and enfolds the whole plant when young. It is *simple*, *double*, or *stellated*, very much cut; as in *Lycopodium stellatum.*

VO'LVULUS. (From *volvo*, to roll up: so called because it was supposed to be a twist-

ing of the bowels.) An old name of *ileus*. See *Iliac passion*.

Volvulus terrestris. Small bind-weed. The *Convolvulus minor*.

VO'MER. (*er, eris.* m.: so named from its great resemblance to a plough-share.) A slender thin bone, separating the nostrils from each other, consisting of two plates much compressed together, very dense and strong, yet so thin as to be transparent; these two plates seem at every edge to separate from each other, and thus a groove is formed at every side. — 1. This groove on the upper edge, or, as it may be called, its base, is wide, and receives into it the projecting points of the ethmoid and sphenoid bones; and thus it stands very firmly and securely on the skull, and capable of resisting blows of considerable violence.—2. The groove, upon the lower part, is narrower, and receives the rising line in the middle of the palate plate, where the bones join to form the palate suture. At the fore part it is united by a ragged surface, and by something like a groove, to the middle cartilage of the nose; and as the vomer receives the other bones into its grooves, it is, as it were, locked in on all sides, receiving support and strength from each, but more particularly from the thick and strong membrane which covers the whole, and which is so continuous as to resemble a periosteum, or rather a continued ligament, from its strength: thus the slender vomer possesses sufficient strength to avert from it all those evils which must inevitably have occurred, had it been less strongly or otherwise constructed.

VO'MICA. (*a, æ.* f.; from *vomo*, to spit up: because the matter is spit up.) In a wide sense, an abscess in any of the viscera: the term, however, is restricted to an abscess in the substance of the lungs, formed by the resolution of tubercles. See *Tubercle*, and *Phthisis*.

VOMITING. *Vomitio.* A forcible ejection of food, or any other substance, from the stomach, through the œsophagus and mouth.

That internal sensation which announces the necessity of vomiting is called *nausea;* it consists of a general uneasiness, with a feeling of dizziness in the head, or in the epigastric region: the lower lip trembles, and the saliva flows in abundance. Instantly, and involuntarily, convulsive contractions of the abdominal muscles, and at the same time of the diaphragm, succeed to this state: the first are not very intense, but those that follow are more so: they at last become such, that the matters contained in the stomach surmount the resistance of the *cardia*, and are thus darted, as it were, into the œsophagus and mouth: the same effect is produced many times in succession: it ceases for a time, and begins again after some interval.

At the instant that the matters driven from the stomach traverse the pharynx and the mouth, the glottis shuts, the *velum* of the palate rises, and becomes horizontal, as in deglutition; nevertheless, every time that one vomits, a certain quantity of liquid is introduced, either into the larynx or the nasal canals.

Vomiting was long believed to depend upon the rapid convulsive contraction of the stomach; but it has been shown, by a series of experiments, that, in the process, this viscus is nearly passive; and that the true agents of vomiting are, on the one hand, the diaphragm, and, on the other, the large abdominal muscles.

This has been brought forward by M. Magendie as a new fact; but the passiveness of the stomach in the act of vomiting was maintained by John Hunter.

In the ordinary state, the diaphragm and the muscles of the abdomen co-operate in vomiting; but each of them can, nevertheless, produce it separately. Thus, an animal still vomits, though the diaphragm has been rendered immoveable by cutting the diaphragmatic nerves; it vomits the same though the whole abdominal muscles have been taken away by the knife, with the precaution of leaving the linea alba and the peritonæum untouched. See *Sickness*.

Vomiting of blood. See *Hæmatemesis*.

Vomituri'tio. (*o. onis.* f.) Retching, or the ineffectual effort to vomit.

Vomitus cruentus. See *Hæmatemesis*.

Voracious appetite. See *Bulimia*.

Voracity. See *Bulimia*.

Voraciousness. See *Bulimia*.

Vox abscissa. A loss of voice. See *Aphonia*.

Vulga'go. The asarabacca was so called. See *Asarum*.

Vulnera'ria. (*a. æ.* f.; from *vulnus*, a wound.) The name of a species of *anthyllis*, from its supposed virtues in healing wounds. See *Anthyllis vulneraria*.

Vulneraria aqua. Arquebusade.

VU'LNUS. (*us, eris.* n.) A wound. See *Wound*.

Vulnus sclope'ticum. A gun-shot wound.

Vulpis morbus. Alopecia, or baldness. See *Alopecia*.

VU'LVA. (*a, æ.* f.; the womb.) Applied by anatomists — 1. To the external parts of generation in the female.

2. To a foramen in the brain, more commonly called *foramen commune anterius*. See *Encephalos*.

Vulva'ria. (*a, æ.* f.; from *vulva:* so named from its smell, or from its former use in disorders of the womb.) Stinking orach. See *Chenopodium vulvaria*.

W.

WADE'S DROPS. Compound tincture of benzoin.

Wakefulness. See *Agrypnia.*

Wake-robin. See *Arum.*

Wall-flower. See *Cheiranthus.*

Wall-pellitory. See *Parietaria.*

Wall-pepper. See *Sedum acre.*

Wall-rue. See *Asplenium murale.*

Wall-wort. The *Sambucus ebulus.*

Walnut. See *Juglans.*

WALTON. A town near Tewkesbury, in Gloucestershire, where there is a mineral chalybeate spring, the waters of which have been found chiefly efficacious in obstructions and other affections of the glands.

WARD'S ESSENCE FOR HEADACH. The compound camphor liniment.

WARD'S PASTE. A remedy for the piles, nearly the same as the *confectio piperis nigri* of the pharmacopœias.

WARD'S RED DROPS. A strong solution of emetic tartar in wine.

WARD'S WHITE DROPS. A preparation made by dissolving mercury in nitric acid, and adding a solution of carbonate of ammonia or a solution of corrosive sublimate and carbonate of ammonia.

WARNER'S CORDIAL. A tincture made with rhubarb, senna, saffron, liquorice, raisins, and brandy.

Warty. See *Verrucosus.*

WASHERWOMAN'S SCALL. A variety of *psoriasis diffusa*, peculiar to washerwomen. See *Psoriasis.*

Watchfulness. See *Agrypnia.*

WATER. *Aqua.* A transparent fluid, without colour, smell, or taste; in a very slight degree compressible; when pure not liable to spontaneous change; liquid in the common temperature of our atmosphere, assuming the solid form at 32° Fahrenheit, and the gaseous at 212°, but returning unaltered to its liquid state on resuming any degree of heat between these points; capable of dissolving a greater number of natural bodies than any other fluid whatever, and especially those known by the name of the saline; performing the most important functions in the vegetable and animal kingdoms, and entering largely into their composition as a constituent part.

Native water is seldom, if ever, found perfectly pure. The waters that flow within, or upon the surface of the earth, contain various earthy, saline, metallic, vegetable, or animal particles, according to the substances over or through which they pass. Rain and snow waters are much purer than these, although they also contain whatever floats in the air, or has been exhaled along with the watery vapours.

The purity of water may be known by the following marks or properties of pure water: —

1. Pure water is lighter than water that is not pure.

2. Pure water is more fluid than water that is not pure.

3. It has no colour, smell, or taste.

4. It wets more easily than the waters containing metallic and earthy salts, called hard waters, and feels softer when touched.

5. Soap, or a solution of soap in alkohol, mixes easily and perfectly with it.

6. It is not rendered turbid by adding to it a solution of gold in aqua regia, or a solution of silver, or of lead, or of mercury, in nitric acid, or a solution of acetate of lead in water.

Water was, till modern times, considered as an elementary or simple substance.

Previous to the month of October 1776, the celebrated Macquer, assisted by Sigaud de la Fond, made an experiment by burning hydrogen gas in a bottle, without explosion, and holding a white china saucer over the flame. His intention appears to have been that of ascertaining whether any fuliginous smoke was produced; and he observes, that the saucer remained perfectly clean and white, but was moistened with perceptible drops of a clear fluid, resembling water; and which, in fact, appeared to him and his assistant to be nothing but pure water. He does not say whether any test was applied to ascertain this purity, neither does he make any remark on the fact.

In the summer of the year 1781, Mr. Henry Cavendish was busied in examining what becomes of the air lost by combustion, and made those valuable experiments which were read before the Royal Society on the 15th of January 1784. He burned 500,000 grain measures of hydrogen gas, with about two and a half times the quantity of common air; and, by causing the burned air to pass through a glass tube eight feet in length, 135 grains of pure water were condensed. He also exploded a mixture of 19,500 grain measures of oxygen gas, and 37,000 of hydrogen, in a close vessel. The condensed liquor was found to contain a small portion of nitric acid, when the mixture of the air was such, that the burned air still contained a considerable proportion of oxygen. In this case it may be presumed, that some of the oxygen combines with a portion of nitrogen present.

In the mean time, Lavoisier, during the winter of 1781–1782, together with Gingembre, filled a bottle of six pints with hydrogen; which being fired, and two ounces of lime-water poured in, was instantly stopped with a cork, through which a flexible tube communicating with a vessel of oxygen was passed. The inflammation ceased, except at the orifice of the tube, through which the oxygen was passed, where a beautiful flame appeared. The combustion con-

tinued a considerable time, during which the lime-water was agitated in the bottle. Neither this, nor the same experiment repeated with pure water, and with a weak solution of alkali instead of lime-water, afforded the information sought after; for the substances were not at all altered.

The inference of Mr. Warltire, respecting the moisture on the inside of the glass in which Dr. Priestley first fired hydrogen and common air, was, that these airs, by combustion, deposited the moisture they contained. Mr. Watt, however, inferred from these experiments, that water is a compound of the burned airs, which have given out their latent heat by combustion; and communicated his sentiments to Dr. Priestley, in a letter dated April 26. 1783.

It does not appear that the composition of water was known or admitted in France till the summer of 1783, when Lavoisier and De la Place, on the 24th of June, repeated the experiment of burning hydrogen and oxygen in a glass vessel over mercury, in a still greater quantity than had been burned by Mr. Cavendish. The result was nearly five gross of pure water. Monge made a similar experiment at Paris nearly at the same time, or perhaps before.

This assiduous and accurate philosopher then proceeded, in conjunction with Meusnier, to pass the steam of water through a red-hot iron tube, and found that the iron was oxidised, and hydrogen disengaged; and the steam of water being passed over a variety of other combustible or oxidable substances, produced similar results, the water disappearing and hydrogen being disengaged. These capital experiments were accounted for by Lavoisier, by supposing the water to be decomposed into its component parts, oxygen and hydrogen, the former of which unites with the ignited substance, while the latter is disengaged.

The grand experiment of the composition of water, by Fourcroy, Vauquelin, and Seguin, was begun on Wednesday, May 13. 1790, and was finished on Friday the 22d of the same month. The combustion was kept up 185 hours with little interruption, during which time the machine was not quitted for a moment. The experimenters alternately refreshed themselves when fatigued, by lying for a few hours on mattresses in the laboratory.

To obtain the hydrogen, 1. Zinc was melted and rubbed into a powder in a very hot mortar. 2. This metal was dissolved in concentrated sulphuric acid, diluted with seven parts of water. The air procured was made to pass through caustic alkali. To obtain the oxygen, two pounds and a half of crystallised hyperoxymuriate of potash were distilled, and the air was transferred through caustic alkali.

The volume of hydrogen employed was 25963·568 cubic inches, and the weight was 1039·358 grains.

The volume of oxygen was 12570·942, and the weight was 6209·869 grains.

The total weight of both elastic fluids was 7249·227.

The weight of water obtained was 7244 grains, or 12 ounces 4 gros 45 grains.

The weight of water which should have been obtained was 12 ounces 4 gros 49·227 grains.

The deficit was 4·227 grains.

The quantity of azotic air before the experiment was 415·256 cubic inches, and at the close of it 467. The excess after the experiment was, consequently, 51·744 cubic inches. This augmentation is to be attributed, the academicians think, to the small quantity of atmospheric air in the cylinders of the gasometers, at the time the other airs were introduced. These additional 51 cubic inches could not arise from the hydrogen, for experiment showed that it contained no azotic air. Some addition of this last fluid, the experimenters think, cannot be avoided, on account of the construction of the machine.

The water being examined, was found to be as pure as distilled water. Its specific gravity to distilled water was as 18671 : 18670.

The decomposition of water is effected by electricity in a most elegant manner.

The composition of water is best demonstrated by exploding 2 volumes of hydrogen and 1 of oxygen, in the eudiometer. They disappear totally, and pure water results. A cubic inch of this liquid, at 60°, weighs 252·52 grains; consisting of

28·06 grains hydrogen, and
224·46 oxygen.

The bulk of the former gas is	1325	cubic inches.
That of the latter is	662	
	1987	

Hence there is a condensation of nearly two thousand volumes into one; and one volume of water contains 662 volumes of oxygen. The prime equivalent of water is 1·125; composed of a prime of oxygen = 1·0 + a prime of hydrogen = 0·125; or 9 parts by weight of water consist of 8 oxygen + 1 hydrogen.

The simple waters are the following: —

1. *Distilled water.* This is the lightest of all others, containing neither solid nor gaseous substances in solution, is perfectly void of taste and smell, colourless and beautifully transparent, has a soft feel, and wets the fingers more readily than any other. It mixes uniformly with soap into a smooth opaline mixture, but may be added to a solution of soap in spirit of wine without injuring its transparency. The clearness of distilled water is not impaired by the most delicate chemical re-agents, such as lime-water, a solution of barytes in any acid, nitrated silver, or acid of sugar. When evaporated in a silver vessel it leaves no residuum: if preserved from access of foreign matter floating in the air, it may be kept for ages unaltered in vessels upon which it has no action, as it does not possess within itself the power of decomposition. As it freezes exactly at 32° of Fahrenheit, and boils at 212° under the atmospherical pressure of 29·8 inches, these points are made use of as the standard ones for thermometrical division; and its specific weight being always the same under the mean pressure and temperature, it is employed for the comparative standard of specific gravity.

Pure distilled water can only be procured

from water which contains no volatile matters that will rise in distillation, and continue still in union with the vapour when condensed. Many substances are volatile during distillation; but most of the gases, such as common air, carbonic acid, and the like, are incapable of uniting with water at a high temperature: other bodies, however, such as vegetable essential oil, and, in general, much of that which gives the peculiar odour to vegetable and animal matter, will remain in water after distillation. So the steam of many animal and vegetable decoctions has a certain flavour which distinguishes it from pure water; and the aqueous exhalation from living bodies, which is a kind of distillation, has a similar impregnation.

To obtain distilled water perfectly pure, much stress was laid by former chemists on repeating the process a great number of times; but it was found by Lavoisier, that rain water once distilled, rejecting the first and last products, was as pure a water as could be procured by any subsequent distillations.

Distilled water appears to possess a higher power than any other as a solvent of all animal and vegetable matter, and these it holds in solution as little as possible altered from the state in which they existed in the body that yielded them. Hence the great practical utility of that kind of chemical analysis which presents the proximate constituent parts of these bodies, and which is effected particularly by the assistance of pure water. On the other hand, a saline, earthy, or otherwise impure water, will alter the texture of some of the parts, impair their solubility, produce material changes on the colouring matter, and become a less accurate analyser on account of the admixture of foreign contents.

Distilled water is seldom employed to any extent in the preparation of food, or in manufactures, on account of the trouble of procuring it in large quantities; but for preparing a great number of medicines, and in almost every one of the nicer chemical processes that are carried on in the liquid way, this water is an essential requisite. The only cases in which it has been used largely as an article of drink, have been in those important trials made of the practicability of procuring it by condensing the steam of sea water, by means of a simple apparatus adapted to a ship's boiler; and these have fully shown the ease with which a large quantity of fresh water, of the purest kind, may be had at sea, at a moderate expense, whereby one of the most distressing of all wants may be relieved. There are one or two circumstances which seem to show that water, when not already loaded with foreign matter, may become a solvent for concretions in urinary passages. At least, we know that very material advantage has been derived in these cases from very pure natural springs; and hence a course of distilled water has been recommended as a fair subject of experiment.

2. *Rain water*, the next in purity to distilled water, is that which has undergone a natural distillation from the earth, and is condensed in the form of rain. This is a water so nearly approaching to absolute purity as probably to be equal to distilled water for every purpose except in the nicer chemical experiments. The foreign contents of rain water appear to vary according to the state of the air through which it falls. The heterogeneous atmosphere of a smoky town will give some impregnation to rain as it passes through, and this, though it may not be at once perceptible on chemical examination, will yet render it liable to spontaneous change; and hence rain water, if long kept, especially in hot climates, acquires a strong smell, becomes full of animalcula, and in some degree putrid. According to Margraaf, the constant foreign contents of rain water appear to be some traces of the muriatic and nitric acids; but as this water is always very soft, it is admirably adapted for dissolving soap, or for the solution of alimentary or colouring matter, and it is accordingly used largely for these purposes. The specific gravity of rain water is so nearly the same as that of distilled water, that it requires the most delicate instruments to ascertain the difference. Rain that falls in towns acquires a small quantity of sulphate of lime and calcareous matter from the mortar and plaster of the houses.

2. *Ice* and *snow water*. This equals rain water in purity, and, when fresh melted, contains no air, which is expelled during freezing. In cold climates, and in high latitudes, thawed snow forms the constant drink of the inhabitants during winter; and the vast masses of ice which float on the polar seas afford an abundant supply to the mariner. It is well known, that in a weak brine, exposed to a moderate freezing cold, it is only the watery part that congeals, leaving the unfrozen liquor proportionably stronger of the salt. The same happens with a dilute solution of vegetable acids, with fermented liquors, and the like; and advantage is taken of this property to reduce the saline part to a more concentrated form. Snow water has long lain under the imputation of occasioning those strumous swellings in the neck which deform the inhabitants of many of the Alpine valleys; but this opinion is not supported by any well-authenticated indisputable facts, and is rendered still more improbable, if not entirely overturned, by the frequency of the disease in Sumatra, where ice and snow are never seen, and its being quite unknown in Chili and in Thibet, though the rivers of those countries are chiefly supplied by the melting of the snow, with which the countries are covered.

4. *Spring water*. Under this comprehensive class are included all waters that spring from some depth beneath the soil, and are used at the fountain head, or at least before they have run any considerable distance exposed to the air. It is obvious that spring water will be as various in its contents as the substances that compose the soil through which it flows. When the ingredients are not such as to give any peculiar medical or sensible properties, and the water is used for common purposes, it is distinguished as a hard or soft spring, sweet or brackish, clear or turbid, and the like. Ordinary springs insensibly pass into *mineral springs*, as their foreign

contents become more notable and uncommon; though sometimes waters have acquired great medical reputation from mere purity. See *Mineral waters*.

By far the greater number of springs are cold; but as they take their origin at some depth from the surface, and below the influence of the external atmosphere, their temperature is, in general, pretty uniform during every vicissitude of season, and always several degrees higher than the freezing point. Others, again, arise constantly hot, or with a temperature always exceeding the summer heat; and the warmth possessed by the water is entirely independent of that of the atmosphere, and varies little winter or summer.

One of the principal inconveniences in almost every spring water, is its hardness, owing to the presence of earthy salts, which, in by far the greater number of cases, are only the insipid substances chalk and selenite, which do not impair the taste of the water; whilst the air which it contains, and its grateful coolness, render it a most agreeable, and generally a perfectly innocent drink; though, sometimes, in weak stomachs, it is apt to occasion an uneasy sense of weight in that organ, followed by a degree of dyspepsia. The quantity of earthy salts varies considerably; but, in general, it appears that the proportion of five grains of these in the pint will constitute a hard water, unfit for washing with soap, and for many other purposes of household use or manufactures. The water of deep wells is always, *ceteris paribus*, much harder than that of springs which overflow their channel; for much agitation and exposure to air produce a gradual deposition of the calcareous earth; and hence spring water often incrusts to a considerable thickness the inside of any kind of tube through which it flows, as it arises from the earth. The specific gravity of these waters is also, in general, greater than that of any other kind of water, that of the sea excepted. Springs that overflow their channel, and form to themselves a limited bed, pass insensibly into the state of stream, or river water, and become thereby altered in some of their chemical properties.

5. *River water.* This is in general much softer and more free from earthy salts than the last, but contains less air of any kind: for, by the agitation of a long current, and in most cases a great increase of temperature, it loses common air and carbonic acid, and, with this last, much of the lime which it held in solution. The specific gravity thereby becomes less, the taste not so harsh, but less fresh and agreeable, and out of a hard spring is often made a stream of sufficient purity for most of the purposes requiring soft water. Some streams, however, that arise from a clean silicious rock, and flow in a sandy or stony bed, are, from the outset, remarkably pure. Such are the mountain lakes and rivulets in the rocky districts of Wales, the source of the beautiful waters of the Dee, and numberless other rivers that flow through the hollow of every valley. Switzerland has long been celebrated for the purity and excellence of its waters, which pour in copious streams from the mountains, and give rise to some of the finest rivers in Europe. An excellent observer and naturalist, the illustrious Haller, thus speaks of the Swiss waters: — "Vulgaribus aquis Helvetia super omnes fere Europæ regiones excellit. Nusquam liquidas illas aquas et crystalli simillimas se mihi obtulisse memini postquam ex Helvetiâ excessi; ex scopulis enim nostræ per puros silices percolatæ nulla terra vitiantur." Some of them never freeze in the severest winter, the cause of which is probably, as Haller conjectures, that they spring at once out of a subterraneous reservoir so deep as to be out of the reach of frost; and during their short course, when exposed to day, they have not time to be cooled down from 53°, their original temperature, to below the freezing point.

