ADVERTISEMENT.

A T the time that the following observa-tions, on the Influenza, were written, it was the author's intentions to give them a place, in a collection of Phyfical and Medical Effays, which he was then preparing to lay before the public. But his health, for feveral months paft, having been fo bad, as to oblige him to abandon every literary, and philosophical pursuit, that required either thought or labour; he has now loft all hopes of being foon able to accomplifh his original defign. Defirous, however, of affording all the affiftance, in his power, to those, who may wish to collect and transmit to posterity, a full and faithful history of the late Epidemical Catarrh, the author is determined to withhold no longer, from the public, an account of the appearances which it exhibited in the city and neighbourhood of Durham.

To the account of the Influenza, the author has prefixed a Difcourfe on the Improvement of Medicine, in which he has not only endeavoured to afcertain the chief caufes that have confpired to obftruct its progrefs, but likewife to point out the moft likely means of carrying it to as high a degree of perfection, as a fcience of fo intricate a nature, can be expected to attain.

DISCOURSE

A

On the IMPROVEMENT of

MEDICAL KNOWLEDGE.

IN an age, when the ufeful and liberal arts have attained a degree of perfection, unknown to former times; when the fpirit of genuine Philofophy has pervaded the most fecret recesses of nature, and diffipated the mists of ignorance and error, which so long darkened the face of science, we cannot but lament that Medicine, an art bestowed on man, for his comfort and prefervation, should not have kept pace with the other branches of useful knowledge.

As

As man, indeed, is by nature mortal, no power of art can render him immortal. But no just conclusion can thence be drawn, either against the utility of Medicine, or the poffibility of its farther improvement. If we confider that near two-thirds of mankind fall victims to difease, before they even attain the meridian of life; and only caft an eye on the prodigious numbers of every age and fex, who either languish in flow lingering diftempers, or fuffer all the torture of unrelenting pain, we cannot certainly doubt that Phyfic, well underflood, and judicioufly applied, would prolong the lives of millions, and often afford at leaft a temporary relief, to those whose miseries it cannot entirely remove.

To what caufes then fhall we afcribe the flow progrefs of a fcience, which, if duly cultivated, promifes fuch ineftimable advantages to mankind? The obftacles which have concurred to retard the advancement of the healing art are many and various, but they may all be traced either to the difficulties attending the ftudy, and practice of Medicine; or to the indolence, and often too mercenary difpofition of thofe who, in every age and country, have practifed it, as a lucrative profession.

The fludy of Medicine is of that intricate and extensive nature, that without a previous acquaintance with almost every branch of natural Philosophy, without a retentive memory, and a comprehensive genius, no confiderable proficiency can be made in it; and he, B 2 who who poffeffes not a more than common fhare of fagacity, joined to great coolnefs of temper, folidity of judgment, and an habit of nice difcernment, will never practife the healing art, with any fignal degree of fuccefs.

There is likewife a train of difagreeable circumftances, infeparable from the practice of Phylic, which will ever prevent its being fo generally cultivated, as the other liberal arts. Though a defire of knowledge, implanted by nature in the human mind, leads man to the investigation of truth, yet he feldom applies to any fcience with ardour, which tends not both to his amusement and emolument. But, he indeed must have an uncommon thirst for knowledge, who, without any lucrative view, shall pass his life in hofpitals, shall wantonly expose himfelf

felf to the infection of contagious difeafes, and voluntarily fubmit to behold the fhocking fcenes of anguifh and diftrefs, which daily occur to the Medical practitioner.

We are told that Pythagoras, and fome other celebrated fages of antient Greece, not content with teaching Medicine, as a branch of Philofophy, and fpeculating upon it in the fchools, travelled from city to city, inftructing and curing without reward, all who came to them. Hippocrates muft have had fuch exalted characters in view, when he, with enthufiafin, pronounces him, who is both a Phyfician and a Philofopher, to be little inferior to the Gods*. But fuch inftances of fub-

> * Ι'πτρός γάς φιλόσοφος, Ισόθεος. Περί ευχημοσυνγς.

fublime philanthropy, are not to be met with, among the Philofophers, or the Phyficians of modern times. In this mercenary and felfifh age, I am afraid, the craft is more fludied than the art of Medicine.

The facility, with which worth and genius may be fupplanted, by the fpecious arts of infinuation and oftentation, has ever proved, to Phyficians of a mercenary disposition, a temptation too ftrong to be refifted. In no other liberal profession is it possible to impose fo much on the judgment of mankind as to acquire fame and fortune, without fome share of real merit. In vain would a painter by his addrefs, and felf applaufe, attempt to convince the public of his fuperior excellence, if the fpecimens, which he exhibited of his skill and ingenuity, supported not his prepretensions to their attention and approbation. In vain would a lawyer expect to rife to any eminence at the bar, without giving indubitable proofs of his abilities, knowledge, and diligence.

But in Medicine it is widely different. The public have no certain teft, no infallible criterion, by which they can eftimate a Phyfician's professional merit. Those only are the competent judges of his skill, who follow the fame profeffion, and it is rarely their interest to proclaim his fame. Hence, do we fee Phyficians, whofe fole claim to the confidence of the public, is derived from their address, from the patronage of a great man, or a few lucky, but accidental cures, acquire riches and renown; whilst men of real abilities, skill, and experience, but modest, unaffuming, and unprotected by the great, live

live in obfcurity, neglected, and unrewarded for the pains which they have taken to render themfelves ufeful to the community, and worthy of their favour and fupport.

It is true indeed, that, in the prefent age, Phyficians feldom affume that air of folemnity, or affect that gravity of deportment and appearance of myftery, by which vain pretenders were formerly wont to conceal their ignorance, and impose on the credulity of mankind; but the uncertainty of the reward due to merit, leads many to content themfelves with a fuperficial knowledge of their profession, and to think their time better employed in the acquifition of the arts of infinuation and addrefs, which bring equal reputation and emolument, with infinitely lefs labour and fatigue. Thus is a science, which has for

for its object, health, the choiceft bleffing that heaven beflows on mortal man, fhamefully proftituted, degraded into a mere trade, and rendered in the hands of mercenary Phyficians, and unlettered Quacks, the inftrument of his deftruction.

Various other caufes have confpired to retard the advancement of the healing art, but none, I believe, hath fo effentially hurt its intereft, as the early division of practitioners into the oppofite fects of Dogmatifm and Empyricifm. At a period when the vifionary doctrines of Plato and Ariftotle, under pretence of teaching Phyficians to reafon with clearnefs and precifion, had withdrawn their attention, from experience and obfervation, and infpired them with the avowed prefumption of undertaking the cure of all difeafes, from a C know-

(10)

knowledge of their proximate caufe, Serapion ftood forth, and with matchlefs arrogance, maintained that reafoning is foreign to the art of Medicine. He infifted that experience is the fole guide to fafe and fuccefsful practice, and pronounced their temerity fatal, who truft, in any inftance, to the direction of their underftanding.

Such was the origin of the Empyric fect, and it is difficult to determine, whether the flate, in which Serapion found, or that, in which he left Medicine, was the more unfavorable to its improvement. Be that as it may, it hath fince continued a fubject of ferious debate in the fchools of Phyfic, whether the Dogmatic, or the Empyric plan, leads to the more fuccefsful practice.

Who-

Whoever shall cooly and impartially weigh the merits of the question, will hardly, I think, hefitate to pronounce both opinions, strictly understood, to be equally unphilosophical, and detrimental to the caufe of Medicine. For whilft the Dogmatift, blinded with his fictions, and inattentive to the obvious phænomena of nature, grounds his practice on vague hypothefes, and vifionary fystems; the Empyric, trufting with implicit faith in the infallibility of certain remedies, but despising all anatomical and phyfiological knowledge; and regardlefs of the circumstances peculiar to his patient, undertakes the cure of difeases totally unacquainted with their caufes, and fully fatisfied with barely knowing the genus to which they belong. The confusion, the uncertainty, and the danger which C 2 manimanifeftly attend the practice of either fect, fufficiently point out the abfurdity of both : and must convince every Physician, who is wedded to neither party, that theory, without experience, or experience without reasoning, is equally incapable of leading to a fafe and fuccefsful treatment of difeases.

