Early in the ſpring of 1710, the parliament of Paris, hoping that the corn cut off by the preceding winter would ſhoot out again, as it did after the winter of 1608, mentioned by Mezeray, forbid ſowing anew the lands which had been ſown the autumn before: but the expectation now proved groundleſs, the plants having been totally deſtroyed by repeated froſts, intermixed with frequent thaws; ſo that had it not been for the barley that was ſowed afterwards, which yielded ſuch prodigious crops, that the French ſtill call that year the year of barley, the dearth muſt have been much more dreadful than it was. In that very ſpring, after the hard winter, ſeveral people in the dutchy of Berry, and elſewhere, ſowed wheat, which ſpouted well, and grew, but did not ſpindle; whereupon ſome mowed their crops, and others turned in cattle to feed as in a meadow; but after another winter had paſſed over them, theſe very fields yielded the next year as plentifully, as if they had been ſown anew. In incloſed grounds, the corn near hedges, which ſecured it from the north wind, reſiſted all the rigour of that exceſſive cold; and in other places, where the poor peaſants raked up all the ſnow they could collect, and ſpread it with their hands upon the uncovered ſpots of their ſmall fields, their corn was preſerved, and yielded a good crop.

A gentleman, now living in England, had a field of wheat ſo greatly damaged by alternate froſt and thaw, that the neighbouring farmers thought he could not do better than plough it up for ſpring corn; but obſerving that many of the plants were yet alive, and in a condition to be recovered, though thinly ſcattered, he hand-hoed the whole, and reaped three quarters of corn from each acre of this land.

FROWAR, the name of an edge tool, uſed in cleaving laths.

FRUIT, the produce of a tree or plant, in which the ſeeds are contained.

Thouſands of objects teach us, that moiſture and warmth are the great cauſes of putrefaction. From the decay of many otherwiſe laſting bodies, we learn, that the alternate changes of heat and cold, of dryneſs and moiſture, moulder to pieces even the ſolid oak. Theſe general cauſes of putrefaction and decay ſhould therefore be avoided, or prevented, as much as poſſible; and to this end an equal ſtate of the air, with regard to heat and dryneſs, becomes neceſſary in a repoſitory for the preſervation of fruit. The want of dryneſs renders cellars in general unfit for this purpoſe; though ſome of them may, perhaps, be dry enough; and if they are, the other requiſite, of an equal ſtate of heat, is uſually found in them: but as this is not often the caſe, it is ſurely worth the gentleman's while to provide a receptacle on purpoſe for his fruit. A cloſet, ſurrounded every way with good walls, and furniſhed with double doors, promiſes the beſt ſucceſs. In this cloſet, different compartments, or bins, may be made of brick, which continues much drier than ſtone or wood. Large jars, or caſks, will alſo anſwer the ſame end, when they are cloſely ſtopped; and ſo do boxes, as it is well known to the London fruiterers. Either of theſe may be proportioned to the quantity which it is adviſable to keep in each, that is, to the quantity that is to be conſumed within a few days; for even in ſuch a place the fruit ſhould be expoſed to the air as little as can be, before it is eaten. Experience will ſoon ſhew to the good manager the importance of this caution.

When the fruit, we mean chiefly apples and pears, for they are fitteſt for keeping, has been carefully gathered by hand, in perfectly dry weather, and ſweated for ſome days, in heaps on a clean floor, till it has diſcharged its watery and crude juices, each apple or pear muſt be rubbed ſingly with a coarſe cloath, to clean and dry them, and if the leaſt hurt or ſpeck tending to putrefaction appears at this wiping, all the fruit ſo marked muſt be laid aſide, as unfit for keeping. A layer of very dry ſtraw ſhould be laid at the bottom of the veſſel, whatever it be, in which they are to be preſerved, and upon this a layer of perfectly ſound apples or pears; then another layer of ſtraw over them, a layer of fruit upon this, and ſo alternately till the whole intended quantity is put in. We have named ſtraw, becauſe it is eaſieſt to come at; but any other ſubſtance, which is perfectly dry, and leaſt liable to corruption, will do. If, therefore, each layer of fruit is ſheltered above and below with a covering of paper, to preſerve it from the taſte which ſaw duſt might give it, this bids fair to anſwer the deſired purpoſe. On this principle it is that roots are preſerved in ſand: the only objection to which, for the uſe here intended is, that its weight may hurt the fruit, otherwiſe it promiſes well, when perfectly dry.

FRUIT-TREES, a general name for trees that produce eatable fruit, as apples, pears, plums, peaches, apricots, figs, &c. See each under its proper article.

FRUNDELE, two pecks, or half a buſhel.

FRUSHES. *See* RUNNING-THRUSH.

FUDDER, a load. It properly relates to lead, and ſignifies a certain weight, viz. eight pigs, or ſixteen hundred weight.

FULLERS EARTH, a native earth found in many parts of England, and much uſed by fullers in cleaning and ſcouring their cloth. It is of a very fat nature, and very full of that vegetative ſalt that helps the growth of plants; and therefore may be uſed with advantage, where it is found in plenty, on ſome ſorts of land.

FURLONG, the eighth part of a mile.

FURROW, a trench made by the plough.

FURZE, *whins* or *gorſe*, to which C. Baukin and Mr. Ray, give the name of *geniſta ſpinoſa*, and which Linnæus

næus and Miller call *ulex*, propagate themſelves ſo rapidly, by ſowing their ſeeds, that, where they are once eſtabliſhed in a ſpot of ground, they ſoon over-ſpread the whole place; for, as the ſeeds ripen, their pods are opened by the warmth of the ſun, and they are thrown out with an elaſtic jirk to a conſiderable diſtance all around. There they vegetate, and the ground is ſoon filled with young plants, which are not eaſily deſtroyed after they have taken good root. The only way of extirpating them, is by paring off and burning the ſurface of the ground. *See the article* BURN-BAKING.

This is by ſo much the more adviſable, as theſe ſeeds will otherwiſe remain a long while ſound in the earth, and grow whenever they are brought up by ploughing; and alſo becauſe the ſmalleſt fragments of this plant will ſtrike out freſh roots, and ſhoot up anew: but when a good thickneſs of the ſurface is pared off, and burnt, the ſeeds are ſo effectually deſtroyed, and the roots are killed to ſo conſiderable a depth, that neither can again give riſe to new plants; and if a few of theſe do appear, a ſummer fallow will put an entire end to their growth. Their increaſe may likewiſe be prevented by good manuring with marl, chalk, or lime, eſpecially in ſandy ſoils, which are the moſt apt to produce this plant, and which are at the ſame time the moſt benefited by thoſe helps.

However, this very plant, formerly deemed a great nuiſance, is now cultivated to advantage on light, ſandy, dry ſoils, which would otherwiſe turn to little account. The tops of the common Engliſh furze, bruiſed a little, to take off, or to blunt their prickly tips, have been found to be excellent fodder, even for lean ſickly beaſts, and particularly horſes, which they have frequently recovered, and plumped up in a ſhort time. This cuſtom is much practiſed in ſeveral foreign countries, where furze are cultivated purpoſely for fodder; and the peaſant thinks it a happineſs, that his breaking their ſpikes with a mallet enables him to give this wholeſome green food to his cattle in the winter, when often no other ſucculent plant can be had fit for that uſe. The mills which Sir Capel Hanbury has lately erected for this end in Wales, with a patriotic ſpirit, well ſuited to his diſtinguiſhed zeal for the public welfare, will ſave the countryman that laborious taſk, and prove highly beneficial to thoſe who follow his judicious example.

When furze are raiſed on purpoſe for the food of cattle, and eſpecially on ſoils like the above mentioned, their ſeeds ſhould be ſown in February, March, or April, and the ground ſhould be prepared as for barley. Six pounds of them will be ſufficient for an acre of land; and they ſhould be but barely covered over. The young plants muſt be preſerved from cattle during the firſt year, and they will be fit to mow or cut in the next. October is the proper time to begin cutting them. They will continue to ſhoot till Chriſtmas, and be fit for uſe till March. Horſes eat them as readily as they do hay, after they have been bruiſed, or pounded, ſo as to take off their ſharp points; and it is ſaid, that an acre of ground will produce fifteen tons of this fodder, and that it will go as far as an equal quantity of hay. Some mix the bruiſed furze with chopped ſtraw; an hundred of ſtraw to a ton of furze; but only the growth of the year ſhould be cut for cattle.

Poor hungry gravelly ſoils, which would not have let for five ſhillings an acre, have been rendered worth twenty ſhillings an acre, by ſowing them with furze ſeed, in places where fuel has been ſcarce; this being frequently uſed for heating ovens, burning lime and bricks, and alſo for drying malt; but it is not worth cultivating in countries where fuel of any kind is cheap, or upon ſuch lands as will produce good graſs or corn.

Some years ago, the common furze uſed to be much ſown for hedges about fields; and where the ſoil was light, the plants ſoon became ſtrong enough for a fence againſt cattle: but as theſe hedges grow naked at the bottom in a ſhort time, and the plants frequently failed, ſo as to leave conſiderable gaps, this practice has of late been greatly diſuſed. The ſpecies commonly called French furze is the beſt for this purpoſe, becauſe it thickens more near the ground, and grows to a greater height: but its ſhoots are not tender enough for cattle to eat them. This is alſo conſidered as the moſt difficult to extirpate: though Mr. Bradley, who tells us he had ſeen fields of one hundred and fifty acres planted with it in Devonſhire, ſays, that it may be killed by cutting the woody ſtalks within a foot of the root in ſummer time; for that it will not then ſpring up again like the ſmall wild furze or whins, by which name Mr. Markham diſtinguiſhes the ſmaller from the larger ſort. This begins to blow in the middle of January, and continues in bloſſom all the ſummer; while the Engliſh furze does not bloom till towards the end of the ſpring, and finiſhes its bloſſoming at the ſame time as the other.

The marquis of Tourbilly obſerves, that cows, oxen, and moſt other cattle, as well as horſes, feed heartily upon, and are well fed by, the bruiſed tops of furze; and that we may be ſure corn will do well where-ever this plant is met with: for be the ſurface of ground what it will, the ſpontaneous growth of the furze always indicates a depth of good mould underneath; and the continual dropping and rotting of the leaves, will infallibly improve and enrich the ſurface. The flowers of the furze are excellent for bees.

FUZZEN, *or* FUZEN, the natural juice or nouriſhment of any thing; the ſtrength of it.

G.

GALLERY, a kind of covered walk in a garden, formed into porticoes or arches, with horn-beams, lime-trees, or the like.

GALLING *of a horſe's back*, a diſorder occaſioned by heat, and the chafing or pinching of the ſaddle.

In order to prevent it, ſome take a hind's ſkin well garniſhed with hair, and fit it neatly under the pannel of the ſaddle, ſo that the hairy ſide be next the horſe.

When a horſe's back is galled upon a journey, take out a little of the ſtuffing of the pannel over the ſwelling, and ſew a piece of ſoft white leather on the inſide of the pannel; anoint the part with ſalt butter, and every evening wipe it clean, rubbing it till it grow ſoft, anointing it again with butter, or, for want of that, with greaſe: waſh the ſwelling, or hurt, every evening with cold water and ſope, and ſtrew it with ſalt, which ſhould be left on till the horſe be ſaddled in the morning.

GALLON, a meaſure of capacity both for dry and liquid things, containing four quarts; but theſe quarts, and conſequently the gallon itſelf, are different, according to the quality of the thing meaſured: for inſtance, the wine gallon contains 231 cubic inches, and holds eight pounds avoirdupoiſe of pure water: the beer and ale gallon contains 282 ſolid inches, and holds ten pounds three ounces and a quarter avoirdupoiſe, of water; and the gallon for corn, meal, &c. 272$\frac{1}{4}$ cubic inches, and holds nine pounds thirteen ounce of pure water.

GALLOWS *of a plough*, a part of the plough-head, ſo called by farmers, from its reſemblance to the common gallows, as conſiſting of three pieces of timber, of which one is placed tranſverſely over the heads of the other two. *See* PLOUGH.

GAP, a breach, or opening made in a hedge.

GARDEN, a plot of ground cultivated and properly ornamented with a variety of plants, flowers, fruits, &c.

The generality of writers upon this ſubject, and indeed moſt gardeners, in their practice, have, at leaſt till of late years, treated the pleaſure garden, the fruit garden, and the kitchen garden, as three quite diſtinct and ſeparate objects, not only in point of culture, but even of ſituation, ſoil, and incloſure. They are undoubtedly right as to the firſt: but we ſee no reaſon for disjoining the two laſt, unleſs it be in written accounts, where, for the ſake of greater order and perſpicuity, and for the conveniency of the reader, their ſeveral products, and the different ways of managing them, may with propriety be given ſingly, as will be the method here.

The pleaſure or flower garden, being intended ſolely for ornament and recreation, does not belong to this work, the main deſign of which is utility. We ſhall therefore only obſerve, in relation thereto, that the gentleman who can afford to be at the expence of ſuch a garden, for the laying out, planting, and managing of which he will find ample and excellent directions in Mr. Miller's Dictionary, will, of courſe, place it in a properly conſpicuous part, where it may afford the greateſt entertainment to the eye. Conſequently he will order it to be made next to, or juſt againſt, the back front of his houſe, from whence a deſcent of at leaſt three, but rather of ſix or ſeven, ſteps will ſingularly embelliſh the whole. He will allow room for a ſufficiently extenſive lawn, which, if it be the firſt thing that ſtrikes the ſight, will have an elegant effect; for ſpacious walks, one of which, ſo contrived as to be perfectly dry, and every now and then to lead to a ſhady place, or into plantations of ſhrubs, where a perſon may walk in private, ſhould ſurround the whole garden, were it only for the benefit of exerciſe. He will have wilderneſſes, groves, green-houſes, &c. and he will be particularly careful to provide plenty of water, for caſcades, fountains, and winding ſtreams, which laſt, if ſo conducted as to imitate nature, will give life and beauty to the whole, beſides being of neceſſary uſe for watering the ground. Statues and vaſes, judiciouſly diſpoſed, are alſo, here, pleaſing and proper objects: but neither theſe, nor any of the buildings in the garden, whether temples, grottos, alcoves, or other, ſhould by any means be too much multiplied, or crowded.

Mr. Miller obſerves very rightly, ſpeaking of pleaſure gardens in particular, that the great art of laying them out, is to adapt their ſeveral parts to the natural poſition of the ground, ſo as to have as little earth to remove as poſſible; for this is often one of the greateſt expences in making of gardens: though it may with truth be affirmed, that, wherever it has been practiſed, nine times in ten it has proved the worſe: ſo that if, inſtead of levelling hills to form large terraces, ſtiff ſlopes, and even parterres, or ſinking of hollows and raiſing of hills, the ſurface of the ground had been only ſmoothed and well turfed, this would have produced a much better effect; and have been more generally approved, than the greateſt number of thoſe gardens which have been made with an infinite expence both of time and of money.

The boundaries of theſe gardens, whatever they are fenced with, ſhould be carefully hid by plantations of flowering ſhrubs, intermixed with laurels and other evergreens, to conceal the fences, which have a diſagreeable look when they are left naked and expoſed. All the boundaries ſhould not be ſeen from any one point of view: and if the country around affords a variety of pleaſant proſpects, it will be right to bound the pleaſure garden by an ha-ha ditch and wall, to lay open thoſe views.

Neither

Neither the husbandman, nor the country gentleman of moderate fortune, who prefers utility to ostentatious show, can set about an easier or more profitable branch of culture, than that of the kitchen and fruit garden, which may very properly be intermixed, and occupy one and the same spot of ground, since they both require a good, deep soil, and nearly the same exposure. The walls which inclose the kitchen garden, in order to secure its product, will be extremely serviceable for fruit: and, if elegance should be studied, this united garden may still be placed out of view from the dwelling-house.

The chief things to be considered in the choice of a spot of ground for a kitchen and fruit garden are, the situation, the soil, the conveniency of water, the extent most proper to be inclosed, and the manner of inclosing it, and laying it out.

If the husbandman can choose his soil and situation for a garden, the former should be rich, rather stiff than light, and considerably deep. Nor is a moderate degree of moisture here by any means an objection. The situation should be nearly level: because heavy rains would wash away the richest part of the mould, if the declivity were considerable. If he has not a level spot near his house, the ground intended for the garden may be made into flats with terraces supported by strong walls, which will become useful for fruit-trees. A gentle inclination may be preserved, to answer Mr. Miller's idea of having one part of dry ground for early crops, and the low part for late crops, in order that the kitchen may be the better supplied throughout the season with the various sorts of herbs, roots, &c.

He should not be discouraged at some seeming disadvantages to which his soil and situation may expose him; for no difficulty is so great, but that it may be overcome by care, industry, and perseverance. Of this we have a striking instance in the following part of a paper which D. J. Beale read to the Royal Society, some years ago, with a view to the improvement of gardening in Scotland.

"I had, says he, several conferences with Sir Robert Murray (who was an honour to his country, and a blessing to the place where he abode) concerning esculent and olitory gardens, and (under one) nurseries of fruit-trees, and other useful vegetables in Scotland. I represented, that, almost within my memory, they are become the chief relief of England; that austere fruit has been found to yield the strong and sprightly liquor which resembles the wine of the grape; that the return of gain from gardens is great and speedy; and that nurseries are neither a chargeable nor a burthensome addition, but a motive of encouragement to persevere in the noblest kind of agriculture. Sir Robert granted all I said: and I am sure he executed all that he could for the benefit of his own country, and of this. But, said he, there are so many rocks, and such bleak winds, in Scotland, that it can hardly draw in the same yoke with England, for gardens and orchards. I replied, that, in Devonshire and Cornwall they fence their gardens and orchards with Flanders furze and tall holly, from the sea winds; that they have lofty firs and goodly pines in Scotland; and that New England, where the winds are as keen, and the snow and frosts as deep, and as long lasting as in many parts of Scotland, is nevertheless full of fruitful orchards. And if Scotland be farther in the north, yet Norway is rich in boscage; and the seeds of the hemlock, fir, spruce, and cedar, from New England, Newfoundland, and Virginia, may perhaps rejoice in the exchange of Northern America, for the north of this island.

"This, I told Sir Robert, I durst undertake; that when Edinburgh and their chief towns and universities shall plant kitchen gardens, as we do now in England, they shall receive their grateful reward the first year, and bear the charges of their nurseries abundantly, and so hold on, and within seven years secure their posterity of the benefit, and delight themselves with the fruit of their pleasing labour.

"Now for fertilizing rocks, I made bold to repeat it often, that, within a day's journey of the heart of England, I could shew three gardens, the best that I have seen for flowery beauties, English ever-greens, and sallads all the winter long; all these on a hard rock, in most places but one foot deep under earth, in some two, and in very few three, with very lofty hills close to the south side, the declivity of the gardens due north, and the rock perfectly bare next to the walls on the north side. I likewise saw rich hop yards in the same case, but in deeper ground, next to the garden on the south side: and these northern hop yards escaped many blasts, which seized on the hop yards on the south side of the hill. On the steep ascent on the north side of one of these rocky hills, where no plough could come, I saw a gentleman ploughing up the shallow tuf with a hand-plough, for flax; and I saw good flax grow there, to the largeness of a village-field. His hand-plough had a stem of ash, or sally, about seven feet long, and a plate at one side near the end, to turn the turf; a coulter to be let out shorter or longer, to cut the turf four, five, or more inches deep, as the land permitted, and a small iron wheel. This hand-plough the master and the man, by turns, drove before them with a walking speed; having leathern aprons before them, to save their cloaths. For the causes of this hardy fertility, let philosophers account. I am sure of the truth of what I write.

"It is no hard task to shovel down the shallow and mossy turf, from the deepest declivities of rocks, into places where it may have a receptable or stay, and there, with the spade to mix and impregnate it with compost for gardens or vineyards. There too the tenth part of an acre in gardening may yield more profit, than ten acres of ordinary tillage in a corn field." *Philosophical Transactions, number* 116.

On the other hand, we have many proofs that wet, and even very marshy, grounds have been converted into excellent kitchen gardens, after they have been drained. Such was, formerly, all that large part of Paris which still retains the name of *le marais* (the marsh;) and such were, evidently, several of our most profitable gardens around London. The marquis of Turbilly has given us farther instances of this truth in several of his noble improvements; and the Memoirs of the truly patriotic Society of Berne remark very justly, that all legumes and pot-herbs thrive perfectly well in the black, rich, moist, and somewhat rising, grounds, which most commonly skirt the borders of marshes.

As warmth is essentially necessary to a garden, it is advisable that the exposure of the ground intended for this purpose be to the south-east, or south; and that it be protected from the north and north-east, either by high grounds, or plantations of lofty trees at a small distance. Fruit-trees require to be likewise protected from the south-west and west, which are apt, in the autumn, to shake the fruit.

The husbandman should here spare no trouble or expence to render his soil of a proper quality and depth: and if it be not naturally so, he must have recourse to one or other of the methods practised for the improvement of soils, according to the nature of his ground.

Whatever the soil be, the mould in which the plants are to live and thrive should be deep enough to afford their roots full room to extend themselves. It appears by several experiments, that the roots of many plants, not excepting even annuals, pierce to the depth of eighteen inches, and more. To allow therefore a sufficiency of room, though perhaps more than may be really wanted, a depth of three feet of good mould should be allotted them here: and if the soil underneath is clay, or retentive of water, which would be apt to chill the roots of plants, it will be right to exceed even this depth.

Trenching is the most effectual way to obtain a considerable depth of well loosened mould. The common method of doing this, when the soil underneath is clay, is to begin with digging a trench four or five feet wide, either along or across the whole ground; then to lay in the bottom of it, about half a foot thick, long dung, fern, leaves of trees, rotten sticks, weeds, or any other such like trash, to rot and keep the soil from binding; then to fill this up with the earth dug out of the next adjoining trench, laying uppermost the spits that were lowest, and so to continue till the work is finished, without ever going deeper than just to the clay, though the surface be never so shallow. But if the clay be dug into, and part of it be turned up and mixed with the other earth, its bad qualities will soon be corrected by the influencies of the air, rain, tain, and one winter's frofts; it will become good and fertile mould, and the depth of the ftaple will be increafed thereby, efpecially with the addition of a little drift fand, coal, or other afhes. The beft time for trenching of land, that it may receive the benefit of being well mellowed, is the beginning of winter; when alfo, being moift, it is eafy to dig.

When the mould on the furface is but fhallow, and lies on a bed of fand, gravel, or loofe earth, it will be advifable to lay a layer of ftiff earth, inclining to clay, at the bottom of the trench. This will be more efpecially neceffary for the growth of trees, or plants whofe roots naturally pierce deep: for by means of this earth, thofe roots will fpread horizontally in the mould, inftead of ftriking down, as they would otherwife do, into barren earth, which would immediately make the trees decay and become ftinted. And another advantage attending this method will be, that as water cannot fo eafily defcend through this ftiffer foil, the earth will be thereby preferved in a fo much moifter ftate; yet even here the clay fhould not be fuch as is impervious to water; for this, unlefs it lie very deep, would be attended with as bad confequences as the other extreme.

The general practice of gardeners is regularly to trench their ground, and lay it rough in the winter, without fufficiently confidering the quality of the foil, or the nature of the earth which lies underneath. But a little reflection would convince them of their error. Let us, in this light, fee what is the effect of trench in various foils. If the ground is naturally light, and lies on a bed of fand or gravel, it is to be feared that every fubftance brought to improve the foil, together with its fineft and richeft particles, will be carried down into that fand or gravel. Does not too frequent trenching contribute to this lofs? as does likewife laying the furface rough in the winter: for the rains wafh the finer mould into the hollow places, from whence, the depth of the foil being leaft there, it is moft readily carried down into the loofe earth underneath. If the foil underneath is ftiff, frequent trenching is proper in order to bring back to the furface the rich mould that has been wafhed down: and if it be naturally ftrong, the laying of it rough in the winter is an advantage, becaufe the winter's frofts will moulder its tough ftrong particles.

This method of preparing the ground is, undoubtedly, expenfive: but its fertility afterwards will yield an ample reward.

Plenty of water is abfolutely neceffary in this garden, and therefore great care fhould be taken to provide it, in fuch manner that it may become at as eafily as poffible. If a fufficient fupply of it can be obtained from the neighbouring grounds, two or three bafons fhould be made in different parts of the garden, if it be a large one; for when the water is to be carried to a confiderable diftance, the expence attending this neceffary bufinefs will be great, and there will be danger of the plants fuffering for want of it; labourers being very fparing of their work, efpecially when it is toilfome, unlefs they are well looked after. The fize of thefe bafons fhould be proportioned to the quantity of water that will be wanted, or with which they can be fupplied: but their depth fhould not exceed four feet, for fear of accidents, if people fhould chance to fall into them: befides which, deep water is not fo well warmed and tempered by the fun and air, as when it is fhallow.

The methods ufed for collecting and preferving of water in ponds or refervoirs in the field, are equally applicable to the making and replenifhing of thefe bafons in the garden. But it will be proper here to add the following more particular cautions and inftructions of Mr. Miller, who, after obferving, that the beft time of the year for lining thefe bafons with clay, particularly in loofe or fandy land, and for afterwards covering that clay with a thick layer of coarfe gravel, is in autumn, when the fun is declining, and the weather temperate, advifes, "as a farther means of fecuring this clay from being cracked by the heat of the fun, or by froft, to lay upon the rim or top of it, around the fides of the bafon, a ftratum of fand, then a ftratum of good earth, and upon this a layer of thick turf. The grafs thus laid will root in the mould underneath, and bind the whole firmly together: and it fhould be laid as far down the infide of the bafon, as the water is apt to fhrink to, that no part of the clay may be wholly expofed to the weather.

"No trees or fhrubs fhould be fuffered to grow near thefe bafons, left their roots fhould penetrate into them, and thereby occafion holes through which the water would find an eafy paffage. Neither fhould thefe refervoirs be made near to tall trees, becaufe the fhaking of them, by violent winds, would be apt to loofen and crack the clay.

"In countries where clay proper for this purpofe cannot be eafily had, thefe bafons are frequently lined with chalk beaten into fine powder, and made into a fort of mortar, which is rammed down and worked very hard and firm all over their infide. This cement holds water very well, if the pond be not fuffered to remain too long dry: for when this happens, the fun and wind are apt to crack the chalk, and thefe cracks generally extend through its whole thicknefs, fo as to let out the water.

"Some line thefe ponds with bricks laid in terras, which is a good method where the ground is very loofe and fandy; becaufe when thefe walls are well built, the furrounding earth may be rammed down clofe to them, fo as to prevent its falling away, or fettling from them. But, as heat is apt to crack the terras, no part of this lining fhould be left long dry and expofed.

"Others again ufe for this purpofe a cement of powdered tile and lime, two thirds of the former to one third of the latter, beaten well together, and worked up with but little water: for the ftiffer it is, and the more it has been beaten, the better it will be. With this cement they cover the furface of the walls of bafons about two inches thick, laying it very fmooth, and taking great care that no fticks, ftraws, or ftones be mixed with it. This is generally done in dry weather; and as foon as the whole infide of the bafon has been plaiftered in this manner, it is rubbed over with oil or bullock's blood, and the water is let in immediately after. This cement has the property of hardening under water, fo as to be equal to ftone; and it will continue as long found."

Where a fupply of water for bafons and ponds cannot be obtained, wells muft be dug, and it is generally advifed, that the water taken out of them be expofed to the fun and air for fome time, before it is ufed, becaufe, fays Mr. Miller, the rawnefs of this water, when frefh drawn, is not agreeable to the growth of vegetables.

The fize of this garden fhould be in proportion to the wants of the family; but with a much larger allowance of ground than is ufually allotted, in order that the plants may be benefited by ftirring the earth between them whilft they grow. The great and manifeft advantages of this practice, efpecially in the culture of pulfe and garden plants, have been fo evidently fhewn by numbers of experiments related in the former parts of this work, that I cannot but again recommend it here as an object of high importance.

It fhould be inclofed with a wall, either of brick or ftone; but brick is beft, for the greater conveniency of nailing up the fruit-trees which are to be planted againft it. The thicknefs of thefe walls fhould be proportioned to their height, which fome run up to twelve or fourteen feet, or more: but nine or ten will be enough for almoft any kind of fruit; and in this cafe thirteen inches, that is to fay, a brick and an half, will be a fufficient thicknefs; though two bricks will be better, for duration. Their infide fhould be built as fmooth as poffible, and, to ftrengthen them againft high winds, piers fhould be run up with them, at the diftance of about twelve or fourteen feet from each other, according to the ufual extent of the fruit-trees for which they are intended. As to pears, which fpread very wide, and frequently grow much above the height here mentioned, they do not require the affiftance of a wall; unlefs it be fome of the lateft winter forts, and thefe the curious, who will be at the expence, may plant againft walls built on purpofe for them. Thefe piers may project fix or eight inches on the outfide of the wall, for the fake of greater folidity; and they fhould advance about four inches on the infide, for the convenience of fixing to them trellifes, by building the wall on arches; and planting the trees at thofe arched places, as Mr. Hitt advifes, the trees will be thereby enabled to extend their roots underneath the wall; which will prove very advantageous to their growth.

If the quantity of walling which furrounds the kitchen garden be too little to furnifh the defired fupply of fruit, a crofs wall may be built through the middle of this ground; or, where the fize of the garden will admit of it, there may be two crofs walls: but thefe walls muft not, by any means, be lefs than eighty or an hundred feet afunder. More will be yet better.

Mr. Miller is clearly of opinion that the beft afpect for walls in England, is to have one point to the eaftward of the fouth; becaufe thefe will enjoy the benefit of the morning fun, and be lefs expofed to the weft and fouth-weft winds (which are very injurious to fruits in this country) than thofe which are built due fouth. "I know, fays he, that many perfons object to the turning of walls the leaft point to the eaft, on account of the blights which they think come from that quarter in the fpring: but from many years experience and obfervation, I can affirm, that blights as often attack thofe walls which are open to the fouth-weft, as thofe which are built to any other afpect; and I believe thofe who will be at the trouble of obferving for feven years, which afpected walls fuffer moft from blights, will find thofe which are built with a point to the eaftward of the fouth, as feldom blighted as thofe which are turned to any other afpect; therefore in the contrivance of a kitchen garden, there fhould be as great a length of thefe walls built as the fituation of the ground will admit.

" The next beft afpect is due fouth; and the next to that fouth-eaft, which is preferable to the fouth-weft, for the reafons before affigned: but as there will, for the moft part, be fouth-weft and weft walls in every garden, thefe may be planted with fruits which do not require fo much heat to ripen them, as thofe defigned for the beft walls; but wherever there are north walls, thofe will only be proper for baking-pears, plums, and morello cherries for preferving; or fome duke cherries may be planted againft thefe walls, to fupply the table till peaches, nectarines, and plums are ripe."

In whatever manner the wall are made, this garden fhould be well fheltered from the north and north-eaft, by a diftant plantation of high timber-trees, if nature has not otherwife provided a fufficient defence from thofe quarters.

In the diftribution of this garden, particular care fhould be taken to lay the walks out fo as to obtain the greateft convenience that can be for fupplying each part of it with manure and water, and as eafy accefs as poffible to its different quarters, which may be furrounded by a border planted with efpaliers. The manner of forming efpaliers will be directed when we come to fpeak of the training of fruit-trees.

Thefe walks fhould be firm enough to bear at leaft the weight of a loaded wheel-barrow, and wide enough for the convenient carriage of whatever there may be occafion to bring into this garden, or to carry out of it. Mr. Miller is againft making them of gravel; becaufe, as it will very often be neceffary to wheel manure, water, &c. upon them, they would foon be torn up and rendered unfightly; unlefs care be taken that the wheel be broad; or rather that it be a roller as wide as the diftance between the fides of the wheel-barrow.

For the fame reafon he rightly condemns turf-walks here, and advifes, as the beft for a kitchen garden, thofe which are laid with a binding fand. In effect, thefe are the eafieft kept of any: for when either weeds or mofs begin to grow, fcuffling of them over with a Dutch hoe in dry weather, and raking them over a day or two after, will render them as clean as when they were firft laid: or if they are covered with duft taken from great roads, this will bind and become very firm.

If the foil is ftiff and apt to retain water, narrow underground drains fhould be made by the fides of the walks, to carry off that wet: and where the ground is naturally moift, lime rubbifh, flints, chalk, or any other fuch material as can be procured with the leaft expence, fhould be laid at the bottom of thefe walks; or if neither of thefe can be had, the fand fhould be laid thick upon a bed of heath or furze, and the water will drain through this, fo that the walks will be firm and good in all feafons.

The fame means will alfo help greatly to drain away the fuperfluous moifture of the whole ground, if the foil fhould be naturally too wet; for if they are not fufficient, more under-ground drains may be made acrofs different parts of the garden, according to its declivity: for moft kitchen plants are hurt by too much moifture in winter; and trees never produce good fruit when their roots lie in water.

If each quarter of the kitchen garden is to be encompaffed by efpaliers, the walks which divide thofe quarters fhould be wide enough to afford admittance to the warmth of the fun, and to a free current of air. In this cafe they may be, as Mr. Miller directs, fix feet wide in fmall gardens, and ten or twelve in extenfive grounds. On each fide of thefe walks, the efpalier fhould be planted in a border four or five feet wide; by which means the two efpaliers will be far enough afunder for their roots never to injure one another. Thefe borders may be fown with fmall fallading, or any other herbs that do not continue long or root deep; fo that no ground need be loft, and the continual ftirring and manuring of it for thefe productions will be of great fervice to the roots of the trees.

The borders along the fouth and other walls that have a good expofure fhould, in the opinion of this experienced gardener, be at leaft eight or ten feet wide, in order to allow the roots of the fruit-trees that are planted againft them full room to extend themfelves. Such of thefe as face the fouth may be fown for early crops of plants which do not root deep, and thofe that are expofed to the north will do for late crops: but no deep rooting plant, efpecially peafe and beans, fhould ever be placed too near the trees; though moft gardeners are apt to tranfgrefs greatly in this refpect, as well to preferve their crops in winter, as to bring them forward in the fpring: both which ends might be anfwered equally well, and without prejudice to their fruit-trees, by making reed hedges in fome of the warmeft quarters, and fowing clofe to them their early peafe, beans, &c. if fuch fences are found to anfwer the purpofe of forwarding their growth.

It is a general opinion, that plants which are fheltered by walls, fo as to be defended from nipping winds, and to have the additional warmth of the reflected heat of the wall, are leaft liable to be deftroyed by the winter's frofts; for which reafon it is that early crops are moft commonly in borders fo fituated. The fun will undoubtedly give greater motion to the fap of plants there, and they may, for this reafon, feem to be the ftronger. But if we confider, that the walls yield no protection againft the feverity of the night's froft, and that the effect of this froft muft be moft feverely felt by plants whofe fap is in the greateft motion; we may rather fear that this fituation, inftead of being beneficial, may, in fact, counter-act the very end propofed. To be fatisfied of this fact, a gentleman fowed fome early peafe in a border at the foot of a fouth wall, and at the fame time fome others, of the fame fort, in an open field adjacent to to the garden; and he found, that the latter were by much the leaft damaged by the winter's frofts; nor did he perceive any great difference in the feafon of their blooming.

A fquare, or an oblong form, will be moft agreeable to the eye: but it matters not, in other refpects, what fhape this garden is of; efpecially as all grofs irregularities may eafily be hid in the laying of it out. Thus, when this is done, any of the flips cut off by the garden-wall, may, if large enough, and well expofed to the fun, be fet apart for a place to make hot-beds for early cucumbers, melons, &c. One would wifh this fpot to be as near as poffible to the ftables, for the convenience of fupplying it with dung; and to have it without the wall is certainly moft eligible, becaufe that will fave a great deal of filth and litter in the garden, and remove from the nofe and eye an object which is not of the moft pleafing kind. If this flip is long enough to admit of an annual fucceffion of new beds during two or three years, they will be much better than when they are continued more than one year on the fame fpot: and as it will be abfolutely neceffary to fence this melon ground, as it is called, round with a reed hedge, this may be fo contrived as to be moved away in pannels, in fuch manner that there will be no occafion to fhift any thing more than one of the crofs partitions, or fences, each year.

The importance of the precept particularly here, will juftify our mentioning again, that the dunghill, fet apart for this, or for any other purpofe of gardening, or agriculture, ſhould be carefully kept clear from weeds: for if weeds are ſuffered to ſcatter their ſeeds upon the dung, they will be brought into the garden, or other cultivated ground, ſhoot up, damage every crop of uſeful plants, and occaſion a perpetual labour to extirpate them.

Another caution which Mr. Miller gives, as abſolutely neceſſary to be obſerved, is, to carry off all the refuſe leaves and ſtumps of cabbages, the ſtalks of beans, and haulm of peaſe, as ſoon as they have done bearing; becauſe the ill ſcent which moſt people complain of in kitchen gardens is wholly occaſioned by theſe things being ſuffered to rot upon the ground. The leaves of cabbages may be given to hogs, or other animals, while they are freſh, and the reſt of this traſh may be thrown upon the dunghill, which it will help to enrich; or ſuch as will keep may be preſerved, to be thrown in the bottom of the trenches, in that part of the garden which is to be trenched the following autumn.

I muſt here point out a too common neglect of moſt gardeners, which is, the letting of their plants remain on the ground till they have ripened their ſeeds, and wither; not conſidering that whilſt a plant is full of ſap, it preſerves the earth in a looſe ſtate, probably by means of the moiſture perſpired from its roots; but that, when permitted to ſtand till its ſeed is ripe, or the plant withers, it then leaves the impoveriſhed earth dry and hard; being itſelf become entirely void of ſap.

The moſt important points of general culture here conſiſt in good digging, keeping the ground clean, manuring the ſoil, and allowing proper diſtances between the plants, according to their ſeveral kinds and growths. But as the various productions of the kitchen, and thoſe of the fruit, garden require very different treatment, though in the ſame incloſure, it will be right to conſider them ſeparately.

The kitchen garden, if it be rightly managed, is the moſt uſeful and moſt profitable ſpot of ground that either the country gentleman, or the huſbandman, can cultivate. It is indiſpenſably neceſſary to every family in the country, where, the neareſt market town being frequently far off, but poorly furniſhed with plants and roots, and that only on certain ſtated days, perhaps not oftener than once a week, there is no other way to have a variety, or even a ſufficiency, of this exceedingly healthful food, one of whoſe great excellencies conſiſts in its being freſh gathered.

Two eſſential rules to be obſerved in the general management of a kitchen garden are, never to crowd the ground with more plants than it is able to nouriſh properly; and never to let any part of it remain unoccupied, for want of a due ſucceſſion of crops. By this means the maſter, whom I would adviſe always to be his own gardener, at leaſt ſo far as perſonally to direct and ſuperintend whatever is done, may have his table conſtantly ſupplied with ſuch vegetables as he likes beſt, no part of his ground will lie uſeleſs, and each of its products will be brought to perfection.

GARGET, or *Gargol*, a diſtemper incident to hogs; and is known by the creature's hanging down of his head, and carrying it on one ſide, moiſt eyes, ſtaggering, and loſs of appetite.

It is occaſioned by a corruption of the blood, engendered by the eating of rotten fruits, garbidge, carrion, or rank graſs, wherein is much hemlock, &c.

In order to cure this diſeaſe, let the creatures be firſt blooded both under the tail and under the ears, and then the following drink given them:

> Take of chamber-lye one pint; rue and ſouthernwood, cut ſmall, of each a handful; wood-ſoot from an oven, and common ſalt, of each a ſpoonful; hen's dung, near two ſpoonfuls; flowers of brimſtone one ounce: ſtir the whole together, and give two or three horns to each, proportional to their ſize. It is alſo good for a cow to cure the gargal or murrain.

Or you may uſe the following drink in the room of the above;

> Take angelica, rue, ſtavewort, or hog's madder, and May-weed, of each one handful; ſhred them very ſmall, and boil them very well in a pint of milk; and when it is cold enough, add to it a pennyworth of ſallad-oil, and the ſame quantity of treacle. *Mortimer's Huſbandry, vol.* I. *pag*. 250.

GARLICK, a well known plant, cultivated in gardens, and eaſily propagated by parting the cloves, or ſmall bulbs of its root, and planting them in the ſpring, about four or five inches aſunder. They will thrive in almoſt any ſoil or ſituation; but in rich ground their increaſe will be ſurprizing. About the beginning of June their leaves ſhould be tied in knots, to prevent their ſpindling or running to ſeed; and this will alſo tend to enlarge their bulks. As ſoon as their leaves begin to wither and decay, which will be about the middle of July, the roots ſhould be taken up, and kept dry for uſe.

There is a wild ſort of garlick, called crow-garlick, or cow-garlick, that often does great damage to corn in dry ſandy grounds, but will not, according to Mr. Liſle, grow in clays. That gentleman tells us, that he knew a farmer in ſome of whoſe fields it grew in ſuch abundance, that his wheat taſted ſtrong of it, and was thereby damaged from ſixpence to a ſhilling in the buſhel. *Liſle's Huſbandry, vol.* II. *pag*. 313.

GARTH, a yard, a backſide, a croft.

GARNER, a granary, or repoſitory for corn.

GARZIL, hedging wood.

GATE, a frame of timber upon hinges to give a paſſage into incloſed grounds.

GATEWAY, the paſſage through gates of incloſed grounds.

GATTERIDGE-TREE, prickwood.

GAVEL, a row, or ſwarth of corn cut down with the ſcythe.

GAVEL, is alſo a provincial word, ſignifying ground.

GAVEL-KIND, a cuſtom whereby the lands of the father are equally divided at his death among all his ſons.

GAVELOCK, a pitch, or iron-bar for entering ſtakes into the ground.

GEESE, birds too well known to need any deſcription here. They are very profitable to the farmer many ways, for their fleſh, their feathers, and their greaſe. They will live upon commons or any ſort of paſtures, and need very little care or attendance; only they ſhould have plenty of water. The largeſt geeſe are reckoned the beſt: but there is a ſort of Spaniſh gooſe, that is a much better layer and breeder than the Engliſh, eſpecially if the eggs are hatched under an Engliſh gooſe.

Geeſe lay in the ſpring, the earlier the better; becauſe of their price, and their having a ſecond brood. They commonly lay twelve or ſixteen eggs apiece. You may know when they will lay by their carrying ſtraw in their mouth; and when they will ſit, by their continuing on their neſts after they have laid. A gooſe ſits thirty days; but if the weather be fair and warm, they will hatch three or four days ſooner. After the goſlins are hatched, ſome keep them in the houſe ten or twelves days, and feed them with curds, barley-meal, bran, &c. and after they have acquired ſome ſtrength let them out four or five hours a day, taking them in again till they are big enough to defend themſelves from vermin. Others put them out at firſt, and perhaps ſucceed as well as the former. One gander will be ſufficient for five geeſe.

If you would fat green geeſe, you muſt ſhut them up when they are about a month old, and they will be fat in about a month more. Be ſure to let them have always by them, in a ſmall rack, ſome fine hay, which will much haſten their fatting. But for fatting of older geeſe, it is commonly done when they are about ſix months old, in or ſoon after harveſt, when they have been in ſtubble fields, from which food ſome kill them, which is a good way. But thoſe who are deſirous of having them very fat, ſhut them up for a fortnight or three weeks, and feed them with oats, ſplit-beans, barley-meal, or ground malt mixed with milk; but the beſt thing to fatten them with is malt mixed with beer. You muſt however obſerve in fattening all ſorts of water-fowl, that they uſually ſit with their bills upon their rumps, where they ſuck out the greater part of their moiſture and fatneſs, at a ſmall bunch of feathers, which you will find ſtanding upright

on

on their rumps, and always moist, with which they trim their feathers, which renders them more oily and slippery than the feathers of other fowls, and causes the water to slip off them. If therefore these upright feathers are cut away close, they will become fat in less time, and with less meat than otherwise. Geese will likewise feed on, and fatten well with carrots cut small and given them; or if you give them rye before, or about Midsummer, it will strengthen them, and keep them in health, that being commonly their sickly time.

In some countries they shear their geese for feathers, and some pull them twice a year; but the latter is more injurious to them, and therefore it is better staying till their moulting time, and till their death, for the feathers. *Mortimer's Husbandry, vol.* I. *pag.* 255.

GELDING, a castrated animal. For the method of gelding horses, *see the article* HORSE.

GELT-GIMMER, a barren ewe.

GEOFF, or *Goffe*, a mow of hay or corn.

GERMINATION, the act of sprouting or shooting; growth.

GERMINS, buds, tender shoots.

GIGGS, small swellings, or bladders on the inside of the lips and palate of a horse.

They are cured by slitting them open with a knife or lancet, and washing them afterwards with salt and vinegar.

GILL, a rivulet, a beck. It is also a name for ground-ivy, or ale-hoof.

GIMMER-LAMB, or *Gammer-Lamb*, an ewe-lamb.

GLANDERS, a very obstinate and loathsome disease incident to horses.

The cause and seat of the glanders has till lately been so imperfectly handled, and so little understood by the writers on this distemper, that it is no wonder it should be ranked among the incurables: but a new light having been thrown on this whole affair by the study of M. La Fosse, the king of France's farrier, who has been at the pains to trace out, and discover, by dissections, the source and cause of this disorder, we hope the method he has proposed, with some further experiments and improvements, will soon bring to a certainty of cure (in most cases at least) a distemper so dangerous to our horses, and that hitherto has eluded the force of art.

Before we make mention of this work, which has the approbation of the Royal Academy of Sciences, it will not be unacceptable to our readers, we apprehend, to have a more particular account of the symptoms of this disorder from M. La Fosse, that we may the better judge of the merit of our author and his discoveries.

This gentleman then has distinguished seven different kinds of glanders, four of which are incurable:

The first proceeds from ulcerated lungs, the purulent matter of which comes up the trachea, and is discharged through the nostrils, like a whitish liquor, sometimes appearing in lumps and grumes. In this disorder, though the matter is discharged from the nostrils, yet the malady is solely in the lungs.

The second is a wasting humour, which usually seizes horses at the decline of a disease, caused by too hard labour; this defluxion also proceeds from the lungs.

The third is a malignant discharge, which attends the strangles sometimes, and falls upon the lungs, which runs off by the nostrils.

The fourth is, when an acrimonious humour in the farcy seizes these parts, where it soon makes terrible havock.

The fifth kind we shall describe by and by, as arising from taking cold.

The sixth kind is a discharge from the strangles, which sometimes vents itself at the nostrils.

These are the various disorders which have been observed sometimes to throw matter out from the nostrils; let us now describe the real glanders:

The matter then discarged from the nostrils of a glandered horse, is either white, yellow, or greenish, sometimes streaked, or tinged with blood; when the disease is of long standing, and the bones are fouled, the matter turns blackish, and becomes very foetid; and is always attended with a swelling of the kernels or glands under the jaws; in every other respect the horse is generally healthy and sound, till the distemper has been of some continuance.

It is always a bad sign, when the matter sticks to the inside of the nostrils, like glue or stiff paste; when the inside of the nose is raw and looks of a livid, or lead colour, when the matter becomes bloody, and stinks, and when it looks of an ash colour. But when only a limpid fluid is first discharged, and afterwards a whitish matter, the gland under the jaw not increasing, and the disorder of no long continuance, we may expect a speedy cure; for in this case, which arises from taking cold, after a horse has been over-heated, the pituitary membrane is but slightly inflamed, the lymph in the small vessels condensed, and the gland overloaded, but not yet ulcerated.

From these symptoms and some observations made both by Bracken and Gibson, it is plain they were not absolute strangers to the seat of this disorder, though they neglected pushing their inquiries to the fountain-head, and consequently were at a loss to know how to apply the remedy to the parts affected.

But our author, after examining by dissection the carcases of glandered horses, and making a strict scrutiny into the state of the viscera, assisted for that purpose by ingenious and expert anatomists for ten years together, affirms this disease to be altogether local; and that the true seat of it is in the pituitary membrane, which lines the partition along the inside of the nose, the maxillary sinusses or cavities of the cheek-bones on each side the nose, and the frontal sinusses or cavities above the orbits of the eyes; that the viscera, as liver, lungs, &c. of glandered horses are in general exceeding sound; and consequently that the seat of this disorder is not in those parts, as has been asserted by most authors; nor indeed is it probable it should: for how could such horses preserve their appetite, their good appearance, sleek and shining coats; in a word, all the signs of health for many years together (which many glandered horses are known to enjoy) with such distempered bowels?

But on nicely examining the heads of such horses, he found the cavities above-mentioned, more or less, filled with a viscous slimy matter, the membrane which lines both them and the nostrils inflamed, thickened, and corroded with sordid ulcers, which in some cases had eat into the bones. These sinusses or cavities will be better understood by referring to the annexed plate.

He observes, that when glandered horses discharge matter from both nostrils, both sides of the membrane and cavities were affected; but when they ran at one nostril only, that side only was found distempered.

It is a curious remark of our author, that the sublingual glands, or the kernels situated under the jaw-bone, which are always swelled in this distemper, do not discharge their lymph into the mouth, as in man, but into the nostrils; and that he constantly found their obstruction agreed with the discharge; if one gland only was affected, then the horse discharged from one nostril only; but if both were, then the discharge was from both.

He sometimes, though rarely, found the boney partition of the nose carious or rotten; but that the spongy bones about this part must suffer from the acrimony of matter long pent, is not at all to be doubted, though the more solid ones may escape.

The seat of this disorder thus discovered, our author, with great ingenuity, has paved the way for cure, by trepanning these cavities, and taking out a piece of bone, by which means the parts affected may be washed with a proper injection; and, in fine, the ulcers deterged, healed, and dried up.

But as from the observations since made by this gentleman, there are different species of the glanders; so the cure of the milder kinds may first be attempted by injections and fumigations. Thus, after taking cold, should a horse for fifteen or twenty days discharge a limpid fluid, or whitish matter from one or both nostrils, the glands under the jaw rather growing harder than diminishing, we may expect it will degenerate into a true glanders: to prevent which, after first bleeding, and treating him as we have directed for a cold, let an emollient injection, prepared with a decoction of linseed, marshmallows, elder, chamomile flowers, and honey of roses, or such like, be

 thrown

thrown up as far as poſſible with a ſtrong ſyringe, and repeated three times a day: ſhould the running not leſſen, or be removed in a fortnight by the uſe of this injection, a reſtringent one may now be prepared with tincture of roſes, lime-water, &c. and the noſtrils fumigated with the powders of frankincenſe, maſtich, amber, and cinnabar, burnt on an iron heated for that purpoſe, the fume of which may eaſily be conveyed through a tube into the noſtrils.

This method has been found ſucceſsful when uſed in time; but the methods of cure depend on the ſtubbornneſs of the diſorder; and, when inveterate, recourſe muſt be had to the operation above deſcribed.

This operation he has performed on three horſes, two of whom diſcharged from one noſtril only, and the third from both; the two firſt he trepanned on that ſide of the head which was affected, and to the other he performed it on both, and found that the wound and perforation filled up with good fleſh in twenty-ſix days, and the horſes ſuffered no inconvenience from the operation; though after this experiment they were put to death.

The directions and orders of the civil government of France, which hinder people from keeping glandered horſes, long prevented M. La Foſſe repeating his attempts, and puſhing his experiments further; but it is to be hoped that ſo uſeful a project will be purſued to its utmoſt extent, as it ſeems ſo promiſing in the execution, and is ſo important in its conſequences: to which end we ſhall beg leave to animadvert on what has been ſaid, and offer our opinion both in relation to the diſeaſe, the operation, and the manner of conducting the cure.

In order to prove that a great inflammation of the pituitary membrane is always the cauſe of the glanders, M. La Foſſe has attempted to bring on an inflammation upon the ſame membrane, by a corroſive injection; and when the injection was only thrown into one ſide, the maxillary lymphatic glands were ſwelled on the ſame ſide, and that noſtril only produced the diſcharge; but when both noſtrils were injected, theſe ſymptoms appeared on both ſides. This gentleman has alſo obſerved, that the bone of the maxillary ſinus being broke by the kick of another horſe, the uſual ſymptoms of the glanders ſoon appeared, from the inflammation the petuitary membrane ſuffered on the occaſion.

The original ſource and cauſe then of this diſorder ſeems to be an inflammation in the glands, and membrane that lines the noſtrils and theſe cavities, which, if not diſperſed in time, will form matter, and ulcerate and erode the bones, for want of a free diſcharge to unload the cavities, and of proper applications to cleanſe and deterge the ulcers: violent colds, or a feveriſh tranſlation ſettling here, may alſo occaſion the ſame complaint, and are probably the general cauſes.

There is a diſorder in men called *Ozæna*, that has great ſimilitude to this in horſes, and ariſes from an inflammation in the maxillary ſinuſſes, or cavities in the cheek-bones, from whence enſues a collection of matter, which, when the cavity is full, or the head properly inclined, runs over into the noſe, and would conſtantly diſcharge thence like a glandered horſe, was the head continued in the ſame poſition. The ſurgical cure is the taking out one or more teeth from the upper jaw, and perforating the cavity with a proper inſtrument, in order to make a depending orifice for the matter to flow through; and to make way for ſyringing the parts affected with proper injections, which in this caſe are thrown through the cavity into the noſe.

The ſimilarity of theſe two caſes, with the method of cure, and the ſucceſs attending the ſurgical treatment (which was firſt invented and perfected by our countrymen Drake and Cowper) undoubtedly gave the firſt hint for trepanning, and ſyringing theſe cavities in horſes; and it is moſt probable, that when the operation is attempted in time, before the bones become rotten, it will be attended with equal ſucceſs; but after opening the cavities, ſhould it by probing be diſcovered, that the bones are in that ſtate, the beſt way then would be to diſpatch the horſe, to prevent unneceſſary trouble and expence.

The parts fixed on for applying the trepan are pointed out in the plate, and the manner of ſawing out the bone will eaſily be underſtood by a view of the inſtrument, and the explanation annexed.

The perforations being made, our next buſineſs is to prevent their filling up too faſt, as it may be neceſſary to keep them open for ſome weeks before a cure can be affected; for which purpoſe, after the uſe of the injection, let the upper one be filled up with a piece of cork, waxed over, and adapted exactly to its ſize, the lower one may be kept open with a hollow leaden tent, through which there will be a conſtant drain of matter from the ſinus's, which will be greatly favoured by this depending orifice, and both be detained by a proper bondage.

If this method ſhould not prevent the granulations, or ſhoots of the fleſh, from filling up ſo faſt as to choak up the perforation, and by that means hinder the injections paſſing freely, they muſt be ſuppreſſed by rubbing with cauſtic medicines, or touching with the actual cautery; as may alſo the bony edges, which, by obliging them to exfoliate or ſcale off, will retard the healing.

The injection firſt made uſe of, ſhould be of a deterſive nature; as a decoction of birth-wort, gentian, and centaury; to a quarter of which, if two ounces of Ægyptiacum and tincture of myrrh are added, it may be as proper as any; and when the diſcharge is obſerved to abate, and the colour alter to a thick white matter, the injection may be changed for barley-water, honey of roſes, and tincture of myrrh; and, finally, to dry up the humidities, and recover the tone of the relaxed glands, Bates's allum-water, or a ſolution of colcothar, vitriol, lapis medicamentoſus, or ſuch like, in lime-water, will moſt probably complete the cure. Dr. Bracken recommends the following:

> Take of allum and white vitriol powdered, of each four ounces, calcine them in a crucible when cold, powder the calx, and mix it with a gallon of lime-water, and a quart of vinegar, decant the clear for uſe.

But whoever is at all acquainted with practical ſurgery, well knows, that without the aſſiſtance of internals, eſpecially in glandular diſorders, the cure is not ſo eaſily effected, nor rendered compleat or laſting: we therefore adviſe a ſtrong decoction of guaicum chips to be given every day, to a quart or three pints, throughout the cure, and when the matter leſſens, to purge at proper intervals, and put a rowel into the horſe's cheſt, in order to divert the fluids from their old channel; if theſe ſhould not ſucceed, mercurials may be given with the phyſic, and the alterative powders with lime-water may be taken for a time, if the horſe is worth the expence.

An Explanation of the Heads and Trepan. See Plate XVII. *Fig.* 2.

B. B. two lines repreſenting the bounds of the cerebellum, or back part of the brain, which is very ſmall in a horſe, in proportion to that of a man, as well as the brain itſelf, which commences from the line D.

C. C. a line where the ſuperior part of the ſinus frontalis commences, together with a view of the bottom of the ſinus, which terminates between the lines D and E, where there appears a ſubſtance in the form of a pear, which is the os ethmoides, or ſieve-like bone, through which the olfactory nerves paſs, by which the pituitary membrane receives its ſenſibility, and the ſenſe of ſmelling is performed.

E. repreſents the beginning of the maxillary ſinus, which terminates at M.

The ſhaded ſpace, which may be obſerved between theſe two lines, repreſents the great cavities. The oblique ray marked F, is a bony partition, which ſeparates this ſinus into two parts, that have no communication; and ſometimes it happens (though but rarely) that there are two bony partitions; and for this reaſon they are repreſented by the lines marked F and G. It alſo ſometimes happens (but ſtill more ſeldom) that there are horſes, in whoſe heads we do not find any of theſe bony partitions.

N. points out the place of the cornets or horns. O the redoublings. P their middle part. Q the inferior part of them. M the bony canal or pipe which guards the maxillary nerve.

A. A.

A. A. the feptum narium, or partition, which divides the nofe from top to bottom, and conftitutes the two noftrils.

L, in the head that is intire, points out where the trepan fhould be applied on the frontal finus, when we have reafon to believe the glanders is fpread into this finus. However, I think it fafeft to apply it firft on E, for the reafons mentioned in the next explanation, and becaufe the brain may be endangered, fhould the finus be miftook.

E, the place where the trepan may be applied, in order to cleanfe the maxillary finus. The round mark between D and E (which is the impreffion of the trepan) is, however, on experience, preferred by the author, as the propereft place, as one orifice would then be fufficient to wafh all the parts, both above and below, with the injection.

But in general, when the maxillary finus only is affected, penetrate but the upper part, where the fyringe points, or thereabouts, and your expectations will be anfwered; fhould they not, there feems fo little danger in the operation, that you may again perforate at the places above mentioned, higher up. But a proper number of experiments will foon fettle this point with certainty.

H, in the head that is intire, points out the place where another hole, or perforation fhould be made, as a drain to give iffue to the glanderous matter wafhed away by the injection which could not be difcharged without fuch a depending orifice; and perhaps this perforation alone, in many recent cafes, would be fufficient, provided the injection paffed freely upwards, and the hole was kept open by means of a hallow leaden pipe conftantly retained in it for that purpofe, and to procure a free paffage for the matter.

I, reprefents the injection pufhed in by the fyringe, which flows out by the orifice and the noftril K; during the ufe of the fyringe, it is neceffary to hold the noftrils clofe.

If, in the maxillary finus, inftead of one there happens to be two bony partitions, it is abfolutely neceffary to pierce through them both, by means of a ftiletto, or fharp-pointed tuck, as in the manner reprefented in the cut of a horfe's head opened, though this conformation feldom occurs.

As thefe bony partitions may in fome particulars vary, fhould the ftiletto not have the defired effect, and the injection thrown in by the fyringe not come out at H; in fuch cafe the liquor fhould be injected upwards, through the orifice made by the ftiletto or trepan at H.

As in young horfes the frontal and maxillary finuffes are very fmall, it will be proper to direct the trepan towards the interior part of the nofe, otherwife the inftrument might work upon the roots of the teeth, which incline towards the finus, and would in fuch cafe be an infurmountable obftacle to the operation.

R, the inftrument or trepan. S, the handle which turns it. T, the faw-part to be applied to the bone.

From a view of this inftrument, the manner of working it will appear fimple and eafy; the cooper's managing his wimble being a proper directory.

The inftrument called the trephine, which is chiefly ufed by our Englifh furgeons in perforating the fkull, will equally anfwer this purpofe; and if any difficulties fhould arife, notwithftanding this defcription, the gentlemen of the faculty will foon make it familiar and intelligible.

Before the application of the trepan, or trephine, it is quite neceffary to obferve, that a circular piece of the fkin fhould firft be cut off, with the membrane which covers the bone, about the fize of a half crown piece, in order to make the inftrument work the eafier, and to prevent the inconveniencies which might arife from the external wounds healing up too faft.

The fyringe fhould be large enough to contain half a pint of injection.

GLANDIFEROUS, an epithet applied to fuch trees as bear maft or acorns. Thus the oak, beech, &c. are called glandiferous trees.

GLEANING, the action of picking up the ears of corn left behind by the gatherers.

GLEBE, properly fignifies the foil or ground in general; but is particularly applied to the land poffeffed as part of the revenue of an ecclefiaftical benefice.

GLEBOUS, or *gleby*, turfy.

GLEDE, a kite.

GLEN, a valley, a dale.

GLYSTER, or *Clyfter*, a medicine injected into the anus of an animal.

Glyfters are often neceffary for horfes in various diforders, and may be reduced to thefe different kinds, viz. laxative and emollient, purgative and reftringent.

But it fhould be obferved, that before the adminiftration of emollient glyfters in coftive diforders, a fmall hand well oiled fhould be paffed up the horfe's fundament, in order to bring away any hardened dung, which otherwife would be an obftacle to the clyfter's paffage.

A bag and a pipe of a proper form, is to be preferred to a fyringe, which throws up the clyfter with fo much force, that it often furprizes a horfe, and makes him reject it as faft as it goes in: whereas the liquor, when preffed gently from the bag, gives him no furprize or uneafinefs, but paffes eafily up into the bowels, where it fometimes remains a long time, and is extremely ufeful, by cooling and relaxing them; and will fometimes incorporate fo with the dung, as not eafily to be diftinguifhed from the other contents of the guts. Thefe emollient clyfters are extremely ferviceable in moft fevers, and greatly preferable to purging ones; which in general are too pungent, and ftimulate too much, efpecially if aloes are a part of the compofition.

Nutritive clyfters are very neceffary, and often fave a horfe from ftarving, when his jaws are fo locked by convulfions, that nothing can be conveyed by the mouth.

They fhould not exceed a quart or three pints at a time, but be often repeated: nor fhould they be too fat; but made of fheeps heads, trotters, or any other meat broths, milk-pottage, rice-milk ftrained, and many other fuch nourifhing things. For an emollient clyfter take the following:

> Take marfhmallows and chamomile flowers, each a large handful; bay-berries and fweet fennel-feeds bruifed, each an ounce, boil in a gallon of water to three quarts, pour off into a pan, and diffolve in it half a pound of treacle, and a pint of linfeed oil, or any common oil.

To make it more laxative, add four ounces of lenitive electuary, or the fame quantity of cream of tartar, or common purging falts.

> Take two or three handfuls of marfhmallows, fenna one ounce, bitter apple half an ounce, bay-berries and annifeed bruifed, each an ounce, falt of tartar half an ounce; boil a quarter of an hour in three quarts of water, pour off, and add four ounces of fyrup of buckthorn, and half a pint of oil.

This clyfter will purge a horfe pretty brifkly; and may be given fuccefsfully, when an immediate difcharge is wanting; efpecially in fome fevers with inflamed lungs, or other diforders, which require fpeedy relief.

But it is neceffary to caution againft a folution of coarfe aloes for this purpofe, as it has been found to gripe horfes violently, and excite feverifh, and fometimes convulfive fymptoms; and indeed all pungent and ftimulating medicines, as the ftronger purgatives generally are, fhould be given in this form with great caution.

But the generality of emollient clyfters may be prepared with much lefs trouble; as two quarts of water gruel, with half a pound of treacle, a pint of oil, and a handful of common falt, will as effectually anfwer every purpofe. The following is a reftringent clyfter.

> Take pomegranate-bark, or oak bark, two ounces; red rofe-leaves, frefh or dry, a handful; baluftines, an ounce: boil thefe in two quarts of water, till one is nearly confumed; then pour it off, and diffolve in it four ounces of diafcordium; to which may be added a pint of Port-wine.

This will anfwer all common cafes, where reftringents are neceffary, but fhould never be given in larger quantities; for the longer clyfters of this kind lie in the bowels, the more efficacious they are. *Bartlet's Farriery, page* 22.

GOAD, a pointed inftrument with which oxen are driven forward.

GOAR-VETCHES, the ſame with ſummer-vetches. *See the article* VETCHES.

GOAT, a genus of animals, the characters of which, according to Mr. Ray, are theſe: that it is covered with hairs, not with wool; that its horns are leſs crooked than thoſe of the ſheep, and that it has a beard hanging down from its chin, and is of a ſtrong ſmell.

It is very ſingular, that this genus of animals are all able to run and climb about the rugged parts of mountains without falling, though their feet ſeem by no means contrived by nature for any ſuch purpoſes.

Goats may be of great advantage to the farmers in ſome parts of the kingdom, as they will live in rocky barren countries, where nothing elſe can get a ſupport for life. They will climb the ſteepeſt rocks, and there browſe upon briars, heath, and ſhrubs of various kinds, which other creatures will not taſte of. They will feed on graſs in paſtures; but, as they love browſing on trees much better, great care muſt be taken to keep them from valuable plantations.

The greateſt advantage of theſe creatures is their milk, which they yield in large quantities; and which is accounted the beſt milk of all animals. They mix this and cows milk together in many parts of the kingdom, and a very valuable kind of cheeſe is made of it. Beſide this, the kids or young goats are very fine food, and the beſt kinds bring forth theſe two or three at a time, and that twice a year.

Goats hair alſo is valuable; it may be ſheared as the wool from ſheep, and is excellent for making ropes that are to be uſed in the water, as they will laſt a great while longer than thoſe made the common way. A ſort of ſtuff is alſo made of it in ſome places. The beſt kind of goats for keeping to advantage ſhould be choſen in this manner: the male ſhould have a large body, his hair ſhould be long, and his legs ſtraight and ſtiff; the neck ſhould be plain and ſhort, the head ſmall and ſlender, the horns large, the eyes prominent, and the beard long. The female ſhould have a large udder, with large teats, and no horns, or very ſmall ones. They ſhould be kept in flocks, that they may not ſtraggle; and they ſhould have good ſhelter both in ſummer and in winter, the heat and cold being both prejudicial to them. They ſhould be coupled in December. They ſhould have no litter in winter, but only a paved floor kept clean. The kids are to be brought up for the table in the ſame manner as our lambs are. They are recommended to lie among horſes, their ſmell, as ſuppoſed, preventing many diſtempers in thoſe cattle. *Mortimer's Husbandry*, *vol.* I. *pag.* 244.

GOD's-GOOD, yeaſt, or barm.

GOFFE, the ſame with geoff. *See* GEOFF.

GOOL, a ditch.

GOOSBERRIES, the name of a well known fruit cultivated in kitchen gardens.

They are propagated either by ſuckers taken from the old plants, or by cuttings. Theſe laſt are by far preferable, becauſe they generally root the beſt, and are leaſt apt to produce ſuckers, which always weaken the ſtock from whence they proceed. The cuttings ſhould be taken from the handſomeſt ſhoots of the beſt bearing branches of the moſt fruitful ſhrubs: they ſhould be about ſix or eight inches long, and ſhould be taken off, and planted, in autumn, juſt before their leaves begin to fall, about three inches deep, in light earth, expoſed to the morning ſun. Their growth will be promoted by watering of them gently in dry weather, and they will be trained up regularly to a ſtrait ſtem, if all their under ſhoots are rubbed off in the ſummer, as ſoon as they appear, ſo as to leave only the uppermoſt or ſtrongeſt. In the next October, theſe plants will be fit to remove into a nurſery, where, after trimming their roots, and cutting off all ſide branches, they ſhould be ſet a foot aſunder in rows three feet diſtant from each other, in an open ſpot of freſh earth, which has been well dug, and cleanſed from all noxious weeds and roots. They ſhould here be faſtened to ſhort ſticks, or ſtakes, the more effectually to render their ſtems ſtrait and upright; they ſhould be cleared from all lateral ſhoots to the height of about a foot above the ſurface of the earth; and after one year's training in this manner (keeping them clear from weeds, and cutting out all croſs branches, ſo that their heads may not become too thick,) they will be fit to tranſplant to the places where they are to remain. The ſoil, for them to thrive to the greateſt advantage, ſhould then be a rich light ſandy earth; though they will do very well in middling ſoils which are not too ſtrong or moiſt, and in all ſituations. However, their fruit is beſt when they grow in an open expoſure, and not within the ſhade of other trees. The beſt ſeaſon for this tranſplanting is likewiſe in October, when their leaves begin to decay; and will alſo be right then to trim their roots again, to diveſt them of all lateral and all croſs ſhoots, and to ſhorten all their long branches, ſo as to make the head regular. The diſtance at which they ſhould be planted now, if there be a large number of them, is eight feet row from row, and ſix feet aſunder in the rows.

The gardeners around London, who raiſe great quantities of theſe buſhes in order to ſupply the markets with their fruit, prune them ſoon after Michaelmas, and then dig up the ground in the above-mentioned intermediate ſpaces, and plant it with coleworts for ſpring uſe. Their ground is by this means employed all the winter, without hurting the gooſberries; and the coleworts ſo planted often eſcape in hard froſts, when others which are leſs ſheltered are often deſtroyed. This huſbandry is well worth practiſing where land is dear, or where perſons are confined for room.

The common practice of clipping the heads of theſe ſhrubs with ſhears, in order to give them a roundiſh form, is very wrong: becauſe they become thereby ſo crowded with wood, that the fruit which they produce never grows then to half the ſize that it would if the branches were properly thinned with a pruning knife, all the miſplaced ones cut away, and the ſtrong bearing ſhoots ſhortened to about ten inches, with care always to prune them off behind a leaf bud. With this management, with keeping the ground clear from weeds, with digging it at leaſt once a year, and with beſtowing a little rotten dung upon it every other year, the fruit will be near twice as large as that which is raiſed in the common way, and the ſhrubs will continue in vigour much longer.

The large white Dutch, the large amber, the early red, and the early green, both of which laſt are hairy, are generally reckoned the beſt ſorts of gooſberries: but many others, known by the names of the perſons who firſt raiſed them from ſeeds, are alſo much eſteemed.

Gooſberries yield in plenty an agreeable and cooling liquor, the firſt luſciouſneſs of which is ſoon carried off by proper fermentation. Some make gooſberry wine without boiling it all, becauſe the boiling gives it a browniſh colour: but the truth is, that it will ſoon become ſour, if it be not depurated from the groſs lee, with which it abounds, by a proper fermentation.

GOOSE. *See the article* GEESE.

GOOSE-GRASS, or wild tanſy, the name of a troubleſome weed very frequent in clay grounds. The beſt method of deſtroying it is to mow it in ſummer, well dung the land, and never plough it out of heart.

GOSS, or *Gorſe*, the furze.

GOULANS, corn-marigolds.

GRAFT, or *Graſt*, a cion or ſhoot of a tree inſerted into another, ſo as to make it yield fruit of the ſame nature with that of the trees from whence the graft was taken.

In the choice of grafts, the following directions ſhould be carefully obſerved: Firſt, That they are ſhoots of the former year. Secondly, That they are taken from healthy fruitful trees. And, thirdly, That you prefer thoſe grafts which are taken from the lateral or horizontal branches, to thoſe taken from the perpendicular ſhoots. Theſe grafts ſhould be cut off from the trees before the buds begin to ſwell, which is generally three weeks or a month before the ſeaſon for grafting; therefore when they are cut off, they ſhould be laid in the ground with the cut downwards, burying them half their length, and covering their tops with dry litter, to prevent their drying: if a ſmall joint of the former year's wood be cut off with the cion, it will preſerve it the better: and when it is grafted, this may be cut off; for the grafts never muſt be cut to a proper length before they are inſerted into the ſtocks; but till then, the ſhoots ſhould remain their full length, as they were taken from the tree, which will preſerve them better from ſtriking. If theſe grafts are to be carried to a conſi-

considerable distance, it will be proper to put their cut ends into a lump of clay, and to wrap them up in moss, which will preserve them fresh for a month or longer: but these should be cut off earlier from the trees than those which are to be grafted near the place where the trees are growing. For the choice of stocks for grafting, *see the article* STOCK.

GRAFTING, or *Engrafting*, is the taking a shoot from one tree, and inserting it into another, in such a manner that both may unite and form one tree.

The reason for grafting is, that as all good fruits have been accidentally obtained from seeds, so these when sown will often degenerate, and produce such fruit as are not worth cultivating; but when the shoots, cions, or grafts, are taken from such trees as yield good fruit, these will never vary from their kind, whatever be the stock, or tree, on which they are grafted.

The most proper season for grafting is in the spring, just before the rising of the sap, or at least before it rises in any great quantity: but the weather must be neither frosty nor wet; nor should the wind blow very bleak or strong when this operation is performed: for on these circumstances, and upon the exact joining of the inner bark of the cion with the inner bark of the stock, so that the sap which flows between the bark and the wood may be communicated from the one to the other, the success of grafting chiefly depends.

The implements necessary for grafting are, a fine small hand-saw to cut off the heads of large stocks; a good strong knife with a thick back to make clefts in the stocks; a sharp penknife to cut the grafts; a grafting chissel, and a small mallet to pare away the wood; bass, or woollen yarn, to tie the grafts with; and a quantity of clay, or cement, properly prepared, to lay over the incisions, in order to prevent their bleeding, and keep out the air.

The method of preparing the clay intended for this purpose, is to mix thoroughly together a quantity of strong, fat loom, some new stone-horse dung broken into small bits, a little tanners hair, or straw, cut very small, with a little salt, and as much water as will make the whole of the consistence of pretty stiff mortar.

The cement or composition which some have of late used, and which has been found to answer the design of keeping out the air better than the above clay, is made of turpentine, bees-wax, and rosin, melted together. This composition, when of a proper consistence, is laid about a quarter of an inch thick, upon the cut part of the stock round the graft; and has this farther advantage over the clay, that there is no danger of its being hurt by frost; for cold hardens it; and when the heat of summer comes on, by which time it is no longer wanted on the tree, it will melt and fall off without any trouble.

Among the several methods of grafting hitherto known, the following are most approved, and generally practised.

Cleft-GRAFTING, called also STOCK, or SLIT-GRAFTING. This is used chiefly for middle sized stocks, from one to two inches in diameter. The season for it is in the months of February and March; and the method, as now practised, is thus:

The head of the stalk being sawn, or cut off, with a slope, smooth and clean, a perpendicular cleft is made therein, about two inches deep, with a strong knife, or chissel, from the top of the slope, as near to the pith as may be without touching it. In this cleft, the grafting chissel, or a wedge, is put to keep it open. The graft or cion is prepared by cutting it aslope, in form of a wedge, to suit the cleft, only leaving a small shoulder on each side; and when cut, it is to be placed exactly in the cleft, so as that the inner bark of the cion may aptly, and closely, join to the inner part of the bark, or rind of the stock; in the dextrous performance of which, the chief part of the art of grafting consists. That side of the cion, which is to be placed outward, at the part where it is cut wedge-wise and inserted into the cleft of the stock, should be much thicker than the other side, the better to facilitate the exact joining of its rind to that of the stock; for if these two do not unite, the graft will not succeed. The rind of the stock chosen for this way of grafting should therefore not be too thick; because it will then be the less manageable. If the cleft pinch too tight, a small wedge may be left in it to bear the stress. As soon as the graft is properly fixed, the cleft should be closely covered over with clay, or, which some think better, with moss, or the fresh bark of a tree bound on with ozier.

When this method, which is the most ancient, and most common, manner of grafting, is used to stocks that are not strong, a ligature of bass should be made around the stock, to prevent the opening of its slit; and the whole should then be clayed over, or covered with the cement before described, to hinder the air from penetrating into the slit, so as to destroy the graft, only two eyes of which should here be left above the clay, for shooting.

The straightest and smoothest part of the stock should always be preferred for grafting, in whatever way this operation is performed.

GRAFTING *in the Rind*, or *Shoulder*-GRAFTING, likewise called slicing and packing, to distinguish it from grafting in the bark, which will next be spoken of, is performed in the following manner, about the latter end of March, or the beginning of April, on more slender stocks than those which are commonly used for cleft-grafting.

The top of the stock is cut off in a smooth, straight place: then the cion, or graft, is prepared by cutting it on one side from the joint, or seam, down slope-wise, making the slope about an inch, or an inch and an half long; and observing it is bent, so that the cion may stand nearly upright when it is fixed to the stock. At the top of the slope, a shoulder is made, whereby it is to rest on the crown of the stock. The whole slope must be plain and smooth, that it may lie even to the side of the stock. The length of the cion used here may be about four inches from the shoulder, for a standard tree; but for a dwarf, or wall-tree, it may be six inches. When the cion is prepared, the outside of its sloped end, from the shoulder downward, is applied to the west, or south-west side of the stock, and its length and breadth measured thereon; which done, the bark of the stock (but not any of its wood) is cut away to those dimensions, that the cut part of the cion may be fitted in as exactly as possible. In doing this, regard must be had to the bigness of the stock, and the thickness of its bark, in order to proportion thereto the length and breadth of the cut part of the cion; otherwise the passages of the sap in the stock and cion will not meet, and the cion will then of course perish. When the cut part of the cion is exactly fitted to, and laid on that of the stock, they are bound together with woollen yarn, and covered with clay an inch above, and as far below, the head of the stock; working it round the cion, till it become sharp at top, that the rain may run down it.

This method has several advantages over the former. Among these are, that the wound heals up sooner, and that, in the mean time, it is in less danger from the weather: that it does less injury to the stocks and grafts, by avoiding all severe splittings and pinchings; that the bark is more easily placed in the passage of the sap here, than in the cleft; that the graft thrives and shoots with greater vigour, and bears sooner in this way than in that; and that it is practicable on smaller stocks than the other, which must have a good body, and consistence, before they can bear cleaving.

GRAFTING *in the Bark* is performed thus. Prepare the stock and cion as for grafting in the rind, both as to time and manner; but, instead of cutting out the bark of the stock, slit it down, on the south-west side, from the top, almost as long as the sloped part of the cion, and at the top of the slit loosen the bark with the point of your knife. Then thrust an instrument, made of very hard wood, ivory, silver, or the like, and formed at the end like the slope-end of the cion, but much less, down, between the bark and wood, to make room for the cion; which being put in, the bark is to be so managed, as that it may close exactly to the stock and edges of the cion, and the whole is then to be bound up, and covered as before.

Whip-GRAFTING, or *Tongue*-GRAFTING, is proper for small stocks, from an inch diameter to a quarter of an inch, or even less. Mr. Worlidge, Mr. London, Mr. Miller, and others, speak of it as the most effectual way of of any, and that which is moſt in uſe, becauſe the cion covers the ſtock much ſooner in this method than in any other; for here the cion and the ſtock muſt always be of the ſame thickneſs. There are three ways of performing it, and all of them may be practiſed ſomewhat later than either of the foregoing.

The firſt is, to ſlope the cion off a full inch, or more; then to do the ſame to the ſtock; and afterwards to tie the one to the other, with baſs or yarn, ſo as to join them cloſely at every part, but particularly at the rind; and then to cover the joint carefully with well tempered clay. The baſs uſed for this, or for any other binding, ſhould be taken from a ſound mat, and be ſoaked in water for ſome hours, to increaſe its ſtrength, and render it the more pliable.

The ſecond way is, to make a ſhoulder in the graft, and, the head of the ſtock being cut off and ſmoothed, to join it as in grafting in the rind.

The third method, which is an improvement of the laſt, is properly named tipping or tonguing. This is done by cutting the ſtock off ſlanting, as before, and leaving at its upper ſide a thin piece, or tongue, as it is called, of the wood, pared away like the lower end of a cion. The cion is then ſloped, and tongued, in the ſame manner as the ſtock, and a ſlit is made in each of them, downward in the ſtock, and upward in the graft, on the ſide oppoſite to the tongue, ſo that each may receive the tongue of the other. The cion is then joined to the ſtock, as cloſely as can be, particularly at the bark; a ligature is made round them with baſs or woollen yarn, and the engrafted part is well covered with clay or cement.

Side-GRAFTING. In this, the cion is prepared as in whip-grafting; but the head of the ſtock is not cut off at the time of performing the operation. Inſtead of that, ſo much of the bark as the cion will cover is pared off from the weſt-ſide of the ſtock; then both the cion and the ſtock are ſlit in the laſt mentioned manner of whip-grafting, and they are bound together, and cloſed up with clay. At the year's end, the top of the ſtock is cut off at the grafted place, ſlopewiſe; and the wound is covered with clay or cement.

Scutcheon-GRAFTING is another method of grafting in the rind, by ſlitting the bark of the ſtock in form of the capital letter T, looſening it with the point of a knife, and inſerting a cion prepared as above. This is practiſed in June, July, and Auguſt; eſpecially if the bark does not part eaſily from the ſtock; and in caſe of failure, it is properly ſupplied by cleft grafting, in the enſuing month of February or March.

Crown-GRAFTING is only practiſed in the larger trees, which are capable of receiving a number of grafts, and are too big to be cloven; for theſe, the head or main branches, being cut off horizontally, four or more grafts are placed round the ſtock, between the bark and the rind, ſomewhat in the manner of a crown. The moſt proper time for performing this is about the latter end of March, or the beginning of April. After the intended number of cions are inſerted, which is done exactly in the ſame manner as that already delivered for grafting in the rind, the whole crown of the ſtock is well clayed over, and only two eyes of each cion are left uncovered; that being ſufficient for their ſhooting.

This method of grafting was more practiſed formerly than it is at preſent; many people having been diſcouraged by the ill ſucceſs that has frequently attended their cions, which have been blown out of the ſtock, by ſtrong winds, after they had made large ſhoots, and even after they had grown there five or ſix years. But this accident may be prevented, by tying the cions to ſtakes faſtened to the tree, till they are ſo firmly fixed, as to have almoſt covered the ſtock.

Root-GRAFTING is a modern invention, the deſign of which is ſomewhat different from that of any of the former methods; this being for the propagation, or multiplication, of plants already fitted to produce their fruit.

To perform this, take a graft, or ſprig, of a young tree, which you intend to propagate, and a ſmall piece of the root of another tree of the ſame kind, or of a like genus, and whip-graft them together; obſerving that the but-ends of the graft and root be well united, and that the rind of the root join cloſely to that of the graft. Theſe may, afterwards, be planted out at pleaſure, and the piece of root will collect the nutritive juices, and feed the graft, as the ſtock does the other way.

This method of propagation is very eaſy and expeditious; roots being more plentiful than ſtocks: by this means the pieces of roots of one crab-ſtock, for example, or of one apple-ſtock, will ſerve for twenty or thirty apple grafts; and the like of other trees. It is alſo an excellent way for raiſing of tender trees, which will hardly bear being grafted in the ſtock. Add, that trees thus grafted bear ſooner, and are more eaſily dwarfed than thoſe done any other way.

The only objection againſt this method is, that the young tree grows but ſlowly at firſt, which is occaſioned by the ſmallneſs of the root that feeds the graft; for in all trees the head muſt follow the increaſe of the roots, from whence it hath its nouriſhment.

Reiterated GRAFTING, or GRAFTING *by a double or triple inciſion*, is another method mentioned by Agricola, whoſe work, though chimerical enough in many reſpects, contains, notwithſtanding, ſeveral good things. To perform this, firſt graft a good cion on a ſtock, and cut it away to one half, or a third part; then fix to that remaining part of the cion another graft, of a better kind; and to that a third; for the oftener the tree is grafted, the finer fruit it produces.

By this method the author above mentioned aſſures us, that he produced muſcat pears, which were admirable, making at firſt uſe of a ſtock grafted with a pound-pear, on which he grafted a ſummer bon-chretien; and when the branch of this laſt had ſhot, he grafted on it a cion of a bergamo, which he alſo cut, and grafted on it a cion of a muſcat pear.

GRAFTING *of branches* is alſo commended by Agricola, as a very certain and profitable operation; beſt practiſed on large, full-grown, and even old trees.

To do this, half or more of the branches muſt be lopped off, and grafts of three or four years old be applied to them, taking care to have ſtakes, or other things, to ſupport them againſt the wind, &c.

He adds, that by this method you will have, perhaps, the ſame year, or at leaſt the ſecond or third, ſuch a quantity of fruit, as the youngeſt and ſoundeſt tree would hardly produce.

GRAFTING *by approach*, called alſo *inarching*, and *ablactation*, is uſed only when the tree intended to be grafted, and that from which the graft is to be taken, ſtand ſo near, or can be brought ſo near to each other, that they may be joined together. The method of performing it is thus: the branch to be inarched is fitted to that part of the ſtock where it is to be joined, the rind, and part of the wood, of one ſide of that branch, is then pared away, very ſmooth and even for the length of three inches, and afterwards the other branch, which is to ſerve for the ſtock to which the graft is to be united, is ſerved in the ſame manner, ſo that the two may join cloſely and equally together, that the ſap veſſels may meet. A little tongue is then cut upwards in the graft, and a ſlit is made in the ſtock to receive it; ſo that when they are joined, the tongue prevents their ſlipping, and the graft is the more cloſely united to the ſtock. When they are thus placed exactly together, they muſt be tied with baſs, worſted, or ſome other ſoft thing; and the place of junction muſt be well covered over with grafting clay, to prevent the air from drying the wound, and the wet from rotting the ſtock. A ſtake muſt alſo be fixed in the ground, and both the ſtock and the graft muſt be tied thereto, to prevent their being diſplaced by the wind. When they have remained in this ſtate four months, they will be ſufficiently united, and the graft may then be cut off from the mother tree, obſerving to ſlope it cloſe to the ſtock. It is of great ſervice to the graft then to lay a freſh coat of clay all round the grafted or joined part. This operation ſhould be performed in April or May, that the graft may be perfectly united to the ſtock, before the enſuing winter. It is chiefly practiſed upon oranges, mirtles, jaſmines, firs, pines, and ſome other trees, which do not ſucceed well in the common way of grafting or budding. But though orange trees are here mentioned among the reſt, this prac-

tice

tice is not to be advised for them, or for any other trees, if they are intended to grow large; for that they hardly ever do in this method; and accordingly it is seldom used but for the curiosity of having a young plant with fruit upon it, in a year or two from its having been raised from the seed. This is, indeed, effected by inarching a bearing branch into a young stock: but the plant so treated seldom lives long.

The walnut, fig, and mulberry, will also take by this method of grafting, though neither of them will succeed in any other way; but still they, like all other trees that are thus managed, will remain weak, and stinted in their growth, besides the shortening of their otherwise usual time of duration.

All grafts, particularly of young cions, are subject to be injured by birds; but that may be prevented by binding some small bushes about the tops of the stocks.

The binding of the grafts, whether it be of bass or yarn, should be loosened at least, if it be not entirely taken off at Midsummer, or thereabouts, lest its then too great tightness (as the stock will have increased in bulk, and the binding, perhaps, have been swelled, and consequently shrunk by the weather) should injure the plant.

Escutcheon GRAFTING. *See* INOCULATION.

GRAIN, a general name for all sorts of corn, as wheat, barley, &c.

GRANARY, a building to lay or store corn in, especially that designed to be kept a considerable time.

Experimental philosophy has proved, that the air is the great source of corruption; keep out that, and all is kept out; and the most corruptible substances, such as meal, butter, milk, and the like, have been preserved fresh four months in the exhausted receiver of an air-pump.

They have, near Grand Cairo, a magazine or granary, defended with good walls, and called Joseph's granaries. It is not probable that they are quite so old as the days of that patriarch; but they abundantly prove the utility of such store-houses, by the vast quantities of grain annually preserved in them.

Many parts of Africa abound with granaries of this kind.

They are so many deep pits made in the solid rock; the descent into them is but just large enough for a man to go down into them; but they grow larger as soon as the person is in by, and are usually square, from thirty to forty feet in diameter. In these the great men of the country preserve their corn; they first strew over the floor with straw, then they lay on the corn, still as the heap rises, placing a thin bed of straw between the corn and the sides, as they did at the bottom. In this manner they proceed till the whole cavity is filled: when this is done, they cover the mouth of the entrance with a sort of hurdle of green boughs of trees, interwoven one with another. This they cover with about two feet thickness of sand, and over this raise a ridge of earth, well beat together, in order to throw off the rain both ways, that none may settle on the place and soak into the magazine.

The corn thus stored up always keeps three, four, or more years very good; and, not unfrequently, the proprietor being taken off by the severity of the eastern governments, under which they live, the magazine is forgotten, and some accident discovering it many years afterwards, the corn is almost always found perfectly good in it. All the care they take, in regard to the corn, is to expose it two or three days to the sun's heat, to dry it thoroughly, before they carry it into the magazine.

In the dutchy of Lithuania, and in the Ukraine, the people always preserve their corn in the same manner in wells or pits made in dry places; but in these countries great care is to be taken in the opening these store-rooms; for if people descend into them before they have had sufficient communication with the fresh air, they are often killed by the damps; this, however, is easily guarded against. By these, and numerous other instances of the practice of other countries, it appears evident, that the advantage of these subterranean granaries over all others is very great.

Though these are to be recommended before all others, yet the common granaries may, with proper care, be rendered greatly more useful than they are at present. The grand caution necessary to this purpose is, to guard against the too great humidity, which there always is in places where there is a great number of doors and windows. A too free access of the external air is also to be carefully guarded against; for this brings in with it the eggs of a vast number of different insects, which prey upon, and destroy the corn. A third caution is, when the corn is the produce of the country where it is preserved, not to fill the place with the crop of one place only, but to mix the harvests of two as different provinces as may be, the one dry, the other moist, or otherwise differing as much as may be; thus the contrary qualities of the one will prevent the destruction of the other. These are the three great rules to prevent the corrupting of corn; but when the mischief is once begun, it will prove very difficult to stop it: all the care that can be employed, should therefore be taken in regard to these.

The two great cautions to be observed in the erecting of granaries, are to make them sufficiently strong, and to expose them to the most drying winds. The ordering of the corn in many parts of England is thus: to separate it from dust and other impurities after it is threshed, they toss it with shovels from one end to the other of a long and large room; the lighter substances fall down in the middle of the room, and the corn only is carried from side to side, or end to end of it. After this they screen the corn, and then, bringing it into the granaries, it is spread about half a foot thick, and turned from time to time about twice in a week; once a week they also repeat the screening it. This sort of management they continue about two months, and after that they lay it a foot thick for two months more, and in this time they turn it once a week, or twice, if the season be damp, and now and then screen it again. After about five or six months, they raise it to five or six feet thickness in the heaps, and then they turn it once or twice in a month, and screen it now and then. When it has lain two years, or more, they turn it once in two months, and screen it once a quarter, and, how long soever it is kept, the oftener the turning and screening is repeated, the better the grain will be found to keep.

It is proper to leave an area of a yard wide on every side the heap of corn, and other empty spaces, into which they turn and toss the corn, as often as they find occasion. In Kent they make two square holes at each end of the floor, and one round in the middle, by means of which they throw the corn out of the upper into the lower rooms, and so up again, to turn and air it the better. Their screens are made with two partitions, to separate the dust from the corn which falls into a bag; and when sufficiently full, this is thrown away, the pure and good corn remaining behind.

Corn has, by these means, been kept in our granaries thirty years; and it is observed, that the longer it is kept, the more flour it yields in proportion to the corn, and the purer and whiter the bread is, the superfluous humidity only evaporating in the keeping. At Zurich, in Swisserland, they keep corn eighty years or longer, by the same sorts of methods.

The public granaries at Dantzick are seven, eight, or nine stories high, having a funnel in the midst of every floor, to let down the corn from one to another. They are built so securely, that though every way surrounded with water, the corn contracts no damp, and the vessels have the convenience of coming up to the walls for their lading. The Russians preserve their corn in subterranean granaries, of the figure of a sugar-loaf, wide below, and narrow at top: the sides are well plaistered, and the top covered with stones. They are very careful to have the corn well dried before it is laid into these store-houses, and often dry it by means of ovens, the summer dry weather being too short to effect it sufficiently.

GRANGE, a house or farm furnished with granaries and barns for holding corn, stables for horses, stalls for cattle, &c.

GRANIFEROUS *Pods*, are such as contain small seeds resembling grain.

GRANIVOROUS, an epithet given to animals that feed on corn or seed.

GRAPE, the fruit of the vine. *See the article* VINE.

The best and most general sorts of grapes, either for the garden, for wine, or for verjuice, are 1, the morillons; 2, the chasselas; 3, the muscats; 4, the corinths; 5, the malmsies;

malmſies; 6, the bourguignons; 7, the bourdelais; 8, the ſans-moireau, or grapes without ſtones; 9, the melier; 10, the gamet; and 11, the gouais.

1. The morillons are of ſeveral ſorts, almoſt all of which are well known in moſt places, and of which ſome are very good, both for the table and for making wine.

The early morillon, which we call the July grape, has ſmall, round, black berries, growing looſe on the bunches. It ripens in England about the beginning of Auguſt, has a ſugary juice, with but little flavour, and is very apt to be eaten by birds and flies. It may be allowed a corner in the garden, well expoſed to the ſouth, and ſheltered from the wind; but its only merit is its ripening early.

The morillon taconné, or black cluſter, likewiſe called the meunier, or miller, from the hoary down of its leaves, ripens ſomewhat later than the former, yields plentifully, and makes good wine. The bunches of this are ſhort, the berries oval, and ſo cloſe together, that many of thoſe on the inſide continue green, when the outer ones are perfectly ripe. It delights in a ſandy light ſoil, ripens here in September, and is by ſome called the Burgundy grape; but this name belongs more properly to the common black morillon, which the people of Burgundy diſtinguiſh by the appellation of pineau, and which thoſe of Orleans term the auvernat, becauſe it came originally from Avergne. Its berries are oval, and hang looſer on the bunches than thoſe of the black cluſter grape; by which means they are ripened more equally. This ſort is very ſweet, ſugary, black, good to eat, grows well in almoſt any ſoil, and yields an excellent wine. Its leaf is rounder than that of any other ſort of grapes, and its wood, when cut, is redder. The beſt ſort is that whoſe joints are not above three fingers breadth aſunder. Another ſpecies of this morillon, to which the French give the name of pineau aigret, or tartiſh taſted pineau, has longer, thicker, more pithy, and leſs compact, wood than the former; its joints are at leaſt the breadth of four fingers aſunder; the outſide of its bark is very red, and its leaf is divided into three parts, like that of the fig-tree. The berries of this are ſmaller, and hang in looſer cluſters, than thoſe of the foregoing ſort; nor does it yield much fruit: but the wine that is made of this fruit is ſtrong, and even better than that of the preceding ſpecies. A third ſort of morillon, which the French diſtinguiſhed by the appellation of franc morillon, lampereau, and beaune, bloſſoms earlier than the others, and yields equally good wine. The wood of this is black, as is alſo its fruit, which promiſes greatly whilſt green, but above half of it is generally loſt before it attains to a proper maturity. This vine runs into wood more than either of the former ſorts, and its joints are farther diſtant from each other.

There is alſo a white morillon, which is excellent to eat, but its ſkin is harder than that of the common black morillon; and there is likewiſe, of this ſpecies, the Orleans gray auvernat.

2. The chaſſelas, otherwiſe called muſcadet, or white bar-ſur-aube, is a large, white, and excellent grape, either for eating, for keeping long, for drying, or for making good wine. Its berries do not grow cloſe together; and it is peculiarly fit for ſtony vineyards, becauſe it ripens there the moſt eaſily. There is another ſort of white bar-ſur-aube, a ſpecies of the large corinth, which will be ſpoken of hereafter.

The black chaſſelas, known in Provence and Languedoc by the name of the Greek grape, is ſcarcer than the white: and ſo is alſo the red, the berries of which are likewiſe bigger. Both of theſe are excellent.

3. Almoſt all the muſcat grapes are exquiſite.

The white muſcat, or Frontignan, has long, thick, and very cloſely cluſtered bunches. It is excellent for eating, for preſerving, for making wine, or for drying in an oven, or by the heat of the ſun. As the berries of theſe grapes are very ſmall, and grow extremely cloſe together, they ſhould, eſpecially where it can be done with moſt eaſe, be carefully thinned early in the ſeaſon, that the ſun and air may not be hindered from entering them, and that they may not be rotted by the moiſture which would otherwiſe be detained.

The early white Piémont muſcat, which deſerves ſingular eſteem, has longer bunches, leſs cloſely cluſtered, and more unctuous.

The red or coral muſcat, ſo called from the livelineſs of it colour, has the ſame qualities, its berry is yet firmer, and requires a pretty deal of ſun to ripen it well.

The black muſcat is larger, and grows extremely cloſe. It has not ſo high a flavour; but it is very ſugary, and is much eſteemed, becauſe it is a great bearer, and its fruit ripens pretty early.

The purple muſcat is of a leſs deep colour, and bears very large bunches, which are well garniſhed with large high flavoured berries. This, and the red, yield the moſt vinous juices of all the ſorts of muſcats.

The malmſy muſcat will be ſpoken of under the head of malmſy grapes.

The ribeezatte muſcat has a pretty ſtrong flavour of muſk: its berry is ſmaller than that of the other ſorts, and its juice is ſo ſweet and agreeable, that it would be accounted one of the firſt of grapes, if it was leſs apt to ſhed its bloſſoms, and alſo, if it was leſs apt to degenerate.

The long muſcat, or paſſe-muſqué of Italy, has very long and big bunches of large oval berries, hanging ſomewhat looſe. This is ſcarce, and does not ripen without a great deal of heat: though, if it be but half ripe, it is the beſt of all grapes to preſerve for a ſweetmeat; the fire exalting that fine flavour in it, which the ſun had not time, or power to perfect.

The long purple muſcat, which ſome call the Madeira grape, is rare; but uncommonly beautiful and good.

There is likewiſe the Jeſus muſcat, the berries of which are very large and round. This has a very high perfumed flavour, and is extremely ſcarce.

The gennetin, otherwiſe called the Orleans muſcat, belongs alſo to this ſpecies of grapes. It is very ſugary, apt to ſhed its bloſſoms, and reſembles the melié, or rather the malmſy; for which reaſon ſome call it likewiſe the white malmſy. The dealers in wine at Paris often ſell the gennetin wine for the true muſcat of Frontignan.

4. The black corinth, or, as it is vulgarly called, the currant grape, is ſugary and delicious. Its berries are round, very ſmall, and cloſely cluſtered on the bunch, which, for its thickneſs, is rather long, and they have not any ſtone.

The purple corinth is a little bigger than the black, like which it is an excellent fruit, and has no ſtone; but it is very apt to ſhed its bloſſoms; for which reaſon it ſhould be pruned longer than other vines.

The grape without ſtones is a ſort of white barſur aube, but its berries are ſmaller, and ſomewhat tarter. It is very fit for drying, becauſe it has not any ſtones; for which reaſon it is often called the large corinth, or currant.

It is to be obſerved, that all the muſcats and corinths, being apt to ſhed their bloſſoms, ſhould be pruned long, or grafted upon the bourdelais, when it is not deſired they ſhould have a ſtrong muſky flavour.

5. The malmſy grape is of a greyiſh colour, and the vines which produce it are great bearers. Its berries are ſmall, but very ſugary, high flavoured, early ripe, and ſo full of juice, that, like the Orleans gray auvernat, it is reckoned one of the moſt melting grapes. The red malmſy is of a flame colour, and has the ſame qualities as the ſort before mentioned. The white malmſy is ſcarcer, and ripens leſs early. The gray malmſy is the moſt uſed, and generally thought to be the beſt of the three.

There is likewiſe the muſked malmſy, otherwiſe muſcat de malvoiſie. It comes from Mont-ferrat: the country round about Turin is full of it; and its flavour of muſk is higher than that of any other grape.

6. The bourguignon, or treſſeau, is a pretty large black grape, better to make wine of than to eat. The vines of this ſpecies bear moſt plentifully, and their branches are of a good ſize.

The white bourgignon, called in ſome places mourlon, and in others the clozier, has joints at the diſtance of two fingers and an half broad from each other, its fruit grows on a ſhort ſtalk, its branches are cloſely cluſtered, its leaf is very round, like that of the guoais, and it endures froſty weather.

The noirat, or black grape, otherwiſe called the dyer, or Spaniſh plant, is another ſort of black bourguignon.

Its

Its wood, like that of the former, is hard and very black; the pith of this wood is ſmall and compact; its joints are ſhort; its leaf has a red ſtalk, is of the middle ſize, and quite round. It reſiſts the froſt better than any other vine; but its juice is very flat, and ſerves only to give a deep colour to the wine it is mixed with; for which reaſon a few, and but a few, of theſe vines are planted in each vineyard that is to produce red wine. It is alſo good for wounds. The dyers give a great price for the wine that is made of this grape, to dye their cloths with.

7. The bourdelais is of three ſorts, viz. white, red, and black. Its bunches, and their berries, are very large. It is uſed chiefly to make verjuice, and for ſweet-meats. It is likewiſe an excellent ſtock for grafting all ſorts of grapes, eſpecially thoſe that are apt to ſhed their bloſſoms, ſuch as the Damaſcus, the corinths, and particularly the purple kind of this laſt ſpecies. The muſcats may alſo be engrafted on it, and ſo, in ſhort, may all other vines.

The apricot grape, the Greek vine, and the farineau, are three ſpecies of the bourdelais.

The apricot grape is ſo called, becauſe its fruit is of a golden yellow, like the apricot: its bunches are beautiful, and very large.

The Greek vine, likewiſe called the marvellous grape, and the St. James of Galicia, becauſe that part of Spain is full of it, is red, bears large, round, and ſweet berries, which ripen early, and make good wine. It produces very large, and beautiful bunches; and when the fruit is ripe, its leaves become ſtreaked and bordered with red, as is frequently the caſe of all vines whoſe fruit is variegated with black, purple, and red.

The farineau, or rognon-de-coq, as ſome call it, is white, has ſmall long berries, and is fitter to make verjuice than wine.

8. The ſans-moireau, which the people about Auxerre call quille-de-coq, is, a black grape, excellent for eating and for making wine. Its berries are ſomewhat long, firm, and cloſely cluſtered. There are three ſorts of this vine: the wood of the firſt and beſt is hard, and has ſhort joints; the ſecond is very like the firſt; and the third, called the ſans-moireau chiqueté, or white prunelas, becauſe it has whiter wood than the others. It yields but a flat wine, bears only in ſome years, and its berries are apt to drop off entirely before they are fit to be gathered.

The red prunelas, or negrier, has a red rind, long jointed wood, thick pith, a jagged leaf, and bears large bunches of tranſparent and very red grapes. It is one of the lateſt ripeners, and yields a laſting, but rough wine; for which reaſon a few only of theſe plants are ſet in vineyards of black grapes; but juſt enough to deepen the colour of the wine, and to give it a body. It reſiſts froſt, becauſe its ſtem is tall and ſtrong.

9. The white melié is one of the beſt of grapes for making wine, and for eating. It yields greatly, and has a good juice, which keeps pretty well. It is an excellent fruit for drying.

The black melié is neither ſo well taſted, nor ſo vinous as the white.

The green melié, which ſome call only the green plant, is the moſt eſteemed of this ſpecies of grapes, becauſe it yields greatly, does not ſhed its bloſſoms, and the wine made of it never turns yellow.

The ſurin is a ſpecies of the melié. Its berries are ſomewhat oblong, and a little pointed. The fruit of this vine has an excellent flavour, and is greatly liked in Auvergne.

10. The gamet is a very common grape, yields plentifully, and grows more eaſily than any other: but it affords only a very weak wine, which has but little flavour; nor does this ſort of vine laſt many years. There is a white gamet, and a black gamet.

11. The gouais is likewiſe very common. One ſort of it is white, and another purple, with a bloom, like that on plums. Its vine will laſt an hundred years in the ground. It bears larger and longer bunches than the gamet; but, like it, has too poor a juice to make good wine. It is even inferior to the gamet in this reſpect: but it makes excellent verjuice, and fine ſweet-meats. Very few, if any, of this ſpecies, ſhould be left in a vineyard.

12. Beſides theſe eleven moſt general ſorts of grapes, there are many others, which though leſs uſually ſpoken of, ought to be known.

The beaunier, ſo called becauſe it is very common and much eſteemed at Beaune, is a grape which yields greatly, and has ſome reſemblance to the white gouas. At Auxerre, it is called the ſervinien.

The fromenteau is an exquiſite grape, and well known in Champagne. It is of a gray red, grows in pretty large bunches, which are very cloſely cluſtered, has a tough ſkin, an excellent juice, and makes the beſt of wine. It is to this grape that the famous wine of Sillery owes its merit and renown.

The ſauvignon is a black grape, pretty big and long, very high flavoured, and exceedingly good. There is alſo a white ſauvignon, which has the ſame qualities as the black: but both of them are ſcarce, and not much known.

The pinquant-paul is a very ſweet white grape. It is likewiſe called the bec-d'oiſeau, or bird's bill, and in Italy, pizutelli, pointed, becauſe its berry, which is large and very long, is pointed at each end.

There is alſo the purple pizutelli, otherwiſe called dent-de-loup, or wolf's tooth, which has likewiſe a long berry, but leſs pointed. It is one of the plumpeſt and moſt beautiful of grapes, and yields a pretty good juice, which will keep for a long time.

The grape which the French call the gland, becauſe it is ſhaped like an acorn, is of a deep yellow colour, very ſweet, and keeps well.

The blanquette de limons, is a white grape, tranſparent as glaſs. Its bunch is long and pretty big: it yields greatly, and its juice is very ſweet and delicious.

The white robe, and the black robe, yield alſo plentifully. Their bunches are thick and long, their berries ſmall, and very cloſe together; but, being a ſpecies of the ſmall Bourdelais, they do not ripen eaſily.

The Alicant vine, commonly called the great black Spaniſh, bears bunches of very large berries, which are good to eat, and ſtill better to make the wine ſo vaunted in Spain; uſually called tent, in this country.

The berries of the African grape are as big as plums, and the bunches of them are proportionably large. Theſe berries are rather long than round, and ſomewhat flat towards the point. The wood of this vine is very thick, and its leaf very large. The aſſiſtance of a wall, and a great deal of ſun, are neceſſary to ripen this fruit thoroughly.

The morocco, or barbarou, is a large purple grape, the bunches of which are alſo of an extraordinary ſize. The berries are big, round, and hard, the wood reddiſh, and the leaf ſtreaked with red. Some vines of this ſpecies yield amazingly, and bloſſom three times a year.

The Damaſcus grape is likewiſe excellent to eat; its bunches are very big and long, its berry very large, long, and of an amber colour. It has but one ſtone, and is very apt to ſhed its bloſſoms; for which reaſon it ſhould be pruned long. There is a white ſort, and a red ſort, of this grape.

The Italian grape, otherwiſe called pergoleze, is of two ſorts, viz. the white and the purple. Its bunches are large, and the berries long and looſe ſet; but they require a conſiderable degree of heat to ripen them.

The Mantuan vine yields a very early fruit; for it ripens in the beginning of Auguſt. Its bunch is pretty large, and it does not ſhed its bloſſoms: the berries too are pretty big, rather long than round: they are of a fine rich amber colour, and contain a very vinous juice.

The Auſtrian vine, or cioutat, has a leaf divided like that of parſley: its fruit is white, ſweet, yields well, and reſembles the chaſſelas; but its juice is not vinous.

The Swiſs grape is rather curious than good. Its bunches are thick and long, and their berries are variegated with black and white, ſometimes in ſuch manner that one half of a berry is of one of theſe colours, and the other half of the other.

A ſhort recapitulation of the above-mentioned different ſorts of grapes, will at once ſhew what each of them is fitteſt to be planted for.

GRAPES *proper for the Garden.*

The cioutat; the black and the white chaſſelas; the white, the black, the red, the long, and the muſky muſcat.

cat, with the early Orleans muſcat, commonly called the gennetin; the corinth, ſmall or large, red or purple; the malmſy, gray or red; the Italian, the African, the Damaſcus, the Morocco, the apricot, the white robe, the melié, eſpecially the white; and the Bourdelais.

GRAPES *proper for the Vineyard.*

The pineau, or Auvernat, the gray Auvernat; the white morillon, and the morillon taconné; the gennetin; the pinquant-paul, the beaumier, the treſſeau, and all the bourquignons; the Bourdelais, the Swiſs, the Spaniſh black, or Alicant; the ploqué, the ſans-moireau, or grape without ſtones, the negrier, the fromenteau, the blanquette de limons, and moſt of the garden grapes, eſpecially the melié, the white robe, the black and the red muſcat, and the chaſſelas. A few plants of the gouais may alſo be intermixed with them.

GRAPES *proper for making Verjuice.*

The farineau, the white and the purple gouais, and the white and the black gamet.

GRASS, a general name for moſt of the herbaceous plants uſed in feeding cattle.

The beſt ſeaſon for ſowing graſs-ſeed is the latter end of Auguſt, and the beginning of September, that the graſs may be well rooted before the froſt ſet in, which is apt to turn the plants out of the ground, when they are not well rooted. This ſeed ſhould be ſown in moiſt weather, or when there is a proſpect of ſhowers, which will ſoon bring the graſs up; for, the earth being at that ſeaſon warm, the moiſture will cauſe the ſeed to vegetate in a few days: but, where this cannot be performed in autumn, the ſeeds may be ſown in the ſpring; towards the middle of March will be a good time, if the ſeaſon proves favourable.

The land on which graſs-ſeed is intended to be ſown, ſhould be well ploughed, and cleared from the roots of noxious weeds, ſuch as couch-graſs, fern, ruſhes, heath, gorſe, broom, reſt-harrow, &c. which, if left in the ground, will ſoon get the better of the graſs, and over-run the land. Therefore, in ſuch places where either of theſe weeds abound, it will be a good method to plough up the ſurface in April, and let it lie ſome time to dry; then lay it in ſmall heaps, and burn it. The aſhes ſo produced, when ſpread on the land, will be a good manure for it. The method of burning the land is particularly uſeful; eſpecially, if it is a cold ſtiff ſoil; but where couch-graſs, fern, or reſt-harrow, is in plenty, whoſe roots run far under ground, the land muſt be ploughed two or three times pretty deep in dry weather, and the roots carefully harrowed off each ploughing; which is the moſt ſure method to deſtroy them. Where the land is very low, and of a ſtiff clayey nature, which holds water in winter, it will be of ſingular ſervice to make ſome under-ground drains to carry off the wet; which if detained too long on the ground, will render the graſs ſour. The method of making theſe drains is preſcribed under the article DRAINING.

Before the ſeed is ſown, the ſurface of the ground ſhould be made level and fine, otherwiſe the ſeed will be buried unequal. The quantity of graſs-ſeed for an acre of land is uſually three buſhels, if the ſeed is clean, otherwiſe there muſt be a much greater quantity allowed; when the ſeed is ſown, it muſt be gently harrowed in, and the ground rolled with a wooden roller; which will make the ſurface even, and prevent the ſeeds being blown in patches. When the graſs comes up, if there ſhould be any bare ſpots, where the ſeed has not grown, they may be ſown again, and the ground rolled, which will fix the ſeeds; and the firſt kindly ſhowers will bring up the graſs, and make it very thick.

Some people mix clover and rye-graſs together, allowing ten pounds of clover, and one buſhel of rye-graſs, to an acre: but this is only to be done where the land is deſigned to remain but three or four years in paſture, becauſe neither of theſe kinds are of long duration; ſo that, where the land is deſigned to be laid down for many years, it will be proper to ſow with the graſs-ſeed ſome white trefoil, or Dutch clover; which is an abiding plant, and ſpreads cloſe on the ſurface of the ground, ſending forth roots at every joint; and makes the cloſeſt ſward of any, and is the ſweeteſt feed for cattle: ſo that, whenever land is laid down to paſture, there ſhould always be ſix or eight pounds of this ſeed ſown upon each acre.

The following ſpring, if there ſhould be any thiſtles, ragwort, or ſuch other troubleſome weeds, come up among the graſs, they ſhould carefully be cut up with a ſpaddle before they grow large; and this ſhould be repeated two or three times in the ſummer, which will effectually deſtroy them; for, if theſe plants are ſuffered to ripen their ſeeds, they will be blown all over the ground; their ſeeds having down adhering to them, which aſſiſts their tranſportation; ſo that they are often carried by the wind to a great diſtance, and thereby become very troubleſome weeds to the graſs. For want of this care, how many paſtures may be ſeen almoſt over-run with theſe weeds, eſpecially the ragwort; when a ſmall expence, if applied in time, would have intirely extirpated them! for a man may go over ſeveral acres of land in one day with a ſpaddle, and cut up the weeds juſt below the ſurface of the ground, turning their roots upwards; which if done in dry weather, they will ſoon decay; but this muſt always be performed before the plants come to have their ſeeds formed; becauſe after that many ſorts will live long enough to nouriſh their ſeeds after they are cut, ſo as to ripen them: and there will be a ſupply of weeds for ſome years after, which cannot be extirpated without a much greater expence.

The proper management of paſture land is the leaſt underſtood of any part of agriculture: the farmers never have attended to this, being more inclined to the plough; though the profit attending that has not of late years been ſo great as to encourage them in that part of huſbandry: but theſe people never think of laying down land for paſture, to continue longer than three years; at the end of which time they plough it up again, to ſow it with grain.

Their uſual method is to ſow rye-graſs and trefoil with barley, when they intend to lay down the ground; or ſometimes ſow only clover with the barley; nor is it poſſible to convince theſe people of their error in ſowing corn with this graſs; which they affirm to be uſeful in ſhading the graſs; not conſidering how much the corn draws away the nouriſhment from the graſs: but it is in vain to write to theſe people, who are not to be convinced, either by argument or experiment; ſo much are they led by cuſtom, as not to be led or driven out of their own methods; but, as their practice of huſbandry has greatly leſſened the circumſtances of the farmers, ſo that the lands are daily falling into the hands of the owners, therefore this part of huſbandry ſhould by them be principally attended to, as it may be carried on with much leſs expence: for paſture land requires but few hands to manage; whereas the ſowing of corn is attended with great expence, and the profit is very precarious: but, when this is attended with ſucceſs, and the grain at a moderate price, if the whole labour is to be paid for, there will be little coming to the owner for rent, when the balance is fairly ſtated; but in this moſt gentlemen deceive themſelves, and often ſuppoſe they gain by farming, when, perhaps, the whole rent of the land is loſt: therefore, to avoid the trouble which attends this ſort of huſbandry, it will be the beſt method to turn as much of their land into paſture, as they can; which, by grazing and feeding of ſheep, will be attended with little expence, and a ſure profit.

It is not uncommon for the huſbandman, for want of diſtinguiſhing graſſes for ſeed, to fill his ground with either weeds or bad and imperfect graſſes. Whereas by making a proper choice, he would always have the beſt graſs, and in the greateſt abundance his land will admit of.

In the common way of proceeding, if a farmer wants to lay down his land to graſs, he either takes his ſeeds indiſcriminately from his own foul hay-rick, or ſends to his neighbour for a ſupply. By this means, beſides a certain mixture of rubbiſh, which muſt neceſſarily happen; it is not unlikely, but that what he intends for dry land may have come from moiſt, where it grew naturally, and ſo on the contrary: and the conſequence of this ſlovenly method frequently is, that the ground, inſtead of being covered in one year with a good ſward, is filled with weeds not natural to it, which would never have ſprung up, if they had not been brought thither.

"Argu-

"Arguments, says Mr. Stillingfleet, are never wanting in support of ancient customs, and I am no stranger to those, such as they are, which prejudice and indolence have made use of on this occasion.

"1. Some say then, that if you manure your ground properly, good grasses will come of themselves. I own they will. But the question is, how long it will be before that happens: and why be at the expence of sowing what you must afterwards try to kill? which must be the case, as long as people sow all kinds of rubbish under the name of hay-seeds. Again, if the best way is to let the ground take its chance, why is the farmer at the expence of procuring the seeds of the white and broad clover, which come up in almost all parts of England spontaneously? But if this is allowed not to be the best way in relation to clover of any kind, what reason can be in nature, why grass-seeds only ought not to be sown pure?

"2. Others say, that it is better to have a mixture of different seeds. I will suppose this to be true. But cannot a mixture be had though the seeds be gathered, and separated? and is not a mixture by choice more likely to be proper, than one by chance? especially after a sufficient experience has been had of the particular virtues of each sort, of the different kinds of cattle which each grass is most adapted to, of the different grounds where they will thrive best, &c. all which circumstances are now, in general, wholly unknown, though of the utmost consequence.

"3. It is said by some, that weeds will come up along with the grass. No doubt of it. Can any one imagine that grass-seeds should be exempted from what happens to every other kind of seeds? But I will venture to say, that not near the quantity of weeds will spring up which they imagine, if the grass be sown very thick. Men must be very much put to it, when they make such objections as this last, or indeed any of the others. I am almost inclined to say with a great writer, It is a simple thing to take much pains to answer simple objections.

"One would hardly think it possible, that the slovenly method of proceeding, here complained of, could prevail universally: yet this is the case as to all grasses, except the darnel (or rye) grass, and what is known in some few countries by the name of the Suffolk grass; and this latter instance is owing, I believe, more to the soil than to any care of the husbandman. Now, would the farmer be at the pains of separating, once in his life, half a pint, or a pint, of the different kinds of grass seeds, and take care to sow them separately, in a very little time he would have wherewithal to stock his farm properly, according to the nature of each soil, and might at the same time spread these seeds properly over the nation, by supplying the seed shops.

"I have had frequent experience how easy it is to gather the seeds of grasses, having several times employed children of ten or eleven years old, who have gathered many sorts for me without making any mistakes, after I had once shewn them the sorts I wanted.

"I have procured thus the creeping bent, the fine bent, the sheep's fescue, the crested dog-tail, &c. in sufficient quantities to begin a stock; but, for want of a proper opportunity of cultivating them myself, or meeting with any one who had zeal enough to bestow a proper care on them, my collections of this kind hitherto have only proved, that the scheme is in itself feasible.

"In the year 1761, a little boy gathered, by my directions, as much of the crested dog-tail, in three hours, by the side of a road, as, when shed, yielded, upon weighing, above a quarter of a pound averdupois, perfectly free from husks. As this seed is small, the skilful will easily judge how far such a quantity would go if properly employed.

"My very estimable and ingenious friend Mr. Aldworth, who was witness of the fact which I last mentioned, at my desire, ordered a small part of a meadow, near his seat at Stanlake, which had better grasses, and less mixed, than the rest, to be left unmowed till the seeds were fit for gathering. This piece yielded, upon threshing and sifting, a full bushel by measure, of almost pure seed of the crested dog-tail.

"In case any one should be inclined to follow this example, I think it highly necessary to observe, that care must be taken to mow the grass before it sheds; that it be mowed very early in the morning, before the dew is off the ground, and that it ought not to be spread as in making hay, but left as it falls from the scythe during a sufficient time, and then be gently turned over.

"The number of grasses fit for the farmer is, I believe, very small; perhaps half a dozen, or half a score, are all he need to cultivate; and how small the trouble would be of collecting the seeds of these, and how great the benefit, must be obvious to every one at first sight. Would not any one be looked upon as wild, who should sow wheat, barley, oats, rye, peas, beans, vetches, buck-wheat, turneps, and weeds of all sorts together? Yet how is it much less absurd to do what is equivalent in relation to grasses? does it not import the farmer to have good hay and grass in plenty? and will cattle thrive equally on all sorts of food? We know the contrary. Horses will scarcely eat hay that will do well enough for oxen and cows. Sheep are particularly fond of one sort of grass, and fatten upon it faster than any other in Sweden, if we believe Linnæus. And may they not do the same in England? How shall we know till we have tried? Nor can we say, that what is valuable in Sweden, may be inferior to many other grasses in England, since it appears by the Flora Suecica, that they have all the good ones that we have. But however this may be, I should rather choose to make experiments than conjectures."

The Society for promoting Agriculture, &c. in the province of Britany, has laid down the most rational plan yet formed by any body of men, nobly associated for the welfare of their country, and which promises the greatest advantages to mankind. A part of this plan is the cultivating separately most of the plants which grow naturally in the fields there, in order to know which of them will afford the most and the best food for cattle.

As the husbandman would not be benefited by knowing the particular classes, genera, &c. under which Ray, Linnæus, and other botanists have ranged the several species of grasses, we shall here give the names of such of them as may be cultivated to most advantage in this country, with the best drawings (for which we are indebted to Mr. Stillingfleet) of some of the most profitable sorts, which it will be of service to the farmer to be able to distinguish rightly.

The common dogs grass, quich grass, or couch grass (*Gramen spicâ triticeâ repens vulgare, caninum dictum*) common creeping grass, with a spike like wheat, called dogs grass, will thrive in almost any soil, and can scarcely be got out again after it has once taken possession: so greatly does it multiply by its roots and trailing branches, which put forth roots and shoots at every joint. It grows to the height of four or five feet, with blades so rough and coarse, that few horses will eat them, especially while they are green: but it yields abundant crops of hay, which does well enough for oxen, and therefore deserves, perhaps, more attention than our farmers have yet bestowed upon it. M. Duhamel indicates the best way of making the most of it, when he directs the farmer always to mow it before its seeds ripen, or its stalks grow hard; for after that cattle refuse it; adding, that it soon shoots up again, and will bear frequent cutting.

This plant is well known to all husbandmen, to whom it is a sad plague, when it gets into their arable land. It is the chiendent of the French, who, I must observe here for the benefit of their husbandry, do not distinguish it sufficiently from our

Rye grass, which is C. Bauhin's *Gramen loliaceum angustiore folio, et spica*, Darnel grass, with a narrower leaf and spike; and Linnæus's *Lolium spicâ muticâ*, Darnel with a chaffy spike: for darnel grass, rye grass, and ray grass, are only different names of one and the same plant: though M. Duhamel, mislead by the erroneous spelling of some writers, who have called rye grass ray grass, has been mistakenly induced to think, that these are two different plants with us. We distinguish, indeed, two considerably different species of the rye grass, viz. the foregoing, which, according to Mr. Ray, is the *Lolium rubrum*, or red darnel; and the *Lolium album*, which, according to the same author, is C. Bauhin's *Gramen loliaceum spicâ longiore*, darnel grass, with a longer spike, and the

yvraie

yvraie of the French, by us commonly called darnel only. But both of them are equally rye grafs. It is the laft of thefe fpecies, viz. the *lolium album*, which is chiefly cultivated in England, efpecially in ftrong cold land, upon which it will fucceed better than any other fpecies, and is an earlier feed in the fpring: but it is very coarfe; and unlefs it be cut quite early for hay, it becomes fo hard and wirey in the ftalks, that few cattle care to eat it: for this fort of grafs has but few leaves, and runs all to ftalks. When cattle have been turned in to feed upon it, the remaining ftalks or bents, as they are fometimes called, fhould be mowed off in June; for otherwife they will dry upon the ground, give the pafture the difagreeable appearance of a ftubble field during all the latter part of fummer, and be fo very troublefome to the cattle which feed on it, by tickling their noftrils, that nothing but the want of better grazing will compel them to eat of the young grafs which fhoots up between thefe withered ftems; for they will not eat them. Thofe who think that they do, when ftreightened for food, are greatly miftaken, according to Mr. Miller, who fays, that he has clofely attended to this many years, and has always found thefe bents remaining on the ground untouched, till the frofts, rain, and winds, have deftroyed them in the winter. Befides this, by permitting them to ftand, the after growth of the grafs is greatly retarded, and the beautiful verdure of the fields is loft for three or four months. It therefore is good hufbandry to mow them clofe to the ground, before they become too dry: and if this cutting is then made into hay, it will ferve to feed cart horfes in the winter, fo as to repay the expence of mowing.

The red darnel is a confiderably inferior fpecies of rye grafs; for it has yet narrower leaves, and its ftalks grow hard much fooner. It is very common in moft pafture grounds, becaufe it flowers early, and its feeds ripen and fow themfelves before the hay is cut. They, therefore, who would keep their paftures as clear as poffible from this grafs, fhould always mow them before its feeds are ripe.

Rye grafs is ufually fown with clover, upon fuch lands as are defigned to be plowed again in a few years; and a common method is to fow it with fpring corn. But Mr. Miller, from many repeated trials, has always found, that when this grafs has been fown in Auguft, and a few fhowers have fallen fhortly after, the crop has been by much the beft: for it then has often been fo high as to afford a good feed the fame autumn; and a ton and a half of hay has been mowed early the next fpring off each acre of land, though it has been a cold and four foil. "I am, therefore, fays he, convinced of that being the beft feafon for fowing thefe graffes; though it will be very difficult to perfuade thefe perfons to alter their practice, who have been long wedded to old cuftoms. The quantity of feeds which I allow to an acre is about two bufhels, and eight pounds of the common clover, which, together, will make as good a covering upon the ground as can be defired. But this is not to be practifed upon lands where the beauty of the verdure is principally regarded. It is fitteft for thofe who have only profit in view." However, we muft reckon as an abatement of this profit, that, as M. Duhamel rightly obferves, the ground that has been under rye grafs, which is not fo profitable a crop as either lucerne, fainfoin, or even clover, is not able to bear wheat the next year, as it is after thofe other plants, or after a crop of roots."

According to Mr. Lifle's information, the farmers in the Ifle of Wight prefer rye grafs to hop clover, becaufe, fay they, the rye grafs will bear the winter, and keep to a good head, which the clover will not do. One of his tenants there had an acre and a half of rye grafs upon tolerably good ground, which he fhut up from Michaelmas till within a month of Candlemas, and from thence to the middle of April it kept fifteen ewes and fifteen lambs.

Rye grafs feldom lafts more than three years, as it is commonly managed: but Mr. Lifle is ftrongly of opinion, that, confidering the nature of its roots, and its manner of propagating itfelf, by fending forth fibres from its joints, it may be kept alive many years longer, by dunging it, or by refrefhing it with foil, when it begins to decay, after the fecond or third year: befides which, this will make its roots tiller, and mat on the ground, to the utter fuppreffion and deftruction of all weeds, not excepting even the couch grafs.

An acquaintance of his near Upcern, in Dorfetfhire, told him, that he had as much rye grafs feed on eighteen acres of land, as was worth twenty pounds; and that, after the feed was threfhed out, that hay was better than oat-ftraw fodder. Mr. Lifle himfelf faw a rick of this coarfe ftubbed hay, and a rick of oat ftraw, both of which had been laid open to the cattle, in the fame place; and they would not touch the ftraw, but had made fuch a hole in the rye grafs hay rick, that it was ready to fall. The fame perfon affured Mr. Lifle, that he found the rye grafs to be excellent food for his cattle, if it was mowed green, and not kept for the lucre of the feed. His ufual allowance was three bufhels of this feed to an acre of land, and he ufed to fell it for twenty-two pence, or two fhillings a bufhel.

Another farmer fhewed Mr. Lifle fome of his rye grafs, faying, that he looked upon it as his choiceft fodder for fheep. He mowed it when in the flower; and Mr. Lifle declares, that he thought it very fine hay. Others again, and thofe men of experience, have affirmed, that the very ftubble of the rye grafs, mowed the fame year it was fowed, is, when ploughed in, as good as dunging, and will pay for the feed.

Mr. Lifle agrees with all other experienced hufbandmen, that, though rye grafs will maintain as many cattle on an acre as hop clover will do; yet it does not, like it, improve the land for a fubfequent crop of corn; the reafon of which he takes to be, that the roots of the rye grafs, confifting of a multitude of matty fibres, which run on the furface of the ground, gird and hold the earth fo ftrongly together, that they cannot eafily be difintangled from it by ploughing.

"If I may judge of this grafs, fays Mr. Stillingfleet, by the venifon I have eaten out of a paddock that was chiefly filled with this fpecies, I would by no means recommend it for parks. I know it will be faid, that venifon is never good out of paddock, that the deer muft have room to range, trees to browfe on, &c. I grant there is fome reafon for faying this, but I believe in general it is more owing to the want of proper food, viz. good grafs, than merely to confinement; for paddocks are generally made out of a rich fpot of ground near the houfe, that has conftantly been manured, and of courfe is full of grafs fitter for the dairy or the ftable, than for deer; which hardly ever is the cafe in large parks. No man, will, I fuppofe, pretend to make good pork from a hog fed with grains inftead of peas, tho' he has the liberty of choofing as much ground as he pleafes, and where he pleafes."

In a fubfequent editition of his Obfervations on Graffes, he adds, "I have fince eaten venifon out of a large park, where there was much of this grafs, and it was no better than that out of the paddock. I fhould be apt to think from hence, that this grafs would not be proper for fheep, as I have always obferved that the fame kind of ground which yields good venifon, yields alfo good mutton. For what particular ufes it is good, wants to be tried; whether for the dairy, for fattening cattle, or for horfes. Many are tempted, by the facility of procuring the feed of this grafs, to lay down with it grounds near their houfes, where they want to have a fine turf: but unlefs the foil be very rich, a worfe grafs cannot be chofen for this purpofe, as it will certainly die off entirely in a very few years."

The wall barley, or way bennet, as fome people improperly term it, is evidently from the fhape of its ear, and from every other characterifing circumftance, a rye grafs, or wild rye, as Mr. Ray obferves, though very different from the preceding. It is the *gramen fecalinum et fecale fylveftre*, called tall meadow rye grafs by Mr. Miller, who reckons it an excellent grafs for fowing, becaufe it is very leafy, its ftalks do not become ftiff and hard like many other fpecies, and its roots are perennial. He feems not to doubt, but that it may be rendered very fine by proper care; and as its roots are perennial, rolling will make them mat, fo as to form a very clofe fward. There are three forts of it, viz. the greater, the leffer, and the marfh rye grafs. Mr. Stillingfleet wifhes, that this genus only were to be called rye grafs, and that the old name of darnel

nel were continued to the *gramen loliaceum*, or rye grafs, before fpoken of.