Some river waters, however, that do not take their rise from a rocky soil, and are indeed at first considerably charged with foreign matter, during a long course, even over a rich cultivated plain, become remarkably pure as to saline contents, but often fouled with mud, and vegetable or animal exuviæ, which are rather suspended than held in true solution. Such is that of the Thames, which, taken up at London at low water, is very soft and tolerably good, and, after rest and filtration, it holds but a very small portion of any thing that could prove noxious or impede any manufacture. It is also excellently fitted for sea-store; but it here undergoes a remarkable spontaneous change. No water carried to sea becomes putrid sooner than that of the Thames. When a cask is opened after being kept a month or two, a quantity of inflammable air escapes, and the water is so black and offensive as scarcely to be borne. Upon racking it off, however, into large earthen vessels (oil jars are commonly used for the purpose), and exposing it to the air, it gradually deposits a quantity of black slimy mud, becomes clear as crystal, and remarkably sweet and palatable. The Seine has as high a reputation in France, and appears from accurate experiments to be a river of great purity. It might be expected that a river which has passed by a large town, and received all its impurities, and been used by numerous dyers, tanners, hatters, and the like, that crowd to its banks for the convenience of plenty of water, should thereby acquire such a foulness as to be very perceptible to chemical examination for a considerable distance below the town; but it appears, from the most accurate examination, that where the stream is at all considerable these kinds of impurity have but little influence in permanently altering the quality of the water, especially as they are for the most part only suspended, and not truly dissolved; and, therefore, mere rest, and especially filtration, will restore the water to its original purity. Probably, therefore, the most accurate chemist would find it difficult to distinguish water taken up at London from that procured at Hampton Court, after each has been purified by simple filtration.

6. *Stagnated waters.* The waters that present the greatest impurities to the senses, are those of stagnant pools, and low marshy countries. They are filled with the remains of animal and vegetable matter undergoing decom-

position, and, during that process, becoming in part soluble in water, thereby affording a rich nutriment to the succession of living plants and insects, thereby supplying the place of those that perish. From the want of sufficient agitation in these waters, vegetation goes on undisturbed, and the surface becomes covered with confervæ and other aquatic plants; and as these standing waters are in general shallow, they receive the full influence of the sun, which further promotes all the changes that are going on within them. The taste is generally vapid, and destitute of that freshness and agreeable coolness which distinguish spring water. However, it should be remarked, that stagnant waters are generally soft, and many of the impurities are only suspended, and therefore separable by filtration; and perhaps the unpalatableness of this drink has caused it to be in worse credit than it deserves, on the score of salubrity. The decidedly noxious effects produced by the air of marshes and stagnant pools, have been supposed to extend to the internal use of these waters; and often, especially in hot climates, a residence near these places has been as much condemned on the one account as on the other; and, in like manner, an improvement in health has been as much attributed to a change of water as of air.

WEB. *Tela.* Applied to that which resembles a web; as the arachnoid membrane, cellular tissue, &c.

Web, mucous. The name adopted by Professor Blumenbach for cellular membrane.

Wedge-shaped. See *Cuneiformis.*

WELD. Woald. The *Resela luteola* of Linnæus, which is used as a yellow dye.

WELDING. The property which the particles of iron and platina possess of adhering together from the stroke of the hammer: the above are the only metals which have this property.

Wharton's duct. See *Ductus Wartonianus.*

WHEAL. An elevation of the skin, like that produced by a sharp stroke of a cane, and which is seen in some forms of nettle-rash.

Wheal worm. See *Acarus autumnalis.*

WHEAT. *Triticum.* The seeds of the *Triticum hibernum*, and *æstivum*, of Linnæus, are so termed. It is to these plants we are indebted for our bread, and the various kinds of pastry. The wheat is first ground between mill-stones, and then sifted to obtain its farina or flour. The flower of wheat may be separated into its three constituent parts, in the following manner: — The flower is to be kneaded into a paste with water in an earthen vessel, and the water continued pouring upon it from a cock; this liquid, as it falls upon the paste, takes up from it a very fine white powder, by means of which it acquires the colour and consistency of milk. This process is to be continued till the water run off clear, when the flour will be separated into three distinct parts: 1. A grey elastic matter that sticks to the hand, and on account of its properties has gained the name of the glutinous, or vegeto-animal part. 2. A white powder which falls to the bottom of the water, and is the *fæculum* or starch. 3. A matter which remains dissolved in the water, and seems to be a sort of mucilaginous extract.

Flour, from whatever species of corn obtained, is likewise disposed to vinous fermentation, on account of its saccharine contents. The aptitude for fermentation of these mealy seeds increases if they be first converted into malt; inasmuch as by this process the gluten which forms the germ is separated, and the starchy part appears to be converted into saccharine matter. The making of malt, for which purpose barley and wheat are generally chosen, is as follows: — The grains are put in the malting tub, and immersed in cold water, in a temperate and warm season, changing this fluid several times, especially in hot weather; and they are thus kept soaking till they be sufficiently soft to the touch. Upon this they are piled up in heaps on a roomy, clean, airy floor, where, by the heat spontaneously taking place, the vegetation begins, and the grains germinate. To cause the germination to go on uniformly, the heaps are frequently turned. In this state the vegetation is suffered to continue till the germs have about two thirds or three fourths of the length of the corn. It is carried too far when the leafy germs have begun to sprout.

For this reason, limits are set to the germination, by drying the malt, which is effected by transferring it to the kiln, or by spreading it about in spacious airy lofts. Dried in the last way, it is called air-dried malt; in the first, kiln-malt. In drying this latter, care must be taken that it does not receive a burnt smell, or be in part converted into coal.

From this malt, beer is made by extraction with water and fermentation.

Wheat, buck. See *Polygonum.*

Wheat, Eastern buck. See *Polygonum.*

Wheat, Indian. See *Wheat, Turkey.*

Wheat, Turkey. The Turkey wheat, Indian wheat, Indian corn, or maize, is the produce of the *Zea mays*, a native plant of America, where it is much cultivated, as it is also in some parts of Europe, especially in Italy and Germany. There are many varieties, which differ in the colour of the grain, and are frequently raised in our gardens by way of curiosity, whereby the plant is well known. It is the chief bread corn in some of the southern parts of America, but, since the introduction of rice into Carolina, it is but little used in the northern colonies. It makes

a main part, too, of the food of the poor people in Italy and Germany. This is the sort of wheat mentioned in the book of Ruth, where it is said that Boaz treated Ruth with parched ears of corn dipped in vinegar. This method of eating the roasted ears of Turkey wheat is still practised in the East: they gather in the ears when about half ripe, and having scorched them to their minds, eat them with as much satisfaction as we do the best flour bread.

In several parts of South America they parch the ripe corn, never making it into bread, but grinding it between two stones, mix it with water in a calabash, and so eat it. The Indians make a sort of drink from this grain, which they call *bici*. This liquor is very windy and intoxicating, and has nearly the taste of sour small beer: but they do not use it in common, being too lazy to make it often, and therefore it is chiefly kept for the celebration of feasts and weddings, at which times they mostly get intolerably drunk with it. The manner of making this precious beverage, is to steep a parcel of corn in a vessel of water, till it grows sour; then the old women, being provided with calibashes for the purpose, chew some grains of the corn in their mouths, and spitting it into the calabashes, empty them, spittle and all, into the sour liquor, having previously drawn off the latter into another vessel.

The chewed grain soon raises a fermentation; and when this ceases, the liquor is let off from the dregs, and set by till wanted. In some of the islands in the South Sea, where each individual is his own lawgiver, it is no uncommon thing for a near relation to excuse a murderer for a good drunken bout of *ciri*, which is prepared from this grain.

Wheel-shaped. See *Rotatus.*

WHEEZING. A noisy respiration produced by obstruction of the air passages.

WHELK. A small tubercle which does not suppurate, generally situated on the face; the same as *ionthus*. See *Ionthus.*

WHEY. The fluid part of milk which remains after the curd has been separated. It contains a saccharine matter, some butter, and a small portion of cheese. See *Milk.*

Whirl. See *Verticillus.*

WHISKEY. (From *Usquebaugh*, the Irish name for it.) A dilute alkohol obtained by distilling malt.

WHISPERING. A lowness of speech, caused by uttering the words so feebly as not to produce any vibration of the larynx.

White-bait. See *Clupea latulus.*

WHITEHEAD'S ESSENCE OF MUSTARD. Dr. Paris says this is nothing but balsam of tolu and resin. According to Brande, it is made of camphor, oil of turpentine, and spirit of rosemary, mixed with mustard flour.

WILSON'S GOUT TINCTURE. An infusion of colchicum.

WINE. The name of wine is given in general to all liquors that have become spirituous by fermentation. Thus cider, beer, hydromel, mead, and other similar liquors, are wines.

The principles and theory of the fermentation which produces these liquors are essentially the same. See *Fermentation.*

All those nutritive vegetable and animal matters which contain sugar ready formed, are susceptible of spirituous fermentation. Thus wine may be made of all the juices of plants, the sap of trees, the infusions and decoctions of farinaceous vegetables, the milk of frugivorous animals; and, lastly, it may be made of all ripe succulent fruits. But of all substances susceptible of the spirituous fermentation, none is capable of being converted into so good wine as the juice of the grapes of France, or of other countries that are nearly in the same latitude, or in the same temperature. The grapes of hotter countries, and even those of the southern provinces of France, do indeed furnish wines that have a more agreeable, that is, more of a saccharine taste; but these wines, though they are sufficiently strong, are not so spirituous as those of the provinces near the middle of France: at least from these latter wines the best vinegar and brandy are made. As an example, therefore, of spirituous fermentation in general, we shall describe the method of making wine from the juice of the grapes of France.

This juice, when newly expressed, and before it has begun to ferment, is called *must*, and in common language sweet wine. It is turbid, and has an agreeable and very saccharine taste. It is very laxative; and when drunk too freely, or by persons disposed to diarrhœas, it is apt to occasion these disorders. Its consistence is somewhat less fluid than that of water, and it becomes almost of a pitchy thickness when dried.

When the must is pressed from the grapes, and put into a proper vessel and place, with a temperature between fifty-five and sixty degrees, very sensible effects are produced in it, in a shorter or longer time, according to the nature of the liquor, and the exposure of the place. It then swells, and is so rarefied that it frequently overflows the vessel containing it, if this be nearly full. An intestine motion is excited among its parts, accompanied with a slight hiss.

ing noise and evident ebullition. The bubbles rise to the surface, and at the same time is disengaged a quantity of carbonic acid, of such purity, and so subtle and dangerous, that it is capable of killing, instantly, men and animals exposed to it in a place where the air is not renewed. The skins, stones, and other grosser matters of the grapes are buoyed up by the particles of disengaged air that adhere to their surface, are variously agitated, and are raised in form of a scum, or soft and spongy crust, that covers the whole liquor. During the fermentation, this crust is frequently raised, and broken by the air disengaged from the liquor which forces its way through it; afterwards the crust subsides, and becomes entire as before.

These effects continue while the fermentation is brisk, and at last gradually cease: then the crust, being no longer supported, falls in pieces to the bottom of the liquor. At this time, if we would have a strong and generous wine, all sensible fermentation must be stopped. This is done by putting the wine into close vessels, and carrying these into a cellar or other cool place.

After this first operation, an interval of repose takes place, as is indicated by the cessation of the sensible effects of the spirituous fermentation; and thus enables us to preserve a liquor no less agreeable in its taste, than useful for its reviving and nutritive qualities, when drunk moderately.

If we examine the wine produced by this first fermentation, we shall find that it differs entirely and essentially from the juice of grapes before fermentation. Its sweet and saccharine taste is changed into one that is very different, though still agreeable, and somewhat spirituous and piquant. It has not the laxative quality of must, but affects the head, and occasions, as is well known, drunkenness. Lastly, if it be distilled, it yields, instead of the insipid water obtained from must by distillation with the heat of boiling water, a volatile, spirituous, and inflammable liquor, called spirit of wine, or alkohol. This spirit is consequently a new substance, produced by the kind of fermentation called the vinous or spirituous.

When any liquor undergoes the spirituous fermentation, all its parts seem not to ferment at the same time, otherwise the fermentation would probably be very quickly completed, and the appearances would be much more striking: hence, in a liquor much disposed to fermentation, this motion is more quick and simultaneous than in another liquor less disposed. Experience has shown, that a wine, the fermentation of which is very slow and tedious, is never good or very spirituous; and, therefore, when the weather is too cold, the fermentation is usually accelerated by heating the place in which the wine is made. A proposal has been made by a person very intelligent in economical affairs, to apply a greater than the usual heat to accelerate the fermentation of the wine, in those years in which grapes have not been sufficiently ripened, and when the juice is not sufficiently disposed to fermentation.

A too hasty and violent fermentation is perhaps also hurtful, from the dissipation and loss of some of the spirit; but of this we are not certain. However, we may distinguish, in the ordinary method of making wine of grapes, two periods in the fermentation; the first of which lasts during the appearance of the sensible effects above mentioned, in which the greatest number of fermentable particles ferment. After this first effort of fermentation, these effects sensibly diminish, and ought to be stopped, for reasons hereafter to be mentioned. The fermentative motion of the liquors then ceases. The heterogeneous parts that were suspended in the wine by this motion, and render it muddy, are separated, and form a sediment called the lees; after which the wine becomes clear; but though the operation is then considered as finished, and the fermentation is apparently over, it does not really cease; and it ought to be continued in some degree, if we would have good wine.

In this new wine a part of the liquor probably remains that has not fermented, and which afterwards ferments, but so very slowly, that none of the sensible effects produced in the first fermentation are here perceived. The fermentation, therefore, still continues in the wine, during a longer or shorter time, although in an imperceptible manner; and this is the second period of the spirituous fermentation, which may be called the imperceptible fermentation. We may easily perceive that the effect of this imperceptible fermentation is the gradual increase of the quantity of alkohol. It has also another effect no less advantageous, namely, the separation of the acid salt called tartar from the wine. This matter is, therefore, a second sediment, that is formed in the wine, and adheres to the sides of the containing vessels. As the taste of tartar is harsh and disagreeable, it is evident that the wine, which by means of the insensible fermentation has acquired more alkohol, and has disengaged itself of the greater part of its tartar, ought to be much better and more agreeable; and for this reason chiefly old wine is universally preferable to new wine.

But insensible fermentation can only ripen and ameliorate the wine, if the sensible fermentation have regularly proceeded, and been stopped in due time. We know certainly that if a sufficient time has not been allowed for the first period of the fermentation, the unfermented matter that remains, being in too large a quantity, will then ferment in the bottles, or close vessels, in which the wine is put, and will occasion effects so much more sensible, as the first fermentation shall have been sooner interrupted: hence these wines are always turbid, emit bubbles, and sometimes break the bottles from the large quantity of air disengaged during the fermentation.

We have an instance of these effects in the wine of Champagne, and in others of the same kind. The sensible fermentation of these wines is interrupted, or rather suppressed, that they may have this sparkling quality. It is well known that these wines make the corks fly out of the bottles; that they sparkle and froth when they are poured into glasses; and lastly, that

they have a taste much more lively and piquant than wines that do not sparkle: but this sparkling quality, and all the effects depending on it, are only caused by a considerable quantity of carbonic acid gas, which is disengaged during the confined fermentation that the wine has undergone in close vessels. This air, not having an opportunity of escaping, and of being dissipated as fast as it is disengaged, and being interposed betwixt all the parts of the wine, combines in some measure with them, and adheres in the same manner as it does to certain mineral waters, in which it produces nearly the same effects. When this air is entirely disengaged from these wines, they no longer sparkle, they lose their piquancy of taste, become mild, and even almost insipid.

Such are the qualities that wine acquires in time, when its first fermentation has not continued sufficiently long. These qualities are given purposely to certain kinds of wine, to indulge taste or caprice; but such wines are supposed to be unfit for daily use. Wines for daily use ought to have undergone so completely the sensible fermentation, that the succeeding fermentation shall be insensible, or at least exceedingly little perceived. Wine, in which the first fermentation has been too far advanced, is liable to worse inconveniences than that in which the first fermentation has been too quickly suppressed; for every fermentable liquor is, from its nature, in a continual intestine motion, more or less strong according to circumstances, from the first instant of the spirituous fermentation, till it is completely purified: hence, from the time of the completion of the spirituous fermentation, or even before the wine begins to undergo the acid or acetous fermentation. This acid fermentation is very slow and insensible, when the wine is included in very close vessels, and in a cool place; but it gradually advances, so that in a certain time the wine, instead of being improved, becomes at last sour. This evil cannot be remedied; because the fermentation may advance, but cannot be reverted.

Wine-merchants, therefore, when their wines become sour, can only conceal or absorb this acidity by certain substances, as by alkalis and absorbent earths. But these substances give to wine a dark greenish colour, and a taste which, though not acid, is somewhat disagreeable. Besides, calcareous earths accelerate considerably the total destruction and putrefaction of the wine. Oxide of lead, having the property of forming with the acid of vinegar a salt of an agreeable saccharine taste, which does not alter the colour of the wine, and which, besides, has the advantage of stopping fermentation and putrefaction, might be very well employed to remedy the acidity of wine, if lead and all its preparations were not pernicious to health, as they occasion most terrible colics, and even death, when taken internally. We cannot believe that any wine-merchant, knowing the evil consequences of lead, should, for the sake of gain, employ it for the purpose mentioned; but if there be any such persons, they must be considered as the poisoners and murderers of the public. At Alicant, where very sweet wines are made, it is the practice to mix a little lime with the grapes before they are pressed. This, however, can only neutralise the acid already existing in the grape.

If wine contain litharge, or any other oxide of lead, it may be discovered by evaporating some pints of it to dryness, and melting the residuum in a crucible, at the bottom of which a small button of lead may be found after the fusion: but an easier and more expeditious proof is by pouring into the wine some liquid sulphuret. If the precipitate occasioned by this addition of the sulphuret be white, or only coloured by the wine, we may know that no lead is contained in it; but if the precipitate be dark coloured, brown, or blackish, we may conclude that it contains lead or iron.

The only substances that cannot absorb or destroy, but cover and render supportable the sharpness of wine, without any inconvenience, are sugar, honey, and other saccharine alimentary matters; but they can succeed only when the wine is very little acid, and when an exceedingly small quantity only of these substances is sufficient to produce the desired effect; otherwise the wine would have a sweetish, tart, and not agreeable taste.

From what is here said concerning the acescency of wine, we may conclude that, when this accident happens, it cannot by any good method be remedied, and that nothing remains to be done with sour wine but to sell it to vinegar-makers, as all honest wine-merchants do.

As the *must* of the grape contains a greater proportion of tartar than our currant and gooseberry juices do, Dr. Ure has been accustomed, for many years, to recommend, in his lectures, the addition of a small portion of that salt to our *must*, to make it ferment into a more genuine wine. Dr. M'Culloch has lately prescribed the same addition in his popular treatise on the art of making wine.