Experience is, beyond a doubt, the only folid bafis of Medical fkill, and the practice which is not founded on it, may juftly be regarded as uncertain and hazardous. But, without reafoning, no ufeful experience can be acquired. What will the moft extensive practice avail the Phyfician, who neglects to inveftigate the nature of difeafes; to mark their progress, and to compare the various fuccess of the remedies, which, on different occasions, he has thought proper to employ? It is is therefore, though a common, yet a very mistaken notion, that skill is the neceffary confequence of long and extenfive practice. Unless a Phyfician be both a man of fcience and fagacity, he will derive little useful knowledge from his practice. Tumultuary and indigested observations ferve only to confound and miflead the undiffinguishing practitioner. All who wish to reap advantage from experience, must study nature with unremitting affiduity; but the attention, and the difcernment neceffary, in observing the course of nature, in difeases, fall not to the share of every Phyfician. If Medicine fhould ever attain any high degree of perfection, it can only be in confequence of the accurate and faithful obfervations of fagacious practitioners, and the clofe inductive reasonings of men of deep refearch, quick discernment, and folid judgment.

judgment. Hence were the Empyrics, and the Dogmatifts equally to blame; the former, becaufe they were fo afraid of reafoning, the latter, becaufe they were fo fond of it,

It is, by all Philosophers agreed, that our improvements in the arts and fciences, must in a great measure depend on the number of facts that we can collect concerning them : now the just theory of an art will lead to the difcovery of many useful truths, that would have otherwife for ever efcaped our obfervation : and though by accident we may fometimes stumble on important facts, without reasoning, what will they avail us? It is only by the aid of reafoning that we difcover analogies, that we connect corresponding facts, and reduce them to general principles.

Of all the arguments that have been urged in favour of the Empyric plan, one of the moft fpecious is, that among thofe who ftiled themfelves rational Phyficians, the idleft opinions have, in every age, had their abettors, and the moft groundlefs fictions have been fwallowed with credulity. But this objection to dogmatifm, however juftly it might formerly have been made, has now, it is hoped, loft much of its weight.

In an age, when men are, in all fcientific purfuits, actuated by the true fpirit of Philofophy, Medicine has little to apprehend from theory. Though fond of fpeculation, we have learned to appeal to facts, and to admit those doctrines only, as the foundation of practice, which are fimple, obvious, and certain. Convinced of the intiintimate relation, which the fciences bear to one another, we have ventured to extend our views beyond the contents of the materia medica, and are ambitious to be Philofophers, as well as Phyficians, "medicina enim in phi-"lofophia non fundata, res infirma "eft*." By thus contemplating univerfal nature, we have difcovered the neceflity of cultivating Anatomy, Phyfolger Mathematica, Potany, Chemic

(16)

fiology, Mathematics, Botany, Chemiftry, and every branch of natural fcience. In fhort we have learned that the arts and fciences are all links of the fame chain; and that like the various productions of nature, in the great fcale of being, they all concur in forming one fimple and general fyftem.

It was, from a full conviction, that the ftudy of the healing art should not be

* Baconus de augment. Scientiarum.

(17)

be feparated from that of univerfal fcience, that the moft celebrated philofophers of antiquity taught it merely as a branch of natural knowledge: and to them is due the honour of refcuing Medicine from the hands of quackery and fuperfition, and of raifing it to the dignity of a liberal art. And in this enlightened age, no arguments are neceffary to prove that every fystem of Medicine, which is not founded on the general principles of natural fcience, must be futile and fallacious.

No fooner did Phyficians difcover the advantage, or rather the neceffity of making themfelves acquainted with the different departments of natural knowledge, than they abandoned the fmoother paths of fpeculation, convinced that without purfuing the more humble, patient, and laborious method of in-D veftivefligation, without collecting facts, without comparing them with fcrupulous attention, and reducing them to general principles, their theory muft be imperfect, their practice fluctuating and dangerous. The ftudy of Medicine on this plan is manifeftly a great and arduous undertaking, and fhould therefore be attempted by those only who have both capacity and inclination to go through with it. Vague theory and undigested observation ferve only to bewilder the superficial Dogmatist, and to endanger the lives of mankind.

Of the various caufes which have proved detrimental to the advancement of Medical knowledge, few feem to have had fo fure and permanent an effect as a blind and fervile deference to authorities: But fince the fpirit of a more enlarged Philofophy arofe, and and that knowledge came to be more generally diffused, neither a fuperstitious veneration of antiquity, nor the fanction of great names, has any longer the power to warp our judgment or to withdraw our attention, from obfervation and experiment. We have now learned to contemn theories which lead to no useful confequences, or that have no foundation, but in the heated imagination of fpeculative men. We have likewife the fatisfaction to fee that the load of learned rubbish, with which science, for fo many years, was encumbered and oppreffed, is now, in a great meafure, removed : and there feems, in every country, to prevail a general difposition to expose, to deferved ridicule, those quackish and unworthy arts, which fo long difgraced literature.

D 2

richt they have already

It is now, by all Philosophers, allowed that the only true method of promoting science, is to communicate it with clearness and precision, and in a language, as much divefted of technical terms, as the nature of the fubject will admit. Of the happy effects of this plan, Chymistry furnishes a striking inftance. That fcience laid, for many ages, involved in the deepeft obfcurity, concealed under a language intelligible to none, but a few adepts. and by a ftrange affociation, frequently interwoven with the wildest religious enthufiafm. The Chymifts of the prefent age have the merit of refcuing their art from that obfcurity, of divefting it of the abfurd recondite jargon under which it had been fludioufly concealed; and encouraged by the aftonishing progress they have already made.

made, they carefully avoid every appearance of mystery, and account their labours sufficiently rewarded, if they can extend the boundaries of science, and render their knowledge beneficial to the community.

(21)

All therefore who ferioufly wifh to contribute to the improvement of Medicine, fhould deliver their opinions in a language that every man of fcience fhall readily comprehend. The ftudied ufe of cramp words, and of technical terms, betrays a degree of pedantry inconfiftent with true genius, and real knowledge. The more pleafing the channel through which ufeful information is conveyed, the deeper imprefion will it make, and the more chearfully will it be attended to.

Inftead of adducing many arguments to

to evince the fuperior advantages of a Dogmatic plan, I fhall content myfelf with observing, that it was by adding theory to experience, and experience to theory, that Sydenham, the Hippocrates of later ages, gained immortal fame. His example and writings first awakened the attention of Phylicians, and convinced them that without a careful contemplation of phænomena, without a profound investigation into the laws and operations of nature, in fhort, without painful observation, guided by a just ratiocination, it is impossible to contribute, in any essential manner, to the improvement of Medical knowledge.

The authority and example of Sydenham, foon produced a happy change in the state of Physic: Practitioners roused from their former lethar-

03

conveyed, the deeper imprefion will

gy,

gy, and encouraged by his fuccefs, began to investigate the nature of the difeafes peculiar to the climate, and the fituation in which they lived. They collated and afcertained facts, they detected the fallacy of the prevailing fyftems, and learned to reafon with accuracy and precifion. Their zealous defire to improve Medical fcience, led. them, in every part of Europe, to form themfelves into focieties, with the laudable intention of collecting and tranfmitting to fucceeding ages, fuch facts and obfervations as tend to throw light on the animal œconomy, and on the treatment and cure of difeafes.

Senfible that Medicine is one of those arts, whose progress can only be advanced by a multitude of concurring observations, Lord Bacon very justly ascribes its low and defective state, in his his time, to the indolence of practitioners, whom he accufes of neglecting to write, with care and accuracy, narratives of the more remarkable cafes that occur to them in practice*. Nor can we doubt that if this method, which is ftrongly recommended by the father and founder of the Dogmatic plan, had been faithfully purfued by fucceeding Phyficians, the art of healing would, ere now, have attained a degree of perfection, that a long feries of years will hardly give to it.

It is therefore a duty incumbent on every Medical practitioner, who has at heart the improvement of Phyfic, and the prefervation of the human fpecies, diligently to obferve, and carefully to record the leading fymptoms, the progrefs,

* De Augmentis Scientiarum.

grefs, the treatment, and the event of fuch acute and chronic diffempers, as happen to be accompanied with any unufual circumstances. But above all, he should watch the rife, mark the pro. grefs, afcertain the characters, and investigate the causes of the prevailing epidemics. He fhould diligently compare them with the epidemics of former years; as alfo with those of other feafons and countries. He fhould examine how far they agree, or difagree, in their effential and leading fymptoms, and judge from thence, whether a fimilar, or an entirely different method of treatment ought to be purfued : and in a fair and candid manner, lay before the public the principles on which he proceeded, and the refult of his practice, whether fuccessful, or unfuccessful.