The two beft fpecies of grafs for paftures are, in Mr. Miller's opinion, C. Bauhin's *gramen pratenfe, paniculatum majus, anguftiore folio*, meadow grafs, with large panicles, and a narrower leaf, which is the *poa paniculâ diffufâ, fpiculis, quadrifloribus pubefcentibus culmo erecto tereti*, Flor. Suec. 77. Poa with a diffufed panicle, the fmaller fpikes having four hairy flowers, and a taper erect ftraw; and C. Bauhin's *gramen pratenfe, paniculatum majus, latiore folio*, meadow grafs, with a larger panicle, and broader leaf, which is the *poa paniculâ diffufâ, fpiculis trifloribus glabris, culmo erecto tereti*, Flor. Suec. 76. Poa with a diffufed panicle, fmall fpikes with three flowers, and an upright ftraw.

Thefe feem to be the great meadow graffes Mr. Stillingfleet obferves are common in our beft meadow grounds. He has alfo met with them frequently on banks by the road fide, and near ditches, even where they were not to be found in the adjoining meadows and paftures. But as he has not favoured us with a botanical defcription of them, we can only form conjectures.

If the feeds of thefe two forts were carefully collected and fown feparately, without any mixture of the feed of other grafs, they would not only afford a greater quantity of fodder on the fame fpace of land, but the grafs would alfo be better, the hay fweeter, and the verdure more lafting, than that of any other fpecies. Mr. Miller recommends this particularly to every gentleman who would improve the verdure near his habitation.

The annual meadow grafs makes the fineft of turfs. It grows every where by way fides, and on rich found commons. It is called in fome parts the Suffolk grafs, as we mentioned before. Mr. Stillingfleet fays, he has feen whole fields of it in High Suffolk, without any mixture of other graffes, and as fome of the beft falt butter we have in London comes from that country, it is moft likely to be the beft grafs for the dairy. *See* ANNUAL MEADOW GRASS.

As the next beft to meadow grafs, Mr. Miller recommends Ray's *gramen avenaceum pratenfe elatius, paniculâ flavefcente, locuftis parvis*, taller meadow oat-grafs, with a yellowifh panicle, and fmall hufks, which is the *avena paniculâ laxâ, calycibus trifloris brevibus, flofculis omnibus ariftatis*, Prod. Leyd. 66. Oat-grafs with a loofe panicle, three flowers in each empalement, which is fhort, and all the flowers having awns. Mr. Ray likewife recommends the fmooth mountain oat-grafs, which he calls *gramen avenaceum montanum fpicâ fimplici, ariftis recurvis*, found by Mr. Dale, upon Bartlow hills in Effex, on the edge of Cambridgefhire, in the borders of the corn fields between Newmarket and Exning, and on the chalk hills between Northfleet and Gravefend: and the rough or hairy oat-grafs, which he diftinguifhes by the appellation of *gramen avenaceum hirfutum, paniculâ purpuro-argentiâ fplendente*, and which abounds in the paftures about the earl of Cardigan's houfe at Twittenham, in Middlefex. He alfo includes under this genus, all the feftuca kinds, of which Mr. Stillingfleet gives the following account, in his Obfervation on Graffes, fubjoined to his tranflations of feveral ingenious tracts, felected from the Tranfactions of the Academy of Upfal.

Sheeps fefcue, which he diftinguifhes by the name of *feftuca ovina*, is the grafs moft efteemed for the food of fheep in Sweden, where they have not fuch downs as we have.

Gmelin fays, that the Tartars choofe to fix, during the fummer, in thofe places where there is the greateft plenty of this grafs, becaufe it affords a moft wholfome nourifhment to all kinds of cattle, but chiefly fheep: and he obferves, that the fepulchral monuments of the ancient Tartars are moftly found in places which abound with this grafs, which fhows, adds he, that it has long been valued among them.

This grafs abounds in many parts of England and Wales, and particularly on all the fineft fheep paftures in Herefordfhire, Oxfordfhire, Norfolk, &c. Mr. Stillingfleet obferves, that it is a very early grafs, and that, contrary to what Linnæus fays, either fheep, or fome other animals do eat the flowering ftems of this grafs; for, when he fearched for it upon Banftead downs, he could fee no part of it but the radical leaves, except among bufhes near the hedges, where it was guarded from the fheep.

Mr. Stillingfleet fays, that he has always feen the purple fefcue along with the fine bent and filver hair grafs, which will be fpoken of hereafter, particularly on Banftead downs, in great plenty, in a place inclofed in order to keep the fheep out. From thence he is inclined to think, that this is the chief grafs all over the downs; but as the flowering ftems in the other parts were intirely gone at the time of his viewing it, except along the hedges, he could not be certain in this refpect.

After candidly declaring his want of knowledge of the qualities of the flote fefcue, which he calls *feftuca fluitans*, Mr. Stillingfleet quotes a curious paffage in the Tranfactions of the Academy of Upfal, where the author of a piece entitled *Plantæ Efculentæ* fays, that the feeds of this grafs are gathered yearly in Polland, and from thence carried into Germany, and fometimes into Sweden, and fold under the name of manna feeds, and that they are there much ufed at the tables of the great, on account of their nourifhing quality and agreeable tafte. Mr. Stillingfleet then adds, that one Mr. Dean, a very fenfible farmer at Rufcomb, in Berkfhire, affured him, "that a field of about four acres, which always lay under water, and was occupied by his father when he was a boy, was covered with a kind of grafs that maintained five farm horfes in good heart, from April to the end of harveft, without giving them any other kind of food, and that it yielded more than they could eat." Some of it was carried to Mr. Stillingfleet, who found it to be the flote fefcue, with a mixture of the marfh bent: but whether this laft contributes much towards furnifhing fo good pafture for horfes, feems doubtful to him. They both throw out roots at the joints of the ftalks, and are therefore likely to grow to a great length.

Linnæus fays, that the bran of this grafs will cure horfes troubled with bots, if they are kept from drinking for fome hours.

In the index of dubious plants, at the end of Ray's Synopfis, mention is made of a grafs called *gramen caninum fupinum longiffimum*, longeft fupine dog's grafs, which grows at Maddington in Wiltfhire, and in fome parts of Wales, to the length of twenty-four feet, and is ufed for the fattening of hogs. Its ftalks are of the creeping kind, and touch the ground at feveral of their knots; for they do not rife much in height. Mr. Stillingfleet thinks it the flote fefcue, and rightly advifes farther inquiries concerning it. But he does not feem here to have confulted Mr. Worlidge, who fays, fpeaking of this grafs, that it is extraordinarily fweet, but not fo eafily propagated as hath been imagined, the length thereof being occafioned by the wafhing of a declining fheep down, from whence hafty rains bring with them much of the fatnefs of the dung of the fheep, which fubfides upon the fmall meadows where this grafs grows: fo that in fprings not fubject to thefe fhowers, or on lands not enriched by that fertilifing foil brought down to them, this grafs does not thrive fo well.

The vernal grafs, which Mr. Stillingfleet calls *anthoxanthum odoratum*, and which is at leaft a fpecies of Ray's *gramen vernum fpicâ brevi laxâ*, and of C. Bauhin's *gramen vernum pratenfe fpicâ flavefcente*, vernal grafs, with a loofe yellowifh fpike, is one of the earlieft graffes, and grows very commonly in all our meadows, paftures, and other grounds. It is found in plenty upon thofe paftures which fheep are fond of, and from whence excellent mutton comes; and therefore it is moft likely to be a good grafs for fheep paftures. Mr. Stillingfleet fays, he has found it on all kinds of grounds, from the moft fandy and dry to the moft ftiff and moift, and even in bogs. It is very plentiful in the beft meadows about London, viz. towards Hampftead, and Hendon; and its feeds may be gathered very eafily, as it fheds them upon the leaft rubbing. This grafs gives a grateful odour to hay.

Mr. Lifle remarks, that the *gramen parvum repens purpureâ fpicâ*, fmall creeping grafs, with a purple fpike, is no indication of bad ground, though it be a very bad grafs. Ray fays, that it is very common in paftures. There feems to be a great fweetnefs in it. The fame may be faid of the *gramen criftatum*, or fmooth crefted grafs, which alfo abounds every where in our meadows and paftures.

The meadow fox-tail grafs *(gramen alopecuroides)* abounds in our beft meadows about London, and makes very good hay; perhaps the beft of any that is brought to market here. Mr. Stillingfleet obferved in the fpring of the year 1762, a meadow near Hampftead, which confifted of this grafs chiefly, with fome of the vernal grafs and the corn-brome grafs: but it is fcarce in many parts of England, particularly in Herefordfhire, Berkfhire, and Norfolk; though it might be gathered at almoft any time of the year, even from hay-ricks, as it does not fhed its feeds without rubbing, which is the cafe of but few graffes.

The water fox-tail *(alopecuroides paludofum)* is alfo found in fuch meadows about London as are found and lie under water in the winter. Mr. Stillingfleet thinks it may, perhaps, be a proper grafs to fow on fuch grounds.

Mr. Stillingfleet has always found the fine bent-grafs, which he names *agroftis capillaris*, in great plenty on the beft fheep paftures, as on Malvern-hills, Bagfhot-heath, and all the high grounds in Herefordfhire, Berkfhire, Oxfordfhire, and Norfolk, and other places remarkable for good mutton.

The fame may be faid of the mountain hair-grafs, which he calls *aira flexuofa*; and of the filver hair-grafs, which is his *aira caryophillea*.

The quaking-grafs, cow-quake, or lady's-hair, as it is called in fome places, is the *gramen tremulum maximum*, of C. Bauhin, and J. Ray, and the *briza fpiculis cordatis, flofculis feptendecim*, Hort. Cliff. 23. Briza with heart-fhaped little fpikes, and feventeen flowers in each. Though a very poor and flender grafs, Mr. Lifle thinks it no indication of poor land where it grows: for, as Mr. Ray obferves, it is the moft common grafs of any in all the pafture grounds throughout England.

Mr. Miller defcribes it as having an annual root, which fends up many broad hairy leaves, between which arife flender ftiff ftalks, from a foot to near two feet high, dividing upward into a large loofe panicle, garnifhed with heart-fhaped fmall fpikes, each having about feventeen fmall flofcules, or florets; and thefe, after the flowers are paft, are fucceeded by a fingle feed. The heads hang by flender long foot-ftalks, which are moved by every wind, fo that they generally appear fhaking; from whence it had the name of quaking-grafs. There is a fmaller fpecies of it, which is a native of England; but, I believe, of no greater value than the former. Thefe graffes come to head in May: and this gave rife to the Englifh proverb, May, come fhe early come fhe late, makes the cow quake.

Matweed *(gramen fparteum)* is of the broom kind, and delights in fandy places, near the fea. Even clouds of fand blown over it do not hurt, but, on the contrary, promote its growth. It has been of excellent fervice in fixing loofe fands, as, if I have been rightly informed, it once did very remarkably in Norfolk. Of ten fpecies of this plant, which Mr. Ray diftinguifhes, the following are the chief. 1. *Spartum Plinii, five juncus Hifpanicus*, the true matweed of Pliny, or Spanifh broom; 2. *Gramen fparteum paniculâ brevi folliculo inclusâ*, hooded matweed; 3. *Gramen fparteum marinum Anglicanum*, Englifh fea matweed, or marram; 4. *Spartum maximum maritimum Hollandicum, fpicâ fecalinâ*, the greateft Holland matweed, with a rye fpike; 5. *Gramen fparteum pennatum*, Feather-grafs; and 6. the *Gramen fparteum juncifolium*, or *fpartum parvum*, fmall matweed.

Mr. Stillingfleet fays, that the beft mutton he ever tafted, next to that which comes from hills, where the purple and fheep's fefcue, the fine bent, and the filver hair graffes abound, was fed upon the crefted dog-tail grafs, which he and Mr. Hudfon call *cynofurus criftatus*. He therefore rightly judges it proper for parks; and confirms this opinion, by adding, that he knows a park where this grafs abounds, which is famous for excellent venifon. It makes a very fine turf upon dry, fandy, or chalky foils: but unlefs it be fwept over with the fcythe, its flowering ftems will look brown; as is the cafe of all graffes which are not fed by a variety of animals: for that fome animals will eat the flowering ftems, is evident from commons, where one fcarcely fees any part of the graffes, except the radical leaves.

Mr. Miller thinks the cock's-foot grafs (Ray's *Gramen dactylon*, Hift. p. 1271) the capon's-tail grafs (Ray's *Gramen murorum fpicâ longiffimâ*, Hift. p. 1286) and the millet graffes *(Gramina miliacea)* too coarfe to deferve attention in England; though fome of their fpecies are very ufeful in the warm parts of America, where there is a great fcarcity of finer grafs, and even much better adapted for fuch climates, than any of our European graffes; becaufe many of them lie flat on the ground, and emit roots from their joints, by which means they are well prepared for heat; of which their large and juicy ftalks likewife enable them to bear an extraordinary degree.

The purple, or, as it is commonly called, red meadow trefoil, which is C. Bauhin's *Trifolium pratenfi purpureum*, has already been fufficiently diftinguifhed from the common red clover, or red honeyfuckle (Ray's *Trifolium purpureum majus, pratenfi fimile, Syn.* 328) which though Mr. Lifle thinks otherwife, is undoubtedly a native of England, as is manifeft from its fpontaneous and flourifhing growth on the top of many mountains, particularly in even the moft northern parts of Scotland, where no mortal furely ever dreamt of cultivating it. The fpecies called yellow meadow trefoil, or hop-clover, is C. Bauhin's *Trifolium pratenfe luteum, capitulo lupuli, vel agrarium*; and the fmaller kind of this, commonly called nonefuch, or black feed, is the *Trifolium luteum, lupulinum, minimum*. M. Duhamel rightly prefers the firft of thefe forts for artificial paftures, and obferves, that it is the only fpecies now cultivated in France, for that purpofe.

Our meadows afford us the white meadow trefoil, honeyfuckle-grafs, or white Dutch clover, which is the *trifolium pratenfe album* of C. Bauhin, and by far the beft fort of clover for lafting paftures, becaufe it is the fweeteft and moft abiding of all the plants of this kind.

This white clover, befides being perennial, fends forth roots and fhoots from every joint of its trailing branches, for it does not rife high, and thereby forms the clofeft fward of any of the artificial graffes. It is exceeding fweet food for all forts of cattle: for which reafon a quantity of the feeds of this plant fhould always be fown with the other grafs-feeds, on whatever land is intended to be laid down for pafture. The ufual allowance of this feed is eight pounds to an acre. But it never fhould be fown with corn; becaufe this will weaken it, fo that it will be fcarcely worth ftanding. And yet, as Mr. Miller obferves, fuch is the covetoufnefs of moft farmers, that they will not be prevailed on to alter their old cuftom of laying down their ground with a crop of corn; though they lofe twice the value of that corn, by the poornefs of the grafs, which will not then come to a good fward: and one whole feafon is alfo loft: for if this feed is fown in the fpring, without corn, there will be a crop of hay to mow by the middle, or latter end of July, and a much better after-feed for cattle the following autumn and winter, than the grafs which is fown with corn will produce the fecond year. It may alfo be fown with grafs-feed in autumn, in the manner before directed for the common red clover; and if the feeds grow kindly, this autumnal fowing will afford a good early crop of hay the following fpring. If the ground is well rolled after this crop is taken off, the clover will mat clofe upon it, and form a thick fward.

Confiderable quantities of the feeds of this white clover are imported hither annually from Flanders, by the way of Holland; from whence it has received the name of Dutch clover: not that it is more a native of that country, than of this; for it is very common in the paftures all over England; but the feeds of it were never collected here, for fowing, till of late years; nor are there yet many perfons in this kingdom who fave them, though they may be faved with the fame eafe, and in the fame manner, as is practifed for the red clover. Every farmer who would improve his land, fhould therefore fow an acre or two with this white clover, unmixed, merely for the fake of its feeds, which are often fold at a great price. He will by this means fave the expence of buying them; and he will eafily find purchafers for any quantity he may have to fpare.

I do not know that the narrow leaved plantain, or ribwort *(Plantago anguftifolia)* hath ever been cultivated purpofely

purpofely for the food of cattle. It grows, indeed, in almoft all paftures: but, as it will thrive upon dry very fpots, becaufe it ftrikes a deep root, it may probably deferve farther trial.

The late Dr. Eliot, recommends two forts of graffes, natives of North America, of which he lately fent over a parcel of the feeds to the London Society for the Encouragement of Arts, &c. by whom they have been diftributed here, fo that we may hope foon to know their fuccefs in this country, and of which he has given an account in his Effays upon Field-Hufbandry in New England. *See the articles* BIRD-GRASS, *and* TIMOTHY-GRASS.

GRASS-*Walks*. As to grafs-plats and green walks, they are made, for the moft part, not by fowing grafs-feed, but by laying turfs: and indeed the turfs from a fine common or down, are much preferable to fown grafs: but if walks or plats are to be made by fowing, the beft way is to procure the feed from thofe paftures where the grafs is naturally fine and clear, or elfe the trouble of keeping it from fpiry or benty grafs will be very great, and it will fcarce ever look handfome.

In order to fow grafs-walks, the ground muft be firft dug; and when it has been firft dreffed and laid even, it muft be very carefully raked over, and all the clods and ftones taken off, and then covered over an inch thick with good mould. This being done, the feed is to be fown pretty thick, that it may come up clofe and fhort; it muft then be raked over again, to cover the feed, that if the weather fhould happen to be windy, it may not be blown away. It ought alfo to be obferved, that where grafs is fown in gardens, either for lawns or walks, there fhould always be a good quantity of the white trefoil or Dutch clover fown with it; for this will make a fine turf much fooner than any other fown grafs, and will continue a better verdure than any other of the grafs-tribe.

In order to keep grafs-plats or walks handfome, and in good order, you may fow in autumn frefh feed over any places that are not well filled, or where the grafs is dead; but nothing improves grafs fo much, as mowing and conftant rolling.

When turf is laid in gardens, it is a general practice to cover the furface of the ground, under the turf, either with fand or very poor earth; the defign of this is, to keep the grafs fine, by preventing its growing too rank. This is proper enough for very rich ground, but it is not fo for land that is poor; for when this is practifed in fuch places, the grafs will foon wear out, and decay in patches.

GRASS-*Leafe*, grafs-lands, or lands appropriated to grafs, for feeding of cattle.

GRATTEN, a term ufed in Cornwal, to imply the mowing of grafs, the firft year after the land has been manured with fea-fand; and this operation they call mowing in gratten.

GRAVEL, a congeries of fmall pebbles, which, being mixed with a ftiff loam, makes lafting and elegant walks in our gardens.

Opinions, with regard to the choice of gravel, are various; fome are for having it as white as poffible, and in order to render it the more fo, caufe the walks to be often rolled with ftone-rollers, which add a whitenefs to the furface. But this renders them very troublefome to the eyes, by reflecting too ftrongly the rays of light: fuch gravel, therefore, as will lie fmooth, and reflect the leaft, fhould be preferred. Again, fome fcreen the gravel too fine, but this is an error; for if it be caft into a round heap, and the great ftones only are raked off, it will be the better. There are many kinds of gravel which do not bind, and by this means caufe a continual trouble of rolling, to little or no purpofe; as for fuch, if the gravel be loofe or fandy, you fhould take one load of ftrong loam, and two of gravel, and fo caft them well together.

The beft and moft efteemed gravel is that of Blackheath, in Kent, which being mixed with a proper proportion of loam (found alfo on the fame common) makes the moft beautiful and lafting walks any where; nor is it confined to a few places about London, for we have known feveral tons of it exported to adorn the pope's garden at Rome, although it may be fuppofed fo much beneath his holinefs's dignity to tread upon it; but Italy cannot produce a more handfome *terra firma*.

The month of March is the propereft time for laying gravel; for it is not prudent to do it fooner, or to lay walks in any of the winter months before that time. In making thefe walks, great regard muft be had to the level of the ground, fo as to lay the walks with eafy defcents towards the low parts of the ground, that the wet may be eafily drained off: but when the ground is level, it will be proper to have fink-ftones laid by the fides of the walk, and at convenient diftance, to let off the wet; and when the ground is naturally dry, the drains from the fink-ftones may be contrived fo as to convey the water into feffpools, from which the water will foak away in a fhort time; but in wet lands there fhould be under-ground drains, to convey the water off, either into ponds, ditches, or the neareft place proper to receive it.

Some are apt to lay gravel walks too round, but this is an error; becaufe they are not fo good to walk upon; and befides, it makes them look narrow; one inch is enough in a crown of five feet; and it will be fufficient, if a walk be ten feet wide, that it lies two inches higher in the middle than it does on each fide; if fifteen feet, three inches; if twenty feet, four inches; and fo in proportion.

For the depth of gravel-walks, fix or eight inches may do well enough; and a foot in thicknefs will be fufficient for any; but then there fhould always be a depth of rubbifh laid under the gravel, efpecially if the ground be wet.

Some turn up gravel-walks into ridges, in December, in order to kill the weeds; but this is very wrong, fince it never anfwers the end; and, therefore, if conftantly rolling them after rain and froft, will not effectually kill the weeds and mofs, you fhould turn the walks in March, and lay them down at the fame time.

In order to deftroy worms that fpoil the beauty of gravel or grafs-walks, fome recommend the watering them with water made very bitter, by fteeping walnut-tree leaves in it; but if, in the firft laying of the walks, there be a good bed of lime-rubbifh laid at the bottom, it will prove the moft effectual method to keep out the worms, for they never harbour near lime.

GRAVELLY-*Land*, that which abounds with gravel and fand. *See the article* SANDY-LAND.

The beft manure for this fort of land is marl, or any ftiff clay that will diffolve with the froft, cow-dung, chalk, mud, and half rotten ftraw from the dunghill.

GREASE, a difeafe incident to horfes and other cattle, confifting of fwellings and gourdinefs of the legs.

In order to treat this diforder with fome propriety, without having recourfe to the falling down of humours for its explanation, we fhall confider it as arifing from two different caufes; a fault or relaxation in the veffels, or a bad difpofition of the blood and juices. In order to this, it will be neceffary to obferve, that the blood and juices are carried to the extreme parts by the arteries, and returned by the veins; confequently the blood muft rife perpendicularly in the latter, in order to return from the extremities to the heart. And hence fwellings in the legs of horfes may be eafily accounted for, as a partial ftagnation of the blood and juices may be naturally expected where the circulation is languid, efpecially when there is a want of due exercife, and a proper mufcular compreffion on the veffels to pufh forward the returning blood, and propel the inert, and half ftagnating fluids through their veffels. In fhort, the blood, in fuch cafes, cannot fo eafily afcend and defcend, or a greater quantity will be brought by the arteries than can be returned by the veins.

The greafe then, confidered in this light, muft be treated as a local complaint, where the parts affected are alone concerned, the blood and juices being yet untainted, and in good condition; or as a diforder where they are both complicated: but when it is an attendant on fome other diftemper, as the farcy, yellow dropfy, &c. fuch difeafes muft firft be cured before the greafe can be removed. In the former cafe, moderate exercife, proper dreffing, cleanlinefs, and external application, will anfwer the purpofe; in the latter, internals muft be called in to our affiftance, with proper evacuations.

When a horfe's heels are firft obferved to fwell in the ftable, and fubfide, or go down, on exercife, let care be taken to wafh them very clean every time he comes in, with foap-fuds, chamberlye, or vinegar and water, which, with proper

proper rubbing, will frequently prevent or remove this complaint: or let them be well bathed twice a day with old verjuice, or the following mixture, which will brace up the relaxed veſſels; and if rags dipped in the ſame are rowled on, with a proper bandage, for a few days, it is moſt likely the ſwellings will ſoon be removed by this method only, as the bandage will ſupport the veſſels till they have recovered their tone. To anſwer this end alſo, a laced ſtocking, made of ſtrong canvaſs, or coarſe cloth, neatly fitted to the part, would be found extremely ſerviceable, and might eaſily be contrived by an ingenious mechanic.

> Take rectified ſpirit of wine four ounces, diſſolve it in half an ounce of camphor, to which add wine-vinegar, or old verjuice, ſix ounces; white vitriol, diſſolved in a gill of water, one ounce; mix together, and ſhake the phial when uſed.

But if cracks or ſcratches are obſerved, which ouſe and run, let the hair be clipped away, as well to prevent a lodgment (which becomes ſtinking and offenſive by its ſtay) as to give room for waſhing out dirt or gravel, which, if ſuffered to remain there, would greatly aggravate the diſorder.

When this is the caſe, or the heels are full of hard ſcabs, it is neceſſary to begin the cure with poultices, made either of boiled turneps and lard, with a handful of linſeed powdered, or oat-meal and rye-flour, with a little common turpentine, and hogs lard, boiled up with ſtrong beer grounds, or red wine lees. The digeſtive ointment being applied to the ſores for two or three days, with either of theſe pultices over it, will, by ſoftening them, promote a diſcharge, unload the veſſels, and take down the ſwelling, when they may be dried up with the following:

> Take white vitriol and burnt alum, of each two ounces; Ægyptiacum one ounce; lime water a quart, or three pints: waſh the ſores with a ſponge dipped in this, three times a day, and apply the common white ointment, ſpread on tow; to an ounce of which may be added two drams of ſugar of lead.

Or the following waſh and ointment may be uſed for that purpoſe.

> Take half an ounce of Roman vitriol, diſſolved in a pint of water; then decant off the clear into a quart bottle, add half a pint of camphorated ſpirits of wine, the ſame quantity of vinegar, and two ounces of Ægyptiacum.

> Take honey four ounces, white or red lead, powdered, two ounces, verdigreaſe in fine powder one ounce; mix together.

Some, for this purpoſe, apply allum-curd; others a ſtrong ſolution of allum in verjuice, with honey; and many of theſe forms may eaſily be contrived. But let it be remembered, that as ſoon as the ſwelling is abated, and the moiſture leſſened, it would be very proper to keep the legs and paſterns rolled up with a firm bandage, or linen rowler, two or three fingers wide, in order to brace up the relaxed veſſels, till they have recovered their natural tone.

This method is generally very ſucceſsful, when the diſtemper is only local, and requires no internal medicines: but if the horſe be full and groſs, his legs greatly gorged, ſo that the hair ſtares up, and is what ſome term pen-feathered, and has a large ſtinking diſcharge from deep foul ſores, you may expect to meet with great trouble, as theſe diſorders are very obſtinate to remove, being often occaſioned by a poor dropſical ſtate of blood, or a general bad diſpoſition in the blood and juices.

The cure in this caſe, if the horſe is full and fleſhy, muſt be begun by bleeding, rowels, and repeated purging; after which diuretic medicines are frequently given with ſucceſs. Thus,

> Take four ounces of yellow roſin, one of ſal prunellæ; grind them together with an oiled peſtel, add a dram of oil of amber, and give a quart of forge-water every morning, faſting two hours before and after taking, and ride moderately.

As this drink is found very diſagreeable to ſome horſes, I would recommend the nitre balls in its ſtead, given to the quantity of two ounces a day, for a month or ſix weeks, mixed up with honey, or in his feeds: take the following alſo for that purpoſe.

> Yellow roſin four ounces, ſalt of tartar, and ſal prunellæ, of each two ounces; Venice ſoap half a pound; oil of juniper half an ounce; make them into balls of two ounce weight, and give one every morning.

Or,

> Take nitre two ounces; camphor one dram, honey enough to make into a ball; give as the former.

The legs in this caſe ſhould be bathed or fomented, in order to breath out the ſtagnant juices, or to thin them, ſo that they may be able to circulate freely in the common current. For this purpoſe foment twice a day with a diſcutient fomentation, in which a handful or two of wood aſhes has been boiled; apply then the above poultice, or the following, till the ſwelling has ſubſided, when the ſores may be dreſſed with the green ointment till they are properly digeſted, and then dried up with the water and ointment above recommended.

> Take honey one pound, turpentine ſix ounces, incorporate with a ſpoon; and add of the meal of fenugreek and linſeed, each four ounces; boil in three quarts of red wine lees, to the conſiſtence of a poultice; to which add, when taken from the fire, two ounces of camphor in powder; ſpread it on thick cloths, and apply warm to the legs, ſecuring it on with a ſtrong rowler.

If the ſores are very foul, dreſs them with two parts of the wound ointment, and one of Ægyptiacum; and apply the following, ſpread on thick cloths, and rowled on.

> Take of black ſoap one pound, honey half a pound, burnt allum four ounces, verdigreaſe powdered, two ounces, wheat flour a ſufficient quantity.

If the diuretic balls ſhould not ſucceed, they muſt be changed for the antimonial and mercurial alteratives, already mentioned; but turning a horſe out in a field, where he has a hovel or ſhed to run to at pleaſure, would greatly contribute to quicken the cure; and, indeed, would in general effect it alone: but if this cannot be complied with, let him be turned out in the day time.

If the horſe is not turned out, a large and convenient ſtall is abſolutely neceſſary, with good dreſſing and care: this ſtall ſhould be ſix feet wide, that a tall horſe may ſhoot out his legs at length, ſo that the blood may circulate freely, without meeting with reſiſtance, which it naturally muſt, when a horſe lies all on a heap, or with his legs under him: nor ſhould the ſtable be paved with too great a declivity; for if the horſe ſtands too low with his hind legs, moſt of his weight will reſt upon them; and give him the greaſe, eſpecially if he be at all inclined to be gourdy.

The laſt thing we ſhall recommend, is to make him lie down in the ſtable as often as poſſible. This is undoubtedly of the utmoſt conſequence, as it will not a little contribute to the removal and cure of this diſorder; for by only changing the poſition of his legs, a freer circulation would be obtained, and the ſwelling taken down: whereas it is in general greatly aggravated by the obſtinacy of the horſe, which refuſes to lie down at all, probably from the pain it gives him in bending his legs neceſſary for that purpoſe; by which means the ſtiffneſs and ſwelling increaſes, till the over-gorged and diſtended veſſels are obliged to give way, and, by burſting, diſcharge the fluids that ſhould circulate through them. *Bartlet's Farriery, page* 284.

GREASE melted. *See the article* MOLTEN-GREASE.

GREEN-HOUSE, a conſervatory, or houſe erected in a garden, for preſerving ſuch tender and exotic plants as cannot bear the cold of our winters, if expoſed to the open air.

The following deſcription of a green-houſe is taken from Mr. Miller's Gardener's Dictionary, as the conſervatory

vatory given by that ingenious gardener is very well adapted to this climate.

The length of theſe houſes muſt be proportioned to the number of plants they are intended to contain; but their depth ſhould never be greater than their height in the clear, which, in ſmall or middling houſes, may be ſixteen or eighteen feet, and in large ones from twenty to twenty-four. The windows in front ſhould extend from about one foot and a half above the pavement, to within the ſame diſtance of the ceiling, which will admit of a corniche round the building, over the heads of the windows. In a ſmall green-houſe, the ſaſhes ſhould not be leſs than four or five feet broad; and in a large one, they ought not to exceed ſeven and a half; the ſhutters of which ought to fall back cloſe to the piers on the inſide, that, when open, they may not prevent any of the rays of light from reaching the plants. The piers between theſe windows, ſupporting the building, ſhould be as narrow as poſſible; for which reaſon they ſhould be either of ſtone or well-burnt brick. If they are of ſtone, they ought not to exceed two feet and a half in front, and ſhould be ſloped off backward to about eighteen inches broad, by which means the rays of the ſun will not be obſtructed by the corners of the piers, as they would be if they were ſquare: but if they are built of brick, it will be proper to make them near three feet in front, otherwiſe they will be too weak to ſupport the building: theſe I would alſo adviſe to be ſloped off in the manner directed for the ſtone.

At the back of the green-houſe, there may be erected an houſe for tools, and many other purpoſes; which will be extremely uſeful, and alſo prevent froſt from entering the houſe that way; ſo that the wall between theſe need not be more than two bricks and an half in thickneſs; whereas, were it quite expoſed behind, it ſhould be at leaſt three bricks in thickneſs; and by this contrivance, if you are willing to make an handſome building, and to have a noble room over the green-houſe, you may make the room over the tool-houſe, and carry up the ſtair-caſe in the back, ſo as not to be ſeen in the green-houſe; and hereby you may have a room twenty-five or thirty feet in width, and of a proportionable length: and under this ſtair-caſe, there ſhould be a private door into the green-houſe, at which the gardener may enter in hard froſty weather, when it will not be ſafe to open any of the glaſſes in the front. The floor of the green-houſe, which ſhould be laid either with marble ſtone, or broad tiles, according to the fancy of the owner, muſt be raiſed two feet above the ſurface of the ground whereon the houſe is placed, which, in dry ground, will be ſufficient: but if the ſituation be moiſt and ſpongy, and thereby ſubject to damps, it ſhould be raiſed at leaſt three feet above the ſurface: and if the whole is arched with low brick arches under the floor, it will be of great ſervice in preventing the damps riſing in winter, which are often very hurtful to the plants, eſpecially in great thaws, when the air is often too cold to be admitted into the houſe, to take off the damps. Under the floor, about two feet from the front, I would adviſe a flue of about ten inches in width, and two feet deep, to be carried the whole length of the houſe, which may be returned along the back part, and be carried up in proper funnels adjoining to the tool-houſe, by which the ſmoak may paſs off. The fire-place may be contrived at one end of the houſe, and the door at which the fuel is put in, as alſo the aſh-grate, may be contrived to open into the tool-houſe, ſo that it may be quite hid from the ſight, and be in the dry, and the fuel be laid in the ſame place, whereby it will always be ready for uſe.

I ſuppoſe many people will be ſurpriſed to ſee me direct the making flues under a green-houſe, which has been diſuſed ſo long, and by moſt people thought of ill conſequence, as indeed they have often proved, when under the direction of unſkilful managers, who have thought it neceſſary, whenever the weather was cold, to make fires therein. But however injurious flues have been under ſuch management, yet, when ſkilfully managed, they are of very great ſervice: for though perhaps it may happen that there will be no neceſſity to make any fires in them for two or three years together, as, when the winters prove mild, there will not; yet, in very hard winters, they will be extremely uſeful to keep out the froſt, which cannot be effected any other way, but with great trouble and difficulty.

Withinſide of the windows, in front of the green-houſe, you ſhould have good ſtrong ſhutters, which ſhould be made with hinges, to fold back, that they may fall back quite cloſe to the piers, that the rays of the ſun may not be obſtructed thereby. Theſe ſhutters need not to be above an inch and a half thick, or little more; which, if made to join cloſe, will be ſufficient to keep out our common froſt: and when the weather is ſo cold as to endanger the freezing in the houſe, it is but making a fire in your flue, which will effectually prevent it: and without this conveniency it will be very troubleſome, as I have often ſeen, where perſons have been obliged to nail mats before their windows, or to ſtuff the hollow ſpace between the ſhutters and the glaſs with ſtraw, which, when done, is commonly ſuffered to remain till the froſt goes away; which, if it ſhould continue very long, the keeping the green-houſe cloſely ſhut up, will prove very injurious to the plants: and as it frequently happens, that we have an hour or two of ſun-ſhine in the middle of the day, in continued froſts, which is of great ſervice to plants, when they can enjoy the rays thereof through the glaſſes; ſo when there is nothing more to do than to open the ſhutters, which may be performed in a very ſhort time, and as ſoon ſhut again when the ſun is clouded, the plants may have the benefit thereof whenever it appears; whereas, where there is ſo much trouble to uncover, and as much to cover again, it would take up the whole time in uncovering and ſhutting them up, and thereby the advantage of the ſun's influence be loſt. Beſides, where there is ſo much trouble required to keep out the froſt, it will be a great chance if it be not neglected by the gardener: for if he be not as fond of preſerving his plants, and as much in love with them as his maſter, this labour will be thought too great by him; and if he takes the pains to cover the glaſſes up with mats, &c. he will not care to take them away again, until the weather alters; ſo that the plants will be ſhut up cloſe during the whole continuance of the froſt.

There are ſome people who commonly make uſe of pots filled with charcoal to ſet in their green-houſe in very ſevere froſts; but this is very dangerous to the perſons who attend theſe fires; and I have often known they have been almoſt ſuffocated therewith; and at the ſame time they are very injurious to the plants: nor is the trouble of tending upon theſe ſmall; and the many hazards, to which the uſe of theſe fires is liable, have juſtly brought them into diſuſe with all ſkilful perſons; and as the contrivance of flues, and of the fires, are but ſmall charges, they are much to be preferred to any other method for warming the air of the houſe.

The back part of the houſe ſhould be either laid over with ſtucco, or plaiſtered with mortar, and white waſhed; for otherwiſe the air in ſevere froſt will penetrate through the walls, eſpecially when the froſt is attended with a ſtrong wind; which is often the caſe in the moſt ſevere winters. There are ſome perſons who are at the expence of wainſcoting their green-houſes; but, when this is done, it is proper to plaſter with lime and hair behind the wainſcot, to keep out the cold; and, when they are lined with wainſcot, they ſhould be painted white, as ſhould the ceiling, and every part within-ſide of the houſe: for this reflects the rays of light in much greater quantity than any other colour, and is of ſignal ſervice to plants, eſpecially in the winter, when the houſe is pretty much cloſed, and but a ſmall ſhare of light is admitted through the windows: for, at ſuch times, I have obſerved, that in ſome green-houſes which have been painted black, or of a dark colour, the plants have caſt moſt of their leaves.

Where green-houſes are built in ſuch places as will not admit of rooms over them, or the perſon is unwilling to be at the expence of ſuch building, there muſt be care taken to keep out the froſt from entering through the roof. To prevent which, it will be very proper to have a thickneſs of reeds, heath, or furze, laid between the ceiling and the tiles: in the doing of which, there muſt be care taken in framing the joiſts, ſo as to ſupport theſe, that their weight may not lie upon the ceiling, which might endanger it: for theſe ſhould be laid a foot thick at leaſt, and as ſmooth as poſſible, and faſtened down well with laths, to prevent their riſing; and then cover it over with a coat of lime and hair, which will keep out the air, and alſo prevent mice and other vermin, from harbouring in them; which, if left uncovered, they would certainly do. For want of this precaution, there are many green-houſes built, which will not keep out the froſt in hard winters; and this is many times attributed to the glaſſes in front admitting the cold, when the fault is in the roof: for where there is only the covering, either of tiles or ſlates, and the ceiling, every ſevere froſt will penetrate through them.

In this green-houſe you ſhould have treſſels, which may be moved out and into the houſe; upon which you ſhould fix rows of planks, ſo as to place the pots or tubs of plants in regular rows one above another, whereby the heads of the plants will be ſo ſituated as not to interfere with each other. The loweſt row of plants, which ſhould be the forwardeſt towards the windows, ſhould be placed about four feet therefrom, that there may be a convenient breadth left next the glaſſes to walk in front: and the rows of plants ſhould riſe gradually from the firſt, in ſuch a manner, that the heads of the ſecond rows ſhould be entirely advanced above the firſt, the ſtems only being hid thereby; and, at the backſide of the houſe, there ſhould be allowed a ſpace of at leaſt five feet, for the conveniency of watering the plants; as alſo to admit of a current of air round them, that the damps, occaſioned by the perſpiration of the plants, may be the better diſſipated, which, by being pent in too cloſely, often occaſions a mouldineſs upon the tender ſhoots and leaves; and when the houſe is cloſe ſhut up, this ſtagnating rancid vapour is often very deſtructive to the plants: for which reaſon alſo you ſhould never croud them too cloſe to each other, nor ſhould you ever place ſedums, euphorbiums, torch thiſtles, and other tender ſucculent plants, amongſt oranges, myrtles, and other ever-green-trees; for, by an experiment which I made anno 1729, I found that a ſedum, placed in a green-houſe among ſuch trees, almoſt daily increaſed its weight, although there was no water given to it the whole time; which increaſe of weight was owing to the moiſture imbibed from the air, which, being replete with the rancid vapours perſpired from the other plants, occaſioned the leaves to grow pale, and in a ſhort time they decayed, and dropped off; which I have often obſerved has been the caſe with many other ſucculent plants, when placed in thoſe houſes which were filled with many ſorts of ever-green-trees, that required to be frequently watered.

Therefore, to avoid the inconvenience which attends the placing of plants of very different natures in the ſame houſe, it will be very proper to have two wings added to the main green-houſe; which will greatly add to the beauty of the building, and alſo collect a greater ſhare of heat. The green-houſe ſhould be placed exactly fronting the ſouth; and one of the wings faces the ſouth-eaſt, and the other the ſouth-weſt; ſo that, from the time of the ſun's firſt appearance upon any part of the building, until it goes off at night, it is conſtantly reflected from one part to the other; and the cold winds are alſo kept off from the front of the main green-houſe hereby: and, in the area of this place, you may contrive to place many of the moſt tender exotic plants, which will bear to be expoſed in the ſummer ſeaſon: and in the ſpring, before the weather will permit you to ſet out the plants, the beds and borders of this area may be full of anemonies, ranunculus's, early tulips, &c. which will be paſt flowering, and the roots fit to take out of the ground, by the time you carry out the plants; which will render this place very agreeable during the ſpring ſeaſon that the flowers are blown; and here you may walk and divert yourſelf in a fine day, when, perhaps, the air in moſt other parts of the garden will be too cold for perſons not much uſed thereto, to take pleaſure in being out of the houſe.

In the center of this area may be contrived a ſmall baſon for water, which will be very convenient for watering of plants, and add much to the beauty of the place: beſides, the water, being thus ſituated, will be ſoftened by the heat, which will be reflected from the glaſſes upon it; whereby it will be rendered much better than raw, cold water, for theſe tender plants.

The two wings of the building ſhould be contrived ſo as to maintain plants of different degrees of hardneſs; which muſt be effected by the ſituation and the extent of the fire-place, and the manner of conducting the flues.

But I would here obſerve, that the wing facing the ſouth-eaſt ſhould always be preferred for the warmeſt ſtove; its ſituation being ſuch, as that the ſun, upon its firſt appearance in the morning, ſhines directly upon the glaſſes; which is of great ſervice in warming the air of the houſe, and adding life to the plants, after having been ſhut up during the long nights in the winter ſeaſon. Theſe wings, being ſixty feet in length, may be divided in the middle by partitions of glaſs, with glaſs doors to paſs from one to the other. To each of theſe there ſhould be a fire-place, with flues carried up againſt the back wall, through which the ſmoke ſhould be made to paſs, as many times the length of the houſe, as the height will admit of the number of flues; for the longer the ſmoke is in paſſing, the more heat will be given to the houſe, with a leſs quantity of fuel; which is an article worth conſideration, eſpecially where fuel is dear. By this contrivance, you may keep ſuch plants as require the ſame degree of heat in one part of the houſe, and theſe will thrive in a much leſs warmth in the other part.

The other wing of the houſe, facing the ſouth-weſt, may alſo be divided in the ſame manner, and flues carried through both parts, which may be uſed according to the ſeaſons, or the particular ſorts of plants which are placed therein; ſo that here will be four diviſions in the wings, each of which may be kept up to a different degree of warmth: which, together with the green-houſe, will be ſufficient to maintain plants from all the ſeveral countries of the world; and, without having theſe ſeveral degrees of warmth, it will be impoſſible to preſerve the various kinds of plants from the ſeveral parts of Africa and America, which are annually introduced into the Engliſh gardens; for when plants from very different countries are placed in the ſame houſe, ſome are deſtroyed for want of heat, while others are forced and ſpoiled by too much of it; and this is often the caſe in many places, where there are large collections of plants.

In the building theſe wings, if there are not ſheds running behind them their whole length, the walls ſhould not be leſs than two bricks thick; and if they are more, it will be better; becauſe, where the walls are thin, and expoſed to the open air, the cold will penetrate them; and when the fires are made, the heat will come out through the walls; ſo that it will require a larger quantity of fuel to maintain a proper temperature of warmth in the houſe. The back part of theſe houſes, having ſloping roofs, which are covered either with tiles or ſlates, ſhould alſo be lined with reeds, &c. under the covering, as is before directed for the green-houſe; which will keep out the cold air, and ſave a great expence of fuel; for the cloſer and better theſe houſes are built, and the glaſſes of the ſlope, as alſo in front, well guarded by ſhutters or reeds in a hard froſt, the leſs fuel will be required to warm the houſes; ſo that the firſt expence of building theſe houſes properly will be the cheapeſt, when the after expence of fires is taken into conſideration.

The ſloping glaſſes of theſe houſes ſhould be made to ſlide, and take off; ſo that they may be drawn down more or leſs, in warm weather, to admit air to the plants; and the upright glaſſes in front may be ſo contrived, as that every other may open as doors upon hinges; and the alternate glaſſes may be divided into two: the upper part of each ſhould be contrived ſo as to be drawn down like ſaſhes; ſo that either of theſe may be uſed to admit air, in a greater or leſs quantity, according as there may be occaſion.

But, beſides the conſervatories here mentioned, it will be proper to have a deep hot-bed frame, ſuch as is commonly uſed to raiſe large annuals in the ſpring: into which may be ſet pots of ſuch plants as come from Carolina, Virginia, &c. while the plants are too ſmall to plant in the open air; as alſo may other ſorts from Spain, &c. which require only to be ſcreened from the violence of of the frosts, and should have as much free air as possible in mild weather: which can be no better effected than in one of these frames, where the glasses may be taken off every day when the weather will permit, and put on every night; and in hard frosts, the glass may be covered with mats, straw, pease-haulm, or the like, so as to prevent the frost from entering the pots to freeze the roots of the plants, which is what will, many times, utterly destroy them; though a slight frost pinching the leaves or shoots very seldom does them much harm: if these are sunk a foot or more below the surface of the ground, they will be the better, provided the ground is dry; otherwise they must be wholly above ground: the sides of this frame should be built with brick, with a curb of wood laid round on the top of the wall, into which the gutters, on which the glasses slide, may be laid: the back wall of this frame may be four feet high, and the front one foot and an half; the width about six feet, and the length in proportion to the number of plants. *Miller's Gard. Dict.*

GREEN-SCOURING, a disease to which sheep and bullocks are often subject.

The best remedy for this disorder is verjuice; a wine glass full is enough for a sheep, and a pint for a bullock. *Lisle's Husbandry, vol. II. page* 211.

GRIP, or *Gripe*, a small ditch cut across a meadow or ploughed-field, in order to drain it. It is otherwise called a water-furrow.

GRIPES, a very acute disease to which horses are very often subject.

There seems to be no distemper so little understood by the common farrier, as the gripes or cholic in horses, one general remedy, or method, serving them in all cases; but as this disorder may be produced by very different causes, the method of cure must also vary, otherwise the intended remedy, injudiciously applied, will not only aggravate the complaint, but make it fatal. We shall divide this disorder into three different species: the flatulent or windy, the bilious or inflammatory, and the dry gripes; each of which we shall distinguish by their different symptoms, and then point out the proper remedies.

The flatulent, or windy cholic is thus known. The horse is often lying down, and as suddenly rising again with a spring; he strikes his belly with his hinder-feet, stamps with his fore-feet, and refuses his meat; when the gripes are violent, he will have convulsive twitches, his eyes be turned up, and his limbs stretched out as if dying, his ears and feet being alternately very hot and cold; he falls into profuse sweats, and then into cold damps; strives often to stale, and turns his head frequently to his flanks; he then falls down, rolls about, and often turns on his back; this last symptom proceeds from a stoppage of urine, that almost always attends this sort of cholic, which may be increased by a load of dung pressing on the neck of the bladder.

These are the general symptoms of cholic and gripes from wind, drinking cold water when hot, and when the perspirable matter is retained, or thrown on the bowels by catching cold; in all which cases they are violently distended. Cribbing horses are more particularly subject to this complaint, by reason they are constantly sucking in great quantities of air.

The first intention is to empty the strait gut with a small hand dipt in oil, which frequently makes way for the confined wind to discharge itself; and by easing the neck of the bladder, the suppression of urine is taken off, and the horse stales and gets ease.

Farriers generally strike a fleam into the bars of a horse's mouth, which seems to be of little or no use; for where a quantity of blood is intended to be taken away, the vessels of this part are neither large or numerous enough to furnish it; so that it is more eligible to take it from the neck-vein, and is always proper in full, sanguine, plethoric, young horses.

The following ball and clyster seldom fail of giving relief in these cases:

> Take Strasburgh or Venice turpentine, and juniper-berries pounded, of each half an ounce; salt-prunella, or salt-petre, an ounce; oil of juniper, one dram; salt of tartar, two drams: make into a ball, with any syrup; it may be given whole, and washed down with a decoction of juniper-berries, or a horn or two of ale.

If the horse does not break wind, or stale plentifully, he will find no relief; therefore in an hour or two give him another ball, and add to it a dram of salt of amber; which may be repeated a third time, if found necessary. During the fit the horse may be walked and trotted gently, but should by no means be harrassed beyond his ability, or dragged about till he is jaded.

The following clyster may be given, between the balls, or alone, and repeated occasionally:

> Take chamomile flowers two handfuls; anise, coriander, and fennel seeds, of each an ounce; long pepper half an ounce: boil in three quarts of water to two; and add Daffy's elixir, or gin, half a pint; oil of amber half an ounce, and oil of chamomile eight ounces.

The subsequent balls and drink are also very proper for this purpose, and to remove gripes occasioned by drinking cold water when hot, or catching cold after violent exercise:

> Take powder of anise, cumin, and fennel seeds, of each half an ounce; camphor two drams; pellitory of Spain, one dram; oil of juniper fifty drops, make into a ball with any syrup, and wash it down with a horn or two of ale.

Or,

> Take mithridate, or Venice treacle, two ounces; Matthew's pill two drams; camphor one dram, dissolved in a little spirit of wine; powder of fresh anniseed one ounce; or the same quantity of the cordial ball; dissolve in a pint and half of ale.

Or,

> Take philonium one ounce, or an ounce and an half; tincture of senna, or Daffy's elixir, and sallad oil, of each half a pint: give warm for a drink, and repeat it if necessary.

Either of these medicines are well calculated for this purpose; but as the ingredients may not always be ready at hand, or procureable, we shall put down a couple of drinks that have frequently, on trial, been found successful, and are easily prepared. It is to be observed, that the horse should be well rubbed, clothed, and littered with clean straw up to his belly.

> Take of Castile soap, or hard soap; nitre, or salt-petre, of each one ounce; juniper-berries and ginger, each half an ounce: Venice turpentine, or rosin, dissolved with the yolk of an egg, six drams: mix with a pint and a half of warm ale, or a decoction of juniper-berries, with a large onion boiled with them. This may be repeated twice or thrice.

Or,

> Take a pint of brandy, rum, or geneva, with as much sweet oil, and give for a drink. Should this not succeed, boil an ounce of pepper or ginger, in a quart of milk; and add to it a handful of salt, and half a point of oil: this given warm, will (according to Burdon) purge in two or three hours.

The signs of a horse's recovery, are his lying quiet, without starting, or tumbling, and his gathering up his legs, and ceasing to lash out; and if he continues an hour in this quiet posture, you may conclude all danger over.

The next species of cholic we shall describe, is the bilious or inflammatory, which, besides most of the preceding symptoms, is attended with a fever, great heat, panting, and dryness of the mouth; the horse also generally throws out a little loose dung, with a hot scalding water, which when it appears blackish, or of a reddish colour, and fetid smell, denotes an approaching mortification.

In this case the horse should immediately be bled to the quantity of three quarts; and it should be repeated, if the fymptoms do not abate in a few hours. The emollient clyfter, with two ounces of nitre diffolved in it, fhould be thrown up twice a day, to cool the inflamed bowels; plenty of gum arabic water fhould be taken; and a pint of the following drink given every two or three hours, till feveral loofe ftools are procured; and then it fhould be given only night and morning, till the diforder is removed.

> Take fenna three ounces, falt of tartar half an ounce; infufe in a quart of boiling water an hour or two; then ftrain off, and add two ounces of lenitive electuary, and four of glauber falts.

If this diforder is not removed by thefe means, but the inflammation and fever increafe, attended with a difcharge of the flefh-coloured water above defcribed, the event will moft probably be fatal; and the chief thing to be depended on now, muft be a ftrong decoction of Jefuits bark, given to the quantity of a pint every three hours, with a gill of red port wine.

A quart of the fame may be ufed for a clyfter, with two ounces of Venice turpentine, diffolved with the yolks of two eggs, an ounce of diafcordium, and a pint of red wine, and given twice a day: if the horfe recovers, give two or three mild rhubarb purges.

To a horfe of little value, give the following, which, in thefe cafes, has been found fuccefsful.

> Take diapente one ounce, diafcordium half an ounce, myrrh, in powder, two drams; make it into a ball with two drams of oil of amber, to be given twice or thrice a day.

The laft we fhall defcribe is the dry gripes, or the cholic, which arifes often from coftivenefs: it is difcovered by the horfe's frequent and fruitlefs motion to dung, the blacknefs and hardnefs of the dung, the frequent and quick motion of his tail, the high colour of his urine, and his great reftleffnefs and uneafinefs.

In this cafe the ftrait gut fhould be examined and emptied, with a fmall hand, oiled properly for that purpofe; the emollient oily clyfter, given under the article *clyfter*, fhould be thrown up twice a day; and the above purging drink given, till the bowels are unloaded, and the fymptoms removed.

The diet for a horfe in the gripes fhould be fcalded bran, warm water gruel, or white water, made by diffolving four ounces of gum arabic in a quart of water, and mixing it with this other water.

From this hiftory and divifion of gripes and cholics, with their different treatment, it appears how abfolutely neceffary it is they fhould be well underftood, in order to be managed fkilfully: it is plain, too, that violent hot medicines fhould, in every fpecies of this diforder, be guarded againft, and given with great caution and difcretion, even in the firft kind of flatulent cholic, where indeed they can only be wanted; yet too often, when prepared by the farriers, with oil of turpentine, geneva, pepper, and brine, &c. they even increafe that diforder, by ftimulating the neck of the bladder too forcibly, heating the blood, and inflaming the bowels, till a mortification is brought on them. Thefe are in general the conftant appearance of horfes that die of this diforder, whofe bowels, being examined for that purpofe, have been found inflamed, full of red and livid fpots, fometimes quite black, crifped with extream heat, and rotten.

GRIPS, the fwaiths, or fmall heaps of corn, lying in the field, as it is cut down with the fcythe or fickle.

GROATS, oats, after the fhells are taken off.

GROVE, a fmall wood impervious to the rays of the fun.

Groves are the greateft ornaments of a garden; nor can a garden be complete that has not one or more of thefe. In fmall gardens there is fcarce room to admit of groves of any extent; yet in thefe there fhould be at leaft one contrived, which fhould be as large as the ground will allow of; and where thefe are fmall, there is more fkill required in the difpofition, to give them the appearance of being larger than they really are.

Groves are of two forts, viz. open and clofe; open groves are fuch as have large fhady trees, which ftand at fuch diftances, as that their branches may approach fo near to each other, as to prevent the rays of the fun from penetrating through them: but as fuch trees are a long time in growing to a proper fize for affording a fhade, fo where new groves are planted, the trees muft be placed clofer together, in order to have fhade as foon as poffible; but in planting of thefe groves, it is much the beft way to difpofe all thefe trees irregularly, which will give them a greater magnificence, and alfo form a fhade fooner than when the trees are planted in lines; for when the fun fhines between the rows of trees, as it muft do fome part of the day in fummer, the walks between them will be expofed to the heat, at fuch times, until the branches of thefe trees meet; whereas, in the irregular plantations, the trees intervene, and obftruct the direct rays of the fun.

When a perfon, who is to lay out a garden, is fo happy as to meet with large full grown trees upon the fpot, they fhould remain inviolate, if poffible; for it will be better to put up with many inconveniencies, than to deftroy thefe, which will require an age to retrieve; fo that nothing but that of offending the habitation, by being fo near as to occafion great damps, fhould tempt the cutting them down.

Moft of the groves which have been planted in England, or thofe celebrated gardens in France, are only a few regular lines of trees; many of which join to the habitation, or lead to fome building, or other object: but thefe do not appear fo grand, as thofe which have been made in woods, where the trees have grown accidentally, and at irregular diftances, where the trees have large fpreading heads, and are left at fuch diftance as to permit the grafs to grow under them, then they afford the greateft pleafure; for nothing is more noble than fine fpreading trees with large ftems, growing through grafs, efpecially if the grafs is well kept, and has a good verdure; befide, moft of thefe planted groves have generally a gravel walk, made in a ftrait line between them; which greatly offends the fight of perfons who have a true tafte: therefore, whenever a gravel walk is abfolutely neceffary to be carried through thefe groves, it will be much better to twift it about, according as the trees naturally ftand, than to attempt regularity: but dry walks under large trees are not fo ufeful as in open places; becaufe the dropping of the trees will render thefe walks ufelefs, after rain, for a confiderable time.

Clofe groves have frequently large trees ftanding in them; but the ground is filled under thefe with fhrubs, or under-wood; fo that the walks which are made in them are private, and fcreened from the winds, whereby they are made agreeable for walking, at fuch times when the air is too violent or cold for walking in the more expofed part of the garden.

Thefe are often contrived fo as to bound the open groves, and frequently to hide the walls, or other inclofures of the garden: and when they are properly laid out, with dry walks winding through them, and on the fides of thefe fweet fmelling fhrubs and flowers irregularly planted, they have a charming effect; for here a perfon may walk in private, fheltered from the inclemency of cold or violent winds, and enjoy the greateft fweets of the vegetable kingdom: therefore, where it can be admitted, if they are continued round the whole enclofure of the garden, there will be a much greater extent of walk: and thefe fhrubs will appear the beft boundary where there are not fine profpects to be gained.

Thefe clofe groves are by the French termed bofquets, from the Italian word bofquetto, which fignifies a little wood; and in moft of the French gardens there are many of them planted; but thefe are reduced to regular figures, as ovals, triangles, fquares, and ftars: but thefe have neither the beauty or ufe which thofe have that are made irregularly, and whofe walks are not fhut on each fide by hedges, which prevents the eye from feeing the quarters; and thefe want the fragrancy of the fhrubs and flowers, which are the great delight of thefe private walks; add to this the keeping of the hedges in good order, is attended with a great expence; which is a capital thing to be confidered in the making of gardens. *Miller's Gard. Dict.*

GROUND, a general name for land, be the foil what it will.

The Romans were very attentive to examine the nature of the ground before they broke it up, and diftinguifhed guished it into three situations, champaign, hilly, and mountainous. They rightly approved most of a champaign country, declining gradually from the foot of a hill toward the south, or south-east; if a hill rising gently; and if a mountain neither lofty, nor rugged, but covered with plenty of wood and grass. Either of these situations is eligible, according to the purpose for which the ground is intended; some plants affecting hotter, others colder exposures; some delighting to dwell on hills, others in vallies; and some again being indifferent to either: but, generally speaking, most vegetables choose the warm and kindly soil of low grounds, fertilised by what the rains bring down to them from the hills and more elevated parts.

The spontaneous produce of the earth is an infallible indication of the nature and quality of the ground. Wild thyme shews it to be good for feeding cattle; betony and strawberries direct to wood; camomile points out a mellow soil fit for wheat; burnet indicates land fit for pasture; and mallows denote it proper for the uses of the kitchen-garden, as has been observed by lord Bacon, Mr. Evelyn, and others.

On the contrary, says the last mentioned of these writers, some ground is so cold, as naturally to bring forth nothing but gorse, broom, holly, yew, juniper, ivy, box, &c. which may perhaps direct us to the planting of pines, firs, and other perennial verdures in such places.

Moss, rushes, wild tansy, sedge, flags, fern, yarrow, and withered, blasted, shrubby, and curled plants, are natural indications of a very bad soil.

The nature of the ground may also be pretty well guessed at, by the quality of the water which runs, or is strained through it.

By the smell, which, upon the falling of the first rains after a long drought, is very pleasing, and even fragrant, from good and natural mould; but disagreeable and noxious, if the ground contain any mineral, or other ill quality, as is remarkable in marshes and fenny places.

By the taste, all earths, as well as plants, abounding more or less in their peculiar salts; some sweet and grateful; others bitter, hot, or astringent; and others flat and insipid; easily discovered by the method which Columella directs, of digging up some of the under mould, out of that part of the land which is deemed the worst, and mixing it thoroughly in an earthen vessel, with sweet water, which, when poured off after the grosser parts have subsided, will retain the taste of the earth soaked in it.

The touch will immediately shew whether it be soft, pliant, fat, and slippery; whether it sticks to the fingers, or melts and dissolves on the tongue; in which case the soil may be deemed rich. If it be gritty, light, and porous, it is bad.

Mould fit for the production of plants is of an uniform substance, unmixed with the contrarieties of soft and hard, churlish and mild, moist and dry: neither is it too unctuous or too lean; but light, and crumbles easily; yet is consistent enough to be wrought and kneeded. It is of such due tenacity as to retain a just degree of moisture, and neither soils the fingers, nor cleaves much to the spade, which easily enters it. Of this kind is the soil usually found under the turf of pasture-grounds, upon which cattle have been long fed and foddered. In short, that is the best mould which is blackest, cuts like butter, sticks not obstinately, breaks into small bits, smells sweet, is tempered without crusting or chopping in dry weather, or becoming poachy in wet, which shines after the plough, where flocks of crows follow the ploughman, and, as Pliny expresses it, peck at his very heels.

As to colour, next to the blackish, the pre-eminence is generally given to the darker gray, and after that to the russet: the clear tawny is reputed worse; the light and dark ash-colour (light of weight and resembling ashes) good for very little: and the yellowish red, the worst of all.

The common opinion, that all hot grounds are red or brown; cold and dry, blackish; cold and moist, whitish; hot and moist, ruddy; is, notwithstanding the specious arguments alledged in favour of it, from the exhalation of minerals, the heat of the sun, and other accidents, exploded by Columella, who proposes, as a much surer way to judge of the goodness of land, digging a trench, and afterwards throwing back the same earth that was dug out, treading it down well when it is returned. If, says he, through a kind of ferment as it were, there be more than enough to fill the trench, it is a certain sign that the soil is fat: if there be not enough, we may be sure that it is poor and lean; and if the quantity be just sufficient to fill the hole from whence it was taken, it is of a middling quality.

Mr. Evelyn, after examining the component parts of several sorts of soils, concludes, that the very finest earths and best moulds, however to appearance mixed with divers imperfect bodies, may, for aught we know, consist more of sandy particles, than of any other whatever. Hence he infers, that earth, stript of all heterogeneous particles, retains only weight, and an insipid siccity; and doubts whether it afford any thing more than embracement to the first rudiment of plants, protection to the roots, and stability to the stem; being "unprolific till married to something of a more masculine virtue, which irradiates her womb: but, otherwise, nourishing only from what is added, without any action or material contribution: for, says he, what gives the divers tempers to moulds, seems rather to be caused by the perpetual and successive rotting of vegetable and animal substances, than by any peculiar and separate principle; the clamminess of the earth seeming rather something extrinsical and accidental to it, than natural and originally constitutive. We know indeed, that the earth is, without any artificial auxiliaries, indued with a wonderful prolific virtue: but as this is liable to be lost, or to decay, and never can be expected from some grounds, without helps; it may be worth our while to consider, by what expedients the desired effect of perpetuating its vigour may best be accomplished."

The means of giving and perpetuating this vigour now becomes properly the subject of our farther enquiry, consistent with what was observed before, that in order to the earth's having this vigour, it should be constantly kept in an alkaline or calcarious state. Mr. Evelyn is clearly of this opinion, when he says, "I firmly believe that were salt-petre to be obtained in plenty, we should need but little other compost to meliorate our ground." In other words, could the earth be always kept in a state fit for collecting nitre, it would consequently be always in a state fit for the production of plants. They who are acquainted with chemical researches, know, that nitre is obtained from substances of a mixed nature. Its basis is a calcarious earth, to which must be added putrid or alkaline substances, especially of the vegetable kind.

Mr. Evelyn and some later writers have spoken so much of the effects of nitre, and nitrous earths, in vegetation, that many have imagined nitre to be essentially necessary in the growth of plants: though Dr. Woodward assures us, that, by all the trials he has been able to make, the very contrary seems to be the case; for that nitre, when contiguous to a plant, rather destroys than nourishes it. When, therefore, they mention nitre, and nitrous earths, it is more than probable that they mean earth in a state fit for collecting nitre: but when the alkaline substances are once saturated by the acid in the air, or when the alkali is brought to a neutral salt, as nitre is, its fertile state then ceases, and it becomes a hard compact body, much more impervious to the roots of plants than it was before.

The nature of calcarious substances, and that of the two kinds of alkalis, viz. the fixed alkaline salt of plants, and the volatile alkali arising from animal and putrid vegetable substances, has already been explained.

Farmers commonly say, that lime (to which might be added all other calcarious substances) does not fatten, but only mellows the earth; meaning, according to Dr. Woodward, that it does not contain in itself any thing of the same nature with the vegetable mould, or, in other words, afford any matter fit for the formation of plants; but that it only softens and relaxes the earth; by that means rendering it more capable of entering into, and of nourishing the seeds and vegetables set in it, than it would otherwise be. It is well known how apt lime is to be put into a ferment and commotion by water. Now this commotion can never happen when the lime is mixed with earth (and it retains its qualities of lime) however hard and clodded the ground may be, without opening and loosening it. What Dr. Woodward ſays of ſalt in general, may more properly be applied to the fixed alkaline ſalt of plants. Every one, ſays he, muſt have obſerved, how apt all ſorts of ſalts are to be wrought upon by moiſture, and how eaſily they melt and run with it. When this happens to thoſe that are in the earth, the clods which they are mixed with, moulder and fall aſunder. The ſame gentleman farther obſerves, that if we would render the earth truly fruitful, it muſt be by the addition of ſuch ſubſtances as former crops have robbed it of, or ſuch as contains in itſelf vegetable matter.

The ſeveral manures which are found beſt to promote this end, are chiefly, either parts of vegetables, or of animals; of animals, ſays the doctor, which either derive their own nouriſhment immediately from vegetables, or from other animals that do ſo, and which, being returned to the earth, ſerve for the formation of other ſimilar bodies. Theſe vegetable and animal ſubſtances, are the matter from whence Mr. Evelyn thinks the earth derives that clamminess which he takes to be a ſure indication of a rich ſoil.

If the effects of the putrefaction of vegetable or animal ſubſtances, when mixed with, and ſeparated in the earth, be duly attended to, we ſhall find this a very probable opinion. Vegetables, or animals, if expoſed to the air, ſoon putrify and fly off into the air: but when they are divided into ſmall portions, and mixed with the earth, the earth renders the progreſs of their putrefaction ſlower, and intangles the volatile alkaline particles, which would otherwiſe fly off into the air. Theſe are not only ſtrongly attractive of moiſture, but, like the fixed alkali, attract the acid in the air, and effervesce with it; whence the double advantage of a moiſt and looſe ſoil.

If we attend to the infinite number of animals and vegetables which are rendered volatile by putrefaction, and fly off into the air; and to the quantity of perſpirable matter from animals and vegetables ſent into the air; and alſo to the effects of the acid found every where in the air on ſuch ſubſtances mixed with the earth; we need no longer wonder at the efficacy which writers, in all ages, have aſcribed to the air, with regard to its quality of enriching the earth.

That the peculiar richneſs of ſoils is owing to the putrid or rotten particles mixed with them, is an opinion of long ſtanding. This is Virgil's *putre ſolum*, rotten, crumbling, or looſe earth; and that which Columella diſtinguiſhes by the appellation of *pinguis et putris*, fat and rotten, or fat, looſe, and crumbling, as the ſoil which yields the greateſt profit with the leaſt labour and expence, becauſe it is naturally neareſt that ſtate which cultivation is intended to effect; "for, to cultivate, is no other thing but to open, looſen, and ferment the earth."

From theſe principles it is that we account for the appearances before-mentioned of good ſoils, ſuch as, their blackiſh or dark colour (which is that of all ſoils in a putrid ſtate) their ready crumbling, eaſy mouldering, fragrance of ſmell, &c.

Mr. Evelyn conſtantly imputes the fruitfulneſs of the earth to a nitrous ſalt: but if theſe rich putrid ſubſtances are ſubſtituted inſtead of that ſalt (and it ſeems highly probable that he means them) we ſhall find that his reaſoning will appear full as ſtrong, more intelligible, and indeed more rational. The ſubſtance of p. 312, and 313, of his Philoſophical Diſcourſe of earth, ſo far as relates to this matter, will run thus:

"It is this putrid quality which entices roots to affect the ſurface of the earth, upon which the fertiliſing rains and dews deſcend; which makes all covered and long ſhaded earth, abound in fertility; which reſuſcitates the dead and mortified earth, when languiſhing and ſpent by our indulgence to her verdant offspring; her vigour being quite exhauſted, till the rains and ſhowers gently melt into her boſom what we adminiſter to ſupply that which has been conſumed. It is this which fertiliſes and renders Egypt ſo luxuriantly fruitful after the inundations of the Nile, &c."

GROUND-IVY, the name of a trailing plant, which ſtrikes out roots from the joints of its ſtalks: but as it generally grows under hedges, and upon the ſides of banks, it cannot be of any great diſadvantage to the ſoil.

GRUB, the name of a large maggot, produced from the eggs of a certain ſpecies of butter-fly. It is of a large ſize, and often does great injury to the corn by undermining it, and preying on its roots. It produces the beetle, and is by ſome called the rook-worm, becauſe rooks are particularly fond of it. The beſt way of deſtroying the grub, is good and frequent ploughings, which will clear the ground however infeſted with this inſect, for ſome years at leaſt.

GRUBBING, the clearing of lands from the roots and ſtumps of trees, buſhes, &c.

Mr. Worlidge rightly obſerves, that the beſt and cheapeſt method of grubbing up thorny ſhrubs, broom, graſs, &c. is ingeniouſly delivered by Gabriel Platt. The inſtrument he has recommended for this purpoſe reſembles a three-grained dung-fork, but much larger and ſtronger, according to the bigneſs of the ſhrubs, &c. the ſtale thereof reſembling a large and ſtrong lever. This inſtrument being placed about half a foot, or any other reaſonable diſtance from the root of the ſhrub, &c. and driven to a good depth, with a ſtrong hedging beetle, then raiſed by laying under it a ſtone or log of wood, is pulled down by means of a rope faſtened to the upper end of the ſtale, and the whole buſh wrenched up by the roots.

GUTTERING-*Plough*, a ſmall and ſimple inſtrument uſed in ſome counties for draining wet lands.

It is ſmall, and worked by a ſingle man. A trench four or five inches broad, and ſix or eight deep, may be eaſily made with it; and on that account it is much uſed for making drains in bleaching grounds, and may do very well for wet clay meadow-land, where the ſoil is ſhallow, and apt to produce a large quantity of ruſhes.

It conſiſts of a piece of iron about five inches broad, and pointed at the end. Upon this piece two other pieces are fixed perpendicular to the former, one on each ſide, the fore-edges inclining backward; ſo that the three edges of the inſtrument form a capital A. To the bottom plate is fixed a ſocket, for receiving the ſtale, which is ſet higher or lower by means of a wedge on the under ſide. At the end of the ſtale is a croſs piece three feet long, againſt which the man's breaſt is placed when he ſhoves the inſtrument before him in order to cut the drain. A rib twenty-four inches long is fixed on the ſocket, and at the end of it a peg about a foot long, and two inches diameter is faſtened to the ſide of the ſtale with ſcrews. This peg reſteth on the land, when the clod is turned out of the mouth of the inſtrument.

H.

HACK, a pick-axe, or mattock, having only one, and that a broad end.

HARE, a mift.

HARROW, an inftrument for breaking the clods of earth, and covering the corn when fown. It is a fort of wooden drag, made in the form of a fquare, with large iron-teeth or tines. The reader will find different forts of harrows defcribed under the articles BEANS, LUCERNE, &c.

HART-CLOVER, melilot.

HARVEST, the feafon when the corn is ripe, cut down, and carried into barns, &c.

Wheat which is full of weeds ought to be cut three or four days fooner than ordinary, that the weeds may have time to wither before the corn become too ripe: for if it be not cut till the grains are full ripe, it will be liable to confiderable damage by fhedding, lofs of colour, and injuries from rain, whilft it remains expofed for the weeds to dry. A fingle fhower, indeed, or even a day's gentle rain, whilft it lies in fwarth, is thought to be rather beneficial to the grain, by making it feel dry and flippery, and threfh the better: but all poffible care fhould be taken to guard againft its being wetted too much. When, through any unavoidable accident, it is laid up not thoroughly dry, though it will not take much harm in the mow, it will fweat and cling together when laid in a heap after being threfhed, and look as white, with mouldinefs, as if it had been ftrewed with flour. Such corn will not keep, and therefore fhould be fent to market, and fold, as foon as it is threfhed.

In Oxfordfhire, and feveral other countries, they bind up their wheat in fheaves, though it be full of weeds, and fet three fheaves fomewhat floping againft three others, after which they cover their tops with two fheaves opened at their ear ends, which are extended and placed downward. In this fituation they let their wheat ftand three weeks or a month in the field, before they carry it in; for no wet can hurt it, nor is it apt to grow in the ear, when thus fheltered.

In their wheat-pooks, as they call them, in Wiltfhire, the fheaves are fet in a circle, with their ears uppermoft, and another circle of fheaves is placed upon that, and fo on, contracting each round, till the pile ends in a point, upon which a fheaf opened, and turned with the ears downward, is placed, like the fhackle of a hive; for an ear turned downward will not grow, though ever fo much wet fall upon it, and the bottom of a fheaf being broader than its top, every upper one fhelves over the under, like the eaves of a houfe. A load, or two loads, may be thus put into a pook, which is a very good way to fecure corn againft rain, and to give the weeds among it time to dry. But, as Mr. Lifle rightly judges, this method is not altogether proper when the wheat is intended to be laid up in a rick; becaufe, if the weather prove wet, mice will run to it for fhelter, and will be carried in with the pooks. It is the general way of making wheat-ricks in the ifle of Wight, without thatching.

Though moft corn is bettered by lying awhile in fwarth, or grips, to take the dews, which contribute to render its grain plump and of a good colour; yet its ftraw becomes thereby the worfe for fodder, unlefs it was cut before it had attained full maturity, and lies out no longer than till it be fufficiently ripened.

In hot dry fummers, when the corn ripens fully, and its own vigour gives it a proper colour, and plumps up the grain fo that the hufks readily yield their contents when threfhed, wheat need not lie out in grip, before it is fheaved, or in fheaf, unlefs it be very full of grafs and weeds: but in cold fummers, the wheat is horny and pale, the grains are thin and require being plumped, and their hufks cling fo clofe, that they muft be mellowed, in order to make them threfh well. The full grain which fwells the chaff, even till it opens, in good and fruitful years, lies almoft bare to every moifture; and the heavy ears then fpread and hang over the fheaf, which of courfe opens wider, and lets the rain into the bonds fooner than in lefs kindly feafons, when, the wheat being light, the ears in the fhock ftand more upright and clofer together.

In proportion to the heat of the weather, greater expedition is neceffary in reaping; for corn, when haftily ripened, fcorched up by the fun, and full in grain, foon takes a ftain, is damaged by wet, and eafily fheds at every blaft of wind. The prudent hufbandman fhould therefore, in fuch cafes, employ the greater number of reapers; for he cannot defire more, than that his corn be perfectly ripe, and of a good colour: for which reafon, the lefs it then lies abroad in grip or fheaf, the better it will be. Cutting it high up, fo as to avoid the intermixed grafs as much as poffible, by which means it is the fooner fit for carting, has been found very ferviceable on thefe occafions; and Mr. Lifle is of opinion that, efpecially in hilly countries, corn can never be better houfed, if thorough ripe, hard, and not weedy, than by gripping and carting as faft as it is cut down; becaufe the dampnefs which it takes by lying on the ground all night, is not eafily removed.

It is always moft advifable to turn the grips of wheat which is left out, very early after their being cut down, in order to get them dry as foon as poffible. By this means they are kept the longer from fprouting in the ear, in cafe of rain: for if dripping weather or driving mift fhould enfue, and continue for any time, after they have been already loaded with wet, all the art of man cannot prevent their growing: nay, even independent of other accidents, the bare weight of the ears will fink the grips of wheat to the ground, though they have been laid ever fo

light

light and hollow; and they will certainly be injured thereby, if fuffered to lie long out in wet weather. The beft method of guarding againft this, is by laying them in triangles, as directed by M. de Lille.

A principle fomewhat fimilar to this feems to be the reafon why the farmers in Leicefterfhire, and Northamptonfhire, in particular, where the land is rich, deep, lies flat, and is much inclofed, leave a very high wheat ftubble, upon which the grips are fupported, lie the hollower from the ground, and confequently are the eafier dried by the fun and wind; for it is to be obferved, that the fatter and richer the foil is, the fooner the grips will grow after they have taken wet, if they lie upon the naked ground; much fooner than they would, in the fame cafe, in a hilly country, where the land is poor. Hufbandmen there, befides efteeming it an advantage that they can ftow a greater number of fhort-cut fheaves in their barns, think the lofs of the ftraw compenfated by the excellent thatch which they make of the ftubble. In fome places they mow it for drying malt.

The forwarder the harveft is, and the warmer the feafon, the longer the corn may fafely lay in the field, either in grips, or fheaves: for this expofure to the air, after it is cut down, mellows it, and makes it threfh better and look finer. Thus, when the wheat harveft takes place by the middle, or at leaft before the latter end of July, of which we have had inftances, there can be little danger in letting the wheat lie abroad four or five days or a week, if it be not over ripe when cut, even though a rainy day or two fhould come: for at that time of the year the fun is fo hot, the days are fo long, the grafs fo fhort, and the dews generally fo little, that the corn foon dries, even after a hard fhower; whereas in the middle, and ftill more toward the latter end of Auguft, the rainy feafon frequently begins, the dewy nights grow fo long, the grafs is fo rough, and the fun's drying power fo much abated, that, if wet weather comes on then, the corn will be much more apt to grow.

A caution which Mr. Lifle recommends as fingularly important in hilly countries, is, not to bind the grips of wheat up into fheaves too early in the day; becaufe, in fuch a fituation, the grips take fo great a damp by having laid on the ground, that, though the ftraw, and chaffy ears may feem to be dry when the dew is firft gone off, and after the fun may have fhone an hour or two upon them, yet there will remain an inward dampnefs in the corn, and within the ftraw, which, if laid up in that condition, will come damp from the rick or barn at threfhing time. The afternoon is therefore certainly beft for gripping and binding into fheaves in fuch countries, but fo that this work may be finifhed before the day is over. The bands fhould, however, be laid in the morning, that they may not crack; for the ftraw will not twift after the fun is up, but will be brittle, and break off below the ears. The turning of three or four of the ftubble or bottom ends of the ftraw to the ears of the band, helps greatly to add to its ftrength and toughnefs.

The bands for binding up the fheaves fhould not be fpread but in fair weather, becaufe, being preffed down by the grip or two which it is neceffary to lay upon them to keep them in their places and prevent their being untwifted by the fun, they will grow fooner than any other corn, if rain fhould come; for they cannot dry, on account of their lying undermoft. But though the bands muft always be made while the morning dew is upon them, the fheaves ought not by any means to be bound up wet: if they are, they will certainly grow mouldy.

Farmers do not always attend fufficiently to the binding up of their fheaves, but fuffer the reapers, for difpatch, to tie the bands juft underneath the ears, inftead of binding them at the other end; the confequence of which is, that they will hardly hold together to be flung into the cart at harveft, and will certainly be in great danger of falling to pieces before they are threfhed.

If a little rain is forefeen in harveft time, it is beft to bind the grips up into fheaves as faft as they are made; becaufe fmall fhowers will wet the fingle grips fo much that they cannot be bound up, and thofe fhowers may be the fore-runners of greater rains. The fheaves, being bound, will foon dry after fuch wet. But if a hard rain is forefeen, the beft way is not to bind up into fheaves, becaufe they will then be wet to the bands, and muft all be opened again. One of Mr. Lifle's neighbours, to whom this happened, unfheafed fome of his wheat to dry it, opened it, and turned it fo often, that the ears broke off, by which he loft half his corn. Caution ought therefore to be ufed in this cafe, left by curing one evil we create a worfe.

All farmers agree, that rain which comes with a driving wind, is the worft of any weather for fheaves of wheat out in the field; and that it is worfe than a downright foaking rain for fuch fheaves as are wet to the bands.

In a wet harveft, fmall fheaves are beft, becaufe, thin at top, and falling clofe, the rain does not fink down into the middle of them, and fo go through into the bands, as it is apt to do in great fheaves, which lie broader, and take a larger compafs. Small fheaves are alfo beft, when many weeds are intermixed with the corn, becaufe the air, wind, and fun, have then a greater power to dry them, than they could have if the fheaves were large.

It has been the opinion of fome good farmers, that if the weather be likely to continue fair, it is beft to lay the fheaves, the night after the wheat is cut, one by one, flat on the ground, in order to make their ftraw lie the clofer together, and their ears ftand the ftiffer, and more upright, by which means they will be lefs apt to open at the top, and rain will have the lefs power to penetrate them when laid in fhocks.

Reapers fhould take care, in placing their grips, to lay the ftraw end in the furrow, and the ears out, becaufe thefe will then ftand floping up, and lie tolerably dry, even though rain fhould come; but in the other way, they would foon grow.

Mr. Lifle remarks, in his Obfervations (which might have been thrown into a more regular, as well as more laconic form, before they were publifhed; for that gentleman certainly never intended, that his unconnected notes and memorandums fhould appear in the manner in which he penned them merely for his own ufe) that "one of his reapers, when he had made up fome wheat into fheaves, the wheat being long-eared and lop-heavy, faid, rain had not need meet with thofe fheaves before they were carried home." Mr. Lifle afked him, "Why fo?" To which the other replied, "becaufe the ears being long and heavy, were bufsle-headed, that is, did hang their heads downward into the fheaf, fo that (in cafe a rain fhould run down to the bands) neither fun nor wind could enter in to dry them; whereas, faid he, when the ears are fhort, and not heavy, they ftand upright and hollow, fo that the fun and air may eafily dry them."

The ftraw of blighted wheat, being hollow and fpungy, is very apt to imbibe moifture; for which reafon the beft way is to houfe fuch corn as foon as it is tolerably dry, efpecially if there be the leaft profpect of rain; for if ftraw of that loofe texture fhould once foak in wet, and fhowery weather fhould afterward come on, it would require much more time than other corn to dry and fit it for threfhing.

Experience has fhewn, that wheat keeps better when ftacked in the ear unthrefhed, than its grain does alone, when threfhed out and laid up in granaries: befides which, a farther advantage which attends the ftacking of this corn, is, that the hufbandman need not threfh it but as his markets or other occafions require; whereas, if it were to remain long in the barn, he would not be able to preferve it from rats, mice, and other vermin, which harbour in the walls, roofs, &c. of fuch buildings.

To guard againft thefe enemies, as well as againft the dampnefs of the ground, which would otherwife occafion great lofs (for there have been inftances of its rotting piles of corn to the thicknefs of a yard, or more) four, fix, or more ftrong pofts, according to the intended fize of the ftack, are driven into the ground, beams of a proper ftrength are laid acrofs them, and upon thefe is made a floor to fupport the ftack. Some farmers build thefe platforms for their ftacks fo high from the ground, that there is room to fhelter their carts and other implements of hufbandry under them: and fome again, as an additional fecurity againft rain and birds, erect fides and a roof, by which means they form a kind of barn:

barn: but this is needlefs, if the corn be ftacked, as it ought to be, in fheaves, with the ears turned inward, and the ftraw ends outward, and the top well thatched with good wheat ftraw, which is the beft of any for thatching. They likewife cover the fupporting pofts with tin, for about a foot in breadth from the top, to prevent the mice and rats getting up: but this method foon proves ineffectual, becaufe tin is very apt to ruft, and confequently lofes its fmoothnefs. A better way, as Mr. Mortimer advifes, is to cover thofe pofts with Dutch tiles, fuch as chimnies are commonly fet with, becaufe they will always keep fmooth. Others make their fupporters of two hewn ftones, one of which, being about three feet high, and floped from the bottom, where it is two feet wide, to the top, where it is but a foot thick, ftands upright, and is covered with a large flat ftone, about a yard fquare, or, which is better, of a round form. This not only prevents rats and mice from climbing up, but is alfo a fecurity againft the dampnefs of the ground. Others again, whofe method is the beft of all, lay a foundation of brick as wide as the ftack is intended to be, and build round it a brick wall, about two feet high, capped with hewn ftones, which project fufficiently outward, to hinder the afcent of any fort of vermin. If either rats or mice fhould, by the help of any thing accidentally refted againft the ftack, chance to climb up, and get into the corn, they will not be able to remain there long, becaufe, as they cannot live without water, neceffity will force them down, and their former means of climbing being removed, they cannot get up again. If any of them chance then to be left in the ftack, they will foon die there for want of drink.

Particular care fhould be taken in the ftacking of wheat, always to lay the ear ends of the fheaves inward, and upon a rife, fo as to keep the middle of the ftack full while it is worked up: for in this cafe, when it fettles, the finking will be chiefly on the outfide, which will thereby be made to lie the clofer, and the ftraw ends being outward, and inclining downward, birds cannot get at the grain, nor can rain be driven up to the ears. The fhorteft and thinneft fheaves fhould be ufed in the topping of the ftack, becaufe it cannot be fo conveniently drawn in and narrowed with great long fheaves. They fhould be taken from off the fame ground, if the hufbandman wants to keep any particular fort or growth of corn pure and unmixed. Where lefs nicety is obferved, oats, or fome other kind of coarfe grain, are frequently laid on the top of the ftack of wheat, under the thatch, the better to preferve it from being wet. Wheat, properly ftacked, will keep in perfect order for many years.

Mr. Lifle, who does not approve of ftacking any corn but wheat, when room can be found for it in the barn, thatched a long rick of vetches, brought up fharp, with barley ftraw, to the thicknefs of three feet, and yet found, upon cutting it, that the rain had penetrated through this thick covering, and done confiderable damage to the vetches. He imputes this, firft, to barley-ftraw's being more woolly and fpungy than wheat ftraw, which is clofe and hard; and, fecondly, to the ftack's having fweated and heated pretty much, in which cafe the covering of ftraw is always hollowed and foftened, and confequently rendered the more apt to admit and retain wet.

The ftalks of oats are naturally fo fmooth and flippery, that they are apt to flide in the ftack, which then frequently tumbles down, efpecially if this corn was very dry when carried in. An oat rick muft therefore not be widened by any means beyond its foundation, which generally is of faggots, nor fhould its fides ever bulge out, but, on the contrary, they fhould be gradually contracted. Barley, having a rough ftem, may be piled more upright.

When fparrows rooft at night in holes, under the eaves of a ftack of corn, it is reckoned a fure fign that there are neither rats nor mice in the rick; for their fqueaking and running about in the night, would difturb the birds, fo that they would not ftay there.

HASK, a hufky cough.

HATTOCK, a ftock of corn, confifting of twelve fheaves. In fome countries it implies only three fheaves laid together.

HAVER, a name given to oats in fome parts of England.

HAW, a clofe, or fmall field.

HAW, is alfo the common name for the fruit of the white thorn.

HAW, likewife fignifies a fwelling of a fpongy texture, growing in the inner corner of the eye of a horfe, and fometimes fo large, as to cover a part of the eye.

HAY, a general name for any kind of grafs, cut and dried for the food of cattle.

When grafs is to be made into hay, the farmer will be directed in the feafon for mowing it, by the quality of the grafs. When the crop is very great, it fhould be cut as foon as the bottom of the grafs grows yellow: for if it ftands longer, more will be loft by the quantity of leaves rotted at the bottom, and the ill flavour which thefe will give to the reft, than will be gained by its growth. When other circumftances permit the choice of time, it fhould be when the grafs is in full bloom, before the ftalks begin to harden, and rather early than late, becaufe the more fap remains in the roots, the fooner the next crop will fpring up. There is not, however, any general rule for this; becaufe, in fome cafes, the ripe feeds add a great value to the hay, as in fainfoin and burnet; and, in others, the growth of the grafs itfelf brings a recompenfe, as in the fowl-meadow grafs.

A dewy or dufky morning fhould be chofen for cutting the grafs, becaufe, being then fulleft of fap, it ftands beft to the fcythe. When the high noon-tide fun has dried the grafs, and made it recline its head, the mower will employ his time more ufefully in making the hay already cut, than in continuing to mow, with great additional labour, grafs, which no longer makes the due refiftance.

Our farmers in general are very inattentive to the management of their hay whilft in the cock, to which is in a great meafure owing the lofs which they (or rather the nation) fuftain every year, by the damage which the hay receives from rain.

To guard as much as poffible againft this accident, let the hay-makers follow the mowers, and, if the weather be quite fine, fpread out the grafs as faft as it is cut down, efpecially if it lie fo thick in the fwarth, that neither the air nor fun can pafs freely through it: but if wet be feared, let it remain in the fwarth. At night, make it into grafs cocks, and the next day, as foon as the dew is off the ground, fpread it again, and turn it, that it may wither on the other fide; then handle it, and if you find it dry, make it up into large cocks. If the weather continue favourable during the fecond day, the grafs will, by that time, be fo dry as to bear being kept in thefe cocks till the day on which it is be carted, when it fhould be fpread out again in the morning, to receive a farther drying, if wanted. If thefe cocks are made as tall and as taper as can be, confifting with their ftanding fafely, the winds, by paffing through them, will dry them gently and equally; and though rain fhould fall upon them, it will not do much hurt, becaufe the greateft part of it will run off directly, and the fun and wind will foon dry that which may have penetrated into the cocks. Thefe cocks have therefore a great advantage over the common fmall and low ones: for if a rainy feafon comes on, thefe laft will be fo thoroughly wetted, that the wind will not be able to pierce fufficiently to dry them. More hay is, perhaps, loft for want of making the cocks properly, than by all the rains which happen in the hay-making feafon.

The method here recommended is confirmed by the experience of a New England hufbandman, whofe account of it to the reverend Dr. Elliot run thus:

"I fhall relate to you my own practice in making of hay, though it may feem fmall and trifling at the firft mentioning: but finding that it faves me near two fifths of the time and labour I ufed to be at in this article, and that my hay is, I think, better than when I ufed to purfue the ufual method, I efteem myfelf juftified in communicating it to the public. My method is this: I mow my grafs, and let it lie in the fwarth till the dew is off the next morning: then I turn and fpread my hay, and let it lie in the fun till the after part of the day, when I take it up and cock it well, and never meddle more with it, till I cart it into my barn, or ftack it. If the weather be good, it will do well to cart after it has ftood two days in cock. This, I have found by five or fix years conftant experience, anfwers for any fort of hay, except falt-hay and red clover, of which laft I have not had fo long trial: but with refpect to clover hay, I managed it laft fummer after this manner, viz. I followed my mowers, as they cut the grafs, I fpread it as thin as I could, and before night I put it in cock. The next day, after the dew was off, I fpread it again; in the afternoon, I cocked it a fecond time, and meddled no more with it till I carried it. The appearance of the hay fince, makes me judge that no man has better of the fort. My firft coming into this practice was purely accidental. After cutting my grafs, five or fix years ago, I put it in cock the next day; but my avocations then were fuch, that I had no time in which I could poffibly take any farther care of my hay for many days. When I had difpatched my other affairs, I returned to it, and found it in as good order (that is to fay the bulk of it) as ever I had hay in my life. Reflecting then, how much labour may be faved by this method, I have followed the fame practice ever fince, and find it anfwer very well. The reafon why I think my hay really better is, becaufe I take it for granted, that the more juice or natural moifture we can retain in it, without corrupting and rotting the ftalk, the richer and more nourifhing it is. The too often turning and fpreading of hay in the fun extracts too much of the richnefs thereof; and one day's thus lying will take away fuch a quantity of the moft watery particles, as that the remainder is only fufficient to raife a proper fermentation thereof when in the cock, while the fmallnefs of the body there keeps that fermentation from rifing to fuch a height as to corrupt it. After twenty-four hours, the fermentation will gradually abate; and the pitching of the hay into the cart, and afterwards into the mow, or ftack, fo checks it, that it will not again rife to fuch an height as to be detrimental. Cattle are fonder of this hay, than of that which is made in the common way, and lefs of it will fupport them."

It would be almoft needlefs to obferve, that no narrow wheels fhould ever be brought upon paftures, not even in the drieft feafon of the year, as that of hay-making generally is. The advantages of broad wheels, which help to roll and level the ground, and render the draught much eafier, whether on grafs, or any other foil in which narrow wheels will fink, have been confirmed by experience; and are as felf-evident, as it is that the latter crufh and bury, and thereby deftroy great numbers of the plants of grafs, wherever they are dragged.

If the hay has fweated a little in the cock, there will be the lefs need for its fweating afterwards in the rick, where it will then lie fo much the clofer, and confequently keep the better.

For the method of making lucerne and faintfoin, *fee the articles* LUCERNE *and* SAINTFOIN.

HAY-BOTE, a liberty which a tenant for life, or a term of years, has of taking bufhes, wood, &c. for repairing fences, gates, and the like. It alfo fignifies the liberty of cutting wood, for making rakes and forks ufed in making hay.

HAYN, or *Hayn-up*, implies the action of inclofing with a hedge, in order to preferve grafs-grounds from cattle.

HAZLE-*Mould*, a moderately compact earth, containing a large quantity of refin-coloured fand.

HEAD-LAND, the land running acrofs the others at the head of the field, left for the turning of the plough.

HECK, a door; alfo a rack for cattle to feed at.

HECKLE, an inftrument ufed in the dreffing of flax and hemp. *See the articles* FLAX *and* HEMP.

HEDGE. *See* FENCE.

HEIRS, young trees in coppices.

HEE-GRASS, ftubble of grafs.

HELM, a hovel; alfo ftraw prepared for thatching.

HEMP, the name of a plant too well known to need any defcription here; but it may not be improper to remark, that the flowers and the fruit (commonly called feeds) of hemp always grow feparately on different ftems, and confequently on different plants, as this never has more than one ftem proceeding from the root.

The flower-bearing fpecies, which is the *Cannabis florifera*, Off. *Cannabis erratica*, C. B. P. *Cannabis fœmina*, J. B. *Cannabis fterilis*, Dod. Pempt. and which is moft frequently termed female hemp, fhould properly be called barren hemp, flowering hemp, or male hemp, fince it is this which bears the *farina fœcundans*, or fecundating duft, without being impregnated with which the feeds that grow on the other ftems of the other fpecies would not come to maturity, or at leaft would not be capable of producing plants, when fown.

This other fpecies, which bears the feeds, and which botanifts diftinguifh by the appellation of *Cannabis fructifera*, Off. *Cannabis fativa*, C. B. P. *Cannabis mas*, J. B. *Cannabis fœcunda*, Dod. Pempt. and which is commonly termed male hemp, fhould be called feed-bearing hemp, or female hemp; becaufe it is this which, with the help of the impregnation it receives from the *farina fœcundans* of the male, produces feeds capable of yielding plants of either fpecies.

What may chance to be the future proportion between the number of male plants, and that of female, in a hemp-ground, cannot poffibly be gueffed at the time of fowing, as no fort of mark can be difcerned on the feed, by which they may be diftinguifhed: nor indeed can any judgment be formed in this refpect, before the male plants begin to flower, that is to fay, in general, till about two months after fowing; unlefs it be from a remark which the moft curious obfervers have made, that the male hemp is flenderer than the female, and that all its parts are more delicate: to which may be added, that the male plant is always forwardeft in its growth, and that it generally rifes about half a foot higher than the female; thereby plainly indicating it to be the defign of nature, that the fecundating duft which iffues from the flower may by that means be the more eafily conveyed to the grain on the feed-bearing ftalks, in order to its impregnating that feed.

With regard to the temperature of the air that is fitteft for the growth of hemp, M. du Hamel obferves, in his Treatife on Cordage, that this plant does not like hot countries; that temperate climates fuit it beft; and that it thrives very well in pretty cold regions, fuch as Livonia and Canada, which produce it in abundance, and very good. M. Marcandier is indeed of opinion, that though extremely hot countries are not favourable to its growth, yet, as this plant is but a fhort time in the ground, it may be cultivated in any place that is habitable by men.

The wife legiflature of this country has fhewn its opinion of the importance of raifing hemp in our own dominions, by the bounty given by parliament for the importation of it from North America; and our truly laudable Society for the Encouragement of Arts, Manufactures, and Commerce, has likewife judicioufly contributed to this defirable end, by offering a very confiderable premium to the cultivators of hemp in that vaft province of the Britifh empire.

The foil for hemp fhould be a foft rich loam, eafily brought into fine tilth; and it fhould be well manured. Newly broken up land is found to be peculiarly good for this plant; but flat grounds lying on the fides of rivers, and enriched by the fediment left on them when the waters overflow, are the beft of all for it. If hemp is to be fown on very ftrong foils, they muft be brought into fo good tilth, and be fo well manured, that their mould may remain loofe: in this cafe, fuch foils yield very great crops. Dry lands are not fit for hemp: it does not rife well in them, but remains fhort and ftinted in its growth, and its fibres are then generally too woody, which renders them hard. All thefe are confiderable defects, even for the coarfeft works. It is however true, that, in rainy years, it fucceeds better on dry grounds, than on moift: but as fuch years are not the moft common, the beft fituation for a hemp-ground is generally thought to be along the fide of a ftream, or of a ditch fo full of water, as that the water may conftantly be nearly on a level with the furface, but without overflowing it while the hemp remains on the ground.

It is the cuftom in fome countries to form hemp-grounds, which are appropriated folely to this purpofe: whereupon the author of a very judicious account of the culture of hemp, in the Memoirs of the Royal Society of Agriculture at Tours, juftly obferves, that, " befides that all foils de-

light

light in a change of plants, hemp is ſo far from impoveriſhing the ground, that the leaves which fall from it become a ſufficient manure, and the depth to which the roots go, eſpecially if the crop of hemp be great, leave the ground ſufficiently looſe to ſow upon it even a crop of wheat immediately after the hemp has been pulled, without any other expence than ſowing the ſeed and harrowing it in; or if turnips or a ſpring crop be more convenient to the farmer, theſe alſo will thrive well after the hemp. It is ſaid, that the hemp which grows on an eſtabliſhed hemp-ground is ſofter and more ſilky than that which is raiſed elſewhere: but the difference, if any, is very inconſiderable; for the hemp which grows in the other parts of Anjou, for example, is found to be as good as that which is produced by any of the few eſtabliſhed hemp-grounds in that province."

As it is eſſential to have the ground in exceeding fine tilth, the firſt ploughing ſhould be given it as early in the autumn as the huſbandman's other buſineſs will permit. Some are ſo curious in the preparation of their ground for hemp, that they give this firſt ſtirring by hand; and tho' it be a more tedious and more expenſive way than ploughing, they think that the difference of the crop repays them well. In whatever manner it be done, the ground ſhould be looſened as deep as poſſible, and laid rough, that it may be the better mellowed by the winter's froſt, eſpecially if the ſoil be ſtrong. If the hemp is to be ſown on ground purpoſely broken up, and which is covered with coarſe graſs, or other ſimilar productions, its ſurface ſhould be pared off and burnt; or it ſhould otherwiſe be brought to a perfectly fine tilth. The ground ſhould be ploughed again in February, or more early if the ſeaſon will permit; and then alſo ſhould be laid on the manure, whether of horſe-dung, or the ſcouring of ponds and ditches, after it has had time to ripen; for theſe are preferable to cow-dung; though all manures, which render the earth light, are fit for hemp. Mr. Du Hamel remarks, that marle is not, to his knowledge, uſed for this purpoſe. He likewiſe thinks, that it is beſt to dung the hemp ground every year before the winter ploughing, in order that the dung may have time to rot during that ſeaſon, and that the ſpring ploughing may afterwards mix it the more thoroughly with the earth; for all hemp grounds ſhould be well dunged at leaſt once a year.

To prepare the hemp ground thoroughly for receiving the ſeed, it ſhould have two or three good ploughings in the ſpring, or even more if the farmer's conveniency will permit, and the nature of the ſoil be ſuch as to admit of them; for the more frequently it is ſtirred in the ſpring, in proportion to the quality of the ſoil, the better the crop will be. About a fortnight or three weeks ſhould intervene between each of theſe ploughings, and they ſhould at laſt lay the ground quite ſmooth and even. If any lumps or clods of earth yet remain after all theſe ploughings, they ſhould be broken by hand: for the whole hemp ground muſt be as level, and of as fine a mould, as the beds of a garden.

The firſt ſpring ploughing ſhould be given acroſs the former; and before the next ploughing is the proper time to ſpread ſheeps dung, pidgeons dung, poultry dung, or whatever other ſuch like manures are uſed; though ſtill it is to be feared, that, if the ſpring prove dry, theſe hot dungs may burn the ſeed, which they would not do if they were laid on before the winter: but in this caſe a greater quantity of dung muſt be uſed, or leſs advantage muſt be expected from it.

The ſeaſon for ſowing hemp depends in a great meaſure on the quality of the ſoil. In dry light ground, it ſhould be ſown as ſoon as the danger of froſt, or other inclemency of the weather, is over, in the latter end of April or beginning of May, that ſo it may get up early, and, by covering the ground, prevent the danger of drought. In wet cold grounds, it ſhould be ſown later, that is to ſay, not till the ſun has exhaled the too great moiſture of thoſe grounds; and this may not be till the middle, or even the latter end of May. The author of the before mentioned account of hemp, in the Memoirs of the Royal Society of Agriculture at Tours, adviſes to ſow hemp even ſo late as the latter end of June, in caſe the ſeaſon for it be not favourable ſooner; and he obſerves, that the crop ſown then will be as plentiful, and of as good a quality, as if the ſowing had not been delayed ſo long, eſpecially if a very dry ſeaſon does not come on immediately after. The truth of this is evinced by the experience of thoſe who are obliged to ſow a ſecond, and ſometimes a third crop, when their former ſowing has miſcarried through the inclemency of the weather, and particularly of froſt, which is a great enemy to hemp. Another reaſon too, which he aſſigns in favour of late ſowing of hemp, is, that the huſbandman may by this means have an opportunity of deſtroying the firſt growth of weeds, which would choak the hemp, if it were ſown before they had come up.

The huſbandman ſhould be particularly attentive to the weather, when he ſows hemp; for the ſeaſon then ſhould neither be too dry, nor too rainy. If either of theſe is the caſe, he had better defer his ſowing; though he ſhould, if poſſible, always chooſe a time juſt after a gentle fall of rain.

The hemp ſeed that is ſown ſhould always be of the growth of the preceding year, becauſe, as it is a very oily grain, its oil is apt to become rancid, if it be kept long, and the ſeed then loſes greatly of its vegetative power, inſomuch, that, when it is two years old, many of the grains will not riſe at all; and if it be older, a yet leſs quantity will grow. Experience has alſo proved, that, as in other grain, ſo likewiſe in this, it is adviſable every ſecond or third year to chooſe the ſeed from a ſoil different from that on which it is to be ſown.

When the ſoil is deep, and in fine order, it is beſt to ſow this ſeed thick, eſpecially if the hemp be intended for fine uſes, becauſe the plants run moſt into height, when they ſtand cloſeſt together, and their fibres are then by much the finer. They ſhould not, however, ſtand ſo very thick as to choak one another; becauſe this would occaſion a conſiderable loſs of plants. It is therefore neceſſary to obſerve a medium, the knowledge of which is eaſily acquired by practice: and indeed, in general, hemp grounds ſeldom are too thinly ſtocked with plants, unleſs when part of the ſeed has been deſtroyed by froſts, drought, or other accidents. The uſual quantity is three buſhels to an acre.

As ſoon as the hemp ſeed is ſown, it muſt be carefully covered with earth, either by means of a harrow, if the ground has been ploughed, or with a rake, if it has been dug by hand; and beſides this precaution, the whole hemp ground muſt be conſtantly watered till the ſeed has riſen; for otherwiſe numbers of birds, and eſpecially pigeons, will deſtroy it entirely, without ſparing even the ſeeds that have been well buried. It is true, that pigeons and birds which do not ſcratch, do no great hurt to the grains of corn that are well covered with earth: but the huſks of theſe grains do not riſe up out of the ground with their green ſhoots, as thoſe of hemp always do; and then it is that theſe birds, miſtaking them for perfect ſeeds, tear them away with the young plants to which they adhere, and thereby commit vaſt havock. So greedy are the pigeons, in particular, after theſe ſeeds, that none of the common ways of frightening birds will keep them off: nay, M. Du Hamel aſſures us, that he has ſeen ſtrong men, and even dogs, ſo wearied out with fatigue, as to be forced to give up the taſk, when the hemp ground has been large. Happily this troubleſome work does not laſt long; for when the hemp has put forth a few leaves, it requires no farther tending.

Though hemp cannot be weeded without great hazard of damaging the crop, becauſe whatever plants of it are twiſted, bent down, or broken, through inadvertence of the weeders, or by any other cauſe, never riſe again; yet if the weeds are ſo numerous and rank, as to endanger their ſmothering of the hemp, it is neceſſary to root them out, and the moſt careful perſons muſt be employed for this work, which, when rightly executed, is alſo attended with this farther advantage, that the pulling up of the weeds looſens the ſurface of the earth, and thereby forwards the growth of the plants.

In very dry ſeaſons, it will be proper to overflow the hemp ground, if it can be done. To this end ſome authors adviſe letting in the water from the ditches, as is practiſed for rice grounds. If any parts of the hemp ground are in danger of being burnt up, it will be adviſable to water them, or perhaps rather the whole in ſuch caſe, even by hand.

 If,

If, by any accident, the hemp grows very thin, so as to be thereby in danger of branching out too much, and of becoming woody; this should be an additional motive for keeping it perfectly clear of weeds, in order to let it remain for seed, which will be so much the better for the plants having stood thin.

The male hemp (which is the species that produces the *farina fœcundans*) ripens earlier than the female, generally by three weeks, or even a month: but the time of the ripening of either depends much on the nature of the soil. The male hemp shews its ripeness by turning yellow at top, and whitish at the bottom of the stem: but this sort, in particular, should be pulled rather before it is quite ripe, that is to say, while it is yet somewhat green; for if it be too ripe, its fibres will adhere so strongly to the reed, as not to be separated therefrom, without some loss; neither will they be soft, and consequently not so fit for domestic uses, as those of hemp that is pulled before it has attained to a perfect maturity.

The ripeness of the female or seed-bearing hemp, is known, not only by the same signs as that of the male, but also by the seeds beginning to turn brown, and by the capsules which contain them beginning to open.

As soon as the male hemp is ripe, it is pulled stem by stem, and with caution not to injure the female hemp, which, as we before observed, must remain on the ground some weeks longer, that is to say, till it also is ripe, and then it must likewise be pulled stem by stem.

Each handful that is thus pulled should consist of plants, as nearly as possible of equal length, and their roots in particular should be placed as even as can be. Some tie up each handful, especially of the male hemp, with a stalk of hemp, then lay it in the sun to dry its leaves and flowers, which they afterwards beat off, by striking it against a tree or wall; they then put several of these handfuls together, so as to form a pretty large bundle, and in this condition they carry it to the watering place.

I have just mentioned what M. Du Hamel says of the common practice of drying the hemp before it is steeped: but I must here observe, that it is a matter of doubt, whether this plant should be dried before it is steeped. Those who are for drying it first, say, that the hemp becomes thereby stronger than when it is steeped without having been previously dried: for my part, I must confess, that this drying seems to me to be a needless trouble; for as it is necessary in the steeping of hemp, that a certain degree of putrefaction should arise, sufficient to destroy the texture of that glutinous substance which connects the fibres to the woody part of the hemp, it certainly is more adviseable to lay the hemp in the water as soon as can be after it has been pulled, because the more there is of the natural moisture left in this glutinous substance, the sooner the putrefaction will begin. If, either by design or accident, the hemp has been dried, the putrefaction comes on more slowly and more unequally, and the fibres contract a hardness which the steeping afterwards will not easily correct.

The common height of hemp, when full grown, is from five to six feet: but M. Du Hamel remarks, that the stems of the hemp which is cultivated near Bischwiller, in Alsace, are sometimes upwards of three inches in diameter at their bottom, and above twelve feet high. These, indeed, are so deeply rooted, that even a very strong man can hardly pull them up.

When the female hemp is let stand till its seed is perfectly ripe, its bark becomes woody, and so coarse, that no future operation can bring it to a proper degree of fineness. For this reason, it is generally pulled before the seed is quite ripe: but as it is manifestly the husbandman's interest to sow none but the best seed, he ought not to grudge the sacrificing of the goodness of a small part of his hemp, to the superior advantage of obtaining perfect seed, by letting a proper number of these plants stand till their seeds have attained full maturity. The judicious M. de Chateauvieux, whose attention extended to the most proper method of cultivating every useful plant, did not neglect so important an object as the quality of the hemp employed in cordage, and the means of obtaining its seed in the greatest perfection. However, not having had opportunities of continuing his experiments long enough to draw certain conclusions from them, he invites all those who have the public good at heart, to make experiments which may lead to the utmost improvement of the culture of this plant: "but, says this friend of mankind, these motives of œconomy are vastly inferior to the inestimable advantage of saving ships, their cargoes, and their crews, which often depends on the strength of their sails and cables."

On the twenty-sixth of April, 1753, he sowed six beds with his drill plough, placing six rows in each bed. The beds were seven feet wide, and the soil strong, but in very fine tilth. He treated his plants with great care, according to the principles of the new husbandry: but both that and the ensuing year were unfavourable to the growth of hemp. However, he observes, in general, that his plants were five or six feet high, that their stems were large, and their bark very thick and strong. They were very fruitful in seed, especially the two outer rows, which had profited most by the hoeings. M. Aimen, from forty plants of hemp, raised in the common way, and which might be deemed fine ones, had only a pound and an half of seed; but a single plant which grew by itself, yielded him seven pounds and a half, of much better seed than any that is produced in the common way. From hence it results, that it must be of great advantage to the husbandman to set apart a spot of ground sufficient to rear thereon as many plants of hemp, as will afford him seed enough for the purpose of sowing, and to cultivate them according to the principles of the new husbandry.

In some countries, to complete the ripening of the seed, round holes are dug, about a foot deep, and three or four feet in diameter, in different parts of the hemp ground, and the handfuls of pulled hemp are set as close together as can be in these holes, with their seed ends downward, and their roots uppermost; after which, to keep them in this position, the whole is tied round with bands of straw, and the earth that was taken out of the hole is thrown up all around this great sheaf, so as quite to bury the heads of the hemp, which, when thus covered, heat by means of the moisture contained in them, in the same manner as a stack of green hay, or a heap of dung. This heat completes the ripening of the hempseed, and disposes it the more easily to quit its husks; and when it has been brought to this condition, the hemp is taken out of these holes, where it would become mouldy, if it were left longer in them. But, as is justly observed in the excellent Memoirs of the Royal Society of Agriculture at Tours, it is hard to conceive, how an operation which tends to bring on at least some degree of putrefaction, can ripen the seed; and therefore this must be at best a very dangerous practice, especially as a seed so very oily as that of hemp, and consequently so apt to become rancid, cannot but be liable to be rendered still more so by this degree of heat.

In other places, where the crops of hemp are great, the husbandmen do not bury the heads of their seed hemp in the manner above described, but only lay it in heaps, with the seed ends one against another: others, whose crops are smaller, content themselves with spreading upon the ground a cloth to receive their hempseed; and others again only spread their bundles upon a clean spot of ground, with all the heads turned the same way. The seed ends thus placed are beaten slightly, either with a stick, or a light flail. The seed which falls out easiest is always the ripest and best, and should therefore be reserved for sowing the next spring: and as to that which remains in the heads of the hemp after this operation, it is got out by combing the heads on the teeth of a ripple, which pulls off the leaves, the husks of the seeds, and the seeds themselves, all together. These are gathered in a heap, and left in that condition for a few days, in order that they may heat a little, after which they are spread out to dry, then they are threshed, and finally, the seeds are separated by winnowing and sifting. This second seed is much inferior to the first, and accordingly it is used only for extracting oil from it, or for feeding of poultry.

It is, on this occasion, justly remarked in the Memoirs of the Royal Society of Agriculture at Tours, that by the threshing of hemp there is always danger of bruising some of its seeds, and that the bruised seed will not grow, though it may be fit for yielding oil. Nor is this all; for by threshing out the seed, there is a mixture of imperfect seed with that which is fit for sowing; and this

this is the reaſon why huſbandmen have always found it neceſſary to ſow a greater quantity than would otherwiſe be requiſite, in order to make up for the uncertainty of its growth.

The method of ſeparating the fineſt grains of wheat for ſowing, by throwing the corn to a diſtance on a barn floor, is equally adviſable for obtaining the heavieſt and beſt hemp ſeed, where proper care has not been previouſly taken to provide ſuch. In this caſe, the ripple may be uſed to ſeparate the whole of the ſeed from the plant, and this will prevent the inconveniencies which ariſe from the threſhing or beating out of the ſeed.

The method of laying the hemp down in order to its being ſteeped, is to place it in bundles at the bottom of the water, there to cover it with a little ſtraw, to keep the dirt from ſticking to it, and then to load it with pieces of wood and large ſtones, to keep it down, ſo that it may be always five or ſix inches below the ſurface of the water.

The intention of ſteeping the hemp in water is, to make its bark part the more eaſily from the reed, and to deſtroy the outer ſkin; or, if I may here be allowed the language of anatomiſts, the cellular membrane which connects the hemp with the reed. All this is effected by only a ſmall degree of putrefaction, ſo that it is dangerous to let the hemp lie too long in the water, for it will then be over ſteeped, that is to ſay, the water will not only have acted upon the outer ſkin and the connecting fibres, but it will alſo have leſſened the longitudinal coheſion of the fibres; in ſhort, the hemp will be too much rotted, and in this caſe the ſtrength of thoſe fibres will be proportionably impaired. On the contrary, when the hemp has not lain long enough in water, its bark adheres to the reed, its fibres are hard, and they cannot ever after be rendered ſufficiently fine. There is therefore a medium to be obſerved; and this medium depends, not only on the length of time that the hemp is to remain in the water, but alſo,

1. On the quality of the water; it being ſooner ſteeped ſufficiently in ſtanding water, than in a running ſtream; and ſooner in ſtagnant putrid water, than in that which is clear.

2. On the temperature of the air; for it requires leſs time to be ſufficiently ſteeped in hot weather, than in cold.

3. On the quality of the hemp; that which has been raiſed on a rich mould where it has not wanted for water, and which has been pulled whilſt yet a little green, being ſooner ſteeped to a proper degree, than that which has grown on a ſtiff or dry ground, and which has been let ſtand till it was quite ripe.

In general, when the hemp has been ſteeped but a ſhort time, its fibres are thought to be the better. Hence ariſes the opinion, that hemp ſhould not be ſteeped but in hot weather; and for this reaſon alſo it is that many, when the autumn is cold, defer the ſteeping of their female hemp till the next ſpring. It is likewiſe for the ſame cauſe that ſome prefer ſteeping their hemp in ſtanding water, or even in ſtagnant waters, that is putrid, rather than in ſpring or running water.

M. Du Hamel, to whom we are indebted for the foregoing remarks, ſteeped hemp in different ſorts of water, and it appeared to him, that the fibres of the hemp ſteeped in putrid ſtanding water were ſofter than thoſe of that which had been ſteeped in running water: but they contract in water which does not run, a diſagreeable colour, which does not indeed do any real injury to the hemp, for that which has been thus ſteeped is afterwards the moſt eaſily bleached; but yet, as this colour diſpleaſes, and the hemp is the leſs ſaleable for it, endeavours are always uſed, if poſſible, to make a ſmall ſtream of water paſs through the ſteeping places, thereby to change the water in thoſe places, and to prevent its becoming putrid.

He ſucceeded likewiſe in rendering hemp fit to ſeparate from the reed, by ſpreading it upon a meadow in the ſame manner as is practiſed for bleaching of linnen: but he found this method tedious and troubleſome; nor did the fibres of the hemp ſo prepared ſeem to him to differ much from thoſe of hemp ſteeped in the common way.

He alſo tried the boiling of hemp in water, in hopes of bringing it ſpeedily to the ſame condition as it is in when taken from the uſual place of ſteeping: but when, after having been boiled upwards of ten hours, it was taken out of the water, in order to be dried, it was not at all fit for either peeling or breaking. It is true that, while it yet remained hot and wet, its bark ſeparated eaſily from the reed; but at the ſame time it peeled off like a ribbon; the glutinous ſubſtance which connects the longitudinal fibres, and makes them adhere cloſely to each other, not being at all deſtroyed, ſo that they could not be ſeparated, nor was it poſſible to divide them into fine threads. It is evident from what has now been ſaid, that no preciſe time can be fixed for the ſteeping of hemp; ſince the quality of the hemp, that of the water, and the temperature of the air, haſten or retard this operation.

M. Marcandier is of opinion that the fineſt and cleareſt water is always the beſt for ſteeping hemp; and he approves of the method of thoſe who make a kind of ditch on the edge of a river, where the water, being more ſtill and warm, ferments eaſily, and penetrates more quickly the parcels of hemp that are laid in it. When they are taken out of this ditch, it will be ſufficient to waſh them in the current of the river, which will carry off all the gum and mud that would otherwiſe cleave to them. He holds, that the hemp which has been ſteeped in rivers is always whiteſt, and of the beſt quality; and that that which has lain in ditches, pools, or reſervoirs of ſtanding water, is always of a bad colour, has a very diſagreeable ſmell, is loaded with dirt, and loſes a great deal in the dreſſing. Theſe are M. Marcandier's ſentiments on this ſubject; and if they are the reſult of his experience, as I preſume them to be, I cannot but regret his not having related the particulars of his experiments.

The judiciouſly accurate Memoirs of the Society which the illuſtrious ſtates of Brittany have eſtabliſhed for the improvement of Agriculture, Commerce, and Arts, are more particular in this reſpect, and conſequently more ſatisfactory. After obſerving, that it is ſtill undetermined whether hemp ought to be ſteeped in running or ſtanding water, that each cultivator of this plant gives the preference to the method he has been uſed to follow, and that naturaliſts have not yet written any thing deciſive on the choice of the waters fitteſt for this preparation, the moſt important of any that hemp undergoes, becauſe it is on this that the eaſe and goodneſs of the hackling, ſpinning, and fabricating in a great meaſure depends; the Memoirs, I ſay, of theſe zealous patriots inform us, that one of the members of their office at Rennes thought that this diverſity of opinions and cuſtoms might proceed from running water's being, in fact, always preferable in ſome caſes, and from ſtanding water's being always the beſt in others. For example; in cold and rainy years the plant muſt be weaker, longer green, and fuller of juice, than in dry years, in which laſt the hemp will be ſtronger, but at the ſame time harder and more woody. Why then, ſay they, very judiciouſly, ſhould it be expected that the ſame waters applied to ſo different productions, ſhould have a ſimilar effect upon each?

To remove all doubt in this reſpect, the Society ordered ſome hemp to be pulled in different parts of the province of Brittany, and in different ſtates of growth. Some was pulled before it was ripe, ſome exactly when it was ripe, and ſome ſeveral days after it was ripe. Each of the parcels of theſe three ſorts of hemp was divided into two equal parts, one of which was laid to ſteep in running water, and the other in ſtanding water. They were afterwards hackled with very great care, and examined with the moſt ſcrupulous attention, by a perſon thoroughly acquainted with the defects and good qualities of this commodity.

Minute accounts of every circumſtance attending theſe experiments, and of their reſult, were ſent to the office at Rennes; and the Society, ſenſible of the vaſt importance which the aſcertaining of this point may be of in many reſpects, deſired that they might be repeated in one and the ſame year on the hemp of all the diſtricts of the province, and the reſult of their firſt experiments was as follows:

1. There was a ſenſible difference between the ſame hemp pulled in the three ſtates before-mentioned. 2. All the

the hemp that was ſteeped in running water, was incomparably whiter than that of the ſame quality which was ſteeped in ſtanding water. 3. The hemp which was pulled before it was ripe, acquired the greateſt degree of whiteneſs. 4. The whole of the loſs of ſubſtance, upon ſumming up the waſte occaſioned by each particular preparation, was leaſt upon the whiteſt hemp; but that which had been ſteeped in ſtanding water yielded a greater quantity of fine fibres, and the great loſſes in point of quantity fell upon the firſt dreſſing. 5. The hemp which was judged to be the beſt before it was hackled, did not always preſerve its ſuperiority when hackled. That which was at firſt looked upon as only of a middling, or even of an inferior quality, proved to be the fineſt and beſt after it was hackled. This obſervation is of great importance, eſpecially when the hemp is intended for naval uſes.

"We ſhall not, add theſe truly intelligent patriots, limit our inquiries to a bare repetition of theſe experiments. We purpoſe to extend them further, in order to have facts which may be entirely relied on. We ſhall cauſe the beſt and beſt prepared of each different kind of hemp to be ſpun by the ſame hand, into as ſmall and fine threads as the hemp is capable of affording, that ſo we may judge to which of the different manners of ſteeping this plant the preference is due, by the greater diviſion of which its fibres may be ſuſceptible. Theſe threads ſhall be exactly weighed, and ſhall undergo ſimilar preparations in exactly ſimilar leyes; after which they ſhall be weighed again, in order to judge of their goodneſs by the diminution which each ſhall have ſuffered in the leyes, and by the degree of whiteneſs which each of them ſhall acquire. Theſe experiments, though extremely uſeful in themſelves, are, however, only introductory to a greater enterprize: they will lay a ſure foundation for the improvement of every manufacture of hemp, and particularly of ſail-cloth, which is an article of the utmoſt importance to all commercial nations."

The Memoirs of the Royal Society of Agriculture at Tours, for the year 1761, prefer river water, eſpecially that of rivers which run upon a bed of ſand, as the beſt for ſteeping of hemp; becauſe this water, being clear, renders the colour of the hemp brighter than it would otherwiſe be, as there is not any filth therein to ſully it: and it peels the more eaſily when ſo ſteeped, not being there liable to ſo great a degree of putrefaction, as to break the cohesion of the fibres of its bark. It is not, however, here meant, that the hemp ſhould be ſteeped in the bed of the river, becauſe the inequality of the motion of the water on the ſides, and in the middle of the hemp, would prevent the ariſing of that equal degree of putrefaction which is in this caſe eſſentially neceſſary. On the ſide of ſuch rivers, a hollow ſhould be dug three or four feet deep, and proportioned in extent to the quantity of hemp to be watered.

As it is contrary to law that the places for ſteeping hemp be made in running water, it would be of advantage to contrive them ſo that the waſte water from the ſteeping places ſhould run off upon paſture-grounds; becauſe the quantity of putrid vegetable matter which the water wherein hemp has been ſteeped carries along with it, would greatly enrich thoſe grounds; and with this view likewiſe all the water of pools or other places uſed for the ſteeping of hemp, ſhould be thrown out of them upon the graſs, as ſoon as the hemp has been removed.

It is eſſential to take heed, that the hemp be not, by any means, laid to ſteep in water in which there are any animals that might be apt to gnaw it; for theſe would cut aſunder, and totally deſtroy its fibres. Of this kind are, in particular, thoſe creatures which ſome people call freſh-water ſhrimps.

The common method of judging when the hemp has been ſufficiently ſteeped, is by trying whether the bark parts eaſily from the reed, and can be peeled off its whole length without breaking; for in this caſe it is thought to have been watered enough. However, it muſt alſo be allowed, that long practice enables the peaſants who cultivate hemp to give it, generally, a due degree of ſteeping, though they do ſometimes miſtake: and it is alſo to be obſerved, that it is the conſtant cuſtom of ſome countries to ſteep their hemp more than others. But the ſureſt way of all to diſtinguiſh whether the hemp has been ſteeped enough, is, as the Tours Memoirs remark, to take ſome of the ſtems out of the water, and then to try whether the extremity of the roots ſnaps off ſhort, and whether the bark ſeparates clear from the reed, its whole length; for in theſe caſes it is certain that the hemp has been ſufficiently watered, and it ſhould then be immediately taken out. If the bark does not ſeparate equally, but ſtops chiefly at the ſmall knots which appear on the ſtem, this ſhews that it has not been ſteeped enough.

The uſual duration of the ſteeping of the male hemp is from three to ſix days, according to the weather; and of the female hemp, from five to eight or ten days: but as only a ſmall degree of too much or too little ſteeping is equally hurtful, the utmoſt attention ſhould be exerted to hit the preciſe time of its being duly watered.

Some injudiciouſly neglect to waſh their hemp when it is taken out of the water, becauſe, ſay they, the filth brought out of the water with it will afterwards fall off: but, in the drying of the hemp, this filth gives it a bad colour, and the duſt which ariſes therefrom is extremely prejudicial to the health of the workmen.

When the hemp, after having been properly ſteeped, is taken out of the water, the bundles of it ſhould be untied, and ſpread upon ſand, or upon ſtrong rocky ground; or, if neither of theſe be at hand, it may be laid upon a field that has been lately reaped, and where the ſtubble ſtill remains ſtanding. This ſtubble will keep it hollow, and it will dry the ſooner. Some dry their hemp by ſpreading it out and ſetting it upright againſt a ſunny wall, or by laying it along the ſide of a ditch. Graſs is not fit for laying it on, becauſe there will ariſe from thence a moiſture which will rot the hemp. For this reaſon it is, that the place where hemp is ſpread to dry, ſhould be as free as poſſible from every kind of damp. When the hemp is thoroughly dry, it is bundled up again, and carried home, where it ſhould be kept in a very dry place till it is wanted for peeling or breaking.

The method of peeling hemp is ſo ſimple, that a deſcription of it would be needleſs: even children, and the aged and infirm may perform it with eaſe, by only taking one ſtalk after another, breaking the reed, and ſlipping off the bark. This may likewiſe become the employment of every perſon belonging to the farm in winter evenings, and at ſuch times as the weather will not admit of their working without doors. It muſt however be allowed, that there are ſome inconveniencies attending this method: the peeled hemp comes off in ribbands, which do not anſwer in the hackling ſo well as that which has been broken; more of the uſeleſs membranes, eſpecially towards the root, ſtill adhere to it, and, by increaſing its weight, render it, to uſe the common ſaying on this occaſion, better for the ſeller than for the buyer; beſides which, the hemp does not always peel off in equal lengths, and from thence ariſe conſiderable diſadvantages, and loſs in its future dreſſings.

The hemp which is to be broken ſhould firſt be rendered very dry; becauſe the reed will then be more brittle, and therefore part the more eaſily from the bark. There are ſeveral ways of drying it. Meſſieurs Du Hamel and Marcandier deſcribe a kind of cave or cavern, in which it is commonly dried in many parts of France. This cavern is generally ſix or ſeven feet high, five or ſix feet wide, and nine or ten feet long. A hollow under a rock is often properly made uſe of for this purpoſe: but as that cannot always be met with, it frequently is neceſſary to have recourſe to art. In this caſe, ſome form the top of their vault with dry ſtones, others cover it with broad flat ſtones, and others again only cloſe it with pieces of wood, over which they lay a quantity of earth ſufficient to ſtop up all the interſtices: but which ever of theſe methods is taken, the drying place ſhould be ſo ſituated as to be ſheltered from the north and north-eaſt winds, and be open to the ſouth, that it may receive the benefit of the ſun; becauſe the uſual ſeaſon for breaking of hemp is in clear froſty weather, when the buſineſs of the field is ſuſpended.

At about four feet above the floor of this drying place, and two feet from its mouth or entrance, three bars of wood, about an inch thick are placed acroſs the cavern, from ſide to ſide, and there fixed. On theſe bars is laid, about ſix inches thick, the hemp that is to be dried. A careful perſon, which generally is a woman, then keeps conſtantly burning, under the hemp ſo laid, a ſmall fire made of fragments of the reeds of hemp that has already been broken or peeled. The perſon thus employed muſt be extremely watchful, becauſe, as this kind of fuel is ſoon conſumed, and muſt of courſe be frequently repleniſhed in order to keep a conſtant and regular fire all over the hearth (for this is abſolutely neceſſary) very great care muſt be taken that the flame do not ever riſe ſo high as to ſet fire to the hemp, which is exceedingly combuſtible, eſpecially after it has been dried ſome time. The ſame perſon alſo takes care to turn the hemp from time to time, in order that it may be dried equally in all its parts; and likewiſe to put on freſh hemp, when the former is dry enough to be taken away and ſent to the break.

Where but a ſmall quantity of hemp is to be dried, an oven is doubtleſs the ſafeſt method; and when the hemp is dreſſed at home, it may perhaps be dried as faſt by this means, as the other avocations of the family will admit of its being wanted. The only attention requiſite in this caſe, is that the oven be not ſo hot as to endanger the fine and tender fibres of the hemp: for too great a heat may not only ſcorch them, but likewiſe ſo parch the oil in the hemp, as that the hemp will afterwards remain harſh and dry, and not be ſo eaſily whitened as it might otherwiſe be.

It alſo is uſual, where the quantity of hemp is greater than can be managed with an oven, to dry it on a kiln; and this is a good method; provided the fire here be alſo very moderate, and made of ſuch materials as do not blaze or ſparkle, becauſe of the great aptneſs of dry hemp eaſily to take fire. Coke is perhaps the very beſt fuel that can be uſed for this purpoſe.