The following is Brande's valuable table of the quantity of spirit in different kinds of wine: —

		Proportion of spirit per cent. by measure.
1.	Lissa	26·47
	Ditto	24·35
	Average	25·41
2.	Raisin wine	26·40
	Ditto	25·77
	Ditto	23·20
	Average	25·12
3.	Marsala	26·30
	Ditto	25·05
	Average	25·09
4.	Madeira	24·42
	Ditto	23·93
	Ditto (Sircial)	21·40
	Madeira	19·24
	Average	22·27
5.	Currant wine	20·55
6.	Sherry	19·81
	Ditto	19·83
	Ditto	18·79
	Ditto	18·25
	Average	19·17

7.	Teneriffe	19·79

The wines principally used in medicine are, the *vinum album hispanicum*, or sherry, *vinum canarinum*, canary or sack wine, the *vinum rhenanum*, or Rhenish wine, and the *vinum rubrum*, or Port wine. These differ from each other in the proportion of their constituent principles, and particularly in that of alkohol, which they contain. The qualities of wines depend not only upon the difference of the grapes, as containing more or less of saccharine juice, and the acid matter which accompanies it, but also upon circumstances attending the process of fermentation. New wines are liable to a strong degree of acescency when taken into the stomach, and thereby occasion much flatulency and eructations of acid matter; heartburn and violent pains in the stomach from spasms are also often produced; and the acid matter, by passing into the intestines and mixing with the bile, is apt to occasion colics or excite diarrhœa. Sweet wines are likewise more disposed to become acescent in the stomach than others; but as the quantity of alkohol which they contain is more considerable than appears sensibly to the taste, their acescency is thereby in a great measure counteracted. Red port, and most of the red wines, have an astringent quality, by which they strengthen the stomach, and prove useful in restraining immoderate evacuations; on the contrary, those which are of an acid nature, as Rhenish, pass freely by the kidneys, and gently loosen the belly. But this, and perhaps all the thin or weak wines, though of an agreeable flavour, yet as containing little alkohol, are readily disposed to become acid in the stomach, and thereby to aggravate all arthritic and calculous complaints, as well as to produce the effects of new wine. The general effects of wine are, to stimulate the stomach, exhilarate the spirits, warm the habit, quicken the circulation, promote perspiration, and, in large quantities, to prove intoxicating, and powerfully sedative. In many disorders, wine is universally admitted to be of important service, and especially in fevers of the typhous kind, or those called putrid; in which it is found to raise the pulse, support the strength, promote a diaphoresis, and improve the state of the blood; and in many cases it proves of more immediate advantage than the Peruvian bark. Delirium, which is the consequence of excessive irritability, and a defective state of nervous energy, is often entirely removed by the free use of wine. It is also a well-founded observation, that those who indulge in the use of wine are less subject to fevers of the malignant and intermittent kind,

In the malignant sore throat, in the small-pox, when attended with great debility and fever of the typhous kind, in gangrenes, and in the plague, wine is to be considered as a principal remedy; and in almost all cases of languor, and of great prostration of strength, wine is experienced to be a more grateful and efficacious cordial than can be furnished from the whole class of aromatics.

Wing. See *Ala.*

Winged. See *Alatus*, and *Pinnatus.*

Winter's bark. See *Drimys Winteri*, in the *Supplement.*

Winter cherry. See *Physalis alkekengi.*

WINTERA AROMATICA. The tree which produces the true Winter's bark: so named after Captain Winter, who brought the bark from the Straits of Magellan, in 1579. It is now referred to the genus *Drimys.* See *Drimys Winteri* in the *Supplement.*

WINTERANUS CORTEX. Winter's bark. See *Drimys.*

Winteranus spurius. See *Canella alba.*

Woad. See *Isatis tinctoria.*

Wolf's-bane. See *Aconitum napellus.*

Womb. See *Uterus.*

Womb, inflammation of. See *Hysteritis.*

WOOD. *Lignum.* The hard fibrous substance of which the stems and branches of trees are principally formed. See *Lignum*, in the *Supplement.*

Woodcock. See *Scolopax rusticola.*

Wood-louse. See *Oniscus asellus.*

Wood-sorrel. See *Oxalis acetosella.*

Woody nightshade. See *Solanum.*

WOOLFE'S APPARATUS. A series of glass receivers used in distillation, where it is desired to condense separately the products which come over.

Woolly. See *Lanatus.*

Worm. See *Vermis.*

Worm-bark. See *Geoffræa Surinamensis.*

Worm-grass, perennial. See *Spigelia.*

Wormwood, Tartarian. See *Artemisia.*

WORT. An infusion of malt. This has been found useful in the cure of the scurvy. From one to four pints daily have generally been directed. The proportion recommended in preparing it, is one measure of ground malt to three equal measures of boiling water. The mixture must be well stirred, and left to stand covered three or four hours. It should be made fresh every day.

Wort, St. John's. See *Hypericum.*

Wort, St. Peter's. See *Hypericum.*

Wort, mug. See *Artemisia.*

WOUND. (*Vulnus, eris.* n.) A solution of continuity in any of the soft parts of the body, occasioned by external violence. Wounds are distinguished into *incised*, *punctured*, *contused*, *lacerated*, and *poisoned.* Wounds heal by *adhesion*, or *the first intention* (see *Inflammation*), or by *suppuration*, *granulation*, and *cicatrisation.* See *Abscess.* Incised wounds, in healthy subjects, will generally heal by the first intention, if properl treated. Wounds attended with slight laceration, and punctured wounds, will sometimes do the same. Severe lacerated wounds, contused wounds, and poisoned wounds, never heal in this manner. The consideration of *gun-shot* wounds forms a particular department of surgery. They were erroneously considered by the old surgeons as poisoned wounds: they are, in reality, *lacerated* and *contused* wounds.

Woundwort. See *Laserpitium.*

Wrapper. See *Volva.*

Wrinkled. See *Rugosus.*

Wrist. See *Carpus.*

WRYNECK. *Torticollis. Caput obstipum.* A permanent inclination of the head towards one of the shoulders, not arising from distortion of the vertebræ. It most frequently arises from a contraction of the integuments of the neck from burns, or cicatrices from other causes; but sometimes from a permanent contraction of the sterno-mastoid or platysma myoides muscle. It has sometimes been cured by a division of the muscles and integuments, with proper attention after the operation.

X.

XALA'PPA. (From the province of Xalappa, in New Spain, whence it comes.) Jalap.

XANTHIC ACID. An acid discovered by Zeise: so named from the yellow precipitate it forms with the solutions of several metallic salts.

XANTHIC OXIDE. A substance found by Dr. Marcet, in a urinary calculus, which gives a yellow product with nitric acid.

XA'NTHIUM. (*um, i.* n.; from ξανθος, yellow: so named because it is said to make the hair yellow.) The name of a genus of plants in the Linnæan system. Class, *Monœcia*; Order, *Pentandria.* The lesser burdock.

XANTHIUM STRUMARIUM. The systematic name of the lesser burdock. This herb, as its specific name implies, was once esteemed in the cure of scrofula, but, like most other remedies against this disease, proves ineffectual. The seeds are administered internally in some countries against erysipelas.

XA'NTHOGEN. The name given by Zeise to the supposed radicale of the hydroxanthic acid, which acid, however, he subsequently found to be an oxyacid. See *Hydroxanthic acid*.

XANTHORRHŒ'A. (From ξανθος, yellow, and ῥεω, to flow, on account of the yellow gum which exudes from it.) A genus of plants of the tribe *Asphodelidæ*.

XANTHORRHŒA HASTI'LIS. The grass tree of New South Wales, formerly called *Acarois resinifera*. This plant produces the Botany Bay gum. All the information that has been hitherto collected respecting the history of the yellow gum is the following: — The plant that produces it is low and small, with long grassy leaves; but the fructification of it shoots out in a singular manner from the centre of the leaves, on a single straight stem, to the height of twelve or fourteen feet. Of this stem, which is strong and light, like some of the reed class, the natives usually make their spears. The resin is generally dug up out of the soil under the tree, not collected from it, and may, perhaps, be that which Tasman calls "gum-lac of the ground." Mr. Boles, surgeon of the Lady Penrhyn, gives a somewhat different account; and as this gentleman appears to have paid considerable attention to the subject, his account may certainly be relied upon. After describing the tree in precisely the same manner as above, he observes, that at the top of the trunk of the tree, long grassy leaves grow in great abundance. The gum is found under these leaves in considerable quantities: it commonly exudes in round tears, or drops, from the size of a large pea to that of a marble, and sometimes much larger. These are, by the heat of the sun, frequently so much softened, that they fall on the ground, and in this soft state adhere to whatever they fall upon: hence the gum is frequently found mixed with dirt, wood, the bark of the tree, and various other substances; so that one lump has been seen composed of many small pure pieces of various sizes united together, which weighed nearly half a hundred weight. It is produced in such abundance, that one man may collect thirty or forty pounds in the space of a few hours. The convicts have another method of collecting it: they dig round the tree, and break off pieces of the roots, which always have some, and frequently a considerable quantity of the gum in them. This gum appears nearly, but not entirely, the same as that which exudes from the trunk of the tree; the former is often mixed with a strong smelling resinous substance of a black colour, and is so interwoven in the wood itself, that it is with difficulty separated. The latter appears a pure unmixed resinous substance.

Several experiments have been made, principally with the view of determining what menstrum would dissolve the gum the most readily, and in the greatest quantity, from which it appears alkohol and ether dissolve the most.

The diseases in which this resin is administered are those of the primæ viæ, and principally such as arise from spasm, a debility, a loss of tone, or a diminished action in the muscular fibres of the stomach and bowels, such as loss of appetite, sickness, vomiting, flatulency, heart-burn, pains in the stomach, &c., when they are really idiopathic complaints, and not dependent upon any disease in the stomach, or affections of other parts of the body communicated to the stomach. In debilities and relaxations of the bowels, and the symptoms from thence arising, such as purging and flatulency, it has been found of good effect. In certain cases of diarrhœa, however (and it seemed those in which an unusual degree of irritability prevailed), it did not answer so well, unless given in small doses, and combined with opiates, when the patient seemed to gain greater advantage than when opiates only were had recourse to. In cases of amenorrhœa, depending on (what most of those cases do depend upon) a sluggishness, a debility, and flaccidity of the system, this medicine, when assisted by proper exercise and diet, has, by removing the symptoms of dyspepsia, and by restoring the tone and action of the muscular fibres, been found very serviceable. This medicine does not, in the dose of about half a drachm, appear to possess any remarkably sensible operation. It neither vomits, purges, nor binds the belly, nor does it materially increase the secretion of urine or perspiration. It has, indeed, sometimes been said to purge, and at others to occasion sweating; but they are not constant effects, and when they do occur, it generally depends on some accidental circumstance. It should seem to possess, in a very extensive degree, the property of allaying morbid irritability, and of restoring tone, strength, and action to the debilitated and relaxed fibre. When the gum itself is given, it should always be the pure unmixed part; if given in the form of a draught, it should be mixed in water with mucilage of gum-arabic; if made into pills, a small portion of Castile soap may be employed: it was found the lixiv. sapon. dissolved it entirely. It is commonly, however, made into a tincture, by mixing equal parts of the gum and rectified spirit; one drachm of this tincture (containing half a drachm of the pure gum) made into a draught with water and syrup, by the assistance of fifteen grains of gum-arabic in mucilage, forms an elegant medicine, and at the same time very palatable. Botany Bay gum soon solidifies by the heat of the sun, into pieces of a yellow colour, of various sizes. It pulverises easily without caking; nor does it adhere to the teeth when chewed. It has a slightly sweet, astringent taste. It melts at a moderate heat. When kindled, it emits a white fragrant smoke. It is insoluble in water, but imparts to it the flavour of storax. Out of nine parts, six are soluble in water, and astringent to the taste; and two parts are woody fibre.

XERA'SIA. (*a*, *æ*. f.; Χηρασια; from ξηρος, dry.) A disease of the hair, in which it becomes dry, ceases to grow, and has the appearance of wool covered with dust. — *Galen*.

XEROCOLLY'RIUM. (From ξηρος, dry, and κολλυριον, a collyrium.) A dry collyrium.

XEROMY'RUM. (From ξηρος, dry, and μυρον, an ointment.) A dry ointment.

XEROPHTHA'LMIA. (*a*, *æ*. f. Ξηρος, dry, and οφθαλμια, an inflammation of the eye.)

A dry inflammation of the eye, with diminished secretion of tears.

XI'PHIAS. (From ξιφος, a sword.) The generic name of the sword-fish.

Xiphias gladius. The sword-fish. In Sicily this is eaten as a delicacy.

XI'PHIUM. (From ξιφος, a sword: so named from the sword-like shape of its leaves.) The *Iris pseudacorus*.

XI'PHOID. (*Xiphoides*; from ξιφος, a sword, and ειδος, likeness.) Sword-like: applied to parts which have some resemblance to an ancient sword; hence xiphoid cartilage. See *Cartilago ensiformis*.

Xiphoid cartilage. See *Cartilago ensiformis*.

Xyloaloes. See *Lignum aloes*.

Xylobalsamum. See *Amyris gileadensis*.

XYLOSTRO'MA. (*a*, *æ*. f.; from ξυλον, wood, and στρωμα, a layer: so called because it forms indeterminate expansions, like cloth or leather, in the inside of the trunks or branches of trees.) The name of a genus of plants. Class, *Cryptogamia*; Order, *Fungi*.

Xylostroma giganteum. Oak-leather. This fungus is found in the cracks of oaks, and is used in Ireland as a dressing for ulcers, and in Virginia to spread plasters on.

Y.

YAM. See *Dioscorea*.

Yarrow. See *Achillea millefolium*.

YAWNING. (*Oscitatio, onis*. f.) A phenomenon too common to require description. The physiology of yawning is not very obvious. It is attended with a forced inspiration, and hence stimulates the weary frame by an increased aëration of the blood; but this evidently is not all, and the rest remains to be explained.

YAWS. The name of a disease which is endemic in Africa and elsewhere. See *Frambæsia*.

Yellow fever. See *Remittent fever*.

Yellow saunders. See *Santalum album*.

YELLOW-WASH. Red-wash. A lotion made by adding corrosive sublimate to lime-water, in the proportion of two grains to an ounce. A portion of the corrosive sublimate is decomposed, and peroxide of mercury thrown down. So that the wash contains undecomposed bichloride of mercury, and muriate of lime, mixed with peroxide of mercury. It is in common use as an application to venereal sores.

Yest. See *Fermentum*.

Yoked leaf. See *Conjugatus*.

Yolk. See *Vitellus*.

Yorkshire sanicle. See *Pinguicula*.

Ypsi'loglo'ssus. (From υψιλοειδες, the ypsiloid bone, and γλωσσα, the tongue.) A muscle originating in the os hyoides, and terminating in the tongue.

Ypsi'loi'des. (From υ, the Greek letter, called *upsilon*, and ειδος, a likeness.) The os hyoides: so named from its likeness to the Greek letter upsilon.

Y'TTRIA. An earth, discovered in 1794, by Professor Gadolin, in a mineral from Ytterby, in Sweden, since named *Gadolinite*, and found to consist of yttria, silica, and the oxides of iron and cerium. Yttria is of a white colour, insipid, and inodorous. Specific gravity 4·842. It is insoluble in water and in solutions of the pure alkalis, but soluble in solutions of the alkaline carbonates and in the acids. Like other earths it has a metallic base, called *yttrium*, which was discovered by Wöhler in 1828. Yttria is a compound of this substance with oxygen, probably in the proportion of one equivalent of each.

YU'CCA. (*a*, *æ*. f.; *Yucca*, *Yuca*, or *Jucca*, of the original inhabitants of America.) The name of a genus of plants in the Linnæan system. Class, *Hexandria*; Order, *Monogynia*.

Yucca gloriosa. Adam's needle. The roots of this plant are thick and tuberose, and used by the Indians instead of bread, being first reduced into a coarse meal. This, however, is only in times of scarcity.

Z.

ZACCHARUM. See *Saccharum*.

Za'ffran. (Arabic.) Saffron. See *Crocus sativus*.

ZAFFRE. Saffre. The residuum of cobalt after the sulphur, arsenic, and other volatile matters of this mineral have been expelled by calcination.

Zaibac. (Arabic.) Quicksilver.

Za'rza. (Spanish for a briar.) A name of the root called sarsaparilla. See *Sarsaparilla*.

ZE'A. (*a*, *æ*. f.; a name borrowed from the ancient Greeks, whose ζεια appears to have been some kind of *Triticum* or *Hordeum*, agreeing with this genus only as being a grain cultivated for the use of man.) The maize.

Zea mays. The systematic name of the

Indian wheat plant, the common maize, or Indian corn, a native of America, and cultivated in Italy and several parts of Europe, for its grain, which is ground for the same purposes as our wheat. See *Wheat*.

ZEDOA'RIA. (*a*, *æ*. f.) 1. Zedoary.

2. The pharmacopœial name of a species of *Kæmferia*. See *Kæmpferia rotunda*.

ZE'INE. A yellow substance, having the appearance of wax, obtained from maize, or Indian corn.

ZE'RNA. A name given by some barbarous Latin writers to an ulcerated impetigo.

ZERO. The commencement of a scale marked 0: thus we say the zero of Fahrenheit, which is 32° below the melting point of ice; the zero of the centigrade scale, which coincides with the freezing of water. The absolute zero is the imaginary point in the scale of temperature, when the whole heat is exhausted: the term of absolute cold or privation of caloric.

ZIBE'THUM. (*um*, *i*. n.; from *Zobeth*, Arabian.) *Civetta*. Civet. A soft, unctuous, odoriferous substance, about the consistence of honey or butter, of a whitish, yellowish, or brownish colour, sometimes blackish, contained in some excretory follicles near the anus of the *Viverra zibetha*, of Linnæus. It has a grateful smell when diluted, and an unctuous subacrid taste, and is thought to possess stimulating, nervine, and antispasmodic virtues.

Zig-zag. See *Flexuosus*.

ZIMO'ME. (From ζυμη, *fermentum*.) The name given by Taddey, an Italian physician, to one of the constituents of wheat. See *Gluten, vegetable*.

ZINC. (*Zincum*, *i*. n., a German word.) A metal found in nature combined with oxygen, carbonic acid, and sulphuric acid; and mineralised by sulphur. Native oxide of zinc is commonly called *calamine*. It occurs in a loose and in a compact form, amorphous, of a white, grey, yellow, or brown colour, without lustre or transparency. Combined with carbonic acid, it is called *vitreous zinc ore*, or *native carbonate of zinc*. It is found in solid masses, sometimes in six-sided compressed prisms, both ends being covered with pentagons. Its colour is generally greyish, inclining to black. It is often transparent. *Sulphate of zinc* is found efflorescent in the form of stalactites, or in rhombs. *Sulphuret of zinc*, or *blende*, is the most abundant ore.

Metallic zinc is of a bluish-white colour, somewhat brighter than lead; of considerable hardness, and so malleable as not to be broken with the hammer, though it cannot be much extended in this way. It is very easily extended by the rollers of the flatting mill. Its sp. gr. is from 6·9 to 7·2. In a temperature between 210° and 300° of F., it has so much ductility that it can be drawn into wire, as well as laminated.

When broken by bending, its texture appears as if composed of cubical grains. On account of its imperfect malleability, it is difficult to reduce it into small parts by filing or hammering; but it may be granulated, like the malleable metals, by pouring it, when fused, into cold water; or, if it be heated nearly to melting, it is then sufficiently brittle to be pulverised.

It melts long before ignition, at about the 700dth degree of Fahrenheit's thermometer; and, soon after it becomes red-hot, it burns with a dazzling white flame, of a bluish or yellowish tinge, and is oxidised with such rapidity, that it flies up in the form of white flowers, called the *flowers of zinc*, or *philosophical wool*. See *Zinci oxidum*. These are generated so plentifully, that the access of air is soon intercepted; and the combustion ceases, unless the matter be stirred, and a considerable heat kept up. The white oxide of zinc is not volatile, but is driven up merely by the force of the combustion. When it is again urged by a strong heat, it becomes converted into a clear yellow glass. If zinc be heated in closed vessels, it rises without decomposition.

When zinc filings are put into water and atmospheric air, admitted hydrogen is evolved, and the metal becomes incrusted with a grey matter, which has been regarded by some as a suboxide, but which is more generally believed to be a mixture merely of the oxide with metallic zinc.

When zinc is burned in chlorine, a solid substance is formed of a whitish-grey colour, and semitransparent. This is the only chloride of zinc, as there is only one oxide of the metal. It has been called *butter of zinc*, and *muriate of zinc*.

Blende is the native sulphuret of zinc. The mineral, vegetable, and most of the acids act upon zinc; much hydrogen gas is extricated, and salts are formed. The salts used medicinally are the sulphate and acetate. See *Zinci sulphas*.

Zinc, vitriolated. See *Zinci sulphas*.

Zinci acetas. See *Acetas zinci*.

ZINCI OXIDUM. *Zincum calcinatum*. Oxide of zinc. Flowers of zinc. *Nihil album; Lana philosophorum*. Throw gradually little pieces of zinc into a large deep crucible placed obliquely, and made of a white heat, another crucible being placed over it, so that the zinc may be exposed to the air, and that it may be frequently stirred with an iron spatula: take out directly the oxide which is formed from time to time; then pass the white and lighter part of it through a sieve. Lastly, pour water upon this, that a very fine powder may be formed, in the same manner as chalk is directed to be prepared. The properties of this oxide are analogous to those of the sulphate (except that it is hardly active enough to excite vomiting), if given in larger doses; but it is more precarious in its effects; and chiefly used at present as an external astringent.

ZINCI SULPHAS. *Zincum vitriolatum*. *Vitriolum album*. Sulphate of zinc. White vitriol. This occurs native, but not sufficiently pure for medicinal use. It is thus prepared in the pharmacopœia: — Take of zinc broken to little pieces, five ounces; diluted sulphuric acid, two pints. Pour gradually the diluted acid on the zinc, and when the effervescence is over, filter the solution through paper; then boil it down till a pellicle appears, and set it by to crystal-

lise. This preparation is given internally in the dose of from ℈ j. to ℈ ss. as a vomit. In small doses it cures dropsies, intermitting headachs, and some nervous diseases; and is a powerful antispasmodic and tonic. A solution of white vitriol is also used to remove gleets, gonorrhœas, and for cleaning foul ulcers, having an astringent or stimulant effect, according to its strength.