The

The Phyfician, who trufts entirely to memory, the treatment of the various complicated difeafes that come under his care, may indeed ftand high in the effimation of an undifcerning public, but I hold it impoffible that his practice fhould be really attended with any eminent degree of fuccefs. Indolence and neglect, in this particular, betray an indifference to the acquifition of fkill and experience, that is highly culpable, and is the more dangerous in its confequences, that it may be long indulged, without either detection or fufpicion.

To the foregoing general obfervations on the improvement of Medicine, I fhall only add, that the rafh and hafty attempts of Phyficians, to reduce it into the form of a complete and perfect fyftem, tem, have contributed not a little to retard its progrefs. But however ill calculated to promote the true interefts of Phyfic, this rage of fystemyzing may be, it is the rock on which men of genius are apt to split. Genius, naturally impatient of reftraint, ardent and impetuous in its purfuits, delights in building with materials, that the mind contains within itfelf, or with fuch as the imagination can create at pleafure. But the materials requifite to the improvement of the useful arts must be chiefly collected from without, by fuch flow and patient obfervations as little fuits the vivacity of genius. And hence it happens, that men of a warm and lively imagination, often defpife the painful method of experimental inveftigation, and wander heedlefs in the devious paths of fancy, and of fpecu-E 2

lation.

lation. To this caufe, are owing the various contradictory fyftems, which at different periods have prevailed in the fchools of Medicine. In each, we find that conjecture has been fubftituted for fact, and vague reafoning for proof and demonstration. The most obvious bad confequence that arifes from the hasty reduction of the fciences into fyftems, is, that the attention is thereby withdrawn from particular refearches, which alone can give rife to particular discoveries.

It is then manifeft, that Philofophy, and the liberal arts, are much lefs indebted for their improvement, to men of a lively and creative imagination, than to perfons of a clear understanding, and folid judgment, who curbing the luxuriance of fancy, are contented to proceed, in all fcientific purfuits, by

a

a cautious and painful analyfis. But though fpeculation, fubflituted for obfervation, and experiment, has ever proved the bane of true philofophy; yet when judicioufly united to them, it not only tends to perfect the difcoveries already made, and to extend them to a greater number of objects, but likewife furnifhes hints, which may lead to many new and important truths that would efcape thofe, whofe views are confined to the obvious refults of the experiments before them.

From what has been faid in the foregoing pages, it is fufficiently manifeft, that fcientifical reafoning can never clafh with experience; that on the contrary, it not only ferves to confirm our experience, and eftablifh it on a fecure bafis, but likewife fhews us how to extend it, by a just analogy, to

a

a greater number of cafes. We may even venture to affirm, that unlefs reafon and experience go hand in hand, the healing art will never arrive to that degree of perfection, to which we fincerely wifh, and hope it may foon be carried.

An

An ACCOUNT of the

Epidemical Catarrhal Fever.

As it appeared at

DURHAM, in June, 1782.

OF Epidemics fimilar to the late Catarrhal Fever, various inftances are recorded in the annals of Phyfic, of this kind three are accurately defcribed by Huxham*, and three alfo have occurred within our own memory †. But in no Medical writer do we read of any epidemical Catarrh, unlefs perhaps that which raged in 1732-3, that feems to have fpread fo widely, and prevailed fo univerfally, as the Influenza of the prefent year.

It

* De aere et morbis epidem. † In 1762, 1767, and in 1775. It is not, I believe, certainly known, in which quarter of the globe, this difeafe firft arofe. By fome it is fuppofed of European, by others of Afiatic origin. Both opinions are fupported by a variety of plaufible arguments; but as the queftion appears to me of too little importance to deferve a ferious difcuflion, I fhall hazard no conjectures on the fubject, but content myfelf with obferving, that we have no authentic accounts of the Influenza, before it appeared at Peterfburgh in the beginning of February laft.

From Peterfburgh it fpread with aftonifhing rapidity over the whole Ruffian empire, and all the northern parts of the continent. It was imported to London about the middle of the month of May, but reached not Durham till 8th the 7th or 8th of June. It raged here with unufual violence, and prevailed fo generally, that hardly one perfon in fifty efcaped its attack. It began to abate about the 18th, and in a few days entirely difappeared in Durham, but continued for fome time to afflict the neighbouring villages.

So many and various were the phænomena, which marked the invalion, the progrefs and termination of the Influenza, that, in order to defcribe them with accuracy and precifion, all pretenfions to brevity, and to fyftematic order, muft be given up. But notwithftanding the apparent diverfity of fymptoms with which this epidemic made its attack, the conftant and uniform concurrence of certain characteriftic Catarrhous affections, fufficiently fhew-F (34)

ed that there was no specific difference in the nature of the difease.

The difference in the degrees of violence and of danger, with which the Influenza attacked different people, was fo very great, that those who were feized with it, may properly enough be divided into three diffinct classes. In the first class, which very fortunately comprehended the greatest number of patients, the difeafe was attended with fo few troublefome or painful fymptoms, that no Medical affiftance was found neceffary, and after the first day most were able to follow their usual occupations. In the fecond clafs, the difeafe was ufhered in with all the ufual concomitants of fever, and the patient was not only confined to the houfe, but generally to bed .- But it was only in the the third and last class of patients that the fymptoms ran so high, as to portend real danger.

I fhall now proceed to defcribe thefe different flates of the difeafe, but as the firft came rarely under my obfervation, and more efpecially, as it feemed to differ in no effential circumflance from the fimpleft fpecies of common Catarrh, I fhall take no farther notice of it, but immediately go on to the fecond flate.

Of this flate of the Influenza, the firft fymptoms were fuch as ufually attend all febrile attacks: languor, laffitude, difinclination to motion, frequent and alternate returns of hot and cold fits, attended with a dull pain and fenfe of weight in the forehead, and fometimes with vertigo. To these generally F_2 fuc-

fucceeded an unufual heat and fulnefs of the eyes, a straitness and redness of the nostrils, fneezing, the defluxion of a fluid from the mucous membrane of the nofe, fo extremely fharp and acrid, as not only to excoriate the infide thereof, but even to produce not unfrequently fome degree of inflammation of the uvula and tonfils, and to keep up a conftant irritation about the Larynx. In fome the cough was one of the firft fymptoms, but in general it began only to be troublesome at this stage of the diforder. The pulse from the beginning was, in most patients, much quicker and fuller than natural, the tongue white and furred, but feldom dry or parched, and the heat of the fkin by no means fo great as might have been expected, where the febrile fymptoms ran fo high. In most Patients I obferved a very confiderable exacerbation of the fever towards night, which

which in the weak and irritable, was fometimes accompanied with a flight delirium. After a few days, the cough, which at first was hard and dry, became gradually more free and loofe; and in lefs than a week, an eafy and copious expectoration of thick concocted mucus took place. The Influenza, however, was not in all attended with cough. Many had every other pathognomic fymptom of catarrhal fever, without being, at any period of the difeafe, affected with cough. But I generally observed that those people who efcaped the cough, had of all others the greatest discharge from the nose and eyes.

Such was the general courfe of the fecond flate of this epidemic, neither tedious, nor dangerous, where the conflitution was found, and the patient not far advanced in life. But in the third and and last class of patients, the Influenza was attended with dangerous affections of the vital organs, which in feveral instances, proved fatal.

The beginning of the third was not very different from that of the fecond flate of the Influenza, but in a day or two after the first attack, every fymptom was greatly aggravated. The head ach became more violent, the cough more troublefome, the thirst more intolerable, and the pain, occafioned by the cough, under the fternum, either increased and shot through between the shoulders, or shifted to one fide, where it became fixed, produced difficult respiration, and other symptoms of pneumonic inflammation.

Of five patients, whom I attended labouring under the catarrhal fever, complicated with Pleurify, two died; died; and of four whom I found afflicted with peripneumonic fymptoms, one only recovered, two of them indeed were in the agonies of death when I first faw them; but of the third, a young man aged 18, I entertained very fanguine hopes. His cough had abated much of its violence, the pain at his breaft was almost entirely gone, his refpiration became confiderably freer, his ftrength and appetite began to return, in thort he found himfelf to much better in every respect, that he ventured to take an airing in a carriage; he complained of no inconvenience from the motion, and returned in better fpirits than he went out. But the following night he was fuddenly feized with a violent oppreffion at his breaft, attended with great anxiety, and very laborious respiration, and in a few hours he expired. This happened about three weeks from the first attack, as he had had had no cold fhiverings, or any of the other fymptoms, which ufually precede fuppuration of the vital organs, it is probable this young man's death was occafioned by an effufion of ferum into the bronchia, and cellular texture of the lungs.