The operation of breaking hemp, by which general term is however ſtrictly meant only the breaking of the reed, which ſome call the bunn, or woody part of the ſtem, within the bark; for the bark itſelf, of which is made the filamentous ſubſtance that is ſpun and uſed in manufactures, only bends under the hand of the dreſſer, and does not break; this operation, I ſay, has hitherto generally been executed three ways, namely, by beating the hemp with beetles, which is a laborious and tedious work; or by the Dutch hand-break, which is in every reſpect much preferable to the beetle; or by fluted rollers worked by horſes, wind, or water, but of choice by the latter, where a running ſtream can be procured. This laſt is more expeditious, and leſs laborious than either of the other ways; but is dangerous to the workmen employed therein, becauſe, if by any inadvertence the rollers ſhould catch hold of their fingers, the loſs of a limb at leaſt is inevitable. The only means of preventing this dreadful conſequence, in ſuch a caſe, is to have an iron crow at hand, ready to clap inſtantly between the rollers, as is practiſed in ſugar-works, which are of a ſimilar conſtruction.

The fluted rollers are undoubtedly the beſt inſtrument for breaking hemp, becauſe the length of the ſtalk and ſtrength of the reed of this plant muſt render the Dutch-break a very tedious operation, eſpecially when large quantities of hemp are raiſed, as muſt be the caſe wherever a ſufficiency of it is cultivated to anſwer the purpoſes of the great and important manufactures in which it is employed in this nation.

The Moravian hemp mill, uſed in America, is alſo a good inſtrument. It conſiſts of a large heavy ſtone, ſhaped like a ſugar loaf, with the ſmall end cut off. A body of that form will go round in a circle, if it be moved on a plane. This is moved by a water mill, and the hemp, being laid on the floor, in its way, is bruiſed by the weight of the ſtone paſſing over it.

After the hemp has been broken, it undergoes a ſecond operation, which is commonly termed ſwingling or ſcutching. The intention here is, to ſeparate the reed from the hemp, and this is done by one or other of the following ways. In the firſt, the workman takes a handful of hemp in his left hand, and, holding it over the edge of a board, ſtrikes it with the ſharpened edge of a long, flat, and ſtrait piece of wood, commonly called a ſwingle hand, or ſcutcher. The author of the thirty-ſeventh letter in the Dublin Society's Weekly Obſervations recommends that the cutting edge of the ſcutcher be made of a circular form, in order that its greateſt force may fall on the middle of the hemp, and thereby ſpread it, by which means it will be the more equally cleared of the remaining broken pieces of the reed. But this method is, at all events, very laborious and tedious; and therefore water mills have been erected, in which ſeveral ſcutches, fixed in the ſame axle-tree, are moved with great velocity. Here the work is performed with great expedition, and much leſs fatigue to the workmen; but a greater waſte is made of the hemp, owing to the velocity with which this engine is turned.

Before the hemp thus prepared is heckled, it uſually undergoes a third operation, called beetling, the deſign of which is to looſen and thereby more thoroughly ſeparate its fibres. The beetles uſed for this purpoſe are moved either by hand or by water.

We have already deſcribed the inſtruments invented by Mr. Macpherſon for performing theſe operations with very great facility, under the article flax, and therefore need not be repeated here. See the article FLAX.

Mr. Marcandier propoſes, inſtead of ſcutching and beetling the hemp, to give it a ſecond ſteeping after it has been peeled or broken, the better to ſoften the bark that may ſtill remain hard, and not be eaſily brought to a proper degree of fineneſs. For this purpoſe, the hemp intended to be ſteeped a ſecond time is divided into ſmall parcels: theſe are tied looſely round the middle with a piece of packthread, in order that they may be managed eaſily without mixing or entangling them; and the hemp thus tied is laid in a veſſel filled with water, where it is left, more or leſs time, according to the hardneſs of its fibres and the quantity of glutinous adherent matter ſtill remaining on it. Three or four days are always ſufficient for this purpoſe: but a leſs time will do, if the hemp wants only to be cleared of that adherent matter. When it has been thus ſteeped long enough, it ſhould be waſhed very clean in a running ſtream; and if many of the fibres of the hemp are found to cling together in what our author calls ribbands, he adviſes to beat them in the manner that linen is beaten in bleaching.—It is ſafer to err in too little, than in too much ſteeping; becauſe, after the fibres have been looſened in the break, they will be the more liable to be deſtroyed by even only a ſlight degree of putrefaction. When the fibres of the hemp are ſufficiently diſengaged from each other, they ſeem, while immerſed in water, to be as completely dreſſed as if they had already paſſed through the hackle. After this watering, the parcels are opened, ſpread on a board, and laid in the ſun to dry.

M. Marcandier obſerves farther, and likewiſe from his own experience, that, after this preparation, the hemp may be again ſteeped and waſhed in a leye of pot-aſh or wood aſhes, rendered perfectly clear of all filth. This will undoubtedly contribute to the removing of any ſuch matter ſtill remaining in the hemp, as muſt neceſſarily fall off in the future preparations, before the manufacture made of the hemp is fit for uſe. And, indeed, a leye of this kind bids fair to be of ſervice in the preparing of flax as well as hemp; becauſe, both being thereby perfectly freed from every particle which muſt otherwiſe fall off in the future operations of hackling, ſpinning, bleaching, &c. the cloth or other manufacture made of them will be proportionably better and more durable. The time taken up in bleaching will, in particular, be very much ſhortened thereby.

In the whole of this proceſs, the water ſhould be warm, becauſe warm water acts more powerfully than cold in diſſolving the impurities which are to be ſeparated from the hemp; and it is alſo an indulgence to the people employed in this buſineſs, who might otherwiſe be more apt to ſlur over their work. It will therefore be moſt adviſable to perform this operation when the weather is moderately warm, thereby to ſave the trouble and expence of making fire to warm the water or the leye.

M. Marcandier having experienced the efficacy of horſe-cheſnuts in the bleaching of linen and cleanſing of woollen ſtuffs, made likewiſe uſe of a ſolution of them in water, as a leye for preparing hemp in the manner above deſcribed. The method of preparing this leye is as follows: the cheſnuts are peeled, and then raſped as fine as poſſible into ſoft water, in the proportion of two, or, at moſt, three nuts to every quart of water. This is done ten or twelve hours before the mixture is to be used, and in the mean while it is stirred from time to time, the better to dissolve these raspings and impregnate the water. The last stirring is given a quarter of an hour at farthest before the water is drawn off from the coarser part of the raspings, which sinks to the bottom; and this is done, either by inclining the vessel and pouring the leye off gently into another, or by lading it out by hand, while the water is yet white, and froths like soap-suds. In order to use this leye, it is made rather hotter than the hand can well bear, and the hemp is then steeped and washed in it, as in soap-suds.

The hemp thus prepared is carefully dried, laying the fibres smooth and as little intermixed as possible. When dry, it is doubled, and twisted at the ends, or tied up in bundles. The farther business of the hemp-dresser need only be an easy beating of the hemp, and that chiefly to separate the fibres that may have clung together in the drying, and to the common operations of the heckle. The danger so often fatal to the dressers of hemp, from the dust drawn in with their breath, will also be hereby in a great measure avoided; and the hemp thus prepared will be white, smooth, soft, and flexible.

The same author extols highly the various uses to which hemp thus prepared, and even its tow, or what is separated from it by the heckle, may be applied. This hemp, he informs us, may be dyed like silk, wool, or cotton, and may be made into cloth, stuffs, and garments of all kind; and that a great advantage attending the use of this material is, that it will not be in danger of being destroyed by those worms which eat woollen cloth. These advantages attending hemp prepared in the manner which Mr. Marcandier has proposed, may well deserve the farther experiments and attention of our manufactures, especially at Manchester, or wherever else our mixed stuffs are made.

Having now described the manner of cultivating hemp, and the several methods by which it is prepared for the manufacturer; we shall close this article with M. Du Hamel's following directions how to judge of the quality of the hemp that has been dressed, and is intended for manufacturing.

It is of importance that the hemp in bales, for so it is always packed, be not damp; because it would then weigh heavier than it ought, and would be apt to contract a heat, which might end in rottenness. The hemp in each head, or bundle, should be as nearly as possible of equal length, and diminish gradually from the root end to the point. That which has been broken is softer, and its fibres are more separated, than that which has been peeled. From hence it would seem as if this hemp might be worked up with less loss of substance than peeled hemp; but yet, in fact, it generally yields the greatest quantity of refuse, not only because it is never so well cleared from the reed, but also because its fibres being mixed and intangled with each other, a greater number of these are broken when it is heckled. It is, however, on the whole, most probable, that breaking may be the best way of dressing very hard and strong hemp, because the break certainly contributes greatly to render it soft and fine.

Too great a stress is sometimes laid on the colour of hemp: that which is of a silver or pearl colour is reckoned the best, that which has a greenish hue is likewise deemed good, that which has a yellowish cast is less esteemed, and the dark colour only is rejected: but at the same time it should be observed, that the colour of hemp depends chiefly on the sort of water in which it has been steeped, that being dark which has been steeped in standing water, and that light coloured which has been steeped in running water; and therefore, that the colour of the hemp does not in fact deserve very great attention, unless it be black, or of a very dark brown. In these cases, indeed, it may be presumed, that the hemp has either been steeped too much, or that it was packed up so moist as to have been heated in the bale. The smell of the hemp is more to be relied on than its colour; and in consequence thereof, that which has a rotten, mouldy, or heated scent, should be absolutely rejected, whilst that which savours strong of only the natural smell of hemp should be preferred, because this indicates it to be of the growth of the last crop; a circumstance which is much attended to in the rope-yards, because new hemp is found to waste much less in the working than old, though it is at the same time true, that it does not heckle so fine.

In general, it may be laid down as a rule, that the hemp which feels softest, and whose fibres are the finest and most equally separated, is the best.

M. Du Hamel, who has long exercised with distinguished honour, perfect disinterestedness, and judgment equal to his high and well deserved fame, the important office of inspector general of the marine of France, tells us, that the common way of examining the hemp there, in order to judge of its strength and fitness for naval uses, is, to take here and there a little of it out of each bale that is delivered into the royal stores, and to try whether, when a few of its fibres are put together, they break easily, or with difficulty, between one's hands. If they resist much, the hemp is judged to be good; and if, on the contrary, they break easily, it is deemed bad. But this he thinks an erroneous way of judging of its quality, because the fibres of coarse and hard hemp are often strong enough to bear this trial; and yet, as appears from numbers of experiments which he made with admirably nice understanding and precision, the ropes made of that hemp never are near so strong, and consequently not near so serviceable as those made of fine, soft, and supple hemp, the fibres of which might be broken with less force than the former. If, to this fineness, suppleness, softness, and silky feel of the hemp, strength of fibres be added, such hemp is perfect, and the works made of it will be least bulky, and at the same time by far the strongest and most durable. For this reason in particular it is, that the male or karl hemp is always preferred to the female or fimble hemp, especially when this last has been let stand longer than the other, to ripen its seeds, in consequence whereof it become harder and more woody, and does not yield so fine fibres; nor does it, therefore, bear so great a price. The female hemp is generally browner than the male; this last being of a brighter and more silvery colour: but however, if, upon the whole, there be not a greater quantity of female hemp in a bale, than there is of male, M. Du Hamel thinks it need not be complained of.

Two farther, and those very essential, circumstances which the buyer should notice in his choice of hemp, are, first, to examine whether any of the reed be left, and whether it adheres strongly to the hemp; for if it does, this is a sign that the hemp has not been steeped enough: and, secondly, if it be free from all remains of the reed, to examine attentively its upper end, or point; for this will break too easily if it has been steeped too much, otherwise it will retain a proper degree of strength.

The store-rooms for keeping hemp should be raised so high from the ground, as to be very dry; and they should also be well aired. Great care should be taken that the hemp be thoroughly dry before it is piled up in them, and spaces should be left between the piles, for the circulation of fresh air whenever this is requisite. The hemp should also be sorted when it is piled, in such manner as to put together in the same heap, as nearly as possible, that which is of equal length, and of a similar quality.

The owner of these stores should examine them carefully from time to time, by thrusting his arm as far as he can into the piles, in order to judge whether the hemp heats; for if it does, the pile or heap should be immediately taken down, and the bundles should be untied, aired, and afterwards removed into other places.

Rats and mice must be guarded against with all possible caution; for they are extremely fond of forming their nests in hemp, in doing of which they gnaw asunder such quantities, as thereby to occasion very great loss and damage.

HEPS, the fruit of the species of wild rose, generally written hips.

HERBAGE, grass, pasture in general. It is also used to signify the tythe and right of pasture.

HERD, a number of beasts together, generally black cattle.

HERDSMAN, a keeper of herds, one employed in tending cattle.

HIDE, the skin of beasts, but particularly applied to those of large cattle, as bullocks, cows, horses, &c.

HIDE *of Land*, was such a quantity of land as might be ploughed with one plough within the compass of a year, or so much as would maintain a family; some call it sixty, some eighty, and some an hundred acres.

The distribution of this kingdom by hides of land is very ancient, mention being made of it in the laws of king Ina. Henry I. had three shillings for every hide of land, in order to raise a dowry for his daughter: this tax was called hidage.

HIDE-BOUND, a distemper in horses, when the skin sticks so fast to the back and ribs, that the hand cannot separate the one from the other, without great difficulty; his body is at the same time lean, his back-bones stand up, his guts are for the most part deficient in moisture, and his dung dry, and more offensive than common.

If a horse become hide-bound by hard riding and ill keeping, he may be cured by good keeping. If it be the effect of a fever, or some other disease, if that be cured which is the cause, the effect will cease; but if he has no fever upon him, and he is hide-bound only from lowness of blood and spirits, give him boiled barley, white-water, or the like, and when his flesh is raised, harden it with good oats, beans, and moderate exercise.

HILL, an elevation of ground, less than a mountain, a down.

HILLS, are of great use in a garden; as,

1. They serve as screens to keep off the cold, and nipping blasts of the northern and eastern winds.

2. The long ridges and chains of lofty mountains, being generally found to run from east to west, serve to stop the evagation of those vapours towards the poles, without which they would all run from the hot countries, and leave them destitute of rain.

3. They condense those vapours, like alembic heads, into clouds; and so, by a kind of external distillation, give origin to springs and rivers; and, by amassing, cooling, and constipating them, turn them into rain, and by that means render the fervid regions of the torrid zone habitable.

4. They serve for the production of a great number of vegetables and minerals, which are not found in other places.

It hath been found by experiment and calculation, that hills, though they measure twice as much as the plain ground they stand upon, yet the produce of the one can be no more than the other; and therefore, in purchasing land, the hills ought not to be bought for more than their superficial measure, *i. e.* to pay no more for two acres upon the side of an hill, than for one upon the plain, if the soil be equally rich.

It is true, that those lands that are hilly and mountainous are very different, as to their valuable contents, from what are found in flat and plain ground, whether they be planted, sown, or built upon; as for example:

Suppose an hill contains four equal sides, which meet in a point at the top; yet the contents of these four sides can produce no more grain, or bear no more trees, than the plain ground on which the hill stands, or than the base of it; and yet by the measure of the sides there may be double the number of acres, rods, and poles, which they measure on the base or ground-plot.

For as long as all plants preserve their upright method of growing, hilly ground can bear no more plants in number than the plain at the base.

Again, as to building on an hill, the two sides of an hill will bear no more than the same number of houses that can stand in the line at the base.

And as to rails, or park-paling over an hill, though the measure be near double over the hill to the line at the bottom, yet both may be inclosed by the same number of pales of the same breadth. *Miller's Gard. Dict.*

HILLOCK, a little hill.

HIVING *of Bees*, the placing a swarm of bees in a hive, in order to have the benefit of their labours. *See the article* BEE.

HOE, a tool made like a cooper's adz, to cut up weeds in gardens, fields, &c. This tool is commonly called the hand-hoe.

This instrument is of great use, and should be more employed in hacking and clearing the several corners, cracks, and patches of land, in spare times of the year, which would be of no small advantage thereto.

Horse HOE, a large kind of hoe, drawn by horses, and used to stir the intervals in the New Husbandry, and clear the corn from weeds.

Under the article CULTIVATOR, we have described the instruments used abroad for this purpose; and shall here give two very useful instruments of the same kind, invented by the ingenious Mr. Hewitt, who presented them to the Society for the Encouragement of Arts, &c. where they may be seen. The following letter, describing these instruments, was sent by the inventor to the Society.

GENTLEMEN,

Perusing the Essays on Husbandry, I observed particularly, that the author, page 105, expresseth hopes of seeing some "new-invented plough, cheap, simple, and rightly calculated for destroying weeds; keeping plants clean; and stirring the ground:" and, page 106, further says, "now as most people prefer useful, and cheap, to elegant and expensive inventions, it is natural to wish for a hoe-plough intirely simple, and not costly. For the mechanism of those devised hitherto, by the ingenious lovers of agriculture, is of so perplexed, and complicate a nature, that it will no ways answer the common purposes of husbandry: but, being perpetually out of order, will throw the poor ploughman into despondency; and the rather, as neither he, nor the country plough-wright, can comprehend how to rectify any defects, or accidents, except with extreme difficulty."

The very name of a hoe-plough suggested the idea of an instrument, which I shall call a horse-hoe; whose construction is intirely new, simple, and much less costly than a common plough. Such as country plough-wrights, and smiths, are able to make; and such as common ploughmen are able to use: and which seems, according to the hopes of the aforesaid author, to be rightly calculated for destroying weeds; keeping plants clean; and stirring the ground.

This horse-hoe, a model of which I beg leave, in the most respectful manner, to present to this honourable Society, I hope may be of a very extensive use in agriculture, as it must be much more efficacious, and expeditious too, than any kind of hand-hoe for the destruction of weeds, and stirring the ground. For if the instrument does not cut below the crown, or head, of the roots, such roots will sprout again, and the first labour become fruitless; which indeed is too often the case of hand-hoeing: as the labourer, sometimes, only scratches the surface of the earth, and shaves off the leaves of the weeds, the roots remaining intire and unhurt, to vegetate again. With this instrument, the husbandman may hoe the ground so deep, that it will infallibly cut asunder the roots of every weed it meets with, below the crown or head; and, consequently, either destroy them, or at least greatly check their future growth that season.

This instrument is calculated for hoeing the intervals between the generality of plants in straight rows: such as transplanted lucerne, beans, pease, and turnips, sown with a drill-plough, &c. In large gardens, hop-grounds, nurseries, and plantations of young trees, much labour, and expence, in hand-hoeing, may probably be saved by the use of it.

In the county of Norfolk (and probably in many other places) the husbandmen, in the months of March and April, preparing their lands for barley, generally give them a certain number of earths, according to the phrase of that country; or, in other words, plough them a certain number of times. In those months the weather is frequently very dry; and the soil being turned over and over again, and exposed to the sun and wind, becomes so dusty, that a great part of the seed will not grow without rain; which, sometimes not falling in many weeks after the seed-time, causeth the crop to consist of different growths: so that when the first grown crop is ripe for the scythe, the latter is but just eared. This evil, perhaps, may, in some measure, be remedied by the use of this horse-hoe, instead of the common plough, at that season. For this will stir, and loosen, the earth as effectually, as the

The Common Horse Hoe
on Plate 26 Fig A

the other; and, at the same time, neither remove, nor turn it over, which seems to be beneficial, in a drought, upon very light and sandy soils.

With respect to foul summer fallows too, it may be of singular service. The common plough buries the weeds, of which many grow again. This horse-hoe will cut their roots asunder, below the surface of the earth; and by leaving their foliage above it, exposed to the summer sun, the greatest part of them will wither and die: so that they will not give the husbandman much more trouble the remaining part of the summer. And, as this hoe may be eighteen or twenty inches broad, two acres of land may be hoed by it, as soon as one acre can be ploughed, by the common plough.

This new instrument is intended for public benefit; and to the consideration of the public, as well as of this honourable Society in particular, it is freely submitted. If it be judged an useful implement in husbandry, well; if not, the pleasure that has arisen from the hope of doing good, has amply rewarded, for his trouble, the inventor, who has the honour to subscribe himself,

Gentlemen,

Hadleigh, April 19, 1766.

Your most humble, and obedient servant,

William Hewitt.

P. S. Since I had completed this model, I apprehended, that its utility might be rendered still farther extensive, by a very small alteration; therefore, gentlemen, I take the liberty of laying before you another model, calculated for hoeing the furrows between wheat ridges, which all farmers acknowledge to be very good husbandry, though many of them are deterred from the practice of it, for want of a cheap expeditious method of putting it in execution. An instrument of this kind, I am persuaded, will very greatly expedite that useful work: and if it meets with your approbation, gentlemen, many lovers of improvement in agriculture may be induced to give it a fair and impartial trial.

An Explanation of the Horse-Hoe, *Plate* XVII. *Fig.* 3.

A represents a small round curved iron-bar, fixed upon each end of the axle of the wheel, by which the horse-hoe is drawn.

B, the wheel three feet in diameter.

C c two flat iron-bars, three feet long, fixed upon the axle of the wheel, at D d, and to the sides of the hoe; at E e, by bolts and screws: upon these bolts, as well as the axle of the wheel, they are moveable.

F a small round iron-bar, fastened at each end, into the two bars; C c (to strengthen them) at G g, from and to G; these bars may be straight. From G to E, let them be curved.

H, the hoe itself; the breadth of which may vary according to the different distances of the rows of plants, whose intervals are to be hoed.

KK, two little flat curved iron-bars, fixed by bolts, upon which they are moveable, to the bars C c. Each of them pass through a staple, fixed into the sides of the hoe at L l. In both these little bars is a row of holes. In each of the staples, is one hole; and, directly opposite to them, one hole in each of the sides of the hoe: and, by means of two bolts, passing through these holes, and some of the holes in the bars K K, the hoe is fixed to any position; so that the ground may be hoed as near the surface, or as far below it, as is necessary.

M M, two wooden handles, fixed to the two sides of the hoe, and to each other, by the cross bar O; as long, and as high from the ground, as the handles of a common plough.

Figure 4. represents the horse-hoe, intended for hoeing the furrows, between wheat ridges: which differs only, in one respect from the other. That hoe is flat; this is curved. The breadth, and curvature of this, must depend intirely upon the breadth, and curvature of the furrows, to be hoed. In which respect, every sensible farmer can easily direct the smith how to form it. But, after all, if any persons be inclined to make trial of this instrument, I would advise them not to trust to a verbal description, but to send for a model of it to Thomas Tillett, a very ingenious smith at Hadleigh in Suffolk.

HOEING, the breaking or dividing the soil by tillage, while the corn or other plants are growing thereon.

It differs from common tillage, which is always performed before the corn or plants are sown or planted, or in the time of performing it; and it is much more beneficial to the crops than any other tillage. This sort of tillage is performed various ways, and by means of different instruments. Land which, before the tillage, would have yielded little, though the more it is tilled before sowing, the more plenty of corn it yields, yet, if tilled only before the sowing, will always have some weeds, and they will partake of the advantage of the tillage as well as the corn. This is one reason for an after tillage, such as that by hoeing. But there is another consideration that yet more requires it; this is, that as soon as the ploughman has done his business, by ploughing and hoeing the land, after sowing, the soil, of its own accord, begins to undo it all again by tending towards its original texture and specific gravity again; the altering of which was the only business of all the former tillage. The breaking the particles of the earth, and making in it new pores, and new particles, or new superficies, is the great business of the plough and harrow; but, as soon as their use is over, the earth begins to coalesce again into its own form, the particles unite together, and the artificial pores in a great measure close up. The seed is nourished in a worse ground than it was first put into, and the more the plant grows up, and requires a larger supply of food, the worse the pasture becomes. While nourishment is thus denied the growing plants, they are at the same time choaked with weeds, which being of a hardier nature than they, will grow with less supplies, and therefore thrive more vigorously, and rob them of a great part of the little food the land before allowed them.

Farmers in all ages have been acquainted, in some degree, with the use of tillage and dung to crops of useful plants; but they have so ill managed the time of giving these assistances to nature, that there is no doubt but one third part of the nourishment raised by dung and tillage, if it were given to plants and corn at many proper seasons, and proportioned to the different times of their exigencies, would be of more benefit to the crop than the whole is, when applied all together at the time of sowing.

Nature, by what she does in the animal œconomy, seems to point out to us something like the remedying this by hoeing; for when the teeth, as the plough, have tilled that soil or mass which is earth altered; and when the saliva and the juices of the stomach have served to divide and attenuate it, as the salts of dung and other manure do land; after all this, the bile and pancreatic juices are ordained to farther attenuate it, at the very time when it is ready to be exhausted by the numerous mouths of the lacteals, situate in the intestines. This last operation of these juices seems analogous to the meliorating the soil by hoeing, after the plants are grown, and are becoming fit for use.

Transplanting is nearly allied in its nature to hoeing, but it is much inferior. The nature of this will not admit of its being a general thing; and even if it would, hoeing is better: for by transplanting, the plants can only be kept up to a certain period, after which they will not bear it; but hoeing may be used to them with advantage, to their utmost standing, and make them vigorous all the while.

The roots of a plant are all necessarily broken off in transplanting, and it requires some time for it to strike a whole set of new ones; and if the earth about it is not kept thoroughly moistened all this time, the new formed roots will not be able to shoot, and the plant will starve in the midst of plenty: but, on the contrary, in hoeing, the same advantage of a new pasture for the plant is obtained, by the breaking the particles of the earth, and at the same time no more of the roots are broken off than can easily be supplied, and the rest remaining in their places, the plant continues growing without that stop or decay, which must happen on transplanting, and which it recovers only by degrees. It is observed, that some plants are the worse for transplanting: lucerne and saintfoin are never so good after transplanting, as when they are left in their native places, at the fame diftances; and finochia, removed, is never fo good and tender as when it is not.

This laft plant receives fuch a check from tranfplanting in its infancy, that it has afterwards a difeafe like the rickets, which caufes knots and fwellings in it, that fpoil it as a delicacy. All the tap-rooted plants fuffer by tranfplanting; for it is neceffary in this to cut off the long-main root, which afterwards, however good the foil may be, never arrives at the length it otherwife would have had, and which was neceffary for the fuccefs of the plant.

One great benefit of hoeing is, that it keeps plants moift in dry weather, the advantage of which to their growth is eafily feen. This good office it performs on a double account. Firft, as they are better nourifhed by hoeing, they require lefs moifture, and confequently carry off lefs; for thofe plants which receive the greateft increafe, having moft terreftrial nourifhment, carry off the leaft water, in proportion to their augment, as is proved by Woodward's experiments. Thus barley or oats, being fown on a piece of ground well divided by tillage and dung, will come up and grow well without rains, when the fame grains fown on another part of the fame land, not thus dunged or tilled, will fcarce come up at all without rains, or if they do, will wait wholly for the rains for their growth and increafe.

The hoe alfo, particularly the horfe-hoe, for the other does not go deep enough, procures moifture for the roots from the dews which fall moft in dry weather; and thefe dews feem to be the moft enriching of all moifture, as it contains in it a fine black earth, which will fubfide from it in ftanding, and which feems fine enough to be the proper pabulum, or food for plants.

A demonftration that the tilled earth receives an advantage from thefe dews, which the untilled does not, is this; dig a hole in any piece of land, of fuch a depth as the plough ufually goes to; fill this with powdered earth, and, after a day or two, examine the place, and the bottom part of this earth, and bottom of the hole, will be found moift, while all the reft of the ground, at the fame depth, is dry. Or, if a field be tilled in lands, and one land be made fine by frequent deep ploughings, while another is left rough by infufficient tillage, and the whole field be then ploughed acrofs in dry weather, which has continued long, every fine land will be turned up moift, and every rough land as dry as powder from top to bottom.

Although hard ground, when thoroughly foaked with rain, will continue wet longer than fine tilled land adjoining to it, yet, this water ferves rather to chill than to nourifh the plants ftanding in it, and to keep out the other benefits of the atmofphere; it leaves the ground much harder alfo than before, when it is finally exhaled out of it; and when, at length, the earth is then hardened, it can receive no benefit from any thing lefs than a deluge of rain, which feldom falls till the feafon of vegetation is over.

As fine hoed ground is not fo long foaked with rain, fo the dews never fuffer it to become perfectly dry. This appears from the flourifhing ftate of plants in hoed ground, while others near them, but in ground not hoed, are ftarved for want of nourifhment. The common opinion is againft this, but obfervation proves it to be true againft the common opinion. The vulgar are guided by this, however, and will not hoe their ground in dry weather for fear of letting in the drought, as they call it; whereas hoeing this is the only method of keeping away the drought, and without either this, or watering, they muft perifh in thefe feafons. *Tull's Horfe-Hoeing Hufbandry.*

HOG, the name of an animal too well known to need any defcription here.

Thefe creatures are very advantageous to the countryman, not only for their great increafe, but alfo becaufe they feed upon what would otherwife be of no ufe or advantage, but would be thrown away; as whey, wafhings of tubs, grounds of drinks, difh-water, grains, &c. and their flefh being beft falted, or kept in pickle, may be eat in the fpring, when other meat is at the deareft; befides the help it affords to the taking off the produce of the garden, and the variety of difhes of the offal. Swine are indeed very greedy, and very apt to root up ground, and break the fences; and therefore the greater care muft be taken to keep them both well rung and well yoked.

The largeft fwine, and the greateft number for any particular places, are bred in Leicefterfhire, and fome parts of Northamptonfhire, and in the clayey countries adjacent; probably from the large quantities of beans and peafe fown in thofe parts.

The wild kind are not fo large as thofe juft mentioned, but are much more hardy, and better meat.

In the choice of hogs, chufe fuch to breed out of as have long, large bodies, are deep fided and bellied, that have a fhort nofe, thick thighs, fhort legs, high claws, thick neck, a fhort ftrong groin, and a thick chine, well fet with ftrong briftles.

To have too many fows in one yard is not good, for their increafe is fo great, that they will, for want of food, not only devour whatever comes in their way, but eat one another: for a fow will bring forth pigs three times in a year, that is, at the end of every fixteen weeks. It is common for them to have thirteen or fourteen pigs at a litter; but the fow can rear no more than fhe has teats to fuckle them with; the reft muft therefore be deftroyed, or put to other fows. If the fow mifs the time of going to boar, that fhe might in courfe have done, give her fome oats parched in a pan, in her wafh, or the fmall end of a runnet bag, and it will caufe her quickly to go to boar. The pigs which you rear, after you have chofen out the beft for boars and fows, the males muft be gelt, and the fows fpayed; the fpayed gelts, as the farmers call them, are efteemed the moft profitable, becaufe they have a much larger quantity of fat upon their inwards, than other hogs. Young fhoots, which are fwine of about three quarters of a year old, are beft for pork, and thofe of a year, or a year and a half, for bacon. The beft age for a fow to bring forth pigs, is from one to feven years old; and the beft age for the boar, is from two to five years old, at which time it is beft to geld him, or fell him for brawn; the beft pigs to rear, are thofe which are pigged in the fpring, and thofe pigged in March for pork in October.

The beft way of taking care of fwine, is to feed them fo as to keep them in middling plight, till you defign to fat them; for if you keep them too fat, it will endanger their health; and too lean will render them too ravenous. It is good to give them fuch fwill as you have every morning and evening, to make them come home to their ftyes. The reft of the day, let them graze, and get fuch food as they can; but when the corn is upon the ground, you muft be careful to keep them within bounds. Moift fedgy grounds are good for them, the roots of which they will eat; and all forts of haws, heps, floes, crabs, acorns, maft, chefnuts, &c. with which, if you have plenty enough to fat them, their flefh will eat much better and fweeter than if fatted in a ftye. Some, indeed fay, their fat will not be fo folid, nor fo profitable, and therefore they commonly fhut them up for a week or ten days, and feed them with dry peas; but this is a miftake, experience having fhown, that hogs fatted with acorns only have their fat as folid as thofe fatted with peas. In fatting hogs in ftyes, they obferve to give them meat often, and but little at a time, that it may be always frefh; and likewife to give them as much water as they will drink, and to keep them very clean, which will help their fatting, and improve the tafte of their flefh. But where the hufbandman lives remote from woods, or the year fhould fail of producing acorns or mafts, they commonly fat them wholly in ftyes with peas, if cheap; if dear, the meal of barley, rye, or offal corn, according as they are cheapeft, which they mix with water, whey, or fkimmed milk: with thefe they feed them till fat, which will commonly be in about a month's time, and then they feed them with peas a little before they kill them.

Obferve, that every ftye have a yard well paved with ftone, if poffible, for the hog to go out and eafe and air himfelf, that he may keep his lodging the cleaner.

In Liecefterfhire they have a very eafy method of fattening great numbers of fwine, which they do by ftacking up their peas and beans in the form of a fmall cottage. This they fet near fome running brook, and hedge a yard in round about it, taking fome part of the ftream into the yard for the hogs to drink at; into this yard they turn fuch a number of hogs as they think their peas or beans

will

will fat, where they let them live till their provifion is confumed, cutting the rick down, and giving it to them as they can eat it. *Mortimer's Hufbandry, vol.* I. *p.* 244.

HOG-SHEEP, or *Heggrel*, a fheep of a year old.

HOLT, a wood.

HOLM, an ifland in a river; it alfo fignifies the holly.

HOOP, a meafure equal to a peck, or quarter of a bufhel.

HOP, a well known plant of the reptile kind, whofe flower is a principal ingredient in beer, and other malt-liquors.

A rich, deep, mellow, dry foil, rather inclining to fand than clay, is, in general, beft adapted to the cultivation of hops; but a black garden mould is excellent for this purpofe. Stiff clays, fpewy lands, fuch as are apt to be overflown by floods, hard gravels, ftony grounds, very fandy ones, and fuch as are not at leaft a foot and an half deep, are altogether improper for hops.

The beft fituation for hop-grounds is fuch as inclines to the fouth, or lies open to it, fo that they may have the benefit of the fun during the greateft part of the day. It muft alfo be open, for the air to have a free paffage and circulation between the plants, and it fhould be fo fheltered to the eaft, north, and weft, that neither the frofty winds in the fpring may cut off the young fprouts, nor the more ftormy ones in fummer and autumn deftroy the full-grown hops.

The ground and fituation being chofen, the next bufinefs is to prepare it for the planting. In many parts of England, when the ground is broken up for this purpofe, the plough goes firft, and men follow it with the fpades, with which they dig one fpit deep in the furrows where the plough has paffed, throw up the earth thus dug, and fo continue to plough and dig till the whole is done. Either this tillage, if it be well performed, or the deep ploughings, crofs-ploughings, and harrowings, by which careful hufbandmen prepare their land for corn, will fit this for being fown with turnip feeds in the end of July, or beginning of Auguft, and if the turnips are hoed twice, fo as to be left about eight inches afunder, they will yield a good crop, the weeds will be deftroyed, and the ground will be rendered loofe and fine. Another good ploughing after the turnips are taken off, will, with the enfuing winter mellowing, render it fit for being planted with hops in the fpring.

The beft time to begin ploughing is in October, in order that the foil may be properly prepared to receive the benefits of the winter's frofts, rains, and fnows; after which, in the beginning of fpring, it fhould be well and deeply ploughed again, and well harrowed; and after another ploughing in March, which will be of very great fervice, it fhould be harrowed fine, and laid as even as can be.

When the ground is in proper readinefs for planting, ftretch along a ftraight fide of the field, at fifteen or twenty feet diftance from the hedge, and parallel to it, a line with knots or rags tied in it, as far afunder as you defign your hills to be, and ftick in the ground a fharp-pointed ftick at every knot, as marks for the places where the hills are to be made; continue the line in this manner the whole length of the ground, and from this firft row you may mark out the reft of the field, either in fquares, chequer-wife, at the intended diftance of the hills, or in the quincunx form, where the hills of every row lie oppofite to the middle of the firft, in a triangular form.

The diftance of the hills fhould be, in fome meafure, regulated by the nature and goodnefs of the foil: but, in every cafe, they fhould be far enough afunder to admit the hoe-plough at all times without danger to the plants. If the foil be dry and fhallow, fix or feven feet will be a convenient diftance: but if it be rich, moift, and apt to bear large hops and leaves, it may be right to allow eight or nine feet between the hills.

The moft proper feafon for planting hops, is from the beginning of March to near the middle of April, at the time when they begin to fhoot. The Kentifh hufbandmen approve likewife of October: but the common forts are not to be procured then, unlefs it be from a ground that is to be dug up and deftroyed; befides which, there is fome danger of their rotting in the earth, if the winter fhould prove very wet.

There are feveral forts, though the botanifts allow but one fpecies of hops. The moft efteemed are, the long white, the oval, and the long fquare garlic hop. Thefe differ from each other in the colour and fhape of their bells, or hops, in their degree of bearing, and in their time of ripening. The long white is moft valued, becaufe it is a great bearer, and produces the moft beautiful hops; for the beauty of hops confifts in their being of a pale bright green colour. The oval hop is beautiful, but does not yield fo large a crop. There is a fort of this kind of white hop, called the early, or rath hop, which ripens a week or ten days before the common, and is therefore of advantage to thofe who would be firft at market: but it is tenderer than the other, and does not bear near fo plentifully. The long fquare garlic hop is the greateft bearer, more hardy, and fomewhat later ripe that the former; but by reafon of its rednefs towards the ftalk, it is not fo beautiful to the eye, and therefore is not fo much efteemed as the other forts.

Few hop grounds are without fome plants of a fort of hop which many call the female hope, but very erroneoufly; for the female hope is that which is cultivated for ufe, and this, which others name more properly the wild hop, is the male. Towards the middle of July, it puts out a great number of long loofe bunches of fmall flowers, not at all like the true hop; and in fomewhat lefs than a month after, that is to fay, juft before the true hop begins to bloffom, they ripen, and with the leaft motion of the wind, fhed a farina, which is wafted all around, and is by fome, not improbably, thought to be of ufe to impregnate other hops. Thofe who are of this opinion advife, therefore, to leave one or two hills of them ftanding in the hop-ground. But the common practice is to mark them at their firft appearance, and to root them out afterwards, becaufe they do not bear bells or hops, and as they are generally the ftrongeft plants, fets might otherwife be taken from them by miftake.

There is alfo a poor ftarved hop, called a wild hop, which is not judged to be a diftinct fort, but a hop which has degenerated for want of culture.

The planter of hops ought to be extremely careful in the choice of his plants, or fets, particularly in regard to the kind of the hop: for it is a great trouble and lofs to him, when his garden proves to be a mixture of feveral forts of hops, ripening at different times. He who plants the three forts above mentioned, viz. the early, the long white, and the fquare hop, in three diftinct parts of his ground, will have the conveniency of picking them fucceffively as they become ripe.

Hop-fets are cuttings from the roots or branches which grow from the main root or ftock. They fhould be procured, if poffible, from grounds planted with none but the fort which is defired; and they fhould be from five to feven or eight inches long, with three or more joints or buds on them, all the old bind and hollow part of the fet being cut off.

The ground being prepared for planting, as before directed, towards the latter end of February, or in the beginning of March, if the foil be light, or late in March, if it be ftrong and moift, make, in the places marked out by the fticks ftuck in them, holes about twelve or fixteen inches wide, and of a depth proportioned to the nature of the ground. In general, ten or twelve inches will be a fufficient depth. If the ground be fhallow, and you meet with hard clay or gravel, by no means enter into this, for you would then make a bafon to retain water; but, in fuch cafe, inftead of going deeper, raife up a fmall hill of good mould. If there is a good depth of rich mellow mould, dig the hole a foot and a half, or two feet deep, and you will find the hops thrive the better; for their tap roots naturally run downward.

When all things are ready for planting, fill up the holes with the mould before thrown out of them, if it be naturally good, after having firft broke it fine with a fpade: but if the fame earth be not rich enough, make ufe of fine frefh mould, or of the compoft provided for this purpofe. About a peck or two of this will be fufficient for each hill; but no new dung fhould be put into the hole on any account.

Then, with a dibble, or fetting ftick, fuch as gardeners generally ufe for planting of beans, make five or fix holes, the

the depth of your ſets, one in the middle, perpendicular, and the reſt round about, ſloping and meeting at the top near the center: put your ſets therein, ſo that they may ſtand even with the ſurface of the ground; and then preſs the mould cloſe to them, and cover them with fine mould two or three inches thick. A ſtick ſhould be placed on each ſide of the hill to ſecure it.

The ground being thus planted, all that is to be done in the following ſummer, is to keep the hills and alleys clear from weeds by frequent hoeings; to dig the ground in the month of May, and to carry off all the ſtones that are turned up by digging; to raiſe a ſmall hill about the plants; to throw ſome fine mould on their roots; and, in the latter end of May, or beginning of June, to twiſt all the vines and branches together into a bunch or looſe knot, and lay them thus twiſted on the top of the hill.

Towards the latter end of February, or in the beginning of March, in the ſecond year, when the weather is kindly, open the hills, and with a ſharp knife, cut off the ſhoots of the firſt year to within an inch of the old ſtock, together with all the younger ſuckers that have ſprung from the ſets, and cover the ſtock with fine earth. To keep the knife ſharp, you ſhould have a whetſtone always by you at dreſſing.

In the third and following years, when you dig your hop-ground in February, let the earth be taken away with a ſpade or hoe, round about the hill, very near them, that you may the more conveniently come at the ſtock to cut it: then in fair weather, towards the beginning of March, if your hops be weak, begin to dreſs them; but if they are ſtrong, and in heart, the middle or latter end of March will be the beſt time; for late dreſſing reſtrains their too early ſpringing, which is the cauſe of many injuries to the hop.

After the hops are dreſſed in the ſecond year, the next buſineſs is to pole them. Poles of only ten or twelve feet long will do then; but in the third year, by which time they come to their full bearing ſtate, they will require poles of full ſize: this, if the ground be rich, and the hop vigorous, will be from ſixteen to twenty feet, or even more; or there will be danger of loſing great part of the crop.

If the hop be weak, and the ground not rich, the poles ſhould not be more than from fourteen to eighteen feet long for fear of impoveriſhing the root; for the hop will ſoon run itſelf out of heart if over poled; ſo that, as was ſaid before, there is more danger in over poling than in under poling; neither can a good crop be expected from an over poled ground, becauſe the branches which bear the hops grow very little till the buds have over-reached the poles, which they cannot do when the pole is too long. Two ſmall poles are ſufficient for a hill in a young ground.

Towards the latter end of July hops begin to bloſſom, about the beginning of Auguſt they bell, and in forward years, they are ſometimes ripe at the end of Auguſt, or beginning of September. When they begin to change colour, or are eaſily pulled to pieces, when they emit a fragrant ſmell, and when their ſeeds begin to look brown and to grow hard, you may conclude that they are ripe: then pick them with all expedition; for a ſtorm of wind will do them great miſchief at this time; and hops picked green and bright, without bruiſing or diſcolouring, will ſell for a third part more than thoſe that are otherwiſe.

When the poles are drawn up in order to be picked, the vines around them ſhould be cut aſunder, at the height of about three or four feet from the ground; for the cutting of them lower, eſpecially while the hops are green, would occaſion ſo great a flowing of the ſap, as would weaken and hurt the root.

The moſt convenient way of picking them is into a long ſquare frame of wood, called a bin. This frame is made of two poles, or pieces of wood, each nine or ten feet long, and three or four inches broad, joined together at about a foot and a half from each end, by two other pieces three feet long; and it is ſupported by four legs three feet and a half high; ſo that there remain in the middle of it a ſpace ſix feet long, three wide, and three and a half deep. In this ſpace is fixed a coarſe linen cloth, or hop-bag, cut open on one ſide, and hung hollow, either by hitching it on tenter-hooks along the inſide of the frame, or by ſtretching it on the outſide with wooden ſkewers, to receive the hops as they are picked. Three men or women, or four boys or girls, may ſtand at each ſide of the frame, and pick two poles at a time.

When you have raiſed ſome poles, bring them with the hops and vines on them, and lay them lengthwiſe upon the frames; or erect a forked prop at each end of the frame, and reſt the poles thereon, in order to their being picked. There is no occaſion to ſtrip the vines from the poles in order to their being picked. The workmen who raiſes the poles generally carries them to the frames, and the latter being very light, may be eaſily removed from one part of the ground to another.

The ripeſt hops ſhould be firſt picked: but if the hops appear to be equally ripe in all parts of the plantation, it is beſt to begin to pick them on the eaſt or north-ſide of the ground, the more effectually to guard againſt the ſouth-weſt wind's breaking into the garden.

Having choſen a ſpot of ground which contains eleven hills, place the bin upon the hill which is in the center, and after theſe are picked, remove it into another ſpot of the ſame extent, and ſo proceed till the whole is finiſhed.

The hops ſhould be picked as free as poſſible from leaves and ſtalks; for theſe would be of greater prejudice to the ſale, than any ſeeming advantage which might be expected from their weight. The bin ſhould be emptied two or three times a day into a large cloth of coarſe linen, in which the hops ſhould be immediately ſtitched up with ſkewers, and carried directly to the oaſt, or kiln, to be dried: for if they remain long in the bin, or cloth, they will ſweat and be diſcoloured.

If any brown hops are met with in the picking, care ſhould be taken to ſeparate them from the reſt, by putting them into a baſket by themſelves.

If the weather be very hot, or rainy, cut no more hops than may be picked in an hour: but, if it be poſſible, gather them in fair weather only, and when they are dry; for this precaution will ſave ſome expence of coals, and contribute to the better preſervation of their colour when they are dried. No hops ſhould be gathered when the dew is on them, for that would make them become mouldy.

When you have taken the poles from the hills, twiſt together the remaining ends of the binds, that they may not get among people's legs, and hinder their work.

Before you draw the poles, obſerve whether the hops of one pole be entangled above with thoſe of another, and if they are, cut them aſunder with a ſharp hook fixed at the end of a long pole.

If the garden be large, it may be worth while to raiſe a ſhed in the midſt of it, to ſhelter the pickers and the hops from the ſun and rain; and to lay hops in overnight, to be picked early the next morning before the dew is off the other hops. This ſhed will alſo ſerve for preſerving your poles in winter.

If there be either rain or dew upon the hops at the time when they muſt be gathered, ſhake the pole, and they will dry the ſooner. If they are over-ripe when gathered, they will ſhed their ſeeds in which the chief ſtrength of the hop conſiſts; nor will they then look ſo green, but ſomewhat brown, which is a great diminution of their value. It therefore is better to pull the hops, a little before they are ripe, than to wait till they are full ripe. Four pounds of undried hops, thorough ripe, will make one pound of dry; and five pounds of hops ſcarcely ripe, though in their full prime, will make no more when they are dried.

There are two principal ſorts of hops, viz. the green and the brown. The former yields by much the beſt colour when dried, and the other is the moſt plentiful bearer.

Brown hops are fit for brown ale, but the hops for fine pale beer muſt be green; for which reaſon theſe laſt are moſt eſteemed.

As faſt as you pick hops, dry them on a kiln; otherwiſe they will change colour: but if you cannot dry them immediately, and muſt keep them a little while, ſpread them on a floor, and by that means the damage which they will receive in a day or two will not be great.

They who have five or ſix acres of hops, may employ ten frames at a time in picking.

If any of the rath-ripe, or early hops, which bloſſom and ripen a week or ten days ſooner than the other ſorts, happen to be intermixed in the ſame plantation, they ſhould be watched carefully, in order to their being gathered in time; for if they hang till they are over ripe, they will ſhed their ſeeds, turn brown, and thereby not only become bad themſelves, but ſpoil the ſale of the others with which they are mixed. It is therefore adviſable to mark at the bloſſoming ſeaſon, the hills in which they are, in order to dig them up and replant thoſe ſpots: for the trouble of pulling them up ſeparately, when they are ſcattered here and there in a hop-ground, and of carrying them, ſometimes a conſiderable way, to a convenient place, to be picked, is very great, and cannot be avoided otherwiſe than by either baniſhing them totally, which would not be quite conſiſtent with the huſbandman's profit, as they fetch a good price by their coming firſt to market; or, which is the beſt way, by planting them in a garden by themſelves.

Very particular care ſhould be taken that the hops be thoroughly and equally dried. In this lies the greateſt difficulty and art in the management of them: for if they are over-dried, they will change colour, look brown, and be judged to be burnt, whereby their value will be greatly diminiſhed; and if they be under-dried, they will loſe their colour and flavour. Experience has ſhewn, that an handful only of under-dried hops will ſpoil many pounds of others, by taking away their fine ſmell and colour.

The beſt way of drying them is with a charcoal fire, on a kiln covered with hair-cloth, of the ſame form and faſhion as is uſed for drying of malt, under which head this common ſort of kiln will be more particularly ſpoken of hereafter. It is found to ſuffice in places where only a few hops are raiſed, and a great deal of malt is made: but where the hop-planters have a much greater quantity of hops than can be dried in due time on their malt-kiln, (for hops, as was ſaid before, ought to be dried as ſoon as poſſible after they are picked) they build, in the following manner, ſeveral ſmall kilns on purpoſe for drying of hops.

Eight or ten acres of hop-ground require a building of about ſixty feet long, and fifteen wide in the clear. At one end of this building is a boarded room, to receive the green hops which are brought from the hop-ground, and which lie ſpread out there till there be room to put them on the kilns: at the end of the building is another large boarded room, for receiving the hops from the kiln when they are dried, and for them to lie in heaps to ſweat till they are fit for bagging. In the intermediate part of the building, three or four kilns, of eight or ten feet ſquare each, are conſtructed thus, cloſe to one another.

If the middle building is, we will ſuppoſe, twenty-eight feet long, and fifteen feet wide, there will be room for three kilns of eight feet ſquare each in the clear, and for their reſpective walls. Theſe kilns ſhould lie in a line along the back wall, and will come forward above nine feet; ſo that there will remain a paſſage five feet wide and twenty-eight feet long at the front of the kilns.

To form each kiln, build the walls of brick, nine inches thick, and let each of the four ſides be eight feet long in the clear, and ſeven feet high. The principal parts of the kiln are, in the upper part, the bed or floor whereon the hops are to be laid in order to their being dried; and in the under part, the furnace, ſteddle, or lanthorn, for the fire. The bed or floor in a kiln of eight feet ſquare, ſhould be about ſix feet from the lower floor, ſo that it it will be about a foot below the top of the wall. This foot of wall riſing above the bed, ſerves to keep in the hops on the kiln, and for men to walk upon round about the kiln, to look to the drying of the hops. The bed, or floor, may be made of wooden rails an inch ſquare, laid very even and level, into a croſs beam, a quarter of an inch aſunder: or if the kiln be arched below, the floor may be laid with long bricks, or ſtones reſting on the tops of the arches, at about two inches diſtance from each other.

In making the lower part of the kiln, place the mouth of the furnace at the bottom, in the middle of the front wall of the kiln, and let it be fourteen inches wide and ſixteen high. Joining to the mouth of the furnace on the inſide, build the ſteddle or lanthorn, of brick, four inches thick. This lanthorn ſhould be fourteen or ſixteen inches wide, three feet perpendicularly high in the ſide walls, and it ſhould reach from the front wall of the kiln to within a foot and an half of the back wall; ſo that there will be room for a man to paſs between it and the back wall, and the length of the lanthorn thus made will be about ſix feet. On its ſide walls, bricks of a foot length are to be raiſed on their ends, leaning to and bearing upon one another, ſo as to form a covering like the roof of a houſe; or the top of the lanthorn may be regularly arched over.

In building the ſide walls of the lanthorn, after you have laid the two firſt rows of brick, leave at the end of every brick in the three or four following rows, an open ſpace or hole, four or five inches wide, chequer-wiſe, both in the ſides and in the back, and lay the uppermoſt row or two of bricks cloſe together, as in the bottom rows, for the better ſupport of the roof. By this means there will be three or four rows of holes, which are deſigned to convey the heat equally to all parts under the hair-cloth. The roof ſhould be well plaiſtered on the inſide with hair and lime, that it may the better reflect the heat.

In the front-part of the kiln, on one ſide of the furnace, and at the height of two feet from the ground, a ſmall door ſhould be made, three feet high, and two wide, ſo that a man may eaſily get in to ſet every thing to rights about the ſteddle. There ſhould alſo be ſteps or ſtairs to go to the upper floor, where the hops are dried; and as there is a paſſage below, five feet wide, along the front of the kilns; ſo will there be, directly over head on the upper floor, a like paſſage, which will be of uſe for bringing the green hops from their room, and laying them on the kiln, and for carrying them to the ſtore-room after they are dried. For greater conveniency, both theſe rooms ſhould be on the ſame floor as the upper-part of the kiln.

A farther caution neceſſary to be obſerved, is that no holes be made within a foot of the fire-place or mouth of the furnace, and that all the parts about the kiln be conſtructed ſo cloſe that no wind or air may poſſibly get in. The farther end of the ſteddle ſhould be built of brick up to the top, with holes in it as in the ſides.

The kiln ſhould be ſquare, and may be ten, twelve, or fourteen feet over at the top; but there ſhould be a due proportion between the height and breadth of the kiln, and the ſize of the ſteddle where the fire is kept, viz. if the kiln be twelve feet ſquare on the top, it ſhould be nine feet high from the fire, and the ſteddle ſhould be ſix feet and an half ſquare; and ſo proportionably in other dimenſions. Theſe kilns are made at a ſmall expence.

In drying of hops, firſt lay the hair-cloth very even on the bed or floor of the kiln, and ſpread the green hops thereon, about ſix inches thick, laying them with a rake as ſmooth as poſſible, not thicker in one place than another. Let the kiln be moderately warmed before you lay on the hops; then keep an even and ſteady fire under them, but not too fierce at firſt, for fear of ſcorching them; and let not the fire ſlacken, but rather increaſe it till the hops are nearly dried, leſt the moiſture or ſweat, which the fire has raiſed, fall back and diſcolour the hops. For theſe reaſons chiefly it is, that no cool air ſhould be ſuffered to come into the kiln while the hops are drying, and that wind, which would make the fire burn too violently, ſhould not be permitted to blow on the mouth of the furnace. After the hops have lain thus about ſeven, eight, or nine hours, have left off ſweating, and leap up when beaten with a ſtick, then turn them upſide down with a broad malt-ſhovel, or ſcoop made for that purpoſe, or caſt them up into a heap in the middle, and afterwards ſpread them equally on all ſides. Let them remain in this ſituation for two or three hours more, till every hop, if poſſible, be thoroughly and equally dried; and then with a hair-cloth, remove them to the heap where they are to lie till they are bagged. If they do not dry in one place ſo much as in the reſt, which may be perceived by touching them with a ſtick or wand, and obſerving whether they rattle when ſo touched, as they will do when dry; make them thinner in the places where they rattle leaſt. They muſt not be turned while they ſweat; for that will burn them, and make them loſe their colour. The fire may be diminiſhed a little before they are turned, and refreſhed again afterwards: but thoſe times excepted, the heat ſhould be kept as equal as poſſible.

Hops are fully dried when their inner ſtalks become brittle and break ſhort on rubbing, and when their leaves fall

fall off easily, and feel very crisp. When they crackle and leap a little, as they will do upon the bursting of their seed, then is the time to take them off the kiln.

If the fuel used for this purpose be either wood or turf, it should be charred first, because smoke spoils the colour and smell of hops. Charcoal made of old rotten poles is most commonly used. Cinders of sea-coal are also very good; and it is found by experience that Kilkenny coal dries hops perfectly well, because it does not smoke, and gives a constant uniform heat for a long time. The fire should be made at the mouth only of the furnace; for the air will disperse the heat sufficiently from thence to all parts of the kiln: and that it may be constantly of the same gentle degree, neither too strong nor too weak, it may be of service to make use of a thermometer, by marking upon which the degree of heat proper for drying hops, as soon as that degree is ascertained by experiment, you may always after know how to regulate your fire with great exactness: for, putting the thermometer within-side the kiln for a short time, you may observe, by the height of the liquor, when the heat is come to a right pitch, and when it is either too high or too low, and so increase or slacken the fire accordingly. Any servant may, with the help of this instrument, be able to mend and correct the fire with great certainty, and not be liable to commit mistakes, which often prove exceedingly detrimental to the hops. When you begin drying, lose no time in the prosecution of that work, but employ people night and day, to attend it with the utmost care, till it be finished. A large malt-shovel full of charcoal, thrown into the mouth of the furnace of a kiln eight feet square, will last an hour.

It is observed that hops dried in the sun lose their richness of flavour, as other herbs do when they are dried that way. If they are laid on a floor to dry, without using a fire, they will lose their strength, be apt to sweat or ferment upon change of weather, and not be fit for packing. Fire exhales their watery parts, and, by retaining the oily, preserves their flavour and colour.

Hops break all to powder if they are bagged hot from the kiln. To prevent this, they should be laid in a heap, to sweat and grow tough; and if they are then covered for a while close with blankets, to keep the air from them, they will bag the better. There is no limited time for their sweating, that varying according to the weather: three or four days are commonly sufficient; but it is a certain rule, that when the hops feel moist and clammy, and can be squeezed in the hand, or trodden close, without breaking, they are then fit for bagging. The harder they are trodden, the better they will keep.

The bags proper for this occasion are made of coarse linen cloth. They are commonly about eleven feet long, and near two yards and a half in circumference, and contain about two hundred and an half weight of hops. The small bags, called pockets, contain about half that weight.

The manner of bagging is thus: make a round or a square hole, but a round one is most convenient, about twenty-six or thirty inches over, in the floor of the chamber where the hops are laid in heaps after they are sweated. This hole should be large enough to receive the bag, and for a man to go up and down it with ease. Tie with a piece of packthread, an handful of hops in each lower corner of the bag, to serve as handles for the more easy lifting or removing of the bag; and, with packthread, fasten the mouth of the bag to a frame, or hoop, somewhat larger than the mouth of the hole, that the hoop may rest on its edges, and strong enough to bear the weight of the hops when the bag is full, and of the man who treads them. The upper part of the bag being thus fixed by the hoop, let the rest of it hang down through the hole; but not so near to the lower floor as to touch the ground: then throw into it a bushel or two of hops, and let a man go into the bag, and with shoes that have no heels, tread the hops down on every side, as hard as he can, till they lie close. Let more hops be then cast into the bag, and be trodden down as before; and continue this till the bag is full. When that is done, untie it from the hoop, let it down, and sew up its mouth as close as you can, observing at the same time to tie up some hops in the upper corners, as was done before in the lower. The harder the hops are pressed, and the closer and thicker the bag is, the longer and better the hops will keep.

When they are thus bagged, lay them upon a boarded floor, and in a dry place; for dampness would injure them greatly. At the same time all proper measures must be taken to guard against rats and mice, which, though they do not eat hops, are very apt to spoil them, by making nests and lodging in them.

Some, in treading the hops, use a fifty pound weight, fastened to a rope, and placed in the middle of the bag. The man in the bag treads about it with his feet, and lifts it up now and then, to press them the closer together.

As soon as the hops are picked, strip their haulm or vines from off the poles, and, as your last work, lay the poles up so that they may be preserved. This is done either by stacking, piling, or housing.

The stacking is performed thus: set up three poles, like an erect triangle, or rather six poles, let into the ground with an iron crow, and placed circularly, but inclining to one another so as to meet, and be tied fast together with bands of the haulm of the hops, within a yard of the top. The poles destined for the same stack should then be erected speedily against this frame; for if they are suffered to lie on the ground, especially in wet weather, they will receive more damage in a fortnight, than by their standing out upright all the rest of the year. When they are set up, about three hundred to a stack, bind them round with a rope of twisted haulm, to keep them together. By this means the outer poles only are subject to the injuries of the weather, and keep all the inner ones dry, excepting at their tops and bottoms, the former of which are for the most part exposed to the air, as the latter are to the moisture of the earth. It is therefore a good method to cover the top of the stacks of poles with haulm, and to lay stones, bricks, or sand, at their bottom, to preserve their but ends from rotting.

Many chuse to pile them up lengthwise, in different parts of the hop ground, laying three or four old poles athwart at bottom, to preserve them from the dampness of the earth, and setting several poles erect in the ground on each side of the pile, to prevent its slipping: they then lay the poles on one another, placing the smaller ends inwards, and the bigger outward; so that the pile should consequently be somewhat longer than the poles: and when it is raised high enough, they bind it across with ropes of twisted haulm, to keep it upright and steady, and then cover it with haulm, to defend the poles from rain. This is a better method than the former; but the best way of all to preserve the poles, is to build in the hop ground a shed or two, which may serve as a shelter for picking the hops in summer, and laying up the poles in winter, with least danger of their being hurt or stolen.

From October to March, there is nothing to be done in the hop ground, but to provide and bring manure into it, and to give the alleys their winter's digging or ploughing.

If you bring dung into your ground, be sure it be well rotted, and lay it on the alleys to mix with the earth, but not on the hills, dung being apt to produce vermin, which are extremely injurious to hops. Cold dungs, such as cows and hogs dung, are better for hops than horse dung, unless the soil be cold and wet, and then hot dung, such as that of sheep, and even of pigeons, will not be improper.

A small dunging every second year is sufficient, and a plentiful dunging will serve for three years, if the soil be tolerably good.

Dung was formerly more in use for hop grounds than it is at present, experience having shewn, that lime, lime-stone, gravel, sea-sand, marle, especially the shelly marle, ashes, and many other manures, are the most proper means of correcting the defects of soils, answer the end better, and last much longer.

The management of the hop ground during the third and every subsequent year (for it will continue to yield good crops during upwards of twenty years, if it be rightly cultivated) is the same as above directed; so that it will require pretty constant care and attendance, especially from the beginning of March to the end of September. This you may lay down as a certain rule, that the more pains you take, and the greater expence you are at, in the due culture of the ground, and management of the hops, the greater will be your profit.

The charge of an acre of hop ground, in most parts of England where hops are cultivated, is computed thus: three pounds for the husbandry, four pounds for the wear of the poles, five pounds for picking and drying, one pound ten shillings for dung, one pound for rent, and ten shillings for tythe; in all, fifteen pounds a year: but in some places they pay four or five pounds an acre yearly for the rent of the land.

The hop planters in England commonly agree with hop dressers, to do, for three pounds to three pounds ten shillings an acre, all the husbandry part, in which is included the summer and winter digging of the ground, the pruning and dressing of the hops and hills, the poling and tying, several hoeings and making up the hills from time to time, the laying of the dung on the ground, and all other works, except the bringing of the dung to the ground, and the picking and drying of the hops, which last businesses are performed by others; so that a gentleman has little trouble with his hop ground: he need only be careful that the undertaker does every part of the work in its proper season; and it is so much the interest of the undertaker to be punctual in this, that, if he neglects hoing when the weeds appear, he will, by such neglect, greatly multiply his trouble and labour in rooting them out afterwards.

An English acre requires about three thousand poles, the price of which varies according to their size. In several places it is usual to give as many shillings for an hundred poles as the poles are feet long; so that for an hundred poles of twenty feet long they give twenty shillings; but where poles are in great plenty, they give but fifteen shillings for those of that length. A recruit of five hundred poles yearly will keep an acre of hop ground in constant repair; so that poles are about a third part of the yearly charge, the picking and drying are estimated at another third, and the rest is laid out in the managing of the ground.

The hop planters in England reckon, that they have but a moderate return when the produce of an acre of hops does not sell for more than thirty pounds. They frequently have fifty, sixty, eighty, or an hundred pounds for an acre; nay, some have got considerably more than even this last sum for every acre of hops, at a time when the crops of other hop grounds have failed in general, and theirs have succeeded. But if, on one hand, such extraordinary profit, being very uncertain, is not to be depended upon; so, on the other, it should not be passed over quite unnoticed, because it is among the chances which may make amends for failing years. Upon the whole, if the total charge of an acre of hops is computed as above, at fifteen pounds a year, and its produce, at an average of years, at thirty pounds only, the clear profit from an acre will be fifteen pounds a year.

Though it be common in England to see ten, twenty, thirty, or more acres of hop ground in the hands of one man; and though some who spare neither care, industry, or expence, to make their plantations of this kind flourish, receive two thousand pounds a year for their hops, notwithstanding the high price of labour, manure, and every other article relating to their proper management; yet the intelligent husbandman will easily perceive,that it is not prudent for poor farmers, or men of small fortune, to engage far in this branch of improvement; for it requires a pretty considerable stock at first to cultivate a large plantation, to furnish it with poles, and to perform every other requisite. The expence will necessarily be great, and the undertaker must expect to lie out of his money for two or three years, before he can have any return of profit; and even when his hops do come to their bearing-state, and he is in hopes of making good the charges he has been at, a bad season may frustrate his expectation. Small parcels of hops, suitable to the abilities of the farmer; for even the poorest may easily spare time and labour, to plant a few of them in a corner of his garden, or other ground, and to set sallies, willows, or ash, for poles in his hedges or elsewhere, will yield him a pretty profit, without his laying out any money: so that, in setting forth the expences and risk which attend the cultivation of hops, we mean only to caution the husbandman, whose circumstances are but middling, against embarking too far in this branch of agriculture.

Ground that is fit for the raising of hops, is also fit for the raising of hop-poles of one kind or other. But to be more particular: low, wet, cold, marshy, boggy soils, or such as are situated near rivers, are fit for all the aquatic sorts, such as poplars, abeles, alders, willows, osiers, and sallies, which produce hop-poles in four or five years from their first planting. If the soil be dry and warm, or a strong, mellow, rich loam, the ash and the chesnut, which make the best poles for hops, will thrive greatly therein, and be fit for poles in nine or ten years from the time of setting them: and if these are planted around the hop-ground, they will both shelter the ground, and afford a supply of poles, without the expence of carriage. Elms also are quick growers; and when they are planted close together, they shoot up tall and strait, and make good poles.

Ash and chesnut poles, but especially those of chesnut, are so tough and durable, that three sets of them will last twenty years: but poles of alder, poplar, abele, osiers, or sallies soon rot, or become brittle; so that five sets of them, at least, will be requisite within that time. The aquatic kinds are therefore to be esteemed only for a first supply, till the plantations of ash and chesnut become fit for the future recruit of the hop-ground.

Hops are, like other vegetables, liable to various accidents and distempers, the principal and most fatal of which are the fly, the fen or mould, the mildew, and what the planters call fire-blasts.

The reverend Dr. Hales, treating of this subject in his excellent Treatise of Vegetable Statics, gives us the following account of the state of hops in Kent, in the year 1725, which he received from Mr. Austen of Canterbury, who was a very great planter, and an accurate observer.

" In mid April, not half the shoots appeared above ground; so that the planters knew not how to pole them to the best advantage.

" Upon opening the hills, this defect of the shoot was found to be owing to the multitude and variety of vermin that lay preying upon the roots, and of which the increase was imputed to a long and almost uninterrupted series of dry weather for three months before. Towards the end of April, many of the hop vines were infested with flies.

" About the 20th of May there was a very unequal appearance, some vines being run seven feet, others not above three or four, some just tied to poles, and some not visible; and this disproportionate inequality in their size continued through the whole time of their growth.

" The flies now appeared upon the leaves of the forwardest vines, but not in such numbers here as they did in most other places. About the middle of June the flies increased, yet not so as to endanger the crop; but in distant plantations they were exceedingly multiplied, so as to swarm towards the end of the month.

" On the 27th of June some specks of fen appeared. From this day to the 9th of July the weather was very dry. At this time, when it was said that the hops in most parts of the kingdom looked black and sickly, and seemed past recovery, ours held out pretty well, in the opinion of the most skilful planters. The great leaves were indeed discoloured, and a little withered, and the fen was somewhat increased.

" From the 9th of July to the 23d, the fen increased a great deal; but the flies and lice decreased, it raining much daily. In a week more, the fen, which seemed to be almost at a stand, was considerably increased, especially in those lands where it first appeared.

" About the middle of August the vines had done growing both in stem and branch, and the forwardest began to be in hop, the rest in bloom: the fen continued spreading where it was not before perceived; and not only the leaves, but many of the burs also were tainted with it.

" About the 20th of August some of the hops were infected with the fen, and the whole branches were corrupted by it. Half the plantations had escaped pretty well hitherto, and from this time the fen increased but little: but several days of wind and rain in the follow- ing

ing week diſtorted the plants ſo that many of them began to dwindle, and at laſt came to nothing; and of thoſe which then remained in bloom ſome never turned to hops, whilſt many of thoſe which did were ſo ſmall, that they ſcarcely exceeded the ſize of a good large bur.

"We did not begin to pick till the 8th of September, which is eighteen days later than we began before. The crop was little above two hundred on an acre of ground, and not good. The beſt hops ſold this year at Way-hill, for ſixteen pounds the hundred."

As a farther means of inveſtigating of the cauſe of this pernicious diſtemper, Dr. Hales relates the following experiment, which he himſelf made on hops. In the month of July, he cut off two thriving hop vines, near to the ground, in a thick ſhady part of the garden, and left the pole ſtill ſtanding. He ſtripped the leaves from off one of theſe vines, and left them on the other, and then ſet their ſtems in known quantities of water in little bottles. That with leaves imbibed in a twelve hours day, four ounces, and that without leaves only three fourths of one ounce.

He took another hop-pole with its vines on it, and having carried it out of the hop-ground into a free and open expoſure, theſe plants imbibed and perſpired there double the quantity of the before-mentioned which had leaves on it, in the hop-ground. This ſeems to indicate that the reaſon why the hop-vines on the outſide of gardens, where they are moſt expoſed to the air, are ſhort and poor, in compariſon of thoſe in the middle of the ground, is, becauſe, being much drier there, their fibres harden ſooner, and therefore they cannot grow ſo kindly as thoſe in the middle of the ground, which, by the ſhade and ſhelter they afford each other, are always kept moiſter and more ductile.

From this perſpiration of their fluid, the ſame attentive obſerver of nature forms the following calculation. There being a thouſand hills in an acre of hop-ground, and each hill having three poles, and each pole three vines, the number of vines will be 9000, each of which perſpiring four ounces, the ſum of all the ounces perſpired by an acre in twelve hours of day will be 36000, equal 15750000 grains, equal 62007 cubic inches, or 220 gallons, which being divided by 6272640, the number of ſquare inches in an acre, it will be found, that the quantity of liquor perſpired by all the hop-vines will be equal to an area of liquor as broad as an acre, and $\frac{1}{101}$ part of an inch deep, beſides what is evaporated from the earth.

Now this quantity of moiſture, in a kindly ſtate of the air, if daily carried off, is ſufficient to keep the hops in a healthy ſtate: but in a rainy moiſt ſtate of air, without a due mixture of dry weather, too much moiſture hovers about the hops, ſo as to hinder, in ſome meaſure, the kindly perſpiration of the leaves, whereby the ſtagnating ſap corrupts, and breeds mouldy fen, which often ſpoils whole tracts of, till then, flouriſhing hop-grounds.

This was the caſe in the year 1723, when, for twelve or fourteen days, almoſt continual rains fell, about the latter half of July, after four months of dry weather; upon which the moſt flouriſhing and promiſing hops were all infected with mould, or fen, in their leaves and fruit, while the then poor and unpromiſing hops eſcaped, and produced plenty, becauſe they, being ſmall, did not perſpire ſo great a quantity as others, nor did they confine the perſpired vapour ſo much as the large thriving vines did in their ſhady thickets.

The planters of hops remark, that when a mould, or fen, has once got poſſeſſion of any part of the ground, it ſoon over-runs the whole, and that even the graſs, and other herbs under the hops, are infected with it. The reaſon probably is, that the exceeding ſmall ſeeds of this quick growing mould, or moſs (for ſuch in fact it is) coming ſoon to maturity, are eaſily blown over the whole ground; and it is undoubtedly owing to the ſame cauſe, viz. to the remaining diſperſed ſeeds of the preceding year's fen, that ſome grounds are infeſted with this diſtemper for ſeveral years running. The means before pointed out for curing the moſs on fruit-trees ſhould therefore be aſſiduouſly recurred to here, at leaſt ſo far as they can be applied to hops; and, at all events, particular care ſhould be taken to keep the land always in fine tilth, conſtantly free from weeds, and to burn all the fenny hop-vines, in a place remote from the garden, as ſoon as they are picked. We have already ſeen inſtances of the cure of moſs upon fruit-trees, by the uſe of hog's dung; and there is no room to doubt the efficacy of the ſame remedy when applied to mouldy, or moſſy hops.

Mr. Auſten, of Canterbury, obſerves that the fen is more fatal to thoſe grounds which lie low, and are cloſely ſheltered, than to ſuch as have a high, and open ſituation; to thoſe that lie ſhelving to the north, more than to thoſe whoſe ſlope is towards the ſouth; to the middle of hop-grounds, more than to their outſides, and to dry and light grounds more than to moiſt and ſtiff ſoils. This was very apparent throughout his plantations, where the land was prepared and planted in the ſame manner, and at the ſame time.

The mildew, which lights upon hops, is a white dew, that falls in ſummer at ſun-riſe, chiefly when the hops are in flower. Its fall is ſo unequal, that it ſometimes embraces a whole diſtrict, and ſometimes only parts of it. This dew dries up the hops, withers and conſumes their leaves, and conſequently ruins the crop. "There is," ſay the authors of the Journal Oeconomique, whoſe account of this diſtemper, to which hops are extremely liable, we ſhall copy here, "no other remedy from nature againſt this miſchance, except rain ſufficient to waſh the plant, and clear it entirely from this fatal dew: but as rain ſeldom comes quite ſeaſonably to the relief of the plant thus affected, artificial means have been ſought, for inſuring it againſt this accident. Some have ſurrounded their hop-grounds with hogs-dung; others have employed perſons to go through the ground with veſſels full of beech-aſhes, and to throw them upon the hops while the mildew was falling; and both ſides, profiting by their experience, pretend to have found a ſpecific preſervative againſt the bad effects of the mildew. They have even proceeded ſo far, as that each ſide affirm their's to be the only remedy. Thoſe who uſe hog-dung ſay, that the aſhes may probably hinder the action of the dew upon the plant; but that they muſt, at the ſame time, ſtop up its pores, and deprive the ſoil of its humidity; a circumſtance equally ruinous to the plant: and that, beſides, beech is not to be found every where, and if it muſt be brought from afar, the remedy would in ſome meaſure become impracticable, by the ſcarcity and difficulty of procuring it. The partiſans of the aſhes ſay, that they cannot comprehend how hog-dung laid round the hop-ground in the ſpring, ſhould preſerve ſuch virtue as to deſtroy the bad quality of this mildew in the ſummer. In ſhort, to render this diſcuſſion complete, each ſide alledges, that the trials which they have made of the other's remedy did not ſucceed.

"This diſpute, the ſubject of which is highly intereſting to all countries where beer is the common drink, excited a naturaliſt to examine the nature of this mildew; and with the aſſiſtance of a microſcope he perceived it to be full of the eggs of little inſects, which fly in vaſt numbers in the air while the hop is in bloſſom. Theſe inſects gnaw the leaves even of trees, and, like others of their ſpecies, undergo various metamorphoſes. This diſcovery induced him to believe, that, as inſects are not apt to attack perfectly healthy trees, or vigorous plants, but only ſuch as are feeble and ſickly (they being indued with ſuch nice ſenſations as to diſtinguiſh by the outſide only, perhaps by the ſmell, a plant which is vitiated within, though it may appear to us to be quite fair and ſound) hog-dung might probably give ſuch vigour to the hop, as to render theſe little animals afraid to attack it: for it has been remarked, that the inſects which nip a leaf, leave it as ſoon as they find in it an abundant juice, the ſalts of which, it may be preſumed, are too ſtrong for them; and that they fix on thoſe only which begin to decay and loſe their ſap. Aſhes may likewiſe have the power of hurting them, and its ſalts may be capable of giving them diſturbance. But late experience hinders us from giving entire credit to theſe two remedies, and ſhews, that if they have ſometimes preſerved hops from the effects of the mildew, we are not to conclude that they will always anſwer this deſirable end.

"A very good huſbandman ſaw his hops ſpoiled by the mildew, notwithſtanding the dung with which they were ſurrounded, and the aſhes that were thrown upon them: in a little time the leaves of the plants were covered with millions fong winded. Nor will this appear ftrange, if it be confidered, that in hot countries the bones of animals are harder than in the cold; and for this reafon it is, that though their fhank bones are fmaller than the horfes of this country, yet their legs are ftronger.

The Spanifh horfes, which are placed next to the Barb in rank, have a long thick neck, with a large mane; the head full large, and fometimes the fore-top large; the ears long, but well placed; the eyes full of fire, and the air noble and fpirited; the fhoulders thick, and the cheft broad; the back often fomething low; the ribs round, but the belly often too large; the croup generally round and large, though in fome longifh; the legs beautiful and without hair; the finew well detached; the paftern fometimes longifh like the Barbs; the foot a little lengthened like that of a mule; and the heel often too high. The fine bred Spanifh horfes are plump, well-fet, and place the legs well on the ground; they have alfo a great deal of motion in their paces; great agility, fire, and ftatelinefs. Their coat is generally black, or a light chefnut; though there are fome of all the ufual colours. But it is very feldom that any are feen with white legs or muzzles; the Spaniards having fuch a diflike of thefe marks, that they never breed from horfes which have them. A ftar in the forehead is all they require; but they value horfes of one intire dark colour as much as we defpife them: both thefe prejudices, though oppofite, are perhaps equally ill founded, there being very good horfes with all kinds of marks; and fome excellent among thofe which are all of one colour. This minute difference in the coat does not proceed from the nature or conftitution of the horfe; but from an external, and at the fame time fo fuperficial a quality, that a flight wound in the fkin is fufficient to produce a white fpot: further, the Spanifh horfes, whether intirely of one colour, or not, are all marked on the off-thigh with the mark of the ftud where they were bred. They are not ufually large fized; though fome rife to fourteen hands and one or two inches. Thofe of Upper Andalufia are efteemed the beft of all, though they are apt to have the head too long; but this blemifh is overlooked in confideration of their excellent qualities; as courage, gracefulnefs, obedience, ambition; and, in activity, they even exceed the Barbs. Thefe advantages recommend them above all other horfes in the world, whether for war, ftate, or the manage.

The fineft Englifh horfes greatly refemble the Arabians and Barbs in fhape; indeed they owe their origin to them; but the head is much larger, though well made, and has a fine fore-top; the ears longer, but properly placed. By the ears alone an Englifh horfe may be diftinguifhed from the Barb: but the greater difference is in the fize; the Englifh horfes are much larger and well-fet. Their common height is fourteen hands two inches, and even fifteen hands is not very extraordinary. They are all colours, and all marks; are generally ftrong, mettlefome, bold, bearing great fatigue, excellent for hunting and racing, but want air and agility; they are ftiff, and have little freedom in their fhoulders.

The Italian horfes were formerly much finer than at prefent, the ftuds having been neglected there for fome time paft paft: the kingdom of Naples, however, ftill affords fine horfes, efpecially for carriages; but they have, in general, large heads and thick necks: they are alfo untractable, confequently are difficult to be trained. Thefe defects are, however, in fome meafure, compenfated by the largenefs of their fize, their fpirit, and the beauty of their motions. They are excellent for parade, and very much affect ftatelinefs.

The Danifh horfes are of fuch a large fize, and fo well fet, that they are preferred to all others for coach horfes: fome are perfectly well moulded, though in general their formation is not very regular; moft of them having a thick neck, broad fhoulders, the back a little too long and low; and the croup too contracted for the breadth of the cheft; but they all move well, and are in general excellent for war and ftate. They are of all colours, even the moft uncommon; the pye and fpotted being feldom feen but in Danifh horfes.

Germany affords fome fine horfes, but the generality are heavy and thick winded; though moft of them come from Turkifh and Barbary horfes, of which there are many ftuds; as alfo of Spanifh and Italian horfes: thus they make no figure in hunting and racing; whereas the horfes of Hungary, Tranfylvania, &c. are very light and fleet: the Huffars and Hungarians flit their noftrils, with a view, it is faid, to mend their wind, and, at the fame time, to prevent their neighing in the field; it being affirmed that horfes, whofe noftrils have been flit, cannot neigh. It has not indeed been in my power to examine this particular; but it feems natural to think, that the operation can only weaken their neighing. The Hungarian, Croatian, and Polifh horfes are noted for having what iscalled the mark in all their fore teeth, which continues to old age.

The Dutch horfes are very good for coaches, and are moft commonly ufed in France. The beft come from Friezland. The countries of Bergue and Juliers alfo breed very good ones. The Flemifh horfes are far inferior to thofe of Holland; they have generally large heads, broad feet, and their legs fubject to dropfical fwellings. The two latter are capital faults in coach horfes.

France produces horfes of all kinds, but not many which may be called fine. The beft faddle horfes come from the Limofin, being fomething like the Barb, and excellent hunters, but of a flow growth. They muft not be broke young, nor put to any fervice till they are eight years old. Auvergne, Poitou, and the territory of Morvant, in Burgundy, alfo produces very good ponies. But Normandy, next to Limofin, affords the fineft horfes; and if not fuch excellent hunters, they are preferable to the reft for war, are better fet, and fooner trained. Lower Normandy and Cotentin, are famous for very fine coach horfes; they are lighter, and more fprightly than the Dutch horfes: Franche-compté, and the Boulonnois furnifh very good draught horfes; but a general fault in the French horfes, is the width of their fhoulders; whereas thofe of the Barbs are too much contracted. *Buffon.*

Though the moft experienced horfemen are not always agreed in fome points relating to the fhape, make, and goings of a horfe, yet they almoft always accord in this, that there ought to be a juft proportion in all his parts. That even when he is taken to pieces, and examined fingly in his particular members, though fome defects may appear, yet when they all bear a juft correfpondence one to another, and concur in fuch a manner as to render his action eafy, juft, and regular; fuch a horfe cannot be greatly difagreeable, but will, for the moft part, move well, and with a tolerable good grace. On the other hand, fuppofe a horfe has fome parts exquifitely fine, and others indifferent, which frequently happens, it will mar his beauty, and caufe him to look difagreeable, and for the moft part affect his gait and action.

In order to have a horfe beautiful and finely made, it has been agreed, on all hands, that his head fhould not be long nor too large, rather lean than flefhy; his ears thin and narrow, and of a becoming length, well fet on, pointing inwards; his brow or forehead not too broad and flat; his nofe fomewhat rifing, and of a good turn; his noftrils wide and thin; his muzzle fmall; his mouth neither deep nor too fhallow, with a ftar or fnip down his forehead, or a blaze, which is no way unbecoming, unlefs it be too large and difproportioned.

Horfes that are thus marked have generally one or more of their feet white, which is alfo very beautiful, and looks lively. His jaws fhould be thin and fufficiently wide, not approaching too near together, nor too high upwards towards the onfet, that he may have fufficient room to carry his head eafy, and in good place. His eyes well formed, fprightly, and of a middle fize. His neck fhould be arched towards the middle, arifing by a beautiful gradation out of his breaft and fhoulders, the mufcles thereof diftinct, but no where overcharged with flefh, growing fmaller and thinner, as it approaches towards his head. His fhoulders fhould be thin from the withers, with a gradual enlargement downwards, that his bofom or breaft be not too narrow nor too grofs. His fore-legs ftraight and well placed; his joints lean and bony; his knees not bending, and his pafterns not too long; his feet round and fmooth, and his finews firm and well braced; his carcafe rather round than flat; his back not too low, and for ftrength and durablenefs pretty even and ftraight. His ribs rather home than open, as they approach towards his haunches; his buttocks round, and the mufcles not too flefhy but diftinct; his hocks or gambrels neither ftanding too wide, nor too near together; his hocks fhould be lean and no ways puffed or flefhy; his pafterns fhort, his legs flat and thin, and his tail fet in a good place, rather high than low, rifing upon every motion of his body. The more thefe properties concur in any horfe, the more beautiful he muft be, efpecially when they correfpond and agree in due proportion, one to another; and the more a horfe is wanting in thefe, the more plain and ordinary he will appear.

HORSE-HOE, *fee the articles* CULTIVATOR *and* HOE.

HORSE-HOEING, the operation of cultivating plants according to the principles of the New Hufbandry; viz. by hoeing the intervals or alley between the rows of corn, and by that means fupplying the plants with frefh nourifhment.

" I have tried, fays M. de Valliers, to hoe my alleys after M. de Chateauvieux's method, which I look upon as the beft and moft expeditious; notwithftanding that feveral difficulties which I have met with in the practice of it, have obliged me to give it up. For example, the great furrow in the middle of the alley is, according to his directions, to be filled up by two turns of the plough, one on the right-hand, and the other on the left, after which it is to be opened again by one turn of the cultivator with two mould-boards, or two or three turns of the common plough.

" When I fet about this work, the firft turn of the plough, if the fhare went to any depth worth fpeaking of, always filled up the furrow in fuch manner, that to prevent its being poached by the horfes, I tried to make them walk on one fide, upon the upper-ground, and confequently very near to the rows of corn: but then, in the firft place, I could not avoid the deftruction of a great number of plants, without giving fuch attention as was not only exceffively troublefome, but almoft impracticable: and fecondly, I could plough only the furface; becaufe, as the furrow was filled, the plough could turn up but very little earth, without being choaked, and becoming extremely heavy.

" If, to fave the plants, I made the horfes tread partly upon the mould turned over into the furrow, the plough choaked equally, and for the fame reafon, whenever the furrow was cut deep. All I could do in this cafe, was to give only a fuperficial ploughing: and with that it was impoffible to ufe the cultivator with two mould-boards, to form the furrow, becaufe that inftrument cannot work in any but a loofe well-tilled ground.

" All thefe inconveniencies may not happen in a foil different from mine. I am the more inclined to think this, as M. de Chateauvieux certainly does not experience them: but at the fame time I muft likewife obferve, that this juftly celebrated gentleman has inftruments fo perfect, and directs his fervants with fuch fuperior judgment, that few can expect eafily to equal him in the practice of the New Hufbandry.

" Not being able, for the above reafons, to do with one turn of the cultivator with two mould-boards, what, as M. de Chateauvieux himfelf obferves, can frequently not be done with lefs than three or four turns of the common plough, which, added to the two turns that are given to fill up the furrow, make in all five or fix bouts, I purfued, and with great advantage, nearly the method before defcribed. I fay nearly that method, becaufe I have made fome few alterations, by which I think it is rendered both eafier and better.

" 1. I make the mould-board twelve or thirteen inches deep, inftead of nine or ten that it was before. The furrows are by this means made wider, and the plough is more eafily drawn, becaufe it finds more room to difcharge its load of earth in, and fuffers lefs preffure.

" 2. To give the fecond hoeing with the plough, inftead of continuing to turn the earth over towards that fide of the alley where only one furrow was turned up at the ending of the firft ploughing, I, on the contrary, begin this fecond at that furrow, approaching, if poffible, to within two or three inches of the row of corn, and then I make a furrow in the contrary direction, which turns the earth up againft that row.

" My reafon for ploughing fo near the rows, when I give this fecond hoeing, is, that I have obferved that the rains which fall pretty frequently in the fpring, between the firft ploughing and the fecond, harden the earth greatly, and that drought afterwards hardens it ftill more, fo that the roots of plants can no longer pierce or fpread in it with eafe: and yet nothing is more neceffary, in order to their being benefited by every culture of the earth, than that they fhould find an eafy paffage into the mould which lies next to the rows. It is therefore highly proper to ftir that mould, when the fecond hoeing with the plough is given, which, with me, is when the corn has begun to fpindle; that being the time when the plants fhoot with the greateft vigour, and when their roots ought confequently to begin to extend to fome diftance.

" I have not perceived that the plants have been at all damaged by the plough's coming fo near them. They ought to be fo much the lefs hurt thereby, as the rows are placed over a furrow which has been cut deep; a fituation which, alone, is capable of making the corn tiller, and pufh ftrongly: though the affiftance of culture is likewife neceffary, to fupply the ftalks and ears with plentiful nourifhment.

" I am the better pleafed with this method of bringing the hoe-plough almoft clofe to the rows, as it facilitates a very important operation ftrongly recommended by M. Duhamel, and which I never before thought practicable: I mean, the raifing up of the earth about the bottom of the plants; as well to give them greater nourifhment, as to prevent their being lodged. The following is my method on this occafion.

" When I fill up the furrow which I have cut as clofe as poffible to the row, I hold the plough floping, in fuch manner that the earth is forced away from it, and is raifed up about the plants. If this flope is not fufficient, which may fometimes depend on the condition of the ground, or the dexterity of the ploughman, I, in that cafe, make the mould-board two or three inches wider, when I ufed to fill the furrow, than it was when I made that furrow: and to this end I fcrew on to the extremity of the mould-board, a thin plate of iron about four or five inches wide. Thofe who practife the New Hufbandry in fo extenfive a manner as to employ feveral ploughs, will find no inconvenience in having one, larger than the reft, purpofely for this important operation. As I do not give this fecond hoeing with the plough, till after the corn has begun to fpindle, it is eafy for me to avoid burying the plants, efpecially if there are no great clods in the ground: but, at all events, I always earth the plants up as much as poffible, when there is no other danger than that of burying here and there a few of them, becaufe that accident is eafily remedied afterwards, if it be worth while.

" When I am to give the third hoeing with the plough, I confider the condition of the ground. If it is in good tilth, well loofened, and free from weeds, I ufe only the cultivator: otherwife I ufe the plough, three or four turns of which are fufficient to perform this operation in the following manner:

" The firft cut turns the earth over into the middle furrow: the fecond and third are in a contrray direction; and the fourth takes up what was loofened by the third, whereby the furrow is replaced in the middle of the alley. Some time after this, and efpecially if a fhower of rain has fallen, I cut that furrow ftill deeper, by one turn of the fingle or double cultivator, as M. de Chateauvieux directs.

" But as, even after all thefe ploughings, the great furrow may chance to be neither deep enough, nor fufficiently cleared of mould, owing either to the imperfection of the inftruments made ufe of, or to the inaptitude of the ploughman, that defect may eafily be remedied after harveft, by giving one ploughing more, which is to be begun by throwing up the earth to the right and left towards the fummit of the beds; that is to fay, over the ftubble. This practice is alfo confirmed by M. de Chateauvieux's inftructions.

" The one ploughing extraordinary which this operation requires, ought not to be thought much of; becaufe the moft important point in the New Hufbandry certainly is, the providing of a good depth of well ftirred mould, for the plants to extend their roots in."

HOT-BEDS, beds of earth enriched with manure, in order to forward vegetation, when the feafon or climate is not warm enough for the purpofe.

By means of hot-beds, fkilfully managed, the feeds of plants, brought from any country between the tropics, may be made to flourifh even under the poles.

Heat and humidity being the great inftruments of vegetation, to promote the growth of any plants, thefe muft be duly proportioned, fo as neither to exceed nor come fhort of the bounds nature has allotted for it.

The ufual way of making hot-beds, is of horfe litter and grafs mixed together, and left on a heap for eight or ten days to putrify, and then removed into a bed, and covered up with glaffes.

For raifing cauliflowers, cucumbers, melons, radifhes, and other tender plants and flowers in January or February, Mortimer directs to provide a warm place, defended from all the winds, by being inclofed with a pale or hedge of reeds or ftraw, about fix or feven feet high. Within this raife a bed two or three feet high, and three feet over, of frefh horfe dung, about feven or eight days old; then tread it down very hard, make it level, and, if you will, edge it round with boards or brick, laying fine rich mould about three or four inches thick on it. When you find by your finger, that the extreme heat of the bed is over, plant your feeds at pleafure, and fet your forks four or five inches above the bed, to fupport the frame, and cover with ftraw or mat, to fecure the feeds and plants from cold and wet; only uncover them in a warm day, an hour before noon, and cover them again an hour after. Obferve to earth up your plants, as they fhoot up, and, when able to bear the cold, tranfplant them.

In Holland they ufe hot-beds made of fand; and likewife of tanners bark, which, when once rightly prepared, will maintain an equable heat for fix months.

Bradley propofes very juftly a thermometer to be ufed to regulate the heat of the hot-beds. Thus, a hot-bed for cucumbers muft be kept fo hot as to raife the fpirit in a glafs to the fame height as the natural temperature of the weather will raife it about the end of May and June, when cucumbers will grow without artificial heat or fhelter.

HOVEL, a fhed open on the fides, and covered overhead.

HOVEN, a difeafe common to cattle, on eating too greedily of green clover. It confifts in the paunch of the creature being fwelled to a very great degree, which often, if not prevented, puts an end to the creature's life. The fureft method of curing this terrible difeafe, is that of making an incifion into the paunch of the beaft, and by that means the wind, which caufed the fwelling, will efcape through the orifice, and the creature recover.

A correfpondent of the editors of the Mufeum Rufticum has given the following account of his performing this operation.

" I took, fays he, a fharp-pointed pen-knife, and fixing my eye on the moft prominent part of his belly, thruft the blade through the integuments quite into the abdomen: there iffued out a great guft of wind very fetid, with fome water of a redifh colour: the bullock feemed eafier, but far from well; for the wound prefently clofed up, and admitted no more air to efcape; fo that I was under the neceffity of ftabbing him twice more in different parts of the belly before he was thoroughly relieved, which, by the help of a clyfter after the laft ftab, was prefently brought about: and here give me leave, gentlemen, before I leave this fubject, to give a few cautions to thofe who may be under the neceffity, one time or other, of performing this very ufeful operation: reflection and experience warrant me in them, therefore I fhall freely proceed.

" Firft then, if it be performed with a pen-knife, not to be fearful in pufhing in the blade a proper length, till you find wind iffue out; for if the wind be in the cavity of the belly, you cannot poffibly hurt the gut, the whole body of the wind being between you and it, which no reafonable bladed pen-knife can touch; and if the wind fhould be pent up in the inteftine, you muft penetrate it before the beaft can be relieved. To this laft, perhaps, it may be objected, that we run the hazard of killing the beaft by wounding the gut; but I am far from thinking fo, as I have feen many wounds of the inteftine, both in man and beaft, very happily cured: yet granting there might be fome danger in it, ftill we are certain, if the poor beaft can get no relief, it muft die; and fo circumftanced, furely, gentlemen, a doubtful remedy is better than none at all.

" Another caution is, that where thefe wounds are made in the belly with a proper pen-knife, it is not advifeable to have them fown up; for where there is a continual motion or action, as there is in the mufcles of the belly and parts adjacent, fuch a practice is not only unwarrantable, but cruel; and why fhould we not behave with humanity to the brute fpecies, as well as any other?

" My laft caution and advice is, that upon all thefe occafions, when the beaft is relieved of his wind, a proper clyfter fhould be thrown up immediately, as hot as he can bear it: thefe clyfters ftrangely relieve them, by acting as a warm, comforting bath to their diftempered bowels, and emptying the fame of the load of muck within them."

HOVER-GROUND, light ground.

HOUSE-BOTE, an allowance of timber out of the lord's woods, for the repairs of a houfe.

HULLS, the chaff, or hufks of corn.

HURDLES, are certain frames made either of fplit timber, or of hazel-rods, wattled together, to ferve for gates in inclofures, or to make fheep-folds, &c.

HURDS, or *Herds* of flax or hemp, the coarfer parts feparated in the dreffings from the tear or fine ftuff.

HURLE-BONE, in a horfe, a bone near the middle of the buttock, very apt to go out of its fockets with a hurt or ftrain.

HUSBANDRY, the bufinefs or employment of a farmer, or perfon who cultivates land, &c.

Hufbandry is divided into two kinds, and diftinguifhed by the epithets old and new. The former is that which has been practifed in all countries from the moft early times; and the latter that introduced by the ingenious Mr. Tull, and often called the horfe-hoeing hufbandry.

Experience fhews, that land, though ever fo well tilled in the autumn, when wheat, for example, is fown, hardens and foddens in the winter; its particles, beaten down by heavy rains, and funk by their own weight, approach each other daily more and more; the roots of the plants cultivated have confequently lefs and lefs room to extend themfelves in queft of their neceffary food; and their interftices in the earth become of courfe fo few and clofe, that they are not able to pierce through them, whilft weeds fpring up, and rob them of their nourifhment. By this means the earth, reduced to nearly the fame condition as if it had not been ploughed at all, is unable to affift the plants fown in it in the fpring, when they ought to fhoot with the greateft vigour. They confequently then ftand moft of all in need of the plough to deftroy the weeds, to lay frefh earth to their roots in the room of that earth which they have exhaufted, to break the particles of the ground anew, fo as to enable their roots to fpread, in order to their gathering an ample provifion of food, which then does them the greateft fervice.

In the common hufbandry, the whole attention is to provide a great ftore of nourifhment for the wheat, at a time when it fcarcely confumes any, as it then produces only a few blades, after which it is left to itfelf, at a feafon when it might, and fhould be moft affifted by proper culture; a management as prepofterous as it would be to give a child a great deal of food, and diminifh it gradually as he grows bigger; or, to ufe Mr. Tull's comparifon, to give filk-worms, before they are hatched, treble the full ftock of leaves neceffary to maintain them, till they have finifhed their fpinning, and not to allow them any when they really want being fed.

The great advantage of having land in fine tilth before it is fowed, is univerfally acknowledged: but we muft not ftop at thofe firft preparations. Plants require a continuation of culture while they grow, and muft not be forfaken till they have attained their full maturity.

Thofe who are againft the frequent ploughings ufed in the New Hufbandry, are afraid of drying the earth too much; becaufe, fay they, the moifture efcapes more eafily from a well loofened foil, than from a hard and clofe earth.

In

In anſwer to this it will appear from many of the following experiments, that, even in the drieſt weather, land cultivated according to the new method, continues conſtantly moiſter than that which is managed in the old way. Inſtead of a ſtagnant wet, more hurtful, perhaps, than beneficial, to plants; earth made fine to a good depth, is prepared, as the reverend Dr. Elliot expreſſes it, "with open mouth, to drink and retain the dew, which, when it falls upon the land that is untilled, or but poorly tilled, does not ſink far, but is carried off by the next ſun's heat." That dew is one of the greateſt fertilizers of the earth, has been repeatedly proved; and that it will penetrate ſo deep in a fine looſe ſoil, as to keep that moiſt, while the ground badly tilled is parched up, appears, among many demonſtrations, from Mr. Evelyn's experiment of digging a hole, and filling it up with its former mould well pulverized: or, as Mr. Tull obſerves, till a field in lands; make one land very fine by frequent deep ploughings, and let another be rough, by inſufficient tillage, alternately: then plough the whole field croſs-wiſe in the drieſt weather, which has continued long; and you will perceive, by the colour of the earth, that every fine land will be turned up moiſt; but every rough land will be as dry as powder, from top to bottom.

Another proof of the benefits which ariſe from ſtirring the ground well and often between plants, while they grow, and conſequently a confirmation of the fundamental principle of the horſe-hoeing huſbandry, is thus drawn by Dr. Elliot, from the common manner of raiſing Indian corn.

"The land, ſays he, being previouſly prepared, planted, and the corn come up, we plough a furrow off from the corn on each ſide, then hoe it, and the next time plough up to the corn; ſo that this tillage is nearly the ſame as is now propoſed for wheat, or whatever we would plant: only by the way, I would obſerve, that the ploughings between the rows, for Indian corn, is ſo ſhallow, that one would be apt to think it intended for nothing more than merely to kill the graſs and weeds; whereas it is found by experience, that, though there be neither graſs nor weeds, the ploughing and hoeing will make the corn grow, and that the more the land is ploughed and hoed, the better and longer it will reſiſt drought, and yield the better crop: nay, what is ſtill more remarkable, if the Indian corn be well tilled, the next crop, whether it be oats or flax, will be proportionably greater aud better; ſo that the land muſt have gained ſtrength and richneſs. If it were not ſo, why did not the Indian crop exhauſt and ſpend the ſtrength of the land, eſpecially when we conſider how large that corn is made to grow by good tillage? But we find the contrary; the better the crop of Indian corn, the better the crop will be of oats. There is no ſort of huſbandry, wherein the ſuperior force and virtue of tillage doth ſo evidently appear, as in the raiſing of Indian corn: for if you ſhould plough and harrow the beſt of land, and ſow or plant the corn, and never do any thing more to it, there will be leſs corn than if you ſhould plant poor land, and tend it well: the poor land well ploughed and hoed, ſhall bring a greater crop than the rich land. We hereby ſee the efficacy and advantage of this repeated tillage, which falls in ſucceſſively, according to the exigency and want of the plant in its ſeveral degrees of growth, and keeps the land in a proper ſtate. Why ſhould it not have the ſame effect upon wheat, and every other plant that is ſuſceptible of the like culture?"

If ſeveral rows of wheat are ſown in a poor but well ploughed land, the blades of the corn will turn yellow in the ſpring, eſpecially in dry weather. Let the earth bordering upon theſe rows be ploughed deep, in ſome places near, and in others farther from the rows, and the plants will reſume their proper colour; firſt in the places neareſt to the new ploughed ground, and afterwards gradually in the others, according to their diſtance; which proves that they recover their verdure, in proportion as their roots reach the looſe mould. This holds equally true in all plants; for Mr. Tull declares, that he does not remember ever to have ſeen a poor one contiguous to a well-hoed interval, unleſs overpowered by a too great multitude of other plants, an exception which muſt be equally made if it were a plant that required more or leſs heat or moiſture than the ſoil or climate afforded; and that, on the contrary, he has ſeen plants grow to an amazing ſize, when the earth around them has been frequently tilled. He mentions, among others, a plant of ray-graſs, which chanced to ſtand in a turnip field, where, being hoed as the turnips were, it acquired a bulk at leaſt equal to a thouſand plants of the ſame ſpecies; and a plant of muſtard, which grew higher than he could reach, ſo as to be more like a tree than an herb.

The ſtirring of the earth about the plants whilſt they grow, is productive of ſuch excellent effects, that, in ſome parts of Berkſhire, and in many places in France, they hand-hoe their corn, particularly wheat, and find that the crops amply repay all the charge and trouble of this expenſive operation; which, however, cannot be performed but in well-peopled countries. Every huſbandman will immediately ſee, how much a hoe-plough is preferable for this work, and that, to uſe it rightly, the corn muſt neceſſarily be planted in regular rows, as it is in the new huſbandry.

Our reaſon tells us, that the longeſt lived plants ſtand moſt in need of this culture. Perennials require it more than annuals, and wheat which is ſown in autumn, and does not ripen till nine months after, want it more than ſpring-corn, which occupies the ground only for a few months. The former has to conquer a ſoil rendered hard during the courſe of the winter; but the other has not that difficulty to ſurmount, though both of them, and indeed all ſorts of plants, are greatly invigorated by the repeated laying of fine freſh earth to their roots. Every one knows the vaſt efficacy of wood land, before its native ſtrength and vigour are exhauſted; and ſuch, in ſome degree, is that which this tillage furniſhes; beſides being conſtantly attended with the advantage of deſtroying weeds. How far this laſt important part of agriculture was well executed by the ſarcling, or ſarriſon, as Mr. Tull calls it, of the ancients, we ſhall not pretend to ſay, becauſe we have no clear account of the manner in which it was performed; but it does not ſeem to have been in any way equal to the horſe-hoeing huſbandry, which likewiſe, among its many other excellencies, keeps the land from going out of tilth.

We ſhall here add Mr. Duhamel's obſervations on the uſe of dung, as given by that gentleman in his Elements of Agriculture.

"It is often, ſays he, more advantageous to increaſe the fertility of land by ploughing, than by dung: 1. Becauſe, in general, only a certain quantity of dung can be had, the product of twenty acres being ſcarcely ſufficient to produce enough for four or five; whereas the particles of the earth may be divided and ſubdivided almoſt to infinity. The help derived from dung is therefore limited; whilſt no bounds can be ſet to the benefits that may accrue from ploughing.

"2. Few plants raiſed in dung ever have the fine flavour of thoſe which grow in a good ſoil moderately dunged. Our kitchen gardens and our other grounds afford daily inſtances of this truth. Pulſe, pot-herbs, and fruit, are ſeldom ſo good in the neighbourhood of great cities, where dung abounds, as in country gardens, where but little of it is uſed. The corn raiſed in thoſe exceſſively dunged lands, yields a great deal of bran, and not much fine flour, and is difficult to keep. Nice horſes will not eat oats of the growth of fields manured with human ordure. But nothing is ſo ſtriking as the difference between the wine of an undunged vineyard, and that of vines which have been greatly dunged.

"3. Dung, which is ſuppoſed to act by fermentation, cauſes indeed an inward diviſion of the particles of the earth, which muſt be very uſeful, as well as the food which it furniſhes to plants: but the plough, beſides dividing thoſe particles, changes their ſituation, and turns the ground upſide down, ſo that the part which was expoſed to the influences of the air and dews, takes the place of another part which is brought from within the earth, up to its ſurface. The conſequence of this is, that well ploughed land is not exhauſted by weeds, and that it admits the moiſture of rains and dews, together with the rays of the ſun, all of which contribute greatly to render it fertile, as has been proved by very many experiments.

"4. Dung attracts infects, and thofe infects gnaw plants. It is well known that the roots of trees planted in dunged ground, are very liable to be damaged by infects: and this is one of the chief reafons why florifts banifh dung from their gardens. Worms, grubs, and other fuch like vermin, make dreadful havock in their beds of flowers; and I have feen meadows where the grafs has been entirely deftroyed, by their eating its roots.

"I muft add, that moft forts of dung contain a great many feeds which fill the land with weeds.

"5. It is true that dung is equally ferviceable to light lands, and to ftrong; but the fame may be faid of ploughing.

"Land is too ftrong when its particles lie fo clofe together, that the roots of plants cannot extend between them, without great difficulty in queft of their neceffary food; for want of which they will remain poor and fickly: but when the ground has been well loofened by repeated ploughings, and its plants are fet at greater diftances from each other, thofe roots will be able to fpread freely on all fides, to pervade every minute chafm, and to collect fuch quantities of food as will make the plants grow ftrong and vigorous. The friendly influences of the atmofphere will then penetrate to them. What plainly proves the good effects of loofening fuch foils, is, that their fertility is fometimes increafed by a mixture of fand, inftead of dung. Now fand does not afford any nutritive fubftance; but only hinders the particles of the earth from re-uniting too clofely.

"Ploughing is equally beneficial to light lands, for the very contrary reafon; though thefe do not require fo much of it as the other. There is no danger of their being exhaufted by any expofure to the fun; but, on the contrary, they acquire an additional degree of fertility by the ftirring and grinding of their particles, and are thereby the better fitted to receive the moifture of rains and dews, and the falutary influences of the air and fun; whilft their inward pores are at the fame time better adapted to the proper extenfions of the roots of plants, by their being leffened.

"But let the benefits arifing from dung be ever fo great, let the means of obtaining enough of it be ever fo eafy, and let even its defects be corrected as much as can be, ftill it will not be the lefs true, that frequent ploughing is of infinite fervice to land.

"For this reafon it is, that land intended for wheat is ploughed three or four times before the grain is fowed. Some farmers, who could not dung all their lands, ploughed part of them double the ufual number of times, and reaped greater crops from thefe, than from thofe which were dunged. The expence of the ploughings extraordinary will be much lefs than the price of the dung neceffary for the land, if the farmer is obliged to purchafe it.

"In 1759, M. Delu gave three ploughings to fome of his fields intended for oats; and though that year was very dry and unfavourable to fpring corn, his oats kept up well till they were perfectly ripe, and yielded a full crop of excellent grain.

"He gave five ploughings to a piece of wheat-land, which had not been dunged, and at harveft, had taller and finer corn there, than in the neighbouring grounds which had been dunged and cultivated in the ufual way. In fhort, the advantage of thorough tillage, while the plants are growing, is fo great, that, in many places, it has been found amply to repay even the expence of digging between the rows of corn.

"The farmer muft not think of practifing the New Hufbandry in land which cannot be brought to a fine tilth: for as no remedies are proper for all difeafes, fo no one culture can fuit every kind of foil.

"I have met with very zealous hufbandmen, who have been in a great hurry to procure all the inftruments proper for the horfe-hoeing hufbandry, before they had examined whether their ground was fit for ufing them. In walking over the fields, I have found them in fo bad order as to be full of clods, ftones, and all forts of weeds: only the bare furface of the land had been fcratched, by what they called ploughing; and indeed their common inftruments of tillage were fo imperfect, that it was hardly poffible for them to do more. I advifed them to deftroy thofe weeds by good and frequent ploughing, to procure good inftruments, to loofen the ground to a proper depth, to collect good manures, to drain their land well by trenches and ditches, and, in fhort, to practice the Old Hufbandry completely, before they attempted the new; for, in fact, all the requifites in the former muft be the foundation of the latter.

"To anfwer the ends of this hufbandry, the feeds muft be diftributed fo fparingly, that each plant may have room to extend its roots in fuch manner that they may be able to collect an abundant quantity of food; each plant muft be enabled to tiller greatly, fo as to produce a confiderable number of ftalks; and each ftalk muft be enabled to bear a fine long ear, well filled with grains to its very point.

"To effect the firft of thefe qualities, the field, after being thoroughly ploughed and well harrowed, muft be divided by furrows, the fpaces between which may be of fuch breadth as fhall be judged moft proper; for neither their precife width, nor the diftance between the rows of corn, is yet fully determined. In the middle of thefe fpaces, which will be diftinguifhed by the name of beds, the wheat, or other grain, is to be fown in one, two, or more rows. An inch will be fufficient for the diftance between the grains, lengthwife of the row; though that may be fomewhat lefs, if the ground be not very good for wheat; or, on the contrary, fomewhat more if it be excellent for that grain. By this diftribution, each plant will find, in the intermediate fpaces between the beds, and in the beds themfelves, a fufficient extent of earth wherein to collect its neceffary food; for thofe intermediate fpaces, which I fhall call alleys, muft be wide enough to admit of ftirring the ground in them while the plants grow: but to anfwer the fecond and third intentions, it is of confequence that thefe ftirrings be performed at proper feafons, becaufe each of them is to produce its particular effect.

"It is effentially neceffary that the rows of corn be fown very ftraight; a circumftance which, though it be attended with fome trouble, ought not to difcourage the hufbandman, becaufe the great difficulty will be only the firft time. After the ground has been once rightly fown, it will be eafy to continue in the fame regular tract every following year, without taking the precautions I am now going to obferve.

"If the field be not very large, a furrow traced with a fpade or pickaxe, directed by a line ftretched acrofs the ground, will enable the ploughman to guide the horfe that draws the drill; and he will take care to leave a proper interval between one furrow and another, if three rows are to be fown.

"If the extent of ground be too great for the above method, poles or ftakes may be ftuck, five feet afunder, at each end of the field, to guide the ploughman, who, with a common plough, will trace fmall furrows, by the help of which the horfe and drill may be properly directed.

"It will be right, if poffible, to fuit the direction of the furrows to the declivity of the land, that the water may drain down to the loweft part of the field, where a ditch fhould be dug to carry it off: and it will alfo be neceffary, to make them lengthwife of the field, if convenient, that the lefs ground may be loft by the fpace which muft be left for the plough to turn in.

"After the feed is put into the hoppers of the drill, the horfe which draws this inftrument muft be made to walk flowly in the furrow before traced by way of guide: and in order to drop as nearly as poffible the intended quantity of feed, the outlet of the hopper muft be proportioned to the fize of the grain.

"As it will be fomewhat difficult to manage the drill rightly at firft, till the hufbandman becomes ufed to it, he fhould look over his field as foon as the corn has fprouted, and then drop by hand a few grains in the places where it may have failed.

"The land fhould be fown about the middle of September, or, at fartheft, by the end of that month: and it will be right always to try the goodnefs of the feed beforehand, by fowing fifty or an hundred grains of it in a fine mould, or moift ground, where it will foon appear whether they all rife.

"Land which retains water ſhould be ploughed once in October, when the weather is fine. In doing this, a furrow ſhould be firſt cut in the middle of the alleys, and then it ſhould be filled with the earth on each ſide, even ſo far as to arch it up, and leave only a ſmall furrow on either ſide, cloſe to the beds, to drain off the wet, which would prove very prejudicial to the plants if it were to remain long near their roots. This looſening of the earth will alſo fit it for being mellowed by the winter's froſts; to which, however, care muſt be taken not to expoſe the roots of the corn, by leaving them too bare of mould. The moſt proper time for this ſtirring of the ground is when the plants have ſhot out ſome blades.

"The ſecond horſe-hoeing, which ſhould be given as ſoon as the hard froſts are paſt, that is to ſay, by the end of March, is intended to make the plants tiller; and will have this effect, if, after the earth near the rows has been ſtirred a little, that which was before laid up in the middle of the alleys be returned back to the furrows at their ſides. This earth, having been mellowed during the winter, will afford excellent nouriſhment to the plants now beginning to vegetate apace, and they will ſoon put forth their multiplied ſtalks.

"The third hoeing, which is the ſecond after winter, and is intended to ſtrengthen the ſtalks, ſhould be performed when the ears of the corn begin to appear. This culture, which is looked upon as the leaſt important of all, and is ſometimes even omitted without any great inconvenience, need not be any thing more than a ſlight ſtirring of the earth, in which it will however be right to begin to hollow the alleys.

"The laſt ſtirring of the earth between the rows of corn is one of the moſt important, being that which makes the grains ſwell, and grow full bodied to the very point of the ear. The moſt proper time for this is when the ears begin to bloom: but as the corn is then high, only one furrow can be cut in the middle of the alleys, the earth of which ſhould be laid up to the ſtems of the plants on each ſide. The plough will hardly be able to paſs more than twice in this furrow, which ſhould, however, be made as deep as poſſible, in order to bank up the greater quantity of earth. By this operation, the now fallow alleys are prepared for the next ſowing; for it is in the middle of them that the corn is to be planted the following year; and the now eared wheat is earthed up, to prevent its being lodged; though in general corn thus cultivated is leſs apt to be beaten down, than that which is raiſed in the common way, becauſe the ſtraw of this, being more expoſed to the air, becomes harder, and acquires a firmer texture, eſpecially toward its bottom. It is for this reaſon that a tuft of corn, which ſtands quite ſingle, is ſcarcely ever beaten down by the weather.

"Theſe repeated hoeings of the earth will certainly be rewarded with a very plentiful crop, unleſs the ſeaſons prove extremely bad.

"When the corn is reaped, all poſſible care ſhould be taken not to trample upon the adjoining ploughed ground.

"It is well known, that vigorous plants do not ripen their ſeeds ſo ſoon as thoſe which have been ſtinted in their growth: for this reaſon the corn cultivated according to the principles of the new huſbandry, ripens later than in the common way, and ſhould therefore be ſown ſomewhat earlier.

"We will now ſuppoſe that the crop is reaped, and that the ſame field is to be ſown again with wheat the next year, and every year after, as it may be, becauſe the rows of corn are placed each time in the middle of the former alleys, which have been ploughed during the whole year, without producing any thing. Thus, the only difference between this new method and the old huſbandry is, that inſtead of reſting, or fallowing, a whole field, whilſt another whole field is under corn, and each of them is ſeparate from the other; the fallow here is in the ſame field as the corn, being interpoſed by means of alleys, which are the part reſted between the beds, which are the part cultivated: but there is this great advantage here, that the ſtirring of the earth in the alleys, which are not planted, not only prepares the ſoil admirably for being ſown the next year, but invigorates the plants actually growing in the beds.

"If it be thought proper to dung the alleys, in order prepare them for the reception of the ſeed, the dung, which ſhould be thoroughly rotten, muſt be laid in the bottom of the deep furrow before made in the middle of them, and there covered with the earth which was thrown up towards the rows of wheat. If the land does not want dunging, this deep furrow is filled up without it; and this ſhould be done immediately after harveſt, that there may be time to give the ground another ſtirring, which need only be a ſlight one, before the ſowing of the rows, which are now to be in the middle of the former alleys; and the alleys of this year will be in the place of the laſt year's ſtubble.

"Though land, cultivated according to the principles of the new huſbandry, does not require ſo much dunging as that which is managed in the old way, yet this manure will always help to enrich the ſoil, eſpecially if it be uſed in the manner here directed. By being thoroughly rotten when it is laid in the furrow, and there covered over immediately after harveſt, it will have time to mellow and diffuſe its influence, and not be apt afterwards to choak up the ſhares of the drill; an inconvenience which does not happen with pigeons dung, which therefore need not be ſtrewed till the ground is ploughed for ſowing.

"It is farther obſerved:

"1. That if dung be uſed for the ſecond year's crop, very little of it will ſuffice, becauſe it need only be laid in the bottom of the furrows.

"2. That there can hardly be any occaſion for dung this ſecond year, becauſe, if the earth of the beds in which the wheat grew was good, that of the alleys, of the ſame ſoil, muſt be ſtill better, by reaſon of its having been fallowed and well tilled.

"3. That the ſecond year's wheat is placed in a moſt advantageous ſituation, its roots having a depth of twelve or fifteen inches to extend themſelves in, by means of the furrow which was in the middle of the alley. For this reaſon, corn ought to thrive beſt in thoſe lands which have been longeſt cultivated according to the new huſbandry.

"The earth in the alleys is to be horſe-hoed during the ſecond year, in the ſame manner, and at the ſame ſeaſons, as in the firſt.

"This frequency of hoeing ought not to be objected to; for the labour of the firſt hoeing, to make the furrows on each ſide of the rows, and lay the earth up in the middle of the alleys, cannot be great; and the ſecond only returns that earth into thoſe furrows: the third is only to ſtir the ſurface of the ſoil: the fourth and laſt is to make the deep furrow in the middle of the alleys, and bank up the rows of corn on each ſide, with the earth taken out of it; ſo that neither of theſe operations ever extends to above a third part of the ground, at any one time.

"The whole field might indeed be ploughed up after harveſt: but I would adviſe the huſbandman not to touch the ſtubble then, becauſe the rows of that will help him to guide the drill in ſtraight lines, and the yet unrotten ſtraw might be apt to clog the ſhares of the drill, ſo as to prevent their working properly. However, if the ſtubble be very ſhort, this caution becomes the leſs material, and the whole field may then be ploughed; though ſtill it will be neceſſary to plough it again in October, in order to make drains to carry off the wet.

"It is almoſt needleſs to obſerve, that all the operations of which I have been ſpeaking, muſt often be performed either a little earlier, or ſomewhat later, according as the year is more or leſs forward; and that it will always be neceſſary to wait till the ground is dry enough to be ploughed without danger of its clodding; a circumſtance which varies greatly, according to the nature of the ſoil."

The editors of the laſt edition of Mr. Tull's Horſe-hoeing Huſbandry, give, in their preface to that work, the following comparative calculation of the expence and profit of the old method of culture and the new, drawn up by a gentleman who has practiſed both for ſome years, and who has no attachment to the new huſbandry, farther than he has found it anſwer in his trials. They candidly appeal to experience, "whether every article in this calculation is not eſtimated in favour of the common huſbandry; whether the expence be not rated lower than most farmers find it; and whether the crop be not such as they would rejoice to see, but seldom do.

" In the new husbandry, every article is put at its full value, and the crop of each year is computed four bushels short of the other, though, in several years experience, it has equalled, and generally exceeded, those of the neighbourhood in the old way."

An Estimate of the Expence and Profit of Ten Acres of Land, in Twenty Years.

I. In the Old Way.

	l. s. d.	l. s. d.
First year for wheat costs 33l. 5s. viz.		
First ploughing at 6s. per acre —	3 0 0	
Second and third ditto, at 8s. per acre	4 0 0	
Manure, 30s. per acre — — —	15 0 0	
		22 0 0
Two harrowings and sowings, at 2s. 6d. per acre — — — —	1 5 0	
Seed, three bushels per acre, at 4s. per bushel — — — — —	6 0 0	
Weeding, at 2s. per acre — —	1 0 0	
Reaping, binding, and carrying in, at 6s. per acre — — — — —	3 0 0	
		11 5 0
Second year for barley costs 11l. 6s. 8d.		
Once ploughing, at 6s. per acre —	3 0 0	
Harrowing and sowing, at 1s. 6d. per acre — — — — — —	0 15 0	
Seed, four bushels per acre, at 2s. —	4 0 0	
Weeding, at 1s. per acre — —	0 10 0	
Cutting, raking, and carrying, at 3s. 2d. per acre — — — —	1 11 8	
Grass-seeds, at 3s. per acre — —	1 10 0	
		11 6 8
Third and fourth years lying in grass cost nothing.		44 11 8
So that the expence of ten acres in four years comes to 44l. 11s. 8d. and in twenty years to		222 18 4
First year's produce is half a load of wheat per acre, at 7l. per acre — — — — — —		35 0 0
Second year's produce is two quarters of barley per acre, at 1l. per acre — — —		20 0 0
Third and fourth year's grass is valued at 1l. 10s. per acre — — — — — — —		15 0 0
So that the produce of ten acres in four years is		70 0 0
And in twenty years it will be — — —		350 0 0
Deduct the expences — — — — — —		222 18 4
And there remains clear profit on ten acres in twenty years by the old way — — —		127 1 8

II. In the New Way.

	l. s. d.	l. s. d.
First year's extraordinary expence is For ploughing and manuring the land, the same as in the old way —		22 0 0
Ploughing once more, at 4s. per acre	2 0 0	
Seed, nine gallons per acre, at 4s. per bushel — — — — —	2 5 0	
Drilling, at 7d. per acre — —	0 5 10	
Hand-hoeing and weeding, at 2s. 6d. per acre — — — — —	1 5 0	
Horse-hoeing, six times, at 10s. per acre — — — — — —	5 0 0	
Reaping, binding, and carrying in, at 6s. per acre — — — —	3 0 0	
The standing annual charge on ten acres is — — — — —	13 15 10	
Therefore the expence on ten acres in twenty years is — — —		275 16 8
Add the extraordinaries of the first year, and the sum is — — — — — — — —		297 16 8
The yearly produce is at least two quarters of wheat per acre, at 1s. 8d. per quarter, which on ten acres in twenty years amounts to		560 0 0
Therefore, all things paid, there remains clear profit on ten acres in twenty years, by the new way — — — — — — —		262 3 4

" So that the profit on ten acres of land in twenty years, in the new way, exceeds that in the old by one hundred and thirty-five pounds one shilling and eightpence, and consequently is considerably more than double thereof: an ample encouragement to practise a method whereby so great advantage will arise from so small a quantity of land, in the compass of twenty-one years lease; one year being allowed, both in the old and new way, of preparing the ground.

" It ought withal to be observed, that Mr. Tull's husbandry requires no manure at all, though we have here, to prevent objections, allowed the charge thereof for the first year; and moreover, that though the crop of wheat from the drill-plough is here put only at two quuarters on an acre, yet Mr. Tull himself, by actual experiment and measure, found the produce of his drilled wheat crop amount to almost four quarters on an acre: and, as he has delivered this fact upon his own knowledge, so there is no reason to doubt of his veracity, which has never yet been called in question. But that we might not be supposed to have any prejudice in favour of his scheme, we have chosen to take the calculations of others rather than his, having no other view in what we have said, than to promote the cause of truth, and the public welfare."

The following account of the advantage of the drilling and horse-hoeing tillage, above the broad-cast tillage, is extracted from the account of the Experiments sent to the Society of Arts, &c.

The manner and expence of cultivating lands for corn in several counties in England, being materially different, it is thought proper to prefix to these calculations of the comparative profits arising from the broad-cast, and from the drilling and horse-hoeing tillage in Cumberland and Yorkshire, an account as well of the prices of labour, &c. as of the manner in which each kind of tillage is practised in these several counties: to the end that farmers, who are the persons more immediately interested, may have every circumstance exposed to their view, that may the better enable them to form their judgments on the following estimate:

The Prices of Labour, &c. in Cumberland.

	s. d.
Ploughing per acre — —	3 6
Manure, per one horse cart load — —	0 4
Lime per bushel (Winchester) — —	0 2
Hire of man and one horse cart per day —	1 10
Ditto of a labourer per day — —	0 10
Horse-hoeing per acre drilled — —	1 2
Rent of land per acre — —	8 0
Harrowing per acre — —	0 6
Wheat per bushel — —	4 0

The Kind of Soil on which the Experiments were made, in Cumberland.

A heavy moist soil on a clay bottom, rather too stiff for barley.

The Broad-cast Tillage of one Acre of Land, in Cumberland.

N. B. The land on which the experiments were made in this county, were ploughed out of lea, and bore a crop of oats.

The first Year for Turnips.	Expences. l. s. d.
Three ploughings with two horses, the first in March, second in May, third in June —	0 10 6
60 one horse cart loads of manure —	1 0 0
90 bushels (Winchester) of lime —	0 15 0
Six days work of man and horse leading the manure, and two ditto the lime —	0 14 8
Two days work of a labourer spreading the manure — —	0 1 8
Seed and sowing — —	0 2 0
Three harrowings — —	0 1 6
Total expence the first year	3 5 4

N. B. In the above, as well as in all the following calculations, the expence of reaping, threshing, and sending

ing to market, is omitted, it being countervailed by the price or value of the ſtraw (according to general eſtimation) which laſt is likewiſe omitted in the computation of the value of the crops.

The value of the crop of turnips computed 3l.

The Prices of Labour, &c. in Yorkſhire.

	s.	d.
Ploughing per acre	4	0
Manure per load	2	6
Hoeing an acre of turnips in broad-caſt, during a ſeaſon	6	0
Hand-hoeing per acre drilled	2	6
Horſe-hoeing ditto	1	0
Drilling per acre	0	6
Rent of land	15	0

The Kind of Soil on which the Experiments were made, in Yorkſhire.

Inclining to a hazle mould, but light and dry.

The Broad-caſt Tillage of one Acre of Land, in Yorkſhire.

The firſt Year for Turnips.	Expences. l.	s.	d.
Four ploughings	0	16	0
Harrowing and ſeed	0	2	0
Hoeing the turnips	0	6	0
15 load of dung	1	17	6
Total expence	3	6	0

Value of the crop of turnips, 2l.

The Broad-caſt Tillage of one Acre of Land, in Cumberland.

The ſecond Year for fallow, and the third Year for Wheat.

	Expences. l.	s.	d.
Four ploughings	0	14	0
Four harrowings and ſowing	0	2	6
Seed-wheat	0	12	0
Total expence	1	8	6

The value of the crop, viz.
3 quarters of wheat, at 4s. per buſhel, 4l. 16s.

N. B. In this country the broad-caſt tillage does not admit a fourth year's crop without a conſiderable loſs: therefore after the third year the land is again manured, and the ſame proceſs repeated for three years more, and ſo on from three years to three years.

The Broad-caſt Tillage of one Acre of Land, in Yorkſhire.

The ſecond Year for Barley.

	Expences. l.	s.	d.
Two ploughings and harrowings	0	10	0
Three buſhels of ſeed-barley and weeding	0	8	0
Total expences	0	18	0

Value of the crop of barley, viz
Four quarters at 18s. per quarter, 3l. 12s.

The third Year for Clover.

	l.	s.	d.
14 pounds weight of clover-ſeed	0	4	0

Value of two crops clover, 1l. 10s.

The fourth Year for Wheat.

	l.	s.	d.
One Ploughing and Harrowing	0	7	0
Three buſhels of ſeed and weeding	0	16	0
Total expence	1	3	0

Value of the crop of wheat, viz.
Three quarters at 1l. 16s. per quarter 5l. 8s.

N. B. In this kind of tillage the land never lies fallow: and after the fourth year, the ſame proceſs is repeated for four years more, and ſo on.

The Drilling and Horſe-hoeing Tillage of one acre of Land in Cumberland.

N. B. The land on which the experiments were made in this county were firſt ploughed out of lea, and bore a crop of oats.

The firſt Year for Turnips.	Expences. l.	s.	d.
Three ploughings with two horſes, viz. the firſt in March, ſecond in May, third in June	0	10	6
30 one horſe cart loads of manure	0	10	0
45 buſhels (Wincheſter) of lime	0	7	6
Three days work of a man and horſe leading the manure, and one ditto the lime	0	7	4
One day's work of a labourer ſpreading ditto	0	0	10
Seed	0	0	6
Harrowing and drilling	0	1	6
Three horſe-hoeings, each equal to one-third of an acre	0	3	6
Total expence	2	1	8

Value of the crop of turnips 2l. 10s.

The ſecond Year for Barley.	l.	s.	d.
Two ploughings, viz. the firſt in March, and the ſecond in April or May	0	7	0
Seed-barley, viz. one buſhel (Wincheſter)	0	2	0
Harrowing and drilling	0	1	6
Three horſe-hoeings	0	3	6
Total expence	0	14	0

Value of the crop of barley, 1l. 16s.

The third Year for Wheat.	l.	s.	d.
One ploughing before Michaelmas	0	3	6
Seed-wheat	0	3	6
Harrowing and drilling	0	1	0
Five horſe-hoeings	0	5	10
Total expence	0	13	10

Value of the crop of wheat, viz. 15 buſh. 3l.

N. B. The fourth year a ſecond crop of barley, and the fifth year a ſecond crop of wheat at the like expence, and with like profit, and then after the fifth year, the whole proceſs is repeated. The ridges are formed five feet and half wide, and a treble row of drills ſeven inches aſunder, on the top of each ridge.

The Drilling and Horſe-hoeing Tillage of one Acre of Land, in Yorkſhire.

For Barley.	Expences. l.	s.	d.
Two ploughings, viz. the firſt in autumn, and the ſecond in ſpring	0	8	0
Seed-barley, viz. one buſhel, or four pecks	0	2	$1\frac{1}{2}$
Three horſe-hoeings, viz. on the 30th of May, 7th of June, and the beginning of July	0	3	0
One hand-hoeing on the 8th of June	0	2	6
Total expence annually	0	15	$7\frac{1}{2}$

Value of the crop, viz. 3 qrs. 6 buſh. 2 pecks, at 18 s. per qr. 3l. 8s. $7\frac{1}{2}$d.