Zincum. See *Zinc.*

Zincum calcinatum. See *Zinci oxidum.*

Zincum vitriolatum. See *Zinci sulphas.*

Zincum vitriolatum purificatum. See *Zinci sulphas.*

ZINGI. An ancient name of the stellated aniseed. See *Illicium anisatum.*

ZI'NGIBER. (*Zingiberis, is.* f. *Zingiber, eris.* n. *Zingiberi*, indec. Ζιγγιβερις, of Dioscorides, a name which the Greeks seem to have taken from the Arabians, when they got the plant.) The name of a genus of plants, according to Roscoe. Class, *Monandria*; Order, *Monogynia.*

ZINGIBER ALBUM. Ginger-root when deprived of its radicles and sordes.

ZINGIBER NIGRUM. The root of the *zingiber officinale* is so called when suffered to dry with its radicles and the sordes which usually hang to it.

ZINGIBER OFFICINALE. The systematic name of the ginger plant. *Zingiber album; Zingiber nigrum; Zingiber commune; Zinziber; Amomum zingiber.* The white and black ginger are both the produce of the same plant, the difference depending upon the mode of preparing them. Ginger is generally considered as an aromatic, and less pungent and heating to the system than might be expected from its effects upon the organ of taste. It is used as an antispasmodic and carminative. The cases in which it is more immediately serviceable are flatulent colics, debility, and laxity of the stomach and intestines; and in torpid and phlegmatic constitutions to excite brisker vascular action. It is seldom given but in combination with other medicines. In the pharmacopœias it is directed in the form of a syrup and a tincture, and in many compositions ordered as a subsidiary ingredient.

Zinziber. See *Zingiber.*

ZIRCO'NIA. Zircon. An earth discovered in the year 1793, by Klaproth of Berlin, in the Zircon or Jargon, a gem first brought from the island of Ceylon; but also found in France, Spain, and other parts of Europe. Its colour is either grey, greenish, yellowish, reddish-brown, or purple. It has little lustre, and is nearly opake. Zircon is likewise found in another gem called the hyacinth.

Zircon is a fine white powder, without taste or smell, but somewhat harsh to the touch. It is insoluble in water; yet, if slowly dried, it coalesces into a semi-transparent yellowish mass, like gum-arabic, which retains one third its weight of water. It unites with all the acids. It is insoluble in pure alkalies; but the alkaline carbonates dissolve it. The metallic base of this earth, named *zirconium*, was discovered by Berzelius, in 1824.

ZIZA'NIA. (*a, æ.* f.; an ancient name, ζιζανιον, of the Greeks, synonymous with the *lolium*, of the Latins.) The name of a genus of plants in the Linnæan system. Class, *Monœcia*; Order, *Hexandria.*

ZIZANIA AQUATICA. The systematic name of a reed, the grain of which is much esteemed in Jamaica and Virginia. The Indians are exceedingly fond of it, and account it more delicious than rice.

ZI'ZYPHUS. The jujubes were formerly so called. See *Rhamnus zizyphus.*

ZO'NA. (From ζωννυμι, to surround.) The shingles. See *Erysipelas.*

ZOOCY'STUS. (*us, i.* m.; from ζωον, an animal, and κυστις, a cyst, or bladder: so called because it is an animal formed like a bladder.) A zoocyst, or animal formed of membranous cyst distended with an aqueous fluid.

ZOO'LOGY. (*Zoologia, æ.* f.; from ζωον, an animal, and λογος, a discourse.) That part of natural history which treats of animals.

ZOO'NIC. (*Zoonicus*; from ζωον, an animal.) Appertaining to an animal substance.

ZOONIC ACID. In the liquid procured by distillation from animal substances, which had been supposed to contain only carbonate of ammonia and an oil, Berthollet imagined he had discovered a peculiar acid, to which he gave the name of zoonic. Thénard, however, has demonstrated that it is merely acetic acid combined with animal matter.

ZOONO'MIA. (*a, æ.* f.; from ζωον, an animal, and νομος, a law.) The laws of organic life.

ZOOPHYTE. (*Zoophyton, i.* n.; from ζωον, an animal, and φυτον, a plant, because the animals so called have some external resemblance to plants.) A term which has been very vaguely applied in natural history, and which it would be well to discard altogether. Cuvier calls all the radiated animals zoophytes.

ZOOTOMY. (*Zootomia, æ.* f.; from ζωον, an animal, and τεμνω, to cut.) The dissection of animals.

ZO'STER. (From ζωννυμι, to gird.) A kind of erysipelas which goes round the body like a girdle.

ZU'CHAR. (Arabic.) Sugar.

ZUMATE. A compound of the zumic acid with a salifiable basis.

ZUMIC. (*Zumicus*; from ζυμη, leaven.) Belonging to leaven.

ZUMIC ACID. *Acidum zumicum.* An acid produced from vegetable substances which have undergone the acetous fermentation. Its claim to be considered as a distinct compound is doubtful. See *Nanceic acid.*

ZYGO'MA. (From ζυγος, a yoke: because it transmits the tendon of the temporal muscle like a yoke.) The cavity under the zygomatic process of the temporal bone and os malæ.

ZYGOMATIC. (*Zygomaticus*; from *zygoma.*) Belonging to the zygoma.

ZYGOMATIC PROCESS. An apophysis of the os jugale, and another of the temporal bone, are so called.

Zygomatic suture. *Sutura zygomatica.* The union of the zygomatic process of the temporal bone to the cheek bone.

Zygomaticus major. This muscle arises from the cheek bone near the zygomatic suture, taking a direction downwards and inwards to the angle of the mouth. It is a long slender muscle, which ends by mixing its fibres with the orbicularis oris, and the depressor of the lip.

Zygomaticus minor. This muscle arises a little higher up than the zygomaticus major, upon the cheek bone, but nearer the nose; it is much more slender than that muscle, and is often wanting. It is the zygomatic muscle that marks the face with that line which extends from the cheek bone to the corner of the mouth, which is particularly distinguishable in some persons. The zygomatic muscles pull the angles of the mouth up as in laughter, and from, in this way, rendering the face distorted, it has obtained the name of distortor oris. The strong action of this muscle is more particularly seen in laughter, rage, or grinning,

ZYGO'PHYLLUM. (*um*, *i.* n.; from ζυγος, a yoke, and φυλλον, a leaf.) Each leaf of most of this species is composed of a pair of leaflets, yoked as it were together.

Zygophyllum fabago. This plant, called also *Fabaginea*, *Fabago*, *Capparis portulago*, *Capparis fabago*, and *Peplios lutetianorum*, is a good bitter, and much used by the Syrians as an helminthogogue.

Zytho'gala. (From ζυθος, beer, and γαλα, milk.) A mixture of beer and milk, forming the old beverage known by the name of *posset-drink.*

ZZ. The ancients signify *Myrrh* by these two letters, from ζμυρνη, a name for it common amongst them. They have also been used for *Zingiber.*

SUPPLEMENT.

ABDOMINA'LES. An order of fishes which have the ventral fins behind the pectoral.

ACANTHA'CEÆ. A natural family of plants of which the genus *Acanthus* is the type.

ACA'NTHOPTERY'GII. (From ακανθα, a spine, and πτερυξ, a fin.) An order of fishes which have fins furnished with hard and pointed rays.

ACERA'CEÆ. *Acerineæ.* A natural family of plants, of which the genus *Acer* is the type.

ACETAS FERRI. A compound of acetic acid and oxide of iron. It is ordered by the Dublin College, and is a mild and efficacious chalybeate. It is seldom used.

ACIDUM HYDROCYANICUM DILUTUM. Diluted hydrocyanic acid. The London College, in the last edition of their pharmacopœia, have very properly introduced a formula for a diluted hydrocyanic acid adapted for medicinal use. The directions are as follows: take of ferrocyanide of potassium, two ounces; sulphuric acid, an ounce and a half; distilled water, a pint and a half. Mix the acid with four fluid ounces of the water, and to these when cool and put into a glass retort, add the ferrocyanide of potassium, first dissolved in half a pint of the water. Pour eight fluid ounces of the water into a cooled receiver; then, the retort being fitted on, let six fluid ounces of acid, distilled with a gentle heat in a sand bath, pass over into this water; lastly, add six more fluid ounces of distilled water, or as much as may be sufficient, that 12·7 grains of nitrate of silver dissolved in distilled water may be accurately saturated by 100 grains of this acid.

Diluted hydrocyanic acid may be also prepared when it is more immediately wanted, from forty-eight grains and a half of cyanide of silver, added to a fluid ounce of distilled water, mixed with thirty-nine grains and a half of hydrochloric acid. Shake all these in a well-stopped phial, and after a short interval pour off the clear liquor into another vessel. Keep this for use, the access of light being prevented. The dose is from ♏ ij. to ♏ vj. or viij.

ACIDUM SULPHURICUM AROMATICUM. Aromatic sulphuric acid. The Edinburgh and Dublin Colleges give the following formula for this medicine. Take of alkohol, two pounds; sulphuric acid, six ounces. Drop the acid gradually into the alkohol. Digest the mixture with a very gentle heat in a covered vessel for three days; then add cinnamon bark bruised, an ounce and a half; ginger root bruised, an ounce. Digest again in a close vessel for six days; then filter through paper placed in a glass funnel. This preparation has generally been regarded as an imperfect ether, but Dr. A. T. Thomson regards it as merely an alkohol solution of the acid and oils. It is a good form for exhibiting sulphuric acid as a tonic, and may be advantageously combined with the decoction of cinchona. The dose is from ten to thirty minims twice or thrice a day.

Aconitum anthora. See *Anthora.*

ACONITUM LYCOCTONUM. A species of aconite which has the same poisonous qualities as the *Aconitum napellus.*

AGA'VE. The name of a genus of plants. Class, *Hexandria;* Order, *Monogynia.*

AGAVE AMERICANA. The American aloe. This plant abounds in a saccharine sap, which flows freely from incision made in the root or leaves, and from this sap the Mexicans prepare the alkoholic liquor called pulque. An absurd belief used to prevail that the American aloe blossomed only once in a century. It flowers like any other plant.

A'LÆ INGRA'SSII. The lesser pterygoid processes of the sphenoid bone, are so named after Philip Ingrassias.

ALPI'NIA. A genus of plants named in honour of Prosper Alpinus. Class, *Monandria;* Order, *Monogynia.*

ALPINIA CARDAMO'MUM. The plant which produces the lesser or common cardamom seeds. It was formerly referred to the genus *Amomum,* and had also a genus made for it under the name of *Matonia,* in honour of the late Dr. Maton. It is an East Indian plant, growing to the height of about twelve feet. Cardamom seeds have an agreeable aromatic flavour, which they owe to an essential oil. They yield their active matter to alkohol and ether, and less perfectly to water. They are in constant use as a stomachic and carminative, and enter into many officinal preparations. The dose of the powdered seeds is from five to twenty grains, but they are generally given in the form of the compound tincture. See *Tinctura cardamomi compositi.*

AMBULANCE. A movable hospital attached to the French armies, provided with everything necessar for the care of the wounded.

Amydaline. *Amygdalina.* A crystallisable principle found by MM. Robiquet and Boutron Charlard in the bitter almond.

Anacardium orientale. The plant which produces the Malacca bean, nearly resembling the Cashew nut.

Anæmia, partial. An account of the disease called anæmia, or bloodlessness, as it affects the whole system, has already been given in the article *Anæmia.* M. Andral has described certain local or partial forms of anæmia, which he has particularly observed in the brain, heart, liver, stomach, intestinal canal, and some of the voluntary muscles. The causes of partial anæmia are referred by M. Andral, 1. To diminution of a principal artery. 2. To certain states of the nervous system. 3. To hyperæmia, or sanguine plethora of other organs. 4. To a previous hyperæmia of the organ affected with anæmia. Lastly, in some cases the state of anæmia exists in particular organs, without our being able to trace it to any of the above causes.

ANANA'SSA. The name of a genus of plants. Class, *Hexandria*, Order, *Monogynia*; so named from the Peruvian word *Nanas*, a pine-apple.

Ananassa sativa. Formerly called *Bromelia ananas.* The pine-apple, generally considered the finest flavoured of all fruits. In tropical countries the pine-apple has been considered medicinal in diseases of the kidneys.

Andra'chne. *Adrachne.* Ανδραχνη. Αδραχνη. A name which has been given to a variety of plants, but chiefly to the *purslane* — *Portulaca oleracea* of Linnæus.

Antimonii potassio-tartras. The name given by the London College of Physicians in the recent edition of their pharmacopœia, to the emetic tartar, *antimonium tartarizatum* of the former pharmacopœia.

Aqua vitriolica camphorata. *Aqua camphorata.* Camphorated water. Take of white vitriol, Armenian bole, of each four ounces; camphor, an ounce; and powder them together. Sprinkle this powder, one ounce at a time, into four pounds of boiling water, and stir it briskly: then take it off the fire, and filter off the clear liquor. A preparation formerly much used as a detergent to ulcers and a collyrium in chronic ophthalmia.

Aqua naphæ. Orange-flower water.

Anomalies of organization. The expression used by M. Isidore Geoffroy de St. Hilaire, for what are generally called monsters. See *Monsters.* The study of these anomalies he calls *Teratology.* See *Teratology.* Various classifications of monsters have been published, from that of Fortunius Licetus, in his work *De Monstrorum Causis, Naturâ, et Differentiis*, first printed in 1616, to that of M. Breschet, in the article *Déviation Organique*, in the *Dictionnaire de Médecine.* The latter has been generally adopted in the present day; but the work of M. Isidore G. St. Hilaire, which has been recently completed, contains the most philosophical and extended classification of monsters, as well as the most ingenious views and elaborate investigation of the subject that have yet appeared. It was intended to have given a tabular view of his system, but the size to which the present edition of this Dictionary has grown, and the necessity for its immediate publication, oblige us to omit it, and refer the reader to M. St. Hilaire's work, entitled *Histoire Générale et Particulière des Anomalies de l'Organization chez l'Homme et les Animaux*, the first volume of which was published at Paris in 1832, and the last in 1836.

Aqua labyrinthi. A fluid contained within the labyrinth of the ear. See *Auris.*

Arbor saturni. Lead tree. If a piece of zinc be suspended in a solution of acetate of lead, metallic lead is deposited in an arborescent form upon the zinc. This is called *arbor saturni*, or the lead tree.

Arcus senilis. *Gerontoxon*, or more properly, *gerontotoxon. Leucoma gerontoxon.* An arched or circular opacity of the cornea, generally of a whitish colour; mostly found at the circumference of the cornea with a pellucid circle in the centre, and hence not impeding vision. — *Sauvages.* It occurs in old persons, and cannot be removed.

ARMENI'ACA. The name of a genus of plants. Class, *Icosandria*; Order, *Monogynia*: detached from the genus *prunus*, and called *Armeniaca*, because it was originally brought from Armenia.

Armeniaca vulgaris. *Prunus Armeniaca.* The apricot, a fine-flavoured and wholesome fruit, but less juicy than the peach or nectarine. There are very numerous varieties of the apricot.

Arteria centralis retinæ. A very small branch of the ophthalmic artery, which penetrates the substance of the optic nerve, and runs embedded within it till it arrives at the retina, on the internal surface of which it is dispersed in numerous minute branches. One branch passes through the vitreous humour to the posterior surface of the capsule of the crystalline lens.

Astakillos. *Araneum.* Names given by Paracelsus to a gangrenous ulceration of the feet and legs.

ATA'XO-ADYNA'MIC. (*Ataxo-adynamicus*; from αταξια, disorder, and αδυναμια, debility.) A term applied by the French to typhus fever — *fièvre ataxo-adynamique.*

Balsam of liquorice. A nostrum which, according to Dr. Paris, consists principally of Paregoric elixir, very strongly impregnated with oil of anise.

Baynton's adhesive plaster. This consists of six drachms of resin, melted with a pound of lead plaster.

Baynton's bandage. This consists in the application of strips of adhesive plaster round the leg in regular order, one above the other, and with their edges in contact. It is of the greatest use in indolent ulcers of the leg, and acts, both by approximating the edges of the ulcers to each other, and by its uniform pressure on the neighbouring parts.

Bellows sound. *Bruit de soufflet.* A sound resembling that which is produced by the action of a pair of bellows. It is heard in cases of enlargement of the heart, or contraction of its orifices. It is rarely constant, but ceases and

returns abruptly, often without any apparent cause. It sometimes exists in a heart that is perfectly healthy, especially in hysterical or highly nervous subjects. The same sort of sound, only sharper and more whizzing, is heard in different arteries, often without any assignable cause. It is always loud and distinct in cases of aneurismal varix. When the bellows sound, as heard at the heart, becomes somewhat rough to the ear, it passes into what is called the *rasp sound*. See *Rasp sound*.

BI'MANA. (From *bis*, twice, and *manus*, a hand.) An order of the class *Mammalia*, formed to receive the genus *homo*, man being the only animal that has two hands and no more, for all the other animals which have hands, as the monkeys, have in reality four hands, the lower pair of which are vulgarly called the feet.

Black drop. See *Gutta nigra*.

Boerhaave's red pill. A nostrum, the basis of which is cinnabar.

Boletus laricis. *Agaricus albus.* The agaric of the larch. It grows parasitically on the larch tree. The internal part of the fungus is light and friable, and has been used as a drastic purgative in the dose of one or two drachms in powder.

BONPLA'NDIA. (So named after M. Bonpland.) A genus of plants. Class, *Pentandria*; Order, *Monogynia*. The plant which produces the Angustura bark. It was formerly called *Cusparia febrifuga*. It is a lofty tree, growing in the forests of South America. The bark called *Angustura bark* and *Cortex cuspariæ*, is brought to Europe in flat pieces, gray and wrinkled externally, and yellowish brown and smooth within. Its taste is bitter and slightly aromatic. Water, assisted by heat, extracts its virtues, which do not appear to be dissipated by decoction. Proof spirit takes up all its active matter. It was originally introduced in the West Indies as a febrifuge, in which character it has failed. It is however a good tonic bitter, and has been found useful in typhoid fevers, chronic dysentery, &c. It may be given in powder in the dose of from ten to twenty grains. An infusion made with two drachms of the bark, to half a pint of water, may be exhibited in the dose of from one to three ounces three or four times a day. The Edinburgh College orders a tincture made with two ounces of the bruised bark to two pounds and a half of proof spirit: the dose is one or two drachms.

A few years since, Angustura bark got into undeserved disgrace from a spurious and poisonous bark being imported along with it, and mistaken for it. See *Brucea pseudo-ferruginea*, and *Brucia*.

Brodum's nervous cordial. A nostrum said by Dr. Paris to consist of gentian, columba, cardamom, and cinchona, with compound spirit of lavender and wine of iron.

Bro'ncho-hæmorrha'gia. (From *βρογχος*, the wind-pipe, and *αιμορραγια*, a flow of blood.) A term applied by M. Andral to an exudation of blood from the bronchial membrane, as opposed to *pneumo-hæmorrhagia*, or hæmorrhage from the rupture of vessels in the lungs.

Bruit de frottement. See *Friction, sound of.*

Bruit de rape. See *Rasp sound.*

Bruit de soufflet. See *Bellows sound.*

Bu'tea frondo'sa. An East Indian leguminous plant, which yields a red astringent gum, which has been reckoned as a species of kino.

CALOPHY'LLUM. (From *καλος*, beautiful, and *φυλλον*, a leaf.) A tropical genus of plants, distinguished for the beauty of their leaves. Class, *Polyandria*; Order, *Monogynia*. The *Calophyllum inophyllum*, *tacamahaca*, *calaba*, and *spectabile*, afford a kind of tacamahaca, called *Mauritius tacamahaca*. They also yield an oil used for burning. That of C. *Calaba* is called *Oleum sanctæ Mariæ*, and is used also for the table.

CAMBO'GIA. (From Kamboja, a river of Siam, on the banks of which the tree that affords the gum grows.) Gamboge. A well known gum-resin, extensively used as a yellow pigment, and employed also in medicine. It has generally been thought to be the produce of the *Stalagmites cambogioides*; but there is reason to believe that the best is procured from a species of *Garcinia*, named accordingly *Garcinia cambogioides*. Several species of *Stalagmites*, however, as the *S. pictorius*, *cambogioides*, *Cochinchinensis*, and *elliptica*, afford a gum-resin differing very little from the genuine gamboge, and often substituted for it. Gamboge is obtained both by breaking the leaves and young shoots of the plants, and from incisions in the bark. According to M. Braconnot, gamboge contains one part of cerasine and four of resin. It is not known on what its cathartic power depends. Gamboge is a drastic, irritating, and hydragogue purgative, acting frequently also as an emetic. As a hydragogue it is best given along with bitartrate of potash, which both assists and mitigates its action. It is given as an anthelmintic combined with calomel. As a purgative merely, it is usually combined with rhubarb, or aloes, and aromatics. The *Pilula cambogiæ composita* of the pharmacopœia, is a convenient form for its administration. The dose of gamboge, in substance, is from two to six grains.