The third state of the Influenza was particularly fevere on people in the decline of life, on those especially who were of a relaxed phlegmatic conftitution, and fubject either to the humid afthma, or to an habitual cough. In the courfe of my practice, I had an opportunity of vifiting feveral perfons of both fexes, who came under the above defcription, and in fix of them the diforder was attended with every fymptom of fpurious peripneumony, all copious evacuations in fuch patients were productive of the utmost danger. But fuch was the acuteness of the pains in different

rent parts of the cheft, and fo great the difficulty of breathing, that it was by no means eafy to determine whether true pneumonic inflammation was really prefentor not. Mifled by thefe ambiguous appearances, fome unwary practitioners had recourfe to the lancet: of the fix elderly people, whom I attended in the influenza, complicated with fpurious peripneumony, three had been bled; but inftead of receiving any relief, they from that moment began to fink under the difeafe, and every attempt to fupport the vis vite by warm cordials, and external ftimuli, proved ineffectual.

The death of these patients was manifeftly occasioned by such an effusion of ferum into the bronchia, and cellular texture of the lungs, as entirely overcame the powers of expectoration : whence suffocation necessarily ensued. To the other three performs I was called G pretty (42)

pretty early in the difeafe, and by the use of expectorants, opiates, and tonicks, they had all the good fortune to recover.

The lofs of ftrength which attended every ftage of the influenza, was much more confiderable than is ufual in fevers of apparently equal violence and duration. Many who had not the diforder in a very fevere manner, complained of fuch a weaknefs of the lower extremities, feveral days after every fymptom of fever had left them, that they could hardly without affiftance walk from one room to another; this, however, was feldom the cafe, unlefs where the diforder had been carried off by very profufe perfpiration *.

Though

* Huxham observes that this was the cafe in the catarrhal fever of 33, when the lancet had been imprudently used. Though it was extremely common for people, who had almost got the better of the influenza, to have either one or two relapses, if they were not particularly careful to guard against the evening damps; yet I met with no instance of a second attack of the disease, after a perfect recovery had taken place. But I had frequently occasion to observe that a relapse was more severe and of longer duration than the first attack.

No inftance fell under my obfervation in which the influenza laid the foundation of pulmonary confumption, unlefs where the lungs were already in a difeafed ftate*. In three cafes where I G_2 had

* Three months ago, when this account of the Influenza was written, the author little apprehended that he himfelf was to prove an exception to the above obfervation. But his cafe is now too evident to be miftaken, he was feized with the Influenza foon after it appeared in Durham, but took nothing for it, till the febrile exacerbations had for fome time fulpected the formation of tubercles, fuppuration now feems to have taken place:

From the above account of the Influenza, it appears that it prevailed more generally, and was attended with more dangerous and fatal effects in the city of Durham, than in most places of the fame fize in Britain. To what particular cause this should be attributed is difficult to determine. Durham has been always supposed, and I believe very justly, one of the most heal-

bations in the night began to run very high. He then found it neceffary to have recourfe to diaphoretic medicines, and when under the operation of thefe, he was unfortunately called up to the fick feveral nights fucceffively; in confequence of this, all his complaints were confiderably aggravated, and a pain fixed in his fide, which has baffled every remedy. As the cough, and hectic fever have been daily increasing fince the cold weather fet in, he is advifed by Dr Cullen, and feveral other medical Gentlemen of eminence, to pass this winter in a warmer climate; and, in compliance with their advice, he proposes setting out immediately for Lisbon. healthy places in the kingdom. During the fpace of fix years, that I have refided in it, the Influenza is the only difeafe that appeared deferving the name of Epidemic. Nor is this more than what might reafonably be expected from the dry and airy fituation of the place, as well as from the fmall number of inhabitants, in proportion to the ground it covers. How then fhall we account for the Influenza having raged with much more feverity in Durham, than in places infinitely more populous, and more unhealthy?

The caufe of the peculiar malignancy of the Influenza here, muft, in my opinion, be fought for in the flate of the air. The uncommon feverity of the weather had rendered the fpring in this, as well as in every other part of the ifland, unufually backward. From the beginning of March till the laft week

week in May, few days passed without fnow, fleet, or rain, and the wind, during that period, blew almost inceffantly from the north or north-east quarters. But for a week before the late Epidemic appeared in Durham, the weather was remarkably ferene, the air dry and fultry. Two accurate thermometers (Fahrenheit's fcale) hanging in the fhade vibrated, for feveral days before the Influenza broke out, and the whole time it prevailed, from 68° to 64°. This observation was taken at eleven in the morning, and three in the afternoon. It must however be observed, that the nights were frequently thick, hazy, and chilly.

Is it not therefore highly probable that fuch a fudden transition from very cold to very hot weather must have been attended with very deleterious effects to the human body? It will readily,

readily, I prefume, be granted that the fudden relaxation produced by the continued application of a degree of heat to which the body had been fo long unaccuftomed, must not only have rendered it more fusceptible of the contagion. but likewise more incapable of throw-. ing it foon off. Nor is it unreafonable to fuppose that the heat of the air would render the contagion more active, increase the septic tendency of the fluids. and make all copious evacuations more dangerous. I am the more inclined to this opinion becaufe the blood taken from patients who had no evident marks of topical inflammation, inftead of exhibiting a firm craffamentum and buffy coat, as is usual in catarrhal affections, was generally found to be in a diffolved ftate. The putrefcent tendency of the fluids was fo manifest in feveral instances, that I found it neceffary to recommend the peruvian bark and antifeptics. Bur

But whilft I maintain that the temperature of the air contributed not a little to render the Influenza more fevere and more fatal at Durham than elfewhere, I am by no means of their opinion, who afcribe the production and propagation of this Epidemic to a particular difposition of the atmosphere. Various facts and arguments may be adduced to prove that the late catarrhal fever depended not on any fuch constitution of the air, but was diffeminated by contagious effluvia, and was as certainly a specific contagion as the measles or the fmall pox. The aftonishing rapidity with which the Influenza fpread over the greatest part of Europe, is alone fufficient not only to evince its contagious nature, but to fhew that the contagion of Catarrh is, of all others, the most diffusible.

But

But in order more fully to afcertain the remote causes, and the specific nature of the late Epidemic, it will be neceffary to offer fome general observations on the etiology of catarrhal fever in general.

The Catarrh is a difeafe, to which, as far as we know, the inhabitants of every climate are more or lefs fubject, but it appears from obfervation that it prevails most in those countries where great and fudden changes in the temperature of the atmosphere most frequently occur. Pathologists diffinguish it into fporadical, epidemical, and contagious. When Catarrh is produced by cold, it feldom affects many people at one time, and in this cafe, it is faid, to be fporadical: But when it can be traced either to a particular constitution of the atmosphere, or to a contagious H

ef-

(50)

effluvia, it has always been observed to prevail epidemically.

The frequency of catarrhal affections, in the fpring and autumn, evidently proceed from the great viciflitudes, which, at those feafons, the temperature of the air daily undergoes in this variable climate. The immediate effect of any confiderable degree of cold applied to the human body, is to check the cutaneous perspiration, and in confequence of this, there generally enfues a fudden determination of the circulating fluids to the mucous membrane, which lines the nofe, the fauces, the trachea, and the bronchia. In this unufual afflux of fluids to thefe parts. and in the inflammation, which in a greater or lefs degree always attends it. confifts the proximate caufe of catarrhal fever.

But

But though the application of cold to the furface of the body when heated; or even the fedative power of grief, fear, and of fuch other depreffing paffions, as, by diminishing the nervous energy, induce an atony of the extreme veffels, and lay the foundation of febrile fpafin, may fufficiently account for fporadical catarrh, it would be highly abfurd to afcribe the late Influenza to any caufe, which was not as general as the difeafe itfelf. Every circumstance in the history of this epidemic tends to prove that it never could have been fo widely diffeminated by local or partial caufes. It arofe in a diftant corner of Europe, it rapidly extended its baneful influence over countries, where we have every reafon to believe both the fenfible and infenfible qualities of the air, to be extremely different wherever it came: it attacked indiferiminately the young and the old, the H 2 healthy,

healthy, and the infirm, the chearful, and the melancholic.

(52).

But that no doubts may remain, whether the epidemical catarrh of the prefent year, was propagated by a particular difposition of the air, or by contagious effluvia ; let us compare the different feafons in which it appeared in different countries : at Petersburgh this difeafe began to prevail in the month of February, and at Durham about the 8th of June; that is, it raged at Peterfburgh during the coldeft part of the winter, and at Durham during the hotteft fummer weather. Can there be any thing more improbable than that the fame conflitution of the atmosphere fhould be compatible with fuch extremes in its temperature? It is much more confonant to reafon and analogy to fuppofe, that between the months of February and June there had occurred every

(53)

every possible vicifitude in the state of the air.