For Wheat.	l.	s.	d.
Two ploughings	0	8	0
Seed-wheat, viz. one buſhel, or four pecks	0	4	4
Three horſe-hoeings	0	3	0
One hand-hoeing	0	2	6
Total annual expence	0	17	10

Value of the crop of wheat, viz. 2 qrs. at 1l. 16s. per qr. 3l. 12s.

N. B. The ridges are here formed four feet and a half wide; and a double row of ſeed, ten inches aſunder, drilled on the top of each ridge: the intervals for horſe-hoeing being thus three feet eight inches. The ſame proceſs, and the ſame expence, is repeated annually: and a piece of ground in Yorkſhire, under this method of tillage, had yielded the eighth ſucceſſive crop, viz. four of barley, and four of wheat, at the time the account was ſent to the Society, of the values above ſpecified, without ever having had any manure beſtowed upon it, and without ſhewing any ſign of impoveriſhment, being then, to all appearance, in full heart.

An Eſtimate of the Advantage of the Drilling and Horſe-hoeing Tillage, above the Broad-caſt Tillage, as both are practiſed in Cumberland and Yorkſhire.

In order to aſcertain the proper method of calculation, whereby to arrive at a deciſive eſtimate of the comparative profits from the two kinds of tillage; it becomes, in ſome meaſure, expedient here to inſert an abſtract of two experiments, contained in the accounts mentioned in the title page: and the rather that experiments of this kind, coming ſo properly authorized to the Society, ought not to remain in obſcurity. Theſe experiments were made to prove the difference of the acreable produce, and the difference of the rate of increaſe from the ſeed ſown as well in broad-caſt, as in various forms of drilling

In Yorkſhire.

Quantity of ſeed ſown on one acre.

		Pecks.	Prod	Rate of increaſe.
A. D. 1763.	In broad-caſt - -	10	178	Seventeen-fold.
	In equidiſtant drills -	6	194	Thirty-two-fold.
	In double drills, 11 inch. aſunder, and 4 feet 10 inches interval -	3	102	Thirty-four-fold.
	In treble drills, 7 inches aſunder, and 4 feet 3 inches interval -	2	100	Fifty-fold.

Quantity of ſeed ſown on one acre.

		Pecks.	Pro	Rate of increaſe.
A. D. 1765.	In broad-caſt (barley) -	9	137	Fifteen-fold.
	In equidiſtant drills -	8	144	Eighteen-fold.
	In double drills, 10 inch. diſtant, and 3 feet 8 inches interval - -	4	136	Thirty-four-fold.

N. B. This laſt is that preferred in the Yorkſhire drilling-tillage before ſpecified.

Now firſt, That the rate of increaſe alone is not the proper ſtandard to form a judgment of the profits of either kind of tillage, will be evident from a ſlight attention to the foregoing experiment. The quantity of ſeed requiſite to ſow an acre of land is in itſelf ſo ſmall, viz. at the utmoſt but eight or ten pecks, that it is of very little conſequence to a farmer, whether he ſows ten pecks (as in the common broad-caſt) or only two pecks (as in the treble drill method) on an acre. But when he conſiders that from the firſt, his acre will produce him 178 pecks, and from the ſecond but 100 pecks; there appears ſuch a difference in the acreable produce as muſt engage his attention: ſo that taking nothing into the account beſides the quantity of ſeed ſown the acreable produce, and the rate of increaſe, he muſt neceſſarily prefer the method which gives him the 178 pecks on an acre, to that which gives him only 100 pecks, notwithſtanding that the latter is an increaſe fifty-fold, and the former only ſeventeen fold.

But, ſecondly, That neither is the acreable produce the proper foundation for our calculations, is evident from this, that the expence of cultivating for the 178 pecks per acre, may happen to be proportionably greater than that of cultivating for the 100 pecks per acre, ſo that the profit upon each may be equal; in which caſe the farmer muſt prefer the 100 pecks per acre as affording him an equal profit at a leſs expence, though in fact it be the leſſer acreable produce. And if the expence of the 178 pecks per acre were any thing greater than proportionable, there would then be a double reaſon for preferring the leſſer acreable produce, viz. as giving a greater profit at a leſs expence.

Laſtly, It is plain from what has been ſaid, that the proper ground for calculating the comparative profits of each kind of tillage will be found in conſidering the expences and the returns made in each, in any given time, and when corn is at any given price. For thus it will eaſily and plainly appear, in which of theſe two kinds of tillage a farmer can turn his ſtock of money to beſt account; which is the only material queſtion. Nor can the inſtability of the price of corn, any wiſe impeach the certainty of this method of calculation, ſince to whatever price it riſes or falls, the returns from each kind of tillage muſt riſe or fall in like manner; ſo that the difference of profit muſt always remain proportionally the ſame.

This then is the method of calculation obſerved in the following eſtimate.

In Cumberland.

Broadcaſt tillage of one acre.

	Seed ſown.	Expence. l. s. d.	Value of the crop l. s. d.

Calculation

Calculation in Cumberland.

	l.	s.	d.
The neceffary expences for three years tillage of one acre in broadcaft, viz. 4 l. 13 s. 10 d. producing neat profit only	1	18	2
Will, from the above accounts, be fufficient to till 1 Acr. 1 R. 16 P. for the fame number of years in drilling, and will produce neat profit	3	10	9
Difference of profit from 4 l. 13 s. 10 d. in three years in favour of drilling	1	12	7

But fince this method of drilling tillage requires a renewal of manure only every five years, whereas the broadcaft method requires it every three years; therefore, taking the profits in each kind of tillage for fifteen years together, will give the true proportions.

	l.	s.	d.
Thus the faid fum of 4 l. 13 s. 10 d. in broadcaft tillage for fifteen years, will produce a neat profit of	9	10	10
But the fame expended in drilling and horfe-hoeing tillage, will, in the fame number of years, produce a neat profit of	22	1	2½

And whatever price corn, &c. bears, the returns made by each kind of tillage will bear a price proportional to thefe two fums; or the profits on the drilling tillage in this county for fifteen years together, will always be to that on the broadcaft tillage, for the fame time as 22 l. 1 s. 2½ d. is to 9 l. 10 s. 10 d. that is as 23 is to 10 nearly.

Calculation in Yorkfhire.

	l.	s.	d.
The neceffary expences for four years tillage of one acre in the improved broadcaft tillage, viz. 5 l. 6 s. 6 d. producing neat profit only	4	3	6
Will be fufficient to till 1 acre 2 R. 22 P. 6. for the fame number of years in the drilling method, and will produce a neat profit			
In barley	12	19	0
In wheat	12	17	1½

Which is more than three times the profit that is yielded by the broadcaft method.

A comparative Calculation of Expence and Profit between the Drill and the Common Hufbandry, taken from Mr. Baker's Report to the Dublin Society of his Experiments in Agriculture, for the Year 1765. Publifhed by Order of that Society.

An Eftimate of the Expence upon a Plantation * Acre of Wheat, in the Common Hufbandry.

	l.	s.	d.
To the firft ploughing, commonly called breaking for fallow, 8 horfes, 8 s. 2 ploughmen, 1 s. 4 d. 2 drivers, 1 s.	0	10	4
To the firft harrowing, 4 horfes, 4 s. a driver, 6 d.	0	4	6
To the fecond ploughing, commonly called gaurowing	0	10	4
To the fecond harrowing	0	4	6
To the third ploughing, commonly called ftretching	0	10	4
To fowing the feed, 8 horfes, 8 s. 2 ploughmen, 1 s. 4 d. 2 drivers, 1 s. the feedman, 8 d.	0	11	0
To feed wheat, one barrel	1	0	0
To rent for the year of fallow	0	18	0
To ditto, the year the crop is growing	0	18	0
	5	7	0

In this account 40 s. are charged for 40 horfes, imployed in the culture of one acre for wheat, in the common hufbandry; a charge which ought to be confidered by the farmer; for he actually buys and maintains his horfes for this bufinefs.

The crop which follows wheat is generally oats; but fometimes peas are fown inftead of oats; with fome, the practice is to let the peas follow oats; in which cafe they fallow only every fourth year; but where land receives no other affiftance than what arifes from fallow, it is a bad practice not to fallow every third year. It is the general practice to plough but once for oats; and therefore it fhall be ftated fo; but it is a much better practice to plough the wheat ftubble once before winter, and again in the fpring.

An eftimate of expence upon an acre of oats.

	l.	s.	d.
To ploughing once	0	10	4
To feed oats, 2 barrels	0	12	0
To harrowing 4 s. 6 d. feed-man 4 d.	0	4	10
To one year's rent	0	18	0
	2	5	2

Thefe two crops confume three years; after which the farmer is to begin again, and to incur every article of expence ftated in the above accounts, in order to obtain two crops more.

* An Irifh acre contains 7840 fquare yards.

An Eftimate of Expence upon a Plantation Acre of Wheat in the Drill Hufbandry, the firft Year.

	l.	s.	d.	
To ploughing 4 times, to prepare the fallow	2	1	4	This is the fame charge as in preparing for the common hufbandry.
To harrowing twice for ditto	0	9	0	This is the fame alfo.
To rent for the year of fallow	0	18	0	This charge is faved after the firft year.
To harrowing with the drill harrows	0	0	6½	Four acres a day may be harrowed with one horfe.
To fowing with the drill plough	0	1	1	From three to five acres may be fown in a day.
To feed wheat generally 5 ftone, but fuppofe 6	0	6	0	
To the firft, or winter hoeing	0	1	7	Two acres may be hoed in a day, two horfes, plough-man and driver: the defign of this hoeing is to leave the plants dry, and to meliorate the earth.
To the fpring hoeing with the cultivator	0	1	1	To deepen the foil, one horfe, plough-man, and driver.
To the third hoeing, i. e. to return the meliorated earth to the corn	0	1	7	To make the corn tiller, i. e. to increafe its branches.
To the fourth and final hoeing	0	1	1	To fill the grain, and render it large.
To rent, the year the corn is growing	0	18	0	
	4	19	3½	

☞ Although the drill culture for the firft year is very near as expenfive as the common, yet after taking the crop, the expence and labour of fallow, and the lofs of time, is not to be incurred again, as is unavoidable in the common hufbandry.

An Eſtimate of Expence upon an Acre of Drilled-Wheat after the firſt crop.

	l.	s.	d.	
To ploughing the land once —	0	10	4	One ploughing is all that is neceſſary.
To harrowing with the drill harrow —	0	0	6½	
To ſowing with the drill-plough —	0	1	1	
To ſeed-wheat — —	0	6	0	Be it remembered, five ſtone is enough.
	0	17	11½	
To four times horſe-hoeing, as before ſtated	0	5	4	
To one year's rent — —	0	18	0	
	2	1	3½	

Thus the land is ſown again with wheat every year, and inſtead of 4 l. 9 s. which is the farmer's expence in the common huſbandry, excluſive of one year's rent of the land: in the drill method it is no more than 17 s. 11½ d. and the total expence, inſtead of 5 l. 7 s. is no more than 2 l. 1 s. 3½ d. rent included; whereby there is a ſaving of 3 l. 5 s. 8½ d. an acre.

Before the account of profit and loſs upon theſe different methods of culture be ſtated, it will be neceſſary to take notice of an objection, which may perhaps be made to the above charge of ploughing in the common huſbandry.

It is pretended, that three quarters of an acre may be ploughed in a day, with one plough: but can it be done effectually? The land may, indeed, be ſcratched, but cannot really be ploughed as it ought to be.

The farmer ought to be cautioned againſt a trick too frequently practiſed in ploughing.

When a ploughman enters his plough and paſſes acroſs the field, he turns a ſod about a foot broad; when he is to return, he enters his plough about four feet diſtant from the outſide of the former furrow, and ſo turns another ſod of the ſame breadth, which, when turned, juſt meets the former ſod; thus four feet of the land appear to be ploughed, whereas the fact is, that the two feet lying under the ſods is not touched with the plough at all.

This deception, added to the practice of juſt ſkimming the ground, enables hirelings to undertake ploughing at ſix and ſeven ſhillings an acre.

But if a plantation acre of land be well and effectually ploughed, ten ſhillings and four-pence as charged above, will not appear too much; and it is, in fact, ſupported by the common courſe of buſineſs.

When wheat is to be ſown, it is the general cuſtom to ſend a barrel of ſeed into the field with two ploughs, which is to ſow an acre of land, and that is the uſual day's work for two ploughs in the general courſe of buſineſs.

Let us ſee then, what the expence will amount to: eight cattle will be eight ſhillings, two ploughmen one ſhilling and four-pence; two drivers one ſhilling, and the ſeed-man eight-pence, which in all makes eleven ſhillings, and correſponds with the above charge.

One Acre of Wheat and Oats in the Common Huſbandry, for fifteen Years.

Dr.	l.	s.	d.	*Per Contra*, Cr.	l.	s.	d.
To the expence on a wheat crop, 2d year	5	7	0	By the produce of wheat, 9 barrels, at 20s.	9	0	0

To clear profit ariſing upon an acre of land in fifteen years in the Drill-Huſbandry —	52	3	11
To clear profit ariſing upon an acre of land in fifteen years in the common huſbandry —	27	19	2
Greater profit on the drilled acre in fifteen years — — —	24	4	9

Which amounts to 1l. 12s. 3¼d. *per annum*, for fifteen years on the acre, more than by the common huſbandry.

In

In the drill-hufbandry the crops are ftated at three barrels of wheat lefs upon an acre than in the common hufbandry, that it may not be fuppofed to be over-rated; but in the common hufbandry, the crops are rated at the higheft; fourteen barrels of oats an acre, are alfo allowed in the common hufbandry, which every farmer muft admit to be great allowance upon the general produce.

That the drill culture will produce fix barrels an acre, is fully proved in Mr. Baker's report at large, which will fhortly be publifhed, where it will be fhewn, that much more has been produced.

Doubtlefs it will be obferved, that in fifteen years fourteen wheat crops are obtained in the drill-hufbandry; in the common hufbandry only five wheat and five oat crops; the five other years are not only loft, but are an heavy expence to the farmer.

A farmer having forty acres of tillage, fuppofing him to direct his attention to bringing it to the drill culture, would make in fifteen years 969 l. 10 s. more than he can in the common hufbandry: which is fuch an advantage, that the greater profit in the drilled acre in fifteen years will purchafe the fee fimple of that in the common hufbandry, at twenty-feven years purchafe, valuing the land eighteen fhillings an acre.

Thus it appears, that in every fifteen years the fee fimple of all the tillage lands of the kingdom, is loft to the community by the common courfe of tillage.

In ftating thefe accounts, no mention is made of fences, water cutting the land, weeding and reaping, as thefe articles of expence depend upon a variety of circumftances: but will, in general, be more upon the common hufbandry than the drill.

We fhall conclude this article with the following experiments made by that accurate and intelligent hufbandman M. de Chateauvieux.

Experiments made in the Year 1751, *by* M. Lullin de Chateauvieux, *firft Syndic of the City and Republic of* Geneva.

"In October 1750, fays M. de Chateauvieux, I began my experiments on a fpot of ground, of a rich ftrong foil, one hundred and fixty feet long and forty-two feet wide. Not being then provided with proper inftruments for the horfe-hoeing hufbandry, I ordered it to be dug with the fpade, and laid it out in feven beds of equal fize. Great care was taken to break the clods thoroughly, and to dig the earth very deep. The beds, which were in a loofe ftate, were raifed high in the middle.

"On the fourteenth of October, I fowed three of thefe beds with wheat, two with barley, and two with oats. I muft obferve that, in this country, it would have been better to have fowed a fortnight earlier.

"I made three furrows in each bed, fo fhallow, that the feed was not buried above half an inch deep. The wheat was dropped by hand in fingle grains, at the diftance of fix inches from each other. The barley was dropped at the diftance of nine inches, becaufe it branches more than wheat. Though oats branch more than either, yet, as they are a tender plant, and apt to be killed by the winter's cold, I fowed them at the diftance of three inches one grain from another.

"I ufed 2880 grains of wheat, weighing three ounces fifteen penny-weights, to fow the three beds. In one of the beds of barley I fowed four rows. I employed 1491 grains, weighing two ounces, in the fowing of two beds; and four ounces of oats were fufficient to fow the two other beds. I neglected to count the grains of the oats.

"Thefe feeds came up very well, and though they grew but little before winter, yet fome of them put forth their fecond blade. They foon fuftained a confiderable lofs. Numbers of fmall fnails eat many of the plants clofe to the earth. I judged it neceffary to fupply this lofs by fowing frefh feed.

"The winter was very unfavourable to corn. We had almoft continual rains, with little fnow or froft. The corn in general fuffered greatly, and the crops were very inconfiderable in this country.

"Early in the fpring, thefe plants made ftrong fhoots, and had much the better of the corn in the common way. Their blades were very large, and of a deep green, and the number of ftalks increafed greatly. The alleys were hoed in good time, and the advantage refulting from this operation was very manifeft. I vifited my plants towards the latter end of April, and found their numbers greatly diminifhed. The mifchief which the fnails had done them was almoft the only caufe. The inclemency of the winter likewife deftroyed fome: fo that I found I had loft 1068 plants of wheat, and had but 1812 remaining. My plants of barley fell fhort by 412, their number being reduced to 1079. The winter deftroyed fo many plants of the oats, that very few were left.

"From this time, all the plants grew exceedingly: they branched fo much, that, as far as I could judge, every plant of wheat, taking them one with another, produced twenty-eight ftalks, the barley above forty, and the oats ftill more. Each plant formed a large tuft, fome of fixty, eighty, and above a third part of the plants of about 150 ftalks: fo that, though they were at firft at a great diftance from each other, in June and July they entirely covered the furface of the alleys. All thefe fpindled, and produced, each in its kind, very long and large ears, full of grain from end to end. They ripened kindly, but had not yet got over all their mifchances. Thefe fine ears became a prey to birds, which could not be kept off. This is an inconvenience to which all fmall experiments are liable. That I might fave fomething, I was obliged to cut my corn down before it was quite ripe. But before I did that, I examined perfonally, with all poffible care, what might be the amount of the lofs which I had fuftained by the birds: and befides this, I fent for four farmers, in quality of appraifers, to eftimate the damage. They all agreed, that it was above half the crop, and affured me I fhould not miftake if I reckoned it as fuch. I had formed the fame judgment myfelf. We found the lofs fomewhat lefs confiderable in the barley. As to the oats, it could not be fo well afcertained; but we believed it could not be lefs than a third part of the crop.

"While the wheat ripened, I difcovered that fome of the plants were blighted. All thefe, whether blighted totally or only in part, were plucked up by my direction, before I cut down the reft of the crop. They amounted to 297; fo that I was reduced to 1515 plants, the feed of which, after deducting that which produced the 297 blighted plants, is reduced to two ounces and fix penny-weights. The 1515 plants were the whole produce of the crop, and thefe yielded fifty-five pounds of eighteen ounces to the pound. But the fame ground and plants produced likewife what was eaten by the birds; for which it is but juft to make an allowance. The whole produce will then have been in reality 110 pounds, which to me feemed very confiderable.

"I made another enquiry, which I judged to be of fome importance: this was, to know whether the number of the fineft and largeft ears, was greater than that of the middling and fmalleft. I examined them with the utmoft attention, and found almoft all the ears of equal beauty; at leaft nineteen out of twenty, I am confident, were fo.

"I was likewife willing to know what number of grains might be contained in each ear. To this end, without regarding the proportion I had found between the number of the fineft ears and that of the fmalleft, I took twelve middle fized ears, twelve of the fmalleft, and twelve of the fineft.

"The twelve middling ears contained one with another thirty-feven grains;

"The twelve fmalleft ears, thirty grains; and

"The twelve fineft ears, fifty grains apiece.

"The 1079 plants of barley, produced feventy-five pounds of eighteen ounces to the pound. What was eaten by the birds fhould likewife be added here.

"My oats produced one hundred and three pounds of eighteen ounces, exclufive of what was deftroyed by the birds.

"This little experiment fhews, that the new hufbandry will be equally profitable for all forts of grain.

Obfervations on the foregoing Experiment, by M. De Chateauvieux.

"The quantity of wheat gathered from the three beds, feems to me as great as could be expected. Though I had

had but fifty-five pounds, yet adding thereto the fifty-five eaten by the birds, this little spot yielded one hundred and ten pounds. In large fields we are not so sensible of what the birds destroy.

"If we likewise take into this account, the 1068 plants destroyed by the snails, and the 297 blighted plants, making together 1365, these would have yielded 100 pounds of wheat, and the whole crop would have been 210 pounds; for it cannot be doubted but they would have yielded in the same proportion as the 1515. What proves it is, that in a space about thirty feet long, at the end of the beds, which escaped the snails, very few plants failed; and the rest were very thriving, and branched greatly; so that it is evident, the whole ground could easily have nourished all the plants that were intended to grow on it, and which were at the distance of six inches from each other. I make this remark, in order ro shew what may be expected from the following experiments, it being an easy matter to sow the ground so as to have the desired number of plants.

"I suppose then, and I think justly, that this small spot of ground can produce 210 pounds of wheat at one crop: but the inestimable advantage of the new husbandry is, that it keeps the earth in a state fit for sowing every year; so that in two years it can yield 420 pounds; whereas, in the common husbandry of this country, the farmer can have but one crop in that time, being obliged to sow his land only every second year; and that one crop will fall greatly short of the two which the new husbandry will produce. A vast advantage in favour of this last.

"Without being too partial to the new husbandry, we may expect that the second and following crops will be more plentiful, the earth being in finer tilth. Accordingly, the wheat with which I have sowed these three beds a second time, is already visibly benefited by the looser state of the mould, which was so frequently stirred in the summer. I have provided against the accidents which destroyed so many of my plants, by sowing thicker. Instead of three ounces, fifteen penny weights of wheat, which I sowed last year, I have now sowed nine ounces, and twelve penny-weights; and though the snails have again eaten many of the plants this year, close to the ground, a sufficient number still remains, by means of the additional seed, to fill the beds, and they are equally distributed.

"I shall now compare the crop I have been speaking of, with that of the experiment which I made on the same spot of ground in the year 1729, in order to see whether I could not obtain a more plentiful return, by sowing thinner than is usually practised. The ground was ploughed and sowed in the common way. I employed six pounds of wheat to sow it, being somewhat less than half the usual quantity. The plants looked extremely well during the whole time of their growth, and produced above double the quantity that wheat did in the common fields. They yielded me 105 pounds of wheat. Even in this way I could have but one crop in two years: and it appears that I have not exaggerated the produce of the new husbandry, in making it 420 pounds in the same space of time, which is a clear gain of 315 pounds.

"I afterwards tried some other experiments; one of which, made in the year 1746, I must now mention. I tried two things at the same time: first, whether wheat would grow after it had been kept several years; and, secondly, whether sowing each grain at six inches distance, would turn to account. As I did not intend to make the experiment on a large field, I chose for it a spot of strong earth, in bad condition, fit for making bricks. I sowed in it three quarters of an ounce of wheat, which I had preserved carefully for eight years. It rose pretty well; but about one fourth of the grains did not sprout at all. After the winter, these plants grew very strong. I delayed seeing them too long, for I found them quite choaked with weeds. I sent a woman to weed them, who, unluckily, at the same time pulled up almost all the plants of wheat: the finest suffered most, she not imagining that they could be wheat. There were but about forty plants left, and those at very great and unequal distances. These produced tufts of upwards of fifty stalks, with ears five or six inches long, containing a great deal of grain, which became the prey of birds. This experiment, if it answered no other end, is at least a proof of the goodness of the new husbandry.

"The good success of these little experiments, was a strong inducement to me to make more considerable ones: but in order to this, it was necessary to be provided with a proper hoe and drill-plough; for I must confess, that Mr. Tull's did not appear to me to be such. Its great fault is, that it is too complex.

"Being provided with a proper hoe-plough, I soon became sensible of the advantages of it. Numbers of such ploughs are already used in this country; and, which is saying a great deal, even our farmers make use of them.

"This is the plough which I used all this summer in preparing my ground. It did admirably well in the alleys of my experiment, after the corn was above four feet high. No plant was hurt by it, and I could bring the plough as near to them as I pleased. Thus it fully and conveniently performs this hoeing, in which I have seldom used more than one horse. I have likewise prepared with it the ground sowed with wheat this autumn.

"My new hoe and drill-plough have made it easy for me to enlarge my experiments this year. However, I thought it most adviseable to proceed by degrees; and have therefore restricted myself to the culture of about ten acres, according to the new husbandry, part of which is in a very strong soil, part in a very light soil, and part in a middling and stony soil.

"What I have had chiefly in view in my experiments this year is, "to know exactly what quantity of seed will produce the most plentiful crop." To this end, I have sowed wheat in different degrees of thickness, dropping the grains some at one inch, and some at two, and so on, to the distance of six inches from each other.

"All this wheat has at present a fine appearance, and the plants are infinitely stronger than those in the common fields: their blades are much larger, and of a very deep green colour. What is more, they have already branched, and promise a great number of stalks. I have counted on some plants twenty, and on others twenty-five. Upon the whole, there is great reason to expect a plentiful crop.

"I have made another experiment with the drill-plough, with which I have sowed some of my common fields. Instead of distributing the seed by hand, in the broadcast way, as in the old husbandry, I have sowed the whole field with this instrument, without leaving any alleys. This has saved a great deal of seed, having employed only twelve pounds of eighteen ounces, to sow the same extent of ground as used to be sowed with 110 pounds. Yet I think this sufficiently thick: the plants are very fine, and of a deep green. They have already begun to branch, and promise many stalks. Hitherto my wheat gives me reason to be pleased with the experiment I am making. I have sowed about thirty acres in this manner."

Experiments made by M. Lullin de Chateauvieux, *in the Year* 1752.

"My experiments this year are of three kinds. The first was made on the same spot as the last year's experiment: the second, on a piece of ground which was made into beds for the first time; and the third, on a field ploughed in broad lands in the common way, but sowed with the drill-plough, in equally distant rows, without any intermediate alleys.

First Experiment, Numb. I.

"I have already mentioned, that this spot was sowed with wheat, the beds being now made in the middle of the former alleys. The summer hoeings had brought this ground to so fine and loose a state, that, after one ploughing, I sowed the three beds with the drill-plough, on the twenty-fifth of September; and to prevent the accidents I before met with, I increased the quantity of seed to nine ounces fifteen penny-weights.

"The wheat rose extremely well, and the rows were full of plants, which became very strong and thriving before the winter. Though snails destroyed a great number

ber of them, as they had done the year before, yet I judged the rows sufficiently stored with plants, and thought that this accident would do no great damage to the crop.

" The winter was pretty favourable to corn in general. My plants made very strong shoots in the spring; but I found some chasms in the rows which I had not perceived in the autumn. I imputed this in some measure to the inclemency of the winter, which had undoubtedly destroyed several weak plants. These chasms were but few, and the worst of them had about two plants in fifteen inches.

" I horse-hoed the alleys for the first time on the ninth of March, and a second time on the twenty-fifth of May. The ground was in so loose a state, that I thought it needless to hoe it afterwards, especially as the wheat was in an exceeding good way. It continued of a very deep green till it ripened; the blades were extremely large; and the plants branched much more than they had done the year before. It was a common thing to find plants with between sixty and seventy stalks, which, in general, grew to above five feet and some inches high, and were crowned with large ears quite full of grain.

" As soon as the wheat had done blossoming, I found it necessary to defend it against the birds. Thanks to the care that was now taken, they did it less hurt this year than the last: but still they eat a great deal of it, though I cannot precisely determine the quantity.

" As soon as the wheat appeared to be near ripe, in order to preserve it from the farther plunder of those robbers, I reaped it, on the twentieth of July, though I would rather have chosen to let it stand five or six days longer. It remained in the field four days, to dry, and was threshed towards the latter end of August. It yielded an hundred and forty-two pounds of wheat, at eighteen ounces to the pound.

" This wheat was very fine, perfectly clean, and the grain much larger than in the common way.

" This experiment gives just rise to the following remarks:

" First, The earth of these three beds having been pulverized and brought to a very loose state by the horse-hoeings in 1751, the plants were stronger, and more thriving than those of the year before; a circumstance which contributed to the increase of the crop.

" Secondly, This crop justifies my estimate, that this spot of ground could yield 210 pounds of wheat in one season, if cultivated according the principles of the New Husbandry: for if we add to the 142 pounds reaped this year, the loss occasioned by the birds and snails, it is pretty evident that the whole produce would have nearly amounted to 210 pounds.

" Luckily, that I might be more thoroughly satisfied what loss I suffered by the birds, I counted in two different places how many stalks the plants in the three rows had yielded. On a length of ten feet, I found 1600 in one place, and 2030 in another. As I would always avoid over-straining my calculations, I shall only suppose that every ten feet in length produces 1600 stalks: the beds, being 160 feet long, will consequently contain at least 25600 stalks, and the three beds together 76800 stalks, or ears.

" To know, in the next place, how many pounds of wheat might be contained in that number of ears, I had as many of them threshed, a month after harvest, as yielded a pound of eighteen ounces. They were taken at random, without culling them, out of a sheaf which seemed to have been but little damaged by the birds.

" Three hundred and sixty ears yielded those eighteen ounces of wheat: so that, dividing 76800, the whole number of ears, by 360, the produce of the crop would be 213 pounds six ounces, at eighteen ounces to the pound, or 240 pounds of sixteen ounces. Hence it appears, that my first estimate was pretty just, and that the produce may be even more considerable hereafter.

" Thirdly, This spot was clear of weeds; though it used to be over-run with them. It appears by this, that the New Husbandry destroys them effectually; though this advantage will be less felt the first year, than in other subsequent years.

" From the observation which I made, that the plants were in a more thriving state this year, than in 1751, it follows, that the earth, far from having been exhausted by the nourishment it had yielded the plants during that year, became more fruitful in this: which can be imputed only to the new culture; the land having received no other assistance, either by dung or manure.

" The wheat was this year, upon a very exact search, free from smut or blight. I found but one blighted ear, though there were numbers of such in the fields contiguous to mine. I cannot however impute this favourable circumstance to the new culture alone: it may have contributed thereto, and may lessen the quantity; but to be sure of that requires the experience of some years."

EXPERIMENT, Numb. II.

" This experiment was made on a larger piece of ground, formed into beds six feet wide. The distance from the middle of one bed to the middle of the next, was also six feet; and the whole extent of the spot was about an acre and a quarter. Each bed was sowed with three rows of wheat.

" The small quantity of seed with which this ground was sowed, certainly required that every grain should grow: but the intended number of plants fell greatly short, several of the grains not rising at all, and many of those which did rise, being destroyed by insects. The greatest damage was done by snails. There were great chasms in the rows, without any plants. As far as I could judge, between a third and fourth part of the rows did not produce any thing.

" The hoeings were performed this year at proper seasons, and rather more frequently to make up for the neglect of the former year: for the ground was not in sufficiently fine tilth when the wheat was sowed.

" On the fourteenth and fifteenth of October 1751, the alleys were ploughed for the first time before winter.

" On the ninth and tenth of March 1752, they were ploughed again for the first time after winter.

" From the eighteenth to the twenty-fourth of April, the ground was weeded.

" On the twenty-ninth of April, the alleys were stirred with the cultivator; which was again repeated on the twenty-fifth of May and the seventh of June.

" This wheat made a fine appearance; the length of the stalks, and the largeness of the ears, shewed how much the new culture promoted the growth of these plants, which branched nearly as much as those of Num. I. This field was reaped on the twenty-fifth of July.

" I shall join to the account of what this crop produced, an estimate of what might have been expected if the same ground had been cultivated in the common way."

Comparison of the Produce of the same Field, cultivated according to the Old, and according to the New Husbandry.

" This field, which is of a very good and strong soil, was very badly ploughed last year by reason of the frequent and heavy rains, and had not been dunged for several years. In the common way, it used to be sowed with 318 pounds of wheat. This year, it was made into beds six feet wide, and was sowed on the twenty-fifth of September, with only ten pounds of wheat.

Produce of this field under the new culture in 1752.

" This field, laid out in beds, produced, of very fine large grained wheat		926 lb.
To be deducted.		
" Though this wheat was very clean, yet four parts in a hundred were sifted from it, as small corn; valued at — — — —	37 lb.	47 lb.
" For the seed sown — —	10 lb.	
Neat produce -		879 lb.

4 H

" In

" In this huſbandry, the ſame field is ſowed every year; ſo that, ſuppoſing the crop of 1753 to be only equal to this of 1752, (and there is no doubt but it will be greater) it will again produce — — — — —	879 lb.
Amount of the two crops —	1758 lb.

Produce of the old Culture.

" If we judge of it by the beſt crops of former years, it will be three times the quantity of the ſeed, viz. — — — — — —	954 lb.

To be deducted.

" Loſs by ſifting, fifteen per cent. It has often been twenty-five and thirty per cent. and even more. Every time this field was ſowed, the corn was lodged, which prevented the ears from filling, and rendered the grains ſmall and ſhrivelled — — —	143 lb.	461 lb.
For the ſeed — — — —	318 lb.	
Neat produce —		493 lb.
" Conſequently the balance, in favour of the New Huſbandry, is — — — —		386 lb.
		879 lb.

" As this field yields but one crop in two years, in the common huſbandry, it would produce in that ſpace only — — — —	493 lb.
" From whence it follows, that the neat profit of the new culture in the ſame ſpace of time, exceeds the other by — — — —	1265 lb.
	1758 lb.

" Suppoſing this field never to produce a greater crop than that of this year, it is evident that it is beſt to follow the new method. But we can already promiſe, that the ſucceeding crops will be more plentiful. The field is now ſown in the new way; it has not yet ſuffered any damage by inſects; and the rows are well ſtored with plants, whoſe more thriving ſtate promiſes a better crop than that of the laſt year.

" It may perhaps be thought odd, that I ſhould limit the produce of the field ſowed in the common way, to three times the ſeed. I know there are lands in this country which yield more, viz. four or five times the ſeed, and ſometimes upwards: but then it muſt be granted, that there are but few ſuch lands; and that they are fields in extraordinary fine tilth, and enriched with manure. I therefore ſpeak of our lands in general, taking good and bad together. In this caſe, I ſay, the produce, one year with another, will not exceed three for one.

" My fields have always been as well cultivated as any in the country. I have computed the amount of my crops for ſixteen years running, viz. from 1730 to 1745, incluſively. Theſe accounts were carefully kept by a ſteward who died a few years ago, and I do not find that the produce ever was greater than what I have been ſaying, one year with another."

Experiment, Numb. III.

" About an acre and ſeventeen poles of ground, in another field, was laid out in beds like the former. This land, which is very ſtrong, was but in bad tilth, notwithſtanding the care I took to break the earth thoroughly, and reduce it into ſmall particles. Frequent rains were the cauſe of this. It was ſowed with the drill-plough on the twenty-fourth of September. Only ſeven pounds of wheat were uſed. The plants roſe pretty well: but towards the end of autumn, they were deſtroyed daily by inſects, and thereby reduced to a very ſmall number, which greatly diminiſhed the crop.

" On the ſixteenth of October 1751, the alleys were ploughed for the firſt time before winter.

H U S

" On the tenth and eleventh of March 1752, they received their firſt ploughing after winter.

" On the firſt of May the ground was weeded.

" On the twenty-third of May the alleys received their ſecond ſtirring with the cultivator, and on the twelfth of June they were ploughed.

" The plants which came up were very fine, and branched greatly: the ears were like thoſe of the experiments I have already mentioned, and the grain equally large. Though the produce was but 392 pounds, yet it is a fine crop for the ſmall number of plants that eſcaped unhurt.

" As I know the cauſes to which the ſcantineſs of this crop was owing, I make no doubt but it will equal that of any of the other fields next year. It is now ſowed for the ſecond time in the new way. The rows are well ſtored with plants, and the corn is in as good condition as can be deſired."

Experiment, Numb. IV.

" This experiment was made at the diſtance of ſix miles from my houſe, on a light poor ſoil, which induced me to dung it. The beds were about ſix feet wide, and were ſowed on the twenty-firſt of September with three pounds and three quarters of wheat, which produced fine plants and large ears, and yielded 196 pounds. Though the earth had not been well ſtirred, nor at proper ſeaſons, yet the corn ſowed in it produced greatly. The dung undoubtedly helped to make up for the want of due culture."

Experiments

Made on Fields ſown in equally diſtant Rows with the Drill-Plough.

Numb. V.

" I have ſowed fields cultivated in every reſpect in the common way, except in the manner of diſtributing the ſeed, which was done with the drill-plough. The whole field was covered with rows of wheat, diſtant from each other ſeven inches and a half.

" The advantages which I propoſed to myſelf by ſowing in this manner, were, firſt, the ſaving of ſeed, and preventing the earth from being over-ſtocked with plants; ſecondly, burying the ſeed at a proper depth; thirdly, having the plants at equal diſtances: and, laſtly, the little ſtirring of the ground, and breaking of the clods, which the drill-plough effects at the ſame time that it ſows. Theſe things ſeemed to me more likely to be attended with ſucceſs than the common way of ſowing.

" The plants of this wheat were very fine; their deep green colour ſhewed their ſtrength: the largeneſs of their blades, and the number of their ſtalks, ſhewed likewiſe that they found greater plenty of nouriſhment than wheat in the common way. The plants had in general four, ſix, eight, ten, or more ſtalks; ſo that theſe fields, which, till the month of April, ſeemed ſcarcely to have been ſown, changed then ſo as hardly to be known again, by the number of ſtalks which ſhot forth at that time. The wheat was taller than that in the common way, and the ears larger and better filled with grain.

" An account of the produce will ſhew what may be expected from this manner of ſowing.

" *Account of the Produce of the ſame Field ſowed Part in the old Way, and Part with the Drill plough, on the fourteenth, fifteenth, and ſixteenth of September*, 1751.

" The whole of this field uſed commonly to be ſowed with twenty meaſures of wheat, each meaſure containing 106 pounds of eighteen ounces. Three meaſures, or 318 pounds of wheat, were ſown in the uſual way in the richeſt part of the field. The remaining part, which would have required 1802 pounds in the common way, was ſowed with the drill-plough with only 265 pounds.

" The ſoil was middling, neither too ſtrong nor too light, and pretty ſtony. The land was poor, becauſe it had not been dunged, which indeed it ſeldom was, the owner not having more than was neceſſary for his vines.

Produce

Produce of the new huſbandry.

The 265 pounds of wheat produced		5450 lb.
To be deducted.		
For ſmall and bad grain ſifted out, 4 per cent.	218	483 lb.
For the ſeed	265	
Neat produce		4967 lb.

" If the other part of the field, which was ſowed with the three meaſures in the old way, had been ſown with the drill-plough, it would have yielded	960 lb.

To be deducted.		
Loſs by ſifting, 4 per cent.	38 lb.	84 lb
For the ſeed	46 lb.	
Neat produce to be added to the above		876 lb.
Neat produce of the whole		5843 lb.

Produce of the old huſbandry.

" That part of the field which was ſowed with the three meaſures of 106 pounds each, produced thrice the quantity of the ſeed, mixed with bad grain. The ſame meaſure of this grain weighed but 103 pounds. This field yields no more even in the beſt years. If the whole of it had been ſowed in the old way, it would have produced 6180 lb.

To be deducted.		
Loſs by ſifting, 15 per cent. It has often been 25 and 30 per cent.	927 lb.	3047 lb.
For the ſeed	2120 lb.	
Neat produce - - - -		3133 lb.
Balance in favour of the new method		2710 lb.
		5843 lb.

Experiment, Numb. VI.

" I ſowed, continues M. de Chateauvieux, another field of about three roods and fifteen poles in the ſame manner, with thirty pounds of wheat, reckoning 18 ounces to the pound, on the twenty-fourth of September. The ſoil was ſtrong, and in fine tilth. The wheat grew in every reſpect like that of the preceding article, with this only perceptible difference, that the ſtraw was ſomewhat longer, and the ears larger. It was not threſhed till the beginning of December, and yielded 809 pounds of very fine wheat (the pound 18 ounces.) The produce of this field was greater than that of the former, in proportion to the quantity of ſeed. But the ſoil of this was better, and in finer tilth."

Experiment, Numb. VII.

" This experiment was made about three miles from me, on a piece of ground of the extent of about two roods and twenty-ſeven poles. This land is neither too ſtrong nor too light, and may be called a pretty rich ſoil. It was ploughed three times, like other lands, and had not been dunged for many years. It uſed to be ſowed with 165, or 170 pounds of wheat. It was now ſowed on the fifth of October with only twenty-four pounds. Though the ſeaſon was ſo far advanced, this ſeed came up pretty well before winter. The plants throve greatly in the ſpring, and the field became covered with ſtrong ſtalks, and very large ears, full of fine plump grain.

" The crop yielded 800 pounds of clean wheat, without mixture of any other ſeeds. Deducting from this the twenty-four pounds of ſeed, the neat produce is 776 pounds. This field, when ſowed in the common way, produces in the beſt years about 875 pounds, from which if we deduct 165 pounds for the ſeed, the neat produce will be 710 pounds. Thus we ſee that the ſame ground ſowed with the drill-plough, produced 66 pounds more than when ſown in the common way. But as wheat raiſed in this laſt way is always mixed with abundance of ſeeds of weeds, which muſt be ſeparated by ſifting, an allowance muſt likewiſe be made for that; and the profit will then not be limited to the 66 pounds only, which the owner reaped more than in the common way.

" I omit ſeveral experiments of wheat ſowed in beds, and with the drill-plough, in equally diſtant rows, the ſucceſs of which has been nearly equal to that of thoſe I have already ſpoken of. I ſhall mention only one more, and that on account of a circumſtance which deſerves to be known. I made it on a light ſoil, the worſt I knew of, full of pretty large ſtones, and which had not been dunged in the memory of man. The ſtones did not hinder the drill-plough from dropping the ſeeds very gradually. I choſe this bad ſoil on purpoſe to ſee how wheat would thrive in it. I allowed too little ſeed, conſidering the badneſs of the ground. The ſtones prevented many plants from riſing, and many more were deſtroyed by inſects; ſo that the corn was very thin, and the crop ſmall. I was however pleaſed with it, becauſe I found the plants grew almoſt as ſtrong as in a good ſoil, and the ears were as large, and as full of grain.

" A little before harveſt, the wheat of all theſe experiments ſuſtained many heavy rains, accompanied with very high winds; and though the ſtraw was much longer than that of the wheat which had been ſowed in the common way, the corn was not lodged, whilſt a great deal was laid flat in the neighbouring fields. Some indeed was bent, but that is different from being lodged. This laſt ſituation is very hurtful to the filling of the grain; but its being bent is attended with no inconvenience. I am even inclined to think that it may be of ſervice to the wheat not to remain in a perpendicular direction, and I intend next year to be particularly attentive to this.

" It is not at all to be wondered at, that plants ſown in the common way ſhould not thrive ſo well as theſe which grow in beds. The former, not having been aſſiſted by the ſtirring of the mould, cannot draw ſo much nouriſhment from the earth as thoſe in beds. The ſize of theſe laſt has indeed exceeded my expectation. There is reaſon to be ſatisfied with this manner of ſowing, even if it were attended with no greater advantage than this year's crops afforded. But if the quantity of ſeed is increaſed, ſo that the field be ſtocked with as many plants as it can nouriſh, the profit will be ſo much the more conſiderable.

" It is time to return to our experiments on fields laid out in beds, which are the more immediate object of the new huſbandry.

" Thoſe which I have made this year have not brought the produce of the new culture to near what it will be hereafter, as will appear from what I ſhall next obſerve."

Reflections of M. de Chateauvieux, which prove the Truth of the Principles on which the New Huſbandry is founded.

" We ſee by the experiment, Numb. I. that the earth, by being in a looſer or more divided ſtate the ſecond year, is fitter to afford a greater quantity of nouriſhment to plants, whoſe productions will always be proportioned to the eaſe with which they can reach that nouriſhment.

" I was in hopes that the experiments of this year would have enabled me to determine what quantity of ſeed it is beſt to ſow, in order to obtain the greateſt crop. The lands on which I ſowed the moſt ſeed laſt year, ſhewed me plainly, that it would be right to increaſe the quantity, in order to provide againſt the accidents by which the plants had been thinned too much.

" But this increaſe of ſeed ſhould be regulated with great diſcretion, regard being had both to the circumſtances of the ſeaſon in which the ſeed is ſowed, and to the condition of the ground in which it is planted. If the ſoil is in very fine tilth, leſs ſeed will be ſufficient.

" The experiments of this year ſhew, that there are but three principal means by which we can obtain the utmoſt

moſt production that plants are capable of affording. Theſe means are practicable only in the new huſbandry; for in that alone each bed has the number of plants it can properly nouriſh, which is the ſource of plenty.

"The firſt means is, to make the plants produce a great number of ſtalks.

"The ſecond is, to make each ſtalk bear a large ear.

"The third is, to make each ear be quite full of plump grain.

"Theſe effects cannot be obtained in the old huſbandry, becauſe they can only be procured by frequently ſtirring the earth.

"All my experiments this year ſhew the truth of this, but eſpecially the experiments Numb. I. and II.

"It is therefore by ſtirring the alleys while the plants are yet young and growing, that we can make them produce a number of ſtalks, cauſe thoſe ſtalks to bear large ears, and fill each ear with large plump grain. But to obtain theſe advantages, it is of great conſequence, that the hoeings be performed at proper ſeaſons, each having its peculiar effects.

"The ploughing before winter, is intended to drain off the water, which, if it ſhould remain long near the plants, would chill and greatly hurt them; and to lay up the earth to be mouldered by the winter's froſt. It is hereby enabled the better to ſupply the plants with their neceſſary food in the ſpring. This may be done at the farmer's conveniency, from the time that the plants have three or four blades, till the froſt ſets in: and even in the winter, if it does not freeze, ploughing will always be of ſervice.

"The firſt ploughing after winter is of great importance. It is to this that we owe the number of ſtalks which the plants produce. That it may have this effect, it muſt be performed as ſoon as the ſevere colds are paſt; and, at lateſt, as ſoon as the plants begin to ſhoot. If it be delayed longer, it will contribute very little towards their branching. It will ſerve only to make the ſtalks grow longer. If any new ones ſhoot out, they will not thrive ſo well as the firſt; and therefore it is of great conſequence that they ſhoot out all together.

"The hoeings which are performed from this time, till the wheat has done bloſſoming, ſtrengthen the plants, lengthen their ſtalks, and enlarge their ears. The ſeaſon of theſe hoeings is not ſo exactly limited as that of the former, and the frequency of them will depend greatly on the ſtate of the ground; for it muſt not be touched when it is too moiſt. If the ſeaſon is kindly, they may be repeated two, three, or four times: but I think one hoeing highly neceſſary juſt before the ears break forth. They certainly grow longer and larger by it.

"The laſt hoeing is the moſt important of all, and that which can leaſt be diſpenſed with. It muſt be performed as ſoon as the bloſſom is gone off the wheat. This fills the whole ear, and ſwells the grain.

"When farmers become ſenſible of the good effects of theſe frequent ſtirrings, they will not neglect to repeat them at proper ſeaſons. It is by a ſucceſſion of them, that, in my opinion, crops may be brought to their higheſt perfection: and if unfavourable ſeaſons prevent their being given at their proper times, a diminution of the crop will moſt aſſuredly enſue.

"No one who conſiders the produce of the ears of corn on lands cultivated according to the New, and the Old Huſbandry, will, I believe, doubt which of theſe is to be preferred. I ſhall beſtow a few moments, to point out the difference which I have found between the one and the other.

"I ſaid before, that 360 ears yielded me eighteen ounces of wheat. Here is a determined fact; and I am certain that I have not enlarged it; becauſe the birds had eaten ſome of the grain; otherwiſe fewer ears would have produced thoſe eighteen ounces.

"When, in the year 1750, I firſt began to inquire into the principles of the New Huſbandry, I judged that t might be of ſome importance to know what is the uſual produce of a plant of wheat when cultivated in the common way. That year was reckoned a very good one for wheat, which appeared clean and good as it ſtood upon the ground. I took this method to come at the knowledge I wanted.

"I took part of a ſheaf which appeared to me very good, and which was the produce of a very rich field. I divided it into three parcels. In the firſt parcel were all the good ears: the middling and ſmall ears were in the ſecond, and the ears in which there was no grain, or where the grain was faulty, compoſed the third.

"The wheat being thus divided, I counted the number of ears in each parcel. I found 400 in the firſt, which conſiſted of the beſt ears; 1600 in the ſecond, which contained the middling and ſmalleſt ears; and in the third, 750 ears, or plants whoſe grain was faulty. I made no account of a great number of imperfect ſhoots, which were not ſix inches long.

"The fields did not look ſo poor to the eye, as this ſeparation proved them to be. This firſt operation was therefore neceſſary to come at the truth.

"When the grain was cleared from the ears, I found, that the 400 ears contained five ounces and a half of wheat, and that the 1600 contained ſeven ounces.

"My curioſity did not lead me to inquire into the contents of the third parcel; knowing that there was no good grain in it.

"In the purſuit of this inquiry, I found that taking one ear with another, of the 400, there were but eleven grains of wheat in each; and that in the 1600, taking one ear with another, there were but three grains and a half to an ear. Eight hundred of theſe grains weighed but an ounce.

"If we add theſe parcels together, we ſhall find that 2000 ears yielded but twelve ounces and a half of wheat, and that it would require 2890 ears of the ſame goodneſs to yield eighteen ounces.

"I confeſs that I was aſtoniſhed at the reſult of my inquiry; which I could not have believed, if I had not ſeen it. But at the ſame time, how greatly was my expectation raiſed, of the advantages of the new culture!

"I have this year formed a greater extent of ground into beds. Too frequent rains have prevented my laying down more than thirty acres in this manner: but I have ſowed all the reſt of my farm with the drill-plough in equally diſtant rows. I have increaſed the quantity of ſeed; regard being had to each circumſtance neceſſary to be attended to; ſo that in ſome fields I have ſown double the quantity of ſeed that was employed in the year 1751: in others ſomewhat more, and in others again leſs.

"All my fields look extremely well, and make a much better appearance than they did laſt year. They are abundantly ſtocked with very ſtrong plants, of a deep green colour: the blades are long and large, and cover the earth better than the common wheat.

"Hitherto, theſe plants have not ſuſtained any loſs, except in one ſpot of about half an acre, where they were gnawed aſunder, juſt under the ſurface of the earth, by inſects. I immediately ſowed it again, and by this means have quite repaired the damage. The inſects have not appeared ſince.

"One of the moſt happy effects of my experiments, is, that they have created a deſire in many perſons in theſe parts, to begin the practice of the New Huſbandry, with trials of conſiderable extent. One perſon, convinced of its excellency, has laid out and ſowed at leaſt twenty-eight acres in beds: another has ſowed with the drill-plough, an hundred and fifty acres ploughed in broad lands. All the land that has been ſowed in beds amounts to about fifty acres: and upwards of two hundred acres, in broad lands, have been ſown with the drill-plough. Every one who has ſeen theſe fields, even the very ploughmen not excepted, agree that they look extremely well, and that they never ſaw, in this country, plants of ſuch ſtrength and vigour as the wheat that was firſt ſown.

"I am extremely happy that my drill-plough has been of ſo general uſe. It has performed regularly every where: people having ſowed with it exactly the intended quantities of grain."

EXPERIMENTS *made by* M. Lullin de Chateauvieux, *in the Year* 1753.

"I am the better pleaſed with being able to give a ſatisfactory account of the ſucceſs of my experiments this year, as the ſeaſons have not been favourable, and extraordinary

ordinary accidents have greatly diminifhed the produce of the crops.

"I fhall divide this account into feveral articles.

"The firft will contain the experiments made on lands laid out in beds, which have borne their fecond and third crop. To this will be added fome obfervations relative thereto.

"The fubject of the fecond will be a detail of experiments made on lands formed into beds, which have yielded only their firft crop. This too will be followed by fome remarks.

"The third will confift of the experiments of two perfons on lands made into beds, of which the firft crop was reaped this year: to which will be fubjoined fome neceffary reflections.

"The fourth article will contain an account of feveral experiments made by divers lovers of agriculture, on lands fown in equally diftant rows, but with the drill-plough.

"As we think it will be extremely ufeful to fhew, by the experiments which have been made this year, that lands produce more corn in the New Hufbandry than in the old, we fhall give an account, in the fifth article, of the crops of fields fown in the common way for fixteen years together; and of thofe of the fame fields cultivated according to the New Hufbandry, fuppofing them not to yield better crops in future years, than they have done in this; a fuppofition the leaft favourable that can be to the new culture, fince we calculate only upon the produce of the firft year's crop, and that too diminifhed by the extraordinary accidents which we fhall mention.

"To fhew the truth of this article more fully, it will be proved in the fixth, that the beft field in the country, though it had been well dunged, yielded lefs wheat than thofe on which the experiments were made, and on which no dung was ufed.

"The feventh article will confift of reflections and obfervations on our practice of the New Hufbandry; and the eighth will fhew the difpofition of our lands for the crop in 1754.

"To avoid repetitions, we fhall obferve here, once for all, that no dung or other manure was ufed in any of our fields, and that our pound confifts of fixteen ounces.

Experiments made on Lands laid out in Beds, which have borne a fecond and third Crop, with fome Obfervations particularly relating thereto.

EXPERIMENT, Numb. I.

N. B. This experiment is marked with the fame number in the year 1752.

"I fhould have known the full produce of this third fucceffive crop on the beds of this field, continues M. de Chateauvieux, if the hail which fell on the third of June had not damaged it greatly. The abundance of rain which fell at the fame time, and immediately after the hail, did ftill greater hurt; for the earth of part of the beds was wafhed away by the torrent of water, fome of the plants were forced out of their places, others were entirely covered with earth, and many were torn up by the roots; fo that it was not poffible to judge what this year's produce would have been by the few plants that were left.

"I am very forry that this accident deprived me of a certain proof, that this year's crop would have been more plentiful than that of 1752: for it would have been evident, that the earth becomes more and more fruitful by the New Hufbandry: a truth which it is of confequence to eftablifh. I can therefore only affirm by conjecture, that this crop would have been greater. My conjectures are indeed fo ftrong, that they amount almoft to a demonftration.

"I draw them from hence, that the corn had a very fine appearance before winter; that the plants grew with great ftrength in the fpring; that they branched more than formerly; that the ears were certainly larger; that they bloffomed extremely well (they were in full bloom by the thirtieth of May;) and, laftly, that they have yielded more ftraw than in 1752.

"It neceffarily follows from hence, that had it not been for the hail and torrents of water, the crop would have been greater than in 1752.

"Though the following experiment fuffered the fame accidents (except that the beds were not broken up by the water) it will fupply the want of that information which we were deprived of in the other, and ftrengthen our conjectures.

EXPERIMENT, Numb. II.

N. B. This experiment is marked with the fame number in the year 1752.

"As I hope this experiment will be found very inftructive, I fhall relate it with the fame care as it was executed. I therefore beg it may be particularly attended to; for it will confirm the advantages of the New Hufbandry. But before I enter into a detail, of which I fhall endeavour not to omit any effential circumftance, it is neceffary to repeat here, that in the journal of 1751, I faid, firft, that the ploughings which had been given in order to prepare the ground for being fown in 1752, had not loofened it fufficiently, and that I tried to remedy this defect by fubfequent culture. Secondly, That this field was fowed on the twenty-fifth of September with 11 pounds and 4 ounces of wheat. Thirdly, That the crop yielded a thoufand and forty-two pounds twelve ounces; and, laftly, That the appearance of the young plants promifed a much greater crop in 1753.

"The culture beftowed upon thefe lands in 1752, rendered them more and more loofe and well divided; fo that with only one ploughing after harveft, which was performed with eafe, I formed new beds, the ridge of which was now in the place where the furrow in the middle of the alley was before. But the earth was ftirred deeper and made much loofer than in 1752. I had already attained almoft a perfect tilth, and eafily forefaw that I might quite complete it in 1753.

"Whilft I laboured affiduoufly in the culture of wheat, from which I would not fuffer any thing to divert my attention too much, till I fhould arrive at a good and certain practice of the New Hufbandry; I neverthelefs determined to begin experiments on lucerne and faintfoin, to cultivate them nearly in the fame manner as wheat. What prompted me to this was, the fuccefs of a fmall experiment the year before. Accordingly, taking this object likewife into ferious confideration, I refolved to leave a part of this field for lucerne, and to fow the reft with wheat. It contained in all one acre, one rood, and eighteen poles, formed into forty-five beds. I left for the lucerne nine beds, the extent of which was about a quarter of an acre, and deftined the furplus to be fowed with wheat as before. I am now very attentive to the experiments on lucerne and faintfoin, and fhall begin next year to give an account of them, and of my manner of proceeding. My practice in this will be found different, in many refpects, from the method which is commonly purfued. I will venture to affirm, that there will be room to be fatisfied with the fuccefs of this branch of hufbandry, than which none can be more interefting, plenty of fodder being as neceffary as plenty of corn.

"I muft therefore beg leave to give the produce of this field, as if the whole of it had been fowed with wheat. This I do, in order to compare the produce of 1753 with that of 1752, as it cannot be doubted but that the nine beds now under lucerne, would each of them have yielded as much wheat, as any of the beds did that were fown with it: nay, perhaps fome pounds more, the lucerne being fown in what I thought the richeft part of the ground. This field was fowed on the firft of September. I increafed the quantity of feed, fowing this time thirty-four pounds fourteen ounces of wheat; whereas in 1751, I fowed but eleven pounds four ounces. Though I fowed this year more than thrice the weight of feed that I did in 1751, it muft not be inferred, that I tripled the number of grains capable of producing plants, becaufe this year's fowing was made with wheat of the produce of the new culture, the grains of which are much larger than thofe of the common wheat which I ufed in 1751, and of which a greater number is confequently required to make up an equal weight.

"This wheat having been ſown pretty early, its plants had time to grow very ſtrong before winter, the cold of which they bore very well: and the ploughing I gave them on the fifteenth of October, by cutting a very deep furrow within about three inches of the rows, ſecured them from the damage which corn frequently ſuffers from rain and the melting of ſnow.

"In the ſpring they made ſtrong ſhoots, grew apace, and branched very abundantly. I aſſiſted them, as I am going to relate, at proper ſeaſons, both with reſpect to the condition of the plants and earth, and to the temperature of the weather.

"On the fifteenth of March, 1753, I gave them the firſt ploughing after winter.

"On the twenty-ſixth the beds were weeded.

"On the eleventh of April, I ſtirred the alleys with the cultivator.

"On the twenty-ſixth, the thiſtles were plucked up.

"On the fourteenth of May, the ſtirring was repeated with the plough.

"On the fifteenth, the ears began to appear.

"On the twenty-ninth, the fourth ſtirring was given with the cultivator with mould-boards.

"On the thirtieth, the wheat was in full bloom.

"On the third of June, the wheat ſuſtained a violent ſtorm of hail and rain.

"On the thirteenth, the fifth ſtirring was given with the new plough with two ſhares, or double cultivator.

"I beg leave to obſerve, that there needs no better proof that wheat, cultivated according to the New Huſbandry, will be little apt to be lodged, than the eaſe with which I performed the fifth culture, after the accidents which happened on the third of June, when the corn had attained its greateſt height. So far was it from being laid thereby, that the whole extent of the plough found free admittance into the alleys, and this laſt culture could be given without damaging the ſtalks.

"Though the whole of our ploughing and hoeing may be performed extremely well with my plough, and the inſtrument which I call the *cultivator*, yet I have thought of making this taſk ſtill more eaſy. Two new inſtruments (not indeed abſolutely neceſſary) will anſwer this end. I propoſe them only as very uſeful, and proper to be employed only the ſecond or third year, when the earth has acquired part of that minute diviſion, of which it is ſuſceptible.

"The cultivator with mould-boards, and the plough with two ſhares, are inſtruments which I have invented this year. I have found them extremely uſeful to give the two laſt ſtirrings, better, and in leſs time than our other inſtruments. The reader may not be diſpleaſed to know what firſt ſet me upon contriving them.

"One cannot enter properly into the ſpirit of the New Huſbandry, without being thoroughly convinced, that the earth cannot be too minutely divided: I will even ſay, till it is reduced to a perfect powder; and that, when one has been ſo happy as to attain this point, it muſt be kept in that ſtate. This will always be done beſt, by uſing the moſt proper inſtruments.

"I obſerved one day, whilſt I was horſe-hoeing my wheat, my plough being then at work, and the earth in a very looſe ſtate, that every time the alleys were ſtirred, they were thrown into a different form; for it is neceſſary ſometimes to make a deep furrow in the middle of the alleys, and at other times to raiſe a ridge in them; and yet, in whatever form the alleys were to be, I had only my plough to perform theſe different operations. It did not ſeem to me reaſonable to ſuppoſe, that two ſo different works could be done equally well with one and the ſame inſtrument; from whence I concluded, that it was neceſſary to have an inſtrument for each of theſe purpoſes.

"I ſoon found what I wanted. The cultivator with mould-boards opens a large furrow in the middle of the alley, by turning over the earth at the ſame time to both ſides. The plough with two ſhares, on the contrary, at the ſame time takes up the earth on both ſides, and turns it into the furrow, which it fills, and thereby lays the foundation of a new bed.

"Theſe inſtruments have this farther advantage, that, without requiring a greater number of cattle, they perform as much work at once going over the ground, as the plough can do in two, and ſometimes three operations. I return to my experiment.

"On the twenty-third of June, the wheat ſuſtained a violent hurricane, which laſted an hour. Several great pear trees were blown down in my orchards, and many large branches were broke off from other trees.

"On the eighth of July, a ſcorching wind blew, which ſhed a great deal of the ripe corn.

"On the ninth the wheat was reaped.

"A month after harveſt, it was threſhed.

"This field yielded 1575 pounds of wheat, deducting from which the thirty-four pounds fourteen ounces uſed for ſeed, the neat produce remaining is 1540 pounds two ounces. Conſequently, in 1753, this field produced 533 pounds four ounces more than in 1752, including what was ſaved in the ſeed.

"The grain of this wheat was very large, and ſo clean, that it did not want ſifting. It yielded plenty of very fine flour, which made exceeding white and well taſted bread.

Experiment, Numb. III.

N. B. This field is marked with the ſame number in the year 1752.

"This field contains one acre and ſixteen poles, and was but in poor tilth. It was ſowed on the twenty-fourth of September, 1751, with ſeven pounds fourteen ounces of wheat, and yielded 441 pounds.

"It was brought into better tilth in 1752, but the beds were not raiſed high enough: I would have given them another ploughing, if the rainy ſeaſon had not prevented it. They were ſown on the eighth of September, with twenty-four pounds twelve ounces of very large grained wheat. The plants were extremely fine before winter, and the rows were well filled. In the ſpring, I found that there were fewer plants than in autumn: inſects had deſtroyed ſeveral of them. I likewiſe imputed the loſs of many to the flatneſs of the beds. The plants acquired freſh vigour after the winter, made ſtrong ſhoots, and branched extremely well. I treated this field in the ſame manner as the former. The plants made nearly the ſame progreſs. They were reaped on the fourteenth of July, and yielded 724 pounds eight ounces. Thus we ſee, that this field yielded 283 pounds eight ounces more in 1753 than in 1752.

Obſervations on theſe Experiments.

"I obſerved in my former experiments, that, as the mould was not ſufficiently looſened, the fields, which were laid out in beds, could not produce ſo plentiful a crop the firſt year, as they would the ſecond or third year, when the earth ſhould be more thoroughly divided. It is evident, that whoever ſhould have given up the New Huſbandry, upon the bad ſucceſs of the firſt year, would have deceived himſelf. Theſe experiments plainly ſhew, that the charge of the firſt year is fully recompenced by the profit of the ſecond, and that this profit will increaſe from year to year.

"Whoever now tries the New Huſbandry, may reaſonably expect better crops than mine, even the firſt year; becauſe, 1. They now know how the earth ſhould be prepared: 2. They may be provided with inſtruments, already experienced to anſwer the deſired purpoſe with conveniency and eaſe. The different circumſtances to be attended to, are likewiſe known. From the knowledge I have acquired in theſe matters, I can ſay, that the preſent appearance of the corn, which I have ſowed this year in beds, promiſes a very great crop. I ſhall likewiſe have occaſion, in the courſe of theſe obſervations, to ſhew, that though the firſt crop may ſeem very ſmall, yet it is in fact more profitable than that of lands cultivated in the common way.

"Let us now proceed to the preſent ſtate of the lands cultivated for two years according to the New Huſbandry, and obſerve what the effects have already been.

When the corn was ſowed, the beds were in a much looſer ſtate than before, and the ſeed was conſequently covered with a fine mould. It came up better: the roots extended themſelves more eaſily, and increaſed in number,

ber, in a foil which fcarcely refifted them: the plants were ftronger, and better able to bear the feverity of the winter; and, by a fmall increafe of the feed, the earth was better filled with plants, and thereby better able to fuftain the accidents which had thinned them before. After the winter frofts were over, the mould was in fo loofe a ftate, that it looked as if it had been newly ploughed; a very different ftate from that of land in the common hufbandry, which, at this feafon, is hard, compact, and very little fitted to afford an eafy paffage to the tender roots of plants. How eafy too did this render all the fubfequent culture! The weeds, already greatly diminifhed, did little damage to the corn; and we may readily conceive that the earth, in this loofe ftate, was eafily penetrated by the rains, dews, and moifture of the atmofphere.

" The effects were, that the plants grew ftronger and taller than before; that they branched into a greater number of ftalks; that the ears were very large, and well filled with grain, if we may judge by thofe which efcaped the hail: that the wheat was very clean; and laftly, that the crop was greater than that of the preceding year, though it had been confiderably diminifhed by the hail, the hurricane, and the fcorching wind which made many of the ears fhed their corn. I tried every poffible means of afcertaining the lofs occafioned by thefe accidents; but in vain. I have therefore given up an uncertain calculation; and can only fay, that I am fure the lofs was very great.

Experiments *made on Lands which had borne a firft Crop, with Remarks on thefe Experiments.*

" We did not expect that the fields we are now going to fpeak of, would yield a crop near equal to that of the fields treated of in the foregoing article. We knew, that the mould is never fufficiently broken and divided the firft year that a field is laid out in beds. Befides, during almoft all the laft year, the earth was too moift to be cultivated properly. The wet mould could not be divided into fmall particles, nor could it be ploughed fo frequently as to admit of fowing it fo early as it fhould have been.

" But every year will not be fo unfavourable to this hufbandry: and when there are alternate changes, fuch as we have had this year, of wet weather and of fair, which will afford time for the different ploughings, we may, with fome certainty, promife ourfelves a greater crop; fince, as we have feen, this depends chiefly upon the good or bad ftate of the earth.

" The whole management of thefe fields having been nearly the fame as that of the fecond experiment, it would be needlefs to give a particular detail of it in our account of the other experiments.

Experiments, Numb. IV.

" This field is a very ftrong good foil. In the Old Hufbandry, great ftrength was required to plough it, and it was neceffary to catch the feafons when they were neither too wet nor too dry. It contains thirteen acres, two roods, and twenty poles. I laid near one half of it out in beds, which, with the alleys, were each about fix feet wide. Part of thefe beds were fown on the thirtieth of Auguft. Conftant rains hindered the fowing of the reft till the twenty-fixth of September. An hundred and eighty-one pounds of wheat were employed in fowing the whole. What was firft fowed, came up well, and the plants were very ftrong before winter: but in one place, almoft all of them were deftroyed by infects. I fowed this fpot a fecond time. The frefh feed was fcarcely able to rife before winter, and yielded much lefs than the beds which had not met with the like accident. The wheat of the beds which were fown on the twenty-fixth of September, was a long time before it fprung up; owing to the drynefs of the earth, which continued almoft the whole month of October. The froft in November ftopt the farther progrefs of the plants. Their produce was much fhort of what was fowed firft; which fhews plainly how effentially neceffary it is to fow early.

" This wheat muft of courfe grow very unequally. Some beds were extremely beautiful, others middling, and the reft very poor: yet, throughout the whole, the ears were very large, and well filled with grain; and the crop would ftill have been a good one, had it not fuffered by the hail which fell on the third of June, and by the other accidents mentioned in the fecond experiment.

" The wheat, being perfectly ripe, was reaped on the 13th and 17th of July. It was threfhed two months after, and the whole produce of this half of the field was 3370 pounds of very fine and perfectly clean large-grained wheat, which yielded a great deal of flour.

" The other half of this field was fowed in equally diftant rows, with the drill-plough, by which means a great deal was faved in the feed: for only 479 pounds of wheat were employed to fow this ground, which, in the common way, would have required about 2016 pounds.

" It was fowed on the 23d, 24th, 26th, 27th and 29th of Auguft. We could work only a few hours each day, on account of the frequent fhowers of rain.

" This wheat rofe perfectly well, grew very ftrong before winter; and was of a deep green colour, which it retained till it began to ripen. The number of ftalks increafed in the fpring. They grew very long, and bore large ears. In fhort, they promifed a fine harveft. But the hail on the 3d of June foon changed the face of the field. It cut off a great number of the ears, broke down many ftalks, and damaged all thofe ears whofe ftalks were ftrong enough to remain upright. This misfortune was common to all my wheat.

" This wheat, being ripe, was reaped on the 9th, 10th, and 11th of July, in very hot, dry weather. It was threfhed a month after harveft, and yielded 5386 pounds of excellent grain.

" Here is an experiment made upon a large extent of ground, cultivated two different ways, and divided into two almoft equal portions, both of which fuffered the fame accidents as equally as could be, according to the beft of my judgment. This experiment offers us a very interefting inftruction.

" The defign of our experiments is, to know which of the different methods of hufbandry is moft ufeful; which will beft promote the public welfare, be moft beneficial to the owners of land, and bid faireft to fecure their productions.

" Let us now compare the produce of each half of this field. It will convince us of a truth of great confequence to be known, viz. that land will produce much more corn when cultivated in beds according to the New Hufbandry, than when it is only fowed in equally diftant rows with the drill-plough; though this laft method is, indifputably, better than the Old Hufbandry.

" We have feen that the part of this field which was fowed in equally diftant rows with the drill-plough, produced 5386 pounds of wheat. If it is continued to be cultivated in the fame manner, it will be in fallow in 1754, and yield no produce: and thus it will bring a crop only every other year.

" The other part of this field, which we formed into beds, produced 3370 pounds of wheat, and is already fown again for a crop to be reaped in 1754. Suppofing this crop to be only equal to that of 1753, the produce of the two years will be 6740 pounds of wheat. Hence it is evident, that, in two years, the produce of the beds will be 1354 pounds more than that of the rows. This difference is very confiderable: and if we would fee it in a yet ftronger light, let us extend the fame calculation to a longer time: for example, to ten years, during which the part fowed in rows will yield only five crops, which, at 5386 pounds a crop, will amount in all to

	26930 lb.
" The part fowed in beds will yield ten crops, which, at 3370 pounds a crop, make — — — — — — —	33700 lb.
" The difference in favour of the beds will therefore be, in ten years, — —	6770 lb.

" We here fuppofe the feafons to be, in every refpect, like the year 1753. But as our obfervations have conftantly fhewn that the crops are always greater after the firft year, which is likewife juftified by the firft, fecond, and third experiments, we may even now venture to pronounce, that the part of our field, which is fowed in beds, in in order to be reaped in the year 1754, and which now makes a promifing appearance, will yield double the quantity it did in 1753. The profit will therefore be much more confiderable than we have made it in the above calculation.

Experiment, Numb. V.

" This field is of a very ftiff foil. It contains five acres and eight poles, and lies floping towards the weft. The beds were well formed, but the earth could not be fufficiently broken, nor could it be fown early enough, on account of the frequent rains. It was fowed on the 8th and 25th of September, with 139 pounds of wheat. The corn came up well, and made a fine appearance before winter. It throve well during the fpring, and when ripe, I cut it down, viz. on the 14th and 28th of July, and the crop yielded 2205 pounds of very fine wheat.

Experiment, Numb. VI.

" This field was reaped in 1752, and immediately formed into beds, with a defign to fow it that fame year. I could not expect that land in fo bad tilth would produce much. My only aim then was, to form it into beds a year fooner. It contained one acre, two roods, and fifteen poles, and was fowed with forty-five pounds of wheat, which yielded 724 pounds.

Experiment, Numb. VII.

" My defire to practife the New Hufbandry upon all my lands as foon as poffible, made me plough another field, which had likewife been reaped in 1752. I could however lay only a part of it out in beds: the reft was fowed in equally diftant rows with the drill-plough. This field could have but one ploughing: nor could that be completed, though feveral ploughs were employed till the 15th, 17th, and 18th of November. The earth was fo moift, that it divided only into large clods. However, I fowed it foon after ploughing, not expecting a great crop. The extent of this field is about fix acres, three roods, and fix poles. It was fowed with 412 pounds of wheat, of which only a fmall part rofe before winter. The number of plants increafed greatly in the fpring: they could not branch fo much as thofe of the foregoing experiments, and the grain beginning to look a little fhrivelled, I reaped it on the 21ft, 23d, and 24th of July. Though this wheat had fuffered the fame accidents as the other, yet it yielded 2646 pounds.

Experiments *made on Lands laid out in Beds, and of which the firft Crop was reaped in* 1753; *with Reflections on thefe Experiments.*

" In our journal of 1752, we mentioned a perfon's having fowed at leaft twenty-eight acres in beds. Though thefe experiments did not anfwer well, we have thought proper to mention them, in order to fhew the caufes to which their want of fuccefs ought to be imputed. They will ferve to inftruct us in fome practices which are more neceffary than might otherwife be imagined, and will fix our attention to circumftances which ought not to be neglected by any one who defires to make the moft of his ground.

Experiment, Numb. VIII.

" Thefe twenty-eight acres were laid out in beds about fix feet wide. The foil is ftrong, and apt to grow very hard. Three rows were fown in each bed.

" Only 460 pounds of wheat were ufed to fow this field, which yielded but 3150 pounds of very clean grain.

" This is a very fmall crop. Let us fee to what it was owing.

" 1. This land was very badly ploughed: it could only be divided into great clods, incapable of fupplying the wants of the plants, and of letting them imbibe the nourifhment neceffary for their growth. That the bad ftate of the land was the chief caufe of the fmuttinefs of this crop, appears from this circumftance; that, in fome fmall parts of the fame field, where the mould was better divided, the wheat was finer, branched tolerably well, and produced a greater number of flourifhing plants.

" 2. This field was fowed too late, viz. not till the laft week in November. Only part of the feeds fprung up before winter; and thefe plants, not rifing in a good feafon, could not make the progrefs that might have been expected.

" 3. Too little feed was fown. It was the more neceffary to fow a larger quantity, as numbers of grains cannot fhoot at all in the ground badly prepared, and many of thofe which do fhoot, are fo buried under the great clods, that they are not able to rife. This field was therefore not fufficiently ftocked with plants.

" Laftly, the hail mentioned before, greatly diminifhed the crop: which, independent of that accident, would not have been plentiful.

" The owner of this field, after remarking thefe bad confequences arifing from the defect of culture, has endeavoured to remedy them, by giving, after harveft, feveral ploughings, which have broken and divided the earth more thoroughly, and prepared the beds for being fowed in good time: the quantity of feed has likewife been increafed; the plants have had time to get ftrength before winter, and their prefent ftate promifes that the next crop will be better. Far from being difcouraged by the bad fuccefs of a firft trial, the perfon we are fpeaking of, convinced of the excellence of the New Hufbandry, is but the more refolved to purfue it. He juftly afcribes the fcantinefs of this crop, not to any defect in the principles of the New Hufbandry, but folely to its having been badly executed the firft year. He foon perceived that thefe faults might eafily be remedied, the fecond year; and therefore has not only continued to cultivate and fow the fame field, but has likewife fowed at leaft twenty-five acres more, laid out in beds, which have been much better ploughed than thofe of the laft year: every circumftance of the new culture has been duly attended to, and the corn, even now, promifes a more plentiful return.

Experiment, Numb. IX.

" Small experiments have led to much greater. As thofe fmall ones are neceffary at firft, not only to create a confidence in the New Hufbandry, but likewife to accuftom people to the practices which it requires, I fhall relate one of this kind, made by a perfon who has adopted the New Hufbandry from principle, and who is every way qualified to inftruct us, and to execute well what he has once conceived to be right.

" A piece of ground, 270 feet long, and twenty-feven feet wide, was made into fix beds, to be fowed with only two rows. This fpot could not be prepared till the firft week in September, nor fowed till the twenty-fourth of October. The earth was very dry, and the wheat rofe unequally, and made little progrefs before winter. By a negligence in the firft hoeing, almoft whole rows of the plants were torn up. In proportion to what was reaped, this little fpot would have yielded 180 pounds of very fine wheat.

" A meafure of oats, which was fowed in beds in a proper feafon, yielded 112 meafures.

" Encouraged by this fuccefs, the fame perfon intends to practife the New Hufbandry in a larger way. He has already formed about ten acres into beds, which are now fown: and he will continue in 1755, and the following years, to lay out twelve acres a year in beds, till he has difpofed all his lands in that manner.

" Another thing intended by this experiment, was, to know whether two rows would not produce a larger crop, in proportion, than three. The fuccefs of this promifes very fair; but it will be right to continue trying it, and likewife to fee what multiplying the rows will do. We fhall fpeak of this hereafter, in order to determine, by real products, what number of rows will beft fuit this hufbandry.

Experiments *made on Fields fowed in equally diftant Rows with the Drill-Plough, by feveral Lovers of Agriculture; as related by* M. de Chateauvieux.

Experiment, Numb. X.

" This, and the following experiment, were made by the fame perfon who made the feventh, mentioned in our journal

journal of 1752, the refult of which encouraged him to proceed to larger trials, and to prove the advantages of this hufbandry, by new examples. To be more exact in thefe experiments, he refolved to try the Old and the New Hufbandry in the fame field.

"For this purpofe he chofe a field, the foil of which is reckoned equally good in every part. Its whole extent is five acres, two roods, and fifteen poles, fquare meafure. Of this two acres, three roods, and 15 poles were deftined to be fown in the old way; and two acres, and three roods, to be fown in equally diftant rows with the drill-plough. The whole field was equally ploughed and dunged, and fowed on the fame day, viz. the 19th of September, with the fame wheat. In fhort, there was no other difference than in the quantity of feed, and the manner of fowing it.

"The part of this field which was fowed in the old way took up 698 pounds ten ounces of wheat, which produced 2969 pounds of very fine grain. This is about four and a quarter for one.

"The other part of the field was fowed with the drill-plough, with 243 pounds, which yielded 3187 pounds two ounces of very fine large-grained wheat. The proportion here is as thirteen to one.

"We find in favour of the drill-hufbandry; firft, that, though the furface of this ground was fifteen poles lefs than that of the other, yet it produced 208 pounds two ounces of wheat more: and, fecondly, that, deducting the feed of each crop, this neat produce is ftill more confiderable, as appears by the following account.

Produce of the part fowed in the common way	2969 lb.	
To be deducted for the feed	698 lb.	
Remains	2271 lb	
	lb.	oz.
Produce of the part fowed with the drill plough	3187	2
To be deducted for the feed	243	-
Remains	2944	2

"Which is 663 pounds two ounces more than the produce of the Old Hufbandry.

"The whole field was fomewhat damaged by the hail on the third of June, which leffened both the crops a little.

Experiment, Numb. XI.

"Another field, the foil of which is better than that of the former, having been well ploughed, was fowed in equally diftant rows, with the drill-plough, on the tenth of October. It contains one acre, three roods, feven poles, and two yards of ground, was not dunged, and was fowed with 121 pounds eight ounces of wheat, which yielded 2979 pounds of very fine clean corn; which is twenty-four for one.

"This return is very confiderable, and greatly furpaffes that of the foregoing experiment. It fhould be remembered, that the furface of this field is lefs. It did not, indeed, receive any damage from the hail.

Experiment, Numb. XII.

"We mentioned in the journal of 1752, a perfon's having fown about 150 acres in equally diftant rows, with the drill-plough; and we obferved, that a great part of the ground could not be well ploughed, and that the whole of it could not be fowed till November and December. Thefe two circumftances gave no room to hope for much fuccefs. About forty acres, which were the laft fown, were dunged: but thefe yielded the leaft crop of any.

"This great extent of ground was fowed with 9932 pounds of wheat. To have fown it all in the common way, would have required 29524 pounds of wheat. Confequently here is a faving of 19592 pounds of wheat, in the feed.

"The foil of thefe fields being of different qualities, their produce was proportioned thereto, varying from exceeding good to very bad. The 150 acres yielded in all 86058 pounds of wheat. The crop would have been more confiderable, if about thirty acres had not been greatly damaged by hail. The lofs which it occafioned, fhews plainly the great probability of having larger returns in other years, when we become more perfect in the practice of the New Hufbandry, to the want of which the bad fuccefs of this firft trial has certainly been owing in a great meafure. All the lands of this farm are now fowed again with the drill-plough. They confift of about 200 acres, and afford a pleafing profpect for the enfuing harveft.

Experiment, Numb. XIII.

"A field of four acres, was fowed in the middle of October with 243 pounds of wheat. It ufed generally to require about 850 pounds. It yielded 2268 pounds. This, adds the perfon who has fent me this account, is as much as I have had from any other field fown in the old way.

Experiment, Numb. XIV.

"The fame perfon who made the foregoing experiment, fowed another field of about four acres and a half, of a poorer and colder foil, towards the middle of November, with 333 pounds of wheat. In the old way, it ufed to be fowed with 972 pounds. It yielded 1260 pounds. The corn in this field remained thin. It did not branch fo well as that of the former. The perfon who fends me this account of thefe two experiments adds: "It muft be obferved, that the drought, as well of the autumn as of the fpring, was unfavourable, efpecially to the late fown wheat. Thefe experiments have encouraged me to purchafe a drill-plough, and to fow all my lands with it in equally diftant rows, according to the new method, this year 1753: only I have obferved to fow earlier, viz. between the middle of Auguft and the middle of September; and thicker, that is to fay, forty-five pounds, on the fame extent of ground where I fowed but thirty-four pounds and an half, and forty-one pounds and an half in 1752. My plants, hitherto, make a fine appearance, and are very thick: their blades are large, and the whole is in great vigour."

Experiment, Numb. XV. by M. de Chateauvieux.

"I have extended my experiments to an eftate where I have not time to make any long ftay myfelf, fo that what is done there is left to the difcretion of fervants, whofe eye, as is well known, is not like that of the mafter.

"The lands of this place are very poor: they produce but little corn, though that little is exceeding good. In 1752, they were very badly ploughed, and this ploughing was fpoiled by heavy rains, juft as we were going to fow. I ordered the whole to be fowed with the drill-plough, except two acres, which were fown in the old way. Some few fields were a little better ploughed than the reft. Thefe produced pretty good wheat, the others were very poor. However, I have reafon to be pleafed with my having fowed in this manner. I judge of it by the produce of the two acres which were fown in the common way, and which yielded me no more than exactly the quantity of the feed beftowed upon them.

"The true caufe of this was the bad condition of the lands. They are in much better tilth this year. All of them have been fown with the drill-plough, in a favourable feafon, and my fervants affure me that the corn rifes finely.

M. de Chateauvieux's *Account of the Crops produced during Sixteen fucceffive Years, by Fields cultivated and fown in the common Way, and of which Part was conftantly dunged; compared with a Crop of the fame Fields cultivated without Dung, according to the New Hufbandry, even fuppofing them not to yield more than they did in 1753, which was their firft Crop, and which was greatly diminifhed by the unforefeen and extraordinary Accidents already mentioned.*

"The refult of our experiments would be of little ufe, if it extended no farther than our private inftruction. To render it of more general fervice, we fhall here give a com-

compariſon of the produce of lands cultivated according to the Old Huſbandry, and according to the New, that every one may judge which of the two is moſt likely to anſwer beſt.

" This parallel will ſhew how much the New Huſbandry is ſuperior in point of advantage to the Old. We are to ſuppoſe all the circumſtances of the ſeaſons to be like thoſe of the years of which we have compared the products. But as the expence of culture is an object well worth conſidering, and as that expence may not be equal in both ways, I beg leave to lay down here as a fact, " That the charge of the new culture is leſs than that of the old." I have tried it, and find it ſo; as I ſhall, hereafter, prove beyond diſpute.

" By the old culture, in the farm which I now cultivate in the new way, I ſhould have had but two fields ſown in 1752; to be reaped in 1753, viz. that of the experiment Numb. IV. and that of the experiment Numb. V. Theſe two fields contain together eighteen acres, two roods, and twenty-eight poles. I have calculated their produce during ſixteen years, viz. from 1730, to 1745, incluſively. They have yielded, in that time, eight crops, the total produce of which has been 146863 pounds of wheat: deducting from which, 42130 pounds for the ſeed ſown in the eight years, the neat produce will be reduced to 104733 pounds.

" It is proper to obſerve that this wheat was meaſured every year in the barn, as ſoon as it was threſhed, and before it was ſifted: an operation which always occaſions a conſiderable diminution, though we do not make any allowance for it here.

" Let us now ſee what crops the preceding experiments give us room reaſonably to expect from the ſame two fields in ſixteen ſucceſſive years of the New Huſbandry; to judge only by that of this firſt year, 1753, unfavourable as it is.

" The field, Numb. IV. was ſowed, half in beds, and half in equally diſtant rows. I am obliged to ſuppoſe it to have been ſowed entirely in beds; for it cannot be doubted but that the part which was ſowed in rows, would have produced as much as the other: conſequently the whole crop of the two halves, at 3370 pounds each, would have been 6740 pounds.

" As the ſame fields yielded a crop every year, in the New Huſbandry, we ſhall have ſixteen crops inſtead of eight: ſo that, multiplying the firſt year's crop, 6740 pounds, by ſixteen, the total produce will be 107840 pounds; to which muſt be added that of the experiment Numb. V. which was 2205 pounds; which being alſo multiplied by ſixteen, will produce a farther quantity of 35280 pounds for the ſixteen crops. This, added to the amount of the experiment Numb. IV. will make in all 143120 pounds of wheat for the ſixteen years.

" If we afterwards deduct from this, the quantity of ſeed uſed in theſe two fields during the ſixteen years, which amounts to 8016 pounds, the neat produce will be — — — — —	135104 lb.
" In the old way, the ſame fields would produce, in ſixteen years, only — —	104733 lb.
" The difference in favour of the new culture is therefore — — — —	30371 lb.

" Beſides the advantage of reaping a much greater quantity of corn, there are others which highly merit our attention. This corn is not mixed with any ſeeds of weeds, and its quality is greatly improved by the abundance of nouriſhment which the plants are ſupplied with by the frequent ſtirrings of the earth in this huſbandry, more than in the old.

" But how fine a proſpect does the propoſition which we advanced before, afford us beyond all this! viz. " That the crops of the ſecond and following years, would be ſtill more plentiful than the firſt." What ſome might then think only an object of hope and ſpeculation, is already realized, and proved by experience. All this deſerves the moſt ſerious attention. The New Huſbandry will certainly, in time, acquire a ſuperiority over the Old, greater than we can now imagine.

Proofs that the beſt Field in the Country, though the greateſt Part of it was dunged, yielded leſs Wheat than thoſe of the Experiments, Numb. II. *and* XI. *in which no Dung was uſed. By* M. de Chateauvieux.

" The proofs of the advantages of the New Huſbandry cannot be too greatly multiplied; and all thoſe which are the reſult of experience, deſerve to be communicated to the public.

" The field we are going to ſpeak of, is generally, and juſtly, reckoned the beſt in the country. Its ſoil is excellent, very deep, and extremely fertile. This field is dunged very often. Its nearneſs to the farm-yards renders the carriage of manure extremely eaſy, and is the cauſe of its getting perhaps more of it than may be neceſſary. Its ſituation too is excellent, riſing on all ſides above the neighbouring grounds, and the highways which ſurround it; by which means it is leſs expoſed to be hurt by wet, the water finding an eaſy drain from off it.

" The extent of this field is 6087 fathoms (four acres and eight poles.) It was ſowed in 1752, for the harveſt of 1753, and the greateſt part of it was well dunged.

" It is not the cuſtom of the place I am ſpeaking of, to deſcribe the extent of a field by the number of acres contained in it, but by the number of meaſures of wheat with which it is ſowed. Eight meaſures uſed generally to be employed to ſow this: but the quantity of ſeed was leſſened this laſt time, and only ſeven meaſures were ſown. We have hitherto ſuppoſed the ſurface of this field to be equal to that of the other fields of the ſame country, in which eight meaſures of ſeed are ſown.

" But as I was deſirous to be more preciſely exact, in order to form the compariſon I purpoſed making, I had recourſe to the geometrical plans of the lands, and found the contents of this field to be, as I ſaid before, 6087 fathoms: now, the cuſtom of the village to which it belongs is always to ſow at leaſt eleven meaſures in a ſpace like this. One field, among others, very near to this, and which is but twenty-four fathoms and thirty-two feet larger, has always been ſown with twelve meaſures.

" A new cauſe of the fruitfulneſs of this field, unknown before my obſervations, is, that the farmer wiſely took care to ſow it with a leſs quantity of ſeed. The plants throve better, when the land was not over ſtocked with them. This field will therefore help to prove the truth of one of the firſt principles of the New Huſbandry, viz. that the quantity of ſeed generally uſed ought to be diminiſhed: a propoſition which deſerves our entire confidence, becauſe the ſeed here has, from time immemorial, been reduced to eight meaſures, and they have been ſufficient to produce very plentiful crops. The farther reduction made in 1752, to ſeven meaſures, muſt alſo be approved of, ſince the crop which theſe yielded was very fine.

" Theſe preliminary obſervations ſeemed neceſſary, before we proceeded in our detail. This field was ſowed with about 850 pounds of wheat. It was finer during the whole ſummer than any wheat in the common way. It was reaped at a proper time, and yielded about 6646 pounds, from which muſt be deducted, firſt, the 850 pounds of ſeed; and, ſecondly, the value of the dung, which is equal at leaſt to 1260 pounds of wheat, together with 2110 pounds; which deducted from 6646 pounds, the total produce, leave for the neat produce 4536 pounds.

" The crop of 1753 was diminiſhed by the hail on the third of June. The value of this loſs is not known; but we may fairly compare it with the experiment Numb. II. which likewiſe ſuffered by the ſame hail. We confeſs that this compariſon is not abſolutely exact, with reſpect to this accident; but it muſt alſo be granted, that this circumſtance cannot occaſion any very great error. We muſt likewiſe premiſe, that we ſhall not reckon the produce of a ſmall ſpot which is pretty commonly ſowed in March in the year of fallow, becauſe it hardly equals the expence of dung and ploughing.

" The neat produce of the experiment Numb. XI. on a field ſowed in equally diſtant rows, was 2857 pounds eight ounces. But the extent of that field being only one

one acre, three roods, seven poles, and two yards, we must calculate what the crop would have been in proportion, if that extent had been four acres and eight poles (6087 fathoms) supposing it of the same quality. We shall find, that the field on which our experiment was made, would have produced neat 8006 pounds of wheat; deducting from which 4536 pounds, for the neat produce of the field cultivated in the old way. The difference in favour of the New Husbandry, without dung, will be 3470 pounds of wheat.

" We have seen by the experiment Numb. II. that this field laid out in beds, and having borne its second crop, yielded neat 1540 pounds of wheat. Its extent is but one acre, one rood, and eighteen poles; so that we are to see what crop it would have yielded if its extent had been four acres and eight poles, supposing the quality of the soil to be the same. The rule of three shews us again, that its neat produce would have been 5681 pounds of wheat, which we are to double for the amount of the next year's crop, every year yielding a crop in the New Husbandry; whereas the field it is compared with would lie fallow this year. Thus two years will yield 11362 pounds of wheat; from which deducting 4536 pounds for the neat produce of the same field, cultivated in the old way, during the same space of time, the difference will be 6826 pounds of wheat in favour of the New Husbandry.

Reflections and Observations on the Practice of the New Husbandry, by M. de Chateauvieux.

" The chief object of our reflections last year was, the effect which ploughing and culture have upon plants. They seem to us to be confirmed by the following observations.

" 1. The productions were greatest in those places where the earth had been most loosened, and brought to the finest tilth.

" 2. We have seen plainly, that, in order to improve our tillage, it is necessary to make the great furrow in the middle of the alleys very deep, because that furrow being afterwards filled up, and a new bed made over it, there is a greater depth of light well loosened mould immediately under the roots of the plants.

" 3. We can affirm, that we have this year, without much trouble, ploughed our beds from fifteen to eighteen inches deep, which is very considerable; but we must not flatter ourselves, that this depth can always be attained the first year; it is by continuing this same culture that we shall insensibly reach it.

" 4. To have great success, requires proper care and judgment in performing every part of the New Husbandry. The culture which is well executed, will be of very great use; but that, on the contrary, which is badly done, will be of no service to the plants, and may even prove very detrimental to the next year's crop.

" 5. To perform this culture with advantage, it is therefore necessary to observe this important maxim of tillage, so little attended to by many farmers, " never to set the plough to work, when the earth is too moist." I have adhered to it strictly, and have never suffered my lands to be touched till they were dry. We have tilled when the weather has been very dry and very hot, and then it was that our culture had the best effect; the stiffest land having been broken by the preceding ploughings, was provided with the moisture necessary for plants, from its surface to the bottom of the furrows; and the plants were sensibly benefited by all our frequent stirrings.

" 6. I was so struck with this, that I marked several stalks, to see how much they grew each day. From the time that the ears began to appear, till they had done blossoming, I found that they grew an inch in four and twenty hours. The hottest days were those in which the stalks grew most, whilst all vegetation seemed almost suspended in the wheat in the common way.

" 7. This observation led me to another. I was greatly surprised one day to find my stalks just as I had left them the day before. The next day, and the day after, I found them still the same. In short, they grew no longer from that time.

" So sudden a change raised my curiosity greatly, and I resolved to find out the cause of it. The time when they ceased to grow, was immediately after they had done blossoming. I judged that from that time all the sap was conveyed to the ear, to form the grains, and that the rest of the plant had only what was necessary to prevent its drying too soon. This dispensation of the nutritive juices seemed to me very remarkable: all their forces seem then to unite, in order to form, fill, and ripen the grain, which is the most useful part. I was afterwards confirmed in this, by observing, that it was from that very time that the stalks and blades began insensibly to lose their deep green colour, and that this green grew lighter and lighter every day; a sure sign of a diminution of sap in those parts.

" 8. It is likewise of very great importance to know, which is the most proper time for sowing; for the growth of plants depends greatly on this circumstance. Late sowings have not answered; but the early ones have produced plants, whose vigour has enabled them the better to resist the winter's cold, and to branch out the more abundantly. By attending to this circumstance, the farmer will enjoy the desirable advantage of having his corn ripen early, and of its being less exposed to the dangers of the summer season; for we have seen that the wheat which was sowed first in the new method, ripened thoroughly as soon as that which was sowed in the old way. It is proper to know this, in order to be sensible of the necessity of beginning to plough early, that the seed may be sowed in due time.

" 9. I must beg leave again to make a few reflections relative to the quantity of seed most proper to be sown. It is of the utmost importance to know how to proportion the quantity of the seed to the strength and richness of the soil, so that each may have its due proportion. The experiments already made, help to direct us; but I think others still necessary, before we can trust absolutely to our knowledge in this point.

" At present I shall only advise sowing the same quantity of seed as I did in 1752. I fancy that proportion will not differ greatly from what a longer practice will shew to be best. However, the same quantity of seed will not do for every soil. It must be varied with judgement, and regulated according to the circumstances of the season, and the better or worse condition of the land. I think, too, that in the first, and even the second year of the trials which may be made, it will be proper to sow a little thicker than I did in 1752. The farmer will easily perceive, that when his lands are well loosened and brought to a good tilth, they will require less seed; but till then, he will do well not to be over sparing of it.

" 10. We cannot yet determine so exactly as we could wish, what breadth the beds, including the alleys, should be of, to make the ground produce the greatest quantity of corn; nor whether it would be best to sow more or less than three rows. We confess, that we should be glad to see a longer series of accurate experiments, and to have a greater knowledge of this matter, before we pretend to fix it. Our beds have always been about six feet wide.

" M. Duhamel, who first introduced this New Husbandry in France, intends to make experiments by sowing only two rows. If they should yield more grain, the breadth of the beds may certainly be diminished: and as it is of consequence to multiply and vary experiments, in order to determine this point, we now have several beds sown, some in two, and some in three rows. I have likewise tried what multiplying the number of rows in some fields would do; and the result of this experiment promises an advantage in that way of sowing. The success of this first trial was as follows.

" When the field of the experiment Numb. II. was sowed, I observed, among the rest, ten beds which the ploughman had made wider than the others. I was sorry at first, that any part of the ground should be lost; but, upon second thoughts, I determined to sow those beds with two turns of the drill-plough; and consequently to plant them with six rows of wheat. I did so; and when the first ploughing after winter was given, little regard was paid to the two outside rows, which were torn up by the plough in several parts; so that there remained but four or five rows in those places.

" The

"The wheat of these beds, not excepting even the middle rows, grew as high, and branched as much as that of the others, in which there were but three rows. I examined them frequently with great care, and was assisted therein by several persons, very capable of judging and making good observations. The only difference we could distinguish, and that was scarcely perceptible, was in the ears, which we thought rather shorter in the middle rows than in the others; but as there was a greater quantity of them, we judged that these beds would yield the most grain.

"We were not mistaken; for their produce was as follows: the ten beds, sown with six rows each, yielded ninety-one pounds of wheat more than ten beds sown with three rows each. But as this result does not set the matter in a sufficiently clear light, we must have recourse to the following calculation. The six rowed beds took up more ground than those which had but three rows: two beds more might have been made out of the surplus of their breadth; so that there would, in that case, have been twelve beds instead of ten. The question therefore is, whether this ground, made into ten beds, produced more than it would have done if it had been made into twelve beds of three rows each. To which I answer, that it did produce thirty-eight pounds more; and that there was likewise a seventh part more straw.

"As this experiment deserved to be repeated, I have tried it in a larger way. I have laid several acres out in beds of about seven feet wide: they are sown with six rows: the plants are very fine, and I impatiently wait the event.

"Though I have continued not to dung my fields, the plants still grow very tall, and produce fine long ears, well filled with plump grain.

"I am indebted to the New Husbandry for the recovery and improvement of worn-out meadows. They have already yielded me plenty of fodder, the value of which ought to be added to the produce of the fields, because the New Husbandry is the immediate cause that manure can be spared to enrich those meadows.

General Disposition of the Lands for the Crop of 1754.

"The more I have studied the principles of the New Husbandry, the more I have been convinced of the advantages attending it. My experiments have not only confirmed me in this opinion; but they have likewise shewed me, that my practice has been consistent with those principles. This made me determine to lay the whole of one of my farms out in the new way, as soon as I possibly could; its extent being no more than I can direct almost the whole culture of myself.

"I have compleated it this year. All the fields, of which only half used to be sowed every year in our old way, are now laid out in beds. I have sowed them all, with a design to continue doing so for the future every year. They look exceeding well hitherto: the plants are extremely fine, and promise a greater crop next year, than that of the experiments of the foregoing years.

"These experiments have likewise made a strong impression on several persons in this country, each of whom judged of the New Husbandry, as his inclination, or prospect of advantage, directed. It is true, our farmers are more generally inclined to sow their lands in equally distant rows, with the drill-plough, than to lay them out in beds; the proper management of which, say they, is attended with much more care and trouble. My drill-plough is preferred on account of its simplicity. It began to be used last year, and numbers of fields near this city (Geneva) have been sowed with it this year.

"Several of our peasants have likewise tried the drill-plough, and their example will be of consequence hereafter. Their unwillingness to come into any new practice is well known: but this seems to get the better of their prejudices; and the prospect they now have of greater crops than usual, makes them regret their not having sowed a larger extent of ground in this manner.

"We have about an hundred and fifty acres sowed in beds, and also near a thousand sowed in equally distant rows. Such large experiments, and made on different soils, cannot but afford new instruction: the facts will be better ascertained, and people will be more thoroughly convinced that the greater product of the crops is owing to the New Husbandry, and not to favourable circumstances, to which they are too apt to impute it. These experiments, say they, have been made on the very best soils; it is much easier to prepare two or three roods of ground, than an extent of several acres; these little spots have been cultivated with vast care; it is almost impossible to bestow the same attention upon large tracts of land.—Luckily, several lovers of agriculture are making large experiments, which already prove, that the New Husbandry may easily be practised in any extent of ground whatever."

CONCLUSION.

"Any one may now judge, by the experiments which have been made these last four years, and by the success which has attended them, how far the principles of the New Husbandry are justly founded, and how far we are in the right road to give still farther demonstrations of its excellence.

"The lands on which it has been already practised, leave no room to doubt that all its operations may be performed with ease: and at the same time they prove to those who shall be inclined to cultivate any part of their farms in the same way, that they may do it with equal advantage.

"Convenient instruments for executing this culture are already invented and made. The use which has been, and still is, made of them, ought to increase our confidence in them. It is by their means that the two most essential articles towards securing success, are obtained: the first is, the means of forming, ploughing, and cultivating the beds, with great ease and little expence: the second, that of sowing land more regularly, and of giving it the exact quantity of seed that may be thought most proper, by means of the drill-plough, which buries the seed at its proper depth in the furrows, covers it over, and, in short, performs the whole business of sowing, with great dispatch, and a considerable saving of seed.

"The chief obstacles being now removed, we may reasonably hope that the New Husbandry will gain ground every year. Numbers of intelligent persons, truly zealous for the public good, have seen how my lands were cultivated, and have been curious enough to be present at all the operations of this culture. They have frequently told me, that the public have not a right notion either of the New Husbandry in general, or of the ease with which it is performed. They themselves have wondered at it, and pressed me to publish a circumstantial account of the manner in which I have introduced this new method into our country, that they might also instruct their countrymen therein. I have yielded to their solicitations; and shall continue to communicate my farther observations in this fourth year of my practice of the New Husbandry."

EXPERIMENTS *made by* M. Lullin de Chateauvieux, *in the Year* 1754.

"My experiments in the year 1754, will afford a fresh proof of what I said in my accounts of those of the preceding years, viz. that land, by continuing to be cultivated in the new way, will become more and more fertile, and produce greater crops even in the second or third year, than in the first; because the earth will then be in a looser state, which is highly necessary in order to have plentiful productions.

"This proof ought to be received with so much the more confidence, as the seasons of the year 1754 were not favourable to the growth of corn. It was an extremely dry year; the earth had not the degree of moisture which is necessary to promote the vegetation of plants; the wheat was in general very thin and low, and numbers of farmers did not reap above half the crop that the same lands had yielded them in 1752.

"The wheat suffered great accidents early; for it was rusted in October and November. Till then it was very strong, and promised well; but afterwards, it turned yellow on a sudden. The rust made a great progress. I met with places where the ground was entirely covered with the

the powder of this diſtemper. The vegetation of the plants before winter, was from that time nearly at a ſtand.

" They were likewiſe hurt, and perhaps ſtill more, by the froſts which began again in March, and laſted till the 20th of that month. Theſe froſts rooted up prodigious numbers of plants of the wheat ſowed in the common way, which withered in a few days. Some fields ſuffered ſo much by this accident, that it became neceſſary to plough them anew, and to ſow them again with oats, or other ſpring corn.

" To ſhew the reſult of my experiments more diſtinctly; I ſhall range them in the following order.

" The firſt article will contain an account of three experiments made on lands laid out in beds, and which have borne a third and a fourth ſucceſſive crop; to which I ſhall add ſome remarks particularly relative thereto.

" In the ſecond article, I ſhall relate four experiments which I made on lands formed into beds, which had borne a ſecond crop. Theſe too will be accompanied with ſome reflections.

" The third article will give an account of three experiments made on lands formed into beds, which have borne a firſt crop, and of the manner in which I tilled them, in order to prepare them for ſowing. This will give riſe to ſeveral remarks.

" The fourth article will inform the public of ſome other experiments made on lands laid out in beds, which have yielded a firſt and ſecond crop. This will be followed by ſome intereſting obſervations.

" In the fifth article I ſhall relate ſeveral experiments made by divers lovers of agriculture, on lands ſowed in equally diſtant rows with the drill-plough.

" The ſixth article will contain an account of the produce of ſeveral fields ſowed in equally diſtant rows, with the drill-plough.

" In the ſeventh, I ſhall make ſome general obſervations on the experiments contained in the foregoing articles.

" I ſhall ſpeak, in the eighth article, of the experiments which I have made on beds ſowed with ſix rows of wheat, and compare their produce with that of others, ſowed with only three rows. The reſult of this will enable us to judge how many rows it may be beſt to ſow.

" In the ninth article, I ſhall give a circumſtantial detail of an experiment which I made in order to be more ſure of the beſt way of ſowing the beds; and to be able to determine more exactly, what quantity of ſeed is moſt likely to produce the greateſt crop.

" Before I enter upon either of theſe ſubjects, it will be proper to obſerve, that I have not uſed any dung, or any ſort of manure, for my fields or beds; purpoſely to be the more certain of the effects of this new culture, and to ſee what land could do by mere dint of ſtirring it. My dung has been laid, as uſual, upon my graſs lands, where it continues to be of wonderful advantage.

" I ſhall continue to reckon by the pound of ſixteen ounces."

EXPERIMENTS *made on Lands formed into Beds, which have yielded a Third and a Fourth ſucceſſive Crop: with ſome Obſervations particularly relative thereto.*

EXPERIMENT, Numb. I.

N. B. This field is marked with the ſame number in the journals of 1751, 1752, and 1753; and is the ſpot on which I made my firſt experiments in 1751. This is the fourth ſucceſſive crop.

" The ſmall ſpot of ground on which I made the experiment I am going to ſpeak of, being only a ſingle bed, 160 feet long and five feet wide, would not deſerve to be taken notice of in this account, were it not for a circumſtance extremely remarkable, and the more worthy of our attention, as the ſucceſs it was attended with, affords an unexpected and indiſputable proof of the fruitfulneſs which may be expected from land cultivated in the new way. If farmers will but continue it to the third or fourth year, they will then be ſure of having their ground in excellent tilth, well looſened and divided, and its pores properly opened, and exceedingly multiplied. That this will be the caſe, cannot be doubted. Yet ſome may perhaps be weary of cultivating their lands for ſo long a time, before they attain that perfection of culture, which we have all along declared to be neceſſary, in order to have great ſucceſs.

" To prevent the diſguſt which might ariſe from ſo diſtant an expectation, and to encourage the lovers of the New Huſbandry, I ſhall obſerve, in the firſt place, that there are, in every country, conſiderable tracts of good land, which may be brought to a proper tilth in leſs time. I am, however, ſenſible how much the progreſs of the New Huſbandry would be promoted by the finding of ſome ſhorter way to break and looſen the earth, in ſoils of an inferior quality; and accordingly I have tried whether this cannot be done.

" I have ſucceeded therein fully to my ſatisfaction; and can now ſay with certainty, that land may be brought to a ſufficiently looſe ſtate, even the firſt year, by ploughing it in the manner I ſhall explain in the third article, experiments VIII. IX. and X. the crops of which were very good.

" The moſt certain and moſt inconteſtable principle of the New Huſbandry, is, that the earth muſt be thoroughly looſened by deep and frequent ploughings and repeated culture. In conſequence of this, I examined very carefully whether my lands were more looſened and rendered lighter by my manner of performing the operations of the New Huſbandry, than they were when cultivated in the common way. All my obſervations convinced me that they were.

" The firſt glance of the eye ſhewed me, that the ſurface of the ground was ſmoother: on ſounding the ploughings, I found them deeper; leſs ſtrength was required to plough: two horſes, and ſometimes only one, or a ſingle ox, did with eaſe what would otherwiſe have required at leaſt double that number of cattle. A manifeſt proof that my lands were in excellent tilth.

" If, after having thus examined the lands themſelves, I conſidered their productions, I had a freſh proof of their being brought to that ſtate of pulverization, in which alone plants can thrive well. My wheat was infinitely ſtronger than that in the common way; and, upon a minute examination, I found, that each plant had a greater quantity of roots, ſtronger, thicker, and much longer, than other wheat; and that the blades were broader and longer, and of a much deeper green. The plants had generally a great number of very thick and long ſtalks, which were crowned with large ears quite full of grain, and much heavier than thoſe of the wheat raiſed in the common way.

" All theſe obſervations were ſufficient to convince me, that my lands were in the ſtate I wiſhed them to be; that is to ſay, that they were looſened and divided ſo as to be capable of yielding great productions.

" It was therefore leſs to ſatisfy myſelf, than to give the public a farther proof of the excellence of the New Huſbandry, that I made the experiment I am now going to relate. It is an intereſting one in every reſpect; and I doubt not but that it will induce many others to make the like trial. I can aſſure them that they will find it well worth their while.

" When the harveſt of 1753 was over, I immediately ſet about ploughing my fields, and forming the new beds that were to be ſowed. The year was a very dry one. I uſed frequently to walk, both over the beds, and over the fields cultivated in the common way, where the corn had likewiſe been lately cut down.

" The firſt thing that ſtruck me in theſe walks was, the difference which I found in the ſtubble. That of the fields cultivated in the common way was ſo poor and weak, that it ſcarcely oppoſed the motion of my feet. That of the beds, on the contrary, reſiſted greatly; I often felt it break under my feet, and frequently met with tufts of twenty, thirty, forty, and ſometimes more ſtalks, which ſtopt me ſhort, like ſo many little buſhes.

" I am the more particular in my account of this ſtubble, becauſe it ſhews the great ſtrength of the plants; which they would not have had if the earth had been leſs well prepared. Beſides, this ſtubble has its real uſe, as I ſhall ſhew elſewhere. It is a much better manure for land, than the common ſtubble.

" This obfervation led me to examine carefully what other differences I could find between the fields cultivated either way. The moft important is, the ftate of compreffion which thofe in the common way were in after harveft. They offered nothing pleafing or fatisfactory to the eye; the earth was extremely hard, clofe and compact; and its furface almoft as firm as that of a beaten road.

" The fields in the new way, prepared by better ploughings made at proper feafons, were, on the contrary, ftill very light and foft in the middle of the beds, in the intervals between the rows of ftubble. The earth gave way like fand, when trod upon; and though it was very dry, I thruft a ftick of green willow eight or ten inches deep into it, with great eafe, though I could not by any means pufh it at all into the land which had been cultivated in the common way. This plainly fhews the better ftate of the former.

" Laftly, I compared thefe fields with thofe that were in fallow, which had been ploughed, and were intended to be fowed in autumn. I found the tops of the late reaped beds, in much better condition than the common fields which were under fallow. This made me immediately conclude, that thefe very beds might be fowed again with fuccefs, in the fame places where the corn grew the year before, without ploughing them.

" I thought, however, that, if this trial did fucceed, it would be owing, in fome meafure, to the culture of the alleys, and that this would fully prove their utility. This was another reafon for my trying the experiment.

" It appears by this, that my chief defign was to try whether the fame ground could be fowed, in the fame place, two years running, without ploughing; and to fee how ftrong the plants would, in that cafe, be at harveft.

" I was confequently to avoid, in fowing it, every thing that might fupply the want of ploughing, and to ftir only juft fo much earth as was abfolutely neceffary in order to bury the feed. This confideration prevented my ufing the drill-plough, the fhare and harrow of which divide and loofen the earth perfectly well, as deep as the feed is planted.

" All that I did to this bed, was, barely to pull up the ftubble, and afterwards draw a line with a ftick, as if it had been for fowing lettice. The feed was dropped by hand into three of thefe channels, and afterwards covered with a rake.

" Birds had done great damage to the wheat which I fowed the year before in this ground. To avoid this accident now, I fowed a kind of corn called fpelt, which is ufed in many places inftead of wheat. The Germans cultivate it greatly. The fpelt which I fowed is of a fomewhat different kind. The grain of both forts is inclofed in double hufks, very thick, and of which the outer one does not open eafily; fo that birds cannot well pick out the grains.

" I fowed this bed very thick, concluding that the plants would not branch much: and I fowed it early, viz. on the nineteenth of July, becaufe this grain remains a whole year in the ground, from the time of fowing till it is ripe. I ufed in all eleven ounces of feed, which foon fprung up, and the plants made very ftrong fhoots; but I thought them too thick.

" As this ground had not been ploughed, I thought it was proper to affift the plants otherwife as early as I could. They were weeded on the twenty-fecond of Auguft.

" Thefe plants grew fo extremely thick, that their blades covered the ground four feet round, before winter, in fuch manner that the earth could not even be feen through them. The rows were from a foot to a foot and an half high, and the whole had already fpindled, which made me forry I had fowed fo early; fearing left plants fo forward before winter, as thefe were, fhould be killed by the froft; and, in order to fecure fome refource in cafe that fhould happen, I ordered part of the bed to be mowed on the fixth of November, but did not touch the reft. I muft here obferve by the way, that the part which was mowed had feweft ftalks at harveft. At the fame time I gave the alleys their firft plouging before winter. Upon opening a furrow near the rows, I faw fuch a prodigious quantity of long roots, interwoven as it were with one another, that I continued to hope well of the fuccefs.

" Seeing, however, fo many roots uncovered and expofed to the air and froft, I was tempted to fill the furrows up again, in order to preferve them from it: but confidering, that by leaving the furrows open, the part of the bed in which the plants were, and which had not been ploughed, would be much more expofed to the froft, which would then penetrate the earth through its furface, and through both fides of the furrows, whereby it would be greatly divided, and perhaps meliorated more than by ploughing, I preferred leaving the furrows open, and have had no caufe to repent it.

" I confidered too, that fuppofing thefe roots expofed to the air fhould perifh, which was no more than I might reafonably expect, the plants had other roots on their other fide, which, ftill remaining covered with earth, would be fufficient to fupply them with the neceffary nourifhment till fpring.

" After winter, the ploughings were performed in proper weather, and the bed was weeded. I fhall not repeat the detail of thefe operations, either here or in the following experiments. What I faid of them in the year 1753, may fuffice, as they have not been varied fince.

" The plants which I have been fpeaking of, grew amazingly in thicknefs, height, and largenefs of ears. They were reaped on the twenty-fifth of July, and yielded five hundred and forty ounces; which is forty-nine times the feed, and an ounce over. The birds did no damage at all. This is after the rate of 2041 pounds, or thirty-four bufhels to an acre, which is a good crop.

" This experiment amounts to a complete demonftration of the fuperiority of the New Hufbandry. It fhews, beyond all doubt, how much the earth is more perfectly tilled by it, and that this tilth is lafting, if care be taken to preferve it by good culture, performed at proper times, and with judgment.

" Can it be thought that a field cultivated in the old way, will, with only pulling up the ftubble, and without ploughing it feveral times, even though it be harrowed, ever produce a crop of any corn whatever? Part of the feed might indeed fhoot, and the plants might grow fome inches high: but they would certainly perifh for want of nourifhment, which they would not be able to draw from fuch a foil, by reafon of its extreme hardnefs: and confequently they never would be able to produce any grain.

" It was of great importance to fhew, by an unexceptionable experiment, that lands are brought to much better tilth by the New Hufbandry than by the old. This is now completely proved; and no doubt can any longer be made, that the confequence we drew from it is equally certain; viz. that land fo prepared, will produce more than lands which are cultivated in the common way. This fact, which is founded on the principles of found philofophy, is likewife confirmed by repeated experience.

" The partifans of both kinds of hufbandry will do well to confider, that the great principle which we are endeavouring to inculcate, and on which almoft the whole fuccefs of the New Hufbandry depends, is admitted in the Old Hufbandry: viz. thoroughly to divide and loofen the earth. This principle is fo generally received, that there is not a hufbandman who does not know that one ploughing more than ordinary does his land as much good as dunging it would do. His experience has certainly taught him, that this extraordinary ploughing produces him better crops: but he is not fufficiently fenfible, that, of all the ways of improving his land, no one is more effectual, or lefs expenfive than this. Were the full value of it known, it would be practifed more: and every farmer would give all his lands at leaft one ploughing extraordinary.

" What we propofe, is therefore not a novelty capable of giving any hufbandman the leaft diflike to the New Hufbandry. We all proceed upon the fame principle, and agree as to its effect. All of us fay, the earth muft be well divided and thoroughly loofened: but we differ in the manner of doing it. We propofe a method by which the ground is much better prepared than in the old way. In this confifts all the novelty. Whoever rightly confiders it, and compares it with the principles and experiments, will readily receive it; but he that is determined beforehand, not to enter into this examination, will never enjoy the benefits of it, but will continue plodding on in the old beaten

beaten track; not from reafon, but becaufe others did fo before him.

"The advantages of the New Hufbandry are however fo great, that it would be doing the public an injury, not to endeavour to make them more and more known. The fitteft way to anfwer this end, feems to be, to exhort all hufbandmen to convince themfelves, by ftudying the theory of the New Hufbandry, weighing the folidity of its principles, and confulting the experiments which have been already made.

"Every man of common underftanding, cannot but fucceed in the practical part; and his example being imitated by others, the New Hufbandry would foon become the general method."

Experiment, Numb. II.

N. B. This field is marked with the fame number in the journals of 1752 and 1753.

For the crop of 1752, it was fowed with eleven pounds four ounces of wheat, which yielded 1041 pounds twelve ounces.

For the crop of 1753, it was fowed with thirty-four pounds fourteen ounces, which produced 1575 pounds.

For the crop of 1754, it was fowed with fixty-one pounds fourteen ounces, which yielded 1820 pounds.

"This field, which was to be fowed for the third time, having been brought to a good tilth by former ploughings, I prepared it immediately after harveft, by giving it a ploughing like that of the laft year. I found that I had done right, in increafing the quantity of the feed the fecond year; and, upon examining the plants which the earth had nourifhed, it feemed to me that it could yet bear a greater number, and that I might expect a ftill greater crop, by adding to the feed.

"Accordingly, I fowed it on the fixteenth of Auguft, with fixty-one pounds fourteen ounces of very large and perfectly clean wheat, of my own growth. It was the fame as I ufed for fowing all my fields.

"The plants made a very confiderable progrefs after winter, and fhot up greatly, notwithftanding the extraordinary drought. They began to fpindle on the eighteenth of May; they bloffomed on the firft of June; and, being ripe, I cut them down on the tenth of July. They were threfhed a month after harveft, and yielded 1820 pounds of perfectly clean wheat. Thus we fee, that this field produced in 1754, 245 pounds more than in 1753, and 778 pounds four ounces more than in 1752."

Experiment, Numb. III.

N. B. This field is marked with the fame number in the journal of 1753.

"This field, being now in much finer tilth than it was the laft year, would certainly have produced a greater quantity of wheat. However, I refolved to fow it with a foreign wheat, by way of trial. I did fo, and it yielded me fcarce any crop at all.

"I thought it might be of great fervice to try, whether wheat of a different quality from that which we ufually cultivate, would not yield more than even wheat of the growth of our own country. At all events it was right to make this trial, though the wheat which I ufed for it was by no means proper for fowing in our lands. It was Sicilian wheat, the grain of which is very large and extremely hard. I fowed it on the twenty-firft of Auguft. It rofe well; the plants grew very fine before winter, and were extremely thick. But this wheat, being doubtlefs of a much tenderer nature than our common wheat, could not refift the winter's froft, which almoft entirely deftroyed it. Only a few ftrong plants efcaped. Thefe grew exceeding fine, branched greatly, and produced very large ears, which contained more grains than thofe of the wheat of our country. As the plants which furvived the froft were very few, I reaped only about three times the feed."

Remarks on thefe Experiments.

"It is by experience that we can beft judge how far the advantages afcribed to the New Hufbandry are real. The foregoing experiments give rife to two important obfervations.

"The firft experiment fhews us, that lands are brought to much better tilth by the New Hufbandry, and that they will confequently produce much greater crops than in the old way. Experience proves, that they have done fo.

"The fecond experiment offers us the fame proofs, but upon a much larger extent of ground. We have the products of three fucceeding years, and the gradation of their crops. What ought to be particularly attended to here is, that as the internal pores of the earth became more open, the crops became more plentiful, which juftifies what we faid before, that the crops of the fecond, third, and following years, would be greater than that of the firft.

"It was of great confequence to eftablifh this fact, in order to found our calculations of the products upon certain and approved experiments. The following article will afford ftill farther proofs of this truth."

Experiments made on Lands laid out in Beds, and which had borne a fecond Crop. Reflections on thefe Experiments.

Experiment, Numb. IV.

N. B. This field is marked with the fame number in the journal of 1753.

For the crop of 1753, it was fowed with 181 pounds of wheat, which produced 3370 pounds.

For the crop of 1754, it was fowed with 268 pounds fourteen ounces, which produced 4972 pounds eight ounces.

"I muft remind the reader, that this field was fowed in 1753, half in beds, and half in equally diftant rows with the drill-plough. I will fpeak firft of the part that was laid out in beds, which continued to be cultivated in the fame manner for the crop of 1754.

"The ploughings made during the year 1753, had the fame effect upon this land, that is to fay, they loofened and divided it. It was ploughed with eafe after harveft; and the new beds having been formed and well prepared, I fowed them on the feventeenth and eighteenth of Auguft, increafing the quantity of the feed to 268 pounds fourteen ounces of wheat. The plants rofe well, and throve greatly before winter; and in the fpring they made ftrong fhoots.

"The winter frofts, and perhaps fome infects too, had deftroyed fome plants in the rows. I faw plainly by this, that I had done right in increafing the quantity of the feed. Though the year was dry and hot, the wheat grew to a great height, and ripened well. I reaped it between the tenth and fifteenth of July, and threfhed it out in the winter. This crop yielded me 4972 pounds eight ounces; fo that I had this fecond year 1602 pounds eight ounces more than the firft.

"I fhall fhorten what I have to fay of the other half of this field, which was fowed in equally diftant rows for the crop of 1753. After harveft, I made it into beds. But how furprifing was the difference between the mould of thefe two parts of the fame field, even in this fecond year! That which had been formed into beds, was fine and light; but this was fcarcely divided at all; it was full of great hard clods, many of which it was neceffary to break by hand. Though I had not much hope of its yielding any great crop, confidering the condition it was in, I fowed it on the twenty-ninth and thirty-firft of Auguft.

"Thefe beds were but poorly ftocked with plants, which gathered little ftrength before winter, and indeed always remained very weak and ftinted, and, when reaped, yielded ftill lefs than the other half of the field had done in 1753. But if I have not gained any thing by the crop, I have at leaft brought my beds into fuch tilth as affures me of a more plentiful harveft in 1755."

Experiment, Numb. V.

N. B. This field is marked with the fame number in the journal of 1753.

For

For the crop of 1753, it was fowed with 139 pounds, which produced 2205 pounds.

For the crop of 1754, it was fowed with 224 pounds of wheat, which produced 2283 pound.

" The foil of this field was of fuch a nature, as rendered the loofening of it more difficult than that of the experiments Numb. II. and Numb. III. notwithftanding the culture beftowed upon it in the fummer of 1753, which mended it greatly. Still it was not yet in the condition I could have wifhed, when I fowed it on the eighteenth and twentieth of Auguft. I fowed it thicker than it had ever been planted before, merely on account of the badnefs of its tilth. I beftowed upon it 224 pounds of wheat, which rofe pretty well, but afforded fewer plants than that of the fecond experiment. They branched tolerably, and their ears were very fine. I reaped this crop on the nineteenth and twentieth of July, and it yielded 2283 pounds of wheat, which is feventy-eight pounds more than the firft crop in 1753."

EXPERIMENT, Numb. VI.

N. B. This field is marked with the fame number in the journal of 1753.

For the crop of 1753, it was fowed with forty-five pounds of wheat, which produced 724 pounds.

For the crop of 1754, it was fowed with eighty-two pounds of wheat, which produced 798 pounds.

" What I faid of the foregoing experiment may likewife ferve for this. All the circumftances were alike, except that this field was fowed a few days later, viz. on the twenty-feventh of Auguft. It was reaped on the nineteenth of July, and yielded 798 pounds, which is feventy-four pounds more than in 1753."

EXPERIMENT, Numb. VII.

N. B. This field is marked with the fame number in the journal of 1753.

For the crop of 1753, it was fowed, as well in that part of it which was made into beds, as in that which was fowed in equally diftant rows, with 412 pounds of wheat, which produced 2646 pounds.

For the crop of 1754, the whole field was made into beds, and fowed with 360 pounds, which produced 2467 pounds.

" It muft be remembered, that one half of this field had borne a firft crop, and the other a fecond. From what I have already faid, it will be prefumed, that the mould of the new beds was not in fo good condition as that of the others; confequently the former could not be expected to yield fo good a crop.

" This field was fowed on the twenty-firft and twenty-eighth of Auguft. Its whole extent took up 360 pounds of wheat, which yielded a crop of 2467 pounds. At firft fight, it feems to have yielded lefs now than in 1753; but it muft be obferved, that the beds of this field were of two different ages; thofe which now bore their fecond crop yielded more than in 1753; but as the fheaves were not collected feparately, I cannot tell exactly the difference of their produce."

Reflections on the foregoing Experiments.

" I have now given an account of four fields, which produced their fecond crops in 1754, all of which were greater than thofe of 1753, and efpecially that of the fourth experiment. I am fully fatisfied, that their produce was proportioned to the preparation of the foil. This obfervation fhews of what confequence it is to divide and loofen the earth as much as poffible, by deep ploughing, and thorough hoeing, in order to bring it to a perfect tilth, which may certainly be done, and that in a fhort time, by the means which I fhall point out in the following article.

" Neither our intereft, nor the knowledge we would acquire of the products which the New Hufbandry is capable of yielding, fuffer us to reft fatisfied with knowing, for example, what the crop of thefe four fields was the fecond year, and looking upon that as the moft they will ever produce. We ought likewife to examine, whether their crop was not diminifhed by caufes which we can account for, and which we may reafonably hope will not take place in other years.

" By this examination we fhall find, that the year was not a good one for great crops of wheat. There was not rain enough; the corn grew thin, and yielded but few fheaves. The ears were indeed full of grain, but the quantity was not fufficient to make amends for the thinnefs of the crop.

" The wheat was rufted in autumn; and though this diftemper fhewed itfelf in that feafon, in which I think it does the plants leaft hurt, yet it prevented their branching, fo much as they would otherwife have done the next fpring. I obferved exactly, that the thinneft places were thofe where the ruft had prevailed moft. Laftly, the frofts which happened in March, did great damage to the wheat. It is therefore not to be wondered at, that the crop was not greater. I hope, and I flatter myfelf, not without foundation, that the fame fields will produce better crops in years exempted from fuch accidents.

" I do not pretend that the New Hufbandry can fecure corn from the effects of all thefe accidents: but I have experienced that the crops cultivated in this manner have fuffered lefs from the intemperature of the feafons, than thofe which have been raifed in the common way: for inftance, they will fuffer lefs by a great drought, or even not be at all affected by it, if dews fall, which penetrate the well-loofened earth; as I have conftantly obferved: and befides this, the roots of the corn in the new way, being much longer, will extend to a confiderably greater depth in ground that has been ploughed deeper, and will find a moifture there, which corn in the common way is deprived off."

EXPERIMENTS *made on Lands laid out in Beds which had borne a firft Crop: with an Account of the Manner in which they were tilled, to prepare them for fowing. Remarks on thefe Experiments.*

" The firft crops of all my fields laid out in beds have hitherto been but fmall. I eafily difcovered that this was owing to two principal caufes, independent of the intemperature of the feafons. The firft was, that I fowed too little feed at firft, and that the quantity was not fufficient to fuftain the accidents which befel my wheat, without being confiderably diminifhed thereby. This I remedied afterwards, by increafing the quantity of the feed; which I have continued to do by little and little, from year to year, in proportion to the condition and quality of my land.

" The fecond caufe was the bad condition of my lands, which could not be fufficiently loofened and divided in fo fhort a time, and therefore did not afford the plants the quantity of nourifhment neceffary to enable them to produce plenty of grain.

" I was in hopes that, by continuing my ploughings, I fhould have better fuccefs the following years: that is to fay, that I fhould bring my land to a loofer ftate, and that if I gained that point, the crops would certainly be greater afterwards.

" Encouraged by this expectation, and provided with my plough and cultivators, I made no doubt of fucceeding. To this end, I refolved to multiply the ploughings: and certainly no one ought ever to hefitate fo to do, even in the common hufbandry; fo great have been the effects produced threby.

" I have often reflected on this paffage in Mr. Duhamel's Treatife of the Culture of Land: One of the prefident Montefquieu's farmers reaped a great crop of Spanifh wheat, from his farm near Clairac, at a time when all his neighbours had very bad crops. The prefident afked him, what he had done to have fuch extraordinary fuccefs. The farmer anfwered, that he had given his ground eleven ploughings between feed-time and harveft; and that, by this means, it had reaped the benefit of all the rains, dews, fogs, &c. whilft the lands of his neighbours were not at all bettered by them, on account of a dry hard cruft which grew over their grounds, for want of ploughing. This

obfervation

obſervation agrees perfectly with the principles on which the New Huſbandry is founded.

" This ſhews us that an active, intelligent, and induſtrious farmer, will always reap the fruit of his labour and expence. But without pretending to ſay that land ought to be ploughed quite ſo many times, we learn from this example, that it would be greatly for the public good, to plough it oftener than is generally practiſed.