Ce'ntrum semicircula're ge'minum. The name given by Vieussens to the small band of medullary substance in the brain, more generally called *Tænia semicircularis*, which see.

Ce'ruline. *Ceruli'na.* If indigo be dissolved in concentrated sulphuric acid, and potash added to the solution, a substance of an intensely blue colour is precipitated. This consists of sulphate of potash, combined with a peculiar colouring matter, which, according to Berzelius, does not saturate any portion of the acid, but stands related to the salt in the same manner as water of crystallisation. The blue colouring matter of this salt is called *ceruline*. Mr. Crum first discovered the nature of this and similar salts, which he named *cæruleo-sulphates*.

Cerusse of antimony. *Cerussa antimonii.* An old preparation, made by throwing into a crucible heated to a white heat, a mixture of one part of regulus of antimony and two of nitre, in successive portions, and then washing

the product with water to abstract the saline matter. The result is an oxide of antimony, which was given as a diaphoretic in the dose of from ten grains to a drachm.

Cetra'ria isla'ndica. The name now given to the species of liver-wort, formerly called *Lichen Islandicus*, or *Iceland moss*. It was formerly extolled as a specific in phthisis. Its real virtues are those of a mucilaginous demulcent, with a slight bitter and tonic property. It is given in the form of decoction. See *Decoctum lichenis*.

Chin cough. Kin cough. (According to S. Johnson, from the Dutch *kinken*, to pant or cough.) An old popular name of the hooping cough.

Chittick's remedy for stone. A fixed alkali dissolved in veal broth. A remedy in vogue half a century ago.

Chloro'xylon vertacilla'tum. A Peruvian plant which affords a green balsam.

Chymia'ter. The same as Iatrochemist. See *Iatrochymicus*.

Cinnabar of antimony. This name was given to the cinnabar formed during an old process for making butter of antimony, in which the muriate of mercury was employed. The cinnabar had no antimony in it, but was common cinnabar or sulphuret of mercury.

Citrate of ammonia. A salt formed by neutralising the sesqui-carbonate of ammonia with citric acid. It is a light diaphoretic.

Citrus limetta. The plant which produces the lime, a fruit resembling a small lemon. The juice has a very fine flavour, varying much in the different varieties.

Citrus paradi'si. The plant which produces the Paradise apple or forbidden fruit, so called from a whimsical notion that it was the fruit with which Eve was tempted. It somewhat resembles the shaddock.

Clairvoyance. The French name for one of those states produced by the imaginary agent called animal magnetism. See *Magnetism, animal*.

Colchi'cia. This name has been given to the alkali supposed to be the active principle of *colchicum*. Veratria was formerly believed to be the active principle of colchicum, as well as of the veratrum, but, according to Geiger and Hesse, this is an error.

Cold cream. *Ceratum Galeni*. This is generally made by melting together a pound of almond oil, and four ounces of white wax, pouring them into a warm mortar, and adding by degrees a pint of rose water. It is a common application to chapped lips, &c.

Confectio archi'genis. A Greek medicine, the same with the *Antidotus Paulina* of Aristarchus. See *Aristarchi Antidotus Paulina*.

Coria'ria myrtifo'lia. A poisonous plant, the leaves of which are used in tanning. In France fatal results have followed from the adulteration of senna with these leaves.

CO'RMUS. (*us*, *i*. m. Κορμος.) Properly a trunk or stem, but now generally applied in *Botany* to a solid bulb, as that of the *colchicum*.

Co'rnua sphenoida'lia. *Ossicula Bertini*. The *ossa triangularia* attached to the sphenoid bone.

Cotyle'don umbili'cus ven'eris. *Cotyledon umbilicus*. Navel-wort. The leaves of this plant have been esteemed emollient, and have been used as an external application to piles.

Cou'marine. A concrete volatile substance which constitutes the odoriferous principle of the Tonka bean. See *Dipterix odorata*.

Creasote. In conformity to usage, this word has been thus spelled in the present work, but it ought to be *creatosote*, the genitive of κρεας being κρεατος.

Cri de cuir. See *New leather sound*.

Crim evil. A disease believed to be endemic in the Crimea, though Guckenberger denies its existence in that country, and asserts its frequency in Astrachan. It seems to be allied to tubercular elephantiasis, and, like it, is intractable and fatal. It commences with fever and violet-coloured tumefaction of the face, followed by red spots or patches on the extremities and various parts of the body.

Davy's safety lamp. See *Carburetted hydrogen*.

DEVE'LOPMENT. The term development is sometimes used synonymously with *growth*, but it is highly necessary to correct physiological reasoning that they should be discriminated. The following observations on this subject are translated from the work of M. Isidore Geoffroy St. Hilaire on the anomalies of organisation: —

In that series of phenomena, hitherto so little observed, but in reality so worthy of attention, which, in a certain number of years, mark the transition from infancy to youth, and from this to adult age, we should carefully distinguish those connected with simple *growth* of the frame, from those which characterise its *development*. Growth results from the gradual augmentation of all parts of the body, quite independently of their number, structure, or functions: development, on the contrary, consists essentially in a modification, — a change more or less obvious. In simple growth, all the previous conditions of organs are preserved, except their volume: every true development, on the contrary, may be compared to the metamorphoses of the fœtus, though the changes be less extensive and remarkable. The first appearance of the deciduous teeth, that of the permanent teeth, and the period of puberty, are the three principal epochs of development in man, and the animals most nearly allied to him. After each of these, the general growth is usually more or less retarded. Thus, the growth is extremely rapid till the appearance of the first set of teeth; somewhat less so from this time till the appearance of the second set; and still a little less till the period of puberty; after which it undergoes a remarkable diminution. When, indeed, the individual has attained complete puberty, — that is to say, perfect aptitude for the generative functions, — the increase of stature becomes almost insensible, or is entirely arrested.

Growt and development, although essen-

tially distinct, have nevertheless a very intimate relation to each other. A certain degree of growth of the whole frame induces a new development, and every development, in its turn, indicates the termination of one period of growth, and the commencement of another, in which the growth proceeds more slowly; as if the apparatus newly developed had appropriated, and concentrated in itself, a great part of the formative energy, which was before more equally distributed among all the organs; or, (in more exact terms, and banishing the abstract phraseology too long used by anatomists,) because the apparatus newly developed necessarily diminishes the activity of the general nutrition, by the increased activity of its own.

These observations apply universally, as well to the earlier periods of development, as to that of puberty. If an infant is remarkable for the rapidity of its growth, and surpasses the ordinary dimensions at the age of two, three, or four months, the teeth almost always speedily appear; and it has even been sometimes observed, that, in very large children, the development of the teeth has preceded birth, or followed it almost immediately. On the other hand, where the general growth of an infant is unusually slow, there is almost always a corresponding retardation of the dentition.

The same remarks hold good with respect to the second dentition as the first; and a comparison of the different species of animals most nearly allied to man in their organisation, discovers the same constant relation between the rapidity of the general growth and the protrusion of the deciduous and permanent teeth. But it is especially between puberty and the general growth that an intimate and very remarkable relation subsists. It may be stated, in a general way, that very precocious growth induces also premature puberty, while complete puberty, in its turn, puts a stop to the general growth. Thus we find, as it were, a circle formed by a series of remarkable phenomena, of which one, resulting from that which precedes it, reacts upon the latter, and causes its cessation.

Dipsacus fullo'num. *Dipsacus sativus.* Fuller's teazle. The root of this plant is somewhat bitter. In France it passes for a diuretic and diaphoretic.

Dipsacus sylvestris. *Labrum veneris.* Wild teazle. The root has been esteemed antiscorbutic.

DI'PTERIX. A genus of plants of the Class *Didelphia*, and Order *Octandria*.

Dipterix odorata. The tree which produces the *Tonka*, or *Tonquin bean*. It is a large and fine tree, growing in the forests of Guiana, and is called by the natives *coumarou*. The wood has been used medicinally, with the same intentions as guaiacum. The beans contain a peculiar principle, named *Coumarine*. See *Coumarine*. They are used in this country to scent snuff, and in the West Indies and America are put into chests of clothes to preserve them from insects.

DRI'MYS. A genus of plants of the Class *Dodecandria*, and Order *Monogynia*.

Drimys Winteri. The plant which produces the Winter's bark, which was found very useful in curing scurvy among the crew of Captain Winter, who accompanied Drake in his voyage round the world. The bark was introduced into Europe by Captain Winter, in 1579. It has also been called *cortex Magellanicus*, because Winter brought it from the straits of Magellan. It is in long quills, somewhat thicker than those of cinnamon. It has a warm, aromatic, bitterish taste, and a pleasant spicy odour. The *canella alba*, or false Winter's bark, is often confounded with the true. The canella has very similar properties to the Winter's bark, and has now generally superseded it.

DYSENTERY. The view taken of this subject in the body of the work is somewhat antiquated; and the editor would gladly have supplied a new article had time permitted. One error in particular requires to be noticed. Dysentery is there spoken of as generally a contagious disease, whereas, in the present day, nobody believes it to be so, except when it occurs epidemically, in connexion with contagious fever.

EMBALMING. *Balsamatio. Conditura cadaverum.* A process by which a dead body is rendered capable of resisting putrefaction, and retaining its form and consistence, for an indefinite period of time. A body so prepared is called a *mummy*. The ancient Egyptians excelled all other people in the art of embalming.

Several processes were in use among them, which were costly or cheap, according to the circumstances of the deceased. These processes are learnedly descanted on by Mr. Pettigrew, in his excellent "History of Ægyptian Mummies," to which we refer the curious reader. Mummy was at one time a very prominent article of the Materia Medica. See *Mummy*.

ENTO'PHYTA. (From ἐντος, within, and φυτον, a plant.) Parasitical fungi growing on the surface, or within the substance, of other plants.

Epipastic silk. Vesicatory silk. Several preparations are sold under these names as substitutes for the common blister; they consist of some preparation of cantharides, spread on silk, and have no advantage over the blister plaster in common use.

Essence of sarsaparilla, compound. A preparation lately invented, which appears to possess all the virtues of the compound decoction in a concentrated form. Half an ounce of it is equal to about half a pint of the ordinary compound decoction. It is given diluted with water.

ETIOLA'TION. (From the French *étiolement.*) That state of plants in which they are pale and watery from the privation of light. It is sometimes applied also by medical writers to paleness of complexion in the human subject, arising from the same cause, or from chronic diseases.

EUCALY'PTUS. The name of a genus of plants. Class, *Icosandria*; Order, *Monogynia*.

EUCALYPTUS RESINI'FERA. This species, which, as well as the others, grows in New South Wales, produces a gum resin which resembles kino, and is said to be equally efficacious.

EVERLASTING PILLS. Pills made of metallic antimony, which are intended to purge; but they must be nearly inert, since they can have no activity but from the slight degree of oxidation they may receive in the alimentary canal.

EXOSMO'SIS. (From εξω, without, and ωσμος, impulsion.) The passage of liquids through the membranes of the living body from within outwards. The opposite of *endosmosis*.

EXTROVE'RSION. *Extroversio. Ecstrophia.* That kind of malformation in which a part is turned wrong side outwards. This occurs principally with reference to the urinary bladder. In the case called extroversion of the bladder, there is a congenital defect of the anterior part of the organ, and of the corresponding portion of the abdominal parietes, so that the internal or mucous surface of the bladder projects in the form of a red tumour above the pubes, in which two papillæ are observed, which are the orifices of the ureters.

Flores martiales. See *Ferri ammonio-chloridum.*

FLUCTUATION PÉRIPHÉRIQUE. A mode of detecting effusion of fluid within the abdomen lately introduced by M. Tarral. It consists in placing both hands on the abdomen, two or three inches apart, and with the two fore-fingers parallel, and then slightly striking the abdomen with the fore-finger of the right hand: this produces an undulation of the fluid, which is readily felt by the fore-finger of the left hand. The same result is obtained if the right hand be quite raised in giving the stroke, provided it be given obliquely as if brushing the surface. —*Piorry, Du Procédé Opératoire.*

Frémissement cataire. See *Purring tremour.*

FRIARS' BALSAM. The compound tincture of benzoin.

FRITILLA'RIA. A genus of plants. Class, *Hexandria;* Order, *Monogynia.*

FRITILLARIA IMPERIALIS. The crown imperial. A plant which grows wild in this country, and is also cultivated in gardens. The bulb has been used externally as a resolvent.

GALACTODE'NDRON U'TILE. The *Palo di Vaca*, or cow tree of South America. It belongs to a genus allied to *Brosimum*. The generic name is derived from γαλα, milk, and δενδρον, a tree, and is applied to this tree because it yields, when tapped, an abundance of white liquid, which is wholesome and nutritious, and is used as milk.

GA'LBANUM. The umbelliferous plant which produces the gum resin called galbanum was formerly referred to the genus *Bubon;* but it has lately been constituted a distinct genus on the authority of Mr. Don, who calls the plant *Galbanum officinale*. It is a native of Persia. The gum resin, as we receive it, is in ductile masses, composed of whitish tears, agglutinated by a pale brown substance. When it is of dark brown or blackish colour it is considered bad. All the specimens are generally mixed with stalks, seeds, and impurities. It agrees in its general properties with the gum resins, and its proper menstruum is proof spirit, which dissolves it slowly, but entirely. Galbanum possesses nearly the same medicinal qualities as assafœtida, but in an inferior degree. The dose is from ten grains to half a drachm, in the form of pills, or triturated into an emulsion with gum-arabic and water. It enters into several officinal preparations, as the *Pilulæ galbani compositæ*, *Emplastrum galbani*, &c.

GALIPE'A. The tree which produces the Angustura, or cusparia bark, is now referred by some botanists to a new genus, under the name *Galipea cusparia*. See *Bonplandia trifoliata.*

GARDE'NIA. A genus of plants of the Class *Pentandria*, and Order *Monogynia*. The roots of the *Gardenia dumetorum* are said by Ainslie to be emetic. The *Gardenia gummifera* affords the East Indian elemi, which exudes from its leaves and bark.

GAROTILLO. The name given to the malignant sore throat by the Spanish writers who first described it. See *Tonsillitis.*

GENERAL ANATOMY. The anatomy of the common textures of which the body is composed, as distinguished from *descriptive anatomy*, which regards the situation, shape, size, colour, connexions, and distribution of parts, without reference to the particular characters of the textures of which they are composed. General anatomy was first established as a distinct branch of the science by Bichat. See *Texture.*

HE'LIX. A class of molluscous animals of the Order *Pulmonea*. The snail. Several varieties of this animal have obtained reputation in the cure of phthisis, atrophy, &c. They were made into a decoction with milk or water, and seem to be in reality very nutritious. They are never used in the present day.

HENBANE OF PERU. An old name of tobacco.

HIPPO'MANE. A genus of plants of the Class *Monœcia*, and Order *Monadelphia.*

HIPPOMANE MANCINELLA. The manchineel tree. The milky sap is very acrid and poisonous, blistering and sphacelating the skin when applied to the surface of the body, and causing death when swallowed, or inserted into a wound. The Indians use it to poison their arrows. It has been generally asserted that a deleterious exhalation proceeds from this tree, which renders it dangerous to remain under its shade. MM. Jacquin and Ricord have, however, remained under the shade of the manchineel for several hours, and passed through forests of these trees without experiencing any bad effect.

HIPPO'MANES. (Ἱππομανες, from ἱππος, a horse, and μαινομαι, to rage.) A name given by the ancients, 1. To a poisonous herb said to drive horses mad if they ate of it.

2. To the fluid which drops from the genital organs of the mare when desirous of the horse.

3. To masses of a gelatinous matter which

are found floating in the fluid of the allantois in mares. Great magical virtues were attributed to this substance, and it was much used in philtres or love potions.

HOOPER'S PILLS. These are said by Dr. Paris to be composed of the aloes and myrrh pill, with sulphate of iron, canella alba, and a portion of ivory black.

HYGIE'NE. The definition of this term given in the body of the work is faulty, but escaped the attention of the editor. Hygiene means that branch of medicine which relates to the preservation of health.

HYMENO'LOGY. (*Hymenologia*, from ὑμην, a membrane, and λογος, a discourse.) That branch of anatomy which treats of membranes.

HY'STERA-PE'TRA. (From ὑστερον, the womb, and πετρα, a stone.) The ancient name of a stone which was said to resemble the uterus in shape, and supposed to act as an emmenagogue when bound on the thigh.

INHALATION. The drawing in of vapours or gases along with the breath. This is practised with a view to the immediate effect of certain substances on the mucous membrane of the air-passages. The vapours of the following substances have been employed in this way, by means of a simple contrivance called an *inhaler*, of which there are several modifications, unnecessary to be described here.

1. *The steam of hot water.* This is often very useful in slight cases of bronchitis, and sometimes allays the cough in phthisis. Various emollient substances have been added to the water, but these have little or no effect. Narcotic substances, as opium, the seeds of henbane, &c., have also been used to medicate the water, and a slight tincture of their virtues seems to be communicated to the steam, as they often produce drowsiness, and have more effect in allaying irritation than the simple vapour of the water. In slight inflammatory sore throat, the vapour of hot water gives great relief, and may be advantageously conjoined with a little vinegar.

2. *Tar vapour.* This was highly extolled by Sir Alexander Crighton as a remedy for phthisis, in the cure of which disease, however, it has entirely failed, as might have been anticipated. In chronic bronchitis this remedy has in many cases proved eminently useful, and the cases of supposed phthisis which have been cured by it have doubtless been of this nature. The vapour is procured by heating tar over a spirit lamp, having previously added a little carbonate of potash, to neutralise any pyrolygneous acid which the tar may contain.

3. *Chlorine gas.* This has been much extolled in France of late years, in the cure of phthisis. In England no such success has attended its use; it has, however, been found extremely serviceable in allaying dyspnœa. The inhalation should be continued for five or six minutes at a time, several times a day. In some cases it will not answer at all, but increases cough and irritation. The mode of exhibiting this remedy is to pour five drops of a saturated aqueous solution of chlorine into a proper glass inhaler, containing water at 86° Fahr., and let the patient inhale the vapour of the chlorine, along with that of the water. The quantity of the solution of chlorine may be gradually increased to forty drops.

4. *The vapour of iodine.* This also has been recommended in phthisis, but it appears to have less efficacy than chlorine. Its most obvious operation, is that of increasing the bronchial secretion.

5. Oxygen and hydrogen gases have been employed in the cure of asthma and phthisis; and carbonic acid, and nitrous oxide, in the latter disease. They are now deservedly discarded.

INTERCALARY DAYS. *Dies intercalares. Dies intercedentes. Dies provocatorii.* Those days in the course of a fever in which there is an attempt at a crisis, which is seldom perfect or salutary; as the third, fifth, ninth, thirteenth, and nineteenth. See *Critical days.*

IPECACUANHA LOZENGES. These are made of ipecacuan, sugar, and mucilage of tragacanth. The proportion of ipecacuan is a quarter of a grain in some, and half a grain in others. They afford a very convenient means of exhibiting small doses of ipecacuan to act upon the bronchial membrane.

JESSOP'S WELL. A spring four miles from Epsom, in Surry. The water is sulphureous, and resembles that of Harrogate.

JUNIPERUS OXYCEDRUS. *Juniperus phœnicea.* Berry-bearing cedar. The wood of this plant yields by distillation the fetid oil called *huile de cade.* The substance called American olibanum exudes from this species of juniper.

LAC LUNÆ. A name of the agaric mineral.

LAC VIRGINEUM. *Lac virginis.* A name given, 1. To the *mercurius philosophorum*, a substance much talked of by the alchemists.

2. To an old preparation made by dissolving litharge, cerusse, and camphor, in vinegar, with the addition of water of solanum, of white lily, and of lettuce. It was named from its milky appearance, and its use by young women as a cosmetic.

3. To a mixture of the alkoholic solution of a balsam with water, by which the benzoic acid and the resin of the balsam are precipitated, and a milky appearance thus given to the mixture.

LAMBDOIDES OS. The os hyoides.

LAPIS SPECULARIS. An old name of selenite or sparry gypsum, formerly used as a remedy for epilepsy and other diseases.

LIGNIN. The woody fibre which constitutes the fibrous structure of vegetable substances, and is the most abundant principle in plants. The different kinds of wood contain about 96 per cent. of lignin. It is prepared by digesting the sawings of any kind of wood successively in alkohol, water, and dilute muriatic acid, until all the substances soluble in the menstrua are removed.