Did it appear in the leaft neceffary, I could adduce feveral incontestable facts refpecting the manner in which the Influenza was propagated over this part of the kingdom, all tending to fhew that it reached different places fooner or later, according as they had more or lefs intercourfe with the metropolis: an irrefragable argument that it depended not on the flate of the air, but was diffeminated by the contagion of human effluvia. But whether the contagion was communicable by means of cloaths or other fomes, or whether it was inhaled with air contaminated by paffing through the lungs of the infected, or received only by touching perfons afflicted with the difeafe, are queftions which admit not of a demonstrative folution ; but from the fingular diffufibility of the contagion, it is reafonable (54)

nable to infer, that it was capable of being propagated in all these different ways.

We are equally puzzled when we attempt to account for the modus operandi of the contagion of catarrhal fever, as the febrile fymptoms appeared not unfrequently before the catarrhal. I am, however, inclined to believe, that this species of contagion acts primarily as a fedative, by diminishing the energy of the brain, and inducing a fpafm of the extreme veffels; but by what particular law of the animal œconomy, the fluids are immediately and invariably determined to the mucous membrane of the nofe, fauces, and bronchia, I fhall leave those to explain who are lefs afraid to tread in the flippery paths of fpeculation and conjecture.

I fhould not have taken fo much pains to afcertain the contagious nature ture of the late epidemical catarrh, did not the prevention of difeafes chiefly depend on a knowledge of their remote caufes. How many thousand Christians at Constantinople and Aleppo have efcaped the plague, the most dreadful of all epidemics, fince they happily difcovered that it is not diffeminated by noxious miasmata floating in the atmosphere, but by the contagion of human effluvia only? They have found out that by fhutting themfelves up, on the approach of the difeafe, and carefully avoiding all communication with the infected, however long and fatally the plague may rage around them, they run no rifk of catching the infection*. By purfuing a plan fomewhat fimilar, feveral families in this county entirely escaped the Influenza.

On comparing the late epidemical catarrh with that of 1732-3, as deferibed

* Lobb on the plague. Ruffel's hiftory of Aleppo.

bed by Dr Huxham, we find that there are several essential circumstances in which they differ *.

The blood in the Influenza of the present year, did not exhibit that inflammatory appearance which it feems to have done in the catarrh of 1732-3. The late epidemic was rarely attended with any confiderable degree of vertigo or delirium; and never to my knowledge with abfceffes in the ears, or imposthumes of the throat; fymptoms, which, according to Huxham, were extremely common in the above mentioned Influenza. The fame author informs us that the difease proved chiefly fatal to infants, and elderly people. How fatal the late epidemic was to people advanced in years of a relaxed phlegmatic conftitution, has been already

* Nux. de Aëre Mens. Feb.

ready fhewn at fufficient length. But with refpect to children, the cafe was here directly contrary to Huxham's obfervations. Very few children in this place or neighbourhood had any attack of the difeafe, and, of those who had it, I faw none in whom it was attended with danger*.

Dr Huxham in endeavouring to account for the caufe of the catarrhal fever which prevailed in the year 1737, pofitively afferts that catarrh is always preceded and accompanied by a very thick and hazy ftate of the atmosphere, and never prevails epidemically but in the winter months. But how egregiously he was mistaken in both these points, fufficiently appears from the feason of the year, and the state of the air, when I

* Huxham de aere et morb. epid. 1733.

the Influenza prevailed in Durham.* That fuch a state of the atmosphere, as Huxham defcribes, is by no means neceffary to the rife or propagation of an epidemical Catarrh, appears from fome observations of Dr Whytt's, on a diftemper fimilar to the Influenza of the prefent year. In the months of September, 1758, an epidemical catarrh appeared in Edinburgh, which by the end of November had reached the most northern parts of Scotland; yet fo remarkably mild and dry was the feafon. that, according to Dr Whytt, the rife of the diftemper could not be afcribed to any of the known qualities of the air +. The only material circumstances in which the epidemic defcribed by Dr Whytt

* Nam et præcedit hunc morbum femper, ac comitatur, craffa admodum, humidaque atmofphæræ temperies : nec graffatur, unquam nifi menfibus hibernis. Obferv. de aere, &c. 1737.

+ London, Med. Obferv. &c. vol. 2.

Whytt feems to have differed from the late Influenza, are, that the former was frequently attended with Diarrhœa and bleedings at the nofe, and the latter feldom, if ever with thefe fymptoms. As to the method of cure, the fame treatment feems to have anfwered in both epidemics.

The moft favourable and moft general termination of the late catarrhal fever was by perfpiration. This difcharge was, in many inftances, extremely copious. Several patients whom I attended, continued in a profufe fweat for 48 hours, without intermiflion. About ten or twelve hours after the fweat broke out, the defluxion from the nofe began to diminifh, and foon became thicker and lefs acrid: the cough too abated of its violence, and an eafy and copious expectoration took place in the courfe of a day or two. Such in gene-

ral

ral was the termination of the Influenza when not attended with local inflammation, or fpurious peripneumony.

It feems to be the general opinion of authors that catarrhal fever, whether produced by cold, or contagious miafmata, is always attended with more or lefs of the phlogiftic diathefis. Hence Sydenham, Huxham, and most modern practitioners, recommend bloodletting, as the first and chief indication of cure. But though catarrhs from cold be generally accompanied with fome degree of inflammatory diathefis, this circumstance ought rather to be afcribed to the feafon of the year, at which they commonly prevail, than to the effential nature of the difease. This observation will appear fufficiently just to those who have seen catarrhal fever complicated with evident fymptoms

(60)

toms of putrefaction: of this feveral inftances are recorded in authors, and two fell under my own obfervation in the late Influenza. Blooding was fo far from being a general indication of cure in the late epidemic, that unlefs acute pains in the cheft, difficulty of breathing, and other marks of topical inflammation were prefent, it was feldom employed without aggravating all the fymptoms, and protracting the difeafe beyond its ufual courfe.

But though blood-letting was in general prejudicial, as well as all copious evacuations by ftool, yet a ftrict obfervance of the antiphlogiftic regimen, that is, a total abftinence from animal food from all fpirituous and fermented liquors, and from everything of a heating and inflammatory nature, was abfolutely neceffary : a ftrict attention to thefe these circumstances joined to a plentiful use of thin diluting liquors, drank moderately warm, and laying in bed to encourage perspiration, was generally found sufficient for the cure of the first and mildest state of the Influenza.

But in the fecond ftate of the difeafe where the febrile fymptoms ran high, where the fkin was hot and parched, the cough hard and frequent, and the difcharge from the nofe, and fauces fharp and copious, the indications of cure were, 1ft. To take off the fpafmodic conftriction of the extreme veffels and to reftore the determination of the blood to the veffels on the furface. 2d, to obviate the effects of the irritation produced by the acrimony of the defluxion from the nofe and bronchia, and to promote expectoration.

Ift. The

Ift. The remedies beft calculated to relax the fpafm affecting the extreme veffels are those which tend to reftore the tone and activity of the fanguiserous fystem, and to determine the force of the circulation to the furface of the body: viz. Diluents, Diaphoretics, Antispasimodics, and Emetics: but of these, the two first were the only remedies I had occasion to employ in the cure of the late epidemic.

The falutary effects of a plentiful ufe of *Diluents*, in most febrile diforders, have been long known to the Physicians of every country. In health, the fluidity of the mass of blood depends upon the quantity of water which it contains; and in fever, though the cutaneous difcharge be often confiderably diminished, yet there continues to exhale from the pores of the skin, from the surface of the

the lungs, and the other excretories, fuch a quantity of the more fluid part of the blood, that the balance of circulation between the larger and fmaller vessels is often entirely destroyed. It is therefore manifest, that in order to prevent the balance of circulation from being deftroyed, or to reftore it when loft, the most effectual means we can employ in either cafe, is to throw in fuch a quantity of watery fluid, as shall supply the constant waste. But though what has been just now faid, accounts in fome measure for the beneficial effects of Diluents in febrile diforders, yet it by no means explains the whole of their operation. Diluents have manifeftly a power of producing a determination to the furface of the body, and of relaxing the fpafmodic conftriction of the extreme veffels, the modus operandi of which, Phyficians have not yet

(65)

yet been able to explain on any certain principles.