" I multiplied my ploughings, in the ſpring, and till ſeed-time. I gave my land ſix ploughings in all: but I aſcribe the great benefit which I received, chiefly to the manner in which thoſe ploughings were performed, and to which I beg the reader ſeriouſly to attend.

" After the beds were formed, my method was this. I changed their poſition, by removing the middle of the beds to the place where the great furrow in the middle of the alley was before; or, to explain myſelf ſtill better, I then performed the ſame ploughing as we do after the firſt crop is reaped.

" This operation is of ſuch importance, that it requires my being ſtill more explicit. I ſhall therefore relate the whole proceſs of the preparation of my land. In the firſt place, I ploughed it twice, as deep as I poſſibly could, in broad lands. The beds were formed at the third ploughing. I afterwards gave a fourth ploughing, to raiſe them ſtill higher, by opening the firſt furrow in the middle, or higheſt part of the beds, and turning the earth on both ſides up againſt that middle, by which means the beds were arched very high, and a great furrow was left in the middle of the alleys. I went farther yet; and this I ought to reckon as a ſeventh operation: I cut the great furrow in the middle of the alley ſtill deeper, with one turn of my cultivator with two mould-boards.

" The beds thus prepared were certainly in excellent order for ſowing: I never had them in ſo good condition before: but I was willing to go ſtill farther, and that for the following reaſon.

" I had obſerved, that there is always a greater depth of fine mould in the middle of the bed, when it is placed in the ſpace before occupied by the main furrow in the middle of the alley. My beds were not diſpoſed in this manner till the ſecond year.

" I therefore thought it adviſeable to change the place of the beds, I did ſo, at the fifth ploughing, by filling up the great furrow, which now became the middle of the new bed. As the earth was in a very looſe ſtate, a great deal of it was heaped up by each turn of the plough, with eaſe to the horſes, and with ſpeed. The middle of the beds was raiſed as much as might have been thought neceſſary: but I raiſed it ſtill higher, at the ſixth and laſt ploughing, by cutting the firſt furrow in the middle of the bed, and turning the earth up from right and left towards it.

" By theſe ploughings, the mould of the beds will be admirably well prepared even the firſt year, and the ſeed ſowed therein will not fail to vegetate very abundantly. It is by this means that I have brought the middle of my beds to the depth of fifteen or eighteen inches of fine looſe mould, in which the perpendicular roots of the plants extend themſelves, and multiply eaſily, and find plenty of nouriſhment, which they afterwards tranſmit to the plants themſelves.

" I ſhall mention farther, as a proof of the fineneſs to which theſe ploughings brought the earth, that I was not obliged to harrow my beds before I ſowed them.

" Some may perhaps object, that all this requires much labour, great trouble, and conſiderable expence: and how, will it be added, can one find time for ſo many ploughings?

" To this I anſwer: firſt, that allowing all this to be true, the crop will make ample amends for it. What follows will eſtabliſh this truth beyond all doubt.

" Secondly, that this labour ought not to diſcourage any one. The four firſt ploughings are abſolutely neceſſary, as all will agree: and the fifth and ſixth are performed with ſuch eaſe, and in ſo much leſs time than the common ploughings, and eſpecially the laſt, for which one horſe will generally be ſufficient, that it will eaſily be perceived I do not propoſe a thing either too difficult or too expenſive to execute.

" The fields of the three experiments of this article, were prepared in the manner I have now related.

Experiment, Numb. VIII.

" The ſoil of this field is very good and ſtrong. Its extent is one acre and twelve poles. I made the beds about ſix feet wide; and each bed was ſowed with two turns of the drill-plough, which were to make ſix rows: but the difficulty of guiding the plough ſo as to keep the three laſt rows exactly parallel to the three firſt, was ſo great, that the two middle rows were frequently jumbled together, ſo that there were in fact but five rows in ſome places. The ſpace which remained between the outer row of one bed, and the outer row of the next bed, left an alley wide enough to be ploughed. I muſt obſerve that our farmers hereabouts liked this way of ſowing much better than the firſt, in which I likewiſe made the beds ſix feet wide, and ſowed them with only three rows.

" I ſowed each row a little thinner than in the former experiments: but as there were more of them in each bed, they would of courſe require a greater quantity of ſeed. This field was ſowed on the 27th of Auguſt, with ſeventy-ſix pounds eight ounces of wheat.

" All my plants were equally fine till winter, and ſhot up with great vigour in the ſpring. They grew exceeding high, branched abundantly, and produced very large ears, among which there was but little difference. This crop was reaped on the 7th of July, and yielded 1462 pounds of wheat.

" This produce made me good amends for the labour I had beſtowed upon the ground. It is after the rate of about 1500 pounds, or twenty-five buſhels to an acre.

Experiment, Numb. IX.

" This field is of a very indifferent quality, and had hitherto yielded but ſmall crops. Its extent is four acres, three roods, eight poles, and nine feet. It was ſowed on the ſeventh and eighth of Auguſt, in the ſame manner as the former, with 249 pounds twelve ounces of wheat.

" The young plants ſhot up as thick, and looked as ſtrong and of as good a colour, as thoſe of the foregoing experiment: but the ruſt took them all in October and November; and their blades, which were of the fineſt green before, turned yellow, and perfectly covered the ground with the powder of this ruſt. My plants ſuffered greatly by this accident. They branched imperfectly, and conſequently grew very thin. Their ſtalks were, however, long, and bore fine ears. They were reaped on the 8th of July, and yielded 2925 pounds of wheat.

Experiment, Numb. X.

" The ſoil of this field is rather inferior, than equal to that of the field we ſpoke of laſt, whoſe fate it likewiſe ſuffered in every reſpect. The young plants were extremely fine, and, in October and November, they were ruſted almoſt as much as the others. This field contains three acres, three roods, and nine poles. As I thought this land inferior to the other, I ſowed it thicker; uſing to this end 294 pounds of wheat. It was ſowed on the 8th, 17th, and 28th of Auguſt; not being able to do it in any three days running. The crop yielded 3055 pounds.

Remarks on theſe Experiments.

" I have now been able to obtain better crops, even the firſt year, by the New Huſbandry, than any I ever had before. I think there can be no doubt but that this ſucceſs is owing firſt, and chiefly, to the better preparation of the ground; and ſecondly, to a proper increaſe of the ſeed. Upon the whole, I am inclined to think, that the ſowing each bed with two turns of the drill-plough increaſed the crop. But of that I ſay no more at preſent, as I intend to treat expreſly of it in the eighth article.

" All my obſervations ſhew, how much I am convinced of the importance of bringing the earth to a fine looſe ſtate: nor can I recommend it too ſtrongly. I have ſenſibly experienced the good effects of it in all my lands, and particularly in thoſe of the ninth and tenth experiments; for, though theſe fields are but of an indifferent quality, they have produced plants equal to thoſe of my very beſt lands.

" After what I have now faid, no one will be furprifed that almoft all my firft crops were but fmall, fince moft of the lands were fown after a fingle ploughing, which was not fufficient to prepare them properly. I was indeed well apprifed of this defect at my firft fetting out: but all I then aimed at was, to lay all my fields into beds as foon as poffible; being thoroughly fatisfied that it would not be long after, before I fhould be able to bring them to a proper tilth, with great eafe and little coft.

" Thefe three experiments not only fhew us how to conduct our works more profitably hereafter; but they likewife difcover a new advantage in this hufbandry, which indeed I fufpected from my very firft experiments. It is of importance to take notice of it here.

" All the experiments made by different perfons, and in different places, have fhewn us, that wheat cultivated according to the New Hufbandry is very little apt to lodge; that the great ftrength of its ftalk fupports it, and that it refifts the force of the wind much better than that which is raifed after the common method, the ftalks of which almoft always give way in ftormy weather.

" It muft however be acknowledged, that the wheat of the new culture is not abfolutely able to refift extremely violent winds accompanied with great rain. But would any one expect that the accident I am now going to fpeaking of, far from hurting the wheat, feemed to me to be of great fervice to it, particularly in very rainy years, or when cold dews fall about the time of its ripening?

" I obferved, in the account of my experiments in 1752, that my wheat was not lodged; but that fome of it was bent, without fuffering any damage thereby. I added, that I imagined it might be of fervice to the wheat not to remain always in an exactly perpendicular fituation. I purpofed watching clofely what effect the fituation of this would have. I could not be fatisfied in this in 1753; but the year 1754 furnifhed me with obfervations, and afforded me advantages with refpect to the quality of wheat, which it is always of very great fervice to know.

" Wheat grows and fhoots up pretty perpendicularly, without altering this direction, unlefs it meets with fome obftacle. The moft formidable is a violent wind, accompanied with great and heavy rains, which lodge it. Every one knows, that when wheat is lodged foon after it has done bloffoming, it yields fcarce any grain; and that what it does yield, is very fmall and fhrivelled, and contains very little flour: a manifeft, and oftentimes very confiderable lofs.

" The wheat which is only bent, continues to grow in that fituation: its ears fwell and fill equally with grain to the very point, abounding plentifully with good and very nourifhing flour. Thus no lofs is fuftained in this cafe; and this inclined fituation of the ftalk does not at all interrupt the functions of the nutritive juices, as in wheat which is lodged. The growth of the plants in this fituation proves plainly that their vegetation is not ftopt.

" This bending of the ftalks no way hinders a fkilful and careful hufbandman from giving another ploughing, if it be neceffary. I had it done in the field of the eighth experiment, without deftroying or hurting a fingle ear.

" All the beds of the three fields on which the experiments mentioned in this article were made, are in the fame direction, viz. from eaft to weft, and lie fomewhat floping towards the weft. Soon after the wheat had done bloffoming, a ftrong fouth wind blew for fome hours, accompanied with a heavy rain, which made all the wheat of thefe three fields incline towards the north. It remained in this fituation till harveft, and the ftalks grew fo crooked that the points of the ears turned down towards the ground: they remained thus fufpended, by the ftrength of the ftalks, which feemed even to increafe; for I did not find that they bent any more, though the weight of the ear increafed as the grain grew riper.

" In this fituation, this wheat continued to profper: the ears filled with grain to the very point: they grew as large and heavy as thofe of the other fields; and had befides the advantage of being of a finer colour. This quality helps corn to fell fooner and more eafily, becaufe the buyer judges by his fight more than by his other fenfes. It is of confequence in all forts of goods, to catch the eye; but there is no fear of its deceiving one in the choice of wheat: the good colour of the grain is always a fure fign of its foundnefs, and invites the purchafer to buy it with confidence.

" Since then there is no fear that any damage will arife from wheat's being bent, there is no caufe to repine or be uneafy at feeing it in that fituation. But, befides what I have been faying, I muft now offer fome reafons why I think it may perhaps be better for wheat to be bent and curved in that manner, than for it to grow almoft quite upright.

" Let us confider what effect rain, the moifture of the air, and dews have upon the ears of corn in both thefe fituations. When the ears ftand upright, and almoft perpendicular, they retain a great deal of wet in rainy and dewy weather. This wet infinuates itfelf very eafily between the hufks which cover the grain, and gets even into the infide of them. This water, thus got within them, remains there, and does not evaporate fo eafily as that which is only upon the outer furface of the hufks, which the motion of the air or the fun diffipates in a fhort time.

" It may happen too, but I fhall not give it as a fact which I have yet fufficiently obferved, that the water which has penetrated between the hufks, touches immediately the grain itfelf. Now this moifture all around it, in whatever manner it gets there, muft certainly be very prejudicial to the grain; and the longer it ftays there, the more hurt it muft do. We have feen fuch continual rains in fome years, that, for feveral days together, even the outfide of the ears could not be wiped dry, but they have remained wet fo long, that the corn has fprouted while it ftood upon the ground. But, without fuppofing the mifchief to be always fo great, wet, by remaining too long upon the grain, may, in fome meafure, ruft it a little, as it rufts ftraw while ftanding. I have feen this happen, though indeed but feldom.

" The imperfection which is often found in the quality of the grains, and their fometimes lefs pleafing tafte, may, with great probability, be imputed to this cafe: and perhaps it may be found upon ftricter inquiries than thofe I have hitherto been able to make, that the moifture too long retained around the grain, towards the latter end of its growth, and particularly that of cold dews, is the real caufe of the fatal and fudden changes which often befall wheat in grain, a little before harveft, and rob us of the beft part of a crop which was juft before thought to be quite out of danger.

" When the wheat is inclined, its ftalks bent downwards arch-wife, and the point of the ears turned towards the ground, it is plain that no wet, either of rain or dews, can fo eafily get at the grain, and that only the outer furface of the hufks will be immediately touched by it: the water, not being able in this fituation to glide in between the interftices of the hufks, will drip down from one hufk to another till it comes to the point, and then will fall to the ground. Thefe hufks are foon dried again; and the ears which grow in this manner are much lefs expofed to the confequences of the wet, than thofe which remain in a perpendicular fituation; and confequently their grain ought to be better conditioned.

" This advantage can be enjoyed only in the New Hufbandry; for in the old way, the wheat is either lodged quite flat, or ftands quite upright; fcarce any of its ftalks are ftrong enough to fupport the fmall weight of the ear, when bent and inclined towards the earth.

Experiments made on Lands laid out in Beds, which have borne a firft and fecond Crop, together with fome interefting Obfervations.

Experiment, Numb. XI.

" In the journal of 1753, I gave an account of the experiments which a perfon had made upon about twenty-eight acres laid out in beds about fix feet wide, and which did not meet with the defired fuccefs. I added, that the fame perfon, perfuaded neverthelefs of the advantages of this culture, had prepared twenty-five acres more in the fame manner, and that all of them were fown for the crop of 1754.

" All

" All this ground was ploughed with care, and part of it was ſown earlier than the year before. Some little addition was likewiſe made to the quantity of the ſeed. The plants in general roſe extremely well, and were ſtrong and healthy before winter, in proportion to the time of their being ſown, and to the quality and condition of the land.

" Such a beginning gave room to hope, that theſe fields would yield a pretty good crop; but the winter ruined all; and ſcarce any thing was reaped from ſo large an extent of ground.

Obſervations on this Experiment.

" It would have been unfair in me not to mention this experiment, though it anſwered ſo badly. The reader may be ſurpriſed at firſt to ſee ſo great a contraſt between this and my own experiments, in which, notwithſtanding the intemperature of the ſeaſons, and other accidents, he finds the crops increaſe as the land becomes better tilled, according to the principles of the New Huſbandry. This increaſe was what we foretold would happen; but the field we are now ſpeaking of, produced leſs the ſecond year than it did the firſt, though even that was very little.

" There muſt then neceſſarily have been ſome differences between theſe fields, to which this great diſparity of their corps was owing. Theſe differences doubtleſs were, either in the quality of the ſoils, the preparation of them, their expoſition, the quantity of the ſeed, the accidents that befel them, which might be greater or leſs in ſome than in others; or, in ſhort, many other cauſes capable of helping or hurting the crop; for otherwiſe, ſuppoſing all theſe things to be equal, or nearly ſo, the diſparity in their crops would not have been great.

" Not to impute the bad ſucceſs of this laſt experiment too lightly to the New Huſbandry, we ought in juſtice to examine, whether it might not be owing to ſome other cauſe, and whether there may not be room to hope for better ſucceſs another time.

" Theſe fields, without being all exactly of the ſame quality, are generally reputed, in the country, cold and ſtiff lands, and very apt to grow hard. Such lands will certainly require more time, more patience, and more perſeverance, to bring them to any degree of tilth; more ploughings will be neceſſary, and thoſe ploughings muſt be given in the moſt proper ſeaſons. By continuing to ſtir them well, their hardneſs and reſiſtance will be overcome, their pores will be opened and multiplied, and plants will then thrive in them as well as in the beſt of ſoils.

" All lands ought to be treated according to their reſpective qualities. There is great reaſon to believe, that this field, when prepared as thoſe of the experiments Numb. VIII. IX. and X. were, will hereafter produce great plenty of corn. What I now ſay, is not mere conjecture. Repeated experiments, the effects of which have been conſtantly the ſame, have taught me, and I can ſafely affirm, that extremely bad lands, which could not ſo much as yield a crop that would pay the expence of tilling them, have been rendered good and fertile merely by ploughing, and without the aſſiſtance of any manure.

" This is a ſtriking truth. It was what firſt determined me to practiſe the New Huſbandry; and therefore it was of conſequence to me to be certain of it. To this end, I reſolved to make a trial upon a ſmall ſpot of ground, which I knew to be incapable of producing any thing in its then ſtate.

" Some years before I had dug away the earth three feet deep, from a ſpace of 360 feet ſquare. Nothing remained in it but a cloſe white clay, fit for potter's uſe. This ſpot, thus circumſtanced, ſeemed to me a proper one for my experiment. As the ſpace was too ſmall for the plough to work in, I made uſe of the ſpade and hoe. It was made into beds, which were afterwards ſown with wheat, and the ſpaces between them were frequently ſtirred. The firſt year my plants were very poor, and branched into only two, three, or four ſtalks apiece. The ſecond year they did much better; and the third year they were as large and fine as any my garden could have produced. This ſpot ſtill continues to produce equally well.

" We have here a remarkable inſtance of what may be done by ſufficiently pulveriſing the earth: that which I am ſpeaking of is now like mould; and, which is very remarkable, it has loſt its former white colour, and now is black. Let us but do the ſame with any of our bad lands, and perſevere in ploughing and ſtirring them a ſufficient time, the ſucceſs will not be doubtful.

" But to return to the ſubject of this article. Some of the fields we were ſpeaking of are ſurrounded by, or border upon woods. This ſituation is far from being good, and it ſeldom happens, but that ſuch a neighbourhood does great injury to the crops.

" I could likewiſe have wiſhed, that a larger quantity of ſeed had been employed to ſow theſe fields. The loſs occaſioned by the froſt might have been leſſened thereby, as it may be preſumed that a greater number of plants would have eſcaped, if they had been thicker in the places where all of them were not intirely deſtroyed.

" We obſerved before, that the young plants were in a fine condition before winter, and that they promiſed well: but the ſeverity of the froſts, doubtleſs too great for the condition and ſituation of theſe lands, did an irreparable injury to almoſt all theſe fields.

" I examined the greateſt part of them in the beginning of the ſpring. Of all thoſe which I ſaw, I found but one ſpot, of three or four acres, where the earth was in the condition it ought to be, that is, well ſtirred and broken, looſe, light, and penetrable. Too few plants were left in this good ſpot: large ſpaces were quite empty in moſt of the rows: but thoſe which reſiſted grew very fine in the ſummer, branched extremely well, and bore fine ears.

" By this one might gueſs what theſe lands were capable of. My opinion is, that, in other years, free from ſuch accidents, the rows will remain well ſtocked with plants, which, finding an equal plenty of nouriſhment, will be nearly of equal ſtrength and beauty in every part, and, altogether, will produce a conſiderable quantity of corn.

" The other fields were infinitely worſe treated. Every thing was deſtroyed for ſeveral acres together. The plants were rooted up by the ſtrength of the froſt, and lay ſcattered upon the ground all along the rows, withered and unable to recover the leaſt vigour. Theſe are the only fields laid out in beds, in which I have ſeen this extraordinary accident; not a plant was rooted up any where elſe. It is very difficult not to ſuſpect, that there muſt have been ſome fault in the ſowing, and that the ſeed, perhaps, was not buried deep enough. The roots which were too near the ſurface of the earth, were nipped by the froſt. They muſt have been ſo, ſuppoſing them to be but about two inches deep. We likewiſe know, with certainty, that if the ſeed had been ſown in good time, the plants would have had roots above ſix inches long; and that ſuch roots would have ſecured them from being killed by the froſt. There is room therefore to believe, that the ſeed was not buried deep enough.

" But even ſuppoſing the plants not to have been deſtroyed, I doubt whether they would have yielded a good crop, becauſe the ground, eſpecially that of the partitions between the rows, was extremely hard and cloſe, and therefore quite unfit to ſupply the plants with their neceſſary nouriſhment.

" This experiment required theſe remarks: many more might be added; but theſe are ſufficient to ſhew, that ſome lands require a double portion of care and labour.

Experiment, Numb. XII.

" The account of the ninth experiment in 1753, promiſed better ſucceſs the next year. The whole culture was performed by the ſame perſon, with great care and extraordinary judgment, in two fields, containing about ten acres. One of theſe fields is much better than the other; the beds were about ſix feet wide; one half of the worſt field was dunged; but not above a third part as much as it would have been in the common way. The ſoil of this field is very ſtiff. It had not been ploughed for fifteen or twenty years, and was not yet sufficiently loosened and divided.

" It was sowed early: the plants rose very well, but were greatly hurt by the frost, excepting those which the dung preserved. The same thing happened to the beds which were sown with six rows.

" The soil of the other field is richer, and of a better quality. The winter did it little hurt. The plants throve by the culture which was given them, but less than was expected, owing, as is supposed, to the great drought of the season. These two fields produced, however, about 7000 pounds of wheat, which is extremely well, especially for a first crop.

" These two fields have given us room to make two reflections: first, That the earth must be well prepared, without which the plants are not able to extend their roots to the ploughed part of the alleys. Secondly, That in dry springs, the plants of wheat preserve one another mutually from the drought, for which reason it is proper to sow somewhat more than would otherwise be necessary.

" The same culture is now practised for the year 1755, and is extended to about fifteen acres more.

Experiment, Numb. XIII.

" I mention this experiment on account of the faults committed by the husbandman, in order that others may take care to avoid them. Near three acres of pretty well ploughed land, made into beds, produced only about 780 pounds of wheat the second year.

" The reasons why this crop was so scanty are evident. In the first place, too little seed was sowed; there ought to have been three times the quantity. Secondly, the beds were of an excessive breadth, all of them being eight or nine feet wide, and sown with only three rows. By this means great part of the ground was lost, which ought carefully to be avoided.

" The ploughings too were made in a very slovenly manner; the husbandman gave them, not when they were necessary, but when it suited his convenience. The reason was, that he was prejudiced against the New Husbandry, and did not desire to see it succeed."

Experiments made by several Lovers of Agriculture, on Lands sown in equally distant Rows with the Drill-plough.

" Some of the principles of the New Husbandry have been adopted in this way of sowing; and even the common ploughing is now performed with more care than it was before the great advantage of thoroughly dividing and breaking the earth was so well known. This method of sowing the land all over in equally distant rows, being, in appearance, easier and more simple than forming it into beds, has now a great number of partizans; and indeed the lands which have been sown in this manner, have yielded much better crops than the fields cultivated in the old way.

Experiment, Numb. XIV.

" It is pretty generally the custom about Geneva, if the land is good, to sow it in April, over the wheat, with clover seed, which yields a crop the next year. Agreeable to this custom, a field of about three acres was sowed with clover in April, 1752. In 1753, it yielded two crops of clover, after which the owner of the ground gave it three good ploughings in the common way. The clods which the plough had left, were broken by hand before the field was sowed; for he was determined not to spare any pains to give it a good preparation.

" About 630 pounds of wheat used generally to be employed to sow this field; but it was now sown on the fourteenth of September, with only 315 pounds. The earth was extremely dry, and the weather very hot, which it continued to be for ten days longer; circumstances which ought to be attended to, and which it will be proper the reader should remember when he comes to the continuation of this experiment in the seventh article.

" This field was plentifully stocked with plants. They yielded 2926 pounds of wheat. In proportion to the produce of the other fields of the same farm, this would have yielded at most only between 18 and 1900 pounds: consequently here is a gain of about 1026 pounds, besides 315 pounds saved in the seed, which makes in all a profit of 1341 pounds.

Experiment, Numb. XV.

" The same person who made the experiments Numb. VII. in 1752, and Numb. X. and XI. in 1753, continued them in comparison with the Old Husbandry. They answered as before, and the same advantages were again confirmed. A detail of the particulars would be needless. I shall only add, that barley, with which the experiment was likewise tried, answered much beyond any thing that was expected, and yielded a prodigious crop.

" The farmer, convinced by such success, of the superiority of the New Husbandry over the Old, immediately desired his landlord not to make any more experiments by way of comparison, but to let him sow all his lands with the drill-plough.

Experiment, Numb. XVI.

" This experiment was made in the same farm where the XIII. and XIV. were made in 1753. All the lands were very well prepared, and sowed with the drill-plough.

" One of these fields, containing about four acres, which used to require 880 pounds of seed, was now sowed with 315 pounds. The plants were extremely fine, both before and after winter, and, when reaped, yielded 4940 pounds of wheat. If it had been sown in the common way, it could not have been expected to yield above 2900 or 3000 pounds; consequently it now produced 1940 pounds more; to which if we add 565 pounds saved in the seed, we shall have 2505 pounds of wheat more by the new, than would have been obtained by the old husbandry.

" Another field, of an inferior quality, the extent of which is near nine acres, used, in the old way, to be sown with 1764 pounds of wheat, and was now sowed with only 819 pounds, which produced about 5720 pounds. Though the difference in the goodness of the lands is considerable, yet the drill-plough still maintains it's superiority: for, if this field had been sowed in the common way, it would have been thought to have produced an exceeding good crop, if it had yielded between 5200 and 5300 pounds, though that would have been 420 pounds less than this, which, added to the 935 pounds saved in the seed, make this crop 1355 pounds greater than it would have been in the old way.

" A small spot, of about an acre and a quarter, which used commonly to be sowed with 157 pounds of wheat, was sowed with sixty-three pounds, and produced about 430 pounds. This is nearly the same proportion as the foregoing experiment.

" These fields, being some better than others, may serve to shew what may be expected from lands of different qualities.

" A piece of ground of thirty acres was likewise plowed with care. This, to have sowed it in the old way, would have required about 6550 pounds of seed, which would have yielded at most 20000 pounds. I even think that I over-rate it in this.

" These thirty acres were sown with 2772 pounds of wheat. Here is, in the first place, a saving of 3778 pounds in the seed, which is a very considerable object. The whole crop yielded about 19000 pounds, which added to the 3778 pounds saved in the seed, make 22778 pounds. The profit therefore is 2278 pounds more in the new way, than in the old.

" To set this experiment in a yet clearer light, I shall add, that the sheaves were strong, the straw fine, the grain very clean and plump, and that half these fields had suffered considerably by the frosts in March.

" The produce of a few detached pieces of land might not have been sufficient to persuade the generality of mankind, so much as to adopt even this change, which consists solely in the manner of sowing the ground. They might still think it imprudent to give up a certain profit for an uncertain one. It will therefore be proper to let them see, by the management of a whole farm, that this husbandry may be practised to very great advantage. This will be shewn in the following article.

Expe-

EXPERIMENT, Numb. XVII.

"This experiment, which is a very confiderable one, was executed on the fame perfon's land, who made the experiment Numb. 12, in 1753. All the lands were fown with the drill-plough. They were plowed four times, and a fmall part of the whole was dunged. I cannot enter into all the details of this operation; but the general refults, which we fhall give, will be fufficient.

"The lands of which we are fpeaking, compofe three farms, fituated in three different villages, about a mile and a half afunder. Thefe lands are of different qualities; fome ftiff, others pretty light, others of a middling quality, and but little ftony.

"About 100 acres were cultivated in the firft farm, forty in the fecond, and forty likewife in the third. In all 180 acres.

		Pounds.	
The quantity of feed ufed in the common way, was,	For the firft farm, fowed in Auguft and September	21420	of wheat
	For the fecond farm, fowed between the 1ft and 15th of October	8190	
	For the third farm, fowed between the 20th and 30th of October	8190	
	In all	37800	

		Pounds.	
The quantity of feed fown with the drill-plough was,	For the firft farm	8190	of wheat.
	For the fecond farm	3276	
	For the third farm	3276	
	In all	14742	
	Saved in the feed	23058	
	Total	37800	

		Pounds.	
Crops in 1754.	Firft farm	70200	of wheat.
	Second farm	22750	
	Third farm	15210	
	Total crop	108160	
	To which muft be added the faving in the feed	23058	
	The whole profit is	lb. 131218	of wheat.

"It will be right to fee now what the fame extent of land might poffibly have produced, if it had been cultivated in the old way. This can indeed only be gueffed at, and I chufe therein to favour the Old Hufbandry. According to the general run of this year's crops, thefe three farms would have produced, at moft, about 95000, or 100000 pounds of wheat; which would confequently have been 31218 pounds fhort of what they yielded in the New Hufbandry.

"This way of ftating the account of the produce of both methods, is a fair one. The faving in the feed is always to be reckoned. But I have perceived, by the queftions which feveral perfons have afked me with regard to accounts thus ftated, that they were not clearly underftood. I fhall therefore throw them into another form, which has been thought more diftinct, but of which the refults will ftill be the fame.

"We will reckon only the real and actual produce, and then fubftract the feed: the remainder will confequently be the neat produce.

NEW METHOD.

Total produce	108160 lb.
To be deducted for the feed	14742 lb.
Neat produce	93418 lb.

OLD METHOD.

Total produce	100000 lb.
To be deducted for the feed	37800 lb.
Neat produce	62200 lb.
"Therefore the new method produced more than the old would have done	31218 lb.
Proof	93418 lb.

"Which refult is the fame as that of the other comparifon.

"Are not fuch advantages well worthy the attention of every one concerned in hufbandry?

EXPERIMENT, Numb. XVIII.

"We faw by the fifteenth experiment in 1753, that the fields which I had fowed, with the drill-plough, in equally diftant rows, yielded very little corn. I mentioned the caufes, which I knew. I have not yet had time to form them into beds, by which means I fhall certainly remedy the too great cohefion of the foil, and without which thofe lands will never yield any other than poor crops, as they have almoft always done whilft cultivated in the old way, which is infinitely lefs fit for lands that require a great deal of ftirring, than for fuch as are naturally fruitful.

"I hope I fhall be able to begin next year to practife the New Hufbandry in this farm. I fhould have done it before now, if I could have made any ftay there: but as I could not, I have only continued to fow it with the drill-plough in equally diftant rows.

"I fhall mention another fmall farm, on which no dung or any other kind of manure was ufed, though it's lands, at leaft the greateft part of them, are but very indifferent.

"I fowed thefe lands towards the end of Auguft and the beginning of September, in pretty hot and dry weather. The whole extent of this little farm is between twenty-two and twenty-three acres, which ufed to take up 4662 pounds of feed: but only 1950 pounds were employed now.

"Some places looked well enough: but in general the wheat came up thin. I was however very well fatisfied with my crop, which yielded about 13000 pounds of exceeding fine wheat, fo clean that it wanted no fifting. If I had not fowed with the drill-plough, I fhould fcarcely have reaped more than barely the feed: for that was the cafe with all my neighbours, who had only about their feed and half as much over; and many of their crops yielded ftill lefs. It is not to be fuppofed that I fhould have fared better than them, if I had followed the old way, as they did."

Summary Accounts of the Products of feveral Pieces of Land fowed in equally diftant Rows with the Drill-Plough.

EXPERIMENT, Numb. XIX.

"As nothing but a great number of experiments, repeated under different circumftances and in different places, can convince many of the advantages of the new hufbandry; I am the more readily induced to mention all that have come to my knowledge; though there are among them feveral of which I have not been able to get fo particular a detail as I could have wifhed: all that has been told me in relation to many of them being, that thofe who made them were well fatisfied with the crops they had obtained by means of the drill-plough, and that they intended to continue ufing it: but the following experiments will merit the reader's attention.

"The lands I am going to fpeak of are fituated in a diftrict of near thirty fquare miles, and there are great differences in their qualities and fituations; they were not all plowed with equal care: fome of them were dunged, and others were not; and laftly, the drought was greater in fome places than in others. Notwithftanding all thefe diverfities, it will appear from what we are going to fay, that the ufe of the drill-plough was every where attended with uncommon fuccefs.

"To ſhorten, and at the ſame time give the reader a full view of the purport of this article, I have drawn up a table of the extent of the ſeveral pieces of land, the quantity of ſeed uſed for ſowing them in the old way, the quantity they were ſown with in the New Huſbandry, and their produce in this laſt culture. Though theſe experiments are not related ſo exactly as my own, I am ſure there is no miſtake of any conſequence in them.

"I ſhould have been very glad to have known likewiſe the exact products of the crops in the old way. I have done all I could to come at the knowledge of them, but have obtained only very few ſatisfactory accounts. All that I have been able to learn, amounts only to a confirmation of what I found in my accounts of the culture and produce of my own eſtate; of which an exact account has been kept for about forty years paſt. Beyond that time, my papers furniſh me with only the produce of now and then a year, but not of any number of years together. Theſe detached hints have however afforded me ſome curious and uſeful knowledge. For example, I have learnt by them, that the produce of land was the ſame in the laſt age as it is in this. In the year 1668, which is the fartheſt back that any of my papers take notice of, I find that the crops were like thoſe which the ſame lands have yielded for theſe laſt thirty or forty years.

"All my inquiries have ſhewn me that, in this country, in what are reckoned good years, the lands yield but three times the ſeed; ſeldom more, and often leſs. Some few fields indeed muſt be excepted, which, being of a very extraordinary goodneſs, do produce more: and likewiſe, on the other hand, ſome very bad lands which do not yield ſo much: ſo that, upon the whole, this may be reckoned the medium crop during any number of years.

"The neat produce does not by any means amount to the whole of the crop, in the common huſbandry: for the good grain is frequently ſo mixed with bad, and with the ſeeds of weeds, that it ſuffers a conſiderable diminution thereby. The quantity of perfect grain is therefore what ought to be conſidered: and in this many are apt to deceive themſelves. Whenever people become ſenſible of the ſmall advantage of the common huſbandry, they will be more ready to attend to what is ſaid in favour of the new, and will be inclined to verify it by their own experience. When ſo convinced, they will endeavour to overcome the diſlike which moſt farmers have to this new method. They are, in general, a ſet of men, fit only to execute what they are bid to do; and therefore ought to be directed by perſons of better underſtanding. Patience and perſeverance may by degrees induce them to practiſe the New Huſbandry, which time will bring to its greateſt perfection.

"The following table will help to ſtrengthen theſe reflections."

T A B L E.

Of the Extent, Sowing, and Crops of different Pieces of Land in 1754.

Extent.	Quantity of ſeed in the old way.	Quantity of ſeed in the new way.	Crops.
Acres.	Pounds.	Pounds.	Pounds.
2	336	168	1560
2	356	180	1230
$4\frac{1}{2}$	882	392	2360
$1\frac{1}{2}$	252	130	650
$4\frac{1}{2}$	882	346	2275
$3\frac{1}{2}$	672	283	2080

$2\frac{1}{2}$	694	300	2340
Tot. 44	8926	3809	30940

General Reflections and Obſervations on the EXPERIMENTS *contained in the foregoing Account.*

"After all theſe experiments, I aſk myſelf, whether they are ſufficient to give us a ſatisfactory demonſtration that the New Huſbandry is more profitable than the Old? I anſwer, without heſitation, that it certainly is more profitable, both to the public, and to each individual, whether the lands be cultivated in beds, or whether they are only ſowed in equally diſtant rows, with the drill-plough.

"Such will likewiſe be the anſwer to this queſtion, if the reſult of theſe different experiments be conſidered. In the firſt place, we have thoſe of each field in particular; in the next, we have thoſe of ſome whole farms; and laſtly, we have thoſe contained in the table of the ſixth article, to which laſt I ſhall now limit my reflections.

"We may look upon the produce of forty-four acres ſpread up and down a diſtrict of near thirty ſquare miles, amounting all together to 30940 pounds of wheat, as the medium produce of the generality of lands. I ſhall therefore not dwell upon the produce of each of theſe fields taken ſeparately, but only conſider now, that forty-four acres yielded 30940 pounds of wheat.

"If theſe forty-four acres had been cultivated in the old way, they certainly would not have produced ſo much, ſince we have ſeen that the medium produce is but three times the ſeed; and I am ſatisfied that it would have been leſs in this year 1754. However, I will ſuppoſe the crop to have yielded three times the quantity of the ſeed. Theſe forty-four acres, ſown with 8926 pounds of wheat, would then have produced 26778 pounds; deducting from which 8926 pounds for the ſeed, the neat produce will be reduced to 17852 pounds.

"The forty-four acres ſown with the drill-plough yielded 30940 pounds, from which we are to deduct 3839 pounds, which was all the ſeed that was ſown. The neat produce will then be reduced to 27131 pounds, which is 9279 pounds more than would have been produced in the old way.

"The owners or farmers of theſe forty-four acres had therefore 9279 pounds of corn more. They reaped the firſt benefit of this gain, and the public the next, as ſo much more corn was carried to market than would otherwiſe have been. Such an advantage is very conſiderable, and deſerves the utmoſt attention of the public, whom we invite to conſider it in a more extenſive light. The object will thereby become the more intereſting.

"Let us but conſider how much more corn the whole of this ſpace of thirty ſquare miles would have produced, if all the arable lands in it had been ſown with the drill-plough: how much more grain would it not have afforded for the nouriſhment of the people! what increaſe of income to every individual concerned therein! and how ſure a way to guard againſt future dearths!

"But this is not yet all. Much greater advantages will ſtill reſult from the cultivating of lands entirely in the new way: I mean, by laying them out in beds, and obſerving all the practices of the New Huſbandry. This I proved plainly in my journal of 1753. This demonſtration is fully confirmed by the experiments of 1754, the products of which were greater, and their reſults ſtill more favourable to the new method.

"What has been already ſaid on this important ſubject, ſhews, what the neceſſary operations are, how eaſily they may be performed, and which are the points that merit moſt attention. The theory of the New Huſbandry is now fully proved by experiments; and that great principle, the neceſſity of preparing the earth well by proper ſtirrings, ſo clearly demonſtrated, that it would be needleſs to inſiſt any longer on it.

"But the ſowing of the land, which is of the utmoſt importance to the ſucceſs of the crops, depends greatly on the time and ſeaſon when it is performed, and the care with which it is done. We ſhall therefore give ſome obſervations on that head.

"The three moſt eſſential things which conſtitute a good ſowing, ſeem to me to be, next to the proper preparation of the earth, firſt, the time of ſowing; ſecondly, the

the choice of the feed; and thirdly, the due temperature of the feafon, with refpect to heat or cold, drought or wet; all which greatly influence the ftate of the earth.

"With regard to the time of fowing, I fay, it is better to fow early, than too late, provided the feafon will admit of it. The plants are better able to refift the feverity of the winter, after they have acquired a certain degree of ftrength. There have been years in which fields fown very late, for inftance in December, have done extremely well: but that ought not to be made a general rule; experience fhewing, that fuch late fowings very feldom anfwer.

"By too early fowing, the corn is equally expofed to other dangers. The ftalks which fhoot up before winter cannot well bear hard frofts, which would do no hurt to the wheat when but in blades. I obferved, in the two laft years, 1753 and 1754, that the firft fown wheat, which was attacked by the ruft in autumn, was much more hurt by it than any other. Therefore I think the beft time for fowing, in fuch a climate as Geneva, is, from the 20th of Auguft, to the end of September. If, however, it fhould not be practicable to fow all the lands within that time, the firft fortnight in October may likewife be taken in: but I would not advife this, except in a cafe of neceffity. If all the land fhould not be fown within that time, I think one might expect a better crop by deferring to fow it till fpring. What I have been faying is more particularly applicable to land laid out in beds.

"The fame rules by which I judge of the proper time of fowing here, may eafily be adapted to other climates, in fome of which the land will require being fown earlier, and in others later.

"The choice of the feed is the fecond thing, which to me feems to require more particular care than many may perhaps imagine. Every one certainly endeavours to choofe the beft wheat he can for feed; and it ought likewife to be very clean. Such corn is not difficult to be had, when reaped off the beds cultivated in our way.

"Though wheat fo green that it had fcarce loft its milky quality, fprouted pretty well when I tried the experiment with it; I think it is more proper to fow none but what is thoroughly ripe. The feed has then attained its full perfection; and it is from that ripenefs that we may moft certainly expect the moft vigorous plants.

"The wheat that has been reaped in a warm dry year, feems to me fitter for fowing, than that which has been gathered in a cold wet year: for in fuch a feafon, all the productions of the earth are lefs good; their tafte is lefs favoury; and as that wheat in particular in which there is moft moifture is moft difficult to keep, I infer from thence that the formation of its grain muft be lefs perfect. I fhould therefore prefer wheat a year old, provided the year it was gathered in was warm and dry, to that which may have juft been gathered in too rainy a feafon. Accordingly, I always choofe for fowing, wheat of the growth of my high lands, rather than that which has been produced in flats.

"The benefit accruing from all this care, may, perhaps, not be extremely great; but at the fame time it cofts nothing. Let us do in agriculture what is done in all manufactures: the very fmalleft profits, the very leaft favings, are never neglected. Thofe fmall articles, often repeated, make large fums in the long run, and are a real profit.

"There is another thing of greater confequence, and of which I ftrongly recommend the practice. It will not be attended with any expence. It is, by repeated experiments, always attended with the fame fuccefs, that I have found it to be extremely ferviceable to the firft fprouting of the feed. Chance firft made it known to me.

"I have often fowed, purely to try what wheat was fitteft for fowing. I commonly fowed wheat taken from the heap in the granary. I likewife frequently fowed wheat picked out of the ears the moment before I fowed it. I counted the grains of both forts exactly. Would any one think there could be any difference in the productions of thefe grains? yet I found a confiderable one: what was picked out of the ears always rofe extremely well; fcarce a grain of it ever miffed: whereas numbers of thofe which were taken from the heap, never fprouted at all. I did not perceive this difference at firft; but at laft it ftruck me. I relate the fact as it is, without pretending to account for the caufe of this difference, which would lead me into too long a digreffion. The experiment itfelf may be of real ufe. It fhews us, that inftead of threfhing the wheat intended for feed at any time, without diftinction, it ought not to be threfhed till a very few days, at moft two or three, before it is fowed. A few hands will be able to fupply the feedfmen with as much as they will want. This will not be attended with any fort of expence, and may be the means of faving fomewhat in the feed.

"Perhaps, too, this practice may be attended with a very valuable advantage. I have not, indeed, yet made the trials neceffary to fatisfy myfelf of the reality of what I imagine: but my defire to be of fervice to the public induces me to mention it, that the lovers of agriculture may reflect upon it, and try fuch experiments as will clear up my conjectures.

"Threfhing the feed only juft before it is fowed, may poffibly, in fome meafure, or perhaps entirely, prevent the firft caufe of the diftemper called *fmut*. By this I mean, that the feed which has not been mixed with fmutty wheat, or any infected by its black powder, will be exempt from this diftemper. Not that I take that black powder to be abfolutely the original caufe of this diftemper; but I believe it very capable of communicating it to grains otherwife found.

"I wifh that the multiplicity of my occupations may permit me to endeavour to clear up this matter, and to purfue my obfervations. If I can be fo happy as to make any ufeful difcoveries, I fhall communicate them to the public.

"That nothing may be neglected which can be of any fervice to the feed, great care ought, in my opinion, to be taken in threfhing it, efpecially in the manner which is commonly practifed with flails upon the barn floor, or by trampling it with horfes. In either of thefe ways, a great number of grains are fo bruifed and hurt, that it is impoffible they fhould ever grow. If the wheat intended for feed be not thoroughly dry and hard, the mifchief is ftill greater; much more of it being then abfolutely crufhed by the flail.

"As the New Hufbandry requires much lefs feed, it will be the eafier to execute an operation which might be too long and troublefome to practife for fo great a quantity as is ufed in the old way.

"The method which I advife, and which I myfelf have practifed, is this: let one or two beams, two feet and an half, or three feet thick, be laid acrofs the barn floor: let the threfhers ftand at each fide of the beam, with a loofe fheaf of wheat behind every man, from which he will take a handful at a time, and give it two or three ftrokes againft the beam: this will bring out a great deal of grain, which is to be referved for feed. Thefe ears may be bundled up again, and afterwards threfhed out with the flail for other ufes.

"This method is not fo tedious as fome may imagine: we are fure that not a grain is bruifed; the corns drop very readily out of the ears, efpecially of wheat that has grown in beds: the great fize of the grain helps to open the hufks, and thofe are the moft perfect grains which drop out in this manner. I think I may compare this operation with what is done in the making of wine. The firft running is always the higheft flavoured and beft.

"Though the proper time for fowing be come, the corn ought not to be put into the earth, if the temperature of the feafon is not favourable. It ought, on the contrary, to be deferred in hopes of a change. If the weather is very hot, and the earth extremely dry, there will be an abfolute neceffity of waiting till fome rain has fallen. Without this precaution, the feed will rife but very imperfectly. I am fure of it, by feveral experiments which I have made, and which contradict a common faying of our farmers, that the earth is the beft granary to keep corn. Full of this notion, whenever the ftated time comes round, they fow, without diftinction, in wet or dry land: even heat does not hinder them: they think their feed will certainly fprout well after the firft rain: but I have always experienced that the plants have come up thin.

"I tried an experiment purpofely to fatisfy myfelf, whether one can fow with fuccefs when the weather is very hot, and the earth very dry. Upon reading Mr. Duhamel du Monceau's excellent treatife on the Prefervation of Corn, I obferved, that he had found by his experiments, that wheat which had been dried in a ftove, heated to fixty degrees of M. de Reaumur's thermometer, had loft its faculty of growing.

"From thence I conjectured, that wheat which fhould undergo a heat, for example, of thirty degrees, during a longer time, would be equally parched up, and rendered incapable of vegetating. I confidered the earth, when hot and dry, as a kind of ftove, in which the feed, if it remained too long, without receiving any moifture, may become fo dry, that the greateft part of it will never be able to fprout. I thought this reafoning juft, and therefore determined, in order fully to fatisfy myfelf, to have recourfe to that trufty guide, experience.

"On the eighteenth of July 1754, at four o'clock in the afternoon, I placed M. de Reaumur's thermometer two inches deep in the ground, and fcreened it from the immediate impreffion of the rays of the fun. The liquor rofe to the thirty-firft degree, which fhewed me the heat of the earth.

"The thermometer being afterwards expofed to the fun, the liquor rofe to thirty-fix degrees.

"On the fame day I fowed eighty grains of wheat in this ground. The heat continued nearly the fame during the reft of that month, and almoft all Auguft. On the thirty-firft of July, only ten grains had fhot up, and on the fixteenth of Auguft there were in all fixteen; after which, not one more rofe: confequently fixty-four grains out of the eighty never fprouted at all.

"On the twenty-eighth of July I fowed fifty grains. Only four of them rofe by the fixteenth of Auguft, and not one after. Here were again forty-fix grains which did not grow at all.

"On the fame day I fowed fixty grains in another place. On the fixteenth of Auguft only fix grains had fprouted, and not one plant more ever appeared after: confequently here too were fifty-four grains which never grew. All thefe grains were fown in my garden, in exceeding good mould.

"I was fure that the wheat which I fowed was perfectly found, and in every refpect capable of growing. It was therefore quite clear, that fo great a number of grains out of the whole, which did not fprout at all, had loft the faculty of growing, by their being parched up by the heat and drynefs of the earth. To be ftill more certain of this, three weeks after I had fown thefe grains, I watered half of them feveral times, but to no purpofe; not one of them rofe, and I found feveral of them quite whole in the earth where I fowed them.

"After this experiment, on the eleventh of Auguft I fufpended the fowings which I had begun on the eighth, and did not refume them till the twenty-fixth, after fome rain which fell on the twenty-fecond and twenty-third. Thefe laft fowings rofe much better than the firft.

"Thus it is, that experience and obfervation teach us to leave off bad cuftoms, or fuch as are not founded on principles with which a man of fenfe can reft fatisfied.

"Whenever the produce of the fields on which my experiments were tried, is confidered, it ought always to be remembered, that I ufed no dung on any of thofe lands, and that they received no other improvement than what was owing to a better preparation of the earth, only by ftirring it. Thofe who choofe to have recourfe to dung, will probably reap greater crops: with an hundred loads, they may dung three times more land than is done in the common way; for the dung fhould be fpread very thin, if one would have it be of any fervice. By fpreading it too thick, I believe the plants would grow too rank, and be apt to be lodged.

"The New Hufbandry fupplies the want of dung, not only by ftirring the earth, and not overburdening it with too many plants, but likewife by the ftrong thick ftubble it produces, which affords a moft excellent manure, attended with no expence. It lies ready upon the fpot; the ploughing of the earth buries it; and as it is a long time in rotting, it helps to keep the foil loofe and light, and is repeated every year. I have found ftubble almoft whole at a year's end; and have feen fome not quite confumed at the end of two years.

"But can we be fure that this manure is of any confequence or real advantage? After what I have already feen of its effects, I will venture to fay, that it contributes greatly to increafe the productions of the earth. I have very often plucked up plants remarkable for their beauty, and have frequently found their roots interwoven with tufts of ftubble, which fhewed me the caufe of their extraordinary growth. I fhall foon have more pofitive proofs of this, by the experiments which I am now making to clear up this point."

EXPERIMENTS *made on Beds fown with fix Rows of Wheat: Comparifon of their Produce, with that of Beds fown with only three Rows; and fome Inquiry concerning the Number of Rows which it is beft to fow.*

"In the journal of 1753, Article VII. I gave an account of my fuccefs in fowing beds with two turns of the drill-plough, in order to have fix rows of wheat. It anfwered fo well, that I thought there could be no hazard in fowing a larger extent of ground in the fame manner.

"This experiment fucceeded equally well this year. I fhall not enter into a detail of it, becaufe that would be only a repetition of what I faid on this fubject in 1753. As to the refult, the reader will recollect, that the fame ground made into beds wide enough to be fown with two turns of the drill-plough, which make fix rows, produced more corn than if it had been fown in beds with only one bout of the drill-plough, which would have made but three rows.

"With regard to the quantity of the products of the crops of 1753 and 1754, compared together, I have found that the fix rowed beds produced this year very nearly the fame as they did in 1753; excepting the field of the experiment, No. VIII. which yielded about half as much again as the year before.

"Notwithftanding the profit which I found in thefe experiments, repeated two years running, I do not think it advifable to enlarge the number of rows to fo many as fix. Five will, in my opinion, be very fufficient; and they may be made with one bout of the drill-plough, by giving it five fhares, which is very eafily done. This number of rows will be a proper medium between fix and three.

"Sowing in five rows will not, however, do in all forts of land. I believe it fhould be practifed in none but good foils, and that middling lands fhould continue to be fown with three rows at moft.

"I fhould add farther, with refpect to good lands, that they ought not to be fown with five rows, till after they have been thoroughly well ftirred; and, above all, not till after the main furrow in the middle of the bed has been cut extremely deep, in order that the roots of the middle row, which is the moft diftant from the ploughed alleys, may find a fufficient depth of mould immediately under them, to fupply them with their neceffary nourifhment.

"But at the fame time that a provifion is made for the nourifhment of the plants, care muft be taken not to lofe too much ground, by making the alleys wider than they need be. My experiments have determined me to make my beds, for the future, about fix feet wide. By leaving feven inches diftance between each row, the five rows will take up about two feet four inches, and there will remain three feet eight inches for the breadth of the alleys. This fpace is fufficient for the plough or cultivator to work in with eafe."

EXPERIMENT *made in order to know which is the moft profitable Way of fowing the Beds, and to afcertain more precifely the Quantity of Seed proper to be ufed, in order to have the greateft Crop.*

"The above title divides it naturally into two parts, which I fhall treat feparately.

"It is of great confequence to know which is the moft profitable way of fowing the beds; I mean, that by which they will be ftocked with a proper number of plants: for when too much feed is fown, the plants hurt one another;

ther; and when too little, the earth is not enabled to produce ſo much as it is capable of doing.

" The buſineſs therefore is, to determine what number of plants would be moſt advantageous. Fortunately, the difference is wide enough between the too great, and the too ſmall number; and the produce of the crops cannot be diminiſhed but by an exceſs one way or the other.

" But whatever certainty we may acquire with reſpect to this intereſting point, we cannot flatter ourſelves that we ſhall always be able to keep to it in our practice. The various accidents to which corn is liable, from the hour of its being ſown till it is reaped, will always fruſtrate the methodical arrangement which we may have intended to give the plants.

" The difficulty of ſucceeding in this inquiry ought not however to diſcourage us; for it would be attended with ſuch advantages, as would make very ample amends for all the labour beſtowed upon it. Let us then have recourſe to experiments. Thoſe that are made with this view, will never be quite uſeleſs. If they do not lead us to the very thing we are in ſearch of, they may at leaſt diſcover to us others which may be of ſervice.

" According to our principles, the diſtances between plants ought to be equal throughout the whole length of the rows, that all of them may have an equal quantity of earth from which to draw their nouriſhment.

" Several experiments have ſhewn, that ſix inches is not too great a diſtance for the plants to be at from each other. In this caſe, it would be ſufficient to ſow one grain of wheat at every ſixth inch. According to this diſpoſition, a field well prepared ought to produce the greateſt crop. The plants will very commonly branch out ſo as to have twenty, thirty, or forty ſtalks: I have had ſome with upwards of eighty. It is pity that this exact diſtribution of the ſeed cannot ſubſiſt long. The accidents which I met with, ſoon convinced me, that it was neceſſary to increaſe the quantity of the ſeed, and that very conſiderably.

" However, this does not yet hinder me from thinking, that if any eaſy method could be found, to have a plant of wheat exactly at every ſix inches diſtance in rows, it would be the beſt way of ſowing. I have often conſidered how this could be reduced to practice, as well to ſatisfy my curioſity, as that I might be the better able to proceed in my operations. When a theory is known to be good, one is ſtrongly encouraged to draw all poſſible advantages from it for the practical part: one then proceeds with confidence and pleaſure.

" Experience having convinced me that it never would be poſſible to have a plant at every ſix inches in each row, by ſowing only a ſingle grain of wheat at thoſe diſtances; it naturally followed, that the way to have the ground better covered with plants was, to ſow more grains. The next queſtion was, how many grains ſhould be ſown in each place: ſhould it be two, three, or more? Experience only could clear this doubt. I therefore tried the following experiment. I ſowed a different number of grains in cluſters, ſix inches diſtant from each other, putting one grain in the firſt, two in the ſecond, and ſo on to the ſixth, which had ſix grains: then I began again, and went on as before, till the whole length of the row was ſowed in this manner. The produce of each cluſter was to ſhew me whether it would be beſt to double, triple, or quadruple the ſeed, which it was plain had been ſown too thin, when only a ſingle grain was dropt at every ſix inches.

" The winter of 1753 was already far advanced when theſe thoughts firſt occurred to me. It was then too late to try this experiment with wheat: but, that I might not loſe a year, I did it in the ſpring with barley, not doubting but that corn, which is uſually ſowed in March, might furniſh me with ſome uſeful hints for the culture of that which remains longer in the ground.

" Accordingly, on the ninth of April, 1754, I ordered another bed to be ſowed with barley, in my preſence, and in the manner I have juſt related. I counted all the grains of each cluſter myſelf. They were ſown in three rows. I varied the experiment in the row next to the ſouth, by ſowing no cluſters there of leſs than three, four, five, or ſix grains; and this I continued during the whole length of that row. At harveſt, all the cluſters in which ſeveral grains had been ſown, were ſo thick, that they touched one another.

" What is of moſt conſequence to our culture, is, to know the produce of each cluſter. I ſhall only add, that the cluſters, as they are here ranged under their reſpective numbers, occupied forty feet in length, and that the beds were five feet wide.

RESULTS.

" The ſouth row,
ſowed with 6, 5, 4, and 3 grains,
produced 661, 624, 447, and 493 ſtalks.
In all 2225 ſtalks.

" The middle row,
ſowed with 1, 2, 3, 4, 5, and 6 grains,
produced 48, 72, 147, 204, 219, and 487 ſtalks.
In all 1177 ſtalks.

" The north row,
ſowed with 6, 5, 4, 3, 2, and 1 grains,
produced 502, 372, 345, 276, 200, and 92 ſtalks,
In all 1787 ſtalks.

" Conſequently the whole number of ſtalks in the three rows was 5189. They yielded ſeventeen pounds of grain, beſides a great quantity that was ſhed in reaping.

" On the footing of this crop, an acre would contain at leaſt forty-four beds five feet wide, which was the breadth of the bed on which this experiment was made. The beds would be 222 feet long: the produce of one of them would be ninety-three pounds eight ounces, and that of the 44, 4138 pounds eight ounces; that is to ſay, near nine quarters to the acre: a very conſiderable crop; and which might be carried ſtill much farther by other experiments of this kind, as we ſhall ſoon ſee.

REMARKS.

" The following obſervations deſerve the reader's utmoſt attention. Firſt, By this experiment, I have very near effected what I aimed at, viz. to have two or more plants grow ſo cloſe together as to ſeem but one; and that at ſix inches diſtant from each other. If the three rows had been joined together lengthways, they would have been 120 feet long, and ought to have contained but 240 plants: but the diſtances, which were marked by gueſs, not being exactly ſix inches each, ninety-ſix cluſters were ſown in each row, which made ſixteen cluſters over and above. By this means, ſeveral of them were nearer than ſix inches to each other.

" Two hundred and eighty-eight cluſters were ſown, all of which produced plants, except twenty-five which did not ſprout, or of which the plants periſhed. This deficiency is not very conſiderable: but we muſt obſerve, 1. That almoſt all the places where this happened had been ſown with only one or two grains of wheat: 2. That it was in the middle row that the greateſt number of plants was wanting: 3. That the ſouth row, in which the ſmalleſt quantity ſown for any one tuft was three grains, furniſhed and retained its full number of plants: and laſtly, that almoſt all thoſe which were next to the vacant ſpaces, were ſtronger than the reſt, and thereby made amends for the loſs of the others.

" Secondly, The whole number of the ſtalks amounted to 5189, which is after the rate of forty-three ſtalks and a quarter to a foot: but it is much more conſiderable in the ſouth row, which having produced in all 2225 ſtalks, the proportion is fifty-five and a half to a foot. The cauſe of this difference is eaſily ſeen. The expoſition of that row to the ſouth, being more favourable than that of the others, may have contributed thereto; but it is very plain that it was chiefly owing to this farther circumſtance, that none of the cluſters in that row were ſown with ſo few as one or two grains.

" Thirdly, We ſee that the increaſe of the ſtalks was, in general, in proportion to that of the ſeed; only the cluſters which were ſown with three grains in the ſouth row, produced forty-ſix ſtalks more than thoſe which were ſown with four grains; but ſtill the general refult of the three rows remains exactly in the fame progreffion, as appears by the following

"RECAPITULATION.

Stalks produced by 1 grain	— —	140
— — — —	2 gr.	— —	272
— — — —	3 gr.	— —	916
— — — —	4 gr.	— —	996
— — — —	5 gr.	— —	1215
— — — —	6 gr.	— —	1650
		Total	5189

" Fourthly, The ears were nearly equal, at leaft in two thirds of the length of the rows: the other third furpaffed the reft, as will appear by the following extract of the twelve firft numbers of the fouth row.

Numb. 1	— produced —	87	ftalks.
2	— — — —	122	
3	— — — —	91	
4	— — — —	99

8	— — — —	100	
9	— — — —	87	
10	— — — —	116	
11	— — — —	148	
12	— — — —	68	

" Fifthly, The difference between the produce of the clufters fown with one and with fix grains, is extremely great. The former produced but 140 ftalks; the others multiplied to 1650. It is true that the number of the clufters of fix grains is greateft; which is fome diminution of the difference.

" Sixthly, I obferved feveral ftalks from which others had fhot out, all as ftrong, and as long, as thofe from which they derived their origin. They proceeded from the firft joint above the furface of the earth, generally at the heighth of three, four, or five inches; and were two, three, and fometimes four in number. I never perceived this kind of tillering before; but had, till then, always obferved it to be at the neck, or point of feparation between the roots which defcend, and the ftalks which afcend, that the plants branched out.

" Seventhly, I fufpected, in the fummer, what was the caufe of the great vigour of the plants of this experiment: but I faw it much plainer after harveft: for, upon pulling up fome of the tufts of ftubble, I found their roots innumerable. This fact is ftrictly true. I could not count them upon any one plant that had more than fifteen or twenty ftalks. Thefe roots were in fuch bundles, and fo confufedly interwoven one with another, that, after counting feveral hundreds of them, I was forced to give up the talk. Their length and thicknefs was anfwerable to their number.

" I muft now remind the reader of what I faid before, that the feveral accidents which I met with in my firft experiments fhewed me it was neceffary to increafe the quantity of the feed. I did fo, by fmall degrees, from year to year. It was equally important for the fuccefs of the new culture, not to run into another extreme by loading the earth with more plants than it can nourifh: the crop would be confiderably diminifhed thereby.

" It appears by this experiment, that the clufters which were fown with fix grains did not hurt one another: on the contrary, their being fown in that manner proved an advantage, fince they produced much more than the others: from whence it follows, that one may, without danger, extend the quantity of the feed beyond the limits of the principles of the New Hufbandry. The principles themfelves are not the lefs true; though the farmer is at liberty to ufe his own difcretion in the application of them, according to the nature of his foil.

" Thofe principles, which fuppofe that every plant is to fubfift till harveft, reduce the feed to a very fmall quantity: but numbers of accidents deftroy many of them. Our reafon ought confequently to tell us, that, without deviating too much from the principles which we adopt, we may, and fhould, judicioufly ftock our land with a fufficient number of plants, in order to guard againft unavoidable accidents.

" Still I may be afked, what is that fufficient quantity? I anfwer, that our experiment fhews that fowing fix grains together in a clufter, from fix to fix inches, all the length of the rows, will not be found too thick. By following this rule, one may be almoft certain that the whole ground will be ftocked with a proper number of plants. However, this is to be looked upon only as a general propofition, from which it will often be very proper to deviate in the circumftances we are going to mention:

" When the fowing feafon is favourable.
" When the land is well prepared.
" In countries where the winter feldom is fevere.
" When the land is but little liable to infects.
" When the land is not in danger of being hurt by too much drought, or too much wet. And laftly,
" When the land is good and very fertile.

" In all thefe, and other fuch like cafes, lefs feed fhould be fown; and, in the contrary cafes, more. Prudence, and a careful ftudy of the nature of the foil, ought to be our guides. Two or three years experience will be fufficient to fhew us the practice which will anfwer beft.

" It will be right to repeat our laft mentioned experiment, and even to vary it. In all probability it will afford us ftill greater lights. It will be right, for example, to fow the clufters with a greater number of grains, beginning with fix, the produce of which is known, and going on to feven, eight, and even more, always in clufters, till one comes to a number at which the crop ceafes to yield an equal profit. By this means the two extremes, either of too much or too little feed may be known; and the juft proportion will then eafily be determined.

" Some farther alterations may likewife be made in this experiment. For example, I placed the grains in the earth fo that they touched one another. I will try to place them at fome little diftance from each other, and to range them in a kind of circle, of about three inches diameter. It is reafonable to think, that the plants may make a greater progrefs then, as they will not have all one common centre: fome of them will be nearer to the ploughed alley; their roots will reach it more eafily than before; and will multiply there, which may render the plants more vigorous.

General Difpofition for the farther Progrefs of the New Hufbandry, and particularly for the Crop of 1755.

" It is with uncommmon fatisfaction that we fee the trials of the New Hufbandry multiply daily. A great number of intelligent perfons have fown part of their lands in equally diftant rows, with the drill-plough, for the next harveft. We have already feveral farms, and among them fome confiderable ones, in the neighbourhood of Geneva, which are no longer fown any other way.

" It is much to fee this new method thus readily entered into. Thofe who follow it, will foon begin to take a pleafure in calculating, and will be curious to compare the new crops with the old. Thefe calculations will infenfibly lead to others, on the produce of lands laid out in beds. They will fee, that there can be no hazard in making a few trials. Thus it is, that feveral have been determined to cultivate fome of their lands this year in beds.

" That thefe arguments fhould have their full weight with men capable of reafoning, is not to be wondered at: but I confefs I have been agreeably furprifed, to find this conviction extend to people who can feldom be prevailed upon to leave their beaten track. Some peafants in thefe parts fent a meffenger this winter to tell me, that they began to have a good opinion of my method; that they were aftonifhed at the beauty of my young plants, the like to which they had never feen before; and that, if they continued to do well, and met with no accident, I ought to have a prodigious crop. After this preamble, he continued, faying, that he was directed to beg of me to him the particulars of my experiments; for that feveral of his neighbours had agreed to meet, in order to read them over in the winter, and to make their little reflections upon them. He concluded with adding; "I believe we fhall all agree to fow in equally diftant rows with the drill-plough; and perhaps too we may, by and by, lay our lands out in beds."

"This conduct of the peafants feemed to me fenfible and prudent. I gave them the experiments of 1753, and fent them word, that both my advice and my drill plough were at their fervice; and that it fhould not coft them any thing, if they chofe to make a trial of it. They have been well fatisfied with what they have read, and feem difpofed to accept of my offers.

"I have experienced this year, more than ever, the facility with which lands are cultivated in the new way. No part of the farm where I fome time make a little ftay, is any longer cultivated after the old method. The moft troublefome part is now over: my lands were fown in a favourable feafon; the plants rofe extremely well, and flourifhed perfectly till the beginning of winter; but the feverity of the frofts has proved fatal to many parts of my fields, and will certainly be a detriment to my crops."

Continuation of M. De Chateuvieux's *Experiments in the Years* 1755 *and* 1756.

"My lands were cultivated in 1755, in the fame manner as in the preceding years; I therefore fhall not enter into any detail upon that fubject. When I fowed my fields, they were well prepared to receive the feed; the fpring was pretty kindly; and towards the end of autumn my corn was very fine, excepting fome fpots that were attacked with the ruft fo early as the tenth of November: other places, in which the plants were ftrong and healthy, promifed a moft plentiful crop; and though it was greatly diminifhed by the winter's froft, it proved, upon the whole, fufficient to confirm the advantages of the New Hufbandry, which have been already proved in my former accounts.

"The winter of the year 1754, was extremely fevere. The froft, which was exceffively intenfe, lafted a long time, and killed a prodigious number of plants: thofe that refifted it loft fome of the branches they had fhot out in the autumn before, and the plants fo weakened branched but little in the fpring. The evil would have been infinitely greater, if the ground had chanced to be full of water, when thofe exceeding hard frofts came on; but luckily it was not very wet.

This winter was followed by a very dry fpring, uncommonly hot, and confequently unfit to recover the corn. The fummer, in which there was fcarce any rain or dew, but very frequently fultry fcorching heats, exhaufted the plants in feveral fields. I was not furprifed at it. The feafons were extremely unfavourable to the productions of the earth; and, to add to the misfortune, a vaft quantity of worms did likewife confiderable damage to the corn.

"However, my wheat rofe; the ftraw was pretty near as long as in the preceding years, and the ears were well filled with grain. The ploughings had been well performed, which kept the earth in a ftate of moifture; lefs indeed than in 1754, becaufe but very little dew fell in 1755.

"The wheat cultivated in the old way yielded but few fheaves: the ftraw was fhort; the ears were very full of grain; and, in general, the quality of the corn was excellent.

"There was room to expect good fuccefs from the lands that were fown in 1755, for the crop of 1756. The young plants rofe extremely well, the ground had been properly prepared, and had the degree of moifture neceffary to promote their growth.

"Though fome flight frofts were felt towards the latter end of October, they did not prevent the growth of the corn, the cold abating from the twelfth of November, to the end of that month. M. de Reaumur's thermometer was, during that time, at from fix to eight degrees above the freezing point. At the fame time we had pretty frequent, and often plentiful fhowers of rain.

"The corn was in very good condition at the beginning of the winter, during which there was fcarce any froft, excepting the ten firft days of December, when the thermometer fell to about fix degrees below the freezing point. During the months of January and February, it was pretty conftantly above the freezing point: we had little fnow, but pretty frequent rains.

"The fpring and fummer of 1756 having been extremely rainy, and the earth too much foaked thereby, the plants were poor, and the fummer ploughings could not be performed. For this reafon, I could give feveral of my fields but one ftirring, and others had two. I would not plough whilft the earth was fo very wet: for that would only have hardened, and, as it were, kneaded it; and I judged that fuch bad ploughings would have been equally prejudicial to the corn then growing, and to the preparation of the fallow for the next fowing. I found afterwards, that I had done right.

"It could not be but expected, that fo unfavourable a feafon would prove fatal to the corn. I had obferved during all the month of April, in which there was not any froft, and the thermometer was from five to feven degrees above the freezing point, and towards the end of that month from nine to twelve degrees, that the corn made but little progrefs, and grew yellow. The diftemper continuing to increafe, I perceived in May, that the corn was attacked with what we call the rickets. The bad ftate of the roots of thefe plants, the colour of their blades turned to a blueifh green, and yellow at the point, left no room to doubt what ailed them; and from that time it was eafy to forefee that the crop would certainly be fcanty, not only on account of the fmallnefs of the number of ftalks which the plants had produced, but alfo becaufe their ears would have but little grain.

"In June the healthy plants throve greatly: the ftraw grew long; but yet the fheaves did not yield fo much grain as in the foregoing years by about a fifth part, as nearly as I could judge. The corn was very fine and very clean; and had it not been for this accident, I am confident that the crop would have been very plentiful.

"I did not fee any one field exempt from this diftemper. Exceeding fine corn, cultivated in the old way, was totally infected with it; and the fheaves in general yielded but about half the quantity of grain that they ufually do in good years. Thefe grains were very fmall, and mixed with a great many feeds of weeds.

"Thefe general notions are neceffary, in order to form a right judgment of the refult of my experiment, which I fhall relate in the following order.

"The firft article will comprehend the experiments which I made upon all the fields I laid out in beds, the laft of which now bore their third crop. I have diftinguifhed them by the fame numbers as in the former years, and fhall add to each of them the particular obfervations which relate immediately to it.

"The fecond article will fhew the produce of the lands fown in equally diftant rows with the drill-plough. I fhall make fome reflections upon the ufefulnefs of this practice, which is certainly alway preferable to the common way of fowing.

Experiments *made on Fields laid out in Beds, the laft made of which have borne three fucceffive Crops. Thefe Fields are diftinguifhed by the fame Numbers as in the foregoing Years. Obfervations relating particularly to each Experiment.*

Experiment, Numb. I.

Year 1755.

N. B. This was made on the fame piece of ground as my firft experiment in 1751: and this year's crop was the fixth, without any interruption.

"I gave a very full account, in the ninth article of the year 1754, of the experiment I made in order to be the better able to judge which is the moft profitable way of fowing the beds, and to determine what quality of feed is moft proper to fow, in order to have the greateft crop; and this I called, fowing in clufters, at the diftance of fix inches from the centre of the one to that of the other. I fhall only remind the reader here, that the fpot of ground which was fowed in clufters with barley in the fpring, was part of a bed,

bed, forty feet long, and that the produce of the grain was feventeen pounds weight, befides a confiderable quantity which was fhed in reaping.

" This experiment, which deferved to be repeated, was tried again the fame year, and upon the fame ground which I had fowed with barley. This laft grain being reaped, I fowed the fame bed with wheat on the twenty-third of September following: but it is to be obferved, that I did not plough this fpot after the barley was off, but only plucked up the ftubble, and made three channels, into which the feed was dropped by hand in clufters fix inches afunder.

" As the clufters fown with fix grains, in the experiment of 1754, were thofe which produced the moft ftalks and grains, I fowed all the clufters now with at leaft fix grains, fome with feven, and others with eight, keeping all the grains at fome little diftance from each other. The bed forty feet long contained eighty-three clufters in each row, which were fown with two ounces fix penny-weights of wheat.

" The plants came up very well: I fpared no pains to cultivate them; they throve wonderfully till harveft; their blades, ftalks, ears, and grains, were very fine; and I preferved them from the birds with a net; but as I would not reap them till they were thoroughly ripe, a great deal was fhed in cutting them down, and they yielded me but twenty-eight pounds of corn.

OBSERVATIONS.

" This experiment is a farther confirmation of the refult of the firft which was made in 1754, viz. that fix grains are not too great a number to be fown in a clufter, fix inches diftant from the next clufter. I had not leifure to count the ftalks which each clufter produced; but the twenty-eight pounds of corn which they yielded, feemed to be a fufficient proof.

" The circumftance of not ploughing the bed before it was fowed, confirms the advantages of preparing land according to the New Hufbandry.

" I faid, that the ftubble was plucked up, in order to prepare the bed for being fown. This fhewed me how much ftubble helps to enrich land.

" When this bed was fowed, and the corn fprung up, I ordered the furrows which were made before winter, next to the outward rows, to be opened for about half the length of the bed, and the ftubble to be put into them, and covered over with earth: confequently it was laid in the ground which was cultivated, and in that part of it where the plants were to extend their roots. As the quantity of roots collected there was pretty great, I concluded that the effect of the ftubble ought to be much more vifible in that place, than it can be in fields where the ploughman buries it as chance directs. In effect, that part of the bed became much finer than the reft; the plants produced a greater number of ftalks; and there is no room to doubt, that the ftubble was an excellent manure.

Year 1756. Numb. I.

" I propofed to continue fowing this bed in clufters, and to increafe the quantity of the feed, in order to fee what the effect would be: but, in hopes of better fuccefs, I gave up the thoughts I once had of reaping a third crop from this bed without ploughing it.

" After one ploughing, I fowed it on the fixteenth of September, 1755, in three rows of ninety-three clufters in each row, and ten or fifteen grains in each clufter; and, in order to place them with fome kind of regularity, I made ufe of an iron hoop, about three inches in diameter, which was laid upon the ground at each fpot intended to be fowed, and the grains were dropt at nearly equal diftances, fome round the infide, and fome in the middle of this circle. Each clufter was fowed in this manner. The fpace from one center to another, was about five inches. The feed was covered over lightly with a rake, and the quantity employed in this operation was five ounces twelve penny-weights.

" This wheat was always very fine from its firft rifing till harveft. It was reaped on the thirty-firft of July, and yielded twenty-three pounds of grain.

OBSERVATIONS.

" Though the produce of this bed was lefs now than in 1755, I did not think this difference ought to be imputed to the increafe of the quantity of feed fown; becaufe the plants were as ftrong as could be wifhed for, their ftraw was as long as in the former years, and their ears were as large: but I obferved, that this bed had not been quite free from ficknefs, and that it contained a pretty confiderable number of rickety plants, which yielded but little grain.

" It refults from this experiment, that a certain quantity of feed is neceffary, to counterbalance the many accidents to which corn is perpetually liable.

" Though this bed might have yielded a greater quantity of grain in a more kindly year, yet its produce, even in this, was very confiderable: for if we reckon in proportion the produce of an acre, it would yield 3795 pounds (nearly eight quarters) of grain, produced by fifty-fix pounds ten ounces of feed: which is after the rate of fixty-feven for one.

" To this it will be objected, that though a fmall fpot of ground, like that we have been fpeaking of, was made to produce fo confiderable a quantity of corn, it would probably not be poffible to obtain fuch a crop in proportion from an extent of fome acres of land. It may be fo: but fuppofing the crop to be even greatly inferior, it would ftill be much more confiderable than the common crops.

" Let us examine this queftion more minutely. It is of great confequence not to embrace an opinion, and efpecially a difadvantageous one, before it has been carefully confidered. Let us fee then to what the diminution of the crop may be owing. I fay nothing of the particular accidents which may in general leffen crops: but fuppofing all things equal, in fuch an extent of ground, my opinion is, that the firft and effential caufe of the mifcarriage can be imputed only to the cultivator himfelf, who fees what is beft to be done, but neglects it; and who ought at leaft to endeavour, as much as he poffibly can, to do that in great, which he fees fucceed fo well in fmall.

" I grant that many reflections and reafonings, which feem at firft fight to be extremely appofite, are in reality oftentimes only fpecious and deceitful, and that it is always right to recur to experimental proofs. Luckily we have fuch ready to produce.

" The celebrated Wolfius obferved long ago, that the productions of plants which grow in large pieces of ground, are always fine when the feed has been properly buried, and fowed thin: whence he concluded, that the moft extenfive fields ought to produce as much in proportion as fmall ones, and that it is evident that whenever an experiment has been made with the neceffary precautions, and has fucceeded upon the tenth part of any piece of ground, it ought to fucceed equally upon two, three, or four tenths, and confequently upon the whole of that ground.

" The experience of five years, of which I fhall give an account in the following article, will, I believe, prove this very fufficiently."

EXPERIMENT, Numb. II.

N. B. This field is marked with the fame number in the former experiments.

For the crop of 1752, it was fowed with eleven pounds four ounces of wheat, which produced 1041 pounds twelve ounces.

For the crop of 1753, it was fowed with thirty-four pounds fourteen ounces, which produced 1575 pounds.

For the crop of 1754, it was fowed with fixty-one pounds fourteen ounces, which produced 1820 pounds.

For the crop of 1755, it was fowed with feventy-eight pounds, which produced 1950 pounds.

For the crop of 1756, it was fowed with fifty-one pounds, which produced 1885 pounds.

Year 1755.

" I had now cultivated Smyrna wheat for fome years, fowing the whole of each year's produce, in order to increafe my quantity fo as to be able to fow a pretty large field with it; which I could not complete till 1754, for the crop of 1755.

" The

" The field in queſtion was ſowed with ſeventy-eight pounds of this corn. It roſe very well: but towards the end of winter, I was ſurpriſed to find that a great quantity of plants had been deſtroyed by the froſt; and I ſoon perceived, that almoſt all the ſtrongeſt and healthieſt plants were thoſe of common wheat, and that there were very few of Smyrna wheat. I had obſerved at the time of ſowing, that there was ſome mixture in the ſeed: and as I had ſome of the ſame ſort ſtill remaining, I was able to ſatisfy myſelf that there was a third part of common wheat in the Smyrna wheat which I had ſown; and that it was the former which grew ſo fine, and of which almoſt the whole crop conſiſted.

" This ſhews that Smyrna wheat does not reſiſt hard froſts: but at the ſame time, ſuch winters as that of 1754, very ſeldom happen in this country. This field was reaped on the 19th of July; the common wheat was thorough ripe, and the Smyrna wheat quite green, though its grain was grown very hard.

" I ſeparated the ears of Smyrna wheat from the others, in order to bind them up in diſtinct ſheaves, that I might have their grain pure and unmixed. This field produced 213 pounds of Smyrna wheat, and 1737 pounds of common wheat; in all 1950 pounds; which is a greater crop than that of the preceding years."

Obſervations on Smyrna Wheat.

" My former crops of this wheat, though the quantity was but ſmall, had already ſhewed me plainly that it produces more grain than any other kind. In 1755, the ſheaves of this wheat, of the ſame ſize as thoſe of our common wheat, yielded more grain by half than the others did. It is therefore probable, that the planting of this grain will be attended with advantage, eſpecially in climates not ſubject to too hard froſts.

" But a point of very great importance, is, to know well at what degree of maturity this corn ſhould be reaped. In the two firſt years that I ſowed any of it, the ears were prodigiouſly large, and full of very plump well fed grain; but I was uneaſy at not ſeeing them ripen. They continued green, whilſt I daily expected that they would turn yellow, and the grains grow hard, but in vain. By this delay, the grain waſted ſo much, that I never ſaw any ſmaller, nor ſo much ſhrunk as theſe. However, they ſprouted well when ſowed, and produced very fine plants.

" The third year, I determined to reap them earlier than I had done the firſt. Accordingly, I cut them down as ſoon as I found that the grain had acquired a ſufficient degree of hardneſs, notwithſtanding that the corn was ſtill quite green. The conſequence of this was, that the grain remained exceeding plump and fine."

Year 1756.

" I continued to ſow the ſame field with Smyrna wheat, of which I procured ſome quite pure and unmixed. I ſowed fifty-one pounds of this wheat on the firſt of October. The plants were fine, and ſufficiently forward before winter, and throve prodigiouſly from ſpring till harveſt. But I ought not to omit obſerving, that Smyrna wheat is as apt to be rickety as common wheat, and that numbers of theſe plants were affected with that diſtemper.

" This crop was reaped on the twenty-ninth of July, whilſt it was yet green, and the grain only hardened. It yielded 1885 pounds of exceeding fine, clean, good ſized wheat."

OBSERVATIONS.

" It would be needleſs to make experiments, if the inſtructions which they may afford were not to be attended to: but as thoſe inſtructions will ſometimes eſcape the notice even of the moſt careful obſerver, it is proper always to repeat the experiments, and to continue them conſtantly for ſome time. It is by ſo doing, that the advantages of the New Huſbandry will appear in their true light, and be eſtabliſhed beyond diſpute.

" The field I am now ſpeaking of, and from which I reaped five crops in five ſucceſſive years, preſents us real and very conſiderable advantages, which I ſhall ſet forth in what appears to me the juſteſt and moſt ſtriking manner.

" To this end, I ſhall ſtate exactly the products of the field in queſtion, cultivated in the old and in the new way. I ſhall begin with its produce during ſixteen years that it was cultivated according to the rules of the Old Huſbandry: namely, from the crop of 1730, to that of 1744 incluſively. In this ſpace of time, it produced eight crops; the cuſtom of the country being to ſow but once in two years, and to reſt the ground each alternate year. My account may be depended upon, as perfectly exact. I have extracted it out of a journal kept by a ſteward of mine, who died in 1745, and who was ſcrupulouſly exact even in the ſmalleſt concerns.

" After giving the produce of this field, the ſoil of which is very good and ſtrong, during ſixteen years that it was cultivated in the old way; I ſhall ſhew what the ſame field produced in five years cultivation according to the new method, in order to compare the different products of only five years with thoſe of ſixteen; and afterwards draw a compariſon between both the cultures for ſixteen years, ſuppoſing, which is a great diſadvantage, that the eleven remaining years of the New Huſbandry produced no more than theſe firſt five have done."

Number I.

" *Produce of the Field, Number II. during ſixteen Years that it was cultivated in the old Way; viz. from the Crop of the Year 1730, to that of the Year 1744, incluſively.*

Reflections and Obfervations.

" I dare to fay that very few of thofe who might juft have glanced over the products of the five years during which the field Numb. II. was cultivated in the new way, would have imagined the advantage to be near fo great as it really is, had not the above comparifons been likewife laid before them. If nothing but the hope of great profit can recommend the New Hufbandry to the general practice of our farmers, the above calculations ought at once to determine them; fince they here fee that the fame field produced much more grain in five years, and even in four, when managed in the new way, than it produced before in fixteen years, whilft cultivated according to the old method. I confefs that when I firft began to practife the New Hufbandry, I did not expect fo great advantages. They might have been greater ftill, if I had not committed in the firft years, faults which confiderably diminifhed the crops of 1752 and 1753. Befides thofe firft faults, I committed another, which greatly leffened my crops. I was not aware that the fertility of every field which is ploughed deeper than it has ufually been, is often leffened for fome years, unlefs it be affifted by a fufficient quantity of manure. The new earth which is brought up to the furface by thefe ploughings, remains fo hard and compact, that it cannot be fit for the nourifhment of plants, till after it has been well broken by repeated ploughings, and as it were ripened by the influence of the air, &c.

" This obfervation will be particularly ufeful to all beginners in the New Hufbandry. They muft not be furprifed if their firft crops do not anfwer their wifhes: but the deeper they plough at firft, the greater fuccefs they may juftly expect afterwards. In the mean time they muft fuffer patiently the inconvenience I have been fpeaking of, or remedy it by ufing a great deal of manure.

" Would it be reafonable to defire greater advantages than thofe we have proved above? any man of fenfe may furely be fatisfied with them: but through what fatality does it happen, that infinite numbers will not, or cannot fee them? I know, for inftance, that, excepting a certain number of perfons who have ftudied the New Hufbandry thoroughly, or practifed it with care, it is generally thought in this country, that the field Numb. II. which I have been fpeaking of, has produced me lefs corn than it would have done if it had continued to be cultivated in the old way. Whence does this notion arife: furely from this, That men are apt to judge too precipitately, without examining fufficiently, or calculating right. Whoever really wifhes to be informed, and defires to promote the public welfare, and his own private good, may eafily attain thefe ends: but it muft be by a different road from that which is commonly purfued: it muft be by reckoning and calculating, as I have done with regard to the field in queftion.

" Some fields will not yield fo much as this has done: but yet their produce will be fuch as muft determine all unprejudiced perfons in favour of the New Hufbandry, as I fhall demonftrate by the calculations in the third and fourth articles.

EXPERIMENT, Numb. III.

N. B. The field on which this experiment was made, contains about an acre and a half of ground. I have joined it to that of the experiment Numb. VII. under which its produce is included.

EXPERIMENT, Numb. IV.

Sowed		lb.	oz.		lb.	oz.
In 1753		181		reaped	3370	
1754		268	14		4972	8
1755	1ft half	488			5850	
	2d half	488			2080	
1756		816			3640	

Year 1755.

" One half of this field was laid out in beds in 1753, and the other half not till 1754. I fhall begin with the oldeft, from which I ought to expect the beft crop, as that ground was the beft prepared. It was fowed on the twenty-feventh and twenty-eighth of Auguft, with 488 pounds of wheat. This was a confiderable increafe of feed. I judged it neceffary, and fo it proved; for it preferved this field from being greatly hurt by the froft in winter, which deftroyed a great number of plants. If they had not been fo thick fown, I make no doubt but that the crop would have been confiderably diminifhed. This half was reaped on the eighteenth of July, and yielded 5850 pounds of very fine grain. Here is a crop confiderably greater than the former. It exceeds the firft by 2480 pounds.

" The other half of this field now bore its fecond crop. The fame quantity of feed (418 lb.) was fown, but did not produce fo much as in the other half. As this part lies in a bottom, the froft hurt it more than it did the other, nor had it been fo long laid out in beds; befides which, the rains hindered me from fowing it at the fame time as the other half. It could not be fowed till the twenty-firft, twenty-fecond, twenty-third, and twenty-fourth

fourth of October, which is somewhat late. It was reaped on the nineteenth of July, and yielded 2080 pounds of wheat.

Year 1756.

" This field was sowed on the ninth, tenth, and twelfth of September, with 816 pounds of wheat, and reaped on the twenty-eighth and twenty-ninth of July. The produce was 3640 pounds.

OBSERVATIONS.

" One might justly be surprised at the scantiness of this crop, if, besides what I said before of the general causes which were so prejudicial to the crops of this year, I did not add those which may have more particularly affected this field. My intention was to sow it thicker than it chanced to be; through the fault of the sower, who did not follow my directions. The hurt might perhaps not have been great, if the seasons had proved kindly: but it was of considerable consequence this year, and particularly in this field, in which all the corn was extremely rickety.

EXPERIMENT, Numb. V.

In 1753	139	2205
1754	224	2283
1755	388	2600
1756	544	2700

Year 1755.

" This field still continued to be difficult to bring to good tilth; and therefore required the more seed. It was sowed on the twenty-ninth of August, reaped on the twenty-ninth of July, and produced 2600 pounds of grain.

Year 1756.

" I thought it necessary to continue to increase the seed of this field. It was sowed on the 20th and 22d of September, with 544 pounds of wheat. The young plants looked very fine before winter, and promised better than those of the preceding years. The general accidents of the year affected them. They were reaped on the twenty-sixth of July, and yielded 2700 pounds of corn.

EXPERIMENT, Numb. VI.

1754		82	798
1755	wheat	162	900
	barley	12	nothing
1756 beans and tares 153: value in wheat 780			

Year 1755.

" This field one of those in which the stiffness of the soil resisted longest that degree of pulverisation in which the chief merit of the New Husbandry consists. The first crops were not considerable. In 1754, I could not sow this ground before the fifteenth of October, and yet the plants which it produced were very fine. It was reaped on the twenty-first of July, and produced 900 pounds of wheat.

" The most remarkable thing in this field, was what happened to some beds which I had sowed with twelve pounds of barley. The young plants were exceeding fine in autumn, but the hard frosts of the winter killed every one of them.

" As soon as I perceived this loss, I endeavoured to repair it, by sowing the same beds again with spring barley: and as the two wheat beds next to them had likewise suffered so much as to have but few plants left, I sowed them also with barley.

" These beds were sowed without being ploughed again. The whole charge of this second sowing consisted in passing the drill once over them, and in twenty-eight pounds of barley which was used for the seed. This was done on the eighth of April.

" This barley grew very fine. It was reaped on the first of August, and yielded 270 pounds of grain. I doubt whether that which was sowed before the winter could have produced more: so that I think this crop made me ample amends for the loss of my first seed.

" How great a proof is this of the excellence of the New Husbandry! and how easy a means does this husbandry afford of guarding against dearth, when our young crops chance to be destroyed, by the facility with which the same lands may be sown again, without loss of time, and with scarce any more expence than the bare cost of other seed, which in such times of general distress, will produce crops of other useful grains, even more profitable than those of wheat! An inestimable advantage, which secures the subsistence of the people, and which cannot be obtained by the Old Husbandry. This must be evident to every one who considers that all that is requisite, in such a case, in the New Husbandry, is only to sow again: whereas in the old way, the Husbandman is obliged to plough before he sows, to sow a great deal of seed, and to harrow that seed in after it is sown. The vast saving made in the seed, in the new way, is likewise another very important article in a time of scarcity.

" I reason here upon a supposition of the total loss of all the crops of wheat, which really was the case in 1709.

Year 1756.

" I reserved this field in order to sow it in the spring, with the grain of that season, with which I had not yet made my experiment, except in small spots of ground. I ploughed it before winter: the new beds were well made, and the earth was in such fine tilth in the spring, that I thought I might safely sow it without any farther ploughing. Accordingly I did so on the 26th of April; the too great wetness of the earth not permitting it to be done sooner. One half of this field was sowed with beans, and the other half with tares; in all, 153 pounds of both, which produced a crop equal in value to 780 pounds of wheat.

OBSERVATIONS.

" This year was extremely bad for all grains sown in the spring; most of which yielded but the value of the seed; so that the produce of this field, compared to that of others cultivated in the old way, ought to appear very considerable.

" The success of this experiment shews, that when too much rain, or too great drought, hinders ploughing the land in due time, and some fields cannot be prepared for wheat in the autumn, they may be sowed in the following spring, with the different grains usually planted in March.

EXPERIMENT, Numb. VII.

Sowed.	lb.	Reaped lb.
For 1753	412	2646
1754	360	2467
1755 including the experiment, N° III.	639	4290
1756	1010	6760

Year 1755.

" The soil of this field is of such a nature as to require a greater quantity of seed than many others. I shall doubtless be thought to have increased considerably, in having enlarged that quantity to 639 pounds: and yet this year's experiment makes me judge, that it will still be necessary to sow more another time.

" I sowed this field on the 9th, 10th, and 26th of August, and reaped it on the 16th and 17th of July. It yielded 4290 pounds of grain.

Year 1756.

" I have a meadow adjoining to this field. I ploughed up part of it, which had produced but very little grass for a long time, and turned it into arable land. This addition served to replace another part of the field, which I sowed with lucerne. This last part being less than that which was added from the meadow, the field may have been enlarged about two acres, and the soil is much the better for it.

" This field was sowed with 1010 pounds of wheat, on the 10th, 13th, and 15th of September, and was reaped

reaped on the 23d and 24th of July, when it produced 6760 pounds of corn.

EXPERIMENT, Numb. VIII.

		lb. oz.		
For 1754	were ſown	76 8;	which yielded	1462
1755		157		1300
1756		230		2080

Year 1755.

"This great increaſe of the quantity of ſeed might be wondered at, if I did not obſerve that this field was ſowed with two bouts of the drill-plough; by which means each bed (for they were all wide enough to admit of it) had ſix rows of plants inſtead of three, and conſequently took up double the quantity of ſeed. The event will ſhew that I was right in ſo doing.

"The field was ſowed on the 31ſt of Auguſt, with 157 pounds of wheat. Nothing could make a finer appearance than this corn did at the beginning of winter. The plants, which had already branched very abundantly, made the ground look ſurpriſingly thick covered. The ſtrength of the ſtems, and the deep green of the blades, made me expect extraordinary ſucceſs. They continued thus promiſing during all the winter; and the ſame in February and March, and to the middle of April.

"The ſoil of this field is excellent: but it could not be preſerved from the fatal effect of the ſevere froſts in winter. I was extremely ſurpriſed when, going thither on the 27th of April, I found this wheat, which I had ſeen twelve days before without the leaſt ſymptom of decay, reduced to a moſt deplorable condition: not a ſingle ſtalk remained that was not dead, nor a blade that was not withered. Both the ſtalks and the blades adhered ſo little to the plants, that one might rake them up in heaps, like graſs that has been mowed: in ſhort, nothing could be more melancholy than the appearance of this field.

"The earth was extremely dry, and the weather very hot for the ſeaſon: from the 16th to the 24th of April, M. de Reaumur's thermometer was always, at ſeven o'clock in the morning, at from fifteen to eighteen degrees above the freezing point. I am apt to think that this uncommon temperature of the air compleated what the hard froſts had begun, and which I did not perceive before.

"My firſt thought was, to ſow the field again with barley, as I had done in the caſe of the experiment, Numb. VI. but ſeeing that the diſaſter was general, I examined moſt of the plants with great attention. I ordered the earth to be dug, and found ſome plants quite dead, and others, in pretty great number, which had ſtill ſome vigour, and were provided with very good roots, and of which only the ſtems and blades had periſhed. This gave me ſome hope; which was not a little ſtrengthened by my perceiving that ſeveral of theſe plants were ready to produce new ſhoots, ſome of which could juſt be diſtinguiſhed by their white point, ſcarcely perceptible; others were about the 12th part of an inch long, and others a quarter or half an inch: theſe laſt began to look green.

"Several reaſons induced me to think that theſe plants might ſtill be ſtrong enough to produce new ſtalks, eſpecially if a little rain ſhould chance to fall. I therefore reſolved not to ſow this field again. Fortunately, a good ſhower of rain fell on the 29th, which did them wonderful ſervice. I went to ſee them ſoon after, and found the new ſhoots conſiderably grown: upon which I determined to cultivate the beds with care. By the middle of May, the plants were grown very fine, were loaded with blades and ſtalks, and only ſeemed much thinner than in the autumn: the ſtraw was as long, and the ears were as big, and as full of grain, as the year before. I was obliged to reap this corn early; becauſe, as the heat of the weather had precipitated the ripening of the grain, it might have ſhrunk and ſhrivelled if I had let it ſtand ſome days longer. It was cut down on the 17th of July, and yielded 1000 pounds of grain.

"I am perſuaded that this accident diminiſhed the crop by above half; and this is certainly the reaſon why it produced leſs than that of 1754.

"The ſhape of this field was irregular on the north ſide. The length of the beds in that part decreaſed progreſſively, ſo that thoſe next the end were not above three or four fathoms long. This made the tilling of them very troubleſome, becauſe of the frequent neceſſity of turning the plough. I ordered this triangular part, which was about the third of the field, to be ploughed for ſowing in equally diſtant rows with the drill-plough. The reſt was preſerved in beds, as in the preceding years.

"I ſowed it on the 17th of September, with 230 pounds of wheat, which was reaped on the 24th of July, and yielded 2080 pounds of grain.

EXPERIMENT, Numb. IX.

		lb. oz.		lb.
For 1754	was ſowed	249 12;	which yielded	2925
1755		312		1362
1756		295		2219

Year 1755.

"This field, which had been well prepared, was ſowed on the 27th of Auguſt, with 312 pounds of wheat, which grew very fine and thick till November: but from the 10th to the 18th of that month, a general ruſt ſeized it. I imputed to this diſtemper the ſmallneſs of the crop, which amounted only to 1362 pounds.

Year 1756.

"The ground was extremely well prepared, and better than in the preceding years. It was ſowed on the 24th of September with 295 pounds of wheat, which produced 2219 pounds. It was reaped on the 21ſt of July.

EXPERIMENT, Numb. X.

		lb.		lb.
For 1754	was ſowed	294;	which yielded	3055
1755		397		2210
1756		rye 348		2700

Year 1755.

"This field was ſowed on the 30th of Auguſt, with 397 pounds of wheat, which produced 2210 pounds. I make the ſame remarks on this experiment, as on the preceding, Numb. IX. year 1755.

Year 1756.

"Though it is not uſual for me to ſow rye, becauſe all my lands are fit to bear wheat, I was willing to make a trial with that grain; and accordingly I ſowed this field with it, on the 16th of September. The quantity employed was 348 pounds. The ſtraw was very long, and much thicker than that of rye in the common way: the grains alſo were conſiderably larger. It was reaped on the 19th and 20th of July, and yielded 2700 pounds of grain.

EXPERIMENT, Numb. XI.

Performed by the ſame Perſon who made thoſe of 1754, marked with the ſame Number, and thoſe of 1753, marked Number IX.

"Though the following extract does not agree exactly with the title of this article, I was unwilling to make it a ſeparate one. It contains very intereſting details: the moſt eſſential circumſtances are related with great preciſion; and the conſequences of the reſults are eſtabliſhed by very inſtructive calculations. They ſhew the writer of them to be a ſtudious huſbandman, a very ſkilful naturaliſt, a zealous lover of the public good, who inſtructs by his example, and ſtill more by his knowledge.

"Theſe experiments were made about fifteen miles from Geneva, in a country where it is the cuſtom to ſow the land two years running. The firſt year it is ſowed with wheat; the ſecond, with ſpring corn; and the third it is reſted.

Extract of a Letter to M. de Chateauvieux, *dated* December 7, 1755.

'I received the journal of your laſt year's experiments, 'and have read it with very great pleaſure. If it were 'poſſible for me to make any obſervation of the leaſt im'portance, upon your experiments, which had eſcaped 'you, I ſhould take the liberty to lay it before you, in 'full confidence of your receiving it kindly.

'In general, I aſcribe, as you have done, the different 'ſucceſs of the New Huſbandry, 1. To the intrinſic 'quality of the ſoils, ſome of which ſeem unfit for the 'production of wheat: 2. To the condition of the lands, 'when they firſt began to be cultivated in the new way: '3. To the manner in which they were prepared, ac'cording to the principles of this huſbandry: and laſtly, 'to the quantity of ſeed that was uſed.

'I was particularly pleaſed with your experiment on 'the barley. It is certainly very inſtructing, and con'firms what I before ſuſpected, that in our climate, 'wheat and other plants love ſociety; and that they 'thrive better when numbers of them are planted to'gether, than they would do ſeparately, provided that 'number be not too great. You will certainly not fail 'to repeat that experiment in years leſs hot and leſs dry, 'and upon other plants. Still I am afraid that no fixed 'rule can ever be given with regard to the quantity of 'the ſeed: too many circumſtances influence the con'dition of the ſoil: but it will always be of great ſer'vice to fix certain bounds, within which every one may 'chooſe what ſuits him beſt.

'You will ſee by the account of my little experiments, 'that I have ſowed in the ground of my rows, nearly 'what would have been ſowed by hand in the ſame ſpace. 'But the imperfection of my drill-plough, and the con'dition of my land, obliged me ſo to do; and I have not 'hitherto found any inconvenience from it.

'I ſhorten my reflections, and proceed to my experi'ments.

Produce of the firſt and ſecond Crop of a Field cultivated in the new Way.

'This field contains, according to our meaſure, ſix 'poſes, which are equal to very near four acres and a 'half. The ſoil of it is tolerably good; rather light 'than ſtrong; fitter for rye than wheat. I am the firſt 'that ever ventured to ſow it with wheat. Dung uſed 'to have a great effect upon it for the firſt crop, but the 'ſecond ſeldom ſucceeded: in ſhort, it was the general opi'nion, that nothing could be made of this field without 'the help of a deal of good manure.

'It was well dunged in 1749, and ſowed with maſlin 'corn. The year 1750 was very favourable to corn in 'general, and particularly to that of this field. It yielded 'as much as two middling crops; that is to ſay, ten for 'one: but being ſowed again the ſame year, it yielded, 'in 1751, but two and a half for one. The year 1752 'was the year of reſt, or rather it was ploughed that 'year, according to the old method, and ſowed the 'broad-caſt way, but without dung. The autumn was 'not kindly: the plants roſe poorly: and the crop of '1753 yielded ſcarce three for one, after deducting the 'tythe. It was after this crop that this field was laid out 'in beds of ſix feet wide, and ſowed in the ſame year 'with wheat. As the mould of theſe beds could not be 'prepared properly, and the year 1754 was but a poor 'one for wheat, I was not ſurpriſed at the ſcantineſs of 'the crop. I ſowed twelve of our meaſures, and reaped 'ſeventy-two. Our meaſure of wheat weighs, when it 'is good, twenty-eight pounds; and that of maſlin 'twenty-ſix pounds. I did not weigh mine every year; 'but I am ſure it was always full weight.

'Encouraged, rather than diſheartened, by this trial, I 'ploughed theſe beds up for a new crop, and ſowed them, 'part with maſlin corn, and part with wheat.

'The ſummer of 1754 was ſo dry, that I deferred 'plowing the ſummit of the beds which had borne their 'crops, till the end of autumn. This was attended with 'theſe two inconveniencies: firſt, that the intermediate 'earth, which had been well pulveriſed, being no longer 'ſupported as before, ſlipt away from under the drill, and 'ſpread to the right and left; by which means the plants 'had leſs depth of good mould left, and I loſt part of the 'advantage I hoped for from this culture. The other in'convenience was, that the beds being no longer ſo high 'raiſed as they ſhould have been, the firſt ploughing in 'autumn covered their outmoſt rows in ſeveral places: a 'loſs, by ſo much the more conſiderable, as the rows ſo 'buried would, by their ſituation, have otherwiſe been 'the fineſt of all. I certainly under-rate it, in valuing 'it at only a tenth part of the crop.

'As maſlin is a much quicker grower than wheat, 'and being uncertain whether it could do without dung; 'out of eighteen beds, I dunged twelve, but very ſlight'ly; juſt as I would have dunged the third part of this 'ground, if I had intended to ſow it in the broad-caſt way.

'I ſowed it on the 4th and 5th of October, 1754, with 'two turns of the drill-plough, and very thick, by reaſon 'of the imperfection of my drill, and becauſe the ſeaſon 'was already ſomewhat advanced. A third more ſeed 'was ſowed this year than laſt, viz. eighteen of our 'meaſures.

'The plants roſe well, the rows looked very thick and 'well filled, except thoſe which were hurt by the firſt au'tumnal ploughing, and by cattle which broke in upon 'the ground, and did a deal of damage.

'The plants in the part which had been dunged, were 'very fine all the winter. In the beginning of April they 'grew with ſurpriſing vigour, and were as beautiful as 'could poſſibly be in May and June. They were ſo 'tall, that they hid my plough and horſes, and ſeemed 'to promiſe three times more than the other plants where 'the ground had not been dunged. Theſe laſt grew 'more ſlowly: but juſt before harveſt, they puſhed 'ſtrongly; and if their ſtraw was not ſo long or ſo thick 'as that of the former, there was ſcarce any difference in 'the length of the ears: and the difference of the product 'was but one-fourth in favour of the dunged plants.

'Both the one and the other ſuffered on the 23d of 'May, by a violent north-eaſt wind, which broke a great 'number of the ſtalks of the rye, and tore others up by 'the roots. The ſtalks that were not quite broken, re'covered perfectly, and the loſs was not great with re'ſpect to them. The caſe was different in regard to the 'plants that were broke aſunder or torn up. I reckoned 'the damage ſuſtained by theſe laſt, equal to a tenth part 'of the crop.

'Of the forty-ſeven furrows of this field, eighteen ſowed 'with maſlin yielded me (excluſive of the tythe, which is 'an eleventh part) ſixty of our meaſures. This grain is the 'fineſt of its kind in the whole country, and is equal to the 'common wheat. The meaſure weighed, in the drieſt and 'coldeſt ſeaſon, twenty-ſeven pounds; which is a ninth 'part more than the weight of the common maſlin.

'The twenty-nine furrows ſowed with wheat ſeemed 'to have eſcaped the violent froſts of the winter: but I 'was greatly ſurpriſed in April, to ſee large ſpaces in 'which the plants periſhed daily; and others wherein the 'wheat ſeemed to have diſappeared, to make room for a 'prodigious quantity of ſenvy, which looked extremely 'well.

'I was not at all pleaſed with this change of crop: yet 'though I no longer expected any thing from theſe da'maged places, which amounted to the value of nine 'furrows, I would not give up the good plants which I 'thought might ſtill be in them; and therefore ordered 'them to be weeded carefully, ſeveral times over, by wo'men who deſired only the weeds for their labour. This 'operation was not uſeleſs: the ſurviving plants gathered 'new ſtrength: they branched conſiderably in June; and 'yielded me, at harveſt, about a third part of what I 'reaped from the places which had not been damaged. 'Theſe laſt ſeemed but indifferent during all the ſpring. 'Every one judged this corn inferior to that of the fields 'which had been ſown in equally diſtant rows and dunged: 'but, from the beginning of June, when the other wheat 'began to decline, my rows throve ſo well, that ſome 'parts of them were very greatly ſuperior, both in the 'length of the ſtraw, and the bigneſs of the ears, which 'laſt were every where longer and better filled.

'Notwithſtanding all this, my wheat had ſtill more to 'ſuffer. It was cut juſt before the heavy rains in July, 'and

'and some of it sprouted, as was the case elsewhere. Besides the loss in the quality of the grain, my threshers reckoned that the quantity of it was diminished eight measures. The whole produce was but sixty-eight measures, after deducting the tythe.

'I have entered into this detail, in order to make the following remarks.

'1. As this field, twelve furrows excepted, was not dunged so early as in the year 1749, the superiority of the crop of 1755 over that of 1754, must be imputed chiefly to the New Husbandry. The places on which my finest wheat grew, were not at all extraordinary in 1754, and yet they were not dunged for 1755; consequently the culture, far from exhausting, meliorated the ground.

'2. Some soils are fitter to produce some grains than others; and it is in vain to attempt to force nature. Notwithstanding the good culture, the bad part of my field was yet worse than in 1754; but the senvy in it was finer. I sowed this part with grass, which still covers it, and is very green and vigorous. I judge that radishes or turneps would do very well there.

'3. One must not always judge of a crop by the appearance of the green corn in April and May; because the dung then exerts its greatest strength for the production of the blades, and that appearance is oftentimes deceitful.

'4. The last ploughings ought, if possible, never to be neglected: it is to them that I ascribe the favourable change which happened to my wheat.

'To follow your method, I have now only to compare the produce of this field, with what it yielded when cultivated in the old way. I have not been able to find its exact produce before the year 1750. All I know is, that the crops varied extremely, according as the ground had, or had not been dunged, or the year was more or less kindly.

'I shall therefore estimate the produce of this by that of the neighbouring fields, which are thought to bear a good crop, when a pose of land yields thirty-two of our measures, after deducting the tythe and seed corn. The next crop, whether it be of winter or spring corn, is seldom worth half the first: however, supposing it to be sixteen measures, as the land is rested the third year, the neat produce of the crop for three years will be forty-eight measures, which is sixteen measures a year, and ninety-six measures for the six poses.

'I had, in the new way, 128 measures of wheat and maslin; deducting from which eighteen measures for the seed, there remain neat 110 measures, and a profit of fourteen; for which I am indebted to the New Husbandry.

'If we add to this the eight measures lost by the sprouting of the grain, and the damage done by the ploughing in autumn, it will appear, that, without those two extraordinary accidents, I should have had thirty-five measures more than could have been expected in the old way, and that of a corn, which, supposing all other things equal, is worth twelve per cent. more than any of the common growth.

'I make no doubt, but that if I were to lay in my furrows the dung that is spread yearly upon my lands, and were to take all the precautions necessary to sow and cultivate them properly, the neat produce would be thirty measures, one year with another, which would be a continual plenty.

'However that may be, thus much is certain in favour of the New Husbandry, that, notwithstanding all the accidents, my field produced the second year about double the quantity that it did the first."

First Year's Produce of a Field sowed and cultivated according to the New Husbandry.

'This field contains about three acres and a half. It was divided into beds five feet wide, which were sown alternately with one and with two bouts of the drill-plough; that is to say, with three rows and with six. The ploughings had been but badly performed, and the beds were not raised or arched so high as they should have been. Those that were sown double, that is with six rows, were always superior to the rest. As the soil of this field is generally strong, and fit for wheat, it did not afford the same variations as the former, though some of this wheat sprouted.

'I sowed seventeen measures, and reaped ninety-two, besides the tythe. By the same calculation as before, the neat produce was one measure less than in the old way.

'But it is to be observed, 1. That by the sprouting of the grain, I lost more in this field than in the other. 2. That this was not a good year for wheat. 3. That this field, being bordered by two high-ways, and not being inclosed, was greatly damaged by cattle that got into it. 4. That what grain I did reap was clean, and suffered scarce any diminution by sifting. 5. That if I had sowed all my beds with six rows, I should probably have reaped a fourth part more; so that no blame ought to be imputed here to the New Husbandry. 6. That it is the first year of my trying this husbandry; that my ground had been but very imperfectly prepared, and that it is now in a much better condition for the next crop, though my servants have again committed several blunders. All these considerations seem to me farther proofs of the excellency of the New Husbandry.

'I could prove, that, in point of profit, this last field has yielded me three times as much as it used to do in the old way, and the other field twice as much.

'This may more than suffice for such small experiments as mine. I could wish that they had been greater, and the success more complete. With what pleasure should I offer them to you, whom I look upon as the chief and patron of all who follow the true principles of agriculture!

'Though I have sowed the bad parts of the first field I spoke of with grass, I have added three poses more to the arable against next year, in order to cultivate them in the new way, which I purpose extending to all my lands the next sowing season.

'I have very injudiciously, I doubt, sowed between twelve and thirteen poses with grain which had sprouted. I do not believe the third part of it has come up; but as I sowed thick, and my lands are much better prepared than they were last year, I hope to have at least as good a crop.'

OBSERVATIONS.

"When experiments have been repeated in different places, the circumstances attending them ought to be greatly considered: for if these have been alike, and the event is the same, they serve to establish one another, and merit our confidence in them. The comparison of the last experiments with mine, gives me room to make two important observations. The first is, that both of us have perceived, and for the same reasons, the necessity of sowing a greater quantity of seed than we did in our first experiments. This augmentation produced better crops. We may therefore now lay down as a rule founded on experience, that the quantity of the seed must be what we said in our last accounts, regard being had to the particular considerations mentioned therein.

"The second observation is, that both of us have sowed beds with two bouts of the drill-plough, that is, with six rows of corn; and the event in both cases has been, that the same extent of ground has always produced a greater quantity of grain. It is therefore probable that this method will be found to be the best.

"But as it is possible that the effect may not be the same in different countries, a trial may be made by sowing some beds with three rows, and others with six, and which ever answers best, may afterwards be practised.

"These two observations will be confirmed by some experiments which we shall give in the fifth article.

"Other business prevented this lover of agriculture from following his experiments in 1756, with the same attention as before. The exact, though short, account which we shall give of them, may serve for a sequel to what we have been able to collect in relation to those which he made in 1755.

Year

Year 1756.

"In the firſt place, the field of ſix poſes, or four acres and a half, which bore a crop in 1754, and another in 1755, and which had not been dunged at all ſince the year 1749, being ſurrounded by a greater piece of land, which is ſowed ſometimes with wheat, and ſometimes with artificial graſſes, was ploughed in Auguſt, immediately after harveſt, and ſowed with ſain-foin. The crop of 1756 was very fine, each poſe yielding from twenty-five to thirty hundred weight of hay at the firſt mowing, and half as much at the ſecond. Therefore the New Huſbandry preſerved the ground in good condition, without the help of dung; and its productions do not ſeem to have exhauſted the ſoil.

"The field of about three acres and a half, ſowed with wheat, and which produced ninety-two meaſures of that grain in 1755, produced but ſixty-one in 1756. The inferiority of this crop muſt be aſcribed, 1. To the error of ſowing wheat that had ſprouted, which, in the opinion of all judges, occaſioned a diminution of at leaſt one fourth: 2. To the damage done by cattle (this field lying quite open to them) which was greater this year than it had ever been before, part of the green corn being eaten down twice. This loſs is valued at a tenth part of the crop, independent of the tythe. 3. That the ears were not ſo full of grain this year in this country as they uſed to be: that there was as much ſtraw within ſeven truſſes and a half as in 1755; but the corn ran leſs into grain, though it ſtill had more than the common wheat.

"Upon the whole, all loſſes and accidents deducted, the crop was worth double what the land would have let for.

"This field is now under wheat, which looks extremely fine, excepting one poſe, which muſt be ſowed again with ſomething elſe, on account of the damage the cattle have done to it. The owner of this field intends to continue ſowing it without dung as long as any heart remains in it, in order, ſays he, to confirm myſelf in what I now think, or to find out my error, if I am miſtaken.

"Another field of betwixt nine and ten poſes (equal to about ſeven acres and three roods) produced 160 meaſuers of wheat; but ſome loads of dung had been laid upon it. However, even the places which had not been dunged produced much ſtronger ſtraw than they did the years before, in which they were ſown by hand. It is true, that the dung made the ſtraw ſtronger, but the ears did not yield either more or finer grain. This was likewiſe ſowed with ſprouted corn; but the ſeed was better this year, and accordingly there is a proſpect of a greater crop.

Experiments made on Lands ſown in equally diſtant Rows with the Drill-Plough; with ſome Reflections on the Advantages of this Practice.

EXPERIMENT, Numb. XVII.

"A large extent of land, near Geneva, continued to be ſown with the drill-plough, in equally diſtant rows. I could inſtance the products of a multitude of experiments, to prove that the fields ſowed in this manner, have always produced much greater crops than thoſe which have been ſown in the common way.

"I ſhall mention only a few experiments this year: but they are ſuch as have been made on large tracts of ground, and conſequently are more deciſive than ſmall ones, of which we have already given a ſufficient number in the foregoing journals.

"I ſhall call this Numb. XVII. becauſe it was made by the ſame perſon, and in the ſame places, as that which is marked Number XVII. in the year 1754. I need not repeat what I then ſaid of the ſituation and quality of the land.

"This experiment contains the products of three different farms. About ſeventy acres were cultivated in the firſt, thirty-four in the ſecond, and twenty-ſix in the third: in all 130 acres, which were ſown with wheat in September and October.

Year 1755.

"Quantity of ſeed generally uſed in the old way.	Firſt farm	16002 lb.
	Second farm	7560 lb.
	Third farm	5922 lb.
	Total	29484 lb.
"Quantity of ſeed uſed with the drill-plough.	Firſt farm	7812 lb.
	Second farm	3276 lb.
	Third farm	3150 lb.
	Total	14238 lb.
"Saved in the ſeed - - - - - -		15246 lb.
"Crops of 1755.	Firſt farm	80210 lb.
	Second farm	27690 lb.
	Third farm	27040 lb.
	"Total of the crops	134940 lb.
"To which if we add the ſaving in the ſeed, viz. - - - - - - - - - -		15246 lb.
"The whole produce will be - - -		150186 lb.

"I ſhall now examine what theſe three farms would have produced if they had been cultivated in the old way, ſuppoſing their crops to have been equal to thoſe of 1754; which is much in favour of the Old Huſbandry.

"I find that theſe three farms, which contain about 130 acres, and which would have required 29484 pounds of ſeed, would have produced at moſt from 75000 to 80000 pounds of wheat; which is 54940 pounds leſs than what was reaped in the new way. The following calculation of the real and effective products in both ways, deducting from each the neceſſary quantity of ſeed, will ſhew the advantage of the New Huſbandry in a yet ſtronger light.

NEW HUSBANDRY.

Total produce	134940 lb.
To be deducted for the ſeed	14238 lb.
Neat produce,	120702 lb.

OLD HUSBANDRY.

Total produe,	80000 lb.
To be deducted for the ſeed	29484 lb.
Neat produce,	50516 lb.
Conſequently the balance in favour of the New Huſbandry is,	70186 lb.

"This may perhaps ſeem ſurpriſing to many: but my calculation may be more ſafely depended on, as I have favoured the Old Huſbandry greatly in my eſtimate of the crops in that way, and have made no deduction for the loſs by ſifting, winnowing, &c. which, even in the very beſt years, is always conſiderably greater in the Old Huſbandry, than in the New.

Year 1756.

"The ſame farms continued to be ſown with the drill-plough. I ſhall therefore repeat the ſame calculations, to ſhew the conſtant advantage of the New Huſbandry, which is ſo much the more remarkable this year, as the corn in the common way yielded but very bad crops. The fields in general produced but few ſheaves, and the ſheaves very little grain, and even that was very poor in many places.

"About ninety acres were cultivated in the firſt farm, for the crop of this year; in the ſecond thirty-four, and in the third forty-five: in all 169 acres, which were ſown with wheat in September and October. About thirty of theſe acres had been dunged.

"Quantity

"Quantity of ſeed generally uſed in the old way	Firſt farm	20160 lb.
	Second farm	7560 lb.
	Third farm	10080 lb.
	In all	37800 lb.
"Quantity of ſeed uſed with the drill-plough	Firſt farm	9828 lb.
	Second farm	3654 lb.
	Third farm	5040 lb.
	In all	18522 lb.
"Saved in the feed		19278
		37800 lb.
"Crops of 1746.	Firſt farm	79560 lb.
	Second farm *	19110 lb.
	Third farm	31590 lb.
"Total of the crops		130260 lb.
"To which if we add the ſaving in the ſeed, viz.		19278 lb.
"The whole produce will be		149538 lb.

"* This farm did not produce ſo much corn as it ſhould have done, becauſe near a third part of the fields was almoſt totally ruined by inundations.

"Suppoſing this accident not to have happened, what might theſe fields have produced? If they had been ſown in the common way, they would have yielded leſs grain than in the two preceding years. I have eſtimated it at ſomewhat leſs than that, and the advantage is ſtill in favour of the New Huſbandry. Theſe three farms would have produced at moſt from 88000 to 93000 pounds of wheat; and, according to this eſtimation, which I think a great allowance, the whole crop would be 37260 pounds leſs than it was.

"To ſee the exact reſult, let us continue our calculations, deducting the grain that was uſed for ſeed.

NEW HUSBANDRY.

"Total produce	130260 lb.
"To be deducted for the ſeed	18522 lb.
"Neat produe	111738 lb.

OLD HUSBANDRY.

"Total produce	93000 lb.
"To be deducted for the ſeed	37800 lb.
"Neat produce	55200 lb.
"Conſequently the balance in favour of the New Huſbandry is	75060 lb.

"All theſe calculations prove, year after year, the advantage of uſing the drill-plough. To ſhew how great that advantage is, I ſhall briefly recapitulate what is moſt eſſential in this article.

RECAPITULATION.

"We have ſeen a very conſiderable experiment repeated three years running, and always attended with great ſucceſs. I ſhall now ſum up the eſſential and deciſive facts, which are ſo many unexceptionable witneſſes, who depoſe, That it is much more profitable to ſow lands with the drill-plough, than to ſow them in the common way.

"To this end, I reſume the neat products of the crops.

NEW HUSBANDRY.

Neat produce of the three farms.

In 1754.	93418
1755.	120702
1756.	111738
"Total neat produce of three years	325858

OLD HUSBANDRY.

	Pounds.
In 1754.	62200
1755.	50516
1756.	55200
"Total neat produce of three years	167916
"The difference in favour of the New Huſbandry, in three years amounts to	157942

"This is an object of great importance, not only to the public, whoſe welfare it highly concerns, but to every owner of land. How ſtrongly does it ſhew the vaſt advantage of the drill-huſbandry! We here ſee 169 acres of land produce 157942 pounds of wheat more than they would have done without this favourable culture.

"Any one may eaſily reckon the value of ſuch a quantity of wheat, ſuppoſing it to be of the very beſt ſort, as it really was.

EXPERIMENT, Numb. XVIII.

"I ſhall now give a ſhort account of the ſucceſs of another farm, which I have hitherto ſowed in equally diſtant rows, with the drill-plough. I generally ſow about twenty-three or twenty-four acres of it every year. For the crop of 1755, I uſed 1840 pounds of ſeed corn, which produced 10400 pounds of grain. For the crop of 1756, I ſowed 2772 pounds of wheat, the produce of which was 14560 pounds, which is a great deal, conſidering the quality of the land.

"I ſhall conclude this article with a ſhort detail of two little experiments made by the perſon I laſt ſpoke of, on two fields of different ſoils. The firſt, which contained about two acres, was a light ſoil, and ſomewhat ſtony. The quantity of ſeed generally uſed for that ground, was about 380 pounds weight. It was ſowed very thick, with the drill-plough, and took up 252 pounds of ſeed. I attended carefully to the progreſs of this corn. It ripened well, the ſtraw was very long, and crowned with fine ears, which yielded 2835 pounds of grain.

"The ſecond experiment was made on a ſtiff ſoil. Half the field was ſown in the common way; and the other half in equally diſtant rows with the drill-plough, and only two-thirds of the uſual quantity of ſeed was uſed. This laſt half yielded double what the other did, though it was ſown with a third leſs ſeed.

"The deſign of the following article is, to ſhew that lands which are laid out in beds according to the New Huſbandry, produce more corn than thoſe which are only ſown in equally diſtant rows, with the drill-plough. The proof of this propoſition will reſult from proper calculations, and a compariſon of the products of theſe two different methods.

"It is of no ſmall importance to the public, to know exactly which is the beſt and moſt profitable way to cultivate land. This article deſerves ſtill more attention than the laſt, as it tends to point out the means that are in reality moſt advantageous, though oppoſed by an obſtinate attachment to the Old Huſbandry, and the extreme reluctance with which farmers can ever be induced to try a new practice, which they are almoſt always ready to condemn, without taking the pains to know what it is, and indeed generally, becauſe they are not able to judge of it. It cannot therefore be expected that the theory alone ſhould ſatisfy them that this huſbandry is conſiſtent with the beſt principles of agriculture. If any thing can convince them, it will be a ſeries of facts, and experiments repeated during a courſe of years, always ſucceſsfully in ſo many different places.

"It is highly eſſential to dwell upon the proofs that the Old Huſbandry is leſs profitable than the New, in which the field intended to be ſown is firſt laid out in beds: for, after ſhewing that lands ſo laid out and ſown, produce conſiderably more than thoſe which are ſown only in equally diſtant rows with the drill-plough, as has

has been demonstrated in the foregoing article; and likewise, that these last produce considerably more than they used to do in the Old Husbandry; the superiority of the crops which the beds afford, will certainly appear still more striking, and no doubt will remain of the excellence of the new culture.

" To this end, we shall compare the neat produce of the three farms mentioned in the foregoing article, in this year 1756, with that of the fields which I have laid out in beds.

" In consequence of the general opinion that dung, or any kind of manure, contributes greatly to fertilize land, and makes it produce more than it would otherwise do, it is to be observed, in the first place, that part of the land of the three farms was dunged, and that my fields, cultivated in beds, had not had any dung or other manure for many years.

" Secondly, that the lands of the three farms are always fallowed every second year; whereas my fields have been sown every year since they first began to be cultivated in the new way, and have already borne several crops running.

" Thirdly, it should be considered, that the year 1756 was extremely rainy: a circumstance by no means favourable to strong stiff soils, like mine; and at the same time rather beneficial than hurtful to the three farms, a great part of which is light land, which requires frequent rain.

" Lastly, the reader will remember, that about a third part of the second farm was overflowed, whereby the crop was diminished: but, on the other hand, I think this damage is pretty nearly compensated by the accidents which happened to my field, (experiment Numb. IV.) which certainly lessened the crop considerably.

" These reflections seemed to me necessary, in order to give a just idea of the comparison I am going to make, which, I believe, will be sufficient to prove what I purposed to shew."

Comparison of the Produce of Land sown in equally distant Rows with the Drill-Plough, with that of other Land laid out in Beds.

" The neat produce of the three farms, containing about 169 acres, which were sown in equally distant rows with the drill-plough, was, after deducting the seed,

		Pounds.
Of the	First farm — — — — —	69732
	Second farm — — — — —	15456
	Third farm — — — — —	26550
	Total neat produce —	111738

" Neat produce, after deducting the seed, of the fields laid out in beds, and sown with the drill-plough; with the number of each experiment, and the measure of each field.

					Pounds.
EXPERIMENT, Numb. 2.	—	1½ acre		—	1834
4.	—	15	—	—	2824
5.	—	7½	—	—	2156
6.	—	2½	—	—	627
7.	—	15	—	—	5750
8.	—	1	—	—	1850
9.	—	6	—	—	1924
10.	—	6	—	—	2352
In all		54 acres.			
Total neat produce in 1756				—	19317

" After the beds are once formed, the same fields are sown every year: consequently these will produce another crop in 1757, which, supposing it to be only equal to the last, though there is great reason to think it will be much better, will again be — — — — —	19317
" Fifty-four acres will then produce neat, in two years — — — — — — — —	38634

" The 169 acres of the three farms sown in equally distant rows with the drill-plough, will not produce any thing in 1757, that being their year of fallow; consequently their neat produce in two years, will have been only 111738 pounds of wheat, whilst the fifty-four acres made into beds, will have produced 38634 pounds. But supposing the 169 acres to have been cultivated in beds, and their produce to have been in the same proportion as that of the fifty-four acres, it would amount to 134769 pounds, which is 23031 pounds more than they produced when sown in equally distant rows with the drill. This difference ought never to be forgot.

" The new method of laying the land out in beds, has still greater advantages than this. Our comparison has been only of the neat produce of 169 acres, which were sown the same year in the three farms: but it is to be observed, that these farms consisted of 169 acres more, which were under fallow for the next year's crop. The neat produce of the crops of those 338 acres in the two years of sowing them in equally distant rows with the drill-plough, supposing both crops to be equal, would be

	Pounds.
For the first year, 169 acres — —	111738
For the second year, for the other 169 acres	111738
For the two years — — —	223476

" If these 338 acres were laid out in beds, they would be sown each year, and their neat produce, supposing both years alike, would be,

	Pounds.
For the first year, 338 acres — —	134769
For the second year, 338 acres —	134769
For two years — — —	269538

" So that this calculation proves plainly, that the 338 acres will produce 46062 pounds of wheat more when cultivated in beds, than when sown in equally distant rows with the drill-plough: a difference which, in ten years, will amount to 230310 pounds of grain.

" As great as this advantage is in favour of the beds, it will appear very small when compared to that which the culture in beds has over the Old Husbandry: as the following calculation will shew.

" Let us first settle what would have been the neat produce (by which we always mean that which remains after deducting the seed) of the 169 acres of the three farms, for one year; and afterwards that of the other 169 acres the next year, supposing both crops to be equal.

" We have already seen that the produce of 169 acres would, at most, not have exceeded 55200 pounds of wheat, in 1756. But as that was a bad year, I will make the following comparison on the footing of a good crop, in order to give the Old Husbandry every advantage that can possibly be desired. I will therefore suppose the neat produce of 169 acres to have been the first year

	Pounds.
	76000
And that of the other 169 acres, the next year — — — — —	76000
For the two years —	152000

" We have seen that the same 338 acres cultivated in beds, reckoning their neat produce for two years only on the footing of the bad crop of 1756, would have yielded 269538 pounds of wheat; consequently this culture would have produced in two years 117538 pounds of corn more than the Old Husbandry; and this difference, in ten years, would amount to 587690 pounds.

" The great advantage of the New Husbandry, in general, and that of laying the ground into beds, in particular, is, I think, now fully proved. The difference is great indeed! But I believe it will be still much greater hereafter, when the yearly observations of the followers of this new way, whose number increases daily, shall have brought this culture to a greater degree of perfection; which I hope will, in some measure, be the case next harvest."

Result and Comparison of divers Experiments in Agriculture made at Fontclaire, *near* Avignon, *by* M. d'Elbene, *in the Years* 1757, 1758, *and* 1759. *Communicated to* M. Duhamel, *and published by himself in his Book, entitled, Culture des Terres, Tom.* VI. *C.* I. *Art.* 17.

EXPERIMENTS *made in* 1757.

" The principles of the New Husbandry seemed to me so well established, that I resolved to practise it. To this end, I took into my own hands the farm I am now going to speak of, in 1756; and, not to burthen myself with so considerable a detail as must of course arise from the number of labourers necessary to cultivate such an extent of ground, I divided the greatest part of it into lots, which I assigned to peasants who undertook to perform by hand most of the work that was to be done, and to be at all the expence of harvesting, to the laying up of the corn threshed and winnowed, in consideration of one half of the produce.

" The share of each of these peasants was about three acres, of which one half was to lie fallow every year. They took great care to portion out the land in such manner that the good and bad were equally divided among them.

" Some fields of an excellent quality were not included in this distribution; but the farmers to whom I entrusted them promised me two hundred pounds of wheat for every acre, over and above the half of the product.

" I destined two fields, one of which was pretty good, and the other very bad, to be laid out in beds.

" M. de Chateauvieux was so kind as to send me the ploughs, drill, and cultivator, which he has invented: but I did not receive them in time for this year's preparation of the ground, which had but two ploughings.

" I began to sow a small part of my fields, according to the new method, on the 19th of August. The rest was sown before the 25th of September, and the peasants sowed theirs in the beginning of October.

" The autumn was rainy, and favourable to the rising of the corn, which made a great progress before the beginning of winter: but this season proved so very wet and cold, that my plants suffered greatly in those lands where they are apt to be forced out of the ground by frost: many of them were absolutely torn up in several fields sown according to the old way, or in equally distant rows with the drill plough; and seven or eight acres were stripped entirely of all their growth.

" The beds, being arched, escaped unhurt, because the wet did not settle upon them. Favourable weather in the spring, accompanied with gentle rains, repaired the mischief which the winter had done, wherever any plants remained.