Lignin has neither taste nor odour, undergoes no change by keeping, and is insoluble in alkohol, water, and the dilute acids. By digestion in a concentrated solution of pure potash, it is converted, according to M. Braconnet, into a substance similar to ulmin. Mixed with strong sulphuric acid it suffers decomposition,

and is changed into a matter resembling gum; and on boiling the liquid for some time the mucilage disappears, and a saccharine principle like the sugar of grapes is generated. M. Braconnot finds that several other substances which consist chiefly of woody fibre, such as straw, bark, or linen, yield sugar by a similar treatment. (An. de Ch. et de Ph. vol. xii.) Digested in nitric acid, lignin is converted into the oxalic, malic, and acetic acids.

The ligneous fibre was found by Gay-Lussac and Thenard to consist of carbon 51·43, oxygen 42·73, and hydrogen 5·82. According to Dr. Prout it contains 50 per cent. of carbon. — *Turner.*

Liquor anodynus vegetabilis. A mixture of equal parts of acetic ether, and highly rectified spirit of wine.

Longitudinal sinus, inferior. The small sinus situated at the lower margin of the falx cerebri. It receives the blood from the falx, and from the corpus Callosum and adjacent parts of the brain, and discharges it into the *torcular Herophili.*

Luz. *Lus.* The name of a bone in the human body, much celebrated in Rabbinical writings. It was supposed to be indestructible by any agency whatever, and to contain in it as it were the principle of the resurrection of the body. According to some, it was one of the vertebræ; according to others the sesamoid bone of the great toe, and according to others again, one of the triangular bones near the lambdoidal suture.

MARGARITIC ACID. An acid discovered by MM. Bussy and Lecanu, as one of the products of the saponification of castor oil. It is named from its pearly appearance.

METALLIC TINKLING. *Tintement metallique* of Laennec. An auscultatory sound heard where there exists within the chest, a preternatural cavity containing air, or when air is present in the cavity of the pleura. It resembles the sound produced by gently striking with a pin, a glass or metallic cup, or by letting grains of sand fall into a glass.

Laennec supposed that this sound was always indicative of the co-existence of pneumo-thorax empyema, and a fistulous communication between the pleura and the bronchi. It is now ascertained, however, that neither the effusion of a liquid, nor a bronchial fistula are necessary to its development, although these circumstances are most frequently co-existent with pneumothorax, and a fistulous opening is generally instrumental in the production of the sound. The metallic tinkling occurs as a sign of pneumothorax, or of a large excavation in the substance of the lungs, the former being the cause in a great majority of instances. There is a variety of the metallic tinkling called the *amphoric resonance* or *metallic resonance*—*bourdonnement amphorique* of Laennec: it resembles the sound produced by blowing quickly and forcibly into an empty decanter, or other large vessel with a small aperture. The two sounds above mentioned often pass into each other, or co-exist or alternate with each other, in the same case; generally speaking, however, the sound seems to partake more of the amphoric character, when the cavity containing the air is very large.

Mistura spiritus vini gallici. A compound directed in the recent London Pharmacopœia, consisting of brandy, cinnamon water, each four fluid ounces; the yolks of two eggs; refined sugar, half an ounce; and oil of cinnamon two minims. It is used as a stimulant in the last stage of low fever, and is well adapted to that purpose. The dose is from half an ounce, to an ounce and a half.

Morbid temperature. The natural temperature of the human body, as ascertained by a thermometer placed in the axilla or under the tongue, is generally from 96° to 98° Fahr. Various morbid causes produce considerable changes in the temperature of the body. Thus in the cold stage of ague, the temperature of the surface is much reduced, and in that of malignant cholera still more so. In the hot stage of fevers, on the contrary, the heat of the surface is considerably increased. In common continued fever, the heat of the surface is generally from 100° to 105° Fahr., and varies at different parts of the surface: in the inflammatory form of scarlet fever, the skin generally becomes hotter than in any other disease, the temperature having sometimes risen as high as 112°. The actual degree of morbid temperature is by no means indicated by the feelings of the patient, for in some diseases the individual will often complain of being hot when he feels very cold to the bystanders, and *vice versâ*: thus in the congestive stage of malignant cholera, the patient generally throws off the bedclothes, and complains of distressing heat, although to the touch he is as cold as marble; again at the commencement of fever, after the skin has become uniformly hot to the touch, the patient often complains of alternate heat and cold.

The subject of morbid temperature does not appear to have been sufficiently taken into consideration by physiologists, in connexion with that of animal heat in general. If we regard the phenomena of disease, we meet with almost insurmountable objections, to the theory of animal heat which is most generally received; namely that of Dr. Crawford, which connects it with respiration, and the conversion of arterial into venous blood in the capillary vessels. Confront this view of the subject with the following cases related by John Hunter.

Case I. A gentleman lying apoplectic whilst in bed, would become suddenly cold, and as quickly would become extremely hot: and here there was no alteration in the pulse or breathing.

Case II. A man lying comatose in consequence of injury to the brain, and breathing with only half his usual frequency, was yet extremely hot.

Case III. A boy, who appeared to be dying, breathed so slow that twenty-three seconds elapsed between each act of breathing; the pulse was weak and very slow; the body of purple hue, the blood not passing often enough through the lungs to acquire its scarlet hue: he was very warm, though in the midst of winter, and in a room without a fire.

Again it has been repeatedly observed in malignant cholera, that when the disease is within a few minutes of its fatal termination, when the surface has been deadly cold for hours, the pulse entirely extinct, and respiration almost so, the heat of the surface has suddenly returned, so that at the moment of death and for a short time after, it has been not at all below the natural standard in a state of health. Now in this case no heat can either be developed in the lungs, or become latent in the blood, by the process of arterialisation, because that process does not take place, the blood being as black as pitch; nor can any heat be evolved at the surface of the body, by the change of arterial into venous blood, because the circulation through the minute vessels does not go on; and, if it did, there is no arterialised blood to be changed. The fact here stated has been remarked by several writers, and has been frequently witnessed by the editor. The foregoing observations throw no light on what *is* the source of animal heat; but it seems to demonstrate pretty clearly, that respiration is not the only, nor the principal source.

Morbus cæruleus. Blue disease. A name given to that state produced by a congenital malformation of the heart, or its great vessels, in which the two sides of the heart have a direct communication with each other, so as to interfere with the proper aeration of the blood in the lungs. This may arise from the foramen ovale or ductus arteriosus remaining pervious, or from absence of the partition between the auricles or ventricles. The disease is named from the purple or livid colour of the skin, arising from the circulation of imperfectly arterialised blood.

MORI'NGA. A genus of plants. Class, *Diadelphia*; Order, *Decandria*.

Moringa a'ptera. The plant which produces the Ben nut. This nut affords an oil, which separates, on standing, into two parts, one of which bears a very low temperature without coagulating.

Mo'rphiæ ace'tas. Acetate of morphia. The present London Pharmacopœia directs this salt to be made as follows: — Take of morphia, six drachms; acetic acid, three fluid drachms; distilled water, four fluid ounces. Mix the acid with the water, and add the acid to saturation. Evaporate with a gentle heat, that crystals may be formed. Acetate of morphia is a very powerful and direct sedative. Its dose is from the fourth of a grain to a grain. Half a grain generally produces a full effect.

Mo'rphiæ citra'tis li'quor. Dr. Porter has introduced, under this name, a preparation made by digesting, for twenty-four hours, four ounces of opium, and two ounces of citric acid, in a pint of water. This, however, contains all the other principles of opium, as well as morphia. Dr. Magendie dissolves sixteen grains of pure morphia, and eight of citric acid, in an ounce of distilled water, and colours the solution with cochineal. The dose is from six to thirty drops during the day. The citrate of morphia appears to agree very much with the acetate in its operation.

Mo'rphiæ hydrochlo'ras. Hydrochlorate of morphia. Muriate of morphia. Take of opium, sliced, a pound; crystals of chloride of lead, two ounces, or as much as may be sufficient; purified animal charcoal, three ounces and a half; hydrochloric acid, distilled water, solution of ammonia, each as much as may be sufficient. Macerate the opium in four pints of distilled water for thirty hours, and bruise it; afterwards digest it for twenty hours more and press it. Macerate what remains again and a third time in water, that it may become free from taste, and as often bruise and press it. Evaporate the mixed liquors, with a heat of 140°, to the consistence of a syrup. Then add three pints of distilled water, and when the impurities have subsided pour off the supernatant liquor. Gradually add to this two ounces of chloride of lead, or as much as may be sufficient, first dissolved in four pints of boiling distilled water, till no further precipitate takes place. Pour off the liquor and wash what remains frequently with distilled water. Then evaporate the mixed liquors as before, with a gentle heat, that crystals may be formed. Press these in a cloth, then dissolve them in a pint of distilled water, and digest with an ounce and a half of animal charcoal, with a heat of 120°, and strain. Lastly, the charcoal being thoroughly washed, evaporate the liquors cautiously that pure crystals may be produced. To the liquor poured off from the crystals first separated, previously mixed with a pint of water, gradually drop in as much solution of ammonia, frequently shaking it, as may be sufficient to precipitate all the morphia. To this, washed with distilled water, add hydrochloric acid that it may be saturated: afterwards digest it with two ounces of animal charcoal and strain. Lastly, the animal charcoal being thoroughly washed, evaporate the liquors cautiously, that pure crystals may be produced. The muriate of morphia is considered, by some practitioners, as a more certain and direct sedative than the acetate. The dose is the same.

Morphiæ sulphas. Sulphate of morphia. This may be obtained by dissolving, with a gentle heat, pure morphia in diluted sulphuric acid: the salt is deposited on cooling in silky crystals. According to M. Magendie, the sulphate of morphia sometimes agrees with patients who cannot bear the acetate. The dose is the same as that of the acetate.

MUMMY. (*Mumia*; from the Arabic *mum*, wax.) An embalmed body. Egyptian mummy was highly esteemed for its medicinal virtues by the Arabian physicians, and subsequently a perfect rage for mummy prevailed in Europe. Avicenna declares it to be subtle and resolvent, useful in abscesses and eruptions, fractures, concussions, palsy, hemicrania, epilepsy, vertigo, hæmoptysis, diseases of the throat, cough, palpitation of the heart, weakness of the stomach, nausea, disorders of the liver and spleen, and internal ulcers; he also speaks of it as alexipharmic, and pronounces it to be the best of all remedies for contusions. Its great virtues in healing bruises and wounds were universally admitted; and it was prescribed by practitioners of all nations. The great demand for mummies, and the high price they

bore, induced the Jews to prepare all the dead bodies they could get, in such a manner as to resemble the ancient mummies, which they did by filling the cranium and other cavities with asphaltum, pouring the same substance into incisions made in the limbs, and binding them up; and lastly, exposing the bodies to the heat of the sun, whereby they were quickly dried. This factitious mummy was sold for the real; the Jews realised immense sums of money, and mummy retained its efficacy, till unfortunately, towards the latter end of the sixteenth century, the Christian slave of a Jew at Damietta, who carried on a great traffic in mummies, having been ill used by his master, disclosed the mystery of the mummies to the Pacha, who imprisoned the Jew, and extorted a heavy sum for his release. This was a signal for a universal demand upon the coffers of the Jewish manufacturers, and the traffic consequently ceased. The doctors found that they had been outwitted, and mummy went out of fashion.

Mu'sico-ma'nia. *Musomania.* A species of melancholy characterised by an extreme passion for music. Sauvage gives the specific name, *Muso-mania* to the variety of tarantism in which the patients were music-mad. See *Tarantism.*

Myra'copon. (Μυρακοπον; from μυρον, an ointment, and ακοπον, a remedy against weariness.) An ointment used by the Greeks to relieve lassitude and weariness.

NA'JA. A genus of highly venomous serpents.

Naja vulgaris. *Cobra de capello.* The hooded or spectacled snake. Of this there are numerous varieties, all natives of the East Indies. The bite of the cobra has been considered as more deadly than that of any other serpent; but its fatal effect seems to be hardly so rapid as that of the bite of the rattlesnake. They produce very similar symptoms, and are both almost inevitably fatal, unless the absorption of the poison be prevented by local means used instantaneously after the bite.

Naja hagè. The asp, or aspic. It is only since Napoleon's expedition to Egypt, that the true species of the asp has been distinguished: various Egyptian serpents have been confounded under this name.

The asp is, without doubt, a very deadly serpent; but the exact effects of its bite are hitherto little known. The ancients had a notion that the bite of the asp, though inevitably fatal, was attended by no pain or violent symptoms, and that the person bitten died in a state of profound sleep.

Ne'nuphar. An Arabic name of the white water-lily. See *Nymphæa alba.*

Nerium oleander. The rose laurel, rose bay, or South Sea rose. This plant is common throughout the south of Europe. The wood is poisonous. A decoction of the leaves or bark forms an acrid stimulating wash, which is used by the peasantry in the south of France to cure the itch and destroy vermin.

New leather sound. *Cri de cuir.* A sound somewhat resembling the creaking of the leather of a new saddle. It is believed to arise from the friction of the heart on the pericardium, when the polish of one or both surfaces has been destroyed by consolidated lymph. It is analogous to the sound of friction produced by the grating of the pulmonary on the costal pleura, when either is rendered rough by disease.

Nitric acid. The chemical relations of this acid have been already stated, but an account of its medicinal properties has been omitted. The diluted acid of the pharmacopœia is an excellent tonic, when administered internally, and has been found especially useful in chronic hepatitis. It has been observed also, especially in warm climates, to produce a degree of ptyalism, and sometimes actual salivation. It has been highly recommended in syphilis, but has not sustained its reputation. See *Syphilis.* It has probably done good in cases of venereal ulceration, in virtue of its being a general tonic and stimulant, for it frequently improves the aspect of indolent and ill-conditioned sores, which are not venereal. Nitric acid, combined with muriatic acid, and properly diluted, has been much used of late years as a bath, especially in cases of chronic hepatitis. The practice was introduced by Mr. Scott. See *Balneum.*

The undiluted nitric acid has been lately recommended by Mr. Welbank as an escharotic application to phagedenic ulcers. The surface of the sore is to be well cleansed and dried, and the surrounding skin protected by a thick coating of lard; then a pledget of lint, wetted with the acid, is to be pressed steadily on every point of the diseased surface: by this treatment a slough is formed, which, being cast off, the ulcer assumes a healthy aspect.

A lotion, consisting of two drachms of the diluted acid to a pint of water, is found useful in carious ulcers, and other indolent and ill-conditioned sores.

The dose of the diluted acid, taken internally, is from ten minims to a half drachm, in a cupful of water.

Nomenclature, anatomical. The terms above, below, inside, outside, can convey correct ideas of the relative position of the different parts of a body only while the body and all its parts remain in the same position; now this not being the case with the living animal body, infinite confusion arises from the use of such terms. The late Dr. Barclay, of Edinburgh, made a very praiseworthy attempt to introduce terms which should apply equally well in all positions of the body; and it is a great pity that his "Anatomical Nomenclature" has not been generally adopted, for it is very simple, and admirably suited to the end in view. The following table exhibits the names given by Dr. Barclay to the different aspects of the body: —

1. *Aspects of the head, neck, and trunk.* — A perpendicular plane, dividing the body in halves, is called the *mesial plane.* The aspect of any part looking towards this plane, is called its *mesial* aspect; the aspect of a part looking to the right of this plane is its *dextral* aspect, and to the left its *sinistral* aspect.

2. Aspects of the head: —

Inial. Looking towards the occiput (ινιον).

Coronal. Towards the crown of the head.
Basilar. Towards the base of the skull.
Glabellar or *antinial.* Toward the space between the eyebrows.

3. Aspects of the neck and trunk: —
Atlantal. Looking towards the atlas.
Sacral. Towards the sacrum.
Dorsal. Towards the back.
Sternal. Towards the sternum.

4. Aspects of the four extremities:—
Proximal. Looking towards the end nearest the trunk.
Distal. Towards the end furthest from the trunk.

5. Aspects of the atlantal extremities: —
Radial. Looking towards the radius.
Ulnar. Towards the ulna.
Anconal. Towards the *ancon* or olecranon.
Thenal. Towards the palm of the hand (θεναρ).

6. Aspects of the sacral extremities: —
Tibial. Looking towards the tibia.
Fibular. Towards the fibula.
Rotular. Towards the *rotula* or patella.
Popliteal. Towards the *poples* or ham.

7. Terms of aspect common to the head, neck, trunk, extremities, and viscera: —
Dermal. Looking towards the skin.
Peripheral. Towards the circumference.
Central. Towards the centre.

All these adjective terms are converted into adverbs by substituting *d* for the terminal *l*, or *r*.

Thus, what is generally called the *upper* surface of the diaphragm, is the *atlantal* surface; and adverbially that surface is said to be situated *atlantad.*

The under surface of the brain is its *basilar* surface; and adverbially it is said to be situated *basilad.*

These adverbs are not particularly euphonic; but that is of little consequence.

OLEUM MACIS STILLATITIUM. Distilled oil of mace. An essential oil obtained by distillation from mace. It is of a pale lemon colour, and has the smell of the spice. It is different from the oil commonly called oil of mace, which is a fixed oil obtained by expression from the nutmeg. See *Oleum macis.* There is yet another oil of mace, which is expressed from the mace itself. It is of a red colour, and is more liquid than the nutmeg oil. It is called *true oil of mace, by expression; oleum macis expressum verum.*

OPHTHALMIC ARTERY. A branch of the internal carotid, which enters the orbit through the foramen opticum. It runs at first below and outside of the optic nerve, and then passes above and inside of it to the inner wall of the orbit, along which it runs to the corner of the eye and root of the nose. It gives off the *lachrymal branch* to the lachrymal gland; the *centralis retinæ* to the retina; the *supra orbital,* which passes out at the supra-orbitary foramen, to the forehead; the *ciliary* to the choroid membrane and ciliary processes; *muscular* branches to the muscles of the eyeball; two *ethmoidal* branches, one passing through the posterior internal orbitary foramen, and the other through anterior; *palpebral* branches, to the eyelids; the *nasal* branch, which goes to the root of the nose, where it inosculates minutely with the termination of the facial artery; lastly, the *frontal,* which first runs close to the nasal, and then turns upwards on the forehead, where it anastomoses with the supra-orbital.

OPOPANAX CHIRONIUM. The plant which affords the opopanax of commerce, formerly called *Pastinaca opopanax,* is now referred to a new genus under the above name. Opopanax is a gum-resin which exudes from incisions made in the roots of the plant, and is dried in the sun. It is imported from Turkey and the East Indies. It has been used as an antispasmodic and emmenagogue, but is now seldom prescribed. Dose from ten grains to half a drachm.

PANIS SANCTI MARCI. *Martius panis. Pasta regia.* This name was given to small cakes made of decorticated almonds, sugar, and rose water. They are said to have been made in memory of a dreadful famine which occurred in Saxony in 1407.

PANIS MARTIUS LAXATIVUS SENNERTI. A paste made of almonds, melon seeds, white mechoacan, white sugar, prepared hartshorn, mucilage of tragacanth, and rose water. It was used as a laxative, and particularly recommended in dysentery. Dose six drachms or more.

PESTIS NIGRA. *Black pestilence. The black death.* A most destructive pestilence which occurred in the fourteenth century. It originated in Asia, and traversed the whole of the world then known. The mortality arising from it was so great, that one fourth of the human species are calculated to have fallen victims to it. It was an intense form of the Oriental plague, characterised, like it, by buboes and carbuncles. It received its epithet of black on account of the black petechiæ which appeared on the skin. The fever seems to have been everywhere complicated with a typhoid pneumonia. Dr. Hecker, in his "Epidemics of the Middle Ages," has given a full and interesting account of this pestilence, which was the most severe that has ever ravaged the world.

PHLEBI'TIS. (From φλεψ, a vein, and *itis,* the terminal denoting inflammation.) Inflammation of a vein. Veins are liable to two forms of inflammation, namely, the *circumscribed* and the *diffuse.* The first occurs only from injuries, and we have continual examples of it in the healing of wounded veins, which takes place by adhesive inflammation, as in other textures. The diffuse inflammation of veins may arise spontaneously, or from injuries. It has most frequently been observed in consequence of the operation of venesection. A striking instance of its idiopathic occurrence is presented in the case of uterine phlebitis. See *Puerperal fever.* The veins of the brain have been found inflamed by Abercrombie, and Gendrin, and the veins in various other parts of the body have occasionally been similarly affected.