But in this feverer state of the Influenza, I feldom found that Diluents alone were fufficient to take off the spasm, and reftore the cutaneous difcharge. In most instances, I was obliged to have recourse to Diaphoretics, more active and certain in their operation : what seemed to answer best, was a plentiful use of the volatile or fixed alkali, faturated with the native acid of vegetables; when this did not produce the defired effect, in the course of fix or eight hours, fome more powerful Diaphoretic was added. But, aware of the pernicious effects of all fudorifics of a hot and ftimulating nature, in every cafe of fever, Antimonial medicines were the only Diaphoretics I employed. I generally found that a drachm of An-K timonial

timonial wine added to a pint of the Saline mixture, when taken at fhort intervals in fmall quantities, rarely failed to induce, in the fpace of five or fix hours, a very copious flow of fweat, which was eafily kept up by frequently fipping of thin tepid Diluents.

To fome patients I gave fmall dozes of James's Powder, to others a weak folution of the Emetic Tartar; and where the conftriction on the furface did not readily give way, I frequently added Laudanum to the above Diaphoretics, which feldom failed to allay the violence of the fever, and to induce a profuse perfpiration. I had likewise the fatisfaction to find that an Opiate joined to an Antimonial was always attended with the best effects, in all cafes of great irritability of fystem.

Whether

Whether the fudorific method ought to be purfued in the cure of all fevers, is a queflion involved in too many doubts and difficulties to be difcuffed here. It is fufficient for my purpofe to observe, that the most speedy and most favourable termination of Catarrhal Fever, has always been obtained by perfpiration. This appears from the concurring observations of all the best authors on the fubject: for though Phyficians are not agreed whether obstructed perfpiration be the caufe, or the effect of catarrhal fever; or whether it be not fometimes the one, and fometimes the other, according as the difeafe is produced by cold, or by contagious effluvia, yet they all allow that till the cutaneous excretion be reftored, no abatement of the catarrhal fymptoms ever takes place.

Hence

Hence we perceive that in the cure of Catarrh, the first indication is to reftore the cutaneous discharge, and, that till this be effected, all attempts to allay the cough, and remove particular fymptoms, must prove vain and fruitles. The medicines most proper for this purpose I have already mentioned, but in order to affift their operation, and render their effects more certain and fpeedy, I generally directed warm fomentations to be applied to the lower extremities, and to be continued for a confiderable time. This method of promoting perspiration appears to me preferable to the Pediluvium and Semicupium, both on account of the facility with which it may be repeated as often as neceffary, and because it is performed with lefs fatigue to the patient, and lefs danger of his catching cold.

The

2d. The medicines which I employed to obviate the effects produced by the acrimony of the defluxion from the Nofe and Bronchia, and to promote expectoration were few and fimple. Many patients received confiderable benefit from frequently fipping of a weak infusion of Liquorice root, of Tuffilago, Althæa, &c. in which was diffolved a confiderable quantity of Gum Arabic. But when the defluxion was fo copious and acrid as to render the cough almost inceffant, I generally found that fifteen or twenty grains of Volatile Alkali, and thirty or forty drops of Laudanum, mixed with four or five ounces of a thin folution of Gum Arabic, not only mitigated the violence of the cough, but had likewife a very fenfible effect in promoting expectoration. A table spoonful of this julep was directed to be taken every half hour, as long as the urgency of the

the fymptoms required it; and as the cough was, in general, much more troublefome in the night than the day, this medicine was feldom had recourfe to before the return of the evening exacerbation. In fome cafes, I gave fmall dofes of the Oxymel of Squills joined to an opiate: and when opiates, in every other form, difagreed with the patient, I fometimes found the fyrup of Poppies produce every effect I withed for.

The third and laft ftate of the Influenza, was attended with fuch various and anomolous appearances that it was impoffible to lay down any general indications of cure. There were however two cafes, in this ftate of the difeafe of fo oppofite a nature, that their method of treatment could not be confounded, without the moft imminent danger of the patient's life. The two cafes (71)

cafes I allude to, were those of pneumonic inflammation, and of spurious peripneumony.

When the catarrhal affections were accompanied with a hard and dry cough, pains in the fide, or at the breaft, difficulty of breathing, and the ufual fymptoms of pleurify, the fame method of cure was purfued as in other cafes of pneumonic inflammation, with this difference only, that fome attention was paid to the nature of the epidemic, that the lancet was not fo freely ufed as in the cafe of fimple pleurify, but that blifters were more fo, and almost always with manifest advantage.

The fecond cafe was that of fpurious peripneumony. The fubjects of this ftate of the Influenza, it has been already mentioned, were perfons in the dedecline of life, and efpecially those of relaxed phlegmatic habits: the indications of cure, therefore, were to allay the cough, to promote expectoration, and support the powers of life by bracing and gently ftimulating medicines. To answer the first indication I generally had recourfe to the methods already mentioned, I mean to the use of the Volatile Alkali, and the Tinctura Thebaica, which, when properly and judicioufly exhibited, feldom failed to abate the violence of the cough, and promote a free and copious difcharge of mucus from the Lungs and Bronchia. Sometimes fquills were employed, and feemingly with a good effect, and when the patient complained of any fixed pain, a blifter applied near the part affected generally afforded relief. Bleeding, and all copious evacuations either by ftool or fweat were cautioufly avoided; a gentle

gentle perspiration, however, was always kept up, and glifters or cooling laxatives were used, as often as was judged proper.

external Dimetter bud recourts

The last indication of cure was to fupport the strength of the patient. The medicine I depended on chiefly for this purpose, was wine, which I directed to be added to the water gruel, the panado, or whatever else the patient was wont to take by way of nourifhment. The wines, which were most frequently used, were red and white port, fherry, and Lifbon, and the quantity was carefully proportioned to the degree of debility; the former habits of the patient, and the other circumstances of the cafe. All medicines of a hot. ftimulating inflammatory nature were entirely rejected, and none employed, but fuch as tended to support the fink-L

aroti

ing

(74)

ing powers of nature, without hurrying the circulation. For this reafon, the Volatile Alkali, in fmall dozes, was the only internal, and bliftering the only external ftimulus I had recourfe to. But though, by purfuing the above method of cure, with care and attention, many perfons recovered whom I had found to all appearance in the agonies of death, yet feveral, in fpite of every means I employed to relieve them, funk under the violence of the diforder.

I am happy to have it in my power to lay before the Public, a short, but accurate account of the late Epidemical Catarrh, as it appeared in the town and neighbourhood of Newcastle upon Tyne. For this I am indebted to my Friend Dr Clark, whose singular genius for obserwation, has been long known to the medical world.

A

LETTER

A

TO

Dr LESLIE, F. R. S.

ON THE

INFLUENZA;

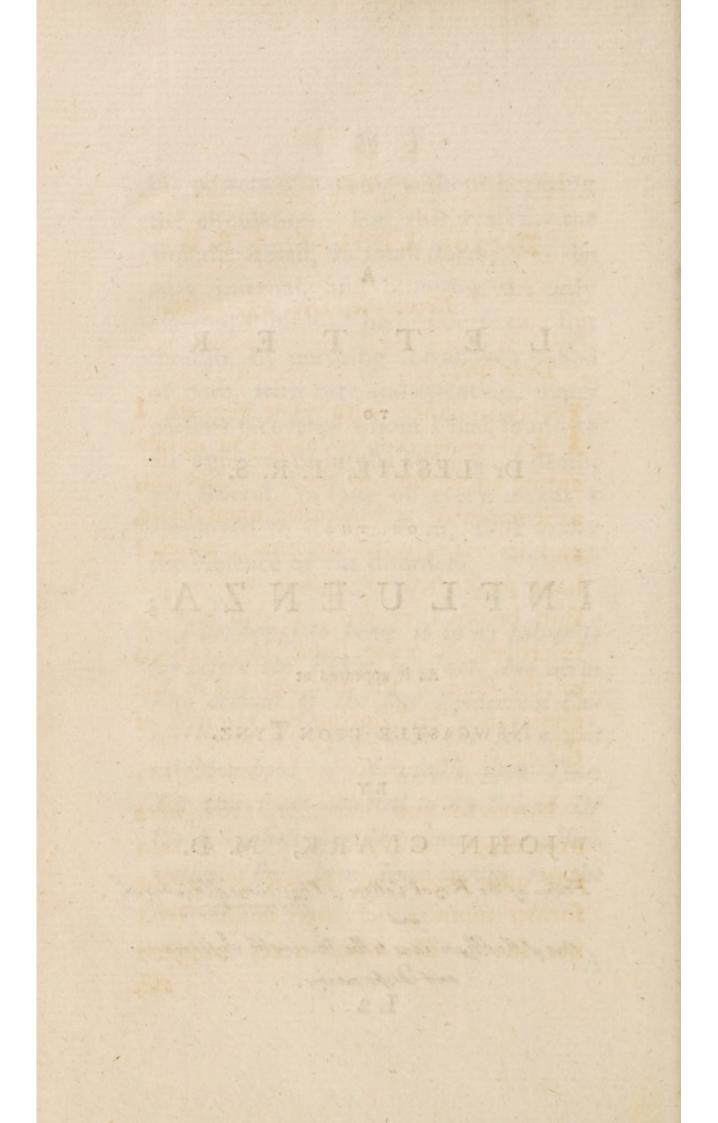

As it appeared at

NEWCASTLE UPON TYNE.