" The wheat in the new way began to ear on the 20th of April; and that in the old way, on the 5th of May. The grain was full grown by the end of this month. Frequent rains and dews which fell in June kept the earth cool, without too much hastening the corn, which was reaped between the 21st of June and the second of July. The sheaves were very long, very heavy, and yielded plentifully in all my land: I found pretty commonly, in my beds, ears which had from eighty to ninety fine plump grains: but in my other ground, the largest did not contain above twenty-five, and part of them was shrivelled.

" The crops were but indifferent in this country, in general. They were very bad in several places; and those of my neighbours who had the best, looked upon this as a middling year. As I had found it a very good one in this farm, I was desirous to ascertain the degree of advantage arising from good culture; for I could not impute the superiority of my crops to any other cause. To this end I computed what these same lands had produced when cultivated in the same way as all others still are in these parts. I could easily do this, as my father, grandfather, and great-grandfather had kept very exact accounts of all their crops, and the original papers relating thereto are now in the hands of my father at Avignon. I there found the whole detail, year by year, ever since 1677, and carefully made from thence the following calculation.

Result of the Produce of the Lands of this Farm from the Year 1677, to 1756, inclusively.

The quantity of land sown in this space of time was	4660 acres.
With - - - - - -	875887 l.
Which yielded - - - - -	2914987 l.
The neat produce, after deducting the seed, was	2039099 l.
But as only one half of the land of this farm was sowed every year, whilst the other half lay fallow, it is evident that this quantity of corn was produced by double the land above-mentioned; that is to say, by	9320 acres.
Which produced - - - - -	2039099 l.
The farmer had half of this product, for the expence of culture. Consequently the landlord had but	1019549 l.
From whence it follows that the landlord received for each acre of land	109 l. 6 oz.

Produce, from 1677, to 1756.

" To estimate this produce in money, I suppose the price of the finest wheat to have been constantly at eight shillings and nine-pence for an hundred pounds weight, which is the medium value in these provinces. The corn of which I now speak was not worth so much; a considerable quantity of oats and rye being included in the above product, and likewise the siftings, which are, taking one year with another, from fifteen to twenty per cent. An exact calculation of the neat produce of some years proved that this diminution was from thirty-five to forty per cent. but to avoid all error, I deducted only thirty per cent. from the fixed price of the finest wheat. This gave me six shillings and three halfpence for an hundred pounds of my corn, and six shillings and eight-pence for the 109 pounds above-mentioned, which was the medium annual produce of each acre of land during the space of eighty years.

" By thus calculating the crops every year, I was enabled to know the advantage of each different kind of culture. The greatest part of my farm was sowed in the old way in 1756; a small portion of it was sowed in equally distant rows with the drill-plough, and only two pieces of ground were managed according to the principles of the New Husbandry.

Produce, in 1757, of the Land sown in the old Way.

I sowed - - - - - - - - - - - -	58 acres.
With - - - - - - - - - - -	9722 l.
They produced - - - - - - - -	55849 l.
Deducting the seed, there remained -	46127 l.
Abating half of this for the year of fallow, in which these lands do not produce any thing	23063 l. 8 oz.
And likewise the husbandman's half, I had, as landlord	11531 l. 12 oz.
So that each acre of land yielded me -	198 l. 13 oz.
Or, at six shillings and three halfpence the quintal, for the reasons before mentioned	12 s. 2 d.

Produce, in 1757, of Land sown in equally distant Rows with the Drill-Plough.

I sowed - - - - - - - - - - - -	2 acres and ½
With - - - - - - - - - - -	198 l. 12 oz.
Which produced - - - - - - -	2400 l.
Deducting the seed, there remained -	2201 l. 4 oz.
Of which abating half for the year of fallow	1100 l. 10 oz.
And deducting also the labourer's half -	550 l. 5 oz.
I had, for the produce of each acre, -	220 l. 2 oz.
Worth, at 6 s. 3 halfpence the quintal,	13 s. 6 d.

Produce,

Produce, in 1757, of the Land sown according to the Principles of the New Husbandry.

I sowed - - - - - - - - - -	5 acres and ½
With - - - - - - - - - -	110 l. 10 oz.
Which yielded - - - - - - -	4837 l. 8 oz.
Deducting the seed, there remained, -	4726 l. 14 oz.
And abating only half of this, for the husbandman's share, because this land is never fallowed, I had, as proprietor	2363 l. 7 oz.
So that my product from each acre, was	411 l. 1 oz.
Which, at 7 s. and 10½ d. the quintal, at which I rate it for the following reasons, makes	32 s. 4½ d.

" I did not think it right to deduct here the thirty per cent. from the medium price of the finest wheat, because all this last was perfect grain, quite clean, and entirely free from any mixture of seeds of weeds; whereas I had not only reaped rye, oats, and barley, among that which was raised in the old way; but the siftings there were very considerable, and the corn, even after that, was not near so fine as the growth of the New Husbandry. I deducted however ten per cent. from the price of the very best wheat, that I might not be any way partial to this method, though I sold its produce at the highest price.

" The advantage of the New Husbandry was infinitely greater than I expected. I am sure that my reckoning is right; for my lands were distributed in such manner that I could not mistake. Each peasant laid his sheaves in a separate heap, threshing them, winnowed their grain, and divided the product with me. My sheaves were also piled up, threshed, and winnowed apart, and their produce was measured before all my servants and a number of peasants, who were astonished at it.

" It is true, that I mixed the sheaves reaped from the ground sowed in equally distant rows with the drill-plough, with those of the beds: but I reckoned before hand the quantity of each, as I could easily do by means of the tythe, which is every twelfth sheaf, and made my calculations according to the number of the sheaves, though those of the beds certainly contained the most grain.

" Some of my neighbours, determined by the great superiority, which they had observed from the very first of my corn in the beds, beyond all the rest, resolved to practise the New Husbandry: but most of them were deterred by a notion of its being too expensive. This objection deserved serious attention. I therefore, to know how far it was really founded, calculated the expence of each kind of culture in a manner less subject to error than any former way of reckoning. I supposed all the work to be done by day-labourers; and I had thereby a sure means of comparison, by supposing, as I could easily do with certainty, the quantity of work which a plough or a man did in a day, and how much each of them earned.

" I made this calculation in 1758, and sent a copy of it to M. de Chateauvieux: but as I had forgot to notice there the charges of weeding and reaping, which are articles of considerable expence, I have inserted that omission in the following more careful computation.

" *Expence of the first Year's Culture of an Acre of Land, when it is first laid out in Beds.*

	l.	s.	d.
" To give an acre of ground that perfect tilth which M. de Chateauvieux describes, will cost, in this country, including the expence of weeding, performed by hand with hoes four inches wide (which will stir the ground pretty well) and all the charges of harvest, to the laying up of the corn winnowed and cleansed	2	3	3
" The culture which I intend to practise, and which consists in only the four first ploughings of the above article, with the same expences of weeding and harvesting, costs	1	12	8
" The culture which I gave to my land in 1756, consisting in one ploughing in broad lands, and a second to arch up the beds, with the expence of weeding and harvesting, as above, cost me - -	1	3	4
"Two ploughings in broad lands in 1757, with the same expences as before in other respects, cost me - - - -	1	8	7½

" *Annual Expence of cultivating an Acre of Land after the Beds are formed.*

	l.	s.	d.
" To bring an acre of land to perfect tilth, by giving it five ploughings, three of which are performed with the plough, and two with the cultivator in the alleys, and a sixth thorough ploughing of the whole ground immediately after harvest, will cost, with the same expences of sowing, weeding and harvesting, as before mentioned - -	1	2	7
" I have not yet given this general ploughing to the whole of any of my fields; but have hitherto restricted the sixth ploughing to the alleys only. This, with the same expences as before for all the rest, has cost me	1	0	0

" *Expence of cultivating an Acre of Land according to the Old Method.*

	l.	s.	d.
" It is proper to observe, that, in all the following calculations, I have charged the husbandman with only half the real cost of each kind of culture for each year, because the lands, being rested alternately, are cultivated only every other year. I give a peasant four acres of land to cultivate, and he ploughs two of them every year. The culture of these two acres cost him (at 2 l. 12 s. each) 5 l. 4 s. which is after the rate of 1 l. 6 s. a year for each of his four acres			
" The perfect culture of our peasants, who give the ground five stirrings by hand, the first with a kind of spade (with which they dig twelve or fourteen inches deep) and the four others, including that which serves to bury the seed, with a sort of hoe or mattock (which stirs the earth eight or ten inches deep) costs, with the usual expences of weeding, getting in the harvest, and cleansing the corn - - - -	1	6	3
" The culture of the peasants, which is now practised throughout the whole of my estate, consists in four stirrings of the earth, the first of which is performed with their spade, with which they are so idle as not to dig deeper than seven or eight inches: the second is given with a kind of hoe, which does not penetrate above five or six inches deep; the third with the common plough of this country, without wheels or mould-board, which even when drawn by the strongest mules, can never enter deeper than five or six inches; and the fourth, which serves to bury the seed, either with that plough or their hoe, which ever they like best. Their expences of weeding, reaping, &c. are the same as in the foregoing article, and it costs them in all for each acre of land - -	0	18	4
" Within these few years past, some more careful husbandmen give the first stirring with a plough with one wheel and a mould-board, drawn by six stout mules. This cuts seven or eight inches deep; and they perform the five other stirrings with their common plough. Their expences of weeding and harvesting are the same as those of the peasants, and each acre costs them	0	15	7
" Some give but two ploughings instead of five, with the common plough of this country. Their expences are the same in other respects, and the acre costs them	0	11	6

" The generality of our husbandmen do not yet use wheel-ploughs. The most diligent among them give six ploughings with the common plough of this country. Their

	l.	s.	d.
expences for weeding and getting in the harveſt are the ſame as above, and the acre ſtands them in - - -	0	13	5
"The ſlothful, who, unhappily, are the greateſt number, give their land only three ploughings with our common plough: but as they cannot avoid the expence of reaping and houſing their corn, each acre coſts them	0	9	2

"The charge of tillage is not near ſo great to thoſe who aſſiſt perſonally at the work, or even to thoſe who keep their own labourers and cattle. A minute examination of this point induces me to think, that it does not coſt the former above half, nor the latter above two thirds of the ſums mentioned in the foregoing accounts.

"From hence it follows, that every huſbandman will be repaid his diſburſements whenever his ſhare of the product, which is always equal to that of the landlord, is, for him who labours perſonally, one half, and for him who does every thing by his ſervants, two thirds of the above ſums; and that he will find a very conſiderable advantage in practiſing any method of which the product will repay his advancing money to day-labourers to do the work.

"A proof of this is, that the peaſants who tilled my lands were very well ſatisfied with their gain, though their expences amounted to eighteen ſhillings and fourpence, and like me, they cleared but thirteen ſhillings and ſixpence by each acre of ground.

"Where the land was ſowed in equally diſtant rows with the drill-plough, the expences were the ſame as in our common way; but the profit was greater.

"Though the expences of the New Huſbandry, where the land was laid out in beds, amounted to 1 l. 3 s. 4 d. an acre; yet it was more advantageous to the huſbandman, who cleared, as I did in quality of landlord, 1 l. 12 s. 6 d.

"We ſee, however, by theſe calculations, and the fact really is, that ſuch expence attends the laying of land out in beds, as may very often not be repaid the firſt year; but when the New Huſbandry is once eſtabliſhed, thoſe expences leſſen; and it appears that the cultivator will find his account in practiſing it, as much as the owner of the land.

Experiments *made in* 1758.

"My ſucceſs determined me to increaſe the number of my beds. I prepared, more carefully than the year before, a large piece of land, the ſoil of which was bad, and of which my farmers uſed always to ſow a part with rye or oats. Several peaſants adopted the method of ſowing in equally diſtant rows with the drill-plough. I ſowed my lands in the New Huſbandry in the month of September, and my other fields in October. The earth was ſtill gravelly, in poor tilth, and wanted moiſture. No rain fell during the months of September, October, and November. The corn roſe but indifferently even in the beſt prepared ſoils, and ſcarce a fourth part of it roſe in the common fields. It made very little progreſs before winter, and was not forwarder in the middle of January than it commonly is a fortnight after being ſown. We had, however, in December, and in the beginning of January, ſome ſlight rains, which, though they did not penetrate far into the earth, were ſufficient to make ſome of the corn that had not yet appeared, ſprout, and even to give the country a greeniſh hue. Froſts, which laſted from the 18th of January to the fourth of February, with ſuch ſeverity as is ſeldom known in this country, ſoon baniſhed this gleam of hope. They were accompanied with an impetuous north wind, which added greatly to the violence of the cold. I viſited my corn as ſoon as the weather began to grow a little mild, and found its blades abſolutely withered, though I ſtill diſcovered, with difficulty, a yet green part in the heart of ſome of the plants: but half of them were ſo totally deſtroyed, as not to retain the leaſt ſign of verdure. In ſome places, which were ſheltered from the wind, the blades were not at all withered, which made me think that the miſchief done to the reſt might proceed from ſome pernicious quality in the ſharp wind, rather than from the froſt.

"Though the plants were dead, they ſtuck faſt in the ground, and none of mine were either rooted up, or laid bare by the froſt. The great drought preſerved them from this accident, which would have totally ruined all the corn.

"The thaw was without rain, of which we had not any till the 14th of April, when it might have been of ſervice to the plants, but that ſnow (a phenomenon almoſt unknown here, even in the winter) fell on the 17th, and was followed by a hard froſt, which laſted two days, and not only prevented the good effects which we expected from the rain, but likewiſe did conſiderable hurt to all the productions of the earth, which, though they did not immediately appear to have been injured thereby, grew but poorly afterwards.

"My corn in the New Huſbandry, where the intervals between the beds had been hoed at the end of February throve well, and began to look promiſing: but within a few days after the froſt, I perceived marks of its being rickety, and this diſtemper ſoon made a rapid progreſs.

"The wheat in the common way, even in the beſt ſoils, was very thin, had not tillered, and was ſtill in nearly the ſame condition as at the end of the winter.

"The rain which fell on the 23d of April did not do any good, nor had we any more of it from that time till the 27th of May. The corn was then in a deplorable condition: the ears of that in the New Huſbandry were beginning to appear; the winter had not left a third part of the plants, and moſt of thoſe that did remain were ſtinted and quite rickety.

"The lands in the old way promiſed ſtill leſs. The plants there, beſides continuing to be very thin, were crooked and rickety, and ſeemed ſcarcely able to put forth their ears.

"Thirteen acres of extraordinary good land, the culture of which was not begun till after the froſt on the 19th of April, were the only ſpot that afforded ſome little hope. 'Till that froſt, the wheat in the beds was greatly ſuperior to any in this ground. Could the cauſe of this alteration proceed from the froſt's acting more powerfully upon, and conſequently doing greater injury to, the plants which were in full ſap, and whoſe ſhoots were yet tender, than on thoſe where the ſap was not yet in motion, and which had not yet begun to ſpindle? I thought ſo, and to me it ſeemed probable.

"Buſineſs obliged me to be abſent during the firſt fort'night in June, and I was greatly ſurpriſed at my return to find the corn, which had ſcarcely begun to ear when I left it, almoſt ready to ripen. Cold dews followed by great heats, and perfectly ſcorching weather which we had from the 6th to the 12th of June, joined to the dryneſs of the earth, occaſioned this ſudden change.

"A violent north-eaſt wind, which blew impetuouſly from the 18th to the 21ſt of June, completed our misfortunes, by ſhedding great part of the corn which bid faireſt to ſucceed. The loſs occaſioned by this accident was valued at one-third of the crop: nor could it well be leſs; for, after ſome ſhowers which fell in July, the whole field was covered with young plants, as thick as if they had been ſown upon the ſtubble.

"The crop was reaped between the 21ſt and 29th of June. It could not be a good one after ſuch adverſe events; nor was I, conſequently, ſurpriſed at finding the reſult of it different from that of the preceding year.

Product, in 1758, *of the Lands ſowed in the old Way.*

'I have kept a ſeparate account of one part of theſe lands, conſiſting in meadow ground newly broken up, and a field that was dunged all over in 1756, which never happened to any other, either wholly or in part. The peaſants charged with the culture of this part engaged to give me two hundred pounds of grain over and above the half of the product.

"*Product*

"*Produce, in* 1758 *of the very good Lands sown in the Old Way.*

I sowed - - - -	13 acres.
With - - -	2424 l. 6 oz.
Which produced - - -	10005 l.
Deducting the seed, there remained	7580 l. 10 oz.
Abating half of this for the year of fallow - - -	3790 l. 5 oz.
And also half of this remainder for the labourer's share, I had, as owner of the land - - -	1895 l. 2 oz.½
So that each acre yielded me -	145 l. 12 oz.½
Worth in money, at six shillings and three halfpence the quintal	8 s. 11 d.½

"The labourer, being obliged by our agreement to give me part of his half, had, in reality, but 46 l. which may be valued at 2 s. 9 d.

"*Produce, in* 1758, *of the ordinary Lands sown in the Old Way.*

I sowed - - -	25 acres.
With - - -	4316 l. 4 oz.
Which produced - -	8760 l.
Deducting the seed, there remained	4443 l. 12 oz.
Allowing half of this for the year of fallow	2221 l. 14 oz.
And half of the remainder for the labourer's share, I had, as landlord	1110 l. 15 oz.
Which makes for each acre -	44 l. 4 oz.½
Worth in money, at six shillings and three halfpence the quintal	2 s. 8 d.½

"I afterwards united these two calculations, in order to have the total product of my lands sown in the old way, and found it to be as follows.

"*Produce in* 1758, *of all the Land sown in the Old Way.*

I sowed - - - -	38 acres.
With - - -	6740 l. 10 oz.
Which produced - -	18765 l.
Deducting the seed, there remained	12024 l. 6 oz.
Allowing half for the year of fallow	6012 l. 3 oz.
And half of this for the labourer's share, I had, as landlord	3006 l. 1 oz.½
Being, for each acre - -	79 l. 2 oz.
Which in money, at six shillings and three halfpence the quintal, is equal to	4 s. 8 d.½

"*Produce in* 1758, *of the Lands sown in equally distant Rows with the Drill-plough.*

I sowed - - -	9 acres.
With - - -	916 l. 14 oz.
Which produced - -	3406 l. 14 oz.
Deducting the seed, there remained	2490 l.
Allowing one half of this for the year of fallow	1245 l.
And deducting again the labourer's half, there remained	622 l. 8 oz.
I received as landlord for each acre, in corn	69 l. 2 oz.
And in money, at six shillings and three halfpence the quintal	4 s. 3 d.

Note, I have included here the product of two thirds of an acre of meadow land newly broken up, which yielded seven times the seed.

"*Produce in* 1758, *of the Lands sown according to the New Husbandry.*

I sowed - - -	18 acres and ½
With - - -	703 l. 4 oz.
Which produced - -	2250 l.
There remained, after deducting the seed	1546 l. 12 oz.
And allowing half of this for the labourer, as the lands in this husbandry are never fallowed, there remained for the landlord	773 l. 6 oz.
Being for each acre in corn	41 l. 11 oz.½
And in money, at 7 s. 10 d.½ the quintal	3 s. 3 d.¼

"Our very unfavourable seasons could not but affect the crops; nor was it possible that any kind of culture should guard against the repeated accidents which befel my corn. The misfortune extended to all the neighbouring provinces, and wheat, which had not been at above nine shillings and two-pence farthing the quintal, for several years past, rose to thirteen shillings and three halfpence, and kept at this price during the whole year, notwithstanding that there was a great deal of old corn in all the granaries, and quantities arrived from other countries.

"This unseasonable weather was not only fatal to the corn, but likewise to all vegetation. Though the leaves of our mulberry trees did not seem to have been much hurt by the frosts in April, they were, however, so damaged, as to become pernicious to the silk-worms, which did not succeed any where. The winter killed all the clover in our fields; we had very little early crops of hay; not any spring corn, and scarcely half the usual quantity of wine and oil: even our saffron, which is a considerable article in this country, produced very few flowers: in short, the oldest man could hardly remember so bad a year. The New Husbandry did not fare better than the Old: it could not resist the rigour of the cold, which destroyed very many of the plants, and all the blades of the corn. The frosts in April were still more fatal by the rickety distemper which they occasioned; and the high winds in June did greater hurt to the wheat in the beds, where the grain was least shrivelled, than to that in the old way. It appeared from an estimate of a number of ears taken as they came, without culling them, that half the product of the beds was lost through this last accident.

"Notwithstanding all these misfortunes, when it is considered, that two thirds of my fields in the New Husbandry were my worst lands, and that the whole of them cannot be compared with those of the farm in general, and much less with lands of the very best quality, it will be found, that this method afforded a profit, though not such as to induce one to prefer it to all others.

"I had already prepared another field of about four acres, in order to lay this likewise out in beds, as in fact I did: but I resolved to wait the event of the year 1759, of which I am now to speak, before I proceeded farther in this method.

Experiments *made in* 1759.

"Rain, which we wanted before harvest, came after it, in such abundance, that all work in the field was suspended during the whole summer.

"Twelve acres of my land in beds suffered greatly by an inundation of the Oveze, a neighbouring river, which overflowed its banks on the 6th of July. The water drowned entirely all this ground, and washed away the summit of the beds in several places. The plough could not begin to work till September; and though the culture which I then gave formed new ridges, yet it could not pulverise the earth, or arch up the parts intended to be sown, which, in many places, were settled lower than the stubble.

"I sowed all my lands in the New Husbandry within the first fortnight in September, and those in the old way before the middle of October. The autumn was very rainy, and consequently favourable to the sprouting of the corn, which was however somewhat too thin in the part that had been overflowed. The plants in the beds were very fine in the beginning of December (at which time I was obliged to lose sight of them) excepting the field of about four acres, which was now sown for the first time in this way, but with two turns of the drill-plough, and in which the corn began to be rusted. I did not return to this farm till the middle of April.

"The winter had been very mild and wet. I found the corn in the beds very fine, and superior to all the rest, but too thin in the places which had been damaged by the flood. The field which began to be rusted in autumn, was now more so, and promised little; but, through the negligence of my servants, the alleys wanted stirring, and

and weeds choaked the corn in ſeveral places. I endeavoured to remedy this by good hoeings and careful weedings, which could not be performed in this advanced ſeaſon, without pulling up many of the plants of corn. Notwithſtanding all of my endeavours to correct the evil, I am perſuaded that this neglect coſt me a part of the crop I might otherwiſe have had.

"We had a good deal of rain on the firſt and ſecond of May; but a ſharp north-eaſt wind, which blew violently during the reſt of that month, hurt the corn greatly when it firſt began to ſpindle, and dried the earth at a time when we never find it too moiſt.

"Gentle rains and plentiful dews, which fell in the beginning of June, ſucceeded this ſtormy weather, and ſeemed to remedy the miſchief which the high winds had done.

"The wheat was cut between the 16th and 27th of June. Its ſtraw was ſhort, though long enough to bind up in ſheaves, which looked well. The grain was plump, and of a very good quality. The only complaint was of its being mixed with a great quantity of darnel.

"We had hopes of a plentiful harveſt. The price of wheat fell at once, towards the end of June, from thirteen ſhillings to ſeven ſhillings and ten-pence the quintal; but by the middle of July it roſe to twelve ſhillings and three-pence, and ſtill keeps at that price in the preſent month of January, 1760, notwithſtanding the immenſe quantities which arrive here daily from other countries.

"Our flattering hopes ſoon vaniſhed. The ſheaves yielded but very little grain, and the harveſt proved extremely bad, contrary to the expectation of every one. I endeavoured to trace the cauſe of this miſtaken opinion, and found it to be, that our huſbandmen had judged by the length of the ears, without conſidering that a great many huſks were ſo empty as not to have the appearance of corn in them. This accident ſeemed to me to have been occaſioned by the plants having loſt their bloſſoms, through the impetuoſity of the winds, which never ceaſed to blow with great violence during the whole time that the wheat was in bloom, and whilſt the grains ſhould have kerned.

"The corn in the New Huſbandry was equally affected by theſe adverſe events; but its ears were better filled with grain, than thoſe of the wheat raiſed in the old way.

"The people in theſe parts look upon this year as having given but half a crop: mine was tolerably good.

Produce, in 1759, of the Lands ſown in the old Way.

I ſowed - - - - - - - - - -	23 acres
With - - - - - - - - - -	3731 l. 4 oz.
Which produced - - - - - -	17202 l. 8 oz.
Remained, after deducting the ſeed -	13471 l. 4 oz.
Allowing half of this for the year of fallow	6735 l. 10 oz.
And half of the remainder for the labourer	3367 l. 13 oz.
I had, for each acre of land - - - -	146 l. 7 oz.
And in money, at ſix ſhillings and three-pence the quintal	9 s.

Produce, in 1759, of the Lands ſown in equally diſtant Rows with the Drill-Plough.

I ſowed - - - - - - - - - -	20 acres. ½
With - - - - - - - - - - -	2353 l. 2 oz.
Which produced - - - - - -	19221 l. 14 oz.
Deducting the ſeed, there remained -	16968 l. 12 oz.
Allowing half of this for the year of fallow	8484 l. 6 oz.
And half the remainder for the labourer's ſhare	4242 l. 3 oz.
I had, for each acre - - - - -	206 l. 15 oz.
And in money, at ſix ſhillings and three halfpence the quintal	12 s. 3½ d.

Produce, in 1759, of the Lands ſown according to the Principles of the New Huſbandry.

I ſowed - - - - - - - - - -	24 acres.
With - - - - - - - - - - -	1261 l. 14 oz.
Which produced - - - - - - -	12150 l.
Deducting the ſeed, there remained -	10888 l. 2 oz.
And only half of this for the labourer's ſhare, as theſe lands are not ever reſted, I had	5444 l. 1 oz.
Which is for each acre of land - -	227 l. 7 oz.
And in money, at 7s. 10½ d. the quintal	17 s. 9 d.

"I may, perhaps, be thought to favour the New Huſbandry in my eſtimate of its produce, in money: but I can aver that, this year, my land in beds, though part of it was deemed fit for rye only, produced nothing but very fine wheat, which ſold at market for twelve ſhillings and three-pence the quintal. My lands ſown in the old way, or in equally diſtant rows with the drill-plough, produced 4200 pounds of oats, 900 pounds of barley, and 800 pounds of rye. The ſiftings of my wheat raiſed in the Old Huſbandry amounted to a twelfth part of the crop; ſo great was the quantity of darnel mixed with it: a quarter part of the remainder ſold only at the price of rye, and the very fineſt part of it fetched no more than 10 s. 6 d. the quintal, at the very market where the wheat of my beds ſold for 12 s. 3 d. without having been ſifted.

"I have, however, deducted ten per cent. from the wheat of the New Huſbandry, though it ſold at the higheſt price, and have abated only thirty per cent. on that of my other lands, though an exact calculation proved to me that the loſs upon it amounted really to thirty-three per cent.

"The dearneſs of corn this year increaſed the price of all the productions of the earth to above one third more than before: a circumſtance which added conſiderably to the value of every advantage in huſbandry, as the expences attending this were ſtill the ſame.

"The reſult of theſe three years afforded a manifeſt evidence of the benefits which accrue from good tillage, and ſeems to prove plainly the ſuperiority of the drill-plough over the common method of ſowing, and that of the New Huſbandry over the Old.

"The harveſt in 1757 was but middling throughout this country, and good in my farm only. It was bad in 1758, becauſe nothing could poſſibly guard againſt ſuch adverſe weather as we then had. In 1759, no one in theſe parts had ſo good crops as mine were. Theſe ſucceſſes cannot be aſcribed to any other cauſe than the manner in which my lands have been cultivated.

"The diſtribution of my lands proves likewiſe evidently the advantage of ſowing in equally diſtant rows with the drill-plough. My peaſants ſpared no pains to render their reſpective portions equally fruitful. They cultivated them in the ſame manner, excepting only in the ſowing of the ſeed, where the drill-plough, ſowing in equally diſtant rows, always yielded a greater profit than the common way.

"The lands ſown in beds yielded ſtill more grain than thoſe ſown either in the old way, or in equally diſtant rows with the drill, in 1757 and 1759. This advantage cannot have been owing to any other cauſe, as I did not uſe dung any where; the culture there was not performed more carefully than in my other grounds; it coſt very little more than that of the peaſants; and a part of the fields in beds is known to be ſome of my worſt land, for which reaſon my farmers had always uſed it for rye.

"The year 1758 was ſo fatal to all the productions of the earth, that we ought rather to wonder at our having had a crop, than at its being very ſcanty.

"I may juſtly flatter myſelf that my ſucceſs will be ſtill greater in future years: my culture is improved by practice, my lands are brought into better tilth, my peaſants become accuſtomed to the new method, their repugnance to it leſſens, and I daily ſee faults of my committing, which now are leſſons to me.

"I was long perplexed about the proper time of ploughing in the ſtubble: but various trials induce me now to think, that this ſhould be done immediately after harveſt. It is what I ſhall practiſe for the future, and I recommend it to all who follow the New Huſbandry. It cannot be done after ſowing, becauſe ploughing then would bury the ſeed; and if it be performed only a little before ſeed time, the clods and ſtubble will neceſſarily obſtruct the operation of the drill-plough.

"My trials during theſe three years have convinced me, that the quantity of ſeed ſhould be diminiſhed in proportion to the goodneſs of the ſoil. The contrary cuſtom prevails in this country, becauſe, ſay our farmers, the richer the land is, the more plants it can nouriſh: but my experience during theſe three years has invariably proved to me that this is a vulgar error."

EXPERIMENTS *made near* Guignes, *in the Province of* Brie, *under the Direction of* M. Rouſſel, *and communicated to* M. Duhamel *in* 1755.

"M. Rouſſel prudently began, as we would advice every one to do, with ſmall experiments. His firſt trial of the New Huſbandry was upon a little ſpot: but being prevented from attending to it in perſon, many faults were committed during his abſence. On his return, which was towards the end of November 1754, he inquired after his crop, and learnt with pleaſure, that ſome grains had produced upwards of ſixty ears a-piece, and that many of theſe ears contained ſixty-four grains. This was ſufficientto ſhew him the excellenceof the new culture, which he immediately determined to extend to larger objects.

He had no time to loſe. Two contiguous pieces of ground, containing twenty-four acres, had been folded, and were juſt going to be ploughed for the laſt time, in order to be ſown according to the uſual practice of the country. Theſe were choſen for the farther trial of the New Huſbandry, and were accordingly ſown with the drill-plough, between the ninth and twenty-firſt of October, with 571 pounds of wheat, including ten pounds and an half, which were uſed to fill up ſome ſpaces where the ſeed had miſſed. This is after the rate of about twenty-four pounds to an acre.

At the ſame time, an adjacent piece of ground, which had been folded like the former, and of which the ſoil was equal to the beſt part of the field ſown in rows, was ſowed in the common way. This laſt contained four acres and a half, and took up, 486 pounds of ſeed, which is 108 pounds to an acre.

The corn came up finely in both fields: but that which was ſown in rows happened to be near a wood, from which numbers of rabbits came, and entirely deſtroyed the plants of near five acres: the roots which they left, were eaten up by worms: and the dung of the ſheep-folds produced a great quantity of weeds. This was not all: as the furrows did not run in the direction of the declivity of the ground, the water lodged in them, ſo that the firſt ploughing, which ought to have been given in March, could not be performed till April, when it left a great many clods.

Theſe clods were grown hard by the time of the ſecond ploughing, which was performed with a plough with two mould-boards, which inſtead of breaking and looſening the ground, and laying freſh earth to the roots, only turned thoſe hard clods over upon the rows.

The third ploughing, which was given with a plough with two ſhares, and in more favourable weather, had a better effect.

Notwithſtanding the accidents which had reduced this piece of wheat to ſo wretched a condition, that the huſbandmen ſaid they were ſure it never would produce a crop worth reaping, and that all the labour beſtowed upon it was thrown away; yet, reckoning upon the ſame footing of twenty-four acres, though it would be but juſt to deduct the five which were abſolutely deſtroyed by the rabbits; and ſuppoſing too the crops of 1756 and 1757 to be no greater than that of 1755; M. Rouſſel's calculation proves, that even theſe three crops will ſtill be better than what the ſame field would produce in the common way.

But, ſays M. Rouſſel, if we do the New Huſbandry part of the juſtice it deſerves; and inſtead of including the five acres which the rabbits deſtroyed, we reckon only the produce of nineteen acres prepared in a hurry, and badly ploughed; and even ſuppoſe them to be no better managed in the following years, and the whole extent of the 24 acres, to be only of the ſame quality as the four acres and a half with which it was intended to be compared; the produce of both, in three years, will be as follows.

The nineteen acres produced 11592 pounds of wheat, which was preferred to any other for ſeed, not only becauſe it was finer, but likewiſe becauſe it was quite free from all ſeeds of weeds. This is after the rate of 610 pounds for every acre.

From this, we are to deduct the ſeed, which is, for each acre, twenty-four pounds.

The neat produce of each acre will then be 586 pounds of wheat, free from all ſeeds of weeds.

Suppoſing the crops to be no greater in the following years, though what we ſhall ſay hereafter will ſhew that they certainly will, each acre will have produced neat at the end of three years, 1758 pounds of wheat.

The other piece of ground, which was cultivated in the old way, in order to make the compariſon, produced 1260 pounds an acre, from which we are to deduct 154 pounds for the feed.

The remaining neat produce is 1106 pounds.

The ſecond year's produce of this ſame acre, ſowed with ſpring corn, can be reckoned at only half the value of the firſt year's crop of wheat; and the third year produces nothing, being the year of fallow.

Thus the total neat produce of the acre cultivated in the common way will be, at the end of three years, only 1659 pounds; whilſt that in the new way, will be 1758 pounds.

M. Rouſſel *gives the following Account of his Experiments in* 1756, *in a Letter to* M. Duhamel.

"In October 1755, I choſe, in the middle of a fallow field which had been well ploughed, and was not expoſed to any of the accidents I met with laſt year, a piece of ground, which, to make a fair compariſon between the new method and the old, I divided into two equal parts, each containing twelve acres. One of theſe ſpots was ſet apart for the New Huſbandry; and the other, exactly of the ſame quality, and quite contiguous, to be ſowed broad-caſt in the old way.

"This laſt ground had been extremely well dunged by the folding of the ſheep. With regard to the other, which was to be cultivated in the new way, and which compoſed ninety-three beds five feet wide, including the alleys; only eight of theſe beds were dunged by ſheep, and that at the ſame time, and to the ſame degree as the ground by which the compariſon was intended to be made: of the other beds, ſeventy-ſix had no ſort of dung or amendment whatever: and nine were dunged more or leſs, in the manner and proportion hereafter mentioned.

"Moſt of thoſe who practiſe the New Huſbandry uſe no dung at all. I ſuppoſed that their reaſon for rejecting this manure was, the difficulty of finding a proper time to apply it; for whilſt the alleys receive their ſeveral ſtirrings, no wheel-carriage can be admitted with dung without hurting the beds which are ſown, and hardening the looſe mould of the alleys: to carry it on the backs of cattle, would be at beſt a very difficult, tedious, and expenſive way, where any conſiderable ſpace is to be dunged: to ſpread it upon the earth only the moment the ſeed is ſown, is a ſure way to clog up the drill-plough, and hinder its operation, if the dung be not thoroughly rotten; and to breed weeds, which by no means ſuit this culture. To remedy theſe inconveniencies, I contrived the following method. I opened in each of the alleys one of thoſe large furrows which muſt always be every year at the concluding of the ſummer hoeings, in the place where the three rows of ſeed are afterwards to be ſown; and by drawing the plough with two mould-boards once through it, I made it fourteen or fifteen inches wide; which is the breadth that the three rows of ſeed require. The ſpace between two of theſe deep furrows, is exactly the breadth of a cart, the wheels of which going in them, hurt no part that has been ploughed, and do not preſs down or harden the looſe mould; nor do the horſes do any damage, becauſe they neceſſarily tread upon the ſtubble of the late reaped beds, in the middle between theſe two furrows. This was the method I uſed to dung the nine beds, in queſtion. The dung was well rotted: it was ſpread at the bottom of the furrows, and immediately covered over by the fame ploughing that made the beds which were fown fome days after. Perhaps this manure may be of more fervice to my lands than to many others, becaufe the foil is naturally cold and backward. The grain is by this means fown upon a kind of gentle hot-bed, the warmth of which promotes the branching and vegetation of the plants. The winter rains and frofts, raife a fermentation. The firft fpring ploughing, by giving it a little air, revives that fermentation at the very time when the fap is moft active, and the plant begins to branch. As the dung rots, a kind of motion is caufed in the earth, which in fome meafure anfwers the end of a flight ploughing, and brings frefh nourifhment to the roots. The fame heat as confumes the ftraw, likewife confumes the little feeds that are in the dung, which might otherwife produce numbers of weeds. When this dung is brought up again to the furface of the earth, by the next year's ploughings, it will no longer have thofe hurtful feeds. It will indeed have loft its heat; but it will ftill have retained all its fatnefs, which will mix with the earth; and land thus conftantly dunged, will in time become a perfectly fine mould. But if thefe layers of dung fhould be fpread too thick, or the dung itfelf be of too hot a nature, the roots of the corn might perhaps be endangered thereby. It was to determine this, that I tried the following experiments, to know the effects of different dungs, and what quantity it is proper to employ.

"Three beds were dunged, in the above manner, with horfe-dung: the firft, which was 1165 feet long, had three loads of dung; the fecond, of 1171 feet, had but two and a half; and the third, 1183 feet, had but two. Three other beds were dunged with cow-dung: one of 868 feet, with two loads and a half; and the fecond of the fame length, with two loads; and the third, of 874 feet, with only one load and a half. The three remaining beds had fheep's dung: the firft, of 842 feet, two loads; the fecond, of 838 feet, one load and a half; and the third, which was of the fame length, one load.

"Thefe beds were diftributed in fuch manner, that each of them was in the middle of two other beds which were not dunged. The field, thus laid out, was fown on the thirteenth, fourteenth, fifteenth, and fixteenth of October, with the drill-plough, which plants three rows in each bed. I ufed 378 pounds of feed; and afterwards ten pounds to fill up the chafms; which is after the rate of thirty-two pounds fix ounces to an acre, and confequently a little too much. Accordingly, when the corn came up, I faw it was too thick fown. The reafon was, that the grain was too fmall, in proportion to the outlets of the drill-plough. At the end of ten days, this corn rofe well. On the eighteenth of December, I obferved that moft of thefe plants had branched into four ftalks, whilft thofe in the common way had but three. I perceived no fenfible difference then, between the dunged and the undunged beds. It was not till the twenty-fourth of January that I faw plainly that the plants of the dunged beds were of a deeper green, and had made longer and more vigorous fhoots than thofe of the undunged beds. By the twentieth of February, five fmaller ftalks iffued out of the five great ones, which was not the cafe with the wheat in the common way. The alleys did not receive their firft ploughing till the 10th of March. Eleven of the main ftalks grew an inch and an half in five days; and I obferved that the moles were rather more bufy in the dunged beds, than in the others. As the earth was yet fomewhat too foft, I thought it needlefs to continue a ploughing which could not do any good, and therefore poftponed it to the twenty-eighth of March, and following days. On the ninth of April, I found a plant with eighteen ftalks in one of the dunged beds: the greateft number of branches that any of the plants in the undunged beds had, was twelve: but, on the other hand, I likewife found fome which had eighteen in the field of comparifon fown in the common way.

"On the ninth of May, this fame plant had twenty ftalks; and from that time it branched no more. The fecond ploughing was not given till three weeks after, viz. the twenty-eighth of May; which, I think, was fomewhat too late after the corn had ceafed to branch. By the twenty-third of June, there were three forts of wheat in all the beds: there were ears in bloffom, others juft going out of bloom, and others not yet out of their hoods. The fineft ears were thofe which came up and bloffomed firft. The moft forward beds were thofe which had been dunged under furrow with fheep's dung: the next to them were the eight beds which had been folded, the plants of which were a little greener than thofe of the undunged beds. The laft ploughing was given on the tenth of July. The grain had then begun to fill: but that in the common way was the moft forward, though it was fowed three weeks later than the other. I know not for what reafon, the wheat of the New Hufbandry began to be reaped on the fourth of Auguft, and that in the old way was let ftand till the thirteenth. The produce of both cultures was as follows.

In the twelve Acres cultivated in the new Way, the three Beds dunged with Horfe-Dung, yielded,

	Sheaves.
The firft, 1165 feet long, dunged with three loads	19
The fellow to it, not dunged, - - - - - -	15
The fecond, 1171 feet long, dunged with two loads and a half	18
The fellow to it, not dunged, - - - - - -	14
The third, 1183 feet long, dunged with two loads	16
The fellow to it, not dunged, - - - - - -	13

The three Beds dunged with Cow-Dung, yielded,

The firft, 868 feet long, and dunged with two loads and a half	16
The fellow to it, not dunged, - - - - - -	11
The fecond, likewife 868 feet long, and dunged with two loads	15
The fellow to it, not dunged, - - - - - -	12
The third, 874 feet long, and dunged with one load and a half	14
The fellow to it, not dunged, - - - - - -	12

The three Beds dunged with Sheep's Dung, yielded,

The firft, 842 feet long, and dunged with two loads	17
The fellow to it, not dunged - - - - - -	10
The fecond, 838 feet long, and dunged with one load and a half,	15
The fellow to it, not dunged - - - - - -	11
The third, alfo 838 feet long, and dunged with one load,	14
The fellow to it, not dunged, - - - - - -	10

The eight Beds which had been folded, two of which were

1171 feet long, three 1177 feet, and three 1183, produced in all,	142
This is near 18 fheaves a-piece.	
The 67 other beds, which had not been dunged, produced in all	814
This is fomewhat more than 12 fheaves a-piece.	
Total produce of the 12 acres cultivated in the new way,	1208
The 12 acres fown in the common broad-caft way, after having been well folded all over, produced	1820

"Thefe facts fhew the advantage of dunging in this manner. It is plain that the beft dung is that of fheep, and that it is more profitable when laid under furrow, than when it is fpread upon the furface of the ground by folding.

"In proportion to the produce of the bed 842 feet long, which was dunged with two loads of fheep's dung, and produced feventeen fheaves; the bed 1165 feet long, which was dunged with three loads of horfe-dung, and produced only nineteen fheaves, would, if dunged with fheep's dung, have produced $23 + \frac{52}{100}$; and the bed dunged with cow-dung, which yielded but fixteen fheaves, would have yielded $17 + \frac{52}{100}$.

"The eight folded beds, whofe whole length was 9412 feet, would have yielded 190 fheaves $+ \frac{3}{100}$, inftead of only

only 142 sheaves, which was the amount of their product.

"It is likewise plain, that if the whole of my twelve acres in the new way had been dunged with sheep's dung, as the bed 242 feet long was; I should, in the same proportion, have reaped 1700 sheaves, which would be but 120 sheaves less than the whole produce of the twelve acres folded all over, and sown in the broad-cast way. But even then, I say, that those 120 sheaves would not be equivalent to the quantity of grain which I saved by sowing according to the New Husbandry. An hundred of our sheaves yielded, in general, little more than 378 pounds of wheat. The 120 sheaves which the twelve acres sown in the broad-cast way produced more than the twelve acres in beds, would therefore yield but 453 pounds. Deduct this from 871 pounds, which I saved in the seed of these last twelve acres sown in the new way, and I shall still be a gainer: for I sowed only 388 pounds in this ground; whereas 1260 pounds were used to sow the other twelve acres in the common way. This would have been the produce of this first year's crop, supposing that the whole of my twelve acres in beds had been dunged in the same manner as the bed 843 feet long. For want of that, I reaped but 1208 sheaves. They have just been threshed, and have yielded only 5040 pounds of grain."

M. Duhamel makes the following remarks on this account of M. Roussel.

"The 1208 sheaves yielded but 5040 pounds of grain; from which we are to deduct 388 pounds for the seed. The neat produce is therefore 4652 pounds, which would make in three years 13956 pounds. The other field in the common way produced 8757 pounds; from which we are to deduct 1260 pounds for the seed: the neat produce is consequently 7497 pounds; the half of which is 3748 pounds and a half, for the value of the next year's crop. This is all that the twelve acres in the common way would produce in three years, and amounts to no more than 11245 pounds and a half: consequently the balance in favour of the New Husbandry in three years, is 2710 pounds and a half, or one fourth part of the whole: and that from a field which was sown in rows for the first time, and of which three fourths were not dunged at all: whilst the other, with which it is compared, had been folded all over, and for the year, produced a very plentiful crop."

Extract of a Letter from a Gentleman in Poitou.

"Being convinced of the advantages of the new method of cultivating land, I resolved to make a trial of it, by comparing the produce of a field cultivated in the common way, with that of another field cultivated according to the New Husbandry: and as M. Duhamel has desired all lovers of agriculture to try by experiments made with care, whether it be most profitable to sow beds with two, or with three rows of corn; or, which is the same thing, to find at what distance the rows ought to be sown; I divided a spot of ground into ten equal parts, which I made into as many beds, each six feet wide.

"In the middle of five of these beds I sowed three rows, seven inches asunder; so that they took up fourteen inches of ground, and there remained four feet ten inches for the breadth of the alleys, which is very sufficient for the horse-hoeing husbandry.

"I sowed three other beds with only two rows, a foot distant from each other; consequently the alleys were five feet wide.

"The two remaining beds were sown with two rows each, three feet asunder. The alleys were therefore but three feet wide: or rather the whole of this last spot may be looked upon as sown in single rows, with alleys three feet wide, which is too narrow a space to admit of horse-hoeing them conveniently.

"Before I speak of the produce of these beds, it will be proper to observe:

"1. That this trial was made with rye. My fear that birds might eat up the wheat, made me prefer rye, which I advise every one to do, when only small experiments are made. This escaped without the least damage; whereas I have observed, that when experiments have been made with wheat, the birds, preferring that to any other grain, have always destroyed a considerable part of the crop.

"2. The beds sown with three rows were near a hedge, which greatly damaged two of them, either by its roots exhausting the ground, or by its shadow keeping that part harder frozen than the rest.

"3. The intervals were not hoed at all, between either the double or the triple rows; only the alleys were horse-hoed; and consequently none but the single rows were hoed on both sides.

"4. On the 25th of February, the alleys were ploughed. I visited them on the second of March, and found, upon examining the plants, that, in these five days, they had shot out roots four inches long into the new stirred mould. I repeated the hoeings at proper times, and the rye continued in good condition till it was reaped. The last hoeing was given after the blossoming was past.

"5. I then examined the roots, and found they had extended eighteen inches into the loose mould. This may seem strange; but I am certain it is true; for I took every precaution not to be deceived.

"6. The alleys between the single rows were hoed but twice, being too narrow to admit the plough after the plants had begun to branch. However, I had not reason to complain of the produce of these single rows.

"Having now given an account of my operations, it is time to speak of the products.

"The ears in my rows were from four to seven inches long, and the stalks from four to six feet high, which was one third taller than in the neighbouring fields cultivated in the old way.

"This spot of ground, in the best years, never produced more than five bushels, including the bushel of seed corn; for that was the quantity generally used: in common years, it has not yielded above four bushels, and frequently much less. We therefore cannot reckon its produce, one year with another, at more than four bushels, including all faulty grains and seeds of weeds, which fall through the sieve, and remain mixed with the good grain. This year it has yielded me seven bushels of fine clean rye, considerably larger than the common sort. I make no account of the seed, the quantity was so small. To prevent this grain's being mixed with any other, and at the same time to judge more exactly of the produce of my ground, I had the sheaves threshed out close by the field; but it was in the middle of a road, where all the grains scattered by the flail could not be gathered up; by which I reckon I lost more than the amount of the seed that was sown in the rows. The produce of my little field was therefore this year, compared to other years, as seven is to four; to which must be added, that it is capable of bearing as great a crop every year, which is not the case in the common husbandry.

"Let us now examine the produce of the rows, and compare them with one another, in order to judge whether it be most profitable to sow in single, double, or triple rows.

"Two beds, the most distant from the hedge, sown with triple rows, yielded each three quarters of a bushel.

"Two beds with double rows, yielded each two thirds of a bushel; consequetnly the three beds with double rows yielded two bushels, and the six rows sown two and two, in three beds, yielded one quarter more than the six rows sown three and three in two beds; but two beds of three rows a-piece yielded one ninth more than two beds of only two rows a-piece; whence we may conclude, that the distance of the rows increases the produce of an equal number of plants; or, which comes to the same, that an equal quantity of seed will produce more grain when the rows are more distant, than when they are sown closer together. But this is not a real profit; because the six double rows take up one third more ground than the six triple rows.

"Each of the single rows yielded seven-eighths of a bushel, which is one seventh more than the triple rows, though they took up no more ground; and their produce would probably have been greater, if they had been hoed two or three times more.

"It appears by this account, that the profit would probably have been on the side of the double rows, if the alleys had been made only four feet wide, instead of five; for by this means I should have gained one fifth more ground; and four feet are a sufficient breadth for the operations

rations of the horse-hoe. Where the single rows are so near as in this experiment, the same ground would scarcely bear another crop the next year, for want of having been sufficiently stirred. To clear up this point by a new experiment, I have sown single rows in the middle of four beds, two of which are four feet wide, and the two others only three. The winter hoeings have been given them with ease, and I hope the others will not be more difficult, at least till all the corn is spindled. What I fear most is, the earth's being carried off the narrow space on which the rows stand, when a thaw comes on, or by the heavy rains which are frequent with us.

"The rest of my field is sowed in two rows, in beds four feet two inches wide. I have done this, because, as it is the general custom here to make our ridges about that breadth, I am in hopes that if I obtain a plentiful crop, I shall be able the more easily to prevail on the farmers of this country to adopt a method, the advantage of which I am sensible of, before I tried the above experiment."

As it will be doubtless expected by our readers, that the advantages resulting from both the Old and New Husandry, should be set in the clearest and most conspicuous point of light under this article; we shall add here two calculations, that lately appeared in the Museum Rusticum, and appear to be made with great accuracy and candor.

The Profit attending Arable and Pasture Land compared, as found by Experience, near Bury, in Suffolk.

The following calculation of the different profit attending arable and pasture land in my neighbourhood, is drawn up not merely from fancy, but from the exact accounts I have kept of my own crops, and the information I have gained from several sensible farmers.

I take twenty acres, and suppose them an addition to a farm; but I should premise such an one as will require some additional cattle to be kept for it, perhaps two horses; but a farm of fifty pounds per annum may be so circumstanced as to require no material standing expences extraordinary for such an addition, in which case the ploughings, &c. will not cost near what I have laid them at; but the fairest way is the supposition I have made. We reckon nothing is either got or lost by four shillings per acre for a clean earth.

Calculation of the Expences and Profit of farming a ploughed or pasture Field of twenty Acres for nine Years, on a Supposition, that it is not a Farm by itself, but an Addition to another of fifty Pounds per Annum, the Soil wet, and a loose Woodcock, Brick Earth, on the Surface, for eighteen Inches deep, and under that a very good stiff Clay, improved by Land-draining.

First Year, Fallow.

	l.	s.	d.
Rent charges	15	0	0
First ploughing, a clean earth	4	0	0
Second ditto, ribbling it close overwart	4	0	0
Harrowing it overwart	0	5	0
Rolling	0	3	0

	141	9	9	Total profit in nine years;			

Which is fifteen pounds fourteen fhillings and eightpence per annum, or rather better than fifteen fhillings per acre.

But I fhould obferve, that as a crop of clover-feed is the moft uncertain and various of any that is grown, I have reckoned lefs for it by far than multitudes produce, though, at the fame time, many bring nothing at all.

I know a field of twenty acres, which I have been often told by feveral who knew the crop, once produced the farmer five bufhels per acre. It was all down on a Friday, and the farmer fufpecting a change of weather, by great rewards to his workmen, and bringing cafks of ale into the field, and feeding them well, tempted them to work in an extraordinary manner all the Saturday, and cleared the whole into barn. It began raining in the night, and fo much fucceeding bad weather came, that the crops were, in general, greatly damaged. His produced, as I faid, one hundred bufhels, all which he fold at three pounds ten fhillings per bufhel, arifing to three hundred and fifty pounds. And a few years ago I faw the fame field with a crop of clover, which did not produce twenty pecks, and that fo wretched as to fetch nothing.

I read this calculation to a farmer, and he obferved, that I fhould reckon eighty bufhels for the crop; and as it is often grown, I will give you another total, with that alteration, that your readers may adopt either, according to their idea of the chance.

which is twenty-one pounds fix fhillings and five-pence per annum, or better than a guinea per acre.

As I mention back-carriage in this calculation, I will explain my meaning. We generally carry our corn to Ipfwich, Manningtree, or Thetford, from which places we load home with coals for blackfmiths, or any perfons that want them, who pay us eighteen fhillings for the carriage of a loading, twelve fhillings per chaldron, and we generally bring one and a half. But as we may accidentally carry our corn where none is to be had, I make fuch allowance as to bring it near the truth.

Calculation of nine Years Expences and Profit of twenty Acres of Grafs-Land, the Soil fuppofed to be the fame as the above Arable-Land, with no other Difference than being Grafs or Ploughed.

Which is twenty-three pounds eleven shillings and two-pence per annum, or one pound three shillings per acre profit.

The above account displays the vastly superior advantages of grass, with us, to arable land.

You will certainly remark, that nothing in the above account is reckoned for losses of stock; but in answer to that I should observe, that nothing is calculated in the arable account for some bad years, when in such land not a quarter of a crop is produced: and I do not mean this calculation as perfect (that is impossible) but only to discover the proportion between the one method and the other; and from what I have observed, and gathered from the information which the most intelligent farmers can give me, I am clearly of opinion, that the chances, on the whole, are much in favour of the grass-land, the crop of hay and seed being much more regular than those of corn, clover, or turneps; and supposing the eighty bushels of clover-seed, yet the grass profit far exceeds the arable, even then; but, as I observed, the probability lies against the latter, supposing the profit to be only fifteen pounds fourteen shillings and eight-pence per annum.

I may remind you, that I supposed this twenty acres to be an addition to a farm, not one by itself, and so compared the respective profits; therefore I have not allowed any thing for the seed which the above-mentioned cattle may accidentally have on the arable land, or turneps which they may expend in the winter; and for this reason, because, although it appears to me that grass is the most profitable husbandry, yet a certain quantity of ploughed land should undoubtedly be a part of every grass-farm, for the raising turneps, some artificial grass, and stover enough for the winter's food.

I hope your readers will peruse this calculation with candour, and believe me, when I assure them it is the nearest truth of any I can make, either from my own experience, or best information. *Museum Rusticum, vol.* III. *p.* 317.

State of the Expence of a hoed Crop of Wheat, and the Profit of it compared with that of the common Husbandry.

I propose here to state the expence of a hoed wheat-crop. If this is done in any place where the price of labour is known, it will be easy from thence to calculate the expence of such crops in any other places.

 When

When wheat is to be horfe-hoed, it is planted upon three-bout ridges, about four feet and eight or nine inches broad. If the foil is poor, they may be made broader, but fhould not be much narrower, otherwife there will not be room enough to plough the intervals. Two rows of wheat, about ten inches afunder, are drilled upon the top of each ridge, and then the intervals or fpaces between the double rows will be about three feet and ten inches wide.

For the firft crop the land fhould be well prepared, and very clean: it will therefore coft more than the following crops; and if the land is not in good heart, the firft crops will be the fmalleft, for hoeing greatly improves it. The following eftimate is of the fucceeding crops.

The neceffary culture for thefe is, once ploughing in autumn, to form the new ridges for the next crop. This may be done with three horfes; for the intervals, by frequent hoeing, are kept in fine tilth, and are ploughed at one bout; and the middle of the ridges where the laft crop ftood, being only the breadth of two narrow furrows, are eafily ploughed at another bout; fo that thefe ridges, which in common ploughing required three bouts with four horfes, are now ploughed at two with three horfes.

The intervals, after the corn is planted, are hoe-ploughed at one bout, to or from the rows. They are ufually thus ploughed four times, once in the beginning of winter, and three times afterwards in the fpring and fummer.

The ten inch partitions, or fpaces, between the rows of wheat, are hand-hoed about the end of March: once is generally fufficient, becaufe the wheat foon afterwards fpreads, covers the partitions, and keeps down the weeds. The rows are alfo to be weeded. This is all the ploughing and hoeing that is commonly neceffary till harveft. But as in fome years it may be proper to plough the ridges in autumn at five or fix furrows, or plough them twice, fometimes to hoe-plough the intervals more than four times, or to give them a trench-ploughing, where the ftaple is deep enough to admit of it, I fhall make a full allowance for thefe, and charge two ploughings and fix horfe-hoeings every year.

The hiring price in fome parts of Middlefex for ploughing a ftrong loam the firft time, in the common way, is feven or eight fhillings an acre; I fhall fay eight fhillings. They work about eight hours, and plough about an acre a day with four horfes. The price of the labour may be thus diftinguifhed: to the ploughman twenty-pence, and boy eight-pence a day, including their beer; and then the horfes and harnefs, &c. will come to feventeen-pence a day each. Twice ploughing therefore in autumn, with three horfes, comes to eight fhillings and nine-pence.

The tops of the ridges are to be rolled with a light roller, or harrowed once or twice with two very light harrows, to break the clods, and lay the tops of the ridges fmooth for drilling. The harrows are faftened together by a pole; and a horfe, walking in the furrow, draws the two harrows, one upon each ridge. A rolling in the fame manner is alfo ufeful in the fpring, when the earth is pretty dry, and before the partitions are hand-hoed. Thefe rollings and harrowings, of two ridges at once by once horfe, are done at a fmall expence; and not being neceffary every year, may coft about four-pence: but to make the total an even fum, I fhall charge for them (and uncovering the plants, if any clods happen to fall upon them at the firft hoe-ploughing) feven-pence halfpenny per acre.

The ufual quantity of feed is three pecks, and if it cofts five fhillings and fix-pence per bufhel, is four fhillings and three halfpence per acre. The drilling is performed by a man and boy, and one horfe. They may drill fix acres a day: I fhall fay but five, which is ninepence per acre.

The intervals fhould be kept in fine tilth: they are hoe-ploughed at one bout: three horfes are fufficient for the firft two hoeings, and two for the reft. I fhall reckon three for each hoeing, and then fix hoeings come to thirteen fhillings and two-pence.

The price for hand-hoeing of beans the firft time is about five fhillings per acre; I fhall call it fix; and as the ten inch partitions, and about two inches on each outfide of the rows, is the whole to be hand-hoed (for the hoe-plough does the reft) thefe are about one fourth part of the ridge, and fhould be done for eighteen-pence an acre: but it is a good way to agree with the hoers to cleanfe the rows alfo of weeds; and as thefe ought to be well done, they expect fomething more than for common work, and they will coft near half a crown per acre.

For reaping the prices are various; from five or fix, to ten fhillings per acre; at a medium, eight fhillings is a high price. The drilled wheat, having fcarcely any weeds in it, and ftanding upon only about a fourth part of the ridge, is eafier and much quicker reaped than fown wheat, and not really worth above half the common price; but, for the above reafon, I fhall allow, for reaping and carrying fix fhillings per acre.

Wheat-ftraw is a valuable article in the neighbourhood of London; and the ftraw, chaff, &c. might be reckoned here to pay for threfhing and carrying the corn to market: where it is otherwife, an allowance is to be made. And as the diftance from the market is uncertain, I fhall charge the carrying out, and at market, a fhilling per quarter, befides the value of the ftraw.

Some eftates are tythe-free; others pay in kind, or a modus. I fhall reckon the tythe at four fhillings per acre.

Suppofe the rent is fixteen fhillings per acre, there remain to be added the taxes, or rates payable by the tenant, which, at two fhillings in the pound-rent, come to nineteen-pence per acre.

I reckon nothing for dung or manure; for land that is proper for wheat, allowing fufficient intervals and hoeing, requires none. If the wheat of the firft crops is weak in the fpring, a top-dreffing of the rows will be of fervice, or afterwards, if the proper hoeings have not been given the preceding year; but this feldom happens; for hoeing makes the plants ftrong, and if then alfo top-dreffed, they would be in danger of lodging.

The whole expence, at thefe prices, of horfe-hoed wheat, is, per acre, as follows:

	l.	s.	d.
Two ploughings in autumn, with three horfes	0	8	9
Harrowing, feed, and drilling - -	0	5	6
Six hoe-ploughings of the intervals, with three horfes - - - - -	0	13	2
Hand-hoeing, weeding, and harvefting	0	8	6
Carrying out twenty bufhels, and at market, (befides the value of the ftraw and chaff) at one fhilling per quarter - -	0	2	6
Tythe, rent, and taxes - -	1	1	7
	3	0	0

This is the whole expence, fuppofing the foil to be a ftrong loam, the wages high, and the horfes hired; but when done by the farmer's own horfes, or the foil lighter, and they work more hours in a day, the expence will be a great deal lefs, as we fhall fee below: in fome places it will not much exceed half this fum.

It has been already fhewn, that one hundred acres of horfe-hoed wheat, much of it a light, poor foil, produced near twenty bufhels per acre; and that a ftrong foil, by a medium of twenty hoed crops, produced about twenty-four bufhels per acre, both nine-gallon meafure; and therefore we might reckon here a middling crop about twenty-four bufhels: but to avoid all fufpicion of partiality, I fhall fuppofe, that a good loam may, one year with another, produce only the leaft of thefe, or twenty bufhels per acre.

The mean price of wheat at Windfor market, for the laft twenty years, ending at Michaelmas, 1762, is nearly four fhilling and eight-pence three farthings per bufhel; and twenty bufhels, at this rate, come to four pounds fourteen fhillings and feven-pence; fo the profit of the horfe-hoed wheat is one pound fourteen fhillings and feven-pence per acre, or above two rents.

Your ingenious correfpondent has above ftated the produce and expence of twenty acres of arable land for nine years, according to the courfe of hufbandry practifed in his neighbourhood, I fhall, by way of comparifon, calculate the profit of thefe twenty acres, fuppofing they had

had been under crops of hoed wheat during theſe nine years.

I reckon, from your correſpondent's account, the wages of his ploughmen to be about fourteen pence, and a boy four-pence a day (if not allowed beer) and the horſes a ſhilling a day each; in all, five ſhillings and ſix-pence, beſides repairs: and if they work more than eight hours, his land being lighter than the above, they may plough about an acre and a half a day, which brings the price for ploughing to near his reckoning of four ſhillings per acre. If this is not exact, he will rectify it. I ſhall ſtate the ploughings and horſe-hoeings in this proportion, and allow three horſes, though fewer will do in this land. The rent-charges, I ſuppoſe, include the tenant's taxes; if not, they are to be added to the expence. As the tythe is not mentioned in his account, I do not charge it here. The other items are computed in proportion to his, and the above, ſtate of the expence; and as I abated four buſhels in the above crop per acre, I ſhall do the ſame here, and reckon a middling crop of hoed wheat at only eighteen buſhels; his producing, by a medium of three crops, twenty-two buſhels and two fifths per acre. The expence of a horſe-hoed acre of this land will be nearly as follows:

				l.	s.	d.
Twice ploughing in autumn, with three horſes, and harrowing - - -				0	3	0½
Seed three pecks (fifteen ſhillings and four-pence per coomb at a medium) and drilling five acres a day - - -				0	3	4½
Six hoe-ploughings, with three horſes				0	4	0
Hand-hoeing (at four ſhillings per acre, reckoned for turnips in the account) and weeding - - - -				0	1	8
Harveſting, three ſhillings and nine-pence: threſhing four coomb and a half, four ſhillings and ten-pence - -				0	8	7
Carrying out four coomb and a half, and at market - - - -				0	4	1½
Rent-charges - - -				0	15	0
Total expence per acre				1	19	9½
The three crops of wheat were ſold, at a medium, for fourteen ſhillings and five-pence and four ſevenths per coomb, which, for eighteen buſhels, comes to -				3	5	0½
Profit per acre				1	5	3
The twenty acres, in nine years, produced ſeven crops, valued at five hundred and three pounds; but in the ninth year, the crop of ſixty coomb is caſt by miſtake at eighty-ſeven pounds, which ſhould be but half that ſum; deducting therefore forty-three pounds ten ſhillings, the produce amounts to - - -				459	10	0
The expence of theſe twenty acres in nine years, as charged - - -	361	10	3	381	10	0
To which is to be added for four hundred loads of dung	20	0	0			
Remains the profit in nine years				77	19	9
Which is, per acre per annum, near				0	8	8

There were eight hundred loads of dung laid upon theſe twenty acres; but it is hardly to be ſuppoſed, that that half that quantity could be made from the ſeven crops; ſo that at leaſt four hundred loads muſt be had elſewhere; and the dung is at a high price in that neighbourhood. I have charged but a ſhilling a load for it.

But if it ſhould be ſuppoſed, that more than four hundred loads could be made from theſe ſeven crops, it muſt alſo be admitted, that a quantity in proportion would be made from the nine crops of wheat, which not being neceſſary in the hoeing culture, is worth, to be ſold, more per load than I have reckoned above; and the value of it ſhould then be added to the profit of the hoed crops.

Let us next compare the whole profit of theſe twenty acres in nine years, in both theſe methods of huſbandry.

	l.	s.	d.
The profit, in nine years, of the hoed crops, amounts to - - -	227	5	0
The profit in that time by the common huſbandry - - - -	77	19	9
Balance in favour of the New Huſbandry	149	5	3

Hence appears the great ſuperiority of the hoeing culture; and even allowing the clover had produced four buſhels of ſeed per acre, the New Huſbandry is ſtill by far the moſt profitable.

HYACINTH, the name of a very beautiful genus of flowers, of which ſeveral ſpecies are now cultivated in the Engliſh gardens.

All the different ſorts of hyacinths are propagated by ſeeds, or of ſets from the old bulbs; the former method has been but little practiſed in England till very lately; but in Holland and Flanders, it has been followed many years, and by this means they have obtained an amazing variety of the moſt beautiful flowers. Few floriſts in England think it worth while to wait four or five years for the flowers of a plant, which, when produced, might not perhaps deſerve to be preſerved; but they do not conſider that it is only the loſs of the firſt four or five years after the ſowing; for if they continue ſowing every year after they begin, there will be a ſucceſſion of flowers annually, which will conſtantly produce ſome ſorts different from what they were before poſſeſſed of; and new flowers being always the moſt valuable to ſkilful gardeners, they will always prove a ſufficient recompence for their trouble and loſs of time beſtowed on their culture.

The method of raiſing theſe flowers from ſeed, is as follows: Firſt, let a ſufficient quantity of good ſeed (which ſhould be ſaved either from ſemi-double, or ſuch ſingle flowers as are large, and have good properties) be provided: Secondly, One or more ſhallow boxes, or pots, ſhould be procured, which muſt be filled with freſh, light, ſandy ſoil, laying the ſurface very level, on which the ſeeds ſhould be ſown as equally as poſſible, and covered about half an inch thick with the ſame light earth: the time for this work is about the middle of Auguſt. Theſe boxes or pots ſhould be placed where they may enjoy the morning ſun only, till the latter end of September, at which time they ſhould be removed into a warmer ſituation, and about the latter end of October be placed under a common hot-bed frame, where they may remain during the winter and ſpring months, to be protected from hard froſts; but they ſhould be expoſed to the open air, when the weather is mild, by taking off the glaſſes. In February or March, the young plants will begin to appear above ground, at which time they muſt be carefully ſcreened from the froſts, otherwiſe they will be deſtroyed while ſo young; but they muſt not be covered at that ſeaſon, except in the night, or very bad weather; for when the plants are come up, they will, if too cloſe covered, draw up very tall and ſlender, and thereby prevent the growth of their roots. At the end of March, if the weather prove good, they may be removed out of the frame, placing them in a warm ſituation; and, if the ſeaſon proves dry, they ſhould now and then have a little water, and be kept very clear from weeds, which would ſoon overſpread the tender plants, and deſtroy them.

Towards the latter end of April, or the beginning of May, theſe boxes ſhould be removed into a cooler ſituation; for the heat of the ſun at that ſeaſon would be too great for theſe tender plants, cauſing their blades to decay much ſooner than they would, if they were ſcreened from its violence. In this ſhady ſituation they ſhould remain during the heat of ſummer, obſerving to keep them conſtantly clear from weeds; but you muſt not place them under the dripping of trees, &c. nor ſhould you give them any water after their blades are decayed; for that would infallibly rot their roots. About the latter end of Auguſt, you ſhould ſift a little light rich earth over the ſurface of the boxes, and then remove them again into a warmer ſituation, and treat them, during the winter, ſpring, and ſummer months, as was before directed; and the ſecond year, about the middle of Auguſt, ſhould be prepared a bed of light, rich, ſandy ſoil, in proportion to the quantity of ſeedling roots, the ſurface of which ſhould be be very even; then take out the earth from the boxes in which the plants were raised, into a sieve, in order to get out all the roots, which, by this time, if they have grown well, will be about the size of small pease: these roots should be placed upon the bed at about three inches asunder, observing to set the bottom part of their roots downwards; then they should be covered over two inches thick with the same light earth; but as it will be impossible to get all the small roots out of the earth in the boxes, the earth should be spread upon another bed equally, and covered over with light earth, by which method none will be lost, be they ever so small.

These beds must be arched over with hoops, and in very hard frosty weather must be covered with mats, &c. to protect them from frost; and in the spring, when the green leaves are above ground, if the weather should be very dry, they should have a little water sparingly; for nothing is more injurious to these bulbs than too great quantities of moisture. During the summer season, the beds must be kept clear from weeds; but after the blades are decayed, the roots should not have any water: in autumn the surface of the bed should be stirred with a very short hand-fork, being exceeding careful not to thrust it so deep as to touch the roots, which, if hurt, are very subject to perish soon after. Then a little fresh, light, rich earth, should be sifted over the bed about an inch thick, or something more. In winter, the beds should be covered again as above directed. In this bed the roots may continue two years; the third summer when the leaves are decayed, the roots should be carefully taken up, and may be kept out of the ground till August, when they should be planted into new beds, prepared as before, at the distance of six inches asunder; in these beds the roots may remain till they flower, during which time they should be treated as before, with this difference only, that instead of covering them with mats in the winter, the surface of the ground should be covered with tanners-bark.

When the flowers begin to shew themselves, those which have good properties should be marked, by thrusting a small stick down by each root; which roots at the time of taking them up should be selected from the rest, and planted by themselves, though it is by no means advisable to reject any of the other roots till they have blown two years, before which their worth cannot be ascertained. When the roots are taken up, they should be laid into the earth again in an horizontal position, leaving the green leaves hanging downwards from the roots, whereby the great moisture contained in their very succulent leaves and flower-stalks will be exhaled, and prevented from entering the roots, which when suffered to return into them, is very often the cause of their rotting. In this position the root should remain until the leaves are quite dried off, when they must be taken up, and after being cleared from all manner of filth which would be hurtful to them, they must be laid up in boxes, where they may be preserved dry until September, which is the proper season for planting them again.

We shall now proceed to the culture of such hyacinths as either have been obtained from Holland, or have been produced from seeds in England. The want of skill in this particular has occasioned the ill-success most people have had with them here, which has occasioned their being so much neglected, supposing their roots to degenerate after they have flowered in England; which is a great mistake, for were the roots managed with the same art as is practised in Holland, there is no reason to doubt but they would thrive full as well with us as there.

The soil in which these flowers succeed best, is a light, sandy, fresh, rich, loamy earth, which may be composed after the following manner: take half fresh earth from a common, or pasture-land, which is of a sandy loam; this should not be taken above eight or nine inches deep at most; and if taken with the turf, or green sward with it, it will still be better, provided it has time to rot; to this should be added a fourth part of sea-sand, and the other fourth part of rotten cow-dung: these should be well mixed together, and thrown into a heap, where the whole may remain till wanted; but the whole should be turned over once every month. If this compost be made two years before it is used, it will be much the better; but if used, sooner, it should be turned oftener, that the parts may the better unite.

This soil should be laid two feet deep in the beds which are designed for hyacinths, and a little rotten cow-dung, or tanners-bark may be laid at the bottom, which will be within reach of the fibres, but should by no means touch the bulb. If the soil be very wet where these beds are made, they should be raised ten or twelve inches above the surface; but if it be dry, they need not be raised above three or four.

The best season for planting these roots is towards the middle or latter end of September, according to the earliness or lateness of the season, or the weather which then happens; but it is advisable never to plant them when the ground is extremely dry, unless there be a prospect of some rain soon after; for if the weather should continue dry a considerable time after, the roots will contract a mouldiness, which will certainly destroy them.

These beds will require no farther care until the frost comes on, at which time they should have some rotten tan spread over the bed, about four inches thick; and if the alleys on each side of the bed are filled up, either with rotten tan, dung, or sand, it will prevent the frost from penetrating the ground to the roots, and secure them from being destroyed; but when the winters prove very severe, it will also be proper to have some pease-haulm, or such like covering laid over them, which will keep out the frost better than mats. But this covering should be taken off whenever the weather is mild, and only continued on in very hard frosts; for where the beds are covered with tan or sea-coal ashes, no common frost can penetrate through, so the other coverings are useless, except in very severe frosts. In February, when the leaves begin to appear, the beds must be arched over with hoops, that they may be covered either with mats, canvas, or some other light covering, to prevent the frost from injuring the buds as they arise above ground; but these coverings must be constantly taken off every day when the weather is mild; otherwise the flower-stems will be drawn up weak, and the foot-stalks of the flowers will be slender, and so rendered incapable of supporting the bells, which is a great disadvantage to the flowers. When these hoops are fixed over the beds, the rotten tan should be taken off; in the doing of which, great care should be taken not to bruise or injure the leaves of the hyacinths which are then coming up.

When the stems of the flowers are advanced to their height, before the flowers are expanded, short sticks should be placed by each root, to which, with a wire formed into a hoop, the stem of the flowers should be fastened, to support them from falling, otherwise, when the bells are fully expanded, their weight will incline them to the ground.

During their season of flowering they should be covered in the heat of the day from the sun, and also from all heavy rains; but they should be permitted to receive gentle showers, as also the morning and evening sun; but if the nights are frosty, they must be constantly defended therefrom. With this management the flowers may be continued in beauty at least three weeks or a month, and sometimes more, according to their strength, or the favourableness of the season.

When their flowers are quite decayed, and the tops of their leaves begin to change their colour, their roots should be lifted with a narrow spade, or some other handy instrument: in the doing of this, the instrument must be carefully thrust down by the side of the root, so as not to bruise or injure it, as also to put it below the bottom of the root; then by the forcing of this instrument on one side, the fibres of the roots are raised and separated from the ground. The design of this is to prevent their receiving any more nourishment from the ground, for by imbibing too much moisture at this season, the roots frequently rot after they are taken up: about a fortnight after this operation, the roots should be entirely taken out of the ground, and then the earth of the beds should be raised into a sharp ridge, laying the roots into it in an horizontal position, with their leaves hanging out, by which means a great part of the moisture contained in their thick succulent stalks and leaves will evaporate, which,

which, if permitted to return back to the roots, would cause them to rot and decay after they are taken up, which has been the general defect of most of the hyacinths in England.

In this position the roots should remain until the green leaves are entirely decayed, which perhaps may be in three weeks time. This is what the Dutch gardeners term, the ripening of their roots, because by this method the roots become firm, and the outer cover is smooth, and of a bright purple colour; whereas those roots which are permitted to remain undisturbed, till the leaves and stalks are quite decayed, will be large, spongy, and their outer coats will be of a pale colour; for the stems of many of these flowers are very large, and contain a great quantity of moisture, which, if suffered to return into the roots, will infallibly cause many of them to perish. After they are so ripened, they may be taken out of the ground, and wiped clean with a soft woollen cloth, taking off all the decayed parts of the leaves and fibres, putting them into open boxes where they may lie singly, and be exposed to the air; but they must be preserved carefully from moisture, nor should they be suffered to remain where the sun may shine upon them. In this manner they may be preserved out of the ground until September, which is the season for planting them again, at which time you must separate all the strong flowering roots, planting them in beds by themselves, that they may make an equal appearance in their flowers; but the off-sets and smaller roots should be planted in another separate bed for one year, in which time they will acquire strength, and by the succeeding year will be as strong as the older roots.

There are some persons who let their hyacinth roots remain two or three years unremoved, by which they have a much greater increase of roots than when they are annually taken up; but the roots by this great increase are frequently degenerated, so as to produce single flowers; therefore it is most advisable to take up the roots every year, which is the most certain method to preserve them in their greatest perfection, though the increase may not be so great. Those roots which are annually removed will be rounder and firmer, than such as stand two years unremoved. *Miller's Gard. Dict.*

HYSSOP, a well known herb, cultivated in every kitchen garden.

It is propagated either by seeds, or slips; and if by seeds, they must be sown in March, upon a bed of light, sandy soil, and when the plants come up, they should be removed to the places where they are to remain, placing them a foot asunder, at least, each way; but if they are designed to abide in this place for a long time, two feet distance will be little enough, for they grow pretty large, especially if they are not frequently cut to keep them within compass: they thrive best upon a poor, dry soil, in which situation they will endure the cold of our climate better than when they are planted in rich ground. If they are propagated by slips, they should be planted either in spring or autumn, in a bed of light earth, where they will take root in about two months, after which they are to be transplanted where they are to continue, managing them as before directed for the seedling plants. *Miller's Gard. Dict.*

J.

JACK, an instrument for turning the spit; also a contrivance for supplying the place of a boy in pulling boots off. It also signifies a support for sawing wood upon.

JAMOCK, or *jannock*, oaten bread made into large loaves.

JARDON, a name given by farriers to a swelling on the out-side of the back of a horse.

It generally proceeds from blows and kicks of other horses; but frequently happens to managed horses, by setting them on their haunches: it is seldom attended with much lameness, unless it has been neglected, or some little process of the bone broken. It should be first treated with coolers and repellents, such as hot vinegar, verjuice, &c. but if any swelling continues hard and insensible, the best way is to blister or fire; but mild blisters alone generally succeed. *Bartlet's Farriery, page* 263.

JAUNDICE, a distemper incident to horses, and generally called, by farriers, the yellows.

Horses are frequentty subject to this distemper, which is known by a dusky yellowness of the eyes; the inside of the mouth and lips, the tongue and bars of the roof of the mouth looking also yellow. The creature is dull, and refuses all manner of food; the fever is slow, yet both that and the yellowness increase together. The dung is often hard and dry, of a pale yellow, or light pale green. His urine is commonly of a dark dirty brown colour; and, when it has settled some time on the pavement, it looks red like blood. He stales with some pain and difficulty, and if the distemper is not checked, soon grows delirious and frantic. The off-side of the belly is sometimes hard and distended; and in old horses, when the liver has been long diseased, the cure is scarce practicable, and ends fatally with a wasting diarrhæa: but when the distemper is recent, and in young horses, there is no fear of a recovery, if the following directions are observed.

> First of all, bleed plentifully; and give the laxative clyster, as horses are apt to be very costive in this distemper; and the next day give him this purge.

> Take of Indian rhubarb, powdered, one ounce and a half; saffron two drams, succotrine aloes six drams, syrup of buckthorn a sufficient quantity.

If the rhubarb should be found too expensive, omit it, and add the same quantity of cream of tartar, and half an ounce of Castile soap, with four drams more of aloes. This may be repeated two or three times, giving intermediately the following balls and drink.

> Take of Æthiop's mineral half an ounce; millepedes the same quantity, Castile soap one ounce; make into a ball, and give one every day, and wash it down with a pint of this decoction.

> Take madder root and turmerick, of each four ounces; burdock root sliced, half a pound; Monk's rhubarb four ounces; liquorice sliced two ounces: boil in a gallon of forge water to three quarts; strain off, and sweeten with honey.

Balls of Castile soap and turmerick may be given also for this purpose, to the quantity of three or four ounces a day, and will in most recent cases succeed.

By these means the distemper generally abates in a week, which may be discovered by an alteration in the horse's eyes and mouth; but the medicines must be continued till the yellowness is intirely removed. Should the distemper prove obstinate, and not submit to this treatment, you must try more potent remedies, viz. mercurial physic, repeated two or three times at proper intervals; and then the following balls:

> Take salt of tartar two ounces, cinnabar of antimony four ounces, live millipedes and filings of steel, of each four ounces, Castile or Venice soap half a pound: make into balls of the size of pullets eggs, and give one night and morning, with a pint of the above drink.

It will be proper, on his recovery, to give him two or three mild purges, and, if a full fat horse, to put in a rowel. *Bartlet's Farriery, page* 156.

ILES, or *oiles*, the beards or the ears of barley, wheat, &c.

INARCHING. *See* GRAFTING.

INCLOSURE, the separation of common grounds into distinct possessions.

The inclosing of lands, and dividing them into different fields, pastures, &c. is a most essential part of their real improvement, and attended with many very considerable advantages, of which we shall here mention only the following:

Inclosures ascertain to every man his just and due property, and thereby prevent an infinity of trespasses, injuries, and other sources of ruinous litigation. They keep the land warm, and add to its fertility, by screening it from violent and nipping winds, which otherwise frequently destroy whole crops; and they also defend it from those drying and scorching winds, which so often blast at once the husbandman's, till then well grounded, expectation. They afford shade in the summer, and shelter in the winter, for cattle, which would otherwise destroy more with their feet than they eat with their mouths, and which, for want of these, might, as Mr. Worlidge observes, lose more of their fat or flesh in one sultry day, than they gain in three cold ones. Their cuttings afford fuel to the industrious husbandman, and, if carefully planted and preserved, they will here and there furnish him with timber for his carts, ploughs, and other utensils, besides sometimes useful fruits. They are an excellent encouragement to good husbandry, and a great remedy against beggary, by employing many poor people in the labour which either the making, or the mending of them constantly requires, and which is amply repaid by the increase of crops: for it has been remarked, not only that well inclosed countries generally maintain treble the number of inhabitants, or more, than the champaign; but also, that those inhabitants are much better fed and clad, than the common run of people in uninclosed lands. To be convinced of this, let any one but examine our vast downs, commons, heaths, wastes, and unimproved forests, badges yet remaining, as Mr. Worlidge properly terms them, of poverty and idleness; but at the same time, thoroughly susceptible of being converted, with proper care, into corn and pasture fields, meadows, gardens, orchards, and pleasant groves, the marks of industry and good husbandry. Let him but compare the naked parts of Wiltshire, Gloucestershire, Hampshire, Surry, &c. with the delightful parts of Kent, Herefordshire, and other countries, and he cannot but be struck with a demonstration of the immensely valuable improvements which may yet be made in very many parts of this kingdom. The now unimproved, un-occupied crown-lands, might alone, or even only a part of them, be rendered an inexhaustible source of unequalled wealth to the sovereign, of a vast increase of his subjects, and of happiness to all.

The common objection against inclosures have been so well refuted by many very able writers, and are daily invalidated by that most unerring test, experience, that it would be needless for us to recapitulate them here: we therefore shall only point out one farther essential advantage attending this great improvement, which is, that it enables the farmer to act as is most agreeable to him in sowing when, and what, he pleases.

Every gentleman, whose estate is not yet inclosed, and who is consequently at liberty to choose the manner and means of doing it, will rationally begin with having a map of it drawn, that he may thereby be enabled to divide and portion it out, with the greater propriety and precision, so as to render it most pleasing to the eye, and most convenient to each farmer. If he has a place of residence upon it, he may make the whole become ornamental to that residence, by a judicious disposition of his hedges and plantations, as has been nobly done at Boughton, in Northamptonshire, by the late duke of Montague, who, with a most refined taste, and truly benevolent mind, disdaining all the little and confined ornaments of a park, executed his fine improvements there in such a manner, as to render them pleasingly beneficial to all his neighbours, as well as to every person settled upon his land. Gubbins, in Hertfordshire, the seat of Sir Jeremy Sambrook, is another charming example of elegance, though less extensive than the former.

Ha-ha walls, and pieces of water, with rails running across them, are an easy means of preserving a fenced level.

The farms should be so divided, that the dwelling of each tenant may be as contiguous to his land as conveniency will admit of, to prevent length of carriage, and to facilitate his due attendance.

Small farms have always been observed to yield the greatest proportional rent, and small inclosures constantly produce the most plentiful crops.

Inclosures for arable lands should be larger than for pastures, that the soil may be kept dry, and the corn be well aired. For the manner of making inclosures, *see the article* FENCE.

ING, a common pasture or meadow.

INOCULATION, a very curious operation in gardening, otherwise called budding.

It is a kind of grafting practised in the summer months on several kinds of stone fruits, as peaches, nectarines, cherries, plums, apricots, &c. also upon oranges, jasmines, and various other sorts of plants, which succeed better by this practice, than by the common method of grafting. The operation is performed in the following manner:

Being provided with a sharp knife, with a flat haft, made for this purpose, as also with the cuttings of the tree intended to be propagated, make choice of a smooth part of the stock intended to be inoculated; if designed to be dwarf, five or six inches from the ground: but if a standard, it should be budded at the height of five and a half, or six feet; then, with your knife, make an horizontal cut acroſs the rind of the ſtock, and from the middle of that cut make a ſlit downwards about two inches in length, being careful not to cut deeper than the thickneſs of the bark, leſt the ſtock is wounded; then having the cutting ready, cut off the leaf from the bud, leaving the foot-ſtalk remaining; cut the bud off lengthways, ſomewhat longer than the ſlit in the ſtock, with part of the wood to it; this done, with your knife ſlip the wood from the bark with a ſudden jerk, and obſerve whether the eye of the bud is left or not, for thoſe buds which loſe their eyes in ſtripping are uſeleſs; then with the handle of the knife gently raiſe the bark on each ſide of the ſlit in the ſtock, and inſert the bud therein, obſerving to place it ſmooth between the rind and wood of the ſtock, cutting off that part of the rind of the bud which may happen to be too long for the ſlit made in the ſtock; ſo having exactly fitted the bud to the ſtock, tie them cloſely round with wetted ſtrong baſs, taking care not to bind round the eye of the bud, which ſhould be left open. In about three weeks or a month, the buds will require to be looſened of the bandage, which, if not done in time, will be very injurious to them, but not to be intirely diveſted of the binding, as it is not amiſs to ſlightly tie them again, which will prevent the bark of the ſtock from flying open, as ſometimes happens, whereby the bud is much injured, if not entirely deſtroyed.

The March following, the ſtock ſhould be cut off about three inches above the place of inoculation, ſloping it the contrary way to the bud; this length is of uſe to faſten the ſhoot which proceeds from the bud, which otherwiſe might be blown out by ſtrong winds: but the autumn following, it ſhould be cut cloſe juſt above the bud, that the place of amputation may the more readily be barked over.

The time for inoculation, is from the middle of June to the latter end of Auguſt, according to the ſeaſon and the forwardneſs of the different ſorts of trees intended to be budded, which muſt be known by trying if the buds will ſeparate from the wood eaſily. The firſt ſort of fruit commonly inoculated, is the apricot, and the laſt the orange; although the orange is commonly budded in Auguſt, it is very proper to try the operation in July, and thoſe ſtocks which miſcarry may be budded the ſucceeding month, or even in September; but let it be done when it will, it is proper to place them in a gentle heat, giving them plenty of water, by which means there will be no reaſon to doubt of their ſucceſs.

In performing this operation, it will be neceſſary to take the opportunity of moiſt cloudy weather, as the bud and ſtock will more readily unite, being more replete with juices than in hot dry weather, when the ſtock will perſpire ſo faſt, as to leave the buds deſtitute of moiſture.

INOM, or *Innom barley*, ſuch barley as is ſown the ſecond crop after the ground is fallowed.

INSECT, a general name for the ſmaller kinds of animals.

With regard to the generation of inſects, the world is now in general convinced, that they are not bred from corruption, but from eggs, though the contrary was believed by the ancients.

Malpighi, Swammerdam, and Redi, have abundantly confuted the doctrine of equivocal generation, as well as the chimerical transformation of the caterpillar into the butterfly, and have ſhewn, that all the members of the butterfly were incloſed under the nympha or ſkin of the caterpillar, as the parts of a plant are in the ſeed.

Inſects take particular care to depoſit their eggs or ſemen in ſuch places where they may have a ſufficient incubation, and where the young, when hatched, may have proper food till they can ſhift for themſelves. Thoſe whoſe food is in the water, lay their eggs there; thoſe to whom fleſh is a proper food, in fleſh; and thoſe to whom the fruits or leaves of vegetables are food, are accordingly depoſited there, but conſtantly the ſame kind in the ſame tree. As for others that require a greater degree of warmth, they are provided by the parent with ſome place in or about the body of other animals, as the feathers of birds, hair of beaſts, ſcales of fiſh, in the noſe, in the fleſh, nay ſome in the bowels of man, and other creatures. And as for others, they make them neſts, by digging into the earth, wood, &c. carrying in and ſealing up proviſions that ſerve for the production of their young, and for their food when produced.

There is obſerved in flies, butterflies, &c. a kind of glue, by which the female faſtens her eggs to the beraing buds of trees, &c. ſo as not to be hurt by rain or froſt.

Mr. Andry, in his Treatiſe *De la Generation des vers dans le Corps de l'Homme*, takes notice, that the ancients were miſtaken in denying that inſects breathed, on account of their wanting lungs; for modern obſervations convince us, that inſects have a greater number of lungs than any other animals. They alſo thought that they had no blood, as many of them had no red liquor like ours; but it is not the colour, but the uſe of the liquor, that is to be regarded. They alſo believed that they had no hearts; whereas our microſcopes now diſcover that, when inſects have ſeveral lungs, they have alſo ſeveral hearts; and this in particular is obſervable in ſilk-worms, who have a continued chain of hearts from the head almoſt to the extremity of the tail; and, as is apparent from ſeveral inſects, who give ſigns of life, long after they are divided into ſeveral parts.

Inſects want no parts that are either neceſſary or convenient for their uſe, or to render them complete in their kind. Some affirm that earth-worms, and thoſe round-tailed worms, which are found in the inteſtines of men, horſes, &c. as alſo ſnails and horſe-leeches, are hermaphrodites; but that ſuch worms as become flies, and that ſilk-worms, are not ſo, being of no ſex, but neſts full of real animals, which in time come out with wings.

Several ſorts of inſects do irreparable injury to the huſbandman, though ſo very minute as hardly to be diſcovered.

Among others, a ſmall kind of worm gets into the roots, chiefly of oats, and, working upward, deſtroys all the inſide of the plant, which periſhes ſoon after. M. Duhamel ſuſpects it to have been an inſect of this kind that deſtroyed vaſt quantities of wheat in the neighbourhood of Geneva, and of which M. de Chateauvieux ſent him the following account. "Our wheat, ſays that illuſtrious huſbandman, in the month of May 1755, ſuſtained a loſs which even that cultivated according to the New Huſbandry did not eſcape. We found in it many little white worms, which afterwards became of a cheſnut colour. They poſt themſelves between the blades, and eat the ſtems. They are uſually found between the firſt joint and the roots. Every ſtalk which they attacked, grew no more, but became yellow and withered. The ſame misfortune befel us in the year 1732. Theſe inſects appeared about the middle of May, and made ſuch havock that the crop was almoſt deſtroyed."

Mr. Liſle mentions, that on the 13th and 14th of June, in pulling up wheat in ear, and ſow-thiſtles, he obſerved among the upper part of the roots of moſt of theſe plants, knots or cluſters of graſs-lice, or green locuſts, as he calls them, which appeared whitiſh when they were but juſt come to their ſhape, and as yet under ground: and among moſt of theſe cluſters he obſerved a fly at her incubation, very turgid of a whitiſh matter; ſhe being then blowing theſe inſects. Her wings were black, and he thought her plainly the ſame as the locuſt, excepting that it had wings. He did not find more than one fly at any one root.

We too often find, in our kitchen-gardens, a ſort of vermin called vine-fretters. They fix upon the roots of leguminous plants, which afterwards gradually turn yellow, and die. M. Tillet ſays he has obſerved the ſame inſect in the roots of wheat.

The cuckow-ſpit, or ſpring-forth, as it is commonly termed, lodges itſelf principally in the joints of plants, ſeldom appears before the latter end of May, and is moſt common when rain has fallen after a ſeries of dry weather. M. Poupart, in his account of this little creature, ſays, that as ſoon as it is out of its egg, it goes to a plant, which it touches with its fundament, and faſtens there a white drop of liquor full of air; that it drops a ſecond near the firſt, then a third, and ſo on till it covers itſelf all over with a ſcum or froth, which keeps it from the heat of the ſun, or ſpiders that would ſuck it. But Mr. Liſle takes this liquid to be nothing but the nightly dew, which falls on the fork or joint of the plant, where the

little

little insect works it into froth with its proboscis, as with a bellows. *See the article* BUTTERFLY.

INSTEP, a name given to that part of a horse's leg, which reaches from the ham to the pastern-joint.

INUNDATION, a flood, or the overflowing of lands by a large collection of water. For the manner of guarding against the bad effects of inundations, *see the article* BANKS.

JUG, a large drinking vessel, with a gibbous or swelling belly.

JURNET, earth-nut.

K.

KEEVE, a fat in which beer is worked or fermented.

KELL, a web, or kind of bag, in which insects are bred.

KID, a small faggot of under or brush-wood.

KIDEROW, a place for keeping a sucking calf.

KIDNEYS, two pretty large glandulous bodies situated in the cavity of a horse's loins upon the two lowermost ribs.

Their use is to separate the urine, which is of great importance to the health and preservation of horses, they being liable to many diseases, which either take their origin from faulty kidneys, or have at least such symptoms, as plainly shew the kidneys to be more or less affected.

The signs of the kidneys being hurt or affected, are a weakness of the back and loins, difficulty of staling, faintness, loss of appetite, and deadness in the eyes; the urine is thick, foul, and sometimes bloody, especially after a violent strain. A horse diseased in his kidney can seldom back, that is, move strait backwards, without pain, which is visible as often as he is put to the trial: the same thing is observable indeed in horses, whose backs have been wrang and wrenched, but with this difference, that in the latter there is seldom any defect or alteration in the urine, except that it is higher coloured.

Bleeding is the prime remedy, and that plentifully, in order to prevent inflammation; and the more so, if a fever attends a difficulty in staling, for then we may suspect the kidneys already inflamed. A rowel in the belly has been found useful, and the following balls may be given twice or thrice a day, with a pint of marshmallow decoction, in which half an ounce of gum-arabic is dissolved, with an ounce of honey.

> Take lucatellus balsam one ounce, spermaceti six drams, sal prunellæ half an ounce; mix into a ball with honey: if the urine is bloody, add half an ounce of Japan earth.

Should the fever continue, bleed largely, give emollient clysters, and the cooling, opening drink, till it abates.

If the urine passes with difficulty and pain, notwithstand these means, give this ball, and repeat it twice or thrice a day, till the horse stales freer and without pain, his urine becomes of a right consistence, and is free from any purulent settlement.

> Take balsam of copivi, or Strasbourg turpentine, and Venice soap, of each one ounce; nitre six drams, myrrh powdered two drams; make into a ball with honey, and wash it down with the marshmallow decoction.

But if this method should not be succesful, and the urine continues turbid, grows coffee coloured or fœtid, the horse losing his appetite and flesh, it is a sure sign of ulceration in the kidney; which if the above remedies do not soon remove, you may depend on it the horse will go into a consumption, and is incurable.

As a suppression of urine arises sometimes from an inflammation of the kidney; so at others, from a paralytic disorder, disabling them in their office of separating the urine from the blood: in this latter case the bladder is usually empty, so that a horse will make no motions to stale, and if he continues a few days in this condition, his body will swell to a great degree, breaking out in blotches all over, and death will soon close the scene.

If it arises from inflammation, bleed largely, and treat the horse as above recommended; but if not, give stimulating clysters, and strong diuretics, such as the following balls once in four hours; for if a horse stales not in thirty hours, his danger must be great.

> Take juniper-berries powdered one ounce, sal prunellæ six drams, ætherial oil of turpentine half an ounce, camphor one dram, oil of juniper two drams; make into a ball with honey, and give after it, three or four horns of the marshmallow decoction and honey.

Or,

> Take squills powdered two or three drams, nitre half an ounce, or six drams; make into a ball with honey.

Or,

The following, which is more forcing, and should be given with caution.

> Take cantharides well dried, from one scruple to half a dram; camphor dissolved in oil of almonds, from one dram to two; nitre and Venice soap, of each an ounce; mix into a ball with syrup of marshmallows.

When

When this last ball is given, the horse should be made to drink plenty of water, with gum-arabic dissolved in it; the following clyster may also be given at the same time.

> Take of Barbadoes aloes two ounces, the same quantity of Venice turpentine, beat up with the yolks of two eggs; jallap powdered two drams; juniper and bay-berries, each a handful, bruised and boiled in two quarts of a decoction of mallows; strain off and mix by degrees with the above, to which add a pint of linseed-oil.

If the complaint is not removed by these means, rub the horse's reins well with two parts of oil of turpentine, and one of oil of amber; and apply a poultice of garlick, horse-radish, mustard-seed, camphor, and green soap, spread on thick cloth, over them. Give the horse also two drams of calomel over night, and a moderate purge the next morning. These, perhaps, are the chief and best remedies that can be given in this generally fatal disorder.

When the stranguty in a horse does not arise from wind, or dung pressing on the neck of the bladder, the cause is from inflammation, or too long a retention of the urine. Such horses make frequent motions to stale, stand wide and straddling, are full, and have their flanks distended. In this case bleed largely; give the following drink, and repeat it every two hours, for two or three times, till the horse is relieved.

> Take Venice turpentine broke with the yolk of an egg one ounce, nitre or sal prunellæ six drams, half a pint of sweet oil, and a pint of white wine.

If this drink should not have the desired effect, the diuretic ball above-mentioned may be given in the same manner, omitting the myrrh.

Give the horse plenty of the marshmallow decoction, in a quart of which dissolve an ounce of nitre and gum-arabic, and two of honey.

Horses subject to a diabetes, or profuse staling, if old, or of weak constitution, are seldom cured; they soon loose their flesh and appetite, grow feeble, their coat staring, and they die rotten. Of a young horse there are more hopes; but he must not be indulged with too much water, or moist food. Give him the following:

> Take jesuits-bark four ounces, bistort and tormentil-root, of each two ounces; boil in two gallons of lime-water to the consumption of half, and give a pint three times a day.

Let the horse drink two or three quarts a day of lime-water; and if these medicines should not succeed, give a quart of strong allum posset, three or four times a day.

This method is proper also for a horse who stales blood; or the following balls may be given for that purpose, if the bleeding is profuse.

> Take bole-armoniac one ounce, Japan earth half an ounce, roch-allum two drams, elixir of vitriol one dram; make into a ball with conserve of roses, and give it every six hours.

As this disorder generally proceeds from too violent exercise, over-straining, &c. repeated bleedings in small quantities are absolutely necessary, till the mouths of the vessels close up. *Bartlet's Farriery, pag.* 159.

KILN, a kind of stove for admitting heat, in order to dry any substance, as malt, hops, &c. *See the articles* MALT *and* HOPS.

KILN also signifies a fabric constructed for burning lime-stone, chalk, &c. into lime.

The kiln commonly used for this purpose is a large pit, generally round, and of a size proportioned to the quantities intended to be burnt. It is widest at the top, and narrower, by degrees, as it comes nearer the bottom. The inside of this pit is sometimes lined with a wall built of lime-stone; but more commonly, and more properly with bricks: at the outside, near the bottom, is a hole, or door, by which the ashes are taken out; and above that, some have an iron-grate, which comes close to the wall round about: but others make an arch with stone, or large pieces of chalk; and upon this they lay a layer of stone, or of whatever else they burn in the kiln; upon this they place a layer of fuel, and so on, layer over layer, till the kiln is full; only observing that the outermost layer be always of the fuel, and not of chalk or stone. When the kiln is thus filled, fire is given at the hole underneath; and the lime is finished in a different time, according to the nature of the substance. That made of chalk is generally burnt in twenty-four hours; but stone often requires sixty hours. Ten bushels of sea-coal, or one hundred of faggots three feet long, will burn forty bushels of chalk, which will yield thirty bushels of unslaked lime. Where chalk is scarce, the chalk rubbish is often worked up into a kind of paste, with water, and made into a sort of bricks, which are dried in the air, and then burnt into lime in the common way: but this is not quite so good as that which is burnt from the chalk-stone.

The experience of late years has shewn that it is more profitable to burn lime in kilns shaped like a hogshead; that is, small in circumference at the bottom, gradually wider towards the middle, and then contracting again upwards to the top. This kiln, as Mr. Lummis observes in his letter to the Edinburgh Society, published by Mr. Maxwell, should be made entirely within the surface of the ground, on the declivity of a little hill, where that situation can be had, so as to allow free accesss to the air-hole or furnace. At the bottom, about a foot from the ground, are iron-bars, placed horizontally arofs, to give the kiln a good draught, and upon these bars are laid, first small wood or furze, then small coals, then stones about the bigness of an egg, then another layer of fuel, and so on, increasing the size of the stones towards the middle of the kiln, where they may be as big as half a peck, and decreasing their size gradually up to the top, observing to lay the smallest nearest to the sides. The stones need not be broken so small for this kiln, as for those above ground; they will be burnt more truly without raw stones, or running into cinders; and not above half the quantity of fuel consumed in the common way, will be used in this.

The following method of constructing another kiln, is thus particularly described in Mr. Maxwell's Collection.

At bottom, the kiln must be three feet four inches wide; and at the height of two feet four inches, three feet six inches. At the depth of four feet and a half, it must be four feet and a half wide. A second slope is then made five feet and a half higher, at the end of which, the kiln, then ten feet deep, should be exactly ten feet wide within the walls. A third slope should heighten it to 14 feet, where it should be exactly 12 feet and a half wide, likewise, within the walls From thence it is run up to the height of nineteen feet, when it should be rather less than fifteen feet wide. The slopes must be made as gradual as possible, and the inner surface of the kiln must be quite smooth, that its contents may fall down equally when the burnt stones are drawn out below. By extending a line from a pole fixed in the center of the bottom or floor of the kiln, to the sides, workmen will easily be guided in making the above-mentioned slopes. This kiln has four vents, opposite to one another, and no cross-irons whereupon to lay the coals and stones, they being supported by old timber, furze, broom, &c. above which the coals are laid: but if the kiln be built on the side of a hill, it can have but three vents. The first layer of stones above the vents should be closely jambed in, and rest against the sides of the wall. A kiln of the above dimensions will burn eighty bushels of lime-stones in a day: but it may be made larger, without altering these dimensions, by only adding two or three feet to the height, which will require strong walls. This addition to the height need not be sloped, but may be made perpendicular.

The late earl of Stair had a kiln at New Liston, and others in Galloway, built in the shape of an egg, opened a little at both ends, and set upon the smallest. This kiln answered exceedingly well, and besides lime-stone, burnt any kind of earth that was thrown into it.

Kilns thus built, swelling at or about the middle, and contracting again at the top, reverberate more strongly, and make a more intense heat, than those which grow wider and wider, and are not contracted.

When the kiln is filled, or finished as it is commonly termed, it should be covered over with sods or strong turf, to keep the heat as intense as possible, and hinder the wind from blowing the fire at the top, or rain from abating or extinguishing it. The stones must be broken in pieces before they are thrown into the kiln; otherwife the air contained in their cavities, being expanded by the heat, will often make them fly with fuch violence as to damage the kiln. For this reafon they fhould be broken fmaller for kilns that are above ground, than for thofe which are underneath. The faving of this labour, and of near half the quantity of fuel, renders thefe laft greatly preferable.

Lime is made of chalk, or of any ftone that is not too cold, or fandy, as free-ftone and the like. All the foft ftones that are of a tolerably clofe texture, will burn to good lime, as will alfo marble, flate, fea-fhells, corals, and flints; but this laft kind of ftone is more difficult to be burnt into lime than the others, except in a reverberatory kiln, becaufe it is apt to run to glafs. The hardeft, firmeft, and whiteft ftones make the beft lime; and when it is made of chalk, that which is formed of the hardeft, ftony kind, is much better than that which is made from the foft; but the harder the ftones are, the more fire it requires to burn them. Both forts may be burnt with wood, coals, turf, furze, or fern, which make a very fierce fire.

Thefe kilns feem to be intended for burning only one kiln full at a time: but where large quantities of lime are wanted, perpetual kilns, that is, kilns where the fire is kept conftantly burning, are conftructed on nearly the fame principles. Here the iron bars at the bottom are abfolutely neceffary, in order to take out the lime as foon as it is burnt. When ftone-lime, which requires the moft violent fire, is burnt in thefe kilns, vents are made near the bottom to be opened occafionally, according as the wind fits, that a ftronger current of air may quicken the fire, and thereby give it the more power. *See the article* LIME.

KILN-ASHES, the afhes made in kilns where wood, ftaw, furz, &c. are burnt. Thefe afhes are a good manure for almoft any kind of foil. In the weft of England, the farmers fift them over their corn and grafs; but this muft not be done in windy weather, becaufe they are fo very light, that they would eafily be blown away. They fucceed beft when laid on juft before rain or fnow.

KINNEL, a powdering-tub.

KIT, a milking-pail, in the form of a churn, with two ears and a cover.

KNAPWEED, the fame with blue-bottle. *See* BLUE-BOTTLE.

KNOT-GRASS, the fame with couch-grafs. *See* COUCH-GRASS.

KNOLL, a little round hill.

KNOLLS, a term ufed in fome counties of England to fignify turneps.

L.

LACTARY, a milk-houfe.

LADIES-SMOCK, *Cuckow-flower*, or *Canterbury-bells*, a perennial weed, and common in pafture grounds. The ftalk is upright, round, and fmooth. The leaves are winged, with the lobes of the lower ones roundifh, and of thofe on the ftalk oblong. The flowers are large, handfome, and white, or purplifh, confifting of four obtufe veined petals. The feeds are contained in erect compreffed pods, about an inch in length, divided into two cells, which, when ripe, burft with a touch, and throw out their feeds to a confiderable diftance.

LAIRE. *See* LAYER.

LAMB, the young of the fheep-kind. *See the article* SHEEP.

LAMENESS, in horfes. *See the article* STRAINS.

LAMPAS, an excrefcence in the roof of a horfe's mouth, which is fometimes fo luxuriant, that it grows about the teeth, and hinders his feeding.

The cure confifts in lightly cauterizing the flefh with a hot iron, taking care that it does not penetrate too deep, fo as to fcale off the thin bone that lies under the upper bars; the part may then be anointed with burnt allum and honey, which is proper for moft fores in the mouth. *Bartlet's Farriery, page* 282.

LAND. *See the article* GROUND *and* SOIL.

LARCH-TREE, a genus of trees, whofe leaves, which are long and narrow, are produced out of little tubercles, in form of a painter's pencil: the cones are produced at remote diftances from the male flowers on the fame tree: the male flowers are very like fmall cones at their firft appearance, but afterwards ftretched out in length.

Thefe trees are propagated by feeds, which fhould be fown in the beginning of March, upon a bed of light foil, expofed only to the morning fun: or otherwife they may be fown in pots or boxes of light earth, and placed near a hedge, where they may have the morning fun only. The feed fhould be covered about half an inch thick with fine light earth, and in very dry weather fhould be gently refrefhed with water. In about fix weeks, if your feeds were good, your plants will come up, at which time you fhould carefully guard them againft the rapacious birds, which would otherwife pull off the heads of the plants, as they thruft themfelves out of the ground with their covers on them: and obſerve to refreſh them with water in dry weather, eſpecially if they are ſown in pots or boxes; as alſo to keep them clear from weeds, which, if ſuffered to grow among the young plants, will ſoon deſtroy them: nor ſhould they be too much expoſed to the ſun, or ſtrong winds, both which are very injurious to theſe plants while they are young: but in October you ſhould, if they are in boxes or pots, remove them into a ſituation where they may be defended from ſharp winds, which are ſometimes hurtful to them, while young; but afterwards, they will indure the ſevereſt weather of our climate.

Theſe trees are very proper for the ſides of barren hills, where few other ſorts will thrive ſo well; nor is this tree very delicate in its ſoil, but will grow much better on poor, ſtrong, ſtony land, than in rich ground; and, during the ſummer, they appear very beautiful; but in autumn they caſt their leaves, whereby ſome people have been deceived, by ſuppoſing them dead, and have deſtroyed them.

From the wounded bark of this tree exudes the pureſt Venice turpentine; and on the body and branches of it grows the agaric, which is a drug uſed in medicine.

LARKSPUR, a genus of plants, whoſe flower conſiſts of five unequal petals, diſpoſed circularly: of theſe the upper one is anteriorly more obtuſe than the others, and is emarginated, and extended behind into a tubulated horn, which is ſtraight, long, and obtuſe. The two ſide petals are nearly of the ſize with the upper; and the two lower are leſs, and ſpread open. The ſtamina are numerous; and the fruit conſiſts of three capſules, of an ovate-ſubulated figure, joined together, which are filled with a number of angulated ſeeds.

There are ſeveral ſpecies of larkſpur; but the ſort which is well known, and common in gardens (particularly thoſe with double flowers of various colours) is much in eſteem, and extremely beautiful.

Theſe are annual, and may be ſown in autumn or ſpring. Where the land is light and dry, the autumn ſowing is to be preferred; for if the plants withſtand the ſeverity of winter, they blow much earlier than thoſe ſown in the ſpring, and their ſpikes of flowers are conſiderably larger. In order to continue their plenitude, all plants with ſingle flowers ſhould be deſtroyed ſo ſoon as they appear, reſerving for ſeed thoſe only which are very double.

They flower in July and Auguſt, and are great ornaments to the pleaſure garden.

LATH, a long, thin, and narrow ſlip of wood, nailed to the rafters of a roof or cieling, in order to ſuſtain the covering.

Theſe are diſtinguiſhed into three kinds, according to the different kinds of wood of which they are made, viz. heart of oak, ſap laths, and deal laths; of which the two laſt are uſed for ceilings and partitions, and the firſt for tiling only.

Laths are alſo diſtinguiſhed according to their length, into five feet, four feet, and three feet laths; though the ſtatute allows but of two lengths, thoſe of five, and thoſe of three feet, each of which ought to be an inch and a half in breadth, and half an inch in thickneſs; but they are commonly leſs.

Lath-Bricks, bricks much longer than ordinary, uſed inſtead of laths, for drying malt; for which purpoſe they are extremely proper, as not being liable to catch fire, and retaining the heat much longer than thoſe of wood; ſo that a very ſmall fire will ſerve after they are once heated.

LATHE, a word uſed in ſome counties in England, to ſignify a barn.

LAVENDER, a well known plant cultivated in moſt gardens, and of which there are two ſorts, diſtinguiſhed by the names of lavender ſpike, and common narrow leaved lavender. They are both propagated by cuttings or ſlips of a year's growth. Theſe ſhould be planted in March, in a ſhady ſituation, or at leaſt they ſhould be ſhaded with mats till they have taken root. They may then be expoſed to the ſun; and after they have acquired ſufficient ſtrength, they ſhould be removed to the places where they are to remain. The broad lavender does not often produce flowers; but when it does, they appear towards the latter end of July, at which time the ſpikes of the common ſort, which bloſſom the earlier of the two, and which is the kind cultivated for medicinal uſes, are fit to be gathered. Both theſe ſorts will grow beſt in the ſummer, if planted in a rich and moiſt ſoil; but then they ſeldom bear the inclemency of the winter: nor will they have half ſo ſtrong an aromatic ſcent, nor laſt near ſo long, as thoſe ſituated on a dry, gravelly, or ſtony ſoil. In ſuch land, or even on a barren rocky ſpot, they will reſiſt all the ſeverity of our hardeſt winters.

LAWN, a large plain in a park, or adjoining to ſome grand ſeat. The moſt convenient ſituation is on the ſouth, or ſouth-eaſt-ſide of the houſe. If the lawn be a ſquare, three avenues may break out from three of the angles, and meet in the fourth angle oppoſite to the houſe: it may be bounded with walks or a ſingle row of lime trees, ſet at a good diſtance from one another. A circle is a good figure for a lawn, but muſt break off before it comes againſt the front. A triangle is a very proper figure, but ſhould be obtuſe or right-angled next the front.

Many perſons have preferred the lime-tree for this purpoſe, on account of their regular growth: but as the leaves of this tree often change their colour, and begin to fall very ſoon in the autumn, occaſioning a great litter in the garden; and from the end of July the trees make but an indifferent appearance, ſo they are not to be eſteemed for theſe plantations.

The elm, oak, beech, and cheſnut, among the deciduous trees, are to be preferred to all others, as they keep their leaves late in autum: and theſe are all of them large growing trees; ſo are very proper for this purpoſe.

If there are ſome clumps of ever-green trees intermixed with the deciduous trees in this plantation, it will add to the beauty of it, eſpecially in the winter ſeaſon: the beſt ſorts for this purpoſe, are the lord Weymouth's pine, the ſilver and ſpruce firs, which will grow faſt, and become large trees; and as the two latter ſorts always grow pyramidically, ſo they will have a good effect to the ſight, when properly diſpoſed with the diciduous trees: but as theſe generally feather out their branches near the ground, they ſhould be planted where they do not obſtruct the view of any diſtant objects.

But as moſt perſons who take pleaſure in beautifying their ſeats in the country, are in haſte for ſhade, they generally plant the trees too cloſe together, and often in ſuch a manner, as to render it difficult, when the trees are advanced, to reduce their number, without injury to the deſign: therefore thoſe trees ſhould be firſt planted, which are deſigned to remain; and then there may be ſome few others planted for preſent ſhade, which may afterwards be taken away. When perſons, who are beautifying their ſeats, meet with full grown trees on the ſpot, it is a great pleaſure; for theſe ſhould not be deſtroyed, if they can poſſibly ſtand. *Miller's Gard. Dict.*

LAYERS, the ſmall tender ſhoots or twigs of trees, laid or buried in the ground, till having ſtruck root, they are ſeparated from the parent-tree, and become diſtinct plants. The manner of performing this operation is as follows:

1. Take ſome of the boughs, and lay them into the ground, about half a foot deep, in fine freſh mould, leaving them with the end of the layer, about a foot, or a foot and a half out of the ground, and keep them moiſt during the ſummer-ſeaſon, and they will probably have taken, and be fit to remove in autumn; and if they have not by that time taken root, they muſt lie longer.

2. Tie a piece of wire hard round the bark of the bough, at the place you intend to lay in the ground; and twiſt the ends of the wire, ſo that they may not unite; and prick the place above the wire, through the bark, with an awl in ſeveral places; and then lay it in the ground, as before directed.

3. Cut a ſlit upwards at a joint, as is practiſed in laying of carnations, which, by gardeners, is called tonguing the layers.

4. Twiſt the place which you deſign to lay in the ground like a withy, and lay it into the ground, as directed in the firſt way of laying.

5. Cut a place round about the bough that is deſigned to be laid, an inch or two, at the place that is moſt convenient to lay into the ground, and manage it as is directed in the firſt method of laying.

The

The feafon for laying hardy trees that fhed their leaves, is in October; but for fuch as are tender in March; for ever-greens, June or Auguft are good feafons.

Though layers may be laid at any time in the year, the before-mentioned feafons are moft proper, for the reafons following; becaufe they have the whole winter and fummer to prepare and draw root; for at thefe times of the year, the fun has fufficient power on the fap of the tree to feed the leaf and bud, but has not power fufficient to make a fhoot.

And if that fmall quantity of fap that does arife be hindered, as it will by fome of the preceding ways of laying, the leaves and buds will gently crave of the layer, and by that means will prepare the layer to take root, or put forth roots a little to maintain itfelf, finding it cannot have it from the mother-plant.

And therefore becaufe it wants but little nourifhment at that time of the year, it is better to lay layers of trees, or to fet cuttings, than at other times, either in the winter, when the fap ftirs but little, or in the fummer, when the fap abounds, or in the fpring, when it begins to rife; becaufe it is then apt to come too fuddenly to draw fap from the layer, before the layer has drawn or prepared for root.

However, the fpring or fummer may do well for fmall plants; becaufe fuch plants, being but fhort-lived, draw root the quicker.

If you would lay young trees from an high ftandard, the boughs of which cannot be bent down to the ground, then you muft make ufe of ofier-bafkets, boxes, or pots, filled with fine fifted mould, mixed with a little rotten willow-duft, which will keep moifture to affift the layer in taking root: this bafket, box, &c. muft be fet upon a poft or treffel, &c. and the bough muft be laid according to either of the four firft ways of laying; but too much head muft not be left on, left that be injured by the wind, or by its own motion rub off the tender root; and the fmaller the boughs are, the lefs way they fhould be fet out of the ground, and care muft be taken to keep them clear from weeds.

The harder the wood is, the better will the young wood take root; but if the wood be foft, the older boughs will take root the beft. *Miller's Gard. Dict.*

LEAF, a part of a plant, commonly very thin and flat, growing in the fpring, and falling off in the autumn.

Leaves are the ornament of the twigs, and confift of a very glutinous matter, being furnifhed every where with veins and nerves. Their office is to fubtilize the nourifhing fap, and convey it to the little buds; and likewife they ferve to cover the flowers and fruits with their fhade, and keep them from other inconveniences; they are to trees what hair is to the human body.

Dr. Grew obferves, that the fibres of leaves confift of two general kinds of veffels, namely, for fap and for air; and are ramified out of greater into lefs, as veins and arteries are in animals.

Mr. Frederick, of Augfbourg, a celebrated gardener, took from the tree a leaf of the opuntia or Indian fig-tree; and fetting it in the earth, it immediately took root, and produced bloffoms and fruit.

The diftinction of leaves, made by thofe who have written on botany, are the following.

A fimple leaf is that which is not divided to the middle.

A compound leaf is divided into feveral parts, each refembling a fimple leaf, as in liquorice, &c.

A digitated leaf is a compound leaf divided into feveral parts, all of which meet together at the tail, as in the hemp, black hellebore, &c.

A trifoliated leaf is a digitated leaf, confifting of three fingers, as the trefoil, &c.

A quinquefoliated leaf is a digitated leaf, confifting of five fingers, as in the quinquefolium.

A pennated leaf is a compound leaf divided into feveral parts, each of which is called a lobe, placed along the middle rib, either alternately, or by pairs. When the middle rib is terminated by an odd lobe, it is faid to be unequally pennated, as in the goats rue, &c. and equally pennated, when it is not terminated by an odd lobe, as in the caffia; when the lobes are all nearly of the fame form and bignefs, it is called an uniform pennated leaf, as in the liquorice; when they are not fo, it is faid to be difform, as in the agrimonia.

A winged leaf is, as it were, divided into feveral pennated leaves, as in the orobus, &c.

A ramofe leaf is that which is ftill farther divided than the winged leaf, as in the ofmund royal, female fern, &c.

An entire leaf or lobe is that which has no divifion on its edges, as in the apple-tree, &c.

A finuated leaf is that which is cut about the edges into feveral long fegments, as in common mallows.

A ferrated leaf is that which is cut about the edges into feveral acute fegments, refembling the teeth of a faw, as in the nettle, &c.

A crenated leaf is that which is cut about the edges into feveral obtufe fegments, as in the betony, &c.

A lacinated or jagged leaf is that which is cut about the edges into feveral pretty deep portions, in an irregular manner, as in the horned poppy, &c.

If the furface of leaves are altered, by reverfing the branches of trees on which they grow, the plants are ftopped in their growth, until the footftalks are turned, and the leaves recover their former pofition. This fhews how neceffary it is to fupport all thofe weak fhoots of plants, which are naturally difpofed for upright growth, which either twine about the neighbouring trees for fupport, or that put out clafpers, by which they take hold of whatever trees or plants grow near them, and are thereby fupported; and, on the contrary, how abfurd is that practice of tying up the fhoots of thofe plants which are naturally difpofed to trail upon the ground, for in both thefe cafes nature is reverfed, and confequently the growth of both forts of plants is greatly retarded.

This is one of the great functions for which the leaves of trees and plants are defigned; but, befides this, there are others of equal importance to the well-being of plants and fruits; the firft is, that of the footftalks and leaves nourifhing and preparing the buds of the future fhoots, which are always formed at the bafe of thofe footftalks, and during the continuance of the leaves in perfect health, thefe buds increafe in their magnitude; and, in the deciduous trees, are brought to maturity before the footftalks feparate from the buds in autumn; but if by accident the leaves are blighted, or if the entire furface of the leaves are cut off, and the footftalks are left remaining, the buds will decay for want of that proper nourifhment which is conveyed to them from the leaves; fo that whenever trees are divefted of their leaves, or thofe leaves are cut, or otherwife impaired, though it may in either cafe happen when the buds may be nearly formed, yet if it is before the footftalks feparate naturally from their branches, the future fhoots will be weakened in proportion to the time when this is done; therefore from all the experiments which have been made in order to know how ferviceable the leaves of trees and plants are to their well-being, it has been found, that when the plants have been divefted of their leaves, or their leaves have been eaten or cut, during their growth, the plants have been remarkably weakened thereby. This fhould teach us not to pull or cut off the leaves of trees, or plants, on any account, while they retain their verdure, and are in health; and this fhews how abfurd that common practice is, of feeding down wheat in the winter and fpring with fheep; for by fo doing, the ftalks are rendered very weak, and the ears are in proportion fhorter; nor are the grains of corn fo plump and well nourifhed, as that which is not fed down upon the fame ground: this is a fact which we can affert from many years experience. It is very evident, that grafs which is often mowed, the blades will be rendered finer in proportion to the frequency of mowing it, yet the fpecies of grafs is the fame with that on the richeft paftures; fo that although this may be a defirable thing for lawns, &c. in gardens, yet where regard is had to the produce, this fhould be avoided.

Another principal ufe of the leaves, is to throw off by tranfpiration what is unneceffary to the growth of the plants, anfwering to the difcharge made by fweat in animal bodies; for as plants receive and tranfpire much more, in equal time, than large animals, fo it appears how neceffary the leaves are to preferve the plants in in perfect health; for it has been found by the most exact calculation, made from repeated experiments, that a plant of the sun-flower receives and perspires, in twenty-four hours, seventeen times more than a man.

We shall beg leave to mention a few, out of the many experiments which have been made by M. Bonnet, of Geneva, to prove that most leaves imbibed the moisture of the air on their under surface, and not from their upper; they are as follows:

He gathered the leaves of sixteen sorts of herbaceous plants when fully grown; of each he put several leaves upon the surface of water in glass vases, some were posited with their upper surface, and others with their under surface upon the water; these were adjusted exactly to the surface of the water, with great care not to let any moisture reach their opposite surfaces, and the same care was taken to prevent their footstalks from receiving any moisture. The glasses in which these leaves were thus placed, were kept in a closet, where the air was very temperate; and as the water in the glasses evaporated, there was, from time to time, a supply of fresh, which was added with a syringe, so that the leaves were not disturbed. The leaves were taken from the following plants; the plantain, the mullein, the wake Robin, the great mallow, the nettle, the marvel of Peru, the kidney-bean, the sun-flower, the cabbage, the baum, the cock's-comb, the purple leaved amaranth, spinach, and the smaller mallow.

Six of these sorts he found continued green a long time, and these were with different surfaces upon the water: they were of the following sorts, the wake Robin, the kidney-bean, the sun-flower, the cabbage, the spinach, and the small mallow; among the others, the following sorts were found to draw the moisture better with their upper than with their under surface, the plantain, the mullein, the great mallow, the nettle, the cock's-comb, and the purple amaranth.

The leaves of the nettle, whose under surfaces were placed upon the water, were decayed in three weeks; whereas those whose upper surfaces touched the water, lasted three weeks.

The leaves of the mullein, whose under surfaces were next the water, did not continue fresh more than five or six days; whereas those whose upper surfaces were next the water, lasted five weeks.

The leaves of the purple amaranth, whose upper surfaces were next the water, continued fresh three months; whereas those whose under surfaces touched the fluid, were decayed in a week.

The leaves of the marvel of Peru and the baum, appeared to have the advantage, whose under surfaces were next the water.

The leaves of the wake Robin, and of the cock's-comb, whose footstalks only were put into the water, continued fresh a longer time than those which were placed with either surface upon the water.

The leaves of the great mallow, the nettle, the sun-flower, the marvel of Peru, and the spinach, whose footstalks were plunged into the water, continued fresh a shorter time, than those which had either of their surfaces upon the water.

The leaves of the mullein, plantain, and amaranth, which received the water at their footstalks, continued fresh much longer than those whose under surfaces touched the water.

It is not difficult to explain the reason of this fact; for the orifices of the sap-vessels in the footstalks are much larger than those of either surface, so that the water insinuates itself in greater quantities, and with more ease, in the first than by the second way.

After this the same gentleman made experiments on the leaves of sixteen sorts of trees and shrubs, of the following sorts: the lilac, the pear-tree, the vine, the aspin, the laurel, the cherry-tree, the plum-tree, the horse-chesnut, the white mulberry, the lime-tree, the poplar, the apricot, the walnut, the filbert, the oak, and the creeper.

Among these species he found, that the lilac, and the aspin, imbibed the water equally with either their upper or under surface; but in all the other sorts, the under surfaces imbibed it in much greater quantities than the upper. The difference was very remarkable in the leaves of the white mulberry, for those whose upper surfaces were laid upon the water, faded in five days; whereas the others, whose under surfaces were next the water, preserved their verdure near six months.

The vine, the poplar, and the walnut, afforded very remarkable instances, how little disposed the upper surfaces of the leaves of ligneous plants are to imbibe the moisture: for the leaves of these three sorts, whose upper surfaces were applied to the water, decayed almost as soon as those which had no nourishment.

In all the experiments made by this curious gentleman upon the various leaves of trees and herbs, it is remarkable that all those leaves, which imbibed their moisture by their upper surface, were such as had that surface covered over with hairs or down; and, on the contrary, where the under surface was garnished with either hairs or down, the nourishment was imbibed by that surface. He also mentions many experiments made by himself, and also by M. Duhamel de Monceau, of the Royal Academy of Sciences at Paris, in rubbing the leaves over with varnish, oil, wax, and honey, to see the effect of these upon various leaves, some of which were rubbed over on both surfaces, others only upon one; some only a part of the surfaces, others the edges of the leaves were rubbed over, and in some only the footstalks of the leaves. They likewise anointed the trunks of some trees and shrubs, leaving the leaves and branches in their natural state.

The result of these experiments was, that where the leaves were covered with varnish on both sides, they presently decayed; and where they were anointed with other things, the leaves continued a shorter time than others, in proportion as the things were more penetrating; and where one surface only was anointed, they continued much longer than those which were anointed on both; and where the pedicle alone was anointed, they continued still longer: but the anointing of the trunks made no sensible alteration, except in very hot weather; when they were both of opinion the anointing them were of service, by hindering the too great transpiration, which tend to weaken the trees: for they observed, that those trees which were varnished, suffered less from the violent heats, than the trees which were left in their natural state.

M. Bonnet also observed, that the tender parts of the leaves which were varnished were destroyed by it, and the tough fibres only left remaining.

We may therefore reasonably conclude, that one great use of leaves is what has been long suspected by many, viz. to perform, in some measure, the same office for the support of vegetable life, as the lungs of animals do for the support of animal life: plants, very probably, drawing through their leaves some part of their nourishment from the air. *Miller's Gard. Dict.*

LEAP, or *Lip*, half a bushel.

LEASE, *Lea*, *Lay*, or *Ley*, implies grassy ground, meadow ground, or unploughed ground, kept for cattle.

LEASE also signifies the letting of lands, tenements, &c. unto another for life; a term of years, under a reserved rent.

LEEK, the name of a well-known herb, cultivated in every kitchen-garden.

Leeks are raised by sowing their seeds in the spring, in the same manner as onions (*see the article* ONIONS) with which these are commonly sown, the two sorts of seeds being mixed according to the proportion which is desired of either sort, though the most common method is to mix an equal quantity of both; for the onions will greatly out-grow the leeks in the spring; but these being drawn off, the leeks will have time to grow large afterwards, so that there may be a moderate crop of both sorts. Many persons, however, sow their leeks in beds in the spring; and in June, after some of their early crops are taken off, they dig up the ground, and plant their leeks out thereon, in rows a foot apart, and six inches asunder in the rows, observing to water them until they have taken root; after which they will require no farther culture but to keep the ground clear from weeds. The leeks thus planted will grow to a large size, provided the ground be good, and therefore this is a very proper method for those who have but little room.

If you would save the seeds of this plant, you should make choice of some of the largest and best you have, which

which muſt remain in the place where they grow until February, when they ſhould be tranſplanted in a row againſt a warm hedge, pale, or wall, about eight inches aſunder; and when their ſtems advance, they ſhould be ſupported by a ſtring, to prevent their being broken down, to which they are very liable, eſpecially when in head, and the cloſer they are drawn to the fence in autumn, the better the ſeeds will ripen; for it ſometimes happens in cold ſummers or autumns, that thoſe which grow in the open garden, do not perfect their ſeeds in this country, eſpecially if there are ſharp froſts early in the autumn, which will entirely ſpoil the ſeed.

When it is ripe (which may be known by the heads changing brown) you ſhould cut off their heads with about a foot or more of the ſtalk to each, and tie them in bundles containing three or four heads, and hang them up in a dry place, where they may remain till Chriſtmas or after, when you may threſh out the ſeeds for uſe. The huſk of theſe ſeeds is very tough, which renders it difficult to beat out the ſeeds; ſome, therefore, who have but a ſmall quantity, rub it hard againſt a rough tile, which will break the huſks, and get the ſeeds out better than moſt other methods. *Miller's Gard. Dict.*

LEES, the more groſs and ponderous parts of liquors, which, being ſeparated by fermentation, fall to the bottom.