Diffuse inflammation of veins gives rise to the most formidable symptoms. The patient is

affected with adynamic fever, and extreme restlessness, anxiety, and depression. Severe and frequent rigors take place, and secondary inflammations occur in various parts of the body, which terminate rapidly in effusion of pus or lymph; more frequently the former. The cellular membrane, the joints, the eye, and the substance of the viscera, are the most frequent seats of the secondary inflammation: the lungs are especially liable to become affected. Diffuse inflammation of veins generally terminates in death, preceded by a highly typhoid state; a black tongue, fluttering pulse, and low delirium. It was, till lately, supposed that the fatal effects of inflammation of a vein arose from the extension of the diseased action to the heart; but it is now ascertained that the bad symptoms arise from the introduction of pus into the blood, which acts as a poison, and is a frequent cause of abscess in the viscera and other parts. It has been further proved that the abscesses in the viscera, joints, &c., which occasionally follow great surgical operations, and which have hitherto appeared so unaccountable, have their real origin in phlebitis. Diffuse inflammation of veins, though generally suppurative, is not necessarily so; and veins, as well as arteries, have sometimes had a portion of their canal obliterated by adhesive inflammation. The treatment of diffuse phlebitis, arising from injury, must at first be decidedly antiphlogistic, as the only chance of preventing suppuration and its formidable consequences resides in the early subjugation of the inflammatory action. Leeches should be applied very numerously and repeatedly along the course of the inflamed vein; and the arm, or other part affected, covered with cold lotions, or emollient or saturnine poultices, according to circumstances. Saline purgatives and diaphoretics should be administered, and a low diet, and absolute rest, enjoined. It is not easy to determine how far general bleeding is likely to be serviceable in this case, because, although it be the most powerful of all the means of arresting the primary inflammation, it is calculated rather to accelerate than to retard the progress of suppuration, if this have actually commenced in any part distant from that first affected. When pus has been taken into the blood and contaminated the whole system, and given rise to secondary suppuration, much need not be said about the treatment, as the evil is quite beyond our control. The only remedies indicated are stimulants, opium, &c., as in the worst form of typhus.

PHLE'BOLITE. (*Phlebo'lithus;* from φλεψ, a vein, and λιθος, a stone.) A venal calculus. Small calculi, varying in size from that of a millet seed to that of a pea, have been found in different veins, most frequently in those of the uterus, bladder, prostate gland, and rectum. They appear to be generally of an oval form, a yellow colour, and concentric lamellated texture. According to the observations of John, Gmelin, and Prout, they consist chiefly of carbonate and phosphate of lime, and animal matter. Various opinions have been entertained as to the mode of their formation. The observations of Dr. Carswell seem to be decisive in favour of their being gradually deposited from the blood.

PLOMBIE'RES. A town in the department of Vosges, in France, which has several mineral springs. One of them is called *Savonneuse*, soapy, from the appearance of the water. It contains subcarbonate, sulphate, and muriate of soda, silica, carbonate of lime, and much vegetable and animal matter. The waters of Plombieres are used as deobstruents in obstructions of the abdominal viscera, and alteratives in chronic cutaneous diseases.

POLYGA'MIA. The twenty-third class of Linnæus's sexual system of plants. In the article Polygamia, in this Dictionary, the orders of the class are incorrectly stated, those of the class Syngenesia having been substituted for them. The orders of the class Polygamia are, *Monœcia*, *Diœcia*, and *Triœcia*. See *Vegetable kingdom*.

PORUS OPTICUS. A small foramen in the sclerotic coat of the eye, which gives passage to the central artery of the retina. See *Oculus*.

POTASSÆ CARBONATIS LIQUOR. *Liquor potassæ subcarbonatis. Aqua kali. Lixivium tartari. Oleum tartari per deliquium.* Solution of carbonate of potash, formerly called *oil of tartar*. Take of carbonate of potash, twenty ounces; distilled water, a pint. Dissolve the carbonate of potash in the water, and strain. Dose from ♏ x to ʒ ij.

POTASSÆ HYDRAS. *Potassa fusa. Kali purum. Lapis infernalis. Lapis septicus. Causticum commune acerrimum.* Hydrate of potash. Fused potash. Take of solution of potash, a gallon. Evaporate the water in a clean iron vessel over the fire, until, the ebullition being finished, the hydrate of potash melts; then pour it into proper moulds. This is a stronger caustic than the potassa cum calce, but more deliquescent, and therefore less manageable. The potassa cum calce is more generally used.

POTASSII CHLO'RIDUM. Chloride of potassium. Muriate of potash. Hydrochlorate of potash. *Sal febrifugus Sylvii. Sal digestivus.* This salt is laxative and diuretic. It was formerly in high esteem for the cure of intermittents. Dose twenty grains.

PULVIS AD GUTTETAM. A celebrated antiepileptic powder formerly in use. It consisted of the roots of cassumuniar, dittany of crete and of peony, missletoe, and seeds of peony, of each half an ounce; human skull, elk's hoof, of each three drachms; castor, red coral, of each two drachms; root of wild valerian, one ounce; with three drops of volatile oil of rue, received on sugar.

PULVIS VIENNENSIS ALBUS VIRGINEUS. *Arcanum album. Bezoarticum lunare. Nives mariæ. Panacea mineralis specificum virgineum.* A powder made by calcining in a crucible one part of *Glacies mariæ* (fibrous amianthus), and two of *Lapis specularis*, rubbing them together, separating the finer part by washing with water, and drying. It was once in vogue as a refrigerant.

PURRING TREMOR. *Bruissement* of Corvisart. *Frémissement cataire* of Laennec. A peculiar

vibration communicated to the hand, in those states of the heart or arteries in which the *bellows*, or *rasp sound*, is detected by the ear. According to Dr. Hope, the purring tremor, though resulting from the same causes as these sounds, requires a stronger current for its production, whence it more frequently accompanies the passage of the blood from the ventricles into the arteries, or, by a retrograde movement, from the ventricles into the auricles, than its passage from the auricles into the ventricles: hence also it is seldom strong, unless the ventricle be hypertrophied, or the circulation hurried. It very much resembles the vibration produced by the purring of a cat, whence its name.

RASP SOUND. *Bruit de râpe.* An auscultatory sound, resembling that caused by the action of a rasp on a piece of wood. A still rougher sound of the same kind, is called *Bruit de scie, Saw sound.* These sounds originate from the same causes as the *bellows sound*, and the three pass into each other by insensible gradations, the difference being merely in the roughness of the sound: the rasp and saw sounds, however, require the presence of the cause in a more intense degree; hence they are more distinctly indicative of disease, while the bellows sound is often heard where the heart is perfectly healthy: the rougher sounds, however, also exist sometimes independently of any organic lesion. The rasp and saw sounds are most frequently connected with contraction of the orifices of the heart from disease of the valves.

Rhamnus infectorius. The plant which produces the grains of Avignon, used as a yellow die. The berries of several other species are used for the same purpose, and Turkey berries are preferred as being larger. The unripe berries are used by the dyers. The ripe berries are purgative.

Rhamnus paliu'rus. *Paliurus aculeatus.* Christ's thorn. The seeds are said to be diuretic, and the leaves astringent.

Riga balsam. The same as the Carpathian balsam. See *Balsamum carpathicum.*

Salvia lyrata. Cancer weed. The radical leaves of this plant, bruised, have been used as an application to cancers and to warts.

Sapo sapientiæ. An alchemical preparation of common salt. — *Ruland.*

Sarsaparilla. In the article on this drug, the observations on its antisyphilitic powers are such as passed current when mercury was believed to be an all powerful specific, and syphilis a disease which never underwent a spontaneous cure. The real efficacy of sarsaparilla in syphilis, seems to be much the same as in other cachectic diseases: it is sometimes very useful, but nobody now believes it to have any specific virtue.

SIGAULTIAN OPERATION. The division of the *symphysis pubis*, with a view to increase the capacity of the pelvis in cases of impracticable labour. It is named from a French surgeon named Sigault, who first performed it. It is entirely discarded.

Smilacine. *Smilacina.* An alkaline substance found by Folchi in the inner part of the root of the *smilax sarsaparilla.*

Sodæ chloras. Chlorate of soda. This may be prepared in the same manner as the chlorate of potash, by substituting soda for potash; but it is not easy to obtain it separate, as it is nearly as soluble as the muriate of soda, requiring only three parts of cold water. In its other properties it resembles the chlorate of potash.

Sphæranthus indicus. *Adaca.* A plant of Malabar which is acrid and aromatic. The leaves are used internally against the colic, and externally against the piles and the itch.

SPU'TA. (*Sputum, i.* n.; from *spuo*, to spit.) The matters discharged by expectoration from the air-passages. The quantity and characters of the sputa are variously modified in different diseases, and hence form one of the grounds of diagnosis. Thus, in *acute bronchitis*, there is generally at first a diminution of the natural secretion; then, when the inflammation is at its height, a transparent, ropy, viscid matter, sometimes streaked with blood, is expectorated with much effort, and with no relief to the patient; lastly, when the inflammation is declining, the sputa become opake, yellow, or greenish white; they are easily brought up, and the expectoration gives great relief. In *chronic bronchitis* the matters ejected are very various, according to the degree of inflammation from which they result, and which is continually changing with the state of the atmosphere, and is different in different parts of the same membrane at one and the same time. It is therefore viscid and ropy, thin and serous, purulent, or tinged with blood. It is sometimes highly fœtid, a state which has been considered as diagnostic of dilated bronchial tubes. In *acute pneumonia*, the matter expectorated is of a rusty colour and viscid, and as the inflammation reaches its height, becomes almost gelatinous. This state of the sputa is very diagnostic of pneumonia. In *tubercular phthisis*, expectoration is either absent in the first stage, or resembles that of bronchitis. In the second or suppurative stage of phthisis, the sputa present the variable characters of those of chronic bronchitis, with some peculiarities, which however are not particularly to be depended on as aids in diagnosis. Fine whitish streaks are often seen, which consist of softened tubercular matter, or small yellowish white masses of crude tubercular matter. Globular, yellowish white masses, apparently composed of pus held together by viscid mucus, have been thought characteristic of phthisis, but they occur also in chronic bronchitis. In the advanced stage of phthisis, when the excavations in the lungs have attained some size, masses of matter of a greenish white or brown colour are spit up, which, from their outline, have the appearance of having filled irregular cavities. Sputa of this kind flatten at the bottom of the vessel into the shape of a piece of money, whence they have been called *nummulary* sputa. These are more characteristic of phthisis than any of the preceding varieties. In a few instances, small

portions of the substance of the lungs have been discharged along with them.

SPHYGMO'METER. (From *σφυγμος*, the pulse, and *μετρον*, a measure.) An instrument invented by M. Herisson, to render the force and frequency of the pulse appreciable to the eye.

Sympathetic ointment. See *Unguentum armarium.*

SYMPATHETIC POWDER. A powder composed of vitriol effloresced by exposure to the heat of the sun, to which some added the usnea of the human skull. It was believed to heal wounds, if it only touched the blood which flowed from them. Sir Kenelm Digby wrote a book full of absurdities about this powder.

TEMPERAMENT. Four temperaments were acknowledged by the ancients, namely, the *sanguine*, the *choleric*, the *phlegmatic*, and the *melancholic*; to these modern physiologists add the *nervous*. The following account of the temperaments is taken from Professor Richerand.

Of the sanguine temperament. — If the heart, and the vessels which carry the blood through every part, are of predominant activity, the pulse will be sharp, frequent, regular, the complexion ruddy, the countenance animated, the shape good, the form softened though distinct, the flesh of tolerable consistence and moderate plumpness, the hair fair and inclining to chestnut; the nervous susceptibility will be lively, and attended with rapid *successibility*, that is to say, that being easily affected by the impressions of outward objects, men of this temperament will pass rapidly from one idea to another; conception will be quick, memory prompt, the imagination lively; they will be addicted to the pleasures of the table and of love, will enjoy a health seldom interrupted by disease, and all their diseases, and these slight, modified by the temperament, will have their seat principally in the circulatory system, as inflammatory fever, the different phlegmasiæ, and active hemorrhage, and will terminate, when moderate, by the mere force of nature, and require the use of the remedies called antiphlogistic, among which bleeding is the chief. The ancients applied the name of *sanguine* to this disposition of body; they considered it as produced by the combination of warmth and moisture, and had very correctly perceived that it existed in the young of both sexes, and was heightened by the spring, the season which has been justly compared to youth, calling that age the spring-time of life.

That the specific characters of the temperament just described may show themselves in all their truth, it is requisite that the moderated development of the lymphatic system coincide with the energy of the sanguiferous system, so that these two sets of vascular organs may be in true equipoise.

If men of this temperament apply themselves, from circumstances, to labours which greatly exert the organs of motion, the muscles, plentifully supplied with nourishment, and disposed to acquire a development proportioned to that of the sanguiferous system, increase in bulk, the sanguineous temperament undergoes a great modification, and there results from it the muscular or athletic temperament, conspicuous by all the outward signs of vigour and strength. The head is very small, the neck sunk, especially backward, the shoulders broad, the chest large, the haunches solid, the intervals of the muscles deeply marked.

The hands, the feet, the knees, all the articulations not covered by muscles, seem very small; the tendons are marked through the skin which covers them; the susceptibility is not great: feeling dull and difficult to rouse, the athletic surmounts all resistance when he has once broken from his habitual tranquillity.

Of the bilious temperament. — If sensibility, which is vivid and easily excited, can dwell long upon one object; if the pulse is strong, hard, and frequent, the sub-cutaneous veins prominent, the skin of a brown, inclining towards yellow, the hair black, moderate fulness of flesh, but firm, the muscles marked, the form harshly expressed — the passions will be violent, the movements of the soul often abrupt and impetuous, the character firm and inflexible. Bold in the conception of a project, constant and indefatigable in its execution, it is among men of this temperament we find those who, in different ages, have governed the destinies of the world: full of courage, boldness, and activity, all have signalised themselves by great virtues or great crimes, and have been the terror or admiration of mankind.

This temperament is further characterised by the premature development of the moral faculties. Scarcely past their youth, the men just described have projected and carried into execution enterprises which would have been sufficient for their fame. An excessive development of the liver, a remarkable superabundance of the biliary juices, most commonly accompanying this constitution of body, in which the sanguiferous system enjoys the greatest energy, to the prejudice of the cellular and lymphatic system, — the ancients gave it the name of *bilious*. The diseases to which those distinguished by it are subject, involve, in fact, either as their principal characteristic, as accessory circumstances, or as complications, the derangement of the action of the hepatic organs, joined to changes of composition in the bile. Among the remedies directed against this sort of diseases, evacuants, and especially emetics, are the best.

If all the characteristics assigned to the bilious temperament are carried to the highest degree of intensity, and to this state is added great susceptibility, — men are irascible, impetuous, violent on the slightest occasions.

Of the melancholic temperament. — When to the bilious temperament is added a disposition to obstruction of any one of the abdominal organs, or derangement of the functions of the nervous system, so that the vital functions are feebly or irregularly performed, the skin takes a deeper hue, the look becomes uneasy and gloomy, the bowels sluggish, all the excretions difficult, the pulse hard and habitually contracted. The general uneasiness affects the mind; the imagination becomes gloomy, the disposition suspicious. The exceedingly multi-

plied varieties of this temperament, called by the ancients the *melancholic*; the diversity of accidents that may bring it on, such as hereditary disease, long grief, excessive study, the abuse of pleasures, &c., justify the opinion which Clerc has proposed in his natural history of man in a state of disease, where he considers the melancholic temperament less as a primitive and natural constitution, than as a diseased affection hereditary or acquired. Distrust and fearfulness, joined to all the disorders of imagination, compose the moral character of this temperament.

As Professor Pinel very justly observes, in his treatise on insanity, the history of men celebrated in the sciences, letters, and arts, has shown us the melancholic under a different light: endowed with exquisite feeling and the finest perception, devoured with an ardent enthusiasm for the beautiful, capable of realising it in rich conceptions, living with men in a state of reserve bordering upon distrust, analysing with care all their actions, catching in sentiment its most delicate shades, but ready in unfavourable interpretations, and seeing all things through the dingy glass of melancholy.

It is extremely difficult to delineate this temperament in a general or abstract manner. Though the groundwork of the picture remains always the same, its numerous circumstances give room for an infinite number of variations.

Of the pituitous or lymphatic temperament. — If the proportion of the fluids to the solids is too great, this superabundance of the humours, which is constantly in favour of the lymphatic system, gives to the whole body considerable bulk, determined by the development and repletion of the cellular tissue. The flesh is soft, the countenance pale, the hair fair, the pulse weak, slow, and soft, the form rounded and without expression, all the vital actions more or less languid, the memory treacherous, the attention not continuous. Men of this temperament, to which the ancients gave the name of *pituitous*, and which we should call *lymphatic*, because it depends really on the excessive development of this system, have, in general, an insurmountable inclination to sloth, averse alike to labours of the mind and body: accordingly, we are not to wonder if we find none of them among Plutarch's illustrious men. Little fitted for business, they have never exercised great empire over their fellow-creatures: they have never changed the face of the globe by their negotiations or their conquests.

In the pituitous, from the excess of watery particles in the fluid which should carry everywhere heat and life, the circulation goes on slowly, the imagination is weak, the passions languid; and from this moderation of the desires spring, on many occasions, those *virtues of temperament*, which, to say it by the by, should not supply their possessors with matter of quite so much self-complacency.

Of the nervous temperament. — The property, by which we are more or less sensible to impressions on our organs, weak in the pituitous, almost nothing in athletes, moderate in those of sanguine temperament, rather quick in the bilious, constitutes by its excess the nervous temperament; — it is seldom natural or primitive, but commonly acquired, and depending on a sedentary and too inactive life, on habitual indulgence in sensuality, on the morbid action of the brain, promoted by reading works of imagination, &c. This temperament shows itself in the emaciation, in the smallness of the muscles (which are soft, and, as it were, in an atrophy), in the vivacity of the sensations, in the suddenness and mutability of the determinations and judgments. Nervous women, whose wills are absolute but changeable, with excess of sensibility, frequently exhibit it with all these characteristics. Often, however, they have something of good looks, the extreme preponderance of the nervous system still allowing a moderate development of the lymphatic. Spasmodic affections are not uncommon amongst them; and when it is observed that, on the other hand, the athletic constitution, directly opposite to the nervous temperament, predisposes to tetanus, may we not say, that the two extremes meet, or produce the same effects?

Antispasmodics are employed with success in the treatment of their diseases, which partake always, more or less, of the temperament. Stimulants, on the contrary, are very suitable to those of a pituitous or lymphatic temperament. The nervous temperament, like the melancholic, is not so much a natural constitution of the body as the first stage of a disease. This temperament, like the nervous affections which are the result of it, has never shown itself but among societies brought to that state of civilisation in which man is the farthest possible from nature.

TERATO'LOGY. (*Teratologia*, æ. f.; from τερας, a monster, and λογος, a discourse.) The name given by M. I. Geoffroy de St. Hilaire to the study of monsters or anomalies of organisation.

TINCTURA OPII AMMONIATA. Ammoniated tincture of opium. Take of opium, two drachms; benzoic acid, saffron cut into shreds, of each three drachms; volatile oil of aniseed, half a drachm; ammoniated alkohol, sixteen ounces. Digest for seven days and filter through paper. This is an Edinburgh formula. It is used chiefly in spasmodic asthma and coughs, unconnected with inflammation. A drachm contains one grain of opium.

TISANE. A form of medicine much used in France, consisting for the most part of an aqueous infusion or decoction of substances of no great activity, which is drunk in considerable quantity. See *Ptisan*.

The following are some of the tisanes most used: —

TISANE ANTISCORBUTIQUE. An infusion of buck bean and the fresh roots of horseradish.

TISANE APE'RITIVE. A decoction of the roots of couch-grass, dandelion, strawberry, and sorrel, sweetened with liquorice.

TISANE ASTRINGENTE. A decoction of harts-horn, ivory, rice, and the roots of tormentil and bistort.

TISANE COMMUNE. A decoction of barley and couch-grass, sweetened with liquorice root.

Tisane de feltz. *Tisane antivenerienne.* A decoction of sarsaparilla, china root, the barks of ivy and box, and sulphuret of antimony, to which is added isinglass and corrosive muriate of mercury.

Tisane pectorale. An infusion of the roots of liquorice and marsh-mallow, Canadian maidenhair, and the flowers of red poppy and coltsfoot, in a decoction of rice.

Tisane royale. *Tisane de vinache.* A decoction of guiac, sarsaparilla, china root, rhubarb, senna, liquorice, sassafras, and coriander, acidulated with lemon juice.

Tolu lozenges. These are made with two pounds of sugar, three ounces of cream of tartar, one ounce of starch, half an ounce of the tincture of balsam of tolu, and a sufficiency of mucilage of tragacanth.

Tonka bean. *Tonquin bean.* See *Dipterix odorata.*

Transcendental anatomy. A term adopted from the French *Anatomie transcendante*, to designate that branch of anatomy which treats of the development of parts; their analogies; the primary model or type according to which they are formed; and their approximations to or deviations from it. It is synonymous with *philosophical anatomy.*

UNICO'RNU. The unicorn. The horn of this fabulous animal was believed, in credulous times, to possess extraordinary cordial and anti-epileptic virtues; and hence it was much sought for, though never found, and divers spurious horns were passed off for it. The fossil bones of various large animals, as the elephant, rhinoceros, &c., were called *Unicornu fossile*, *Ebur fossile*, fossil unicorn, and were esteemed for their astringent, diaphoretic, and other virtues. The tooth of the narwhal, or sea unicorn, *Unicornu marinum*, was also officinal, and had similar medicinal qualities attributed to it.