BY

JOHN CLARK, M. D. Fellow of the Royal College of Physicians of diaburgh, and One of the Physicians to the Newcartle Infirmary,

and Dispensary. L 2

DOCTOR LESLIE, F. R. S.

Newcastle, Dec. 23, 1782.

Dear Sir,

IN compliance with your requeft, I fhall endeavour to give you as accurate an account of the late Influenza, as it appeared at Newcastle upon Tyne, and its vicinity, as the limits which I have prefcribed to myself will admit. But, before I proceed, it will not be improper to make fome observations on the state of the air previous to the appearance, and during the progress of the epidemic.

November and December, 1781, were exceedingly temperate; little or no rain fell, and, except on the last day of the former month, there were neither frost nor show. The winds were, in general, ral, from weft to fouth weft. The mercury in the Thermometer varied exceedingly little, generally vibrating from 40 to 46 degrees on Farenheit's fcale, at ten a. m. and in the laft ten days of December the weather was fo mild, that the mercury in the Thermometer, at the fame hour, vibrated from 49° to 52°.—The greatest height of the Barometer, during these two months, was 30: the least height 29.2.

On the first day of January, 1782, fome fnow fell. On the 11, 12, 13, 14, 18, and 31st, the frost was moderate : during the rest of the month the air was unufually temperate, and dry for the feason. The winds blowed in general from the west. The Thermoneter, at 9 a. m. commonly vibrated from 40° to 46° : its greatest height was 51° : the least height 33° .—The greatest height of the Barometer 30.7: the least height 29.

The

The firft week of February was mild. On the 7th day the wind fhifted to the North, and continued in that quarter to the 21ft, during which time there were froft and fnow, but to no great degree. The remainder of the month was very mild, the winds being wefterly, accompanied with flight thowers. The greateft height of the Thermometer was 47°: the leaft height 30°.— The greateft height of the Barometer 30.8: the leaft height 29.3.

The weather in the beginning of March was mild. On the 13th, the wind fhifted to the north, and the weather was intenfely cold, with froft and fnow till the 18th. From this to the end of the month, the weather was wet, cold, and variable. The greateft height of the Thermometer was 47°: the leaft height 30°.—The greateft height

(80)

height of the Barometer 30.6—The least height 29.

The month of April was cold, wet, and hazy, with very few days free from rain or fleet. The winds were generally from the North or East quarters. The greatest height of the Thermometer was 46°: the least height 37°.—The greatest height of the Barometer 30.6: the least height 29°.

In the beginning of May a very confiderable quantity of fnow fell in the counties of Northumberland, Durham, and Weftmoreland; and during the reft of the month the air continued uncommonly cold, with rain, and fometimes fleet. The winds in the beginning of the month were from the N. E, towards the middle to the end they generally blowed from fouth to fouth weft, weft. The Thermometer, at feven o'clock in the morning, through the whole month, commonly vibrated from 38° to 45° : and, at the fame hour, its greateft height was 52° .—The greateft height of the Barometer was 30.3: its leaft height 29.2.

The beginning of June had fcarcely the appearance of Summer; flight fhowers fell in the day-time, and the nights were foggy, damp, and cold. From the 8th to the 21ft the winds were generally from the fouth weft; the weather was temperate in the daytime, but still continued chilly, hazy, and cold in the nights. From the 22d to the 26th the air was clear, dry, and fultry: the Thermometer, during thefe days, at feven o'clock in the morning, vibrated from 60° to 64°, and, at midday, from 70° to 72°. This was all the M

the fummer we had, for on the 27th a very remarkable change in the flate of the air took place: the wind flifted to N. W. the Thermometer at feven o'clock in the morning funk to 54°, and for 23 fucceflive days, it was never obferved, at the fame hour, to be higher than 58°. The greateft height of the Barometer this month was 30.5: the leaft height 29.6.

The above remarkable conflictution of the air in the winter months, was productive of few difeafes; but the long feries of cold, damp, and wet weather, which continued throughout the whole fpring, and beginning of fummer, introduced colds, coughs, inflammation of the lungs, and intermittents; and thefe diftempers, efpecially intermittents, were unufually prevalent in April, May, and the beginning of June. From former accounts of epidemical mical Catarrhs, it appears, that previous to the diffemper amongft the human fpecies, the horfes and dogs have been affected with defluxions of rheum from the nofe, and fevere coughs, attended with fever. But in this part of the country, at leaft, no fuch complaints prevailed among thefe animals.

In this part of the kingdom, from the beft information I have been able to obtain, the difeafe firft made its appearance at Shields, the port of Newcaftle, on or about the 26th of May; and, what is remarkable, before it feized any perfon in the town, fome fhips had arrived from *London*, where the difeafe was epidemic, whofe crews had laboured under the diftemper on their paffage. And on the 27th and 28th of the fame month, a very confiderable number of veffels came into M 2 the the harbour from the river Thames, after a fail of little more than fortyeight hours. A great many of the failors were ftill ill of the difeafe, which foon afterwards fpread itfelf amongft the reft of the fhips; and alfo was communicated to feveral families on fhore. By the third and fourth of June, it was almost universal both in North and South Shields; and by the 14th it totally difappeared.

Newcaftle being only diftant from Shields about eight miles, and the communication, both by the River and Flys, expeditious, the diftemper foon made its appearance in town. The first family, as far as can be afcertained, was feized on the 28th of May, and as the perfons who were attacked kept a public shop, it is more than probable, that they received the infection from fome failors failors who had arrived from the fhips at Shields *. On the first of June, another family in a house adjoining was attacked : and on the fame day two patients had every fymptom of the complaint, who were afterwards admitted to the benefit of the Newcastle Dispenfary.

But although I have fixed the first appearance of the Influenza in Newcastle to the 28th of May, yet no patient labouring under the distemper, came under my perfonal observation till the first of June. On the second and third

* This opinion of the difeafe being introduced into Newcastle by infection, is farther confirmed by the following fact, for which I am indebted to Alexander Adams, Esq. The master of a vessel who arrived at Shields, in forty-eight hours after he left the river Thames, came to his office on the 28th of May, labouring under the distemper. On the 29th, one of the clerks in the office was feized, and as far as I can learn, was the fecond perfon who was attacked with the difease in town. third of the month many were flightly affected with heavinefs of the head, and defluxion from the nofe. On the 4th fome were more violently feized, and obliged to confine themfelves to the house. On the 5th I visited a great number of patients, who were feverely and fuddenly attacked; and in two or three days more it prevailed univerfally throughout the town. By the 16th it had almost spent its force, and in a week more totally difappeared. In about fix or eight days after the epidemic appeared in Newcastle, the villages and cottages in the neighbourhood were attacked; and it gradually, but rapidly fpread itfelf to the most northern parts of the ifland.

From whatever caufe the prefent Influenza may have originally generated on the continent, where it was first observed ; ved; from the account which has been given of its introduction into this part of the country, there cannot remain a doubt of its being of an infectious nature. It is probable, however, that the manner in which it is communicated, differs widely from that of other contagions. The fmall pox, and plague, for example, when they appear in any town or city, are gradually communicated from perfon to perfon: at first houses, then streets, and at last large portions of the town are infected. The effluvia arifing from the bodies of the fick, in these diseases, not being capable of tainting the air to any confiderable distance, the contagion remains for a long time in a place. But the infection of the Influenza being of an exceedingly diffufible nature, it is reafonable to fuppofe, that the contagious effluvia float in the air to a confiderable diftance

diftance, and, by being applied to the mucous glands in infpiration, infect numbers of perfons at the very fame inftant of time. Hence the difeafe in a few days fpreads like an univerfal conflagration in every place where it is introduced, and foon totally difappears.