The lees of wine, beer, ale, and oil, are excellent manures.

LEET, a little court held within a manor, and called the king's court, on account that its authority to puniſh offences originally belonged to the crown, and from thence deſcended to inferior perſons.

LEMON, *Limon*, in botany, a genus of trees with large ſtiff leaves like the citron, without any appendage at the bottom; the flower conſiſts of many leaves, which expand in form of a roſe: the fruit is almoſt of an oval figure, and divided into ſeveral cells, in which are lodged hard ſeeds, ſurrounded by a thick fleſhy ſubſtance, which, for the moſt part, is full of an acid juice.

All ſorts are propagated by budding or inarching them either on ſtocks of lemons or citrons produced from ſeeds, but they will not readily unite on orange ſtocks; for which reaſon the citrons are preferable to either oranges or lemons for ſtocks, as they readily join with either ſort; and being of larger growth, cauſe the buds of the other ſorts to be much ſtronger than if they were on ſtocks of their own kind.

The culture of the lemon is the ſame with that of the orange-tree, with this difference only, the former being hardier than the latter, will conſequently bring their fruit to maturity with us much better than the orange will, and therefore require to have a greater ſhare of freſh air in winter; for which reaſon they ſhould always be placed near to the doors or windows of the green-houſe: and in ſome curious gardens theſe trees have been planted againſt walls, where, by covering them with glaſſes in winter, and protecting them from ſevere froſts, they have produced plenty of large fruit: as theſe trees do generally produce ſtronger ſhoots, ſo they require more water to be given them than the orange; but as to the tender ſorts, they muſt be treated with a little more care, otherwiſe their fruit will fall off in winter, and come to nothing. *See* ORANGE.

LENTIL, or *bitter Vetch*, the name of a plant of the vetch or tare kind, cultivated in ſome parts of England as fodder for cattle.

Lentils grow to a foot or a foot and a half high, with ſtalks and leaves like thoſe of tares, but ſmaller; and like them they bear their ſeeds, generally three or four in little pods. Theſe ſeeds are round, hard, ſmooth, and flat, but thicker at the ſides. There are two ſorts of lentils, the white and the yellow; but the latter affords the greater quantity of fodder.

The ſeeds of this plant are commonly ſown in March, where the land is dry, but in moiſt ground the time is in April. The uſual quantity of ſeed allowed to an acre of land is from one buſhel and a half to two buſhels. If theſe are ſown in drills in the ſame manner as peaſe, they will ſucceed better, than when they are ſown broad-caſt. The drills ſhould be a foot and a half aſunder to allow room for the hoe to clean the ground between them; for if the weeds are permitted to grow among them, they will get above the lentils, and ſtarve them. *Miller's Gard. Dict.*

LETTUCE, the name of a well known genus of plants cultivated in kitchen-gardens.

Lettuces of all kinds are multiplied only by their ſeeds, which they produce the firſt year, and then die, if they have not been tranſplanted. The ſorts generally cultivated in the kitchen-garden, are 1. The common or garden lettuce. 2. The cabbage lettuce. 3. The Celicia lettuce. 4. The brown Dutch lettuce. 5. The Aleppo lettuce. 6. The imperial lettuce. 7. The green Capuchin lettuce. 8. The Verſailles, or upright white cos-lettuce. 9. The black cos. 10. The red cos. 11. The red Capuchin lettuce. 12. The Roman lettuce. 13. The prince lettuce. 14. The royal lettuce. 15. The Egyptian cos-lettuce.

The firſt of theſe is moſt commonly ſown for very early uſe, to mix with other ſmall ſallad herbs. It is only a degeneracy of the cabbage lettuce, or the latter an improvement of the former by repeated good culture; for the ſeeds of cabbage lettuces which have not cabbaged cloſely, will produce the former ſort, which gardeners diſtinguiſh particularly by the name of lapped lettuce. Theſe may be ſown at any time of the year, only obſerving to make choice of ſhady borders in hot weather, of warm ſituations in the ſpring and autumn, and to ſow under glaſſes in the winter, becauſe ſevere froſts will kill the young plants.

The cabbage lettuce is likewiſe ſown at ſeveral different times, in order to have a ſupply of it throughout the ſeaſon. The firſt crop of this is generally ſown in February, upon an open warm ſpot of ground. When the plants are come up, they ſhould be thinned to the diſtance of about ten inches aſunder every way, either by hoeing them, if their ſuperfluous numbers be not wanted, or by drawing them up by hand where they ſtand too cloſe, and tranſplanting thoſe which are thus removed into other good mould, likewiſe at the diſtance of about ten inches from each other. If this is done before the plants are too large, they will thrive well; though the tranſplanted ones will ſeldom grow ſo big as thoſe which were not removed: but, in return, they will come ſomewhat later, and thereby anſwer the purpoſe of thoſe who do not repeat this ſowing every fortnight.

In proportion to the advance of the ſeaſon, the ſubſequent crops ſhould be ſown in a more ſhady and moiſt ſituation, but by no means under the drip of trees, leſt the plants ſhould run up to ſeed before they cabbage, eſpecially in the heat of ſummer. The laſt crop of theſe lettuces, which are to ſtand all the winter, ſhould be ſown by the middle of Auguſt, pretty thin, upon a good light ſoil, warmly ſituated; and when the plants are come up, they muſt be well weeded, and thinned, by hoeing, ſo that they may not touch each other. The beginning of October will be a proper time for tranſplanting them into warm borders, where they will reſiſt the winter, if it be not very ſevere: but, to guard againſt its inclemency, and thereby be ſure of a crop, it will be adviſable to tranſplant ſome of this growth into a bed which may be arched over with hoops, and covered with mats, ſtraw or peaſe-haulm, in hard weather. They may be ſet pretty cloſe together; and if they are re-tranſplanted in the ſpring, into a warm and rich ſoil, at the diſtance beforementioned, they will do very well; though they will not cabbage ſo ſoon as thoſe which may have been left un-removed under a warm wall, if theſe laſt eſcape the winter, and if the neceſſary caution has been obſerved, of not placing them too cloſe to the wall; for this ſituation would make them run up in height, and conſequently prevent their growing large or hard.

To have good ſeeds of this ſort of lettuce, the plants ſhould be looked over when they are in perfection, and the largeſt, hardeſt, and loweſt growing of them ſhould be marked out by ſticks thruſt into the ground cloſe to them. All the reſt ſhould be carefully rooted out as ſoon as they begin to run up, leaſt the farina of the flowers of theſe inferior ones ſhould intermix with the others, and thereby occaſion a degeneracy of their ſeeds.

The beginning of February is alſo the firſt ſeaſon for ſowing the Cilicia, the imperial, the ſeveral kinds of cos, and the other ſorts of lettuces above-mentioned: but this early ſowing ſhould be upon a gentle hot-bed covered with a frame. The ſecond ſeaſon for theſe, is the latter end of of February, or beginning of March, upon a border of light earth, and in a warm expoſure, and open ſituation, that is to ſay, in a ſituation not ſhaded by trees. When the plants come up on the hot-bed, plenty of freſh air ſhould be admitted to them, to prevent their being drawn up weak; and when they have got five or ſix leaves, they ſhould be tranſplanted into another hot-bed, to bring them forward: but this laſt need only be arched over with hoops, and covered with mats; for they ſhould not be kept too warm there. When they are removed from thence, and planted out for good, which ſhould be as ſoon as they are ſtrong enough to bear it, they ſhould be ſet ſixteen inches aſunder every way, in a well-looſened ſpot of fine good earth. Thoſe which were ſown in the warm borders ſhould alſo be tranſplanted into a ſimilar ſpot, and ſet at the ſame diſtances as the former. If the ſeaſon is dry, care ſhould be taken to water both the one and the other till they have taken root, and then to keep them conſtantly clear from weeds. This is the only culture that any of them will require, except the black cos lettuces, which ſhould be tied up when they are full grown, to whiten their inner leaves, and render them criſp; for they ſeldom cabbage well without this aſſiſtance.

To continue theſe lettuces through the ſeaſon, other crops of them muſt be ſown in April, May, and June; obſerving, for the reaſons before given, to ſow the lateſt in the moſt ſhady ſituation. Towards the middle or latter end of September, ſhould be the laſt ſowing, and the plants produced thereby ſhould be tranſplanted, either under glaſſes, or into a bed arched over with hoops and covered in the winter, to prevent their being deſtroyed by the froſt: but as much free air as poſſible ſhould be admitted to them when the weather is mild, and they ſhould be covered only in hard rains, or when it freezes; for if they are too cloſely covered they will grow mouldy, and ſoon after rot. In the ſpring, they ſhould be removed into a rich light ſoil, and there ſet at leaſt eighteen inches aſunder every way: for if they are planted too cloſe, they will be apt to run up in height, and not to cabbage well.

This is the crop from which it will generally be moſt proper to ſave the ſeeds of theſe lettuces, if they ſucceed well: though it will be right alſo to mark out ſome of the fineſt plants of the crop ſown in the ſpring; becauſe thoſe of this laſt ſowing may ſometimes fail, through the wetneſs of the ſeaſon, even when they are in full bloom, and the others may do well by having more favourable weather: but if both ſhould ſucceed, there will be no room for complaint, ſince the ſeeds of lettuces will grow perfectly well after they are two years old, and, if they have been ſaved with due care, even at the end of three years. Very great caution ſhould be uſed here, not to let any of the common ſorts ſeed among or near theſe more valuable plants; not only for the reaſons before aſſigned, but becauſe they are naturally the moſt apt to degenerate in this country. The beſt way therefore is to keep the plants of each ſort which are intended for ſeed, as ſeparate as poſſible from all others; and to ſuffer none of them to perfect their ſeeds, except ſuch as are entirely approved of.

The Egyptian green cos, the white cos, the Cilicia, and the red cos, are the moſt valuable of all the ſorts of lettuce cultivated in England. The royal and imperial lettuces are very good; but not ſo generally eſteemed. The white cos uſed to be preferred to all others, till of late years, that the Egyptian green cos, and the red cos, have been found to be by far the ſweeteſt and tendereſt. Theſe will endure the common cold of our winters full as well as the white cos: but they are more apt to rot, if the ſeaſon of their cabbaging be very rainy.

The green capuchin and the brown Dutch lettuces are very hardy ſorts, and may be ſown at the ſame ſeaſons as the common cabbage lettuce. They are very proper to plant under a hedge, or other fence, to ſtand the winter; becauſe they will often live there, when moſt of the other ſorts are deſtroyed. They will alſo bear more heat and drought, and therefore are very fit for late ſowings: nor do they run up to ſeed ſo ſoon as the other ſorts, after they are cabbaged. If ſome of them are planted upon a gentle hot-bed in autumn, and well covered with a frame, they will cabbage ſo as to be fit for uſe in February and March, and may be continued till thoſe in the open air are ready for the table. All theſe qualities render them valuable: eſpecially as, in conſequence thereof, they may be had at a time when there are but few others. To prevent their degenerating, none but the largeſt and beſt cabbaged of theſe plants ſhould be ſet apart for ſeed; and all the cautions before given, in this reſpect, ſhould be carefully obſerved here.

Beſides the general rule before-mentioned, of not ſuffering two different ſorts of lettuces ever to ſtand near each other when they bloſſom, leſt the mixing of their farina ſhould make both of them vary from their original, and partake of each other; it is neceſſary, eſpecially for thoſe which run up high, ſuch in particular as the Cilicia, the cos, and the other large growing ſorts, to thruſt down by the ſide of each, a ſtake to which its ſtem ſhould be tied, to prevent its being broken, or blown out of the ground by the wind. The ſeed-branches ſhould be cut as faſt as the ſeeds ripen, without waiting to have the ſeed of the whole plant together; for there will be frequently a fortnight or three weeks difference between the ripening of one part and that of another: and when they are cut, they muſt be ſpread upon a coarſe cloth, in a ſunny place to dry the ſeeds yet more. The ſeeds ſhould then be beaten or rubbed out, dried again in the ſun, and afterwards laid up in a dry place, where neither mice nor other vermin can get at them; for if they do, they will ſoon eat them up.

LIFT, a ſtile that may be opened like a gate.

LILAC, the name of a flowering ſhrub, cultivated in the Engliſh gardens, and ſuppoſed to grow naturally in ſome parts of Perſia, but is ſo hardy as to reſiſt the greateſt cold of this country.

There are three varieties of this ſhrub commonly cultivated here, which differ in the colour of their flowers, and alſo in that of their ſhoots and leaves; one of theſe has white flowers, one blue, and the third has purple flowers; the latter is commonly known by the title of Scotch lilac, to diſtinguiſh it from the other. This is the moſt beautiful of the three, and is probably called the Scotch lilac, becauſe it was firſt mentioned in the catalogue of the Edinburgh garden.

Theſe ſhrubs grow to the height of eighteen or twenty feet in good ground, and are divided into many branches; thoſe of the white ſort grow more erect than the other, and the purple or Scotch lilac has its branches more diffuſed than either. The branches of the white are covered with a ſmooth bark, of a grey colour; thoſe of the other two are darker. The leaves of the white are of a very bright green, but thoſe of the other are of a dark green; their ſhape and ſize are ſo near as not to be diſtinguiſhed thereby. They are heart-ſhaped, and are placed oppoſite. The buds of the future ſhoots, which are very turgid before the leaves fall, are of a very bright green in the white ſort, but thoſe of the other two are of a dark green. The flowers are always produced at the ends of the ſhoots of the former year, and below the flowers come out ſhoots to ſucceed them; for that part upon which the flowers ſtand, decays down to the ſhoots below every winter. There are generally two bunches or panicles of flowers joined at the end of each ſhoot; thoſe of the blue are the ſmalleſt, and are placed thinner than either of the other. The bunches on the white are larger; the flowers are cloſer placed, and larger than the blue; but thoſe of the Scotch are larger, and the flowers are fairer than thoſe of either of the other, ſo make a much finer appearance. The panicles of flowers grow erect, and being intermixed with the fine green leaves, have a fine effect; and if we add to this the fragrancy of their flowers, it may be ranged among the moſt beautiful ſhrubs which now decorate the Engliſh gardens. They flower in May, and when the ſeaſon is cool, theſe ſhrubs will continue three weeks in beauty, but in hot ſeaſons the flowers ſoon fade. Their ſeeds are ripe in September, which if ſown ſoon after, the plants will come up the following ſpring; but as their roots ſend out great plenty of ſuckers annually, ſo few perſons ever take the trouble to propagate theſe plants by ſeeds. I have raiſed ſeveral plants of the three ſorts from ſeeds, and conſtantly found them prove the ſame as the ſhrubs from which the ſeeds were taken. Theſe plants do generally flower the third year from ſeed; and I have always found them not ſo apt to ſend out ſuckers, as thoſe plants which were produced by ſuckers, ſo are much more valuable; for the others put out ſuch plenty of ſuckers, as that if they are not annually taken from the plants, they will ſtarve them.

Theſe plants thrive beſt upon a light, rich ſoil, ſuch as the gardens near London are for the moſt part compoſed of; and there they grow to a much larger ſize, where they are permitted to ſtand unremoved, than in any other part of England; for in ſtrong loam, or upon chalky land, they make little progreſs. If the ſuckers are ſmall, when they are taken from the old plants, they ſhould be planted in a nurſery, in rows three feet aſunder, and one foot diſtance in the rows, where they may ſtand a year or two to get ſtrength, and then they ſhould be removed to the places where they are to remain. The beſt time to tranſplant theſe ſhrubs is in autumn. *Miller's Gard. Dict.*

LILY, the name of a large genus of plants, with a kind of bell-faſhioned flower, and is compoſed of ſix leaves, which are more or leſs expanded and bent back. The piſtil ſtands in the center of the flower, and finally becomes an oblong and trigonal fruit, which is divided into three cells, and contains a number of marginated ſeeds, arranged in a double order one on another. To this muſt be added, that the root is of a bulbous form, and is compoſed of a number of fleſhy ſcales affixed to an axis.

All ſorts of lilies and martagons are propagated by ſowing their ſeeds; and if the ſeeds are carefully ſaved from good flowers, the martagons very frequently afford very beautiful varieties.

The manner of ſowing them is this: ſome ſquare boxes ſhould be provided of about ſix inches deep, with holes bored in the bottoms to let out the wet; theſe muſt be filled with freſh, light, ſandy earth, and the ſeeds muſt be ſown on them pretty thick in the beginning of Auguſt, ſoon after they are ripe, and covered over about half an inch deep with light ſifted earth of the ſame kind. They ſhould be then placed where they may have the morning ſun; and if the weather prove dry, they muſt be watered at times, and the weeds carefully picked out. In the month of October, the boxes are to be removed to a place where they may have as much ſun as poſſible, and be ſecured from the north and north-eaſt winds. In the ſpring the young plants will appear, and the boxes are then to be removed into their former ſituation: they ſhould be watered at times during the ſummer, and in Auguſt the ſmalleſt roots are to be emptied out of theſe boxes, and ſtrewed over a bed of light earth, and covered with about half an inch depth of light earth ſifted over them; they muſt here be watered and ſhaded at times, and defended from the ſeverity of the winter, by a light covering of ſtraw, or peaſe-haulm, in the hardeſt weather. In February, the ſurface of the bed ſhould be cleared, and a little light earth ſifted over it. When the leaves are decayed, the earth ſhould be a little ſtirred over the roots, and in the month of September following, a little light earth ſifted on. In the September of the following year, the roots muſt be tranſplanted to the places where they are to remain, and ſet at eight inches diſtance, the roots being placed four inches below the ſurface: this ſhould be done in moiſt weather. They will now require the ſame care as in the preceding winters; and the ſecond after they are tranſplanted, the ſtrongeſt roots will begin to flower. The fine ones ſhould then be removed at the proper ſeaſon into flower-beds, and planted at great diſtances from one another, that they may flower ſtrong. *Miller's Gard. Dict.*

LIME, a ſoft friable ſubſtance, obtained by calcining or burning ſtones, ſhells, and the like.

The moſt certain way to know whether any ſort of ſtone be fit for making lime, is to drop upon it a little aqua-fortis, ſpirit of ſea-ſalt, or oil of vitriol. All ſtones on which the above, or any other ſtrong acid effervesces or riſes in bubbles, are lime-ſtones, or will burn to lime; and the ſtronger the effervescence is, the fitter they are for that purpoſe. All country gentlemen ſhould keep ſome ſuch ſprit by them, to try the nature of the ſtones that may be found on their eſtates.

All lime is a very good manure, but that made of ſtone is much better than what is made of chalk. It makes the greateſt improvement upon light ſandy ſoils, or upon a dry gravel: wet and cold gravel is leſs benefited by it, and cold clay the leaſt of all. The common allowance is a buſhel to a pole ſquare, or a hundred and ſixty buſhels to an acre. Mr. Lummis laid after the rate of three hundred buſhels on an acre, and found it anſwer extremely well: but that was upon a ſtrong clay. His method of uſing it, as communicated to the Edinburgh Society, and the reſult, he ſays, of what he has experimented to be beſt, is as follows:

In the month of October, he lays together three or four of the largeſt ſtones (burnt into lime) on the ſward or turf of a ſtrong clay ground; or, as many of the ſmall ſtones as are equal to the large ones, ſo that ſeventy or eighty bolls (two hundred and eighty, or three hundred and twenty buſhels) may complete an acre. If rain falls, it melts immediately; if not, it will melt or flake in forty eight hours, or leſs, according to the moiſture of the air. He then ſpreads it directly, leaving no part of it upon the ſpot where the ſtones were laid. This done, he lets it lie twelve months, or till the month of November after the October twelve months, when he ploughs it in, and lets it remain in that ſtate all the winter, during which froſt and rains mellow and prepare the ground for the next ſpring ploughing, and render it fit for barley. He prefers this method to laying the lime on in powder, becauſe, in this laſt way, it is apt to be blown about with the wind, to the great detriment of both men and horſes, ſuch as ſpoiling the mens eyes, hair, and cloaths, and the eyes and hair of the horſes, making their coats look dry and ugly, beſides loſing much of the lime.

The lime laid in the month of October, as above directed, on a ſtrong arable land, which has been ſome years under graſs, and continuing ſpread for about twelve months before it be ploughed in, has been found ſo to alter the graſs to a fine natural clover, that, by feeding of ſheep or black cattle upon it, it has paid the whole charge the firſt year by the graſs; and cattle will chooſe rather to feed on this ground than any other, and grow fatter. If the ground be looſe and open, it may be ploughed in the enſuing March, if limed in October. In either way, it ſo far meliorates the ſward, and the ſoil, that the beſt of crops may be expected for three or four years; and by laying ſome dung upon it the 4th or 5th year, two or three crops more may be obtained; after which the ground will be in excellent order to lay down with graſs ſeeds.

Notwithſtanding that lime is ſo very good a manure, Mr. Lummis prefers marle, if it can be had within the ground, or near the place where it is to be uſed; for tho' it be more chargeable at firſt, yet, laſting five times as long, it is in the end much cheaper. He generally lays near two hundred loads of it upon an acre, at about ſeven or eight buſhels to the load.

Mr. Evelyn adviſes mixing the lime with the turf or ſward, laying them alternately, turf on lime, and lime on turf, in heaps for ſix months; by which means it will become ſo rich and mellow, as to diſſolve and run like aſhes, and carry a much more cheriſhing vigour, than if uſed alone in a greater quantity, and without danger of burning out and exhauſting the vegetative virtue which it ſhould preſerve. It is likewiſe greatly bettered by being mixed with dung, or with mud drawn from the bottom of ponds or rivers. In Weſtmorland, they reap fine crops of barley from their ſandy lands, by manuring them with lime and cow-dung mixed together.

The nature of lime on land is like that of chalk: it works downwards, as the farmers expreſs it, and is therefore beſt treated in the ſame manner, laying it upon a lay the year before it is to be ploughed up. When uſed on land which lies upon a deſcent, it ſhould by all means be mixed with dung, and laid principally on the higher part of the land; the conſequence of which will be, that the rain will waſh out the virtues of the lime and dung together, and carry them to the lower parts as it runs down. In fact, it does better on any land, when mixed with dung, than either of them alone. This is particularly obſerved in Shropſhire, where they lay dung and lime together, about twenty load of the former, and only twenty buſhels of the latter, on an acre of ground. In Leiceſterſhire, they ſow or ſcatter the lime on wheat land when they ſow the wheat; but on barley-land, the laſt

last earth but one, left it should burn the barley if sowed with it in the spring. They allow five quarters to an acre of each, reckoning by the measure in which it comes from the kiln; for after it is slaked, those five quarters will make near ten.

Lime is thought to make corn grow with a thin husk. It is a great destroyer of moss and rushes, even after it has been slaked; as quick lime is of the remnants of furzes, after the old bushes have been grubbed up. Its hot quality renders it apt to over-burn dry soils. It certainly is most efficacious when spread directly from the kiln.

Mr. Lisle, whose account of lime is almost unintelligibly perplexed and confused, thinks it is best, especially on lands that work mellow, to spread and plough it in this manure as soon as it is slacked, rather than to let it lie long in heaps covered with earth. He very properly gives it as a rule to all husbandmen, to be cautious of liming ground, and then ploughing out the heart of it; the bad consequences of which he himself experienced. "I limed, says he, some years ago, in Wiltshire, seven acres for an experiment, and laid down one acre to its own natural grass. In two years time this grass was, and still is, worth forty shillings an acre. The third year, I laid down another acre, which is still worth thirty shillings a year. The rest, which I ploughed five or six years longer, is not worth fifteen groats an acre. I have experienced the like in burn-baking ground."

The practice of Lower Normandy, where lime is chiefly used on lands newly broken up, is thus related by M. Du Hamel.

After giving these lands a shallow ploughing, they carry on the lime as it comes from the kiln, and lay about an hundred weight of it in a heap on every square perch; so that the heaps lie at a perch distance from one another; they then raise the earth all round the heaps, like so many basons: the earth which forms the sides of these basons should be a foot thick: and, lastly, they arch the heaps over with earth, six inches thick. The lime flakes under this covering, and is reduced to powder; but at the same time it increases in bulk, and thereby cracks the earth. If these cracks be not carefully stopped, rain will get through them, and reduce the lime into a paste, or kind of mortar, which will not mix with the earth, or answer the end proposed. Farmers are therefore very careful to examine the heaps from time to time, and stop the cracks. Some only press down the top of the heap with the back of a shovel: but this method is liable to a considerable inconvenience; for if the lime be in a paste within the heap, it is by this means beat together in such manner, that it becomes still more difficult to mix it with the earth: for which reason it is better to stop the crevices, by throughing a little fresh earth over the heap.

When the lime is thoroughly slacked, and reduced to powder, the heaps are cut with a shovel, and the lime is mixed as well as possible with the earth that covered it. This mixture is then thrown up in heaps again, and left exposed to the air for six weeks or two months; for then the rain will not hurt it.

About the beginning of June, this compost of lime and earth is spread upon land; but not by throwing it about unequally, or at random: on the contrary, it is taken up by shovelfuls, and distributed in little heaps, at equal distances, on each perch of ground, it having been observed, that these little heaps promote vegetation, more than if the manure was spread uniformly all over the field; nor is it at all heeded, if small intervals remain unlimed between each shovelful. The field is afterwards ploughed, for the last time, very deep: then, towards the end of June, it is sowed with buck-wheat, which is covered with a harrow; and if any clods remain, they are broken with a hoe.

Buck-wheat occupies the land about a hundred days; so that this grain, sown about the end of June, is gathered about the end of September. When the stalks and roots of this plant are dead and dried, the ground is ploughed up, and immediately sowed with wheat, which is harrowed in. After the wheat has been reaped, the land is ploughed as soon as possible. It is ploughed for the last time, in February or March, in order to sow oats; or in April for barley: but in this case it is turned up two or three times, to make it fine. All these different grains are harrowed in. A roller is passed over the oats when they are come up; and if any clods remain in the barley, they are broken with a hoe.

In the next February or March, the land is ploughed again, in order to sow it with grey pease or vetches: and after these pulse have been reaped, one or two ploughings are given, to prepare it for wheat in the ensuing autumn.

The next year, oats are sowed, sometimes mixed with a little clover; and then the ground is laid down to pasture for three or four years.

Sometimes no buck-wheat is sowed on land newly broken up; but it lies fallow, from the month of March, when it was first ploughed, till October, when it is sowed with wheat, after receiving several ploughings during the intermediate time. These lands being, by this means, brought to a tolerable tilth, not above three quarters of the quantity of lime above-mentioned is used on them, and they generally bear a better crop than those which are first sowed with buck-wheat.

Some farmers think a perch too great a distance for conveniently spreading the lime. They therefore make the heaps less, and increase their number in proportion. Others lay the lime in ridges, from one end of the field to the other; which facilitates the spreading of it. Being persuaded that lime is most efficacious when it lies shallow in the ground, they first plough it in, and then give a second ploughing before they sow, which brings it again near the surface.

Lime is commonly said to enrich land greatly at first, but afterwards, when its efficacy is exhausted, to leave the ground more barren than it was before. Lime readily unites with every unctuous substance, and renders it more soluble in water. By this means, all such particles mixed with the soil may be more speedily converted to the nourishment of vegetables, than they might otherwise be. Indeed, if the farmer's avarice, or want of judgment, tempt him to over-crop the ground, it may be left without matter fit to nourish plants, till a fresh supply is brought: but if it be judiciously cropped, and left in good heart under grass, or any other produce which does not impoverish the soil, the effect of the lime will be more durable, and more advantageous than is generally imagined.

LIME-KILN. *See the article* Kiln.

LIME-STONE, a species of stone which will burn into lime. *See the article* Lime.

LIME-TREE, or *Linden-Tree*, a beautiful tree for walks, and other decorations, in parks, &c. and of which Mr. Miller has enumerated four species.

All the species of the lime-tree are easily propagated by layers, which will, in one year, take good root, and may then be taken off, and planted in a nursery, at four feet distant row from row, and two feet asunder in the rows. The best time to lay them down and to remove them, is, when their leaves begin to fall, that they may take root before the frost comes on, though they may be transplanted any time from September to March, in open weather; but if the soil be dry, it is much the better way to remove them in autumn, because it will save a great expence in watering, especially if the spring should prove dry. In this nursery they may remain four or five years, during which time the ground should be dug every spring, and constantly kept clear from weeds, and the large side shoots pruned off, to cause them to advance in height; but the small twigs must not be pruned off from the stems, because these are absolutely necessary to detain the sap, for the augmentation of their trunks, which are apt to shoot up too slender, when they are entirely divested of all their lateral twigs. If the soil in which they are planted, be a fat loam, they will make a prodigious progress in their growth, so that in three years time they will be fit to transplant out where they are to remain.

They may also be propagated by cuttings; but as this method is not so certain as by layers, the other is generally practised. In order to obtain proper shoots for laying down, a lime-tree is cut down close to the ground, from the roots of which a great number of strong shoots are produced the following year; these will be large enough to lay down the succeeding autumn, especially if the ſmalleſt of them are cut off cloſe early in the ſpring; for when too many ſhoots are ſuffered to grow during the ſummer, they will be much weaker, than if only a ſufficient quantity be left. For the manner of laying down theſe ſhoots, *ſee the article* LAYER.

The timber of the lime-tree is uſed by carvers, it being a ſoft, light wood, as alſo by architects for framing the models of their buildings; the turners likewiſe uſe it for making light bowls, diſhes, &c. but it is too ſoft for any ſtrong purpoſes. *Miller's Gard. Dict.*

LINDEN-TREE. *See the preceding article.*

LING, heath.

LINSEED, the ſeed of the flax. *See the article* FLAX.

LIQUORICE, a plant propagated for medicinal uſes. It grows to about four or five feet high; its ſtalks are hard and woody; its leaves ſmall and roundiſh, ſtanding together on the two ſides of a rib, and making what botaniſts call a winged leaf.

A correſpondent of the editors of the Muſeum Ruſticum has given the following directions for cultivating this plant, founded on a long ſeries of experience.

" The common culture of liquorice is not difficult to be learned; and this, with proper attention, will enable any thinking farmer, that knows his buſineſs, to cultivate it to advantage.

" This plant thrives beſt on a deep, looſe, rich mould; and if it is freſh land, that has not for many years borne corn, the profit will be the greater, as the crop will be larger, and the roots of a finer quality.

" A rich ſandy ſoil, provided it is deep, will do well for this plant; and it muſt always be remembered, that too much moiſture is its greateſt enemy: let no one therefore attempt to plant it on a damp clay, leſt the whole crop be cankered.

" Land cannot be made too fine, nor dug too deep, for liquorice: it ſhould be, at leaſt, moved with the ſpade to the depth of two feet and a half, and if a little deeper, ſo much the better.

" If the land, on which the liquorice-ſets are to be planted, is freſh, rich, and in good heart, it needs no manure for the firſt crop; but if it has been for ſome years in tillage, the planter will do well to give it, in the ſummer time, a good dreſſing of very rotten dung, lime, and coal-aſhes or ſoot, mixed together, ſome months before, in a compoſt: the quantity muſt be regulated by the ſtate of the land, always remembering that this plant requires a great deal of nouriſhment, and is a great impoveriſher of land, though it extracts much of its nouriſhment, or food, from a conſiderable depth, at a diſtance from the ſurface; ſome of the roots running five or ſix feet, at leaſt, into the ground.

" When the ground is properly prepared, reduced to a very fine tilth, and laid level, ſome liquorice runners, or ſets, are to be procured. Theſe muſt be cut into pieces, about eight or nine inches long each, and planted in rows, with dibbers armed with iron points. I make my rows two feet aſunder, put my ſets fifteen inches from each other, and when three rows are planted on a ſix-feet bed, I allow two feet more of interval betwixt bed and bed.

" When I put in my ſets with the dibber, I leave the upper end of each ſet juſt level with the ſurface of the ground: I ſhould have obſerved, that I have all my ſets carefully inſpected before they are carried into the field, to ſee that each of them has one, if not two eyes, or buds, without which they would make no ſhoots.

" When the whole ſpot of ground is planted, I make my labourers dig up the intervals one ſpit deep, and ſpread the earth on the beds: this raiſes them about two inches above the head of the ſets, and by lowering the intervals, ſerves in wet ſeaſons to drain the beds. I generally contrive to get this work done by the laſt week in September; but in favourable years, the middle of October is not too late.

" If the weather proves mild, I have no farther trouble with them during the winter; but if it is likely to freeze hard, I cover the beds with peaſe-haulm, or long dung, or ſome ſuch matter, to forward the growth of the roots in the ſpring, and protect them, during the winter, from the froſts.

" Early in the ſpring, on the firſt appearance of the weeds, I allow my liquorice a thorough hoeing; and this is ſeveral times repeated in the dry weather of the ſummer.

2

" The winter following, I again cover them with long dung, and in the ſpring, before the roots begin to ſhoot, I have the ſpaces betwixt the rows on the beds looſened with a ſpade, and the intervals are well dug: immediately after which, I give the land a ſlight dreſſing of coal-ſoot, ſown by hand: it ſhould be thick enough to make the land look black: this the firſt rains waſh in, and it greatly warms and invigorates the plants.

" The ſecond and third ſummers, all I have to do, is to keep my crop clear of weeds: this, indeed, is very neceſſary, and the hoeings for this purpoſe muſt be more or leſs frequent, according to the ſeaſon; generally, three times in the ſummer are quite ſufficient, eſpecially if the land was well prepared before the ſets were planted.

" Many good ſenſible farmers, whom I have known to cultivate this plant, in autumn have a practice of cutting down the ſtalks, whilſt they are in full ſap, thinking thereby to ſtrengthen the roots. I differ from them, however, in opinion, and am rather apt to imagine, that this cutting of the ſtalks, whilſt the ſap is in motion, muſt be prejudicial to the roots. It is, therefore, my cuſtom, always to defer cutting off the ſtalks, till they are withered, and begin to decay; nature then indicating, that an abſtraction will be of ſervice.

" Theſe roots ſhould have three ſummers growth before they are fit to take up: it is very ſeldom that they have attained a proper ſize at two years end; and if you leave them longer than three years in the ground, the roots are apt to grow ſticky, and loſe a part of their ſaccharine quality.

" I never take them up till the ſap is entirely at reſt, and the leaves and ſtalks are withered: they are then in prime order, and fitteſt for ſale.

" If theſe roots are taken up while the ſap is in motion, either early in the autumn, or late in the ſpring, they are apt to ſhrivel, and loſe much of their weight, and are, beſides, more diſpoſed to ferment and periſh.

" The beſt way of taking them up is, to dig the ground over as deep as the principal roots run, having pickers ready to gather up the roots as faſt as they are thrown up by the ſpade.

" My general practice is to get rid of my roots as ſoon as I conveniently can: and I find it better ſo to do, than to wait for the riſing of the markets. I have had, from one acre of fine, freſh, rich land, above 3000 pounds of ſaleable root, which has produced me above ſixty pounds; but this many years ago, my crops not being general now ſo large.

" When I have taken up a crop of this root, if it was planted on freſh land, I generally prepare the ſame ground to yield me another crop; and this takes me near a year.

" I, in the firſt place, give it, during the winter froſts, a thorough good dreſſing of well-rotted dung, mixed with lime: of this I lay on large quantities, ſtill having regard to the condition of the ſoil, and ploughing it well in the enſuing ſummer.

" In ſuch looſe ſoils, as are proper for this plant, there is no occaſion to dig the land for this crop, the taking up the roots having ſtirred it to a great depth: this, with three or four ſummers ploughings, is ſufficient.

" As to the reſt, I manage the ſame as I did for the preceding crop.

" If the land, which has borne me a crop of liquorice-root, was not freſh land when it was planted, but had been any time in tillage, I ſcarcely ever chuſe to plant it again with the ſame crop, without allowing ſeveral years of interval, at leaſt ſeven; but in this caſe, I frequently ſow oats in the ſpring, to abate the rankneſs of the ſoil; and it will then, with a very ſlight dreſſing, give me a good crop of wheat.

" In my method of cultivating this plant, I always allow ſpace enough for the roots to extend in ſearch of food; and this is my reaſon for planting my rows at two feet diſtance: I am, beſides, very careful of keeping them clear of weeds, and that, particularly, during the firſt ſummer; being very ſenſible that, without this precaution, they would be in great danger of being choaked up, and robbed of their proper ſhare of nouriſhment; particularly, they would receive no benefit from the dews, which are ſo friendly to vegetation; and even the ſun's warmth would be, in a great meaſure, kept from the roots by the ſhade of the weeds.

" Many

"Many, who plant liquorice, allow much leſs ſpace than I do betwixt the rows, and will yet, the firſt ſummer, take off a crop of onions, or ſpinage, or young carrots, and think it ſo much clear profit; but the queſtion is, whether theſe crops may not, during the time they are on the ground, be, to all intents and purpoſes, deemed weeds, having nearly, if not altogether, as bad effects, as weeds would if have permitted to grow with the crop.

"Some, worſe farmers, continue this practice two years of its growth; but it is quite needleſs to condemn this method of culture, as it cannot but ſtand ſelf-condemned.

"In the dreſſings I give my land, for preparing it to receive this plant, experience has convinced me that lime is a much ſweeter manure than ſtable-dung: in fact, this laſt is not, on any account, to be uſed till it is quite rotten, and then lime is very properly added to it as a corrector.

"Some friends of mine, who live very near London, have attempted to cultivate this plant on their lands; but they find it does not anſwer; and this, on account of the great richneſs of the ſoil, owing to the great quantity of London dung laid on it. It is true, the roots were at three years end larger than mine; but they were not ſo bright, but had a blacker coat, and were deemed greatly inferior in quality.

"Should any of your readers be inclined to cultivate this plant, by following theſe directions, not implicitly, but according to their diſcretion, the circumſtances of their ſoil, &c. conſidered, they cannot well fail ſucceeding." *Muſeum Ruſticum, vol.* I. *pag.* 252.

LITTER, the ſtraw laid under horſes, &c.

LIZENED *Corn*, leſſened, ſhrunk, or lank corn.

LOAM, an earth compoſed of diſſimilar particles, hard, ſtiff, denſe, and rough to the touch, and compoſed of ſand and a tough viſcid clay.

LOE, a little round hill, or heap of ſtones.

LOG, a large, ſhapeleſs piece of wood.

LOOP, a hinge of a door.

LOP, a flea.

LOPPED *Milk*, ſuch as ſtands till it ſours and curdles of itſelf.

LOPPING, the cutting off the ſide branches of trees.

It is very obſervable that moſt old trees are hollow within; which does not proceed from the nature of the trees, but is the fault of thoſe who have the management of them, who ſuffer the tops to grow large before they lop them; as the aſh, elm, hornbeam, &c. and perſuade themſelves, that they may have the more great wood; but in the mean time, do not conſider that the cutting off great tops endangers the life of a tree; or, at beſt wounds it ſo, that many trees yearly decay more in their bodies than the yearly tops come to; and at the ſame time that they furniſh themſelves with more great wood, they do it at the loſs of the owner. And, indeed, though the hornbeam and elm will bear great tops, when the body is little more than a ſhell; yet the aſh, if it comes to take wet at the head, very rearely bears more top after the body of the tree decays. Therefore, if once theſe trees decay much in the middle, they will be worth little but for the fire; ſo that if you find a timber-tree decay, it ſhould be cut down in time that the timber be not loſt.

The lopping of young trees, that is, at ten or twelve years old at moſt, will preſerve them much longer, and will occaſion the ſhoots to grow more into wood in one year, than they do in old tops at two or three. Great boughs, ill taken off, ſpoil many a tree; for which reaſon they ſhould always be taken off cloſe and ſmooth, and not parallel to the horizon; and cover the wound with loam and horſe-dung mixed, to prevent the wet from entering into the body of the tree.

When trees are at their full growth, there are ſeveral ſigns of their decay; as the withering or dying of many of their top branches; or if the wet enters at any knot; or they are any wiſe hollow or diſcoloured; if they make but poor ſhoots; or if woodpeckers make any hole in them.

This lopping of trees is only to be underſtood for pollard-trees; becauſe nothing is more injurious to the growth of timber-trees, than that of lopping or cutting off great branches from them. Whoever will be at the trouble of trying the experiment upon two trees of equal age and ſize, growing near each other, to lop or cut off the ſide branches from one of them, and ſuffer all the branches to grow upon the other, will in a few years, find the latter to exceed the other in growth every way; and this will not decay near ſo ſoon.

All ſorts of reſinous trees, or ſuch as abound with a milky juice, ſhould be lopped very ſparingly; for they are ſubject to decay when often cut. The beſt ſeaſon for lopping theſe trees is ſoon after Bartholomew-tide; at which time they ſeldom bleed much, and the wound is commonly healed over before the cold weather comes on. *Miller's Gard. Dict.*

The generality of the world are againſt pruning timber trees at all, and where they naturally grow ſtraight and regular, it is much better let alone. But all common faults in ſhape may be regulated by this lopping them while young, and it can be attended with no ill conſequence to the timber; for the cut not lying near the timber pith cannot affect it, when grown up, and ſquared in the working for beams and other uſes, or to be quartered; for all the defects occaſioned by ſuch wounds, are in the ſuperficial parts, and all the four quarters are perfectly ſound within.

As to the large foreſt trees, they ſhould not be lopped at all, except in caſes of great neceſſity, and then the large boughs muſt not be cut, but only the ſide branches; and even theſe muſt be cut off cloſe, that the bark may ſoon cover the wound, and yet a little ſlanting, that the water may run off, not lodge upon the cut part.

If there is a neceſſity of cutting off a large bough, as by its being broken or cankered, let it be cut off ſlanting at about four feet diſtance from the body of the tree, and that if poſſible near ſome place where there is a young ſhoot from it, which may receive the ſap, and grow up in its place. No ſtump muſt be left ſtanding out farther than this, becauſe they are wounded parts which never can heel, and which will always be letting in the water, and will ſerve as pipes to convey that water into the heart of the body of the tree, and by degrees will utterly ſpoil it. All that grow upright, whether they be large or ſmall branches, muſt in cutting be taken off ſlanting, never evenly, for the ſame reaſon; thoſe boughs that bear from the head are to be cut with the ſlope on the lower ſide, and on any occaſion that great wounds are given to a tree, they ſhould be covered with a mixture of clay and horſe-dung, which will make them heal much ſooner than they otherwiſe would do. *Mortimer's Huſbandry, vol.* II. *page* 91.

To LOWK, to weed corn.

LUCERN, a plant frequently cultivated in the manner of clover, and known among botaniſts by the names of medica and medicago.

It is the alfaſa of the Spaniards, and the lucern grand treffle, or fænum Burgundiacum, as ſome botaniſts call it, of the French. It has a perennial root, and an annual ſtalk, which riſes full three feet high in good land, and is garniſhed at each point with trifoliate leaves, whoſe lobes are ſpear-ſhaped, about an inch and a half long, and half an inch broad, ſawed towards the ſtalks. The flowers grow in ſpikes, which are from two to near three inches in length, ſtanding upon naked footſtalks two inches long, riſing from the wings of the ſtalks: they are of the pea-bloom, or butterfly, kind; of a fine purple colour, and are ſucceeded by compreſſed moon-ſhaped pods, which contain ſeveral kidney-ſhaped ſeeds. It flowers in June, and its ſeed ripens in September.

There are the following varieties of this ſpecies of lucern, viz. one with violet-coloured flowers; another with yellow flowers; a third with yellow and violet flowers mixed; and a fourth with variegated flowers: but, as Mr. Miller obſerves, theſe are only variations of the ſame plant, ariſing accidentally from the ſeed. However, neither the yellow nor the variegated flowered lucern, is ever ſo ſtrong as that with purple flowers; nor is it, conſequently, ſo profitable to the huſbandman.

Columella calls this the choiceſt of all fodder, becauſe it will laſt ten years, and will bear being cut down four, and ſometimes ſix times in a year; it enriches the land on which it grows, fattens the cattle fed with it, it, and is a remedy for fick cattle. About three quarters of an acre of it is abundantly fufficient to feed three horfes during the whole year. Yet, notwithftanding it was fo much efteemed by the ancients, and hath been cultivated to great advantage in France and Switzerland for many years, it has not yet found fo good a reception in England as it juftly deferves; nor is it cultivated here in any confiderable quantity, though it will fucceed as well in this country as in either of the laft mentioned; being extremely hardy, and refifting the fevereft cold of our climate.

Mr. Rocque lays it down as a maxim in his practice, that lucern will grow on any foil, provided it be not fo wet as to rot the roots.

The ftrongeft land is however to be preferred, and the deeper the foil, the better will be the crop, as the roots will have room to extend themfelves.

The land fhould be prepared in the fame manner as for barley, being ploughed, harrowed, and cleaned from all forts of weeds; and the ftronger the land is, of courfe the more ploughing and harrowing it will take to mellow it, fweeten it, and bring it to a fine tilth.

When this work is done, the lucern feed muft be fown broad-caft, (not in drills) in fine weather, after the rate of about fourteen pounds to an acre.

This allowance of feed will be fufficient to fupply the number of plants that will be wanted to yield a full crop; but they will not ftand fo thick as to ftarve one another, though there is fome allowance for part of the feed failing.

But fhould every feed take, the method of culture hereafter recommended will fufficiently reduce the number of the plants, and, without the trouble and expence of the New Hufbandry, give each plant fpace enough to extend its roots, and collect the neceffary quantity of nourifhment.

To return to the culture, before the laft ploughing, the land fhould be manured, not with old rotten ftuff, as is ufual; but with frefh ftable-dung, that has been thrown up in a heap three or four weeks to heat and ferment. This will enable the young plant to pufh forth its leaves and ftalks with luxuriance, and get forward in its growth the firft fummer.

When the dung is in full fermentation, it is to be laid on the land, and ploughed in as foon as poffible, that the falts of the dung may not have time to evaporate: the land muft then be harrowed and fown, and afterwards again harrowed with a light or bufh-harrow; and, laftly, rolled to fettle the ground and break the clods.

If corn is to be fown amongft it, it fhould be only half a crop; otherwife it will be apt to deftroy the lucern, efpecially if it proves a wet feafon, and the corn is rank: but if no corn is fown amongft it, the lucern will thrive much better.

Lucern may be fown from the beginning of March to the end of May; but April, in dry weather, is the beft time.

If much rain falls on the new-fown lucern, it will be apt to fwell too faft, and burft; but if it holds fine three or four days, it will be in no danger.

Mr. Rocque does not approve of drilling the lucern, becaufe the roots are too much confined in the drills: they fay it is to clean the lucern between the rows that they drill it; but it is for want of knowing the nature of lucern, and it difcourages people from fowing it, drilling and hoeing being very expenfive ways; the quickeft and cheapeft, and by much the beft way, being to fow it broad-caft, like clover, as the roots will ftand nearly at equal diftances one from another every way.

Lucern requires, it is true, a great deal of nourifhment from the earth; but there is no occafion this nourifhment fhould be fupplied by the furface. It is well known that the roots of lucern will run to a great depth in the ground, from whence they muft of courfe extract a large quantity of food: this fpares the furface; and in fact the land where lucern grows requires only that the natural grafs fhould be prevented from getting to a head, which it is in our climate very apt to do, and if let alone would foon choke up the lucern.

It is mentioned above, that if corn is fown with lucern, it fhould be only half a crop: fome of your readers may not, perhaps, readily comprehend the meaning of this expreffion; therefore, to render it more clear, I fhall here obferve, that when barley or oats are to grow with lucern, a bufhel only of either, according to Mr. Rocque's method, is to be fown firft on an acre, then fourteen pounds of the lucern.

One thing is to be obferved; that if the corn, notwithftanding its being fown fo thin, fhould grow fo rank as to endanger the lucern, it will be much beft to mow it before the harveft, as it is better to lofe the crop of corn than to kill the lucern.

The barley, or oats, however, need not be entirely loft, as they may, when mown, be given green to cattle; or, if the weather is fine, will make excellent hay, provided they are properly dried; and it is beft to do it in the fwarth, as the rich juices are in that manner lefs exhaufted. To fow it later than May is dangerous, for fear of a dry feafon, or its being eat up by the fly.

Lucern will not grow on frefh-broke up land; it muft be tilled a year or two: peafe and beans, for one year, will prepare the ground; but above all, potatoes excel for fweetening and mellowing of land: the next feafon a fallow for turnips; and when the turnips are fed off with fheep, it will greatly enrich the land, which fhould then be prepared for lucern.

In regard to the tillage, and time of fowing the lucernfeed, the nature of the foil muft be confidered. Heavy ftrong land will require more ploughings and harrowings, and to be later fown; light land will need fewer harrowings and ploughings, and to be fown earlier, that the young plants may have ftrength to fend their roots deep into the ground, before the hot dry weather comes on to hurt them; and if, for the firft time, the land had a trench-ploughing, it would be of great advantage.

In Languedoc they fow no corn with the lucern; and when it is fix or feven inches high, they mow it; by which all the feeds of annual weeds are cut off and killed.

In Normandy, the climate being much the fame as in England, they fow corn with it.

In Picardy, and about Paris, they fow it, fome with, others without corn.

At Avignon, when their lucern begins to decline, they manure their ground and plough afrefh, and fow it with corn and lucern; and the old roots, growing again with the feed, make another fine crop: the ploughing will not hurt the old roots.

If a full crop of barley is fown with lucern, and the barley grows very ftrong, the beft way is to mow the barley when it is in the ear.

If forward peafe are fown on new-broke-up land to prepare it for lucern, it may be done in one year, and turnips fown on it as foon as the peafe are off: the turnips may be fit to feed off by Chriftmas; and as foon as the turnips are off, the land fhould be ploughed, and lie fallow till a proper time to ftir it again; or it may have a trench-ploughing, as before directed.

This method of giving land a trench-ploughing, to prepare it for lucern, is much to be recommended, as it ftirs the earth almoft as deep as if it was dug with a garden fpade: of what advantage this muft be to a plant that fends its roots deep for nourifhment, need not be mentioned, as it cannot but be obvious to every reader.

Was labour cheaper than it is in England, it would doubtlefs be much the beft way to dig by hand all the land that was deftined to lucern: many advantages would refult from this method of tillage, and particularly the weeds and grafs would not be fo apt to grow as in ploughed land.

I would heartily recommend it to fome of the gentlemen in Ireland, to fow with lucern fome of their land that has borne a crop of potatoes; it could not fail fucceeding, and they would have a fair opportunity of trying what crops this plant will, when beft cultivated, yield.

I cannot but think, that on good land that had borne potatoes, there might be five good mowings in a year, particularly in Ireland, where the climate is rather milder than in England; and this without injuring the roots. An eafy experiment would, however, foon make this matter known: I therefore heartily recommend it to the attention of your Irifh readers; they are every day improving their lands,

lands, and will, doubtleſs, not ſuffer this hint to paſs unnoticed.

When we conſider the many advantages reſulting from the culture of this plant, it is aſtoniſhing that it ſhould ſo long eſcape our regard: the hint was given us by the Roman writers on the ſubject of agriculture, but we were too much attached to old cuſtoms to improve it.

In hot ſummers the ſeed may be ſaved in England, but not from the firſt growth; that being generally too rank, and ſubject to rot at bottom.

In Languedoc they ſave it from the third growth; but as this climate is colder, it will not have time to ripen, unleſs ſaved from the ſecond growth.

A dry ſoil is beſt to ſave the ſeed upon, as it is not ſo apt to grow rank; and then it may poſſibly do from the firſt growth.

As lucern, if the land is good, will bear ſeveral crops in one year, like clover; what Mr. Rocque means by the firſt, ſecond, and third growths, are, he ſays, the different crops it produces in one ſummer, which are three, four, and ſometimes five mowings, in caſe no ſeed is ſaved from it; if ſeed is ſaved, it muſt be from the ſecond growth: the ſeed will be ripe in September, and muſt be gathered by hand.

When the plants are one year old, it will be proper with a large harrow, to go over your land as often as is ſufficient to root up annual weeds and graſs.

The harrow will not hurt the lucern, the roots of it being very tough: this muſt be done in dry weather, before it begins to ſprout, which is very early in the ſpring, that the weeds and graſs may die; and if there are any patches of ground where the ſeed miſcarried, a little ſeed muſt be ſown, and the ſpot harrowed: a dreſſing with rotten-dung, at the ſame time, will repay the expences of it by a larger crop: if the harrow ſhould cut or wound any of the roots, they will ſprout and grow notwithſtanding.

The ſecond ſpring, after ſowing, it will be proper to plough the ground, where the lucern grows, with a drill-plough, with a round ſhare, without a fin or feather, and without a coulter, to prevent the roots being too much hurt. It ſhould lie rough a few days to dry and mellow; then, in fine weather, be harrowed down, to mow it the cloſer.

One, not uſed to the culture of this plant, will be apt to think, that ploughing will deſtroy the lucern; but any gentleman, that will take the trouble to call at Mr. Rocque's, may be convinced that experience teaches the contrary.

To make hay of lucern, it ſhould be mowed as ſoon as the bloom appears, or rather ſooner: it muſt not be ſpread, like common graſs, but lie in the ſwarth, like clover, and turned in the ſame manner; or the leaves, which are moſt nutritive, will drop off.

If ſuffered to ſtand too long before it is mowed, the ſtalks will be too hard for the cattle to eat it, and it loſes much of its goodneſs.

The hay is good for all ſorts of cattle; and when horſes are fed with it, they ſhould not have their full allowance of corn; the lucern anſwering, in a great meaſure, the purpoſe of both corn and hay.

It is alſo the moſt profitable of any ſort of fodder to feed horſes with in the ſummer, by mowing and giving it to them green.

If the land is good, the produce is incredible; and according to the goodneſs and depth of the ſoil, ſo will the crops be.

Mr. Rocque ſays he has ſeen lucern mowed five times in a ſeaſon; yielding, at the five mowings, nearly eight loads of hay per acre.

The ſpring ploughing amongſt the lucern muſt be annually repeated: it kills the graſs and weeds, and makes the ground ferment, which promotes vegetation; and the oftener it is refreſhed with a little dung on the ſurface, the better it will pay for the trouble of cultivating it. If the dung is laid on before the winter, that the ſalts may be waſhed in by the rain and ſnow, and ploughed in, in the ſpring, it will greatly add to the profit.

This is the ſubſtance of Mr. Rocque's account of the culture of lucern; but as different ſorts of ſoil may require different methods of tillage, he has ſubjoined the idea of a harrow, with two handles like a plough, which may ſerve in light land inſtead of the plough, and will ſave ſome labour.

The teeth muſt be ſet at ſeven or eight inches apart in the firſt row, and about five inches long without the wood. The ſecond row muſt be placed nine or ten inches behind the firſt, and ſo that the teeth of the ſecond row may be againſt the ſpaces of the firſt row; and they muſt be an inch longer than thoſe in the firſt row, ſo that the ground, being looſened a little by the firſt row, the teeth of the ſecond row may go ſomething deeper; and the teeth of the third and laſt row muſt be an inch longer than thoſe of the ſecond, and placed ſo as that they may go in the ſame tract with the teeth of the firſt row.

The harrow muſt be made of one ſolid piece, four or five inches thick, and the lower ſide muſt be rounded off towards the hinder part where the teeth are longeſt; whereby the perſon that holds it by the handles, preſſing down a little, may force the ſecond and third rows of teeth deeper than the firſt; and, by bearing up a little, he may prevent any but the firſt row from working. A very little practice will be ſufficient to make any one uſe it as occaſion requires; and it will be ſo ſteady that no unevenneſs of the ground will be able to throw it out of its work, as a clod or ſtone will a common harrow.

. . . . .
. . . .   } The manner the teeth are to be placed in.
. . . . .

Let it be remarked, that the foremoſt row of teeth are placed in a line acroſs near the middle of the block or plank; the other two rows behind that; and the fore part of the harrow ſhould be heavier than the hind part when the weight of the harrow is ſuſpended on the firſt row of teeth. The teeth ſhould be pretty ſtrong, and round; their being ſquare, as uſual, may hurt the roots a little, which is to be avoided as much as poſſible, though the conſequence would not be very great.

Farmers are fond of ſowing broad-caſt, it being no eaſy matter to make them comprehend the utility of a drill-plough on any occaſion: the ſight of ſo complicated an inſtrument terrifies them; they think it moves by clock-work: and as to the labourers, it is a very difficult matter indeed to get them to hold it.

I am fully ſenſible, as I have already obſerved, of the good effects of ſowing corn and pulſe regularly with intervals, but cannot approve of this method when applied to artificial graſſes; and it would be well if we were to improve our old practices, before we ſhould even attempt to bring the new methods into general uſe. *Muſeum Ruſticum, vol. I. page* 78.

In the ſucceeding volume of the above work, another correſpondent has made the following remarks on the above method delivered by Mr. Rocque.

This gentleman, ſays our author, owns he is againſt innovations in huſbandry, becauſe it is difficult to bring the farmer from the old methods; and therefore ſeems to conclude, new ones are not to be attempted; at leaſt, that ſeems to be his reaſon for being againſt what he calls innovations.

Under "reſtrictions, &c." he approves of the new culture, but thinks it "prepoſterous to extend it to artificial graſſes;" adding, "the only benefit lucern can receive from the horſe-hoe, is, that it keeps down the natural graſs." This gentleman cannot be a practical cultivator of lucern; neither can he know the uſes of the hoe-plough; if he did, he could not aſſert a fact ſo contradictory in itſelf!

To inaccurate obſervers the ſeedling plant of lucern may appear to have no lateral roots; but a careful examiner will find a great number of ſmall ones, every one, or moſt, of which are furniſhed with freſh nutriment by the operation of the hoe-plough.

We ſhall not contend about Mr. Rocque's ſuperior profit: his ſituation gives him advantages ſuperior to a diſtant reſidence; and therefore that ſhould not be mentioned by a generous writer.

I am a favourer and practiſer of the New Huſbandry; and I do deny that it will be more expenſive than Mr. Rocque's method, but, on the contrary, it will eventually be cheaper.

By his method he may, for a few years, have pretty good crops; but at length his plants will be found to dwindle, and his crops will leſſen, unleſs he annually adds ſeed to the ground; whereas, in the new culture, the crop will be continually improving: as to the quality being inferior, that will be the fault of the owner, if he lets it grow too rank. This argument of your writer makes againſt himſelf, as thereby he admits the ſuperior luxuriance of the plants cultivated by the horſe-hoe.

I have ſown lucern in broad-caſt more than once, and have ſeen others do it; and it ever failed.

Mr. Rocque's rule, as this gentleman ſays, is, "that lucern will grow on any land, if not wet:" this is certainly premature: it ſurely muſt have the occupation of a dry, rich ſoil, or I am ſure, from practice, it will not ſucceed; and as to "the ſtrongeſt being preferred," I believe every one, who tries the cultivation of it on ſuch, and upon light ground, will find the latter beſt adapted to it.

But the notion of ſowing corn with lucern is quite as "prepoſterous," I think, as the new culture for it; and how a man of Mr. Rocque's famed abilities ſhould adopt ſuch a method, I am at a loſs to gueſs. Neither ſhould lucern be ſown in March, as in its infant ſtate it is very tender, and timid of froſt.

This gentleman ſays, "it is for want of knowing the "nature of lucern, that they drill it." I might retort upon him; but his miſtaken zeal, I fear, will more injure the cauſe he means to promote, than I hope it will diſcourage the practice of drilling this valuable plant, as, by all men who adhere to rational principles, that hath been found the moſt ſucceſsful method. See Tull, Duhamel, &c. I ſhould be glad to know what "the ſurface of the ground is to be ſpared for:" is it to give life to the natural graſs, that common and deſtructive enemy of this excellent plant?

Our author mentions the cultivation of it in France, &c. If he was ever at Paris, with his preſent attention, he muſt have ſeen, that after a few years they always plough up the promiſcuous ſown lucern, in order to prepare the ground again for that, or ſome other crop, when the lucern begins to dwindle by the weeds or natural graſs robbing it of its nutriment.

How much more muſt that be the fate of promiſcuous ſown lucern in theſe kingdoms, where he admits graſs is apt to get a-head? That is not the caſe in France, and yet even there promiſcuous ſown crops are ſhort lived.

I know not whether he be as converſant with potato-ground in Ireland as I am; but I cannot omit to inform you the tillage will not do for lucern: for this plant the ground ought to be well pulverized; whereas, in the general potato tillage of this kingdom, not more than about two feet in nine of the ground is cultivated.

The manner of harrowing the lucern, practiſed by Mr. Rocque, although the teeth be round, muſt wound many of the roots: that might be well, as it would thin them; but repeated harrowing will, in time, wound them all; and notwithſtandig they will afford graſs afterwards, yet, when the winter rain comes on, lodgments of water will be made in thoſe wounds, which will bring on putrefaction, to the deſtruction of the plants, unleſs Mr. Rocque has the art of conducting the harrow-pins always in the ſame direction: and, could that be the caſe, what would deſtroy the graſs where they did not paſs?

The manner of ploughing the lucern, practiſed by Mr. Rocque, is ſtill approaching the horſe-hoe, though by no means ſo effectual. I wonder to ſee our author even favour that, ſince it may be deemed an "innovation." This ploughing is to be repeated every year, and harrowing alſo: to this dung is to be added, "as often as may be." I am willing to believe this gentleman knows nothing of the expence which attends theſe operations, *i. e.* ploughing, harrowing, and, above all, dunging, beſides the value of the dung, which would always be acceptable for other grounds; whereas, in the drill way of ſowing lucern, when the land is once put in good order, it may ever be kept ſo by the hoe-plough.

Lucern is a graſs of ſuch ineſtimable value, that it will anſwer almoſt any expence; yet if the moſt certain method to obtain ſucceſs ſhall be found the cheapeſt, there can be no reaſon for purſuing one more precarious and more expenſive, which will be found when Mr. Rocque's method, or at leaſt that ſo warmly recommended by your correſpondent, who aſſerts it to be Mr. Rocque's, is compared in practice with the one I venture to recommend to the practice of my countrymen, which I take upon me to ſay will command ſucceſs, if purſued.

The land ſhould be a flexible loam, dry, deep, and rich, either by nature, or made ſo by art; not but it will ſucceed to admiration ſhould a quarry be under. It ſhould be well pulverized by plough and harrow, laid as flat as poſſible, and cleared of all weeds, particularly ſcutch-graſs: when the ground is in this form, let a ſmall plough, with two mould-boards, be run up and down the field, at every three foot upon the flat ſurface: this will compleatly form three foot ridges. If a pair of drill-harrows be not at hand, let the crown of every ridge be carefully raked clean and even with an iron rake, and one row of ſeed drilled very thin, about half an inch deep, along the middle of every ridge, the middle or latter end of April, (the beginning of May may do) and be carefully covered. This ſowing of the ſeed may be done by hand, if a drill-plough be not ready. By a maſter's attendance, a great deal may be done in a day.

Thus it may remain till weeds begin to appear, when the hoe-plough, or a ſmall common one, ſhould take away every alternate ſide of the ridges, as near the lucern as can be with ſafety. (I go within two or three inches of my drilled crops.) In three or four days, return the mould to the former places with the plough, and then proceed to take off the other ſides of the ridges in like manner, and return it as before.

If the ground be made in good condition before ſowing, a crop may be mowed in July, the produce of which will ſurpriſe any one who is not acquainted with the plant.

In September it will be fit to cut again; but if in the intermediate time weeds ſhould appear, let the hoeing be repeated: thus the weeds will be deſtroyed the firſt year.

After the ſecond cutting, ſend in the plough again, and take off the ſides of every ridge within about ſix inches of the plants, and ſo let them remain till February, when the plough ſhould return the mould to every ridge; and in May the graſs will be ready for cutting, and will continue to afford a crop every month during the ſummer.

The hoeing ſhould be repeated, as before directed, as often as weeds appear; but obſerve never to horſe-hoe it when the ground has any adheſion.

The hoeing before the winter is to keep the plants dry during that ſeaſon, and to meliorate the ſoil of the alleys by the influence and mechanical operation of the winter froſts.

To keep my letter within reaſonable compaſs, I have been ſhort in my directions, but to practical farmers, I hope, ſufficiently plain; if not, any neceſſary explanation I ſhall chearfully furniſh.

Your readers will pleaſe to obſerve, that after the firſt preparation of the ground, if they horſe-hoe the crop regularly every year, the dung which Mr. Rocques's friend recommends (as it may be got eaſily at in London) may be ſaved for other purpoſes, as by this method of managing lucern, the crop and ground will be improving every year.

I appeal then to every impartial judge, whether this method is not cheaper than the ploughing, harrowing, and dunging, ſo warmly recommended by your correſpondent. It is almoſt unneceſſary to urge, that a crop raiſed in this way will, ever after the firſt year, be equal, if not ſuperior, to Mr. Rocque's, as the gentleman admits as large crops may be raiſed in the drill way.

I am a ſtranger to Mr. Rocque and his fried. I have no other motives in troubling you on this ſubject, than a public benefit to mankind, and a gratitude to the memory of Mr. Tull, whoſe ſuperior ingenuity, I bluſh to own it, hath ſhone in France, to the reproach of Engliſhmen. And were we all to join in opinion with your correſpondent (who ſays, "It would be well were we to improve our old practices, before we even attempt to bring the new ones into general uſe") we ſhould indiſcriminately merit the pity of all nations for our perverſeneſs. Perhaps, had Tull been a foreigner, his ſyſtem would have been eſtabliſhed amongſt us long ago.

The

The author of the former account not being fatisfied with the reafons offered by his antagonift, made the following reply; which we thought neceffary to infert, that our readers may judge for themfelves, and follow the method that fhall appear to them the moft rational.

I troubled you the beginning of laft year with a letter on the fubject of lucern, which you were fo obliging as to infert in your firft volume, page 339.

I am ftill an advocate for Mr. Rocque's method of culture in preference to Mr. Miller's, as far as regards this plant; and that for this plain reafon, becaufe I imagine the farmer will be much more likely to adopt the firft than the laft; and the culture of lucern can produce very little advantage to the nation, unlefs it is generally adopted by the common farmers.

My reafon for troubling you, or your readers, at this time, is to remind you, that Mr. Rocque's fmall tract, lately publifhed, contains fome particulars refpecting lucern, which were not noticed in my former letter, and therefore may, with great propriety, be now laid before your readers.

The firft of thefe partitulars relates to the manner of fowing the lucern; and in this Mr. Rocque differs widely from Mr. Miller, as he thinks it fhould not be fown without corn; but I will give you Mr. Rocque's own words, as they carry great weight with them. "You muft not fow lucern without corn, unlefs your fpot of land is too fmall to ufe a harrow in: in that cafe, you muft fow it in drills, and keep it very clean hoed. The drills for fuch fmall fpots are to be ten inches diftant; if wider, it lodges in the drills. The reafon I recommend fowing corn with it, is, to prevent the weeds choaking it; but, you muft fow only for half a crop; otherwife your corn will be apt to deftroy your lucern, efpecially if it proves a wet feafon, and your corn is ftrong. If there is no corn fown amongft it, you muft be obliged to mow the weeds, and run a chance of cutting the lucern with them: and, being very fappy, you cannot imagine how detrimental it is to bleed it, when young; but, when the corn will be fit to mow, the lucern alfo may fafely be cut."

As the duration of lucern has been a queftion long agitated, and not, that I know of, finally determined, it will not be amifs to mention a fact related by this able cultivator, as it will be an encouragement to the planters of lucern.

"As to the duration, it will laft as long as the ground is kept clean. I faw fome at Mr. Middlemar's, at Grantham, in his garden, that was forty years old; and it was very fine. To keep it thorough clean, you muft harrow it every time it is mowed; and, if requifite, at Michaelmas, and in February and March. If you once leave it foul, it will be very expenfive to clean. You muft make ufe of the drill-plough; but let the harrow be ever fo ftrong, you need not fear its hurting it."

In my letter to you, above-mentioned, it is obferved, that in preparing land for lucern, a trench-ploughing would be of great advantage: but in the piece lately publifhed, Mr. Rocque fays, "In cafe you are not well acquainted with the ftate of your ground, you muft trench-plough it twice, according to the directions for ploughing, which are in my Hints upon Burnet; whereby the roots will run down the fooner out of the reach of dry weather: and if the foil, that is turned up, be ever fo four, future ploughings, harrowings, and manurings, will fweeten it fufficiently for the reception of the feed."

Mr. Rocque adds, in this place, that "Lucerne will grow very well in clay land, with provifo the ground works well. The difficulty in thefe lands lies in the harrowing; in dry weather the ground being fo very hard, the harrow can do but little good, unlefs you take the feafon between wet and dry to harrow it, which you certainly muft."

It is alfo obferved, that in the province of Languedoc, in France, the inhabitants mow their lucern when it is fix or feven inches high, in order to kill the annual weeds. Of this practice Mr. Rocque now fays, "By my own experience, I find they are in the wrong; for it bleeds it, fo that the plants make but little progrefs when cut fo young, and are a long time in recovering it. It ought never to be cut but when in bloom."

A great many imagine that the feed might profitably be faved in England; but Mr. Rocque is of a different opinion, and indeed I am inclined to join with him in this refpect, as in this ifland it is at beft but a precarious crop, and can be imported fo cheap, that the feedfman can afford to retail it at nine-pence per pound, at which price it was this year advertifed. Mr. Rocque's obfervation on this point is as follows: "In hot fummers the feed may be faved in England, but not from the firft growth, that being generally too rank, and fubject to rot at bottom: though I think it is needlefs attempting to fave any of the feed in England; for, in the year 1761, which was a very fine fummer, I tried to fave the feed of the fecond growth, on light land, but made nothing of it; not faving above thirty pounds of feed, upon four acres and a half. I alfo tried, that fame fummer, to fave fome off ftiff land; but that proved ftill worfe."

I have only now to give you Mr. Rocque's thoughts on the value of this grafs, which, in my opinion, deferves to be preferred to almoft all others.

This practical cultivator fays, "I have already obferved, it ought not to be cut but when it is in bloffom; and that is but three times a year: but after mowing the third crop, you may, inftead of mowing the fourth, feed it: but when frofts come, you muft take your cattle off; becaufe there are always young fhoots, which would be bruifed, if the cattle were not taken off. If it is rank in September, it is dangerous for cows, being too feeding; but turn horfes and fheep upon it. As there is no grafs, as has yet come to our knowledge, which gives the cows fo much milk, you may let them graze about an hour, at moft, in the afternoon, when the dew is off. When made hay, it is likewife the beft for milk: wherever it is much cultivated, they prefer it to all other kind of hay.

When I was at Monofque, a city in Provence, which was about twenty-feven years ago, the carriers fed their horfes upon it, preferably to any other, without corn; and the mules looked fat and in fine order. Six mules which I hired there, to carry my feeds at Nimes, fed on nothing elfe, and yet carried their load all day long, without unloading. They have the cuftom of hanging little bags to their horfes or mules heads, wherein they put lucern, on which they feed as they go.

It is acknowledged by all connoiffeurs to be the moft feeding of all pafture, either green or in hay. I truft not barely to report, but have experienced it to be fo myfelf. I had colonel Vernon's horfe fent to me from the country, in a very poor condition; and, in fourteen days, he was in very good order. The colonel was furprized to fee how he had throve in that fhort fpace of time.

Many are apt to condemn it, but it is for want of knowing its good qualities. It has been introduced for a long feries of years; but fo little noticed, that one and twenty years ago there was not two hundred weight of lucern grafs feeds to be fold amongft all the feedfmen here in London; and I had much ado to re-introduce it; but now, within thefe three or four years, there is a prodigious confumption of it.

One Mr. Beadle, a farmer in Kent, has fourteen acres of it, for which he had a premium. When I called upon him, which was in the beginning of May laft, he had mowed his lucern, and fold it upon the fpot, for three pounds or three guineas a load. I blamed him for cutting it fo young; but he told me he was compelled to it, to get fodder for eight hundred head of fheep, that he had; but that, a little while after, it grew fo faft, that he could turn his fheep upon it. Thofe that bought his hay muft needs be well acquainted with the goodnefs of it, to fetch it on the fpot, though they were ten or twelve miles diftant.

It is not foggy, like clover or tares. Horfes will work with it green, as well as with hay or corn: they do not fweat with it, as they do with other green fodder. I have been told, one of our poft-mafters kept his horfes both winter and fummer with it, and that his horfes were the beft on the road. They object, the hay of it is difficult to make: it is no more difficult than clover. All hay is difficult to make in wet weather: but when it is a bad feafon to make hay, do as Mr. Allen does; put it up

in

in ricks when dry, and between every bed of hay, of any kind, put a layer of falt, and that will recover all the damage the rain can have done.

I have done it myfelf, this very laft year, with a rick of burnet: to about twelve loads I have put a fack of falt amongft it; and every time my horfe comes near it, he eats it very eagerly, though he can get but at the outfide of it. It will keep in ricks as long as any hay.

Multitudes, at prefent, are pretty well acquainted with the excellence of both thefe graffes: but if any doubt the truth of what I affert, let them take the trouble to enquire into it, of Mr. Shennelly, the tobacconift, at Houndfditch; to whom I have fent a load of lucern, and am to fend another load of the fame, and half a load of burnet hay.

Thofe who are not fatisfied with the theory, may be convinced of the practical part, by feeing a field of mine of lucern, of four acres and a half, at Batterfea, and the manner of working the harrow."

From what has been faid on the fubject of lucern, I hope your farming readers will be induced to adopt the culture of it; as, if they are not blind to their interefts, they cannot but be convinced of the many advantages which would refult to them from fo doing. Mr. Rocque's method of cultivating this plant differs but little from the manner in which they raife clover; and the profit to the landholder will be abundantly greater. *Mufeum Rufticum, vol.* iv. *p.* 259.

The following method of cultivating lucern, is extracted from a very ingenious performance, entitled, *Effays on Hufbandry*, the principal intention of which is to recommend a newly difcovered method of cultivating this plant.

Mr. Rocque, as may be feen above, has adopted the old Roman method of fowing it, broad-caft, and harrowing the land from time to time by way of deftroying the weeds. Mr. Miller recommends the new, or drill, hufbandry for the culture of lucern; but the author of the Effays above-mentioned differs from both thefe practical cultivators, and raifes his lucerne in a nurfery; after which he removes the young plants, and having cut off their ftalks and tap roots, tranfplants them, with great regularity, into the field where they are to ftand for a crop.

I fhall not pretend to decide which is the beft method; yet I may venture to fay, that I know it may be raifed to confiderable profit, both in Mr. Rocque's way, and according to the rules laid down in the new, or horfe-hoeing, hufbandry.

I have no doubt but it may fucceed by tranfplantation; yet I greatly fear that the expences in this method will, when applied to any confiderable extent of land, greatly exceed the worth of the crop.

Thefe Effays being too learned for the honeft farmer's reading, it is very improbable they fhould ever fall into his hands; yet, as it is a great pity he fhould not be permitted to judge for himfelf in a matter which may turn out fo much to his advantage, we have taken the trouble of tranfcribing a few pages of the fecond Effay, which more immediately treats of the culture of lucern by this new method of tranfplanting.

In this extract we have omitted all reafonings that might render the narration obfcure to the farmer; not that we had ourfelves any objection to them, or did not approve of them, but as we were willing the honeft cultivator fhould have as much of this matter laid before his view, in a plain manner, as was neceffary for him to underftand it: when this is done, he may judge for himfelf; and if on trial he finds the method here recommended anfwer, his beft way will be to adopt it in his future practice.

Whoever propofes to fow a lucern-nurfery, or engages in any larger undertaking of cultivating whole fields of fainfoin, trefoil, buck-wheat, fpurrey, fenugreek, fweet, melilot, &c. would be no ways ill-advifed, if he prepared a bit of ground, and fowed a fpoonful of the feeds about a fortnight before he propofed to fow his larger quantity; fince, from the good or bad fuccefs of this little attempt, he may be enabled to judge, whether the feedfman has fupplied him with feeds fit for vegetation. Without fuch precaution, a whole year may be loft; which is a mortifying circumftance in matters of hufbandry.

In the end of March, 1757, a common day-labourer was ordered to fow a pound and a half of lucern-feed, and keep the ground clear from weeds. The feed was fown on one of the leaft promifing pieces of land in all the neighbourhood; but this was done by exprefs order; for it was thought unfair to make the experiment on a better foil than the commoneft fort of grafs-fields. The fpot of earth fet apart for the purpofes, both of nurfery and tranfplantation, was, in former times, a kitchen-garden: but the good foil, to the depth of eighteen inches, had been removed for the fake of manuring a corn-field. [To which we fhall juft add, that the attempt was made in an hilly country, where the ftaple earth is naturally fhallow.] What remained was a cold, yellow, clammy ftratum, which the country people looked upon as mere clay; but, its nature having fince been better examined, it appears to be a mixture of imperfect clay, and imperfect marle. No manure worth mention was ufed upon it, as will appear by the fequel.

To all feeming appearance, little, or next to nothing, could be expected from a piece of ground of fuch an unpromifing caft; but, upon the whole, the experiment proved fuccefsful and eafy.

By the middle of Auguft, the plants were, fome of them, eighteen inches high; and many of them branched out, fubdivided themfelves, and made very fine fide-fhoots: upon which it was refolved to venture upon the fecond part of the experiment, according to the accounts given by M. de Chateauvieux; therefore taking the advantage of a moift feafon, in the beginning of September, (which feafon, by the way, did not laft long) we performed the work in the following manner. [But here let it be juft obferved, in paffing along, that the time of the year, pitched upon for tranfplanting, was, at leaft, three weeks too late for England, though, perhaps, highly proper for the territory of Geneva, or the fouthern parts of France. This therefore is fet down as one of the *mutatis mutandis* fo indifpenfibly neceffary in matters of agriculture, when the practice of one country is copied in another.

Firft the roots were dug up carefully; orders being given before-hand not to attempt drawing them, even with the fmalleft degree of violence, till the earth was entirely loofened at top and at bottom. In the next place, the long tap-roots were cut off eight, nine, or ten inches, difcretionally, below the crown of the plant (the sciffars being generally applied juft beneath the forks of the root, if it be a branching root:) then the ftalks were clipped about five inches above the crown of the plant; and the remaining plant, after thefe amputations, (which may appear, at firft fight, to be very bold ones) was thrown into a large veffel of water which ftood by for that purpofe, in the fhade. Such refrefhment is no ways unneceffary; for this plant is very impatient of heat and funfhine after it is taken up; nay, to fuch a degree, (at leaft the firft half year of its growth) that one may almoft call it a fenfitive plant. The fame day, making ufe of a dibble, or fetting-ftick, and filling every hole with water before the roots are put in, we tranfplanted them in rows, two feet afunder, and each plant fix inches apart in the rows; having firft made little drills, or channels, and fprinkled, or half filled, them with fea-fand and wood-afhes kept dry (two parts of the former to one of the latter;) which was done with a view of loofening the foil, and giving a little warmth to a piece of ground which was naturally cold and clayey; nor was any other manure ufed. The drills were afterwards once watered, to take off the drynefs and heat of the afhes. The roots were placed firmly in the ground, and two inches of the ftalks covered with mould.

Yet here it muft be freely acknowledged, that the hopes of poffeffing a large crop occafioned one miftake, which we chufe rather to mention than fupprefs, as many people may happen to entertain the fame falfe expectances. The miftake was, that we made our rows two feet afunder, which was over-narrow; and placed the plants, in the lines, only fix inches apart, which brought them nearer together than they ought to have ftood, even though the ground was very poor: nor did we forefee, that horfe-hoe ploughing is five times more efficacious, as well as cheaper, than hand-hoeings.

Therefore,

Therefore, after frequent experiments, since made, it appears best to make the lines three feet four inches distant from each other: and if the soil is good, it may not be amiss to allow each plant a foot distance one from another in the lines, for thus the hand-hoers will work more commodiously, and a little hoe-plough may be guided safely up and down the intervals, which will save a great deal of trouble: nor will the future crops be lessened, by such thin transplanting, half so much as may be imagined; but, on the contrary, the plants will be larger, more juicy, and better tasted; which circumstance may be extended in favour of the New Husbandry in general. Space and culture improve the herbage and seeds of plants; in proof whereof I have been assured, from good authority, that all the corn, raised by M. de Chateauvieux, sells at an advanced price; being larger, brighter, and healthier than common corn, and, consequently, more fit for sowing, or making bread.

But, by way of confirming the necessity of allowing lucern roots a good share of space, a friend of the author's filled an acre with plants, according to the first directions; but, the soil proving extremely good, and free from weeds, it soon appeared that the roots stood too close: in consequence whereof, every other plant was taken up the next autumn, and, a fresh acre of land being properly prepared to receive them, he thus gained a new plantation of lucern, at a small expence, with little trouble: and, what is more remarkable, it is thought the second acre bore a larger quantity of herbage than the first would have done, if the plants had continued as they were, without being thinned, to the amount of one half. Of course, there is reason to conclude, that this slight hint, which took its rise from mere accident, ought not to be looked upon as quite unuseful, since two acres may be raised with almost the same expence as a single acre.

In ten days, though a drought succeeded, some transplanted plants made shoots of three inches height; which vigorous growth gave better hopes than had been conceived at first.

It was also some encouragement to the undertaker, that he found wild lucern within two musquet-shots of the place where the nursery was formed. These plants were certainly *aborigines*; for they grew in a part of the kingdom where the name of lucern had rarely been heard of, except by gentlemen. Besides, no person curious in husbandry would have ventured sowing the seeds in such an unpromising piece of ground; for the field, where the wild lucern grew, was a sort of coarse, uncultivated morass, and valued only at about two shillings and sixpence an acre.

Yet still the approach of winter made many persons doubtful concerning the success of this new plantation; nevertheless, it was some satisfaction to recollect, that there is less harsh, severe cold in England (and that almost by one third) than in the territory of Geneva, where the original experiment was made, and where the plant we are speaking of has been known to thrive so extremely well.

At length the winter passed over, and, out of four thousand roots, only thirty or forty perished, whether by frosts, immoderate rains, or any other accident, is hard to say: but the labourer filled up all the vacant spaces from the nursery in about an hour, and in April, 1758, most of the plants were nearly equal in size and strength; of a deep juicy verdure, with few or no discoloured sickly leaves: but, May the eighth, people counted sixty stems from one particular root, and the stalks and leaves of some chosen plants weighed near half a pound at one cutting. Yet we learn, by experience, that lucern must only be considered as in a progressive state, till the third summer after transplanting; and then M. du Hamel assures us, that one flourishing plant will produce a pound of well-dried hay; which is saying a great deal, and much more than I could ever verify; for, if a single plant produces one pound of hay, it must have weighed four pounds when it was green. Yet I have received an account from an eminent physician in our own country, (who planted two acres of lucern by my directions) that many of his plants, in the second year, yielded near half a pound of hay each plant.

As an acre of lucern, thus managed, will contain more roots than one is apt to imagine at first guess, how great must the produce be of four or five cuttings every year, and those confessedly the most nourishing and palatable food that cattle can eat! For thus much is certain, amongst other advantages, that, if a field be industriously hoed, ploughed in the intervals or spaces, and hand-weeded in the rows, for the first two or three years, it is almost sure, that horses, cows, or sheep, will hardly find a single weed in a large quantity of green food.

We will now mention the state of our transplanted lucern in its second year, namely, 1758.

And here let it be remembered, that what cultivators call a proper time for cutting is, when the plants are about fifteen or sixteen inches high, at an average, throughout the field: but this must be understood in a relative sense, for some plants will be two or three feet high, and others may not be above ten inches, or one foot, in height, according to the circumstances of health, space, situation, &c. of the several roots.

The cuttings of the year 1758 were as follow: May 8th, June 7th, July 12th, August 20th, and October 1st.

In the year 1759, it was cut five times, and six times in 1760; which made sixteen cuttings in three years. Nay, by the ninth of April, in 1760, some of the lucern plants were near seventeen inches high, at a time when no field in the neighbourhood had grass of four inches height, though you took five or six acres together. The same lucern was cut twice, before any hay-making began in the country round it, if we except some few meadows lying near market-towns.

Having carried on my first experiment thus far, upon almost as unpromising a piece of land as could be found, and being sensible I had made some mistakes from want of experience, (having as yet never seen any transplanted lucern in England) I gave directions for making a small plantation in Berkshire, but still took care to chuse a field that could hardly be called middling land. It was overrun with coarse weeds, had been long out of tillage, and the earth, in most places, was hardly four inches above a bed of chalk; which (let farmers say what they please of it, in respect to saintfoin) is no ways favourable to the growth of lucern, especially if the latter be transplanted; for the chalk flakes, when thaws and rains come on; and it either heaves the plants out of the ground, or exposes the fibres of the roots too much to the cold. Yet upon this I ventured with my eyes open; for Pliny (whose authority I scruple not to take, when I have no other) had given me a caution concerning lucern raised upon chalky lands: but what induced me to make the attempt was, that the goodness of the soil might not lead me to say more concerning the success of an experiment than other people may hope to find.

The little field, or close, consisted of one rood of ground, or a quarter of an acre; which we threw into fifty-four rows, each row containing one hundred and ten plants, or five thousand nine hundred and forty in the whole. In the second year after transplanting, (and lucern is not then arrived to its due size) and at the first annual cutting, (which is not the best cutting, as the herbage suffers much from the winter) I weighed, out of curiosity, a parcel of the prime plants, which, one with another, weighed about one pound and a quarter each. But supposing that every plant weighed only one quarter of a pound, and admitting we give up the sixth cutting, (which is more than one needs to do) then the crop of forty perches, or one fourth of an acre, amounts to a very considerable return of ten tons, at least, of green lucern per acre.

An acre of transplanted lucern, rightly managed, will bring in five pounds a year, free and clear from all expences, and that for a considerable tract of time. Now certainly this advantage deserves well to be considered; for the husbandman is said to be a good manager who makes three rents each year; a first for the landlord, a second for labour, &c. and a third for himself: but an acre of lucern will for several years produce five rents, clear of all out-goings for rates, rent, workmen, manure, &c. supposing the land to let at fifteen shillings an acre, as usually happens in most estates that lie at some distance from cities and market towns. On the contrary, if land be dearer near rich populous places, the ground will be better, and the produce more advantageous. This gives lucern its value near towns and cities, where two or three acres may be rented, but ten or twenty cannot; and sure it is some advantage in husbandry to make one acre supply the place of two or three, and especially where it is difficult to rent land, even at a very high price.

It is certain, that the profits arising from transplanted lucern have been no ways exaggerated in my account; for by some collateral observations it may be easy to carry the value of an acre something higher than has been here represented. Suppose green vetches (which are rarely cut more than once) and green lucern to be of equal value as food for horses (which is making a supposition no good writer on husbandry will allow to the disadvantage of lucern;) now a perch of green vetches (if the crop be good) sells for sixpence at seventy miles distance from London, and a perch of transplanted lucern will weigh as much, or very nearly as much, at two cuttings, out of the four or five annual cuttings; which (every circumstance being duly considered) brings an acre of lucern (to say the least of its advantages in husbandry) to be of equal value with two acres and a half of vetches; not to mention that lucern is a perennial plant, and vetches are annual; which, upon the whole, makes a new difference in point of profit.

As I think it unfair to suppress any unsuccessful circumstances in matters of husbandry, I will here ingenuously confess, that the most material of my mistakes were these: I followed my foreign instructions (which, at that time, were but few) with too much diffidence, and in too literal a manner. I was not enabled, through want of experience, to adapt the husbandry practices of other nations to the English climate. I transplanted too late, filled my rows too full, and allowed not sufficient space for the intervals. By following the French directions over closely, I cut the tap-roots too short in the best plants, and knew not (as it is a point unmentioned by any cultivator of lucern) how to manage a root that was very small. The means of avoiding and rectifying all which mistakes and difficulties are, by the help of subsequent experience, carefully pointed out.

And here it may be worth considering how to apply a field of lucern, carefully and industriously cultivated, to the greatest advantage. In such a case, let us suppose the plantation to consist of two acres, and that four large horses are to be supplied with green fodder, from the end of April till Michaelmas. Now, in order to manage this affair with dexterity, count the number of rows or lines in the lucern field, and place in one of the head-lands thirty land-marks, at equal distances; and thus, having cut a proper portion, day by day, you will be ready to begin afresh, after the last cutting.

When I say you will be ready to begin afresh at the end of thirty days, I must desire to be understood, with a small degree of latitude: for physical accidents are so numerous and unavoidable in regard to the growth of plants, (though lucern is liable to fewer checks and miscarriages than most other cultivated field vegetables) yet still the nature of the thing will not allow us to predict the time of each and every periodical cutting with much certainty; nevertheless, thus much may be depended upon, even for some years successively, that, after the first annual cutting, our directions, here given, will be attended with no inconvenience to the owner; for there will rarely be more than three or four days difference between the times of the second, third, and fourth cuttings: nor will the want of lucern fodder, during such short intervals, be of the least ill consequence; for, surely, that husbandman must be a very improvident manager who has not other grass fields by way of a momentary supply.

The times, therefore, of the second, third, and fourth annual cuttings, are tolerably certain; but the first cutting, according to the nature of the winter, may be accelerated, or retarded, a fortnight, three weeks, and, perhaps, a month.

The time of the fifth cutting is also, in some degree, variable and uncertain, as the solar heat decreases, and the days grow shorter. A sixth cutting, which is seldom of much consequence, chiefly depends on a fortunate season, in conjunction with the industrious good management of the cultivator.

From this succession of fresh green food appears one singular advantage in raising lucern: and in the next place care must be taken, that your plantation be always proportionable to your number of cattle; or, in other words, let it be a rule to you to have rather over much lucern, than too little; for then one cutting may be set apart for hay, which may be given occasionally to favourite horses and sick cattle. But, in case no hay is made, the owner of the ground, even then, by means of the supplies he derives from green lucern, will be enabled to spare a large quantity of other grass for hay-making; and thus two acres of lucern will give him the power of saving two or three tons of hay more than he could have saved otherwise; consequently lucern, in effect, helps to keep cattle both in winter and summer.

By such sort of husbandry, and provident management, the stock of hay for winter will be considerably encreased, and the owner enabled, for the space of five months at least in the other parts of the year, to allow his horses very nearly the same quantities of green food each day; all equally fresh, wholesome, and well tasted: which single circumstance, (if it related to horses only) gives lucern the preference over all other sorts of green fodder hitherto known, and in process of time may be applied (as has been experienced with much success) to the fatting of horned cattle, provided such cautions are used as shall be specified hereafter, and which ought always to be remembered. Now whatever encreases the number of cattle, augments the quantity of dung necessary for carrying on the more successful cultivation of arable lands; and whatever, by multiplying the number of cattle, affords more animal food to man, will of course contribute towards lessening the price of meat, which will assist society in general, and more particularly the manufacturer and peasant; for the grand secret of well-managing a trading populous country is to supply the inhabitants with flesh and corn upon easy terms; for then mankind will multiply of course (supposing the government to be mild and equal;) nor will other nations undersel us in the commodities we export to foreign markets.

Now lucern, in matters of husbandry, comes the nearest of any article yet known, towards attaining the points here proposed; forasmuch as one acre of land, thus cultivated, will support as many cattle in spring, summer, and a part of autumn, as four acres of common, natural, upland grass did before. But this use of lucern is greater, if land be scarce; or if the nation be populous, and the soil has been cultivated to the extent of the old husbandry: for then the introducing this plant is, in effect, the same as creating new land, if the superior produce of lucern, both in quantity and quality, be fairly considered by us.

Yet one thing must be well understood in the new practice of raising lucern. Negligent husbandmen, and such as expect good crops without labour, expence, frequent ploughings, weedings, &c. would act a wise part in not attempting to cultivate the plant here mentioned: nor is it advisable for gentlemen of fortune to commit this part of husbandry to bailiffs and servants, who (be their masters advantage ever so great) will not like the labour (though they are well paid for it) of turning fields into a sort of gardens, and, besides all this, may conceive a prejudice against improvements, and take some small delight to see them miscarry: so that all random, careless, and insincere methods of culture must have nothing to do with raising plants, which, though hardy and long-lived after they attain a certain age, yet are surprisingly delicate and tender when they are young, or when first transplanted; and more especially if wild couch-grass and other weeds should spring up amongst them.

For these reasons, at first setting out, I must advise every good cultivator to be particularly industrious in the extirpation of weeds, and that he over-burdens not the strength of the earth from a principle of avarice, but allows her the just refreshments of manures, and gives her at least some breathing space of ease and repose.

It

It is highly unreasonable to expect success in the management of this plant without care, and highly improbable (if the seeds are good) to miscarry with due care. It is true, many people have failed in the process of this experiment; but then one is generally enabled to point out the error, as likewise the cause of ill success, with tolerable exactness. To begin well in cultivating this plant is doing but little; rules and directions must be cautiously observed for three, or two years at least. Few people make mistakes in the beginning of an experiment: but, generally speaking, after three or four months are expired, the master's attention and keeness wear off, and the bailiff or gardener, (as sometimes the raising of a lucern nursery fall in the province of the latter) are extremely glad not to refresh his memory: for the ones does not like an additional trouble out of his department (a punctilio which has great weight with all servants;) and it is a maxim with the other, never to admit any thing new in matters of husbandry, but admire those sorts of crops which Columella describes; crops that can hold up their heads and prosper under all the negligence of a pretending cultivator.

It is true, many difficulties and discouragements attend making experiments. The continuance of life is as short as that of art is permanent; and few husbandry experiments can be made oftener than once in a year: nor must we reason too much by analogy, from success in one production, to success in another of a different species. Attention also is required, and that even to the minutest circumstances: and again, too many experiments die with the observer; which, though highly useful, did not appear considerable enough for human vanity to establish a system thereon.

Yet still all these difficulties and discouragements may be counter-balanced by the advantages which result afterwards to society.

Lucern cannot easily be freed from manifest disadvantages by any other method of culture than what is here recommended. That it has usually miscarried, when sown with spring-corn, after repeated trials in this kingdom, from the year 1577 to 1764, is well known to many readers; for common wild grass, and particularly couch-grass, may be called its destruction, if not its poison, principally indeed by starving the roots of it, but probably from its effluvia too. This likewise I have always observed in plants of a different species that stand too near each other; they immediately, as it were by a declaration of war, contend for mastery: the roots are constantly attempting depredations and encroachments upon each other; whilst the stalks, especially those of weeds, make the same efforts in longitudinal shoots; and that plant, which over-tops the other, provided the shoots are equally thick and strong, always gains the victory, and, by over-shading and dripping upon its antagonist, forces it to dwindle away and perish. This struggling for life and mastery draws up the plants too weak and spindling, and the conquered plant usually dies. Now weeds, generally speaking, are more hardy, savage, and hungry, than manured vegetables. If such be the case, where is there a country to be found that abounds with foul grass and weeds more than England? So that, if lucern be sown in the usual way amongst corn, like ray-grass, clover, and hop-trefoil, no care can keep an acre clean. It may last two years, (only one crop being tolerable) and then must perish in the common course of nature. A gentleman very lately made this experiment (in good measure against his judgment) for the sake of farmers, in hopes of finding out a cheap, easy, and compendious method of raising lucern; but the crop, at the end of fifteen months, was as near being overpowered and starved as can be imagined; which made him venture to take up and transplant the few good roots that remained, which, being freed from the bad neighbourhood and incumbrance of coarse grass and other weeds, appeared to prosper very well. Again, if lucern be raised in drills, according to the best directions hitherto given by our ingenious countrymen, Tull and Miller, (who, to do them justice, were the first persons, amongst our modern writers, that saw the great advantage of this grass, and pressed the culture of it strongly on the English nation) certain it is, that such a method will greatly exceed the promiscuous sowing of lucern with spring-corn. Yet still, in the practice of drilling, a considerable part of the seeds may be faulty, and then the rows will appear naked and unsupplied with herbage: nor can the hopper be supposed always to drop the little grains at precise distances plant from plant. Nevertheless, such persons as prefer drilling may fill up all the vacant spaces with transplanted roots.

In the method of cultivating lucern, which is here recommended, an acre will be found to contain about such a number of chosen healthy roots as the ground is capable of supporting, and admit a greater number of them than the reader will be apt to imagine, *prima facie*; for it will hold, according to my first experiment, about twenty-six thousand plants: but, if the ground be clean, rich, and well conditioned, it may be more advisable to observe the greater distances already mentioned; upon which principle, the acre will contain about thirteen thousand plants; and this is the number, all things considered, I am most inclined to recommend; for the produce of such an acre will be full as large and profitable as the former, and the ground will be managed with less expence and more convenience.

It may be observed farther, that, in transplanting lucern, there will be one advantage (and that no small one) which can never be obtained in drilling, or promiscuous sowing; each root will stand at a proper distance from its neighbour, and receive its allowance of food in due quantity, without diminution. In the next place, you will seldom see a plant wanting, and rarely (except by mistake) a plant supernumerary: but, if a few sets should chance to die, it will be easy to supply the vacant spaces from the nursery, and that, as people find by experience, in any moist day, from April till the middle of September.

There is another advantage which arises from transplanting lucern; for, by cutting the tap-root, you prevent its penetrating ten or twelve feet perpendicular into the ground, which the plant naturally does in three or four, years, except it be obstructed by a stratum of rock, or chilled at root by weeping springs, or finds admission in a bed of cold watery clay. Then the crop makes a poor appearance, or, perhaps, goes off all at once.

People who hand-hoe or horse-hoe lucern, need not give themselves much pain about breaking or cutting off a lateral root accidentally; not but that some care and caution must always be used: however, what seems to injure the parent-plant proves, in the end, no-ways disadvantageous to it; for horizontal, or side roots, thus cut, or broken, push forth new roots and filaments laterally; and thus the suckers, or tubes that suck nourishment, are multiplied by a cause which had the appearance of lessening their number. Yet transplanted lucern will no-ways bear such rude treatment as the antients sometimes gave to untransplanted lucern, when they thought fit to make it undergo the discipline of harrowing.

How long lucern may last cannot be known by the experiments which are here related, namely, from the spring of 1757 to the beginning of the year 1764; but some persons of credit have observed the plants to continue in good strength and health near twenty years. [I suppose they mean here and there particular plants, and not a whole plantation.] Tull, indeed, tells us that, except lucern be choaked or starved by grass and weeds, he hardly knew when to say it will die a natural death; and probably it may not prove the less long lived for being transplanted; since hand-hoeings, horse-hoeings, and digging, will give new strength and health to the plants. The spreading of the roots will be facilitated by loosening the soil, and letting in the good influences of the atmosphere: their growth also will be augmented by giving them that additional nourishment of which the weeds defrauded them: and, in the last place, all manures will more easily reach them; for thus much is a certain fact in husbandry, that, when the ground is rendered clean, light, and penetrable, the roots love to expand themselves, in order to procure a greater quantity of nourishment.

I fairly acknowledge that I am not enabled, from my own experience, to fix the common duration of lucern, whether transplanted or drilled (and that from no difficulty in the thing itself, but because a sufficient number of years has not elapsed since making my experiments;) but thus much I can take upon me to say, from my own knowledge,

ledge, that lucern fown at random, or by what we call promifcuous fowing, as the ploughman fows rye-grafs and clover, (whether with or without fpring-corn) will not laft to any tolerable purpofe above two years, or three at moft. But, as this plant is of the greateft ufe and value, where land is dear and fcarce, as near cities and towns, I fee no reafon to doubt, but that the fame fpot of ground may be continued as a lucern plantation for half a century at leaft: for if the rows are three feet four inches wide, (which I look upon to be a *fine qua non*) then, whenever the old lucern decays, new lines may be planted in the middle of each interval, which has lain fallow, and alfo been manured and pulverized for a confiderable number of years; and thus progreffively, *vice verfa*, to a long continuance.

Not being able therefore to give pofitive fatisfaction concerning the continuance of lucern rightly managed, I fhall propofe fomething that is not merely a query, and which, perhaps, may give the reader an equivalent information. In a few words, it is as follows: when lucern is grown old, and the owner propofes to break up the plantation, layers might be made from all the principal ftalks, and removed into frefh ground. Thefe layers, in all probability, may fucceed extremely well, according to fome few experiments made abroad in the years 1755 and 1756.

As to the expence and rifque of cultivating fmall quantities of ground, agreeably to the method here laid down, it is to be hoped that curious gentlemen will not be deterred by fome few minute difficulties or objections, but give the prefent experiment fair, patient, and repeated trials; for neither the out-goings nor the hazard will be very confiderable. But at prefent it is no-ways our intention to perfuade farmers (at leaft fuch as are in low circumftances) to quit their little certainty for an advantage which may appear to them quite uncertain.

Let them wait, at leaft for a few years, in hopes fome cheaper and more compendious method may be difcovered for their fakes; and if, at prefent, they make any experiments, let them be in fmall.

The firft point of confideration, when I undertook to recommend tranfplanted lucern to the public, from my own experiments, was to bear conftantly in mind whether the profit counterbalanced the expences and labour of culture, and that in a double, or even treble, proportion; fince, otherwife, I was doing little more than poftponing utility, for the fake of introducing a new fort of hufbandry, which only deferved to be called ingenious.

We all know that the farmer expends much money, and gains very little from a crop of wheat at the expiration of his twelve months; but if we take ten years together, and compare the profits of lucern on the one hand, and wheat, barley, oats, and clover, on the other, the balance will certainly turn in favour of the lucern-crops, and that in a proportion of three, or two, to one, at leaft.

The expence of raifing an acre of lucern in the manner which we recommend, (and fuppofing even digging to be made ufe of inftead of ploughing) amounts, as nearly as I can remember, to the following fums:

	l.	s.	d.
Fine-digging and picking thirty perches for a nurfery	0	12	0
Seed	0	7	0
Hand-weeding the nurfery twice, and tranfplanting into vacant patches fuch plants as ftand too thick.	0	13	0
Digging an acre for receiving the roots	2	10	0
Tranfplanting	1	5	0
Hand-weeding and hand-hoeing the rows, with a four-inch hoe that cuts downwards, and then with a larger plantation-hoe which cuts horizontally	1	0	0
Two horfe-hoeings	0	5	0
Total	6	12	0

It is true, the expences of raifing lucern, in this manner, will vary, when applied to parts of England different from thofe where the experiment was made, as the price of labour may be dearer, and rents run higher; but then the ground ought to prove better, which will balance the difference.

This plantation of lucern may be cut three times the firft year after tranfplanting, as fome repayment for the out-going expences: next year the profit will be more confiderable.

On the other hand, thofe who prefer the drill-method of raifing lucern, as lefs expenfive, may feem to fave about two pounds, or more, upon an acre, at the firft appearance of things; but then the rows, in cafe the crop fucceeds (which is a doubtful point) muft be thinned with good judgment, which will coft money; and the vacancies in them muft be filled at laft with tranfplanted roots: nay, M. de Chateauvieux afferts, that drilled lucern will rarely be fo large and flourifhing as the tranfplanted; for the effects of horfe-hoeing, and the influence of manures, may prove of lefs fervice to the roots of the former, at a depth of twelve or thirteen feet, than to the roots of the latter, whofe fineft imperceptible fibres will hardly defcend above a yard perpendicular.

It is hard to fay at what precife time the affiftance of the hoe-plough fhould be called in: but the owner of the plantation may venture on the attempt, I think, with fafety, in three days after the fecond cutting, about the beginning of June; for the roots then will be tolerably well fettled in the ground, and before that time the flat plantation-hoe may be ufed, chufing fuch an one as is about eight inches and an half wide in the cutting part.

As continued hand-hoeings will be chargeable, troublefome, and almoft endlefs (being in truth little more than a temporary expedient, and flight fcratching the furface of the earth) remember to make a light plough, with which you are to cultivate the fpaces between the rows; and in this cafe you may either invent a plough according to your own fancy, or copy fuch as are ufed at home, or in other countries, on the like occafion.

The fhare of this plough fhould be fharp, about fixteen inches long, with a coulter proportionable; the plough itfelf no heavier than a ftrong lad of fifteen years of age can carry: and thus one horfe, after fome obftructions of no great confequence in the firft attempt, will afterwards draw it with eafe. Yet ftill the trouble will be leffened, if the field be prepared by digging and picking up the roots and ftones, inftead of common ploughing, juft before the ground is to receive the tranfplanted roots: therefore, after a full fecond confideration, the former practice is recommended preferably to the latter; and if the lucern ftands nine or ten years, the difference of the expence will not be perceived.

As the rows will be one yard four inches afunder, there will be room fufficient to guide the plough fafely along the intervals, and yet no room to fpare: it behoves the ploughman therefore to be extremely careful in the flice he cuts next the lines: fuch a ftroke muft be a fhallow and a dexterous one; nor muft he approach too nearly. A man, an horfe, and a boy to lead the horfe, will manage an acre in a day, when they know their bufinefs; for it is more a matter of nicety than fatigue, fince the ground ploughed in an acre will hardly exceed half an acre.

After the firft time of ufing the horfe-hoe plough (which a man's own difcretion, upon confidering the ftrength of the plants, will beft determine) it may be laid down for a general rule, that it will be always found moft convenient to horfe-hoe the intervals (as long as the plantation ftands) the third day after each cutting; for by that time the new fhoots will make the plants vifible, nor will any fide-branches ftand in the plough's way.

It may be proper alfo to hand-weed the lines once a year; and the larger weeds may be taken up expeditioufly with the three-pronged fpade, or the field-fpade.

We will now confider the expences of an acre of lucern the fecond year, which will ftand as follow:

	l.	s.	d.
Clearing the lucern-plants from weeds in the rows by hand	0	8	0
One hand-hoeing of the intervals	0	8	0
Four horfe-hoe ploughings	0	11	0
Compoft-dreffing for manure, or foot, or wood peat afhes, at an average per year	0	10	0
Difperfing the manure	0	3	0
Total	2	0	0

Such

Such will be the yearly charges, or in ſome proportion very like them, during the continuance of your lucern, which I fix at a medium of ten years: M. de Chateauvieux ſays it may laſt twenty; and Pliny goes as far as thirty; though the expreſſion may be looked upon to be exaggerated.

In regard to manuring lucern, it may ſuffice to ſuggeſt here in general terms, that if the ground be ſtiff, cold, and of a clayey tendency, then wood-aſhes, ſoot, and lime, are proper dreſſings. If the ground be hot, ſhallow, and braſhy, a compoſt of calcined clay, dung rotted to a fine mould, and pond mud, long expoſed to ſun and froſts, and frequently turned, may have its uſe: and if the ground proves of a middle nature, then malt-duſt will not be amiſs. All theſe manures are eaſily procured, and therefore we have mentioned none that are ſcarce and dear: but as variations of ſoil are infinite, and few people know the true nature of any field (eſpecially if it be of the mixed kind) we recommend the compoſt dung-hill, as the ſureſt and moſt univerſal aſſiſtant upon ſuch occaſions.

Many other manures may be good for lucern, but dung probably is not one of the beſt, except it be very old, and well corrected with proper mixtures of a ſweet, as well as fertilizing nature, ſufficiently warm and cheriſhing, but noways rank; for dung (eſpecially if it be new) produces in general very luxuriant, troubleſome weeds, inſects in abundance of various kinds, and gives the graſs a foul, cloying, putrefied taſte.

The owner's eye, it is true, may be deceived, and his hopes encouraged by the largeneſs of the crop; but the ſagacious four-footed animals will diſtinguiſh better than we can pretend to diſtinguiſh; and if they could preſent a petition to their maſters, as the white heifers are reported once to have done to the emperor Julian, they would remonſtrate not a little againſt the immoderate uſe of this manure. Nevertheleſs, aſſertions like the preſent ought to be confirmed by ſome proof: an experiment therefore was made upon four acres of graſs-ground, of which one half was dreſſed with ſtable dung, and the other with wood aſhes kept dry. The former moiety appeared the moſt rich and luxuriant of the two, but the cattle always neglected it, till they had bitten the latter down to the bare earth.

Having thus given the reſult of my experience in regard to dung as a manure for lucern, I ſhall ſubjoin only one ſhort caution, which is, that no dung, not even of the beſt kinds, muſt be ſpread on a lucern plantation, till it be two years old at leaſt.

In all grounds inclinable to moiſture, and ſuch particularly as are of a clayey caſt, it is pretty certain, that the preference ought to be given to ſoot-dreſſings, and, after ſoot, to chimney-aſhes (thoſe of green wood eſpecially) provided they are houſed and ſecured from wet; then ſoap-boilers aſhes may take place, coal-aſhes well ſifted, charcoal aſhes, and malt-duſt; nor might the aſhes of lime be amiſs, nor lime itſelf, when mixed with ſuch fine mould as may be found under a ſhort ſweet turf, in lanes or commons. The compoſt-dunghill alſo, as obſerved before, ſhould be applied to, which, at the end of twelve months, having been thrice turned, will ſpread almoſt as well as aſhes or ſoot: nor will ſuch compoſt want ſtrength when it is rightly managed; for if the dunghill be moiſtened at times with the brine, ſoap-ſuds, diſh-waſhings, and chamber-lie, &c. of the family, then, when it is removed into the fields, the ſharp, pungent, ſtrong ſalts, which fly off, will make the labourers ſneeze, and occaſion a ſmarting in their eyes.

When you manure lucern with ſoot, dry chimney-aſhes, lime, ſoap-boilers aſhes, &c. it is ſufficient to dreſs the rows only, becauſe theſe finer ſorts of manures may be diſperſed in the niceſt exacteſt quantities, if ſown in the Berkſhire manner, with a peat-aſh ſpoon; but if coarſer manures are to be employed in larger quantities, as old dung, marle, compoſt-dreſſings, &c. I would then adviſe the proprietor of the field to manure the intervals and rows promiſcuouſly.

Nothing can be more cheaply and eaſily managed than manuring lucern with ſoot-dreſſings; for the labourer, if he makes uſe of a peat-aſh ſpoon and ſeed-lip, may ſprinkle the rows of an acre in four or five hours, walking down the firſt interval and returning by the ſecond, and ſo progreſſively.

Aſhes may be ſown in the ſame manner.

It may not be amiſs to anſwer a couple of queſtions which have been often propoſed.

The firſt queſtion is, How, and in what manner (by way of reſult from the conſiderable number of experiments made by me) I would adviſe any gentleman to prepare three or four acres of land for receiving lucern? this being an undertaking of ſome moment.

The ſecond queſtion is, How to perform this work in the ſhorteſt, ſafeſt, and moſt œconomical manner? Concerning both which points my ideas are as follow, this only premiſed, that I am here endeavouring to make the expence of the undertaking as cheap as poſſible; otherwiſe, where people pay no regard to to a few incidental charges, I would recommend Mr. Boyle's method of preparing a field for receiving tranſplanted lucern, who began his experiments of lucern in the ſame year that I did, but proceeded upon a larger ſcale; for he undertook the culture of ſix acres at once.

His preparation of the field was as follows:

In the year 1757, he gave his field a ſummer fallow, and having thoroughly ploughed and harrowed it (not as farmers underſtand theſe words, but effectually, inſtead of ſuperficially) he ſowed wheat after the ground had been dreſſed with lime. In 1758, his crop of wheat was very great. Immediately after harveſt, he gave the land in queſtion a ſevere diſcipline, uſing every method for pulverizing the earth, and extirpating weeds, that the beſt huſbandmen are acquainted with, either in our kingdoms or abroad; ſo that the field appeared again a perfect fallow. Then ploughing it very narrow and ſharp, he made water thoroughs with the plough, and left it in this condition for the winter 1758.

In ſpring 1759, he made many French drains in the field, as before he had made open ones for the winter; and, by ſtone-picking the land, had nearly ſtones ſufficient to fill them. In March the ſame year (taking advantage of the firſt fine weather) he ſlit the ridges with the plough, and reduced the land to the fineſt tilth he was able, and tranſplanted the lucern from his nurſery in autumn; in the whole proceſs of which he followed Du Hamel exactly.

Nothing in huſbandry could be more ſenſible and maſterly, than this preparation of a large piece of land for receiving lucern.

In the preſent caſe it may ſuffice to ſay, that ſuppoſing the nurſery to be properly prepared, and the ſeeds ſown in the firſt week of April, before the ſeaſon for tranſplanting, according to directions already given; I would recommend a field in good tilth, after barley harveſt, and before oats have been ſown in it. This field ſhould be thoroughly ploughed and harrowed twice, which we will ſuppoſe to be, for example, in the autumn of the preſent year, 1764. After each ploughing and harrowing, there ſhould be a very diligent burn-beating. But if the ſeaſon ſhould prove too wet at the time of a ſecond burn-beating, we make a virtue of neceſſity, and the weeds and trumpery muſt be raked together and carried off.

Then give the field a trench-fallow ploughing for winter, and early in March, 1765 (if the weather anyways permits) having manured your ground as the relative nature of the ſoil requires, and ploughed and harrowed it again to an exquiſite fineneſs, drill in a crop of field-peaſe, as early in the ſpring as is convenient with prudence and ſafety; for this crop muſt be ripe, and removed, by the laſt day of July. Much depends upon this point of foreſight: however the peaſe, by ſtanding thinner than in hand-ſown promiſcuous crops, being at the ſame time banked and hoed with greater eaſe, and enjoying more room, free air, and ſun-ſhine, will, in all probability, gain an advance of ten days at leaſt in their ripening. This will be a great point ſecured; for it is in huſbandry as in war; there are critical moments, which never preſent themſelves a ſecond time in the ſame campaign.

This pea-crop being hacked, and moved from the field by the fourth or fifth of Auguſt, call in all the aſſiſtance you have of huſbandry-ſtrength, or can procure, and plough and harrow the field, and burn the pea-roots, weeds, &c. as often as you have time, before the twentieth of Auguft; and then (your nurfery being fuppofed to be in perfect readinefs) tranfplant your roots as before directed, and contrive to clofe your work by the end of the month."

Mr. Lullin de Chateauvieux has obliged the world with many valuable experiments on the culture of lucern, which muft not be omitted here: but it may not be amifs to give firft Mr. Miller's directions for cultivating lucern, as it has been often mentioned in this article. They are as follows:

"After having well ploughed and harrowed the land very fine, you fhould make a drill quite acrofs the ground, almoft half an inch deep, into which the feeds fhould be fcattered very thin: then cover them over a quarter of an inch thick, or fomewhat more, with the earth: then proceed to make another drill, about a foot and a half from the former, fowing the feeds therein in the fame manner as before, and fo proceed through the whole fpot of ground, allowing the fame diftance between row and row, and fcatter the feeds very thin in the drills. In this manner, an acre of land will require about fix pounds of feed; for when it is fown thicker, if the feeds grow well, the plants will be fo clofe as to fpoil each other in a year or two, the heads of them growing to a confiderable fize, as will alfo the roots, provided they have room. I have meafured the crown of one root, which was in my poffeffion, eighteen inches diameter, from which I cut near four hundred fhoots at one time, which is an extraordinary increafe, and this upon a poor dry gravelly foil, which had not been dunged for many years, but the root was at leaft ten years old; fo that if this crop be well cultivated, it will continue many years, and be equally good as when it was firft fown: for the roots generally run down very deep in the ground, provided the foil be dry; and although they fhould meet a hard gravel a foot below the furface, yet their roots would penetrate it, and make their way downward, as I have experienced, having taken up fome of them, which were above a yard in length, and had run two feet into a rock of gravel, fo hard as not to be loofened without mattocks and crows of iron, and that with much difficulty.

"The reafon for directing this feed to be fown in rows is, that the plants may have room to grow; and for the better ftirring the ground between them, to deftroy the weeds, and encourage the growth of the plants, which may be very eafily effected with a Dutch hoe, juft after the cutting the crop each time, which will caufe the plants to fhoot again in a very little time, and be much ftronger than in fuch places where the ground cannot be ftirred: but when the plants firft come up, the ground between fhould be hoed with a common hoe; and if, in doing of this, you cut up the plants where they are too thick, it will caufe the remaining to be much ftronger. This hoeing fhould be repeated two or three times while the plants are young, according as the weeds are produced, obferving always to do it in dry weather, that the weeds may the better be deftroyed; for if it be done in moift weather, they will root and grow again.

"With this management, the plants will grow to the height of two feet or more, by the beginning of Auguft, when the flowers will begin to appear, at which time the lucern fhould be cut, obferving to do it in a dry feafon, if it is to be made hay, and keep it often turned, that it may foon dry, and be carried off the ground; for if it lie long upon the roots, it will prevent their fhooting again. After the crop is taken off, you fhould ftir the ground between the rows with a hoe, to kill the weeds, and loofen the furface, which will caufe the plants to fhoot out again in a fhort time; fo that by the beginning of September there will be fhoots four or five inches high, when you may turn in fheep upon it to feed it down: nor fhould the fhoots be fuffered to remain upon the plants, which would decay when the frofty weather comes on, and fall down upon the crown of the roots, and prevent their fhooting early in the fucceeding fpring.

"The beft way therefore is to feed it until November, when it will have done fhooting for that feafon: but it fhould not be fed by large cattle the firft year, becaufe the roots being young, would be in danger of being deftroyed, either by their trampling upon them, or their pulling them out of the ground: but fheep will be of fervice to the roots by dunging the ground, provided they do not eat it too clofe, fo as to endanger the crown of the roots.

"In the beginning of February, the ground between the rows fhould be again ftirred with the hoe, to encourage them to fhoot again: but in doing of this you fhould be careful not to injure the crown of the roots, upon which the buds are at that time very turgid, and ready to pufh. With this management, if the foil be warm, by the middle of March the fhoots will be five or fix inches high, when, if you are in want of fodder, you may feed it down till a week in April; after which it fhould be fuffered to grow for a crop, which will be fit to cut the beginning of June, when you fhould obferve to get it off the ground as foon as poffible, and ftir the ground again with the Dutch hoe, which will forward the plants fhooting again, fo that by the middle, or latter end of July, there will be another crop fit to cut, which muft be managed as before; after which it fhould be fed down again in autumn: and as the roots by this time will have taken deep hold in the ground, there will be little danger of hurting them, if you fhould turn in larger cattle; but you muft always obferve not to fuffer them to remain after the roots have done fhooting, left they fhould eat down the crown of the roots below the bud, which would confiderably damage, if not deftroy them.

"In this manner you may continue conftantly to have two crops to cut, and two feedings upon this plant, and in good feafons there may be three crops cut, and two feedings, which will be a great improvement, efpecially as this plant will grow upon dry barren foils, where grafs will come to little, and be of great ufe in dry fummers, when grafs is often burnt up: and as it is an early plant in the fpring, fo it will be of great fervice when fodder falls fhort at that feafon, when it will be fit to feed at leaft a month before grafs or clover; for I have had this plant eight inches high by the tenth of March, old ftyle, at which time the grafs in the fame place has fcarcely been one inch high.

"That cold will not injure this plant, I am fully fatisfied; for in the very cold winter, anno 1728-9, I had fome roots of this plant which were dug up in October, and laid upon the ground in the open air till the beginning of March, when I planted them again, and they fhot out very vigoroufly foon after: nay, even while they lay upon the ground, they ftruck out fibres from the under fide of the roots, and had begun to fhoot green from the crown of the roots. But that wet will deftroy the roots, I am fully convinced; for I fowed a little of the feed upon a moift fpot of ground for a trial, which came up very well, and flourifhed exceedingly during the fummer feafon, but in winter, when the great rains fell, the roots began to rot at bottom, and before the fpring moft of them were deftroyed.

"The beft places to procure the feed from, are Switzerland and the northern parts of France, which fucceeds better with us than that which comes from a more fouthern climate: but this feed may be faved in England in great plenty; in order to which, a fmall quantity of the plants fhould be fuffered to grow uncut till the feeds are ripe, when it muft be cut, and laid to dry in an open barn where the air may freely pafs through: but the feed muft be defended from the wet; for if it be expofed thereto, it will fhoot while it remains in the pod, whereby it will be fpoiled. When it is quite dry, it muft be threfhed out, and cleanfed from the hufk, and preferved in a dry place till the feafon for fowing it: and this feed faved in England is much preferable to any brought from abroad, as I have feveral times experienced; the plants produced from it having been much ftronger than thofe produced from the French, Helvetian, and Turkey feeds, which were fown at the fame time, and on the fame foil and fituation.

"I am inclinable to think that the reafon of this plant's not fucceeding, when it has been fown in England, has either been occafioned by the fowing it with corn, with which it will by no means thrive (for though the plant be very hardy when grown pretty large, yet at its firft coming up, if it be incommoded by any other plant or weeds, it feldom does well; therefore it fhould always be fown by itfelf, and carefully cleared from weeds until it has ftrength, after which it is not eafily deftroyed;) or, perhaps,

haps, people have fown it at a wrong feafon, or in wet weather, whereby the feeds have rotted, and never come up, which hath difcouraged their attempting it again: but however the fuccefs has been, I dare aver, that if the method of fowing or managing this plant, which is here laid down, be duly followed, it will be found to thrive as well as any other fort of fodder now cultivated in England, and will continue much longer: for if the ground be duly ftirred after the cutting of each crop, and the firft crop fed, as hath been directed, the plants will continue in vigour twenty years, or more, without renewing provided they are not permitted to feed, which would weaken the roots more than four times cutting would do.

" The hay of this plant fhould be kept in clofe barns, it being too tender to be kept in ricks open to the air as other hay: but it will remain good, if well dried before it be carried in, three years. The people abroad reckon an acre of this fodder fufficient to keep three horfes all the year round: and I have been affured by perfons of undoubted credit, who have cultivated this plant in England, that three acres of it have fed ten cart-horfes from the end of April to the beginning of October, without any other food, though they have been conftantly worked. Indeed the beft ufe that can be made of this grafs is, to cut it and give it green to the cattle. Where this hath been daily practifed, I have obferved that by the time the field has been cut over, that part which was firft cut, hath been ready to cut again; fo that there has been a conftant fupply in the fame field, from the middle of April to the end of October, when the feafon has continued long mild; and when the fummers have proved fhowery, I have known fix crops cut in one feafon: but in the dry feafons there will be always three. When the plant begins to flower, it fhould then be cut; for if it ftands longer, the ftalks will grow hard, and the under leaves will decay, then the cattle will not fo readily eat it. Where there is a quantity of this cultivated, fome of it fhould be cut before the flowers appear, otherwife there will be too much to cut within a proper time.

" When this is made into hay, it will require a great deal of making: for as the ftalks are very fucculent, it muft be often turned, and expofed a fortnight before it be fit to houfe; for this requires a longer time to make than fainfoin: therefore, when it is cut it fhould be carried to make upon fome grafs-ground; becaufe the earth in the intervals of the rows will wafh up, and mix with the hay in every fhower of rain; and by carrying it off as foon as it is cut, the plants will fhoot out again foon: but it is not fo profitable for hay, as to cut green for all forts of cattle, but efpecially horfes, which are extremely fond of it; and to them it will anfwer the purpofe of both hay and corn, and they may be worked at the fame time juft as much as when they are fed with corn, or dry food." *Miller's Gard. Dict.*

EXPERIMENTS *on Lucern cultivated according to the New Hufbandry, by* M. de Chateauvieux.

" It is truly with regret, fays M. de Chateauvieux, that I am forced to treat a fubject of this importance, in fo fummary a way as the limits of this letter require. However, I hope that even this general account of my experiments may be a guide to thofe who would cultivate this plant. Many perfons who live at a confiderable diftance from this place [Geneva] have already followed my example, and are extremely well fatisfied with their fuccefs.

" Though I agree with M. Duhamel and the other partifans of the New Hufbandry, that lucern and fainfoin thrive beft when cultivated in beds; yet my practice differs, in many refpects, from theirs. This difference confifts in,

1. *The Principle which I apply particularly to the Culture of Lucern.*

" Lucern grows naturally with one large perpendicular, or tap-root, which penetrates very deep into the earth, and has few, if any, lateral roots. From fimilar experiments on other tap-rooted plants, I was induced to think, that this too, by tranfplanting it, and at the fame time cutting off part of its tap-root, might be made to fhoot out feveral horizontal roots, which, reaching into the loofe mould of the alleys, and extending themfelves there, would collect a greater quantity of nourifhment for the plant, and confequently enable it to produce more abundant crops.

" The event has proved, that when we reafon on found principles, we feldom err. My tranfplanted lucern pufhed out numbers of large lateral roots, and thefe branched out again into others, which may be multiplied without end by frequent culture of the alleys: for the horfe-hoe has the fame effect on thefe horizontal roots, as cutting has upon the tap-root.

2. *The Method of tranfplanting the Lucern.*

" I made feveral beds, fome about three feet wide, (including the alleys) into which I tranfplanted a fingle row of lucern; others about three feet nine inches, into which I tranfplanted two rows; and others about four feet three inches wide, in which I put three rows. The defign of this variation was, to fee by which of thefe three methods the fame extent of ground will produce the greateft quantity of lucern. I believe it will require five or fix years to determine exactly which of them will be beft; becaufe, as the plants increafe every year in bulk, their produce alters, and may perhaps not keep in proportion to the firft years, though probably the difference will not be great. But without waiting fo long, I can already fee, that the crop will be greateft by planting only one row on each bed.

" The plants in the fingle rows were fix inches afunder, nor fhould they ever be nearer; and thofe in the double and triple rows, were eight or nine inches diftant from each other. I muft obferve, that I likewife fowed lucern with the drill, in beds, in which it has remained without tranfplanting. It is very fine; but not near fo ftrong and flourifhing as that which I tranfplanted. When lucern is fown where it is to remain, it neceffarily requires being thinned, and that operation takes up more time than tranfplanting it would do."

Rules to be obferved in tranfplanting Lucern into Beds.

" 1. The middle of the beds muft be raifed and arched as high as poffible; and as the lucern is to remain feveral years on the fame ground, no pains fhould be fpared to prepare the earth as well as can be.

" 2. Lucern fhould be fown in the fpring, and in a rich mould, that the plants may be ftrong enough to tranfplant in September.

" 3. Plants two or three years old, may be tranfplanted as well as younger ones.

" 4. They fhould be tranfplanted in September, that they may have time to take frefh root before the winter comes on.

" 5. If they cannot conveniently be tranfplanted in September, it may be done in October, provided the weather be not frofty.

" 6. The mould into which they are tranfplanted fhould be moift; and if the weather be fomewhat rainy, it is fo much the better. In this cafe, I have never found it neceffary to water the plants.

" 7. If lucern is tranfplanted in November or December, there is danger of the frofts forcing many of the plants out of the ground.

" 8. If too warm and dry a feafon prevents tranfplanting in September or October, it is beft to ftay till the winter is paft. The plants will then be fure of taking root, and very few of them will fail.

" 9. If they can be tranfplanted in autumn, they will yield pretty good crops the next year: but if they are not tranfplanted till fpring, the next year's crop will be but indifferent.

" 10. The plants muft be taken up out of the nurfery, with great care and patience, that their roots may not be damaged.

" 11. The roots fhould be left about fix or feven inches long, and the green tops fhould be cut off within about two inches of the crown of the root.

" 12. The

"12. The plants will take root the fooner, if they are put into water as foon as they are taken up, and kept in it till they are planted.

"13. They are planted in holes made with a planting ftick, in the fame manner as cabbages or lettuces are planted in a garden.

"14. The beft way of planting lucern is, to cut a ftrait channel two or three inches deep, and fet the plants in the bottom of it, covering them up to the neck.

"15. Great care fhould be taken not to fuffer any weeds to grow among the lucern; at leaft for the two or three firft years. To this end, the rows fhould be weeded by hand, as well as the edge of the alleys near the plants, where the horfe-hoe cannot go.

"16. The alleys may be ftirred, either with the fingle cultivator, or the cultivator with two mould-boards; which, at the fame time that it deftroys the weeds, keeps the mould loofe.

"17. The firft ftirring may be given with the fingle cultivator, with which a furrow may be cut on each fide of the main furrow in the middle of the alleys, by which means the earth will be turned over on both fides of it.

"18. The fecond ftirring may be given with the cultivator with two mould-boards, by drawing it along the middle of the alleys. This will turn the earth towards the rows. By thefe alternate ftirrings, the alley will be conftantly kept in a loofe ftate.

"19. This culture is fo eafily performed, and in fo fhort a time, that it may be repeated frequently. In this I differ from M. Duhamel, who orders it but feldom. My opinion is, that the alley fhould be ftirred once a month, during the whole time that the lucern is in a growing ftate.

"20. If the alleys keep free from weeds, lefs ftirring them may do: but the mould fhould never be fuffered to grow too hard.

"21. As foon as fome of the plants begin to bloffom, the lucern fhould be cut. It will then make excellent fodder, fuperior to every other kind.

"22. The lucern hay fhould be dried as quick as poffible, and frequently turned. The lefs it is expofed to the heat of the fun, the better fodder it makes.

"23. Lucern muft not be houfed till it is dry: but at the fame time care muft be taken that it be not too dry: for then many of the leaves will fall off, as they dry fooner than the ftalks.

"24. Cattle muft not have too much lucern given them at a time, till they are accuftomed to it.

"25. No cattle fhould ever be fuffered to feed on the beds of lucern. If the earth is very dry, towards the latter end of autumn, fheep will do it the leaft hurt. If the plants are then tall enough to be mowed, the beft way is to cut them, and give them green to the cattle.

"Thefe rules contain all that is effentially neceffary for making and keeping in good order this kind of artificial pafture. I can fafely fay, that whoever tries them, will be abundantly rewarded for his trouble and expence. Sainfoin may be cultivated in the fame manner."

Account of the Produce of Lucern planted in Beds, and cultivated according to the Principles of the New Hufbandry: with fome important Reflections on the Advantages which may be obtained therefrom: by M. de Chateauvieux.