Urethritis venerea. In the article on the disease thus named, or *Gonorrhœa virulenta*, as it is more commonly called, the treatment recommended in the inflammatory stage is that which was current twenty years ago. All judicious surgeons now use anti-phlogistic means till inflammation has subsided. In ordinary cases, cold lotions to the penis, laxatives, and an anti-phlogistic regimen, with mucilaginous drinks, and the internal use of the liquor potassæ, are sufficient; but when the inflammation runs high, or spreads to the neck of the bladder, leeches to the perinæum, or venesection, are called for. Under this treatment the discharge sometimes ceases, along with the inflammatory action which occasioned it; more frequently however it continues, but is thinner and less puriform. It is in this state of the disease that balsamic medicines and cubebs are useful, and astringent injections, if other means should prove ineffectual.

Warwicensis pulvis. The Earl of Warwick's powder. See *Pulvis cornachinus.*

Webster's, Lady, dinner pills. *Lady Crespigny's dinner pills. Pilulæ stomachicæ Mesues. Pilulæ ante cibum.* Take of aloes, six drachms; mastich, and rose leaves, of each two drachms; syrup of wormwood, as much as may be sufficient. Form them into a mass, to be divided into pills of three grains each. This prescription is nearly similar to one of Mesue, the Arabian. One or more of the pills, taken immediately before dinner, have often an excellent stomachic and laxative effect in dyspeptic cases.

WEIGHTS AND MEASURES. So much obscurity hangs over the weights and measures of the Greeks, and the estimate of their proportions by different authors is so various, that it would be futile to attempt any thing like a condensed or tabular view of them.

Dr. Milligan, in his notes to Celsus, gives the annexed table of the Roman weights and measures reduced to grains troy.

	Urna.	Libra.	Uncia.	Denarius.	Scrupulus.	Sextans.	Chalcus.	Grana.
Amphora	= 2	= 80	= 960	= 6720	= 20160	= 40320	= 403200	= 420480
Urna	1	= 40	= 480	= 3360	= 10080	= 26160	= 210600	= 210240
Congius	$\frac{1}{4}$	= 10	= 120	= 840	= 2540	= 5040	= 50400	= 52920
Sextarius	-	$1\frac{2}{3}$	= 20	= 140	= 420	= 840	= 8400	= 8760
Libra	-	1	= 12	= 84	= 252	= 504	= 5040	= 5256
Hemina	-	-	$8\frac{4}{7}$	= 60	= 180	= 360	= 3600	= 3759
Acetabulum	-	-	$2\frac{1}{7}$	= 15	= 45	= 90	= 900	= 939
Sesqui-cyathus		-	$2\frac{1}{7}$	= 15	= 45	= 90	= 900	= 939
Cyathus	-	-	$1\frac{3}{7}$	= 10	= 30	= 60	= 600	= 626
Sescuncia	-	-	$1\frac{1}{2}$	= $10\frac{1}{2}$	= $31\frac{1}{2}$	= 63	= 630	= 657
Uncia	-	-	1	= 7	= 21	= 42	= 420	= 438
Cochleare	-	-	-	$2\frac{1}{2}$	= $7\frac{1}{2}$	= 15	= 150	= 156
Drachma	-	-	-	1	= 3	= 6	= 60	= $62\frac{4}{7}$
Denarius	-	-	-	1	= 3	= 6	= 60	= $62\frac{4}{7}$
Scrupulus	-	-	-	-	- 1	= 2	= 20	= $20\frac{2}{3}$
Scrupulus dimidiatus	-	-	-	-	- $\frac{1}{2}$	= 1	= 10	= $10\frac{1}{3}$
Obolus	-	-	-	-	- -	1	= 10	= $10\frac{1}{3}$
Sextans	-	-	-	-	- -	1	= 10	= $10\frac{1}{3}$
Chalcus	-	-	-	-	- -	-	- 1	= $1\frac{1}{30}$

In the five last lines the *denarius* is calculated, for the sake of round numbers, at sixty-two grains.

The following very complete and useful view of the weights and measures used in England and France, is taken from Mr. Gray's Supplement to the Pharmacopœias.

Medicines, except a few hereafter mentioned,

were formerly sold, and the prescriptions of physicians made up, by the common English weight, called Avoirdupois. The ounce of that weight being then, as appears by all the old authors on arithmetic, subdivided into 8 drams, 24 scruples, and 480 English grains; the medical pound differing from the common by its containing only twelve ounces, while the Troy ounce had for its fractions pennyweights and Troy grains. At length, the College of Physicians, in the edition of the Pharmacopœia of 1720, ordered the drams, scruples, and grains, to be adjusted to the Troy ounce, and hence, as the dispensers of medicines were the only persons who used these small weights, those adjusted to the Avoirdupois ounce went out of use, and were no longer made, and the quarter ounce was the smallest Avoirdupois weight in common use, as it still continues; but as the Italian rotolo for raw silk has been adjusted to the Avoirdupois weight, and made 24 ounces a pound; a smaller weight, the Spanish adarme, equal to the 16th part of the Avoirdupois ounce, was used under the name of a dram, for weighing silk, and this has now become an established fraction of this ounce, but it is scarcely used by any other persons than haberdashers, and for all weights less than the quarter of an ounce Troy, Apothecaries' weights are employed, although, as the Avoirdupois pound is established by statute at 7000 Troy grains, the quarter ounce containing 109 gr. 375, and the dram 27 gr. 34375, are most inconvenient numbers for reduction.

Table of Avoirdupois Weight.

Commercial Fractions.			Troy Grains.	Dec. Fractions.
1 pound		-	7000·	1·0000
15 ounces		-	6562·50	0·9375
14	...	-	6125·00	0·8750

APOTHECARIES' WEIGHT.

A few choice articles of the Materia Medica, as lapis bezoar, seed pearl, white amber, balm of Mecca, oil of cinnamon, and some electuaries, high in popular estimation, and imported from Italy, as Venice treacle and orvietan, were always weighed by the Troy ounce, and its subdivisions into pennyweights and grains, and still pay duties at the Custom-house by that weight, as may be seen in the Book of Rates. But it was not until the directions given in the London Pharmacopœia, edition of 1720, that the Troy ounce was divided into the same fractions of drams, scruples, and grains, as the Avoirdupois, for the purpose of dispensing all such drugs as were ordered by weight. This alteration must have been, and is still, productive of very great confusion, by obliging the same person to have two sets of weights — one for buying and selling, the other for preparing the officinal preparations and compounds, and for making up prescriptions. It does not clearly appear why this alteration was made in respect only to drugs ordered by weight, by which their proportion in the officinal preparations and compositions was increased 1-10th; as the Avoirdupois ounce, with its old divisions into 2 drams, and drops, 60 of which were presumed equal to the dram, was, and is still retained, in respect to drugs that are dispensed by measure.

Table of Apothecaries' Weight.

Usual Fractions.			Troy Grains.	Dec. Fractions.
1 pound		-	5760	1·0000
11 ounces		-	5280	0·9167
10	...	-	4800	0·8333
9	...	or ¾ lb.	4320	0·7500
8	...	-	3840	0·6667
7	...	-	3360	0·5833
6	...	or ½ lb.	2880	0·5000
5	...	-	2400	0·4167
4	...	-	1920	0·3333
3	...	or ¼ lb.	1440	0·2500
2	...	-	960	0·1667
1	...	-	480	0·0833 = 1·0000
7 drams		-	20	0·0729 = 0·7850
6	...	-	360	0·0625 = 0·7500

2	...	-	120	0·0208 = 0·2500
1	...	-	60	0·0104 = 0·1250
2 scruples		-	40	0·0070 = 0·0833
½ dram		-	30	0·0052 = 0·0625
1 scruple		-	20	0·0035 = 0·0416
½	...	-	10	0·0017 = 0·0212
			5	0·0008 = 0·0106
			3	0·0005 = 0·0062
			2	0·0003 = 0·0041
			1	0·0002 = 0·0021

As apothecaries or chemists seldom keep Troy weight beyond 4 or 8 ounces, the relation between the Apothecary or Troy pounds and ounces and the common weight, is often required in preparing the officinal preparations, and is here given; the quarter ounce being used instead of the avoirdupois dram, as the latter weight is seldom or never kept by chemists or dispensers.

Troy or Apothecary Pounds.		Avoirdupois. lb.	oz.	qr.	grains.
100	=	82	4	2	31·250
50	=	41	2	1	15·625
30	=	24	10	3	96·875
20	=	16	7	1	28·125
10	=	8	3	2	68·749
5	=	4	1	3	34·375
3	=	2	7	1	108·125
2	=	1	10	1	35·625
1	=		13	0	72·500

Apothecary Weight.		Avoirdupois. oz.	qr.	grains.
℥ ix	=	9	3	54·375
℥vj, or lbss	=	6	2	36·250
iij	=	3	1	18·125
ij	=	2	0	85·000
j	=	1	0	42·500
ʒ iv, or ℥ ss	=		2	21·250
ʒ ij	=		1	10·625

Although the quarter ounce is only 109 grains 375, it will be convenient, in adding two or more of these reductions together, to take the even 110 grains as its value.

The Scotch pound trone is equal to 9600 grains Scotch Troy weight, or 527 gr. English 925: the Scotch Dutch Troy pound is equal to 7680 Scotch grains, or 7620 gr. Engl. 8: both pounds are divided into 16 ounces, the ounce Dutch equal to 476 gr. Engl. 3.

Besides the regular weights, articles are sometimes quoted by the weight of seeds or kernels, as the weight of a nutmeg, or of so many black pepper-corns. In India they use the paddy weight, or that of the grains of rough rice, each of which is equal to about 2-5ths of a grain; the gulivindum weight, or that of a jumble bead, equal to about 1 grain 5-16ths; the retti weight, equal to about 2 grains 3-16ths. Gold coins are sometimes used, as the gold fanam weight, equal to 8 grains; the star pagoda weight, equal to about 84 grains.

FRENCH WEIGHTS.

Before the Revolution there was only one pile of weights in common use: in endeavouring to introduce one upon philosophical principles, there are now no less than four.

The old French Poids de Marc, established by Charlemagne.

French Weight.		Troy Grains.	Avoirdupois. lb.	oz.	dr.	gr.
1 livre, poids de marc	=	7561·000	= 1	1	4	13·125
1 livre, poids de médecine	=	5670·750	=	12	15	10·594
1 marc, or 8 ounces	=	3780·500	=	8	10	7·062
4 ounces - -	=	1890·250	=	4	5	3·522
2 ounces - -	=	945·125	=	2	2	15·438
1 ounce - -	=	472·562	=	1	1	7·717
6 gros or dragmes -	=	344·421	=		12	16·296
¾ ounce, or 4 gros -	=	236·281	=		8	17·531
½ gros - -	=	118·140	=		4	8·765
1 .. - -	=	59·070	=		2	4·383
½ .. or 36 grains -	=	29·535	=		1	2·192
¼ ... or 18 grains -	=	14·767				
12 grains - -	=	9·843				
6 ... - -	=	4·922				
3 ... - -	=	2·461				
2 .. - -	=	1·640				
1 grain - -	=	0·820				

The Revolutionists, misled by the apparent facility of a decimal scale, introduced the metrical system in 1795.

Metrical Weights.	Old Fr. Weight. lb.	oz.	gros.	gr.	Avoirdupois. lb.	oz.	dr.	gr.
1 myriogramme -	29	6	6	63·500	22	1	0	2·450
1 kilogramme, or kilo	2	0	5	35·150	2	3	4	22·125
1 hectogramme -		3	2	10·710		3	8	2·152
1 decagramme -			2	44·270			5	17·721
1 gramme - -				18·320				15·444
1 decigramme -				1·880				1·544
1 centigramme -				0·180				0·154
1 milligramme -				0·018				0·015

A metrical quintal is 10 myriogrammes.
A millier is 1000 kilos.

The academicians complain much that the great government departments of the navy and artillery have never adopted this weight, not considering the great expense that it would occasion to recast all the artillery and balls.

The faculty of medicine at Paris, in translating their Codex Medicamentorum, or Pharmacopœia, into this new system of weights, did not esteem it necessary to use the exact reduction, but adopted a system of round numbers, and in some parts quoted both the old and the new weights, that the preparers might use either: thus a third system of weights was established.

Old French Weight.	Exact Metrical Weight. Grammes.	Round Numbers of the Codex. Grammes.
2 lb. -	970·02 -	1000·
1 lb. -	489·51 -	500·
½ lb. -	244·75 -	250·
4 ounces -	122·376 -	128·
2 ... -	61·188 -	64·
1 ounce -	30·594 -	32·
½ ... -	15·297 -	16·
2 gros -	7·6485 -	8·
1 ... -	3·82 -	4·
36 grains -	1·91 -	2·
20 ... -	1·062 -	1·
10 ... -	0·531 -	0·5
2 ... -	0·1062 -	0·1
1 grain -	00·531 -	0·05
½ ... -	0·0265 -	0·0

It is not a little singular, that the medical faculty of Paris should, like that of London, prefer creating a new pile of weights, to employing those which are used by all other persons.

In 1812, the metrical system was abandoned; but instead of reverting to the old pound of Charlemagne, a new pound was decreed; and thus four systems of weights are in common use, including that of the Codex.

New French Weight.	Metrical Weight. Grammes.	lb.	Avoirdupois. oz.	dr.	grains.
1 lb. -	= 500·	= 1	1	10	11·07
½ lb. -	= 250·	=	8	13	5·03
¼ lb., or 4 oz.	= 125·	=	4	6	16·18
2 oz. -	= 62·5	=	2	3	8·09
1 oz. -	= 31·25	=	1	1	17·71
½ oz., or 4 gros	= 15·625	=		8	22·52
2 gros -	= 7·812	=		4	11·26
1 gros -	= 3·906	=		2	5·63
½ gros -	= 1·9021	=		1	2·81
1 grain -	= 0·0542	=			0·90

The franc piece of silver, with 1-10th of copper, weighs 5 grammes.

The sous of copper also weighs 5 grammes.

The confusion thus introduced by continual alterations may be easily conceived. The same confusion exists even in their linear measures,

so that persons are obliged to carry a triangular rule, containing on one side the old royal foot equal to 12 inches ·792 English, with its inches, lines, and points; on a second, the decimetres centimetres of the metrical system; and on the third, the new foot of 1812, being the third part of the metre, and equal to 13 inches ·123 English.

ENGLISH MEASURES.

In the old editions of the London Pharmacopœia, the liquids were compounded by Avoirdupois weight; and the following terms were used for expressing a determinate number of ounces.

The cyathus, or cup -	for	1½ oz.
Hemina, or cotyle -	...	9 ...
Libra, or pint -	...	12 ...
Sextarius, or 1-6th of a congius -	...	18 ...
Congius, or gallon -	..	108 ..

In 1720, when the Pharmacopœia was improved by Sir Hans Sloane and Dr. Quincy, the liquids were ordered by measure, and the gallon adopted by the London College was that just enacted for wine and spirituous liquors, containing 231 cubic inches, divided into 8 pints; they divided the pint which holds 16 Avoirdupois ounces, 10 drachms, 17 grains of water, into 16 ounces, and these into 8 drachms. Smaller quantities were ordered by drops, supposed to be equal to grains; but now the drachm measure is divided into 60 minims, and graduated tubes used to measure them, so that the old divisions of the Avoirdupois ounce were, and are still, retained in respect to liquids.

Aëriform fluids are measured by cubic inches.

The relation between wine measure, with the College divisions, and cubic inches, is thus expressed.

Wine and Medical Measure.	Cubic inches.	1000th parts.
10 gallons - - -	2310	·000
5 ... - - -	1155	·000
3 ... - - -	693	·000
2 ... - - -	462	·000
1 ... - - -	231	·000
½ gallon, or 4 pints - -	115	·500
2 pints - - -	57	·750
1 pint - - -	28	·875
¾ pint, or 12 oz. medical measure	21	·645
½ pint, or 8 oz. - - -	14	·437
¼ pint, or 4 oz. - - -	7	·218
2 oz. - - -	3	·609
1 oz. - - -	1	·804
6 drachms - - -	1	·353
4 ... - - -	0	·902
2 ... - - -	0	·451
1 drachm - - -	0	·225
½ drachm, or 30 minims -	0	·112
20 minims - - -	0	·074
10 ... - - -	0	·037
5 ... - - -	0	·018
3 ... - - -	0	·011
2 ... - - -	0	·007
1 ... - - -	0	·003
Scotch gill - - -	6	·462
——— mutchken - -	25	·85
Scotch choppen - - -	51	·7
——— pint - - -	103	·4
——— quart - - -	206	·8
——— gallon - - -	827	·28

The Scotch pint is equal to 41 oz. trone of Tay water, or 55 oz. Troy of Leith water: specific gravity of Tay water 100, of Leith water 103.

Ale and beer measure is seldom mentioned by medical or chemical writers: the gallon contains 282 cubic inches; 32 gallons are a London barrel of ale, 34 a country barrel of either ale or beer, and 36 a London barrel of beer. Nor is dry measure often used; the Winchester bushel, of 8 gallons, measures 2150 cubic inches ·4, or one cubic foot ·822, and the quarter 8 bushels.

The imperial gallon, lately added to the others in use, is established by the weight of distilled water it will hold at 62 deg. Fahr., the barometer standing at 30 inches.

The gallon is to hold 10 Avoird. pounds of water, and must consequently measure 277 cubic inches ·274.

The pint is to hold 20 Avoird. ounces, and should of course measure 34 cubic inches ·659.

The Avoird. ounce measure of water is therefore 1 cubic inch ·73298.

The Troy ounce of water measures 1 cubic inch ·9013214.

The weight of a cubic inch of water is 252 grains ·456; and that of a cubic foot is 62 Avoirdupois pounds ·3206.

A cubic foot of air, or 1728 cubic inches, weighs 528 Troy grains ·367, or 1 Avoird. oz., 3 dr., 8 grains ·23.

Besides these measures, other irregular measures of uncertain content, are used: —

A table spoonful, *cochlearium magnum*, of syrop, ℥ ss.; distilled waters, ℥ iijss. to ℥ ss.; spirits and tinctures, ℥ ij. to ℥ iij.

A desert spoonful, *cochlearium mediocre*, of water, ℥ ij.

A tea or coffee spoonful, *cochlearium parvum*, of syrop, ℥ j. to ℥ ij.; distilled waters, ℈ jss. to ℈ ij.; spirit and tinctures, ℈ j. to ℈ jss.; light powder, as magnesia, ℈ ss. to ℈ j.; heavy powder, as sulphur, ℈ jss. to ℈ ij.; metallic oxide, ℥ j. to ℈ iiij.

A thimbleful, *clypeola metallica pro digitis*, is usually the same as tea spoonful.

A tea-cup, *vasculum pro thea*, ℥ iij. to ℥ iv.

A wine-glass, *scyphus pro vino*, *cyathus*, ℥ jss.

FRENCH MEASURES.

In the Codex the liquids are used by weight, and the chemists do the same; so that it is only in common affairs that measures are employed.

Old French Measure.	English cubic inches.
Liquid Measure.	
Poisson - - - -	3·631
Pinte - - - -	58·110
Dry Measure.	
Litron - - - -	49·617
Boisseau .. - -	793·856

	ubic feet.
Minot - - - -	1·378
Mine - - - -	2·756
Septier - - - -	5·512
Muid - - - -	66·146
Mine, charcoal - - -	7·350
Voie, fire wood - - -	65·489

Metrical Measure of 1795.	English cubic feet.
Myriolitre - - -	353·1712
Kilolitre, or 1 metre cube - -	35·3171
Stere of firewood - - -	
Hectolitre - - -	3·5377
Decistere of charcoal - -	

	Cubic inches.
Decalitre - - -	610·2800
Litre, or 1 decimetre cube -	61·0280
Decilitre - - -	6·1028
Centilitre - - -	0·6102
Millilitre, or 1 centimetre cube -	0·0610

In the new French measures, decreed in 1812, the pinte is to be the same as the metrical litre, and the boisseau is to be 12 litres and a half, equal to 763 English cubic inches ·35.

Une verre à vin, ℥ viij. ; une verre d'un seul traite, ℥ v. ; une verre au liqueur, ʒ vj. ; une cuiller à bouche, ʒ v. ; une cuiller à café, 5-4ths of a dram; un seau, 48 lb., of 16 ounces ; un bassin, 4 lb.

WOORA'RA. *Ourari.* A very destructive poison of Guiana, which contains *strychnia.* The plant from which it is prepared is unknown ; but it most likely belongs to the genus *strychnos,* or some one nearly allied to it.

THE END.