The propagation of Epidemical Catarrhs, which, at former periods, have fo often infefted Europe, and fometimes extended themfelves to the continent of America, must depend upon fome general cause; and none can be more universal than contagion, except miasmata*. But

* It has already been remarked that epidemical catarrhs have often been found to prevail amongft brutes before the human fpecies have been infected, which fhews the caufes of thefe diffempers to be general, and probably to proceed from infectious *miafmata* floating in the air. The epidemical Influenza of the year 1733, the most widely fpreading epidemic of which we have any account, first appeared univerfally amongst the horfes, before it attacked the human fpecies; and from the collected memoirs But whilft I fuppofe that the late Influenza did not become epidemical from any change of the fenfible qualities of the air, with refpect to heat, cold, moifture, or drynefs; yet fuch a conflitution of the atmosphere, as has been defcribed to have taken place in this country, before the appearance, and N during

moirs of different countries, its progrefs has been accurately afcertained. It invaded Saxony, and the neighbouring countries in Germany, about the 15th of November, 1732, and lafted in its vigour till the 20th of the month. It appeared at Edinburgh about the 17th of December; and raged at the fame time at Bafil, in Switzerland. It appeared in London and Flanders after the first week in January, 1733; towards the middle of the month it reached Paris : and in the end of it Ireland. In the middle of February Leghorn was attacked; and near the end of it Naples and Madrid. It began in America before it attacked Britain, appearing in New England about the middle of October, and travelled fouthwards to Barbadoes. Jamaica, Peru, and Mexico much at the fame rate as it did in Europe. The difeafe in fpreading from place to place, did not observe the direction, but went often contrary to the course of the winds. These facts are flrong prefumptive proofs that the diftemper muft have been diffeminated by infectious miafmata, probably conjoined with the contagion of human effluvia.

during the prevalence of the epidemic, could not fail to render it more general and rapid in its progrefs.

But as the profecution of a fubject of fo intricate a nature, as the investigation of the cause of any epidemic, would make me go beyond the limits which I have proposed, I shall return to the description of the disease.

Amongst adults, no epidemical diftemper was ever more universal than the Influenza of the prefent year. The healthy and the strong, the weakly and tender, those confined to the house, and those who were employed abroad, were equally liable. But the difease was particularly severe to the old and assumption and to women in pregnancy. Infants on the breast, however, were totally exempted; and, as far as came under under my observation, it was neither prevalent amongst, nor dangerous to children under ten years of age.

But although the Influenza was fo universal amongst adults, two families of my acquaintance, who used no means of prevention, did not take the distemper; and in other two families, although the males laboured under the disease, the females escaped. Another circumstance worthy of remark is, if any perfons kept free from the difeafe for a few days after it appeared in the family in which they lived, they were not afterwards liable to be feized. The following was the only exception to this remark, which occurred to me during the epidemic : a young lady who was particularly active in attending her relations, who had the diftemper in a fevere manner in the first week of June, did N 2

did not take the difeafe till about the 24th of the fame month. She laboured under the fever and catarrhal fymptoms to a great degree; and, as far as I know, was the last perfon in the town who was feized with the distemper.

The fymptoms which accompanied this epidemic were extremely various; but it was eafily diftinguifhed by the following characteriftic marks: "The "patients were feized with laffitude, or "general forenefs over the body, a dull "heavy pain in the forehead, particu-"larly acrofs the eye brows, and betwixt "the eyes themfelves. A cough foon "fucceeded, with defluxions from the "nofe and eyes, attended with fome "degree of febrile heat, and quicknefs "of pulfe."

With these fymptoms many continued at their occupations. But in most patients

patients the fever ran fo high, as to make confinement to the house, and very frequently to the bed, indifpenfably requifite. In those who were thus violently feized, the difease came on with coldnefs and fhivering, and fometimes with a giddinefs, and was foon fucceeded with heat, thirft, and inquietude. The pulse often beat from 100 to 120 pulfations in a minute; the catarrhal fymptoms, already mentioned, were aggravated, and, especially after a fit of coughing or fneezing, the patients often complained of foreness and pains in the breaft. In fome the febrile fymptoms ran fo high, as to threaten fome degree of delirium. After the first twenty-four hours, however, the fever generally abated, but a nocturnal exacerbation with fweating took place for fome nights longer.

Some

Some patients were feized with every fymptom of the difeafe, except the cough. Some had the cough and fever without any difcharge from the nofe; and in others the defluxion from the mucous membrane of the nofe, *fauces* and *trachea* was fo great, as to occafion excoriation of the noftrils, forenefs in the throat, and an inceffant troublefome cough. A few alfo, whom I attended, complained of a total privation of their tafte, which continued for feveral days, and fometimes for a week or two, after every fymptom of the complaint had difappeared.

The duration of the fever, in those who were confined, was various. In fome it only lasted for a day; in others it continued for a week; and in a few patients, from neglect, or improper treat-

treatment, it ran out from fourteen to twenty days, attended with many anamolous alarming fymptoms. But the period of the fever was in general from three to four days, and its crifis was effected either by a kindly moisture on the skin, or by profuse perspiration, which, in fome patients, continued for forty-eight hours and longer, without intermiffion. When the fweat began to flow, the catarrhal affection was mitigated, and every fymptom foon difappeared, except a remarkable degree of debility. Relapfes, however, were very frequent, and, especially after exposure to cold, every fymptom recurred with greater violence; but after a perfect recovery, no inftance occurred where the fame patient had the difeafe a fecond time.

The Influenza, in its fimple ftate, though fometimes attended with alarming ing fymptoms, as far as came under my obfervation, proved fatal to none. But it frequently happened, efpecially towards the end of the epidemic, that it was complicated with pleurify and inflammation of the lungs, and, in old perfons, with the *peripneumonia notha*; and, in this way, it carried off feveral perfons in this town. It was likewife, feveral months after the epidemic had difappeared, attended with fatal confequences to perfons who had a tendency to confumption; and to thofe who had the humid afthma.

With respect to the cure: As the difease in its simple state was, in most cases which occurred, free from danger, nothing more was requisite than avoiding catching additional cold; and encouraging sweating, especially when the nocturnal exacerbation came on, by drink-

drinking weak wine whey, or any. other tepid diluting drink. But when the fever ran high, belides tepid Diluents, I found it in many cafes indifpenfably neceffary to prefcribe Antimonials, at first, in fuch doses as to produce gentle vomiting, and, afterwards, in fuch a manner, as to keep up a free perspiration. These remedies, together with the pediluvium, and fometimes an opiate at bed-time, in general foon removed every fymptom of the difease; neither did I ever prefcribe bleeding, except the lungs were evidently inflamed : for the flighter pains of the breaft were carried off as foon as the fweat began to flow; the fever alfo was mitigated, and foon totally difappeared.

In the anamolous cafes, which have been already mentioned, where the fever ran out for fome weeks, the treat-O ment ment was more difficult. But what anfwered beft were Emetics, Antimonials, and Opiates; and when the violence of the fever was reduced, or when remiffions happened, *the Bark* fometimes proved of fingular advantage.

In the complicated flate of the Influenza, attended with fymptoms of active inflammation of the Pleura, or Lungs, I prefcribed V. S. freely, and fometimes had occasion to repeat it for three or four times. But when the fymptoms of inflammation did not run high, this evacuation was more fparingly used. Antimonials, Pectoral Decoctions, and Infusions were given; as alfo mixtures with Gum Ammoniacum, and Oxymel of Squills, when expectoration began to flag. Blifters were early applied, and repeated as often as occafion required. These medicines, together with an opiate occasionally at bedtime,

(99)

time, feldom failed to conduct the patient through this dangerous state of the difease.

When the Influenza was complicated with *peripneumonia notha*, known by a pain over the whole breaft; quick, wheezing, and rattling refpiration; lividity of countenance, with little or no quicknefs of pulfe; the only chance of recovery was to fupport the ftrength of the patient by wine, and cordials; and to relieve the lungs, from the accumulation of ferum, by Antimonial Emetics, Blifters, and expectorating mixtures, with Oxymel of Squills, or Antimonial Wine.

Having thus, though very imperfectly, given you an account of the rife and progrefs of the Influenza, as it appeared at Newcastle, and its vicinity, permit

(100)

mit me, my dear friend, before I conclude, to express my most ardent wishes for your recovery from your present complaints, which have made a voyage to a more temperate climate fo indifpensable. May you soon return in perfect health; and may your life be long preserved for the benefit of the medical profession.

I am,

With the utmost esteem and friendship, Dear Sirk Your most obedient Servant, JOHN CLARK.