"No judgment fhould be formed of what lucern may produce, by the crops of the firft or fecond year: it is then too young to be able to yield much. If we were to calculate even by its third year's produce, we fhould ftill confider, that as the plants increafe every year in bulk and vigour (and where they will ftop I am not yet able to determine) the produce will be proportioned to that increafe, and confequently the crop of each fucceeding year will be greater than that of the former.

"The crops I am going to fpeak of, are thofe of the fecond and third year: but my calculations will be made on that of the third year. It is proper to remember, that the years 1753 and 1754 were uncommonly dry, infomuch that, fometimes, not a drop of rain, nor fcarce any dew, fell between the cutting of one crop and that of another. The feafons were fo unfavourable to the production of grafs, that hay rofe to an exceffive price.

"I fhall firft fay what was the ftate of the plants of lucern in their third year, and afterwards how much hay they yielded.

State of the Plants in their third Year.

"As the part of the plant which I now confider is that which is buried in the earth, I uncovered numbers of them, that I might be able to judge of their general ftate. I was greatly ftruck with the effect which tranfplanting had had upon them. Inftead of one perpendicular root, which they ufually have, all thefe plants had three, four, five, and fometimes more, almoft equally big roots. They were, in general, three quarters of an inch in diameter, and proceeded from the original root, which was now at leaft an inch in diameter, and in many of the plants an inch and a half. After the moft careful fearch that I could poffibly make, I could not find one plant of lucern fown in the common way, though it had ftood twelve, twenty, or more, years, whofe tap-root had grown to the bignefs of an inch diameter: few of them were above half, or at moft three quarters of an inch thick. This difference is very great.

"I likewife found, that the roots of the tranfplanted lucern had produced another kind of roots, of which I faw none about thofe of the old lucern. Thefe were a great number of fibrous roots, fome of which were already one twelfth of an inch in diameter, and looked as if they would alfo become principal roots.

"The ftalks feem to rife out of the earth; and from the firft time of cutting them, a kind of head forms juft above ground, which extends itfelf every year. The firft year, this head was two or three inches wide: the fecond year, it was generally about fix inches over, and this third year, almoft half the plants have a crown ten or twelve inches in diameter: and as many of them have grown fo as to touch one another, their crowns are become of an oval form, having extended themfelves on the fides where they met with no refiftance.

CROPS.

"I have a field of lucern in beds, divided into two parts. This is the third crop of lucern off one of them. The beds are 250 feet long. In 1753, I cut this lucern fix times, viz. in May, June, July, Auguft, September, and the beginning of November. This laft cutting was not near fo plentiful as the others, and I dried it within doors.

"Thefe cuttings off one bed, on which there was but one row of lucern, yielded 140 pounds of well dried hay.

"In 1754, the lucern was late before it began to fhoot, and the earth was drier than the year before. I had but five crops: the firft was cut on the 27th of May; the fecond on the firft of July; the third on the 27th of July; the fourth on the 26th of Auguft; and the fifth on the 23d of October. Thefe five cuttings yielded in all 225 pounds of well dried hay off each bed.

"A field 250 feet long, which was the length of my beds, and 210 feet wide, contains an arpent of our meafure. This arpent, divided into fixty-eight beds, each three feet wide, producing after the rate of 225 pounds of hay off each bed, would yield in all 15300 pounds; which is infinitely more than is ever obtained in the common way.

"The beds with three rows yielded much lefs. The third year, their crops amounted to no more than 169 pounds off each bed, which is a fourth lefs than the others: and as thefe beds are wider, inftead of having fixty-eight, as in the former difpofition of the arpent, there will be only forty-feven, each four feet three inches wide, the total produce of which will be but 7943 pounds: confequently this arpent will yield little more than half as much as an arpent laid out in beds three feet wide, planted with only fingle rows.

Remarks, by M. de Chateauvieux.

"The plants of lucern had the fate of all kinds of plantations; that is to fay, fome of them were more vigorous

gorous than others. The greatest number of the plants produced each of them a pound of dry hay, and some of them yielded two pounds. I look upon these last as such extraordinary productions, that I do not expect many of them to yield the like quantity again. I think one may be very well satisfied, if the plants, one with another, yield a pound of hay apiece every year. This is nearly the result of my experiment on beds which had but one row; and the produce of these would have been still greater, if many of my plants had not failed: in the room of which I set young ones, which could not acquire sufficient strength to yield full crops.

" In these experiments, I have employed no dung: neither have I for any of my corn fields. I have reserved it for improving my pastures and meadows; and intend next to apply it to my lucern, which, I doubt not, but will be much the finer for it. The only thing now remaining is, to know by experience which will be the best way of using it. I have some thoughts on that head, which may render it much more profitable.

Lucern deserves to be cultivated with care: not only on account of the great quantity of fodder which it yields, but likewise because the quality of its hay is superior to any other. The New Husbandry will render it still more perfect. Plants cultivated this way enjoy the benefit of a free circulation of the air, and that circulation keeps them sweet and sound, and free from all mustiness towards their roots: for, being open to the rays of the sun, that great source of kindly vegetation, they attain great perfection in all their parts, both as to their substance, and their flavour. Cattle eat this food greedily, and are better nourished with it, than with any other: but as every excess is bad, too great a quantity should not be given them at once, especially at first, lest it should swell them. The best way is, to bring them to it by degrees.

" I have experienced these qualities in this hay, by comparing it with every other sort. The excellence of this, justifies the principles on which the New Husbandry is founded. I have offered to my horses bundles of every kind of hay, and at the same time a bundle of this hay of lucern. They have not hesitated a moment to prefer the latter. Nothing but its superior qualities could determine them in this choice, which never varied, and has always been in favour of the lucern cultivated in this manner.

" It would be lavishing this excellent fodder, to feed horses entirely with it. It need only be given them by turns with common hay: which will be a great saving: for this lucern will supply the place of oats. I am certain that my horses fed partly with this hay, and without oats, will be in better plight, stronger, and more vigorous, than those which are fed with meadow hay and corn in the usual way. It is now some time since I have fed my coach-horses with it, and have retrenched their oats. Instead of this last food, and at the hours they used to have it, I give them lucern chopt, as the Spaniards do straw to their horses. Mine are as fond of it, and shew the same impatience to find it in their manger, as if it was oats; and since their being put under this diet, they are in better condition than before, and so mettlesome, that the coachman has enough to do to keep them in.

" When I said that retrenching the oats would be a considerable saving, I did not so much mean the saving of the expence of that corn, as the better improving of many vast tracts of land which are sown with oats, and might, with proper management, produce much more useful and more profitable sorts of grain, notwithstanding the too general prejudice, that some lands are not capable of bearing any better. For my part, I am thoroughly satisfied, that whatever ground can bear a crop of oats, can likewise, under the New Husbandry, bear any other grain."

Continuation of M. de Chateauvieux's *Account of his Experiments on Lucern, in the Years* 1755, *and* 1756.

" The great drought of the year 1755, was accompanied with great heat; and the year 1756 was very rainy, and moderately warm, there being but few very hot days in it.

" My lucern was exposed to a most severe winter in 1755, when the frost was excessive hard, and lasted very long. M. de Reaumur's thermometer was some days, at different times, eight, nine, ten, twelve, and thirteen degrees below the freezing point; and on the third of February, a thermometer, in the open air, stood at sixteen degrees below freezing. These severe frosts made me uneasy for my lucern, which, however, bore them, without receiving any damage.

" The rains in 1756 did no hurt to these plants, but they prevented my cutting them at proper times. I had but four crops of lucern this year, being obliged to wait for an appearance of fine weather to dry it in, before I could venture to cut it down. These rains likewise hindered my giving the proper hoeings to the alleys, which were full of weeds during the summer and autumn. I chose rather to leave them in that condition, than attempt to hoe them while the ground was over wet: not doubting but the spring hoeings would easily destroy them.

" In 1755, I cut my lucern five times: the first was, on the third of May, before any flowers appeared: the second, on the twelfth of June: the third, on the fifteenth of July: the fourth, on the twenty-first of August: and the fifth, on the seventh of October. I was obliged to finish the drying of this last cutting, in barns and under cover.

" In 1756, which was the fifth year of these plants, I cut them but four times: the first, on the third of June: the second, on the first of July: the third, on the fourth of August: and the fourth, on the twenty-seventh of September.

A bed 250 feet long, with only one row of lucern,

Yielded	In 1754 - - - - -	225	pounds of dry hay.
	1755 - - - - -	197	
	1756 - - - - -	281	

In three years, 703 pounds.

A bed of the same length, with three rows of lucern,

Yielded	In 1754 - - - - -	169	pounds of dry hay.
	1755 - - - - -	180	
	1756 - - - - -	226	

In three years, 575 pounds.

Observations by M. de Chateauvieux.

" We see, by the above account of three years, that a piece of ground laid out in narrow beds, planted with only one row of lucern, yielded a greater produce than the same extent made into wider beds, and planted with three rows.

" I shall not, however, pretend to determine from this one experiment, that it is best to lay down large fields in this manner. I think it will be right to try first, whether the success will be the same on different soils, and likewise on lands whose exposition may be more or less advantageous. If after repeated trials, the beds which have but one row of plants, yield the greatest quantity of hay, that method is certainly to be preferred. To clear up this point still more to my satisfaction, I continue to plant lucern in beds, some with one, and others with three rows.

" The difference between the crop of 1756, and those of the two preceding years, would induce one to think that rainy seasons are best for the production of hay: but still, the greater quantity which the year 1756 produced, must not be imputed to the rain only: we should likewise consider, that the plants had throve greatly since 1754; that their stems were grown much larger, and their roots much stronger and more numerous, and that they were consequently able to yield much greater crops than before. They have abundantly answered my expectation, both as to quantity and quality.

" With respect to the quantity, it is much greater than that of any common fodder: I mean, of any that the same extent of ground would have produced, if cultivated in the common way, though it would then have been covered with an immense quantity of plants. This is a fact, which numbers of experiments prove, and which we shall cease to wonder at when we consider the great effects of the frequent stirring of the alleys. To this it is that I owe the repetition of my crops, and their being all of nearly equal goodness. I do not exaggerate when I say, that every summer month, which is the time I generally allow between each cutting, will produce shoots two feet long, and sometimes more: and supposing that I cut them but five times a year, each plant will have produced after the rate of nine or ten feet length of shoots, and that in the same time that most meadows will not produce grass above two feet long.

"As to the quality of this hay, I continue to prefer it to all other fodder. My experience has confirmed what I said of it in 1754; and I shall only add, that I have since found, that it is as good at the end of four years, as when it is first cut. If there was any difference, horses would soon be sensible of it: but they eat of either without distinction.

"I feed my horses with it, chiefly in the summer, at which time they do most work, and am more and more sensible of the advantages of it. Five or six pounds of lucern a day, are sufficient for a middle sized horse: but the quantity may be increased or diminished, according as the horse is nourished by it; for in that there is great difference." *Culture des Terres, tom.* IV. *c.* iii. *art.* 15.

The following account of the cultivation of lucern, was communicated to the public by a very ingenious husbandman, and merits the attention of the reader.

Having read and heard a great deal of lucern, I determined to have some of it myself; and Mr. Miller's method seeming to me by far the most rational, I resolved to follow it: accordingly, the seventeenth of July, 1763, I ordered a field of three acres and a half, then under rye-grass and clover, to be ploughed deep, and sown with turnips. The crop was middling: I sold them to a cow-farmer for nine guineas: he drew and carted them home. If I had had sheep, I would have fed them on the field.

By the twenty-seventh of March, 1764, the field had been twice ploughed, the first time ten, and the last time near twelve inches deep, with the Rotheran-plough and four horses a-breast: the soil is light and stoney, with a rock of gravel about ten or twelve inches deep, and had never before been ploughed above six or seven inches deep; however, I knew it was right to go as deep as I could for a tap-rooted plant, as the lucern is.

I was greatly pleased with reading M. Lullin de Chateauvieux's account of his method of transplanting lucern, and determined to follow it, from a full conviction that it must be superior to every other method.

Accordingly I ordered the field to be sown with Poland oats, and laid out about twenty-eight rods in beds four feet wide, alleys one foot and a half, which were sown with lucern in broad-cast by my gardener, in the same manner as you sow cabbages or savoys in seed-beds: one bed, however, out of curiosity, I ordered him to sow in the following manner.

Run a garden-line through the middle of the bed from one end to the other; draw a small drill along the line, about half an inch deep; then move the line six inches, and make another drill, and so on: by this means you will have nine drills on a bed four feet wide. When this is done, fill a quart or pint bottle near full with your lucern-seed, cork the bottle, bore a hole in the cork, and insert a quill cut at each end: this will be found a great assistance in sowing the seed thin and regularly in the drills: and I must observe, that the bed which I sowed in this manner, afforded me much the greatest quantity of plants, and by far the finest. Another advantage attending it is, that it is kept clean with much more ease, and far less expence; for a gardener, with the small three-inch hand-hoe, will clean a great deal of ground in a small space of time. When the bed is sown, the seed must be covered with care: rather chuse the backside of a small rake than the teeth.

By the middle of August, my plants looked very well, and were mostly in bloom, when I ordered them to be mown, and given to my horses and cows, who seemed as if they had a high treat.

The oats being got in, I ordered the field to be deep ploughed again, and then waited for a season of rain to begin my planting, which, by my journal, did not come till the fifteenth and sixteenth of September; and the field being first well harrowed, we went to work the seventeenth, and continued planting till the twenty-ninth; nor can I now see any difference between those planted the seventeenth or twenty-ninth. Though I quite agree with the author of the Essays, that it is best to plant sooner than I did if possible; yet I must observe, that what may do for gardens, or small pieces of ground, will not do for fields. From the last week of August to the middle of September, seems to me a very proper time. But "filling each hole with water, making drills, half filling them with sea-sand or wood ashes, and watering each plant," as the author of the Essays mentions, is an endless and very expensive work.

For my part, I kept my eye on M. Chateauvieux's directions, as laid down above, with regard to that part that relates to planting; but another ingenious gentleman, having cautioned the public against planting on ridges, I must needs say, I was fearful of the rain and frost myself, if planted in that manner, especially on light land; and therefore I ordered my field to be ploughed as level as possible, and made my man, after the field was ploughed, go three bouts on each side the furrows, so that, when harrowed across, you could hardly tell where they were. The field being brought to this order, as I said before, we began to plant the 17th of September: two men with spades dug up the plants, and two women cut them: some care is certainly required in taking them up, but I did not find it great; it was done by common labourers. The women were ordered to cut the plants to about six or seven inches long in the root, and the tops to about two inches, as M. Chateauvieux directs. They did it very handily: their method was to take them up one by one, (so that they could throw by the faulty ones) and when they had about a dozen in their hands, they cut them at top and bottom with one stroke of the knife at each end. Each had a washing-tub by her side, filled to about six inches with water: as they cut the plants, they set them in the tubs; and as they filled one tub, another was brought them.

The method of planting is the same as for cabbages: men who are used to work in gardens will do it very handily with a dibble or planting stick; but that mine might stand with all possible exactness, each man had a garden-line and reel: and as I think I shall be very able to keep them clean with M. Lullin's single cultivator, the rows are only twenty inches apart, and six inches in the lines.

If I find a difficulty in keeping them clean in this method, then by drawing every other row, which may be done with great ease, my plants will stand at the distance directed by M. Chateauvieux, of three feet four inches.

I was very impatient to see the effect transplanting would have, and therefore, as soon as my plants in the seed-bed were about six inches high, I drew several, cut and transplanted them, and in the autumn I took up these plants, and found they had all formed new-tap roots round the bottom of the piece (if I may so call it) planted, and instead of one, they had from five to thirteen new roots: this, you may suppose, gave me great pleasure, and convinced me, that the illustrious Swiss was quite right.

The author of the Essays on Husbandry, I find, cut his plants with scissars: this must be very tedious work; and, with submission, I think he is quite wrong in cutting his plants to the length of nine or ten inches. Six or seven inches seem to me a much properer length; for the ground being dug or ploughed about twelve inches, the new roots will have five or six inches of well-loosened mould to strike into, which must be a great advantage to the plants; and if gravel, or a strong clay, is near the surface, I am convinced mine, or rather M. Lullin's, is the best method.

Yet this gentleman says, he cut his tap-roots too short, and knew not how to manage a root that was very small: in regard to the last, I must observe, that, if they were very small, I ordered them to be thrown away. So much has been said on the necessity of keeping lucern in broad-cast, drills, or transplanted, free from weeds, that I will say nothing on that subject.

At the same time that this gentleman so warmly recommends M. Chateauvieux's method of cultivating lucern by transplanting, he has, I fear, thrown a stumbling-block

in

in the way of moſt gentlemen, and, I think, every farmer; I mean his calculation of the expence: this, therefore, I muſt endeavour to remove.

When I began to cultivate lucern in this manner, the only defect I could find in M. Chateauvieux's account was, that he had not told the public how much ground they were to ſet apart for a nurſery: this deficiency, however, I can ſupply to thoſe who come after me, for ſixteen rod will be about the quantity for an acre; and then, I think, the expence of tranſplanting will ſtand as follows:

	l.	s.	d.
Digging, ſpit-deep, ſixteen rods, at three-pence per rod - - - -	0	4	0
Seed, three pounds, at one ſhilling per pound	0	3	0
Weeding the nurſery twice with the three-inch hand-hoe. (By ſowing in this manner, tranſplanting will not be wanted; nor do I think it proper, as they are to be tranſplanted again) - - -	0	3	0
Ploughing - - - - -	0	10	0
Tranſplanting - - - -	1	5	0
Hand-hoeing the plantation once, the middle or latter end of October, in dry weather, which men uſed to hoeing turnips will do for three or four, but ſay - -	0	5	0
	2	10	0

This, I am perſuaded, is the full expence of making the plantation; yet the author of the Eſſays has ſtrangly worked it up to ſix pounds twelve ſhillings per acre: however, I readily ſubmit this account to the inſpection of every farmer and every gentleman in the kingdom, converſant in matters of this kind.

If the ſpring-ploughing for barley or oats has been nine or ten inches deep, then a ploughing in autumn of twelve inches will be ſufficient, and cannot be charged at more than ten ſhillings. The trenching for the ſeed-beds may be done at leiſure time; ſo may the weeding of the nurſery, and the hand-hoeing of the plantation: then the real expence to the farmer will be only the ſeed and tranſplanting, or one pound eight ſhillings per acre.

As to what this gentleman calls the yearly charges, I can by no means agree to them; for the plantation having been weeded in October, will lie very ſafe and well till the latter end of February, or beginning of March: then, in dry weather, it may be hand-hoed again, the expence of which has before been charged at five ſhillings per acre; to which add four horſe-hoeings after each cutting, at eleven ſhillings, which makes ſixteen ſhillings per acre the annual charge.

I cannot recollect any thing further that is neceſſary to be ſaid on the ſubject of tranſplanted lucern; but as I would have every one, who writes to you on ſubjects of this ſort, tell the truth, the whole truth, and nothing but the truth; ſo I think it but juſt to ſay a word or two on lucern ſown in broad-caſt, or Mr. Rocque's manner. I live within a few miles of Mr. Rocque; and muſt add, that I have paid great attention to the culture and growth of lucern and burnet for ſome years paſt; ſo that I think I am pretty well acquainted with them.

The author of the Eſſays ſays, "If lucern is ſown broad-caſt with corn, no care can keep it clean: it may laſt two years, only one crop being tolerable, and then muſt periſh in the common courſe of nature." And ſeveral of your correſpondents are alſo of opinion it will never ſucceed in this method; but I know it will; for I have ſeen it cut three and four times. To cut it four times, the ſummer muſt be very favourable, and the laſt cutting will be late. Here I muſt remark, that lucern is not only excellent as a green fodder, but as an early one, eſpecially if ſown in drills, or tranſplanted; for that ſown in broad-caſt will not be fit for cutting ſo ſoon as the former, by a fortnight or more; however, the farmer may depend on three good crops in this manner of ſowing.

In the ſpring, 1760, Mr. Rocque ſowed about five acres with lucern and barley: the land is light and hot, but being in good heart, the barley was rank, which obliged him to mow it green, and ſell it to a farmer for feeding cows, &c. Indeed I believe it will always be beſt to do ſo; for the weeds, if there are any, are thus cut down, and the lucern thrives apace. The ſpring following, it may be harrowed with light harrows, and every year after with ſuch harrows as you find clean it beſt. Laſt autumn, when the weather was hot and dry, I ſaw a farmer harrowing Rocque's field with large ox-harrows, and I do not perceive that it is at all hurt. The weeds and trumpery were raked up, and carted to a dung-hill, with which he has this ſpring dreſſed his field, and it is now in a fine thriving condition.

Lucern makes moſt excellent hay: horſes are very fond of it, and, with one quartern of oats, I will be bound any gentleman will be well ſatisfied with the condition of his horſes, even coach-horſes; nor do I ſee it is at all more difficult to be made into hay than clover. *Muſæum Ruſticum, vol.* IV. *page* 307.

Experiments on Lucern, by Mr. John Wynne Baker, publiſhed by the Dublin Society.

The ineſtimable value of this plant has been ſo much ſpoken of by all the ableſt writers on huſbandry, that it is quite unneceſſary for me to ſay any thing in its recommendation.

Here follow my experiments upon it this year.

No.
15. Sown in drills, three feet aſunder.
16. Sown in drills, two feet aſunder.
17. Sown in drills, one foot aſunder.
18. Sown in the common, or broad-caſt way.

I ſowed the ſeed for theſe experiments on the firſt of May, but the middle of April would have been a more proper ſeaſon.

The lucern began to appear on the eighth day: in its firſt appearance, it has two very ſmall leaves of an oval form.

Theſe experiments were treated in the ſame manner as the burnet.

On the ſixteenth of Auguſt, I cut the lucern of each experiment, and the produce of green fodder was as follows:

Number 15. i. e. the three feet drills, produced off one perch, thirty-one pounds and a quarter.
Number 16. i. e. the two-feet drills, produced off one perch, forty-four pounds and a half.
Number 17. i. e. the one-foot drills, produced off one perch, forty-three pounds.
Number 18. i. e. the broad-caſt, produced off one perch, fifty-nine pounds.

Upon the face of theſe experiments, the broad-caſt has the greateſt produce. Above the three-feet drills, twenty-ſeven pounds and three quarters; above the two-feet drills, fourteen pounds and a half; and above the one-foot drills, ſixteen pounds.

Hence it may be concluded, by perſons not acquainted with the nature and culture of this plant, that the broad-caſt ſowing is to be preferred, as yielding the greater produce; but I think that concluſion ſhould not be too haſtily drawn, for the following reaſons.

Theſe crops are all from the firſt cutting after ſowing the ſeed, and therefore the lucern in the broad-caſt was then as good, or probably better, than it will ever be again in any ſucceeding crop, the ground being looſer, and fewer weeds in it, than there ever can be hereafter; for the natural graſs is already riſing in it, although it was managed in the way practiſed by Mr. Rocque; which is to harrow, or rake the ground after cutting the lucern. Another reaſon is, that for the firſt year the plants are in their infancy; but in three years I apprehend the drills will more than treble their produce: whereas, at that time, I ſhould fear the broad-caſt would be quite or near deſtroyed by the natural graſs. In other words, as faſt as the drilled crops improve, I do conceive the broad-caſt will diminiſh.

The culture of lucern in drills, with intervals of only one foot, I find is no better than the broad-caſt, as there is no ſuch thing as horſe-hoeing between the rows, and where the crop ſhould be large, digging would be too expenſive.

But

But upon the comparative experiment, between the two and three feet intervals, I confefs I cannot fo readily pronounce: the two feet produce the moft, by thirteen pounds and a quarter; whether that diftance will continue to do fo, I cannot fay: it may happen that when the roots become large, which is the propereft time to afcertain the fact, that the three-feet drills may have the greater produce; but time alone can determine this point, which really is very material to know.

Second Set of Experiments on Lucern.

Thefe experiments were calculated to difcover how far the roots of this plant would bear being wounded, as in the culture of lucern practifed by Mr. Rocque: I do conceive many of the roots muft be injured, to the manifeft diminution of the crop.

In April, 1763, I fowed a little lucern in my garden. May the firft, 1764, I treated fome of the plants in the following manner, after thinning of them in the row, by taking all others from them, and leaving the plants fingle, and about two feet afunder.

Numb. 1. The root of this plant I fplit from the crown of it downwards, for about an inch.

Numb. 2. The root of this plant was fplit firft in the fame direction as the former, and then I fplit it tranfverfely, for about an inch downwards.

Numb. 3. The root of this plant I cut a flice off one fide, about an inch long, juft below the crown of the root.

Numb. 4. This plant I cut the whole crown of the root off.

Numb. 5. This plant I fplit the root of, in the fame manner as Numb. 1. and then cut about an inch and a half off one fide.

After wounding thefe plants, I dug the earth round them, in order to feed the fibrous roots to the nourifhment of the plants.

They never afterwards made any figure. Towards September, Numb. 1, 2, and 3, threw out a few weak ftems, not worth notice; but Numb. 4, and 5, never grew afterwards.

Thefe experiments I mean to repeat in a greater number, and that for two or three years together, before I fhall venture to draw pofitive conclufions from them: but I think thefe feem to prove, that Mr. Rocque's method is not to be preferred fo much beyond Tull's, Duhamel's, and M. de Chateauvieux's, as his advocates would infinuate. But the fair trial between his method and the drill, will be to experiment carefully upon them for four or five years together; my experiments in wounding the plants, being only calculated to fupport theory by facts; for my notion of the confequences which muft happen from his culture, is no more than theory.

Till I made this fet of experiments, I confefs I never was fenfible of the texture and firmnefs of lucern-roots, which are really very hard to cut, and not much unlike a dried ftick, which I muft confefs feems to favour Mr. Rocque's method, fo far as relates to my apprehenfion of the plants being wounded by his inftruments, which, from the hardnefs of the roots, cannot wound them in the manner I did mine with a knife. And as my purfuits tend only to difcover the truth in matters of hufbandry, for Mr. Rocque's honour, and my own credit, I could not omit to communicate this remark, as I hope the reader will believe I am endeavouring to afcertain the beft culture for lucern, and not writing to leffen Mr. Rocque or his fyftem: every man acting in a private capacity, has a right to adopt fuch as he pleafes; but I, who am acting in a great meafure for the public, think myfelf bound to be confcientioufly exact in my fcrutiny of every fyftem, which I fhall comparatively experiment upon. If I am miftaken in the culture of lucern, I have the fatisfaction of confidering fome of the greateft men, who have ever wrote upon the fubject, are no lefs miftaken than I am.

Notwithftanding all that has been faid by many writers on lucern, as to its tap-roots, yet I find it has many lateral ones, and it is only a few of the plants that fend down but one tap-root, but an infinite number in all fhapes and directions. At a year old, I find the healthy ones are from ten to eighteen inches long; I preferve them of that age now by me, and intend every year to take them up, in order to have them of all ages, the better to fee their progrefs from year to year.

Upon the firft of laft May, fome of my lucern, which was fown the year before, was eighteen inches high; but let it be obferved, that it had the benefit of a fouth afpect, aided by the reflection of a fruit-wall. This induces me to believe, that a declivity with a fouth afpect, will be the moft advantageous fituation for this plant, in this country; for, although lucern will live in the fevereft winters, yet it flourifhes beft under the influence of a warm fun; the only bleffing we feem to want in this country.

In the fummer months I obferve, in a good foil, and under proper culture, it grows about an inch in twenty-four hours; fometimes I have known it grow an inch and a half in the fame time.

Third Set of Experiments on Lucern.

The tranfplanting lucern feems to have been firft thought of by the ingenious and never-fufficiently to be praifed M. de Chateauvieux, whofe reafons for every new attempt are founded upon fuch folid and rational principles, that they have generally fucceeded to his expectations. This gentleman fays, plants of two or three years old may be planted equally well with thofe of one year old.

My plants laft April were all one year old, which, upon taking up for the purpofe of tranfplanting, I found differed very much in their fize, which induced me to divide them into three parcels, *i.e.* the fmalleft, middling, and largeft. Thefe I tranfplanted in the following manner, fix inches afunder in the rows, and the rows three feet.

Numb. 1. Forty of the fmalleft plants, with their tap or leading roots cut off.

Numb. 2. Forty of the middling plants, with their tap or leading roots cut off.

Numb. 3. Forty of the largeft plants, with their tap or leading roots cut off.

Numb. 4. Forty of the middling plants, without cutting their roots.

Numb. 5. Forty of the largeft plants, without cutting their roots.

Numb. 6. Forty of the fmalleft plants, without cutting their roots.

Thefe fix rows of plants were put down the twenty-eighth day of April. I watered them at the time of putting down, and once afterwards.

Very few of them died; fo that the different fizes and methods feem to anfwer equally well the firft feafon.

I intended to have cut the produce of each experiment for weighing; but a few days before that was to be done my horfes got into the place where it grew, and eat fome of it, which difappointed my purpofe. From the appearance of the experiments refpectively, there would have been very little, if any difference in the produce; but a third and fourth year's crops will afcertain how far cutting off the tap-roots will benefit the plants, and how far tranfplanting is preferable to fowing. Be it noted, that the tranfplanted roots make no great figure the firft year.

In order to afcertain, with fome degree of certainty, how far lucern may be worth the farmer's attention, I laft fummer made an experiment with an horfe, to difcover how much he would eat, which being known, we can, from the firft fet of experiments, pretty exactly tell how many horfes an acre of lucern will maintain during the fummer months. The horfe I chofe for this purpofe is a very large one; he had been ploughing from feven o'clock in the morning till feven in the evening, during which time I forbid his having any thing to eat. When he was taken out of the plow, I ordered him into a ftable by himfelf, where I had provided for him fifty-fix pounds of lucern, without any other food for that night, of which he had eat by next morning, forty-nine pounds; a quantity, which I own furprized me.

Lucern will in this country, in favourable feafons, mow four times in a fummer after the firft year, and we may

may safely calculate, that at every cutting it will yield half an hundred weight upon each perch, which at the four cuttings is two hundred weight upon a perch in the season, or sixteen tons upon an acre, *i. e.* thirty-five thousand eight hundred and forty pounds. This is a low calculation; but at this rate, suppose five horses to be allowed forty-nine pounds every twenty-four hours, which is two hundred and forty-five pounds, in that case an acre will maintain them one hundred and forty-six days, which is twenty weeks and six days. No man will contend for it, I believe, that any natural pasture will do any such thing. Add to this profit, the circumstance of making dung all the summer; an object, I am sorry to observe, not sufficiently attended to in this country, amongst the common farmers; if they can make a little for their potatoes, they seem to think of no more.

Lucern should never be sown upon wet or spungy ground, but upon dry rich land, and must always be kept free from weeds.

I sowed some last April in drills, upon ground not six inches deep, above a lime-stone quarry, and it grew very luxuriantly; but the soil is very good.

Turneps are the best preparation of ground that I know of for lucern, particularly if they be raised in drills, in the manner before represented.

My lucern in the broad-cast and one-foot drills, was infected with the rust or mildew, during its growth; this seems to be an objection to the sowing of it with such narrow intervals, or in the broad-cast way, since the two-feet and three-feet drills were in the same place, and they were not at all infected with this disease.

An Account of the comparative Advantages of cultivating Lucern, on the Drill and Broad-cast Methods; for which the Society for the Encouragement of Arts, &c. adjudged their Premium of a Gold Medal.

The farm on which the following experiments were made, is a strong clay; a soil, in the opinion of all writers in agriculture, the most unfriendly to lucern. Encouraged, however, by M. Lullin de Chateauxvieux's experiments, the owner was tempted to try how the lucern would succeed when treated in the manner he proposes: and in the year 1761, he sowed a field of about three acres with lucern in drills, two feet asunder. During the first year, he caused it to be weeded carefully; and from the places where it grew too thick, he supplied those in which it had failed. After every weeding, he caused the intervals to be stirred with a horse-hoe, resembling M. Lullin's single cultivator, which manifestly revived the plants.

In 1762, the plants throve greatly, being kept clean, and horse-hoe'd as in the former year; and the society having published a premium for a comparative trial between lucern sown in broad-cast, and in drills, he determined to try one part of that experiment on this field, and not to bestow on his lucern any manure whatever, or to give it any other help than the horse-hoe.

In 1763, the plants were arrived at a size to yield so full a crop as to maintain five horses, from the middle of May to the end of autumn, or above five months. These horses, though constantly worked very hard, had neither corn or hay given them during all this time; and yet they continued in strength and spirit, and grew fat. A horse which in May was so weak, and in so bad a state of health, that it was thought he could not live, soon recovered, when fed with lucern. The plants were in general between three feet and three feet and a half high, at the first and second cutting. The plants made so many shoots, and these shoots branched so much, that in three weeks after every cutting, or sometimes sooner, the intervals quite disappeared; the whole field being so equally covered, that it looked as if sown in broad-cast. December 1763, January and February 1764, having been uncommonly rainy, the water stood in some parts of the field; and though there was generally such a declivity as that it might have been carried off, he resolved to let it remain, in order to see what effect it would have on the lucern. When the lucern began to rise in the rest of the field, in spring, he found that wherever the water had stood, the plants were killed. He supplied this loss by transplanting lucern from other parts; and these plants throve very well. By a continuance of the same treatment, the lucern remained in a very flourishing state: and retained a beautiful verdure and vigour, during the very great drought of this summer, 1765. It has yielded four cuttings every year, and sometimes five.

Having observed in a root of lucern taken up in the winter, that the spring shoots had no connection or concern with the remains of the shoots of the preceding summers, but proceeded from numbers of little tubercles, with which the head of the root was set very thick; it appeared evident, that the plants could not sustain any damage, though covered with a depth of earth during the winter. This suggested a hint, that the intervals might be plowed as deep as possible early in the winter, turning the earth on the beds; and that by letting the earth remain in this condition till spring, the clay, or strong soil in which the lucern grew, would be mellowed, or loosened, by the winter's frost and rain: and being harrowed smooth in February, the fresh lateral roots, which shoot out in the spring, would find a fine fresh mould to extend themselves in, which must tend greatly to the benefit of the plants. This thought was confirmed by experiment: for the spring crop is amazingly vigorous ever since this practice was followed, and the shoots though of great length, and most plentifully supplied with branches, are so strong, that no rain or wind lays them, even when they have stood to be in full bloom, as is the case with part of the first crop; the horses not being able to consume the lucern before part of it is necessarily in bloom. Another advantage arising from this practice is, that the grass which takes root near the plants, and which cannot be otherwise destroyed but by hand-hoeing, is killed by being so long covered with the earth laid on the beds.

In 1761, a spot of ground of an exactly similar soil was inclosed for a kitchen-garden; and there being part of it, which was not wanted for other use, in the spring of 1762, it was sown with lucern in broad-cast, as a counter experiment to the former. The warmth of the garden, and the partiality of the gardener to this method, who held the field experiments very cheap, gave his lucern every advantage that could be desired. It came up well, and was kept free from weeds; but it neither grew so fast nor so high as the lucern sown in drills. This difference became much more sensible during the second and third years; for in 1764 the field lucern had got the start of it so far, that this did not rise to half the height, nor did it yield a quarter of the quantity of fodder; so that he thought it needless to prosecute the comparison further.

Seeing so very remarkable a difference between the lucern raised in drills, and that raised in broad-cast, he resolved to try what share of this advantage might be placed to the horse-hoe, and what to the distance at which the plants stood; which distance afforded the roots more room to extend in. With this view, in 1764, he sowed a neighbouring field in rows, two feet asunder, intending to horse-hoe one half, and to keep the other free from weeds by hand-hoeing only. The months of April, May, and June, of that year, were so dry that the plants came up thin; and the clay was become so hard, that the horse-hoe could not be made use of till late in the year. Even with this disadvantage there was seen a manifest difference, in favour of the plants that were horse-hoed. The same difference was also observable in the spring of this year: but the uninterrupted drought of this summer has kept the clay so hard that the horse-hoe could not be used.

Computing the rent of the land, and the utmost expence that can attend the horse-hoeings and cuttings, it will be found, that feeding horses with lucern will be a great saving, when compared with the price of the hay and corn, which horses must have necessarily consumed in the same time, being kept to equally hard labour.

LUG, *or* LUGG, the same with pole, or perch, a long measure of sixteen feet and a half.

LUPINES, a species of wild pea, cultivated principally as a manure.

Lupines require the least labour of any thing that is sown; and will thrive in any soil, except the chalky and miry; but delights particularly in poor hungry worn out land, especially if it be dry and sandy. If sown in February or March, after a single very shallow plowing, and slightly harrowed in, or even harrowed in without any plowing,

plowing, it will bloſſom three times between May and Auguſt, and prove an excellent enricher of the ground when plowed in juſt after its ſecond blooming: though Mr. Miller, holding the lupine to be a very great impoveriſher of the ground whilſt it grows, thinks it is ſtill better to parboil the ſeeds, to prevent their ſprouting, and then to ſtrew about ſixteen buſhels of them upon an acre of land, and plow them in. In warm countries, lupines are much ſown in vineyards for this purpoſe only, and are found to be one of the beſt manures that can be laid to the roots of the vines. Their ſeeds ripen towards the end of September, or in the beginning of October. They are very bitter: to remedy which, the Spaniards and Italians, who feed their cattle, horſes not excepted, with them in winter, ſteep them in river water and ſalt till that bitterneſs is gone, and afterwards dry them thoroughly over a fire, or in the ſun. They even make bread of them, when corn is very ſcarce, and put them to ſeveral other culinary uſes. The beſt time for mowing them is after a ſhower of rain, becauſe the ſeeds drop eaſily out of their pods when they are gathered to dry. They muſt, however, be laid up very dry, or worms will ſoon breed in them. The red and the blue lupines, which are frequently planted in our gardens by way of ornament, grow wild, and in great quantities, about Madrid.

LYE, a fluid impregnated with ſalts, &c. *See the article* STEEPS.

LYNCHETS, or *Linchets*, graſs partitions in arable fields.

M.

MADDER, the Engliſh name of a plant, cultivated with great advantage in ſeveral parts of Europe, and lately in England, being a very capital ingredient in the dying buſineſs.

There are ſeveral ſpecies of madder, all of which afford a dye. M. Guettard, of the Royal Academy of Sciences, has experienced that the ladies bed-ſtraw, or cheeſe-rennet (gallium) may be made to yield one; and of this kind is probably the Ray-de-chaye, which is uſed on the coaſt Coromandel for dying red. M. Dambourney has not, indeed, as M. Duhamel remarks, hitherto been able to extract a good colour from the gallium: but there yet remains room to hope that he may be more ſucceſsful in the future experiments which he intends to make on this root.

Mr. Ray mentions and deſcribes four different kinds of gallium or mollugo, baſtard madder, which, after the laudable example of our enterprizing neighbours, ſhould likewiſe afford matter of experiment to thoſe who wiſh well to this country, and particularly to our dyers.

The azala or izari of Smyrna, perhaps more properly written hazala or lizary (according to the eaſtern method of pronunciation) which is the ſort uſed by the French dyers at Darnetal and Aubenas, to give cotton that fine carnation colour for which Adrianople is famed, is a true madder. Some ſpecies of it grow naturally under hedges and in woods; and the roots of theſe, when carefully dried, yield as fine a dye as the azala of Smyrna. M. Dambourney has cultivated a ſpecies of madder which was found growing wild on the rocks of Oiſſel in Normandy, and the roots of this plant have yielded him as beautiful a dye as the azala of the Eaſt. We ſhall hereafter ſpeak of it in his own words: but in the mean time we cannot help obſerving here, that Mr. Ray deſcribes particularly a wild madder which grows not only on the St. Vincent's rock near Briſtol, but alſo on the rocks about Biddeford in Devonſhire, and in great plenty among the hedges almoſt all over that county. As Mr. Ray calls this the *Rubia ſylveſtris Monſpeſſulana major*, and as M. Duhamel ſuſpects M. Dambourney's Oiſſel madder to be that very ſpecies, it ſurely is a matter of great importance to this nation, and well worth the attention of patriots, to follow M. Dambourney's example in making proper trials of it.

The ſpecies moſt commonly cultivated is the *Rubia tinctorum ſativa*, J.B. III. 2.714. and C.B. Pin. 333, commonly known among us by the general name of madder. It is of this ſpecies that the plantations of madder are made in Zealand, and in the neighbourhood of Liſle.

The following method of cultivating this uſeful plant was ſent to the editors of the Muſeum Ruſticum, by a gentleman who has been a practical grower of madder for ſeveral years, and tried it upon land of various kinds.

My firſt trial, ſays he, was upon a ſmall piece of ground near my houſe, of about forty perches of land, lying pretty low and moiſt, of a deep mellow ſoil, and rich black mould, a little inclining to ſandy; and underneath about two feet and a half, and in ſome places three feet of good earth, was a bed of looſe ſand, with a mixture of gravel.

I have been the more particular in the deſcription of the nature of this land, becauſe it produced the beſt Engliſh madder I ever had, both as to quality and quantity.

In March I cauſed this plot to be dug a full ſpit deep; and as it was under natural graſs for ſome years before, I took care in digging to throw the top turf as low as poſſible, turning the mould uppermoſt, in order to prevent the graſs from ſpringing; which had the deſired effect. I alſo took care to pick out all the roots of weeds, and other noxious plants, which were found therein.

In this ſtate it remained about a month; then with a line I divided it into beds of five feet wide, and two feet interval

interval between each bed, raifing them a little in the middle with fome of the earth in the intervals; then with iron-rakes the beds were reduced to a fine garden-mould, leaving them a little rounding, like afparagus beds, in order to fhoot off the rain-water; and having procured fome ftrong packthread, at every foot diftance I tied a fmall piece of white woollen-yarn, and thus continued the whole length of the line, which afterwards ferved as a rule where to fix the plants.

This line was extended the whole length, upon the outermoft bed, fix inches from the fide ridge of it; then with iron-fhod dibbles a madder-plant was fet ftrong in the ground, near every tuft of white yarn fixed along upon the line.

This row being thus planted, the line was removed two feet forwards, which brought it exactly to the middle of the bed: this being alfo finifhed, the line was again removed two feet, and planted as before; and this method I continued till the whole was planted. Thus there were three rows of plants in each bed, at two feet diftance, and one foot apart in the rows; and the diftance between the innermoft row of one bed, and the outermoft row of the next adjoining bed, was three feet.

During the firft fummer I kept the young madder quite clear from weeds, by hand-hoeing, as foon as any appeared: and in October following I took the haulm, that overran the intervals, and fpread it over the beds, without cutting any off; then with a fpade I covered the haulm with the earth from the intervals about two inches thick.

In this condition it remained during the winter, and in March following, the young madder came up very thick and ftrong; and as faft as any weeds appeared, I kept them down by hoeing, as before; but in the fecond fummer I found there was no neceffity of repeating the hoeing after the middle of June, for the haulm was now grown fo very luxuriant as entirely covered the furface of the ground, and thereby prevented the weeds from growing; and in October I again fpread the haulm upon the beds, and covered it over with the earth in the intervals, as before.

There are three good reafons for covering the madder in winter.

The firft is the new dreffing of the beds with frefh untried earth.

Secondly, by this method deep trenches are formed at proper diftances throughout the whole plantation, and confequently the beds are kept dry and healthy, and thereby the roots are prevented from rotting, which otherwife they are apt to do, if the water continues too long foaking on the beds.

The third reafon is ftill more efficacious; for by this means the haulm is entirely rotted, and the volatile falts contained therein are wafhed down to the roots by the winter rains, which tends more to encreafe the vegetation of the plants than double the quantity of any other fort of manure whatfoever, and for this reafon, becaufe the falt, inherent in the haulm, is of the fame kind with that which was before extracted out of the ground by the growing of the madder, and is now returned into the earth again, in order to renew its former office of vegetation.

This, perhaps, may feem new doctrine to moft of your readers; but experience convinces me of the truth of it, not only with regard to madder, but likewife in the propagation of afparagus, which, in a future letter, I may, if I have leifure, explain more fully, by giving the public an account of my making and managing thofe beds.

If this hint was duly attended to, it is my opinion that both farmers and gardeners would find their account in it, in the production of moft forts of vegetables.

But to return more immediately to my fubject.

In the third fummer very little work was required, only two flight hoeings in April and May, owing to the ftrength of the haulm, which covered the ground as in the preceding fummer; and in October following the roots were taken up, and this fmall piece of ground produced one thoufand nine hundred and fixty-five pounds of green roots, which were very large, and the madder, upon trial, found to be exceeding good.

In cultivating madder, great care is to be taken to fee that every fet or plant has fome fmall fibres at the root; and this ought particularly to be obferved by thofe who are employed in taking them out of the ground; for unfkilful perfons, not ufed to the bufinefs, very often draw up fuch as have no fibres at all, and then they certainly mifcarry.

The beft way is, to remove the earth from the mother-plant with a fmall hand-hoe, or fome fuch inftrument; and then you may eafily find which of the young plants has fibres, and which not.

In the fecond fpring you muft be cautious not to take off above two or three fets from each root; but in the third fpring, when they are deeply rooted, you may take off almoft as many as you pleafe, without injury.

The fooner the young plants are fet after they are taken up, the better; and if you are obliged to have them at a diftance, fo that they cannot be fet again in lefs than three or four days after they are taken up, they muft be well watered at firft planting, and repeated as often as you fee occafion, till they have taken root.

In dry feafons, the young plants very often die for want of moifture foon after they are planted; and in large plantations the expence of watering would be too great; therefore I always get my land ready early in the fpring, and wait for fome fhowers falling; and when I find them juft at hand, and fometimes in the rain, I get a great many hands, and immediately go to work, fome taking up, and others raking and planting; fo that the whole is foon finifhed, even in a large piece of ground; and when the plants are well watered at firft, they foon take root, and afterwards they will ftand a dry fummer very well.

In the moft favourable feafons, fome few plants always die foon after they are fet; therefore, about three weeks after planting, you muft go over your madder-ground, and replace fuch as have failed, with the beft and moft likely plants; and if the feafon be dry, let them be well watered at firft planting; but, if after all, you find any mifcarry, (which, in a dry fummer, they fometimes will do) the beft way is to fill up the vacancies, with winter-plants, in October following, juft before you cover the haulm.

Madder may be fuccefsfully planted from the middle of March to the end of May, according as the fpring is either forward or otherwife; but if fhowers fhould happen to fall in April, this is the beft month in the year for planting madder. There fhould be no dung of any kind laid upon the ground during the time the madder is growing, becaufe it has been found to give the madder a bad colour; and if the land is in good heart, and proper for the purpofe, there will be no need of it.

It cannot be expected that any land, even the richeft, fhould produce repeated crops of madder; for which reafon I am told, that the Dutch always allow an interval of fix or feven years, in which time they manure the land very well, and fow it with corn or garden vegetables, and have always large crops, owing to the deep ftirring of the ground, and being clean from weeds; and I can, from my own experience, affert, that the beft crops of corn always fucceeded a madder-crop.

About five years ago, I planted an acre of madder on a light, dry, fandy foil, which produced a tolerable crop, but nothing equal to the other.

I likewife tried it upon an acre of land of a loamy, mellow foil, fomewhat fandy, about a foot deep in mould; and undearneath is a cold, ftiff clay: from this piece I had great expectations, as the plants thrived very well at firft, but in the fecond fummer, when the roots reached the clay, the plants died away, and came to nothing; therefore I am well fatisfied a cold clay is by no means proper for madder.

I have alfo, at this time, two other acres of madder, which I intend to take up next winter; it will then have ftood three fummers. The foil is a deep, hazel mould, worth about twenty fhillings per acre. Inftead of digging it with the fpade, I plough-trenched it at leaft eighteen inches deep, but managed, in all other refpects, like the former. From the appearance it made laft fummer, I have no great expectations from this plantation, though, I fancy, it will be a faving crop.

Expences

Expences attending the Culture of an Acre of Madder, supposing the land to be worth forty Shillings per Acre.

	l.	s.	d.
Rent for three years - - - -	6	0	0
Digging ditto at two-pence per perch -	1	6	8
Dividing ditto into beds, two men one day, at one shilling each - -	0	2	0
Raking ditto, two men one day, at one shilling each - - - - -	0	2	0
Planting ditto with two thousand plants, one day, at one shilling and sixpence each	0	3	0
Six women to take up two thousand ditto, at six-pence each, one day - -	0	3	0
Hoeing the first summer five times -	0	15	0
Covering ditto in autumn the first year	0	6	0
Hoeing ditto the second summer three times	0	9	0
Covering ditto in autumn the second year	0	6	0
Hoeing ditto the third summer twice -	0	4	6
To be paid in lieu of tythe, at five shillings per acre per annum - - -	0	15	0
Digging ditto out of the ground -	5	0	0
Total of expences	15	12	2
As I always allow my people beer when they are about this business, I may add -	0	6	0
Which brings the whole expence to	15	18	2

In the above account I have not reckoned any thing for the plants; for though they cost considerably at first, yet it is then done once for all, to any person who continues to propagate madder, as he has always a constant supply from his own plantations.

	l.	s.	d.
Produce of an acre of madder -	52	12	6
Expences - - - - -	15	18	2
Clear profit - - -	36	4	4

In the business I follow, which is that of a clothier, a great deal of madder is used in dying; and being of opinion that there are many useful discoveries now lying dormant, only for want of proper methods to bring them to light, I determined to try an experiment on madder; accordingly I took twenty pounds of the green root, and having washed it clean from dirt and filth, I bruised it in a large iron mortar, just before using, and with other ingredients I dyed half a pack of wool of a dark, full drab: upon examining my colour, I found it full as good as tho' I had used four pounds of the best umbro madder, imported from Holland; so that, according to this calculation, which is founded on experiment, five pounds of green madder-root is equal to one pound of dry manufactured madder; and as I have found this method to answer, I have continued to use the root in this condition ever since, and find it much the best and cheapest way; for the green root is bruised very easily in the mortar, and thereby saves a great expence in drying, pounding, &c.

Before I quit this subject, I would advise those persons who are inclined to cultivate madder, to be very cautious in the choice of land for this purpose; for hereon their success chiefly depends. Madder being a plant that draws a great deal of nourishment, consequently the richest and deepest lands are to be chosen, and such as lie pretty low; for high lands are seldom fertile.

The following method of cultivating madder, was communicated to the public by M. de Salens, a French gentleman, who is well acquainted with this branch of husbandry.

I am apt to think, says he, there is hardly any kind of soil, but what madder will grow in; but it does not thrive alike in all: on the contrary, scarcely any plant sooner discovers the richness, or poverty of land, by the state of its growth, than madder: in rich land, and a soil that agrees with it, it is luxuriant, and produces a great number of sizeable, well-conditioned roots; but in a poor, dry, hungry soil, the plant is visibly checked in its growth, and the roots of it are small, and few in number.

Madder is a great friend to moisture, and therefore thrives best on a good loam, with a clay bottom. It is very fond of fresh land just broke up; but it must be so situated as not to be subject to be overflowed, as that will destroy the plant.

Madder requires, to come to a state of perfection, a great deal of nourishment; yet it is said not to impoverish the land; and this, in fact, is evident; for when the madder is dug up, the land will be in excellent condition to bear a good crop of wheat.

I have tried several ways, and at length am of opinion, that the best method of raising madder in France, is from the seed: it occasions, indeed, at first, some delay; but by continuing to sow a quantity in the nursery every spring, you will never fail of having plenty of plants.

The seed must be sown on a bed of earth, dug well, and made very fine by the rake, with which instrument the seed must be slightly covered.

When the plants appear, they must be carefully weeded, and set out with a hoe: the bed must, during the whole first and second summer, be kept very well hoed, and clear of weeds; and, if this is done, they may be planted out the second autumn.

I have many reasons for preferring this method in France; but I shall forbear giving a detail of them, because my opinion, with respect to planting madder in England, is different.

The seed of madder does not ripen so well with you, as with us; neither does it, as I have been informed, take so well on being sown. For these reasons, I would recommend it to you, to make your plantation with shoots that are put forth by the old roots in spring. I have practised this method, and met with success.

For madder to succeed well, there should be a great depth of good soil, and it should be turned up very deep with a plough, or, what is much to be preferred, with a spade. When the ground is properly prepared, it should be planted with sets, being the spring shoots pulled up in a madder-plot, with some root to them; for, if they have not some root and fibres, they will not take kindly: these shoots generally come from the layers of the plants, and great care should be had in taking them up, or the crop of madder will be damaged: the best way of doing it is with a dibble that has a flat edge shod with iron; this, on being thrust into the ground, cuts off the root at a proper length, and by gently declining the handle of the dibble, raises the set, without injuring the fibres of the root; and great care should be had not to take up too many of these shoots, or stalks, as they are undoubtedly necessary to the support and thriving of the principal roots, which, were they deprived entirely of their stalks, would certainly perish.

It is scarcely necessary to inform you, that as fast as these sets are taken up, they should be immediately replanted.

To make the method of planting these sets more intelligible to you, I must observe, that they are planted nearly as potatoes are planted in Ireland; that is, a straight furrow is drawn, the sets are put into it, the earth of the second furrow is thrown over them, the second furrow is filled with sets, &c. and so on till the whole ground is planted.

We place the sets here within three inches of each other; but this I think is too near for good land: perhaps they would thrive better, was double the space allowed: when three rows are planted a foot asunder, we leave an interval of four or five feet, according to the state of the land.

Grounds planted with madder, always succeed best when gentle rains fall soon after the work is done, as the sets take root the readier, and the whole gets into a thriving way.

In Holland and Flanders, their method of planting differs from that above described: they take up their sets from an old madder ground in May, and they plant them again immediately with a dibble, about three inches asunder, in rows about fifteen inches from each other; they form their beds about ten feet wide, and leave intervals of only one foot and a half, or thereabout.

The best time of planting a madder-ground is undoubtedly in autumn, as the sets are then best furnished with roots,

roots, and the rains which commonly fall at that season forward their growth.

As the stalks of the madder-plants are to be laid down and covered with earth, the intervals should be every now and then stirred to keep the soil loose. This covering is done when the stalks are about fourteen or fifteen inches long: after the ground has been well cleared of weeds, a part of the shoots in each row are laid down in the intervals on the loose earth, and slightly covered with the same earth; observing, however, not to cover them entirely: the end of each shoot should be left out of the ground, or they will not grow, and the whole work would be thrown away. The intention of laying these shoots down is, that they may be converted into roots, and thereby increase the quantity for sale; but all the shoots must not be laid down, or the disproportion betwixt the stalks and the roots would be too great.

This work may be done with great ease with the common implements: let a furrow be opened close to each side of the bed with a plough: in these the shoots are laid down, and covered slightly with a hoe.

None of the stalks of the madder should be pulled up the first year, as it would too much weaken the roots by disturbing them, and tearing off their fibres.

After laying down the shoots the first year, the madder-ground requires no farther care, except being kept clear of weeds; and in the autumn of the succeeding year it may be taken up, in order to its being prepared for sale: the earth of the intervals must always be kept loose by tillage.

When the madder-roots are taken up, the whole land gets a thorough ploughing, and some fresh roots or sets are regularly planted in rows, in the intervals of the former year; and when this second crop of madder is off, the land will be in fine condition to bear excellent crops of corn; for madder is no impoverisher of land, and the frequent tillage it requires, brings the land into fine tilth, reducing it into as small particles as the bed of a well-kept garden.

The best husbandry is, not to plant the same land in madder for many years afterwards; and whenever it is again planted with that crop, it should be well dunged, manured, and tilled, the preceding year.

When the stalks begin to wither, that is, about the latter end of October, the roots are to be taken up; and the cheapest and shortest way of doing it, is to loosen the earth with a common plough, first taking off the earth-board and coulter: when the earth is thus loosened, women and children may serve to pick up the roots; and wherever any difficulty occurs, the labourers turn up the soil with their spades.

But a much better, though rather more expensive method is, to have the earth of the beds turned into the intervals with a three-pronged fork: by this method the roots are taken up almost without damage; and many which lie a little deep are saved, but which would otherwise have been left in the ground and lost; and particularly most of the vertical or tap-roots are got up.

When the roots are taken up, they are dried as much as possible in the air, afterwards carried to a kiln, and lastly to the mill to be ground.

A light loamy soil is better for madder than a rich strong clay; it loves moisture, but is killed if it is overflowed: therefore, if the soil is in other respects proper, but too wet, it must be first drained, or at least the beds must be raised high, and the intervals sunk low: on the other hand, if the land is too dry, the intervals may safely, and even profitably, be raised above the beds: this will at least prevent the young fresh planted sets from being hurt by too much drowth.

When the upper stratum of soil is deep, it is to be observed, that the land cannot be stirred too deep: the only thing to be apprehended is the expence of doing it: the more the earth is reduced, the more nourishment will it afford to the roots of the madder; they require a great deal: but in general madder pays well for any labour that is bestowed on it.

Dry weather is, if possible, to be chosen for taking up madder roots, as the earth then easily falls off them, and they need not be washed, which is to be avoided; and, in fact, there is no occasion to wash them, unless they grew in a stiff soil, and the weather was very wet when they were taken out of the ground.

Some judgment is required respecting the time of taking up these roots: I have already mentioned that they will, in general, be fit for use by the latter end of the second autumn; but this is not always the case; and it is much better to let them lie in the ground another year than to spoil a crop.

The Dutch often taken them up too small, and the French almost as often let them grow too large. The two extremes are equally to be avoided: the proper time to take them up is, when they are about the size of a swan's quill; they then yield most dye, and are of course most proper for use. The time when they arrive at this proper state, depends not only on the nature of the soil in which they have been planted, but also on the good husbandry that has been bestowed on the land; for without proper tillage they will turn out but an indifferent crop; but if they are planted on a good loam, are well tilled during their growth, and have favourable seasons, they need never be left in the ground longer than the end of the second autumn, whether they are planted in the spring or the autumn.

I have mentioned in this letter many things which will appear trifling to you, when experience has made you more knowing in this culture; for, depend upon it, a greater portion of knowledge is acquired by a little experience than by a great many precepts; the first makes a deep impression on the mind, whilst the latter are soon chased away by new, and perhaps more pleasing ideas.

I would recommend it to you, when you begin to plant madder, to depend more on the judgment you shall form of things, than on any thing you can read on the subject. If you miscarry in some instances, you will certainly rectify matters in your future practice: a sensible man cannot be long in the wrong.

I have not, I know, given you any systematical instructions in the affair of cultivating madder; and this I purposely avoided doing; for, had I attempted telling you in what manner this useful plant ought to be cultivated in England, I should certainly have miscarried, and all I could have said would have amounted only to probable conjecture: had I, on the contrary, given you a circumstantial detail of our methods of practice here in France, it would only have served to mislead you, so much do the climates of the two countries differ. I am therefore in hopes, that my manner of treating the subject will be not only more agreeable, but more useful to you, as I have, for the most part, only mentioned such circumstances as may be equally useful in the culture of this plant in both countries.

Lay it down as a maxim, that the culture of madder, if properly managed, is very profitable; there are few crops pay better; but then the two extremes are to be carefully avoid; we must not let our expences be so large as that no crop will repay them; neither must we be so sparing as to baulk the growth of the plant for want of proper tillage. A great deal is required, yet too much may be bestowed on it, for the reason above mentioned: the golden mean is best in this, as well as in all other matters; and what this mean is, can only be learnt from experience; for it is absolutely impossible to lay down maxims that will suit all countries, all climates, and all soils.

What has hitherto been said relates to the common way of cultivating madder; we therefore shall now give in his own words, the great improvements made in this article by the ingenious M. Dambourney.

"M. Rondeaux, says he, found, eight or ten years ago, on the rocks of Oissel, two plants of madder, which he took up and set in his botanic garden. He afterwards gave me some slips of them, and I planted them in a similar place, out of curiosity: but M. Du Hamel's treatise soon made me perceive the importance of cultivating this plant. I accordingly applied myself to it: and by following all the methods which had been pointed out to me, and those which seemed to coincide with them, I succeeded so far as, in four years, to have plants enough to try this culture in the open field. In the mean time I learnt that M. Peter Dupont cultivated with success, at Elboeuf, plants of madder which he had received from Lille in Flanders.

ders. He was so kind as to make me a present of an hundred sets of them; and this little reinforcement, added to what I had raised of my own, obliged me to seek for room in my garden at Oissel, wherein to extend this culture. Finding no other spot vacant there, but two walks, I sacrificed the pleasure of enjoying them, to my then new and prevailing inclination. I therefore dug up one of them, the soil of which is a yellow and sandy clay, underneath which, at a spade's depth, is a bed of large gravel, close knit with very strong earth: but I did not suffer this to be broken into. I divided the walk lengthwise, and, without dunging it at all, planted in December 1757, in one half of it, first the sets which I had received from Elboeuf, and then, immediately after, but without mixing them, those which I was able to take from my own plantation. The other half of the walk was sowed in the month of April 1758, with seed which I had gathered from my own plants. The other walk was disposed of in the same manner, as fast as I could get plants or seed to stock it; taking care the first year to keep my beds well weeded, and to lay down the branches as fast as they shot out.

"So early as in the autumn of 1758, I gathered seeds from my plants of Oissel madder, whether raised from seeds or from slips; but that of Elboeuf had not then blossomed, though it had put forth stalks three feet high; and even in 1759, it produced blossoms on only a few stalks, whilst the Oissel madder was loaded with them. When the stems were withered, I had the curiosity to take up some of the roots, and was thereby informed of the following interesting facts.

"1. Though it is said positively, in the Dictionnaire Encyclopedique, that madder raised from seed requires five years to grow to the same size as that which is raised from slips attains to in eighteen months, yet I found all things equal in this respect; and if there was any sort of advantage on either side, it was in favour of that which had been sown: both the one and the other occupied the whole depth of the ground so far as it had been loosened, and their roots had, in several places, penetrated through the hard bed of gravel underneath: but in order to pierce through it, three or four roots had twisted themselves together, and shaped themselves exactly to the form of the passage they found between the pebbles, in consequence of which they were more or less choaked there; though they afterwards resumed their natural shape and plumpness in a bed of small pure sand which lies underneath the hard bed, and in which I have been obliged to leave some of them at the depth of four feet.

"It is plain therefore, from this instance, that no time is lost by raising madder from the seed, and that this plant may be raised successfully in the most indifferent soils, even without the help of dung.

"2. I took advantage of some fine days to dry in the sun, but separately, the roots which I had taken up. Every thing seemed to give the preference to those of the Elboeuf species. They were larger and redder than the others, and their powder was finer to look at: but the effect proved very different. To make a fair comparison of them, I dyed, with equal quantities of each of these sorts of madder, two equal parcels of cotton prepared in exactly the same manner: that which was dyed with the madder originally of Oissel took a much brighter colour, and resisted during thirty minutes a boiling which the other could not bear during ten. I likewise compared its effect with that of the Lizary or Hazala of Smyrna, and the advantage, as well in point of brightness as of the durableness of the colour, was also on the side of the Oissel madder.

"This valuable kind appeared to me from that moment to deserve the preference. In the spring of 1760 I sowed all the seed I had of it, part upon hot-beds, and part on beds in my kitchen-garden; and I desired M. Rondeaux to help me to find out more plants of it upon the rocks of Oissel or of Orival: but he assured me that he had searched for such several times, in vain: nor was he more successful in a journey which he took thither last August, with M. Dangerville.

"I therefore determined to have recourse to the suckers which grow around these plants: but though I took them up as carefully as possible, I could scarcely get any that were rooted; and notwithstanding that most of those which I did plant were yellow for the length of from four to eight inches, yet nine of them in ten died. The offsets of the Elboeuf madder, on the contrary, though taken up with but little precaution, have a great many fibres and young roots, and their taking fresh root is sure, provided they are planted in cool weather. Nature seems thus to compensate the cultivator for the scantiness of the seed which this last species produces, whilst the other yields it in abundance.

"Not to neglect any means of multiplying the Oissel madder, I dug up a small spot of it, about the fifteenth of last June, and took from thence all the slender roots which run in great plenty just below the surface of the ground: I cut them into pieces at every second joint, and planted them the same day in channels, where all those that were brown and woody became good plants, and those which were then only yellow and tender rotted.

"The doing of this taught me what I had not learnt from M. Hellot's memoir, nor had any of my correspondents in Holland informed me of it; namely, from what part of the root it is that the most valuable colour is obtained. After all my runners were thus taken off, and replanted, there still remained the stock furnished with lateral and with descending roots, resembling in form and colour large earth-worms. In three days of sun-shine they were dry, and the parenchymæa, or pulpy part of the root, being then lessened in bulk, the outer skin became wrinkled, because it was then too large. To clear them of this wrinkled skin, I had recourse to a method first thought of by M. Paynel of Darnetal, which was, to put these roots in a large sack of coarse canvas, and to shake them strongly therein. The friction of the sack, and of the roots one against another, took off almost all that outer skin, which I afterwards separated by winnowing, and what then remained was that which alone ought to be called fine and true peeled bunch madder, the effect of which is as superior to that of the azala, as the azala is superior to the finest Dutch madder. I would not however advise the cultivators of madder to follow this method, any farther than there may be curious and nice buyers ready to give them a price proportioned to the expences it occasions.

"By thus taking up each species of madder in the spring, one has, as M. Du Hamel gives room to hope, not only the advantage of obtaining suckers and joints of roots for raising new plants, but also, if the season be not quite unfavourable, one may dry the root itself in the sun sufficiently to make it keep, and by this means the expence of drying it with fire in a stove is saved, and the injury which the fire does to the quality of the madder is avoided. The colouring part would be still more valuable, if the root were dried in the shade under a shed open on all sides; and to accelerate this drying I have successfully made use of a bed of half-baked bricks, upon which I have spread the fresh roots. A bed of dry ashes, six inches thick, may also be used: but in this case it must be covered with cloths upon which the roots must be laid, that the ashes may not mix with them when they are turned. A floor of plaister likewise facilitates this drying; and I believe it far preferable to bricks, on account of the ferruginous parts which these generally contain.

"The principal difference which distinguishes the Oissel species is therefore observable in its roots, which are slenderer, of a less bright colour, less furnished with fibres at their joints and those joints farther asunder, than in the Elboeuf madder: but, besides this, an attentive eye will discern many more distinguishing marks.

"In the spring of the second year it rises ten or twelve days earlier than the other sorts, its stalks are slender, and they trail upon the ground as soon as they are a foot long; its leaves are of a pale green, long, narrow, thin, waved along, their edges (pretty much like that of the laurel); its blossoms are disposed in loose spikes, and each of the seeds which succeed those blossoms stands upon a pretty long foot-stalk.

"The Elboeuf madder, which came originally from Flanders, and is the same as the Flemish refugees carried into Holland, puts forth, on the contrary, strong stalks, which have frequent joints, and are able to support themselves even when they are two or three feet long. Its leaves, which are of a deep green, are thick, broad at their

their base, and terminate in a point almost like the leaf of the great mirtle, and they are not at all, or very little, waved. It does not blossom till the second or third year: its flowers are very apt to fall off, and when this accident does not happen, its seeds stand on short foot-stalks. This seed grows very well: but the ease with which well rooted shoots are obtained from this species renders it the less valuable.

" In order to enlarge my plantation, and likewise in hopes of enriching it with a new species, I wrote to Smyrna for some seed of the azala or izary, and luckily received three pounds of it on the 20th of August 1760. It seemed to me absolutely like that of the Oissel madder, and I ventured to sow a small part of it, on the 27th of August, upon an old hot-bed which had lost all its heat. It rose well, and the young plants were not injured by the winter. I transplanted them into open ground at the end of last February, they are now in bloom, and their appearance is exactly like that of the Oissel madder, excepting that their stems are slenderer.

" As to the culture, I set out with scrupulously observing M. Du Hamel's directions: but afterwards I ventured to deviate from them in some points, in order to adapt it to the less attentive genius of our farmers. In the first place, I have experienced the truth of what M. Paynel of Darnetal observed to me, viz. that the plants which are raised from layers, at a great expence, produce only long woody roots, which yield hardly any colour, remain hollow during two years, and produce very few of those vermicular roots, which are the only valuable ones. I have therefore quadrupled the number of plants in a given space; the ground has been well filled with them, and the expence of making layers has been saved; and, thoroughly to accommodate the culture of this plant to the practice which our country people are accustomed to, I have either planted the slips, or sowed the seed, in rows after the plough, as is done for kidney-beans, and the workman used to earth up these performs mechanically the same operations for the madder, the expence of cultivating which in this manner is no more than that of raising those beans in the field.

" Having observed that the east winds in the spring, and the heat of summer, are equally fatal to whatever is then set in the lands about Oissel, and that, on the contrary, whatever will bear planting in the autumn succeeds very well in them; I took up in October last all the plants of two years old madder that were in my garden walks, and these afforded me as many slips as were sufficient to plant half an acre of ground. Very few of them failed, because they were all brown and woody. But as the roots which are taken up in autumn, and which one might wish to be able to keep, cannot be dried without fire; it is advisable to dig up in that season only the quantity necessary to furnish sets for replanting, and from June to September to take up what is intended for sale.

" On the 16th of last February I sowed in a hot-bed the greatest part of the Lizary seeds which I had received from Smyrna, and the rest of them a fortnight after in one of the beds of my kitchen-garden. I raised from them plants enough to stock four hundred and forty square feet of ground, in an open field, where they succeed perfectly well: but this transplanting checks their growth; so that if the seed is sown in the field in May, the crop will be in nearly equal forwardness: but I have not had cause to approve of sowing it earlier in open ground.

" As it is right to make even inconveniencies become lessons of instruction, the impossibility of drying without fire the roots which I took up in October, put me upon trying to use them fresh, in the state they were when dug out of the ground. I therefore washed them well, that no earth might remain upon them: but having myself experienced that, as M. Du Hamel observes, this root loses seven eighths of its weight when it is dried sufficiently to be reduced into powder, I judged that I must proportion my quantity accordingly. I therefore put into a quantity of liquor which would have required a pound of powdered madder, eight pounds of fresh roots bruised in a mortar, and with this I dyed some cotton, in the usual way. When the dying was finished, I found that the liquor was still over-charged, though the cotton had imbibed so deep a dye as to require two boilings to bring it down to the usual colour: upon which I repeated the experiment with six pounds, and afterwards with four pounds, and I found that this last proportion of undried roots is that which gives a colour equal to what is extracted from a pound of dried and powdered madder. One half of the quantity of roots commonly used may therefore be saved by dying with them when they are fresh dug: but, though this is a great saving, it is not the only one.

" 1. There is no need to build kilns or sheds for drying the roots in changeable weather.

" 2. One is exempted from the inconveniences of a too hasty or too slow drying, either of which is equally hurtful to the quality of the madder.

" 3. The waste occasioned by the peeling, garbling, winnowing, &c. of the roots, in the doing of which many, if not all of the small ones, that are not for example thicker than straws, are separated with the refuse parts, and thereby generally lost, is hereby saved.

" 4. The expence of grinding is saved, together with the waste and fraud which may be committed at the mill; and likewise the inconvenience of waiting till the mill is at liberty, which is of no small consequence in places where there are not mills appropriated to the grinding of madder only.

" 5. Lastly, the roots thus used do not evaporate or ferment, as the powdered madder always does if it be not speedily used.

" All these advantages put together may be deemed equivalent to a saving of five eighths in the quantity. The planter who knows how to dye may reap the benefit of them the moment that his roots are large enough to be taken up: the dyers by trade will by degrees be sensible of the advantage, and share the profit with the planter, when the madder grounds are nearer them: they will even find themselves under a necessity of so doing whenever this method shall become general, and this will be a means of rendering it such; for as there is no particular time to be waited for in order to the madder's acquiring maturity, after it has been planted eighteen months; the husbandman who carries a parcel of fresh roots to market will be sure of selling them in that state, and the dyer may buy them daily, in proportion to the quantity he wants; or he may agree with the planter for such and such quantities to be delivered to him at such and such times. I have moreover experienced that these roots may be kept fresh during several months, by laying them in a hole three feet deep, in alternate layers of roots, and of earth.

" This experiment pleases me again in its tending to lessen the expence of dying, and consequently to reduce the price of our dyed stuffs at foreign markets, by which means our trade with other nations may be benefited: and it is likewise new, since neither M. Hellot nor M. Duhamel have pointed it out. I have also experienced that the Elbœuf madder is very good when it is used fresh; a circumstance by so much the more important to be known, as this species is not only the longest lived of any, but also the most easily propagated.

" The principal difficulty now remaining for me to surmount, is to find out some cheap and easy way of taking up the madder, without leaving in the ground its descending roots, which yield the best colour; for the method which I have hitherto practised has been considerably expensive. M. Duhamel proposes a plough which turns over the earth, without a coulter: but if I may judge from what I have seen, this expeditious instrument can suit none but lands where a clayey bottom hinders the vermicular roots from piercing deep. I wrote to Holland, to know how the Dutch manage in this respect: but those zealous patriots are very reserved in every thing relative to this plant, of which we let them be the monopolizers: I was answered, that they use the spade and the fork. However, I shall try what my zeal and what incidents may suggest to me, and shall communicate whatever I may find to answer best.

" An objection which may, perhaps, be started against this branch of husbandry in France, is that there may be danger of its prejudicing that of our corn, which is an article of the greatest necessity. But besides that we have immense tracts of uncultivated lands where it might be established, I can, with M. Duhamel, assert, that the profit of the madder may be had in the best fields of this province (Normandy) without diminishing the crops of the most valuable

valuable corn. In effect, it remains in the ground but eighteen months, and after it is taken up, a single ploughing is sufficient to enable the land to produce very fine wheat, without any manure. Now it is the custom in all our wheat grounds to take a crop but once in three years, and this may be had after the madder. Nay, an advanage may be reaped even in the first year, by sowing, between the rows of madder, onions and other pot-herbs, which do not root deep or occasion much shade: but there will be a still greater profit in making it grow jointly with kidney-beans, because, the rows being regular, nothing would hinder the after-stirrings, which contribute so much to promote vegetation."

M. Dambourney continued his experiments on madder, and gives the following account of them.

"I have restricted myself to the three species which yield the brightest and most lasting colour: these are, the madder originally of Oissel, that which is sometimes found growing wild in the vineyards of Poitou, and the lizary or hazala of Smyrna. All these bear seed in their very first year, and in the second one may gather two thousand seeds from a plant which would not afford at most above twenty or thirty slips. The difference between these means of propagation is striking, and ought to be decisive in all countries where the seed ripens well, as it does in almost every part of France.

"The manner of raising it from the seed, as practised by me, is thus. Along a wall which fences off the north wind, let a trench be dug two feet deep, five feet wide, and of such length as may be most convenient; then, towards the middle of February, let it be filled with hot dung of horses or mules, well pressed down, to within about three inches of the level of the ground, and afterwards fill it quite up to the top with fine mellow mould, pressed down gently, and laid smooth with a rake. A bed of this sort is preferable to any other, because a common labourer can make it very well, whereas it would often be necessary to have recourse to a gardener to make a raised hot-bed. The expence is not to be regarded, because this bed may be sown six times in a year, and the mould which may be taken from it afterwards will be worth as much as the cost of the dung. The using of this bed does not at all prevent sowing likewise in the beds of a kitchen garden; but as this last should not be attempted before the middle of March, for fear of frosts, there will be a great advantage in sowing upon the hot-bed; for a month gained in this season is invaluable.

"On the 20th of February, 1762, I sowed upon such a bed some madder seed in small channels about an inch deep, and three inches asunder. This method is always preferable to sowing in broad-cast, because the seed is better covered, and the weeding is more easily performed. The young plants appeared after nineteen or twenty days, they were watered and weeded when necessary, and on the 30th of April they were fit to be transplanted into open ground.

"As most of our farmers are, unhappily, not able to advance money for a culture from which they have no prospect of reaping a return in less than eighteen months, I tried, last year, what would be the event of sowing madder at the same time as kidney-beans, and in the same furrows of the plough. The beans, which rise in less than eight days, required to be earthed up when the madder had scarcely appeared above ground; and this operation smothered the madder entirely. I therefore judged it most proper, this year, to substitute my young hot-bed plants of madder in lieu of the seed; and accordingly, when the weather was moist, for that is an absolutely necessary circumstance, I set some of my people to plant a piece of ground which had been well prepared for a crop of dwarf-beans. In each furrow of the plough where these beans were sown, women and children placed the young plants of madder six or seven inches asunder, fixing the root in the bottom of the furrow by means of a handful of earth put around it, and resting the green stem against the side of the furrow, the surface of which it exceeded by at least one row of leaves. The ploughman stopped a little at the end of the furrow, till the whole of it was planted: he then opened with his plough, which had a shifting mould-board, a second furrow, in which nothing was either sowed or planted; and at the same time the earth turned up out of this filled the first. A woman finished this filling with a rake, as well to cover the beans completely as to earth up the plants of madder. The third furrow was sowed and planted like the first, and this was continued till the whole extent of the ground was planted in rows fifteen inches asunder. This work, which did not in the least alter the common method of cultivating the beans (excepting that only two thirds of the usual quantity of seed were used) was performed in five hours, by one ploughman, three women, and three children. The ground thus planted contained upwards of twelve thousand sets of madder; and these had taken fresh root and had begun to shoot up when the beans rose. It was weeded twice, its surface was stirred, and the plants were earthed up as usual, without any danger. Both throve well together: the beans were pulled up when they were ripe, and the madder, now sole possessor of the ground, covers it like an artificial grass. The greatest part of it has yielded a little seed. The crop of beans, notwithstanding the drought of this summer, is almost equivalent to the expences, and next year I shall have that of the seed and roots of the madder, at the expence of only a stirring of the surface and a single hoeing in the spring.

"My hot-bed was no sooner cleared, than I sowed it again with madder: but the extraordinary drought of the season obliged me to leave it there till the 6th of August, by which means I lost a crop. I then took advantage of a rainy day to transplant it: and this was done in the same way as before, excepting, that the season was too far advanced to admit of sowing beans at the same time. The length of the roots of the madder likewise required more precautions to fix them with earth at the bottom of the furrow, in which one of the horses being forced to tread in order to open the next furrow, the whole would have been trampled to pieces, or dragged out of the ground. Yet the same number of work people as before-mentioned, set sixteen thousand plants in six hours. The spot is well filled, and the plants will be strong enough to resist the winter.

"On the 15th of May, being deceived by a small rain, I sowed near an acre of ground in alternate rows, as is practised for beans, but only with madder. I used for this purpose three quarts of seed, which I have much regretted; for the constant drought has hardened the surface of the earth so that the young plants have not been able to pierce through it, and consequently all has been lost. The method which I am now going to relate will prevent this inconvenience hereafter.

"I sowed my hot-bed, for the third time, on the 6th of August, with a design to let the young plants remain there all the winter, and not to transplant them till the end of February: but the nineteen or twenty days which this seed requires, in order to its sprouting, disconcerted me. It was necessary, in that hot season, to water frequently by hand, and this, besides wearying out the gardener, laid bare some of the seeds, which grew no more. It then occurred to me, that this might probably be remedied by sowing seed which had already began to sprout. Accordingly, I filled the bottom of a box with moist mould a quarter of an inch thick, then covered this entirely with seeds, and so proceeded in alternate layers, the last of which was of mould. I kept this box well watered, though exposed to the sun, and each day I examined the progress of the seed. It was on the eighth that the germ began to appear, and the very next day it was three quarters of an inch long. I seized that instant to lay in channels made in the hot-bed both the seed and the mould in which it had sprouted: I then smoothed the surface of the bed, and two days after all the rows appeared distinctly. This method likewise saved me a weeding, which I had generally found to be necessary as soon as the seed which had not been made to sprout before-hand had risen. The growth of the young plants was so rapid, that instead of letting them remain there all the winter, as I first intended, I ventured to transplant them into open ground on the 14th of last September. Frost is a little to be feared for this last plantation: the event will be a lesson for the future.

"Eight days before these plants were taken up, I laid another parcel of seed to sprout, in the same manner as before, and therewith immediately replanted my hot-bed. It has risen well, and will pass the winter there. I hope

hope (by thus uſing ſprouted ſeed) to be able next year to raiſe at leaſt ſix crops on the hot-bed. I likewiſe ſowed at the ſame time ſome of this ſprouted ſeed in a bed of my kitchen-garden, where it roſe in four days. I intend alſo to venture ſome of it about the end of next April in a ſpot with beans; and I preſume that as this already ſprouted ſeed will riſe ſooner than them, the plants of madder will be able to bear the firſt weeding and ſtirring neceſſary for the beans; in which caſe the expence of culture will be much leſs than the charge of removing the young plants, and both the hazard and the delay of their taking freſh root will be avoided. If this trial ſucceeds, it will be the greateſt inducement that can be for the farmer to adopt the ſame method, ſince it will require only one ploughman, a woman to ſow the beans after the plough, another to lay the ſprouted madder in the furrow, and a perſon to cover the whole over with a rake.

"The gathering of the ſeed is expenſive when one has but little of it, becauſe, for fear of loſing any of it, it is gathered almoſt ſeed by ſeed. I thought myſelf rich enough this year to try another way of doing this work. I cauſed all the tops to be cut off with a reaping hook when there remained upon them but a few ſeeds that were not ripe, and the whole was then laid upon cloths in the ſun. In two or three days the ſtalks and leaves became ſo brittle, that a few ſtrokes of a ſwitch reduced them into duſt. Two turns of a winnow blew away their duſt, and with it the unripe ſeeds, which, after they had been dried, were found to be lighter than the black or purple ones, in which the horney ſubſtance was formed. I hope next year to be in a condition to proceed with ſtill leſs precaution, that is to ſay, to mow at once all the branches and ſtems, and then to ſeparate the ſeeds from them in the ſame manner as before. It generally is during the whole of the month of September that the ſeed of madder is fit to be gathered.

"After the ſeed has been thus ſeparated from the ſtalks, and winnowed clean, it muſt be expoſed to the ſun till it becomes perfectly dry; for if there remains the leaſt mucouſneſs in the black pulp which ſurrounds it, a fermentation will enſue in the winter, or at leaſt a mouldineſs, which will deſtroy the germ. It muſt afterwards be put up in bags of thin cloth, and theſe ſhould be hung to the cieling of a dry and airy place, as well to preſerve the ſeeds from all moiſture, as from mice, which are very fond of them.

"If it be intended to ſow wheat after the crop of madder, the roots of this laſt muſt be taken up in the beginning of October. It is not poſſible for me yet to point out a better method of doing this, than to begin at one end of the field, and trench the whole ground two or three feet deep, whilſt women gather up the roots as the men purſue their digging. The ground is then ſo well prepared for wheat, without uſing any dung, that two-thirds, or at moſt three-fourths of the uſual quantity of ſeed, will be ſufficient to ſow it.

"The madder now taken up might become burthenſome to the planter, if the conſumer thereof ſhould ſeek to take advantage of the eaſe with which it corrupts: for the huſbandman would in ſuch caſe, be forced either to dry on kilns whatever he takes up in this ſeaſon, or to ſell it at whatever price the buyer ſhould be pleaſed to offer. Theſe inconveniencies ſeemed to me the greateſt obſtacles to the progreſs of this branch of cultivation, becauſe they neceſſarily required, in the common way of proceeding, either that kilns ſhould be built for drying the madder, or that its roots ſhould not be dug up till they were to be ſold. I therefore tried, as follows, to remove theſe diſadvantages. On the ſixth of October 1761, I dug in my garden, a hole three feet deep, into which I threw thirty plants of madder, then filled up the hole, and let it remain thus expoſed to the air and rain. I cauſed it to be opened on the 30th of laſt March, and found all the roots in good condition. It was filled up again till the 15th of September, when, upon its being opened anew, even the vermicular roots, the broken ones, and thoſe which had been ſeparated from the plant, ſeemed to me as firm and as ſound as when they were firſt put into it; but to be certain whether they had not ſuffered ſome alteration imperceptible to the eye, I have dyed with them in compariſon with roots which I took up on purpoſe, and I have not found any difference in the liquor, or in the brightneſs and fixation of the colour.

"The huſbandman may therefore, in caſe of need, keep his crop of madder a year in a hole made in his farm-yard, or in a pit dug at the end of the field; only obſerving to lay it in alternate layers of roots and of earth. He will thus be enabled to wait till he finds a proper opportunity to ſell, and the buyer will no longer have it in his power to tyrannize over him by taking advantage of his neceſſities. The dyer, who will know his own intereſt well enough to adopt my method of dying with freſh roots, may alſo keep them equally well in the ſame manner, in a hole in his cellar, from whence he will take, whenever he pleaſes, whatever quantity of them he has occaſion to uſe.

"It may not be amiſs to repeat here, that when theſe roots are uſed freſh they need only be waſhed a little to clear them of earth, and that the quantity of them put into the dye ſhould be after the rate of four pounds for each pound of ground madder which the operation would require. Theſe roots are cut into middle-ſized pieces, and pounded in mortars of ſtone or wood (iron abſolutely excepted) till they are reduced into a kind of pummice, and this is thrown into the copper when the water (of which I have experienced that, in large works it is hurtful afterwards to increaſe the quantity) is a little more than lukewarm. The liquor is then heated to a degree at which a man can hardly bear to hold his hand in it, and whilſt it is in this ſtate the ſtuff or cotton is puſhed down into it, and there worked about during three quarters of an hour, between hot and boiling, after which the liquor is made to boil during three quarters of an hour more.

"As this liquor remains, after the dying is finiſhed, much finer than that which has been made with the Dutch ground madder, I intend this winter to try whether it may not be put to ſome farther uſes; and I ſhall, in due time, give an account of whatever I may ſucceed in."

M. Duhamel thinks the month of September the moſt proper time for cutting the ſtems of madder, in order to their being made into hay. The Flemings cut theirs in Auguſt: but that is when they do not intend to ſave the ſeed, of which indeed their madder yields but little, as was before obſerved. As Mr. Ray informs us that the madder which grows wild in England preſerves its verdure all the winter, it will become a conſiderable addition to our winter and ſpring ſucculent food for cattle, and this will add greatly to its value; for this plant has been experienced to be an excellent fodder for cattle.

Cows fed with the tops of madder yield plenty of milk, which is a little tinged with red; and the butter of it is yellow and well taſted.

After the madder has been cut for hay, the ground ſhould be gently ſtirred, eſpecially in the alleys, and particularly if theſe are to be planted with madder the next year.

When the ſame ground is to be planted anew with madder, the whole of it ſhould be thoroughly ploughed after all the roots are taken up, and the beds ſhould now be made where the alleys were before. If the ground is ſown with wheat after this ſecond crop of madder has been taken up, the farmer may reaſonably expect an abundant crop of corn: for beſides that madder does not impoveriſh the ground; the weedings and frequent ſtirrings neceſſary for the culture of this plant prepare it well for wheat or any other crop. M. Duhamel confirms this by the following experiments.

A field of madder being dug up, he ſowed it with ſpelt, which was harrowed in, and did not appear for ſix weeks, becauſe the ground was very dry; and even after this, only a ſmall quantity of it ſprouted: yet, at harveſt, this field yielded as many ſheaves as others in the ſame country; but with this eſſential difference, that the ſtraw of theſe was ſix feet long inſtead of four, and the ears were as long again as thoſe in the other fields.

Another year, having ſown ſpring-wheat after a crop of madder, there were, at harveſt, twenty dozen of ſheaves on an arpent (about an acre and one fifth) whilſt the other fields yielded but eight or nine. Likewiſe, another year again, having ſown oats on a piece of ground where the madder had juſt been dug up, it yielded forty dozen of ſheaves to the arpent. The common lands produced that year but five or ſix dozen.

The peasants about Lisle, being in too great a hurry to enjoy the fruits of their labour, take up their madder before its roots have attained a proper size. The Zealanders let their's grow larger. A medium should however be observed; for the roots which have remained long in the ground yield less dye than those which have stood only till they have acquired the bigness peculiar to each kind.

This root, which is one of the best ingredients that can be used for dying wools and stuffs, gives them a red colour, not very bright, it is true; but which resists, without alteration, the influence of the air, the heat of the sun, and the effects of the ingredients made use of to try colours: it contributes also to make other mixed colours lasting: finally, a method is found out of giving cotton a very pleasing and lasting carnation colour with it. All parts of the root do not yield this red; the dye of some parts fades, other parts are worth nothing at all.

In examining a well-conditioned root of madder with a microscope, under the outer bark, in the flesh may be perceived certain red particles, which certainly yield the colour which the root contains; but there is, besides this, seen a great quantity of woody substance of a fallow colour; and this substance probably impairs the first mentioned colour. According to M. de Tourniere, this fallow colour is not so good a shade as the red; and he imagines that leys, &c. give a brightness to the colours dyed with madder in no other respect than by abstracting this fallow colour. The sun and dews have the same effect on yarn dyed with madder, when it is exposed on the grass.

M. de Tourniere also imagines, that the part which yields the red, is, in the green root, dissolved in a mucilaginous juice; for the bark, and the other parts which contain most red, are also most succulent: by drying them in a kiln they lose seven eighths of their weight, and yet the roots are not perfectly dry; for they bend before they break; they are rather bruised than ground by the mill; and this unctuous powder is apt to clot: it is true, that in time they lose this unctuousness, and become dry; but at the same time the quality of the red particles is lowered. These observations are well deserving of attention; for they make it evident to us, that these valuable particles may be impaired by too great a heat: supposing it unctuous, were it too much dried, perhaps water would not dissolve and separate its parts. Finally, these reflections of M. de Tourniere agree very well with the experiments of M. d'Ambournay, and convince us that madder-roots may be used green with very considerable advantage. But green madder can never be used, except when the grounds lie convenient for the dyers: thus, when madder is to be carried to any considerable distance, it must of course be dried, and pulverized. I shall resume this subject.

1. As madder-roots are very apt to ferment when they are bought green, it will be necessary to examine carefully whether they are spotted, or have a musty smell: if the fermentation has given them a black hue, they are by all means to be rejected.

2. The roots to yield a fine dye should be fresh: such as are dusty on being broke must therefore be rejected, and with still greater reason those that are rotten and worm-eaten: on the contrary, such ought to be preferred as have a strong smell somewhat like that of liquorice: the ground-madder should be unctuous, and run into clots on being handled.

3. As madder is sold by weight, it is an advantage to the purchaser to have the roots quite dry; but he should be careful that they have not been kiln-burnt: such as have a strong smell have seldom this defect. Too hasty a drying wrinkles and splits the bark; and, as it then separates very easily from the wood, the most useful part is lost: the bark therefore should be smooth, entire, and adhering to the wood: but we must not confound the true bark with the outer bark, or epidermis, which would only lessen the brightness of the colour.

4. The largest roots are not always the best: they are frequently yellow, and have but little of that red which alone yields the colour. The very small roots are of little value, as they have too much outer bark, which hurts the colour: but those of the best quality are from the size of a goose-quill to that of the end of the little finger.

5. In breaking the roots there may be seen, as I have already observed, two substances differing one from the other: that which inclines to a yellow only, hurts the dye: that of the deep red is the part really useful; consequently the highest coloured roots should be preferred.

It would be a useful discovery could there be a method found out of extracting the red particles without any mixture with the fallow or yellow part: I am of opinion the trials should be made on the green root, that the red particles, which are then in a state of dissolution, may be more easily extracted.

6. As the surest method of knowing the quality of madder is to make a trial of it on some piece of stuff, it will not be amiss if such as plant much of it accustom themselves to make this trial, that they may demonstrate to the purchasers the quality of their roots: the following process for doing it, is extracted from the works of M. Hellot.

To dye a pound of woollen-yarn, a bath must be made with five ounces of allum, and one ounce of red tartar, dissolved in a sufficient quantity of water: the wool that is to be dyed must be well drenched in this liquor: in about a week half a pound of ground madder root is to be thrown into water as hot as you can bear your hand in; and, after having mixed the water and powder together with a stick, the wool is put into it; and the bath must be kept hot for an hour, but not boil; for, if it did, the colour would be dull: but towards the end of the time the bath is made to boil; but the yarn must be instantly taken out.

As very trifling circumstances will affect the beauty of the colour, it will not be amiss to make at the same time two trials with the same yarn; one with the madder that is to be proved, and the other with the fine madder of Zealand, or azala: the beauty of the skains will determine which is the best madder.

As these trials may as well be made on two or four ounces of yarn as a pound, the baths may be made accordingly. I shall now treat of the methods of drying and pulverizing madder.

We have observed that green roots are very apt to ferment: it is therefore necessary to abstract the great quantity of moisture that causes it. If the weather is very dry and hot, it is certainly advisable to take the advantage of it to dry the roots in part, and save wood; but, if the weather is damp, the roots must be spread under sheds, or on barn-floors, and often moved; for, if they were laid in heaps, they would soon heat, and change, more or less, according to the state of fermentation they were in. With care the fermentation of the roots may be greatly lessened; and, according to M. d'Ambournay's opinion, they may even be kept good for some time; but the roots cannot by these means be made dry enough to preserve them from any change. For small crops a common oven will serve; but it must not be heated to above forty-five or fifty degrees of M. de Reaumur's thermometer. But this method is very tedious, and it would require very large ovens to supply the place of kilns. To save the expence of building a kiln, I would recommend the making a place over the roof of the oven, to put the roots in, that they may begin to dry: but, if we grow much madder, it is absolutely necessary to have a kiln proportioned to the quantity that is to be dried, not only of our own crops, but those of the peasants that cannot afford kilns.

The kilns may be made of very different forms, many of which are of equal goodness; but when a man proposes building one, he should be attentive, 1. That it may contain a large quantity of roots: 2. That it may be worked with ease: 3. That as little fuel as possible may be used: 4. And that it be so contrived as to retain an equal and moderate heat. To make these matters easy to planters, we shall describe the kilns that have been long in use at Lisle for drying madder-roots: we shall point out their defects, as well as the defects of two kilns that were successively built at Corbeil; and, lastly, we shall mention the attempts we have made to improve and perfect them.

Description of the Lisle Kiln.

This kiln differs very little from that used for drying malt. To have a general idea of it, we must suppose there is

Scale of 6 Feet.

is a large furnace, in which a great fire is made: this furnace is made under an arch: the hot air and fmoke pafs through a funnel over the furnace, and fpread themfelves in a fpace in form of an inverted pyramid, the bottom of which is covered with a perforated floor, on which the madder-roots are fpread. This is the general form of the kiln; but we fhall give a defcription of it according to the figures in the plate, for the ufe of fuch as intend to build one.

The Fig. 1. Plate XVIII. reprefents the fection of a building, containing a madder-kiln.

In this building may be feen a vault, K, K, a ground-floor, L, L, and a firft floor, G, G, over which we are to fuppofe a granery, H. The foundation of the brick-work of the kiln, is fomewhat lower than the bottom of the vault; the walls terminate in arches, at the bottom of the firft ftory; the fide-walls of the building ferve as upright fupporters; and the arches of the kiln are fuftained by jams, which are put into the fide-walls. All this will be better underftood by explaining the letters of reference.

A, an afh-hole two feet wide, three feet and a half deep, and two feet three inches high. B, the furnace with an iron grating, *b b*, at bottom. C, a pricked line, which determines the height of the furnace door: this aperture is fixteen inches wide, and feventeen high. D, the chimney, B, the perforated funnel, which difperfes the heat, by means of the holes, *i i i*. It is to be obferved, that this chimney is entirely covered at the top, to prevent any thing falling into it. I I I, holes two inches fquare, by which the heat efcapes; they are placed chequerwife. F, an empty fpace, into which the heat goes, out of the funnel before it reaches the upper ftory. G G, a floor fet with fquare tiles, on which the roots are to be fpread one foot and a half thick. Thefe tiles are fifteen inches long, ten or eleven wide, and two thick; they are perforated with conic holes, as here reprefented. H H, tubes four inches wide, by which the fuperfluous fmoke efcapes, and through which fall the dufky particles that drop through the holes in the tiles of the floor G. Thefe tubes are ftopped by a little iron door, which is opened when the heat is too great.

K, the vault in which the fuel is kept. L places where the undried madder is fafely kept. M, iron joifts two inches thick, traverfed by bars which bear the tiles that compofe the floor. N, iron braces fixed to the beam P, to fupport the floor G. P, the beam of the fecond ftory. Q, a cafement or window, to be opened at the beginning of every drying, to let out the fmoke. When the madder begins to dry, thefe cafements are fhut, to keep in the heat. There are alfo in the fecond flooring two trap-doors, which are open to let out the fmoke and fteam.

Fig. 2. reprefents the plan of the furnace. The three iron bars which crofs it, are each two inches and a half broad, and fix lines thick; they are let into the wall three inches; the bars of the grating are one inch fquare, and rivetted to the other bars. In this plan are to be feen the tubes marked H, to fhew that they run the whole depth of the furnace. Thefe tubes are very neceffary to convey into the kiln the heat from the body of the furnace.

Fig. 3. reprefents the plan of the tiled floor, G: it is fixteen feet fquare.

As the furnace we have defcribed refembles that ufed for drying malt, we was willing to obferve in what manner it was dried, and remarked, that they lay it about nine inches thick, and that it is very hot at bottom. When M. de Reaumur's thermometer was applied, it rofe upwards of twenty-two degrees above Zero; but the upper part, being influenced by the external air, heats but little: the fteam that rifes, being condenfed by the cool air, is reduced to water, which occafions the upper part of the bed of malt to be always wet: for this reafon it muft be often turned. In this method, by being often wetted with the fteam, the bed of malt is much retarded in its drying. We imagined this inconvenience might be removed, by preventing the external air from affecting the furface of the bed: and this would be affected by making a covering for it; and, if this covering could be fixed within a foot of the malt, another advantage, which we fhall mention, would refult.

It is well known in phyfics, that the vapours which arife from heated matter, have a great power of penetrating and heating the matter whence they proceeded, provided they are collected, and in fome manner reverberated on the matter to be heated: it is on this principle the machine was conftructed in which the bones of animals could be diffolved; and we know, that in an equal degree of heat, water has eight hundred times more volatility than air; and vapours or fteam contain a great deal of water.

This induced us to think, that it would be of great ufe to reverberate the fteam on malt and madder-roots, by means of the covering above mentioned. M. Villot, a brewer at Paris, who takes all opportunities of improving his beer, has made fome experiments of this nature, and in part fucceeded. It is only neceffary then to contrive a method of putting this in execution in a large building, of which we fhall in due time take notice.

One great defect of the Lifle kiln is, that the fmoke, mixing with the roots, charges them with fuliginous matter, which probably hurts the colour, and is perhaps the caufe of the difference betwixt the Levant madder and that of Lifle, thefe laft being by no means fit for dyeing cotton, as done in the Levant: befides, in thefe kilns the workman cannot properly regulate his fire: thefe defects might be removed by making the middle clofe, and terminating it in a tube of caft or hammered iron, to carry off the fmoke: the floor, fupported by iron bars, might very well be difpenfed with, and inftead of it one of wood, lattice, wicker-work, or iron wire, would do; for the funnel once properly fecured, there would be no danger of fire. In order to enable every one to vary the conftruction of thefe kilns, we fhall add fome reflections and obfervations made with great care by M. de la Levrie, who fuperintended the building of two kilns at Corbeil.

Remarks on the Kiln ufed at Lifle.

It will not be amifs to begin by relating the experiments made with two kilns, built one after the other at Corbeil, to dry madder, as thereby the advantages of that, herein after propofed, will be more evident.

The firft of thefe kilns was twenty-one feet long, twelve wide, and ten feet high: within-fide it was furrounded by three ftages of hurdles, like fhelves, four feet wide, and twenty inches one from the other: the firft ftage was five feet from the ground: on thefe ftages the green madder was laid eight inches thick. In the upper floor was a trap-door, which opened to let out the fteam of the root. The furnace, which was not without defect, went three feet within the kiln: it was fupplied with fuel from without: within-fide it was furnifhed with metal tubes, which paffed through the fire: thefe tubes received at one end the outward air, which they difcharged within, very hot, by an aperture two feet from the ground. The effect produced from this kiln was as follows: the three ftages, being filled with roots, thofe on the upper ftage became dry enough to fend to the mill. It is true, they dried but flowly, becaufe the fteam, which proceeded, though in no great quantity, from the two lower ftages, wetted the under part of the hurdles of the firft ftage, thereby retarding the work. The heat which was not powerful enough to raife all the moifture of the madder-root on the lower ftages in fteam, made them fweat abundantly, fo that the under parts of the hurdles were covered with drops of water as big as the finger's end, which fell from the fecond fhelf on the firft, where they wetted the root; and from the firft fhelf they fell to the ground. On the upper fhelf were very few of thefe drops of water, except for a very fmall fpace of time after the kiln had frefh roots put into it, becaufe at the upper part of the kiln the heat was powerful, and regularly difperfed, whilft at the bottom it was cold. At each ftage was fixed one of M. de Reaumur's thermometers: after four days continual fire the loweft fcarcely rofe to eighteen degrees; the fecond, fomewhat higher; and the uppermoft never paffed eighteen degrees, which is thought fufficient, when the drying is not retarded by any fteam from below. When the dried root was carried to the mill, the root from the fecond ftage, which had loft part of its moifture, was removed to the third, and that of the firft ftage ſtage, ſtill wet, was laid on the ſecond, the firſt ſtage being filled with freſh roots. The loweſt thermometer then fell to fourteen degrees, and the uppermoſt to Zero: this induced them to dry all the roots that were at once put into the kiln, before they admitted any freſh; yet even in this method it was neceſſary to move the roots from the lower to the upper ſtages, where the laſt laying dried faſter than the others. As this work was tedious and troubleſome, it was determined to take down this kiln, and build a new one, now in uſe.

This ſecond kiln is of the ſame length and breadth as the firſt; but the hurdles on which the madder is put are raiſed only ſix feet from the ground, and the apertures of the furnace, which ſupply the hot air, are level with the ground: they, beſides, continued to avail themſelves of the miſtaken advantage of encreaſing the ſurface to contain more roots, by making, as in the firſt, three ſtages of ſhelves. The roots indeed dry in it faſter, becauſe the furnace yields more heat; but this heat is very unequally diſperſed at the different heights, and in the different parts of the length of the kiln; becauſe the ſame inconveniencies ſtill ſubſiſt, as they have made in it, like the other, three ſtages, one above the other, and they have formed the kiln long, without letting the furnace extend through its whole length. They have beſides placed the firſt ſtage too near the fire; but this may be remedied by taking it entirely away, and uſing only the uppermoſt ſtage, which is fifteen feet from the bottom of the kiln, and may extend over the whole of it: the heat will then be more regularly diſperſed. The roots may be laid fifteen or eighteen inches thick, and may be much eaſier attended to than on the ſhelves, which occaſion a great deal of trouble: there might alſo be two furnaces, one at each end of the kiln, and the tubes might be carried over the whole length of it.

From what has been ſaid, we may conclude, that to dry a plant like this, which contains a great deal of moiſture, no advantage can reſult from having a kiln with three ſtages, one hurting the other; ſince the heat tending always upwards, the roots muſt be moved higher, which cannot be done without trouble, loſs of time, and expence; whereas, the ſame quantity may be dried in leſs time on a floor raiſed eighteen or twenty feet above the furnace.

It is certain that a peaſant, who raiſes madder after a proper method, will always be a greater gainer than ſuch as are obliged to hire day-labourers. But the peaſant cannot go to the expence either of a kiln, or a mill: it muſt be planters who raiſe large quantities of it, and can afford the expence, that have them: thus, it is to be preſumed, the peaſants will be under a neceſſity either of ſelling their roots green to the dyers, of taking them up in the ſpring to dry them in the ſun, of drying them in their ovens, when they have only a ſmall quantity; or, finally, of carrying their roots to the kiln, as they do their grapes to the preſs.

The Liſle kiln, though built on a good principle, is too expenſive for a young planter. There muſt be ſtrong walls to ſupport the arches, internal abutments, and bricks to build the arches with. In ſome provinces there is not a workman capable of turning an arch in brick-work. The floor requires many large iron-bars. On the other hand, a kiln in the form of an oblong ſquare, like that at Corbeil, will never heat equally in its whole extent, unleſs tubes be made to convey the ſmoke through various parts of the kiln, before it reaches the chimney, or there is a furnace at each end. All this is expenſive, and ſubject to inconveniencies.

Perhaps then a kiln ſomewhat reſembling a malt-kiln would do; and this might any where be built at a ſmall expence: ſuch a kiln need not be above eighteen feet ſquare, and eighteen or twenty feet high from the ground to the floor. Underneath the floor ſhould be a reverſed pyramid, ſomewhat obtuſe at bottom, to receive the funnel and tubes that are to give the ſupply of hot air: this may be made with quarter-ſtuff covered with lath and plaiſter. This kiln does not require any large furnace. The new kiln at Corbeil is much larger, taken from the ſecond ſtage to the bottom; yet has the heat been brought there to upwards of forty-five degrees. The floor of the kiln is to be made with joiſts eight inches by four, covered with laths, grating, or with hurdles as at Corbeil, where it has already laſted ſeven or eight years: there muſt be walls to ſupport the roof and beams, and it ſhould have two windows: there ſhould be a plaiſter-floor eight or nine feet above the grating, with one or more trap-doors, as they let out the ſteam much better than the windows: laſtly, the beams ſhould be plaiſtered. There is reaſon to think that ſuch a kiln would coſt little, and anſwer the intended purpoſe. It ſhould have been obſerved, that over the grated floor ſhould be laid a large thin cloth, or rather a hair-cloth, riſing round the edges, and faſtened with nails: this is particularly uſeful when ſmall roots are dried, as it prevents their falling through. A foot above the roots may be put wooden traverſes, over which may be laid ſtraw-mats quilted on cloth: this will keep down the ſteam, and may be of great ſervice, as has been already obſerved.

The Furnace of this Kiln.

The furnaces of the Liſle and Zealand kilns are certainly neither of them proper for drying madder, any more than thoſe of the malt-kilns: they have all the ſame defect, as they fill the kiln with ſmoke, which damages the roots. It was this inconvenience induced us to endeavour to contrive one that would give a great deal of heat, without the above defect. This may be probably effected, by not letting the funnel be perforated, and carrying tubes from it which ſhould run under the madder before the ſmoke was diſcharged; and by having other tubes run near the fire, to circulate in the kiln a warm air, which they ſhould receive from without. We have made the trial of ſuch a furnace, and confeſs it did not yield ſufficient heat: the furnace ſhould certainly have been made larger; but the expence is a continual objection, which, beſides being conſiderable, is pure loſs to one that makes experiments for the public good, without being in a ſituation of reaping any profit from them. We ſhall cloſe then what we have to ſay on madder-kilns, by concluding, that malt-kilns ſeem well adapted to the purpoſe; but ſome method muſt be found to prevent the ſmoke damaging the roots.

Madder well dried and cleaned may be ſold in that ſtate to the dyers; but if it is to be pulverized, there will be occaſion for a mill, which we ſhall now deſcribe.

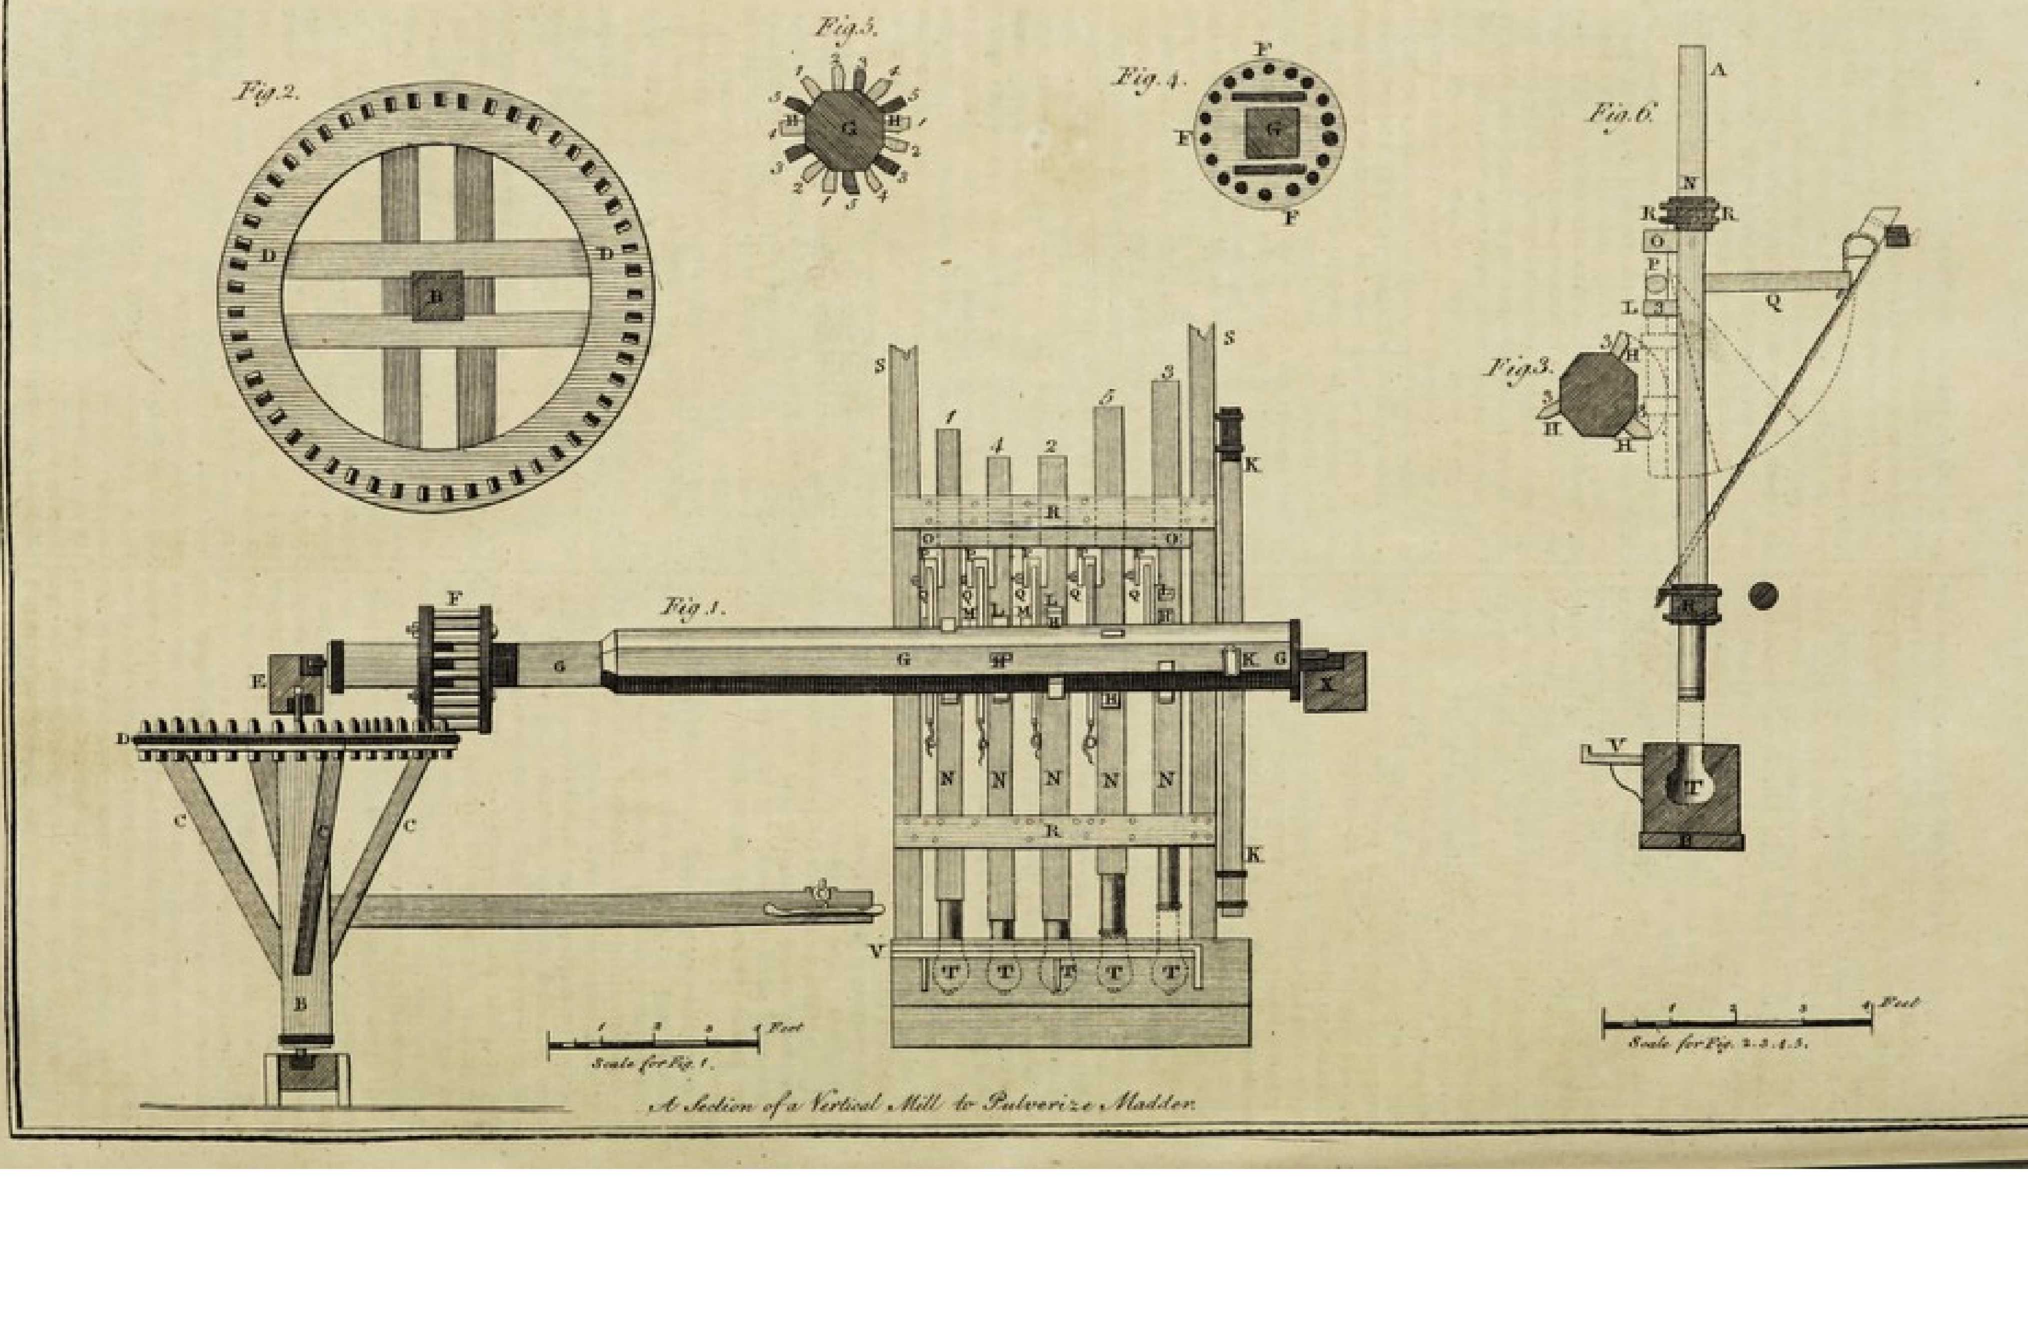
Deſcription of a Mill, at Liſle *in* Flanders, *for pulverizing Madder.*

Plate XIX. Fig. 1. repreſents the parts of a madder mill: it is inſulated, and covered only by a ſlight thatch. The figures 2, 3, 4, 5, and 6, are ſupplementary to the firſt: we muſt have recourſe to them in our explanation of the parts of the mill: they are therefore diſtinguiſhed by the ſame letters, and each piece is repreſented apart.

A is a lever, or pole, nine feet eight inches long, and ſix inches by four in magnitude. B, the axis of the wheel, ſix feet four inches ſix lines high, and nine or ten inches diameter. C, ſtays, or knees, four feet ſix inches long, and four or five inches ſquare. D, the cogged wheel, three feet one inch ſix lines ſemi-diameter, and furniſhed with fifty-ſeven cogs.

The fellies, or circumference of this wheel, muſt be eight inches by four large: they are ſecured by an iron hoop. The traverſes are ſix inches by four thick, pinned and keyed. The cogs are made of apple-tree wood, and project three inches three lines: they are two inches and a half by two, at their inſertion, and two inches and a half by one at the top: and beneath the wheel they are two inches long, and one and a half ſquare: they act on the rounds of the trundle-head about one inch and a half of their length. The pins that faſten them are alſo apple-tree wood.

E is a beam twelve inches ſquare. F, the trundle-head, thirteen inches ſemi-diameter, furniſhed with eighteen rounds, each a foot long, and two inches diameter: the ends of this trundle-head are two inches and a half



A Section of a Vertical Mill to Pulverize Madder.

half thick, and hooped with iron. There are alfo two iron bars pinned on to fecure the joints of the wood.

G is another axle-tree, or turning-beam, eighteen feet fix inches fix lines long, ten inches fquare near the trundle-head, and fourteen inches diameter in its octogonal part. H, lifters four inches nine lines long, five inches broad, two inches and a half thick. Hence it is apparent, that there are fifteen lifters inferted into the axle-tree, to ferve five beetles; that is, three to each. For this reafon the lifters, the catches, and the peftles, are diftinguifhed by the fame figure.

K, flyers four feet five inches long, and four inches fquare: they are loaded with lead at their ends. L, catches, which anfwer to the lifters, H: they project five inches nine lines, and are five inches broad and two and a half thick.

M, other catches inferted into the fides, or thicknefs of the beetles, N, and anfwer to the levers. Q, N, beetles ten feet four inches long, and four inches fquare. They are round at the end next the mortars, and fhod with an iron foot four inches diameter, which may be feen in figure 6. The beetles are numbered in this manner, 1, 4, 2, 5, 3, (Fig. 1.) to fhew the order in which they play when the machine is in motion. O, crofs-bars fix inches by four, which fupport the joints, P.

P, joints eight inches long, fix wide and four thick. An iron pin, keyed, paffes through each joint, and fupports a moveable lever, Q, which acts on the catch, M, when the peftle, N, is to be kept up. Q, levers, two feet three inches fix lines long, three inches thick, by four wide.

R, keeps, fix or eight inches wide to prevent the beetles from being difordered. S, an upright poft four inches fquare, in which the crofs-bars and keeps are inferted. T, mortars cut in a fingle piece of wood fixteen inches fquare: they are eleven inches deep, and their greateft diameter is feven inches: the bottom is lined with lead three or four lines thick.

V, a trough to prevent wafte, over which hangs a cloth, faftened above to the keep, whilft the mill is at work.

X, a beam twelve inches fquare; this beam, and that at the other end, marked E, reft on the timber work that fupports the roof. The fockets and pivots may be fo well comprehended by the plate, that letters of reference were thought unneceffary: the fockets are brafs, the pivots fteel.

We have purpofely omitted giving the dimenfions of every part, to avoid confufion; but the machine may be eafily conftructed by attending to the defcription we have given, which is very exact.

But though the mill defcribed above, is now actually employed in grinding or pulverizing madder at Lifle; yet it labours under feveral imperfections, which we fhall endeavour to point out, and defcribe a mill conftructed in a more perfect manner.

There will be, however, no occafion to defcribe the wheel work of this mill, it being the fame as that of Lifle: it will be fufficient to give the proportion of the parts which compofe it. The pole, or lever, from the center of the axis of the cogged wheel, to the part where the links of the fpring-tree bar are faftened, is nine feet long; the wheel is five feet femi-diameter, and has feventy-two cogs; the trundle-head is ten inches femi-diameter to the center of the rounds, and has twelve rounds; thus it makes fix turns to one of the wheel. The horfe, going three feet in a fecond, makes three rounds and a half in a minute, and the trundle-head twenty. The axle-tree having on its circumference three lifters to every beetle, each beetle makes fix ftrokes in a minute, and the four two hundred and forty in the fame fpace. The fquare part of the axle-tree, on which the trundle-head is fixed, is made out of a piece of wood five inches femi-diameter; the other part of the axle-tree is larger, being feven inches femi-diameter. It is neceffary it fhould be fo large, that the tenons of the lifters may have a proper length and thicknefs: it is much better to be round than an octagon, or any other faced form, as the mortifes may be more regularly made. From the end of the lifters to the center of the axle-tree is twelve inches; fo that in their motion they form a circle two feet diameter: the upper face of thefe lifters is cut in a curve, the radii of which are tangents to the circumference of the above-mentioned circle; the largeft of thefe tangents is twelve inches, and determines the greateft rife of the beetles. By the lifters being thus curved, the refiftance is equal, at whatever height the beetles may be, as they are always in contact with the lifters at the fame diftance from their center of gravity. As there are on the length of the axle-tree twelve lifters in four parts, they form, one with the other, angles of thirty degrees, fuppofing them to be feen one behind the other, as if inferted on the fame plane: on this account, when the firft beetle is raifed to half its height, the fecond is about to rife; the firft quitting the lifter, the third is on the point of rifing, &c. We fay, on the point, becaufe we are to obferve, that the lifters go under the catches, or under that which fupplies their place, five or fix lines; and that the greateft tangent of the curve, being twelve inches, is lefs, by near feven lines, than the fixth part of the circumference of the circle, and gives the firft beetle time to quit the lifter before the third rifes: this is neceffary, that the power may never have more than two beetles to act upon.

The front of the frame-work is that fide before which the axle-tree turns. The frame-work confifts of two beams, ten feet long, and eight inches fquare: betwixt them, at each end, is a traverfe quarter, fix inches by four. In the middle of the length and width of the beams, rife two uprights, which are mortifed and pinned: they are twelve feet eight inches high without their tenons, fourteen inches wide, and fix inches thick, fupported by a brace mortifed into the front at the height of two feet, at the back part four feet and a half. Betwixt thefe two uprights is the block on which the beetles fall: it is made of a piece of dry tough elm, four feet and a half long betwixt the uprights, to which it is joined by a dove-tail two inches thick, and as much deep: it is twenty inches high, and eighteen broad: it refts the whole breadth of its ends on the edge of the beams, and betwixt them, on three pieces of wood, at equal diftances, that lie on the brick-work, which fupports the whole. The block is divided crofs-ways, by a partition two inches thick, parallel with the uprights, and of the fame breadth, fixed into the block by two tenons, and in a groove wide enough to receive its whole thicknefs; the fame is obferved in the back part of the firft keep, which is fixed: the upper end is, in like manner, fixed to the upper-keep: this partition divides the block crofs-ways into two troughs, each twenty inches long, formed by two floping planks; fo that the troughs are four inches and a half wide at the bottom within, eleven inches and a half at the top, and twelve inches perpendicularly high: and to prevent the lofs of the light duft that rifes in the work, the fpace betwixt the edge of the troughs, and the firft keep, is boarded up; the boards at the back-part, as well as the fides of the troughs there, are faftened with grooves and dove-tails into the uprights and partition; thofe before lift up in a groove like a fafh, and are faftened by turn-buckles; the fronts of the troughs take entirely off; the pulverized root is taken out with a wooden fpoon, and a feather broom, and they let it fall on a fhelf before, which has a ledge four inches high: the fronts of the troughs are then put on again, and are filled with branch-madder; the fliding-fhutters are pulled down, and the peftles are fet at liberty to work, which had before been ftopped whilft the troughs were emptied; this takes but little time in doing; and the mill continues going during the time they gather up the root, and bolt or fift it. There are two keeps, which ferve to direct the beetles: the under part of the firft is three feet, and the under part of the fecond ten feet: above the block they are three inches and a half thick; the firft is made level in the front with the back of the groove, that the fliding fhutters may reft on it when they are raifed. Each keep confifts of two parts; thofe at the back are let into the uprights, and pinned to them, and ftrongly faftened to the partition: thofe in the front are made to take down, and put up, as occafion ferves; they flide in the grooves of the uprights, and thofe that run along the middle of the partition: they have, befides, two pins, by which they are kept in their places.

The beetles are, at the lower part, twelve inches wide, eighteen inches high, and four inches thick; so that their face, or bottom, contains forty-eight square inches: the upper part, or stock of each pestle, is eight feet and a half long, four inches wide, and three thick; so that in the whole, they are ten feet long, without comprising the cutters, which are four inches long, and formed like a carpenter's chissel: the blades of them are two inches and a half wide, and the tongues three inches and a half long: there are seventeen to each beetle. There are no catches, because the lifters being in contact with their extremity, always at the same distance, five inches from the center of gravity of the beetles, the resistance occasioned by the friction of the stocks in the keeps, would have been very considerable. To avoid this inconvenience, a mortise twenty-five inches long, and three inches wide, is made in the face of the stocks of the pestles, strengthened on the sides by cheeks two inches thick. The upper parts of these mortises are six feet above the block; that is, on a level with the center of the axle-tree: this part is lined with a plate of copper, strongly screwed, well polished, and rounded at the edge, to facilitate the fall of the beetles. On the side of the beetle-stock, sixteen inches below the upper keep, are fixed catches a full inch thick, two inches high, and projecting four inches, to keep the beetles up while the troughs are emptying.

The levers, which serve for this purpose, are placed behind, and rest on shoulders fixed on a piece of wood, which bears by its two ends on two brackets, mortised and pinned into the two uprights, and supported by braces: these pieces are six inches square. The levers are made of quarter-stuff, six inches and a half square, as well as the lifters of the axle-tree. The upper face of the shortest arm of the lever is rounded like the lifters, in a curve described by the original circle, the radius of which is the space from the middle of the catch to the center of motion of the lever, which should be parallel to the bottom of the catch. The radius of this circle, as well as the greatest of the curve, should be fifteen inches, that the beetle, being raised thirteen or fourteen inches, may not slip off. That the levers may be the stronger, the wood must not be cross-grained; and in the center of motion, it should be traversed by a square iron bar, projecting two inches on each side: these projections, being rounded into pivots, rest on the shoulders in brass sockets. A cord is fastened to the shortest arm, and the end of it is fastened occasionally to wooden pins at the back of the block, to keep the levers somewhat lower than the catches, whilst the beetles are at work. The longest arm lessens by degrees towards the end, till it is reduced to a square: at this part is fixed another cord, which is fastened to the same wooden pins, when the beetles are to be kept up. The above description, with figures on the copper-plate, will be sufficient for an ingenious mechanic to construct a mill of this kind, which will doubtless be of great advantage to this kingdom, as considerable quantities of madder are now planted, and some of it fit for use.

REMARKS.

The beetles of this mill weigh only one hundred pounds with their mounting; perhaps a few pounds more, which may be abstracted by taking off a few inches of the lower part: there are never more than two beetles raised at a time, and one hundred and thirty-three pounds and a half for the power to act upon. A middle-sized horse is generally reckoned able to apply one hundred and eighty pounds of his strength to move a machine, working for four hours together, and going three thousand six hundred yards in an hour: he often goes faster, but so was this mill calculated: there remains then forty-six pounds and two-thirds for the action, which is more than it amounts to in this machine: we may even venture to assert, that the friction of it is less than any other mill of the kind. A horse may bear this work the better, as every five or six minutes there are two or three minutes respite to empty the troughs, and give them a fresh supply. This mill at Corbeil never pulverized above two hundred pounds of roots a day, because that was all the kiln could supply it with; but the time in which this work was done, induces us to think it could easily pulverize four hundred and eighty, or five hundred pounds. They say that the Lisle mill can pulverize five hundred pounds in twenty hours: we scarcely believe it, especially as we imagine it does not work in the night: thus we must suppose it really works only ten hours, like that at Corbeil. Be it as it may, the work of these mills should be calculated by the weight of their beetles, the number of blows they strike in a minute, and the superficies of their bases; that is, the Corbeil mill is to that of Lisle, as four hundred pounds, the weight of the four beetles multiplied by two hundred and forty, the number of blows they strike in a minute, and the product by one hundred and ninety-two, the superficies of the bases of the four beetles, is to three hundred and eighty-five, the weight of the five beetles, multiplied by one hundred forty-two and a half, the number of blows they strike in a minute, and the product by sixty-three, the superficies of the bases of the five beetles; or, after the numbers are reduced, as sixteen is to three; by which it appears, that if the Corbeil mill pulverizes five hundred pounds in twelve hours, that of Lisle should pulverize no more than one hundred.

The indifference they discover in Flanders, with respect to the situation of the kilns and mills, is worthy of blame: they are, it is said, in separate buildings, which have no communication: nothing can be more inconvenient. It is well known at Corbeil, that the root, which they some time ago pulverized in a little hand-mill, fixed in a barn, ten or eleven yards from the kiln, which had no influence to warm it, grew damp, and clogged under the cutters, by which it was much damaged. This work is always done in winter, and it is scarcely possible it should be otherwise: the fogs must therefore be guarded against.

The kiln we have recommended would contain four thousand pounds weight of green madder, which would yield five hundred pounds of dry root when it had been there forty-eight hours: the mill can pulverize this quantity in a day. If one had a very considerable crop, for instance, four hundred thousand pounds, which would yield fifty thousand pounds of dry root, and this is as much as the mill could turn out in four winter months, working every day, it would be necessary to have two kilns. The buildings to contain the kilns and mill might be disposed nearly in the following manner. A building should be erected sixty-three feet long, and twenty-one wide, with a floor twenty or twenty-two feet from the ground, which should be a store-room for part of the green root: the under part should be occupied by the mill and its frame-work, so that at each end there would be a space of eighteen feet to the walls at the extremities: in the middle of this space the apertures of the furnaces to heat the stoves should be made, which should be so situated, that the floors of the kilns should be on a level with that of the store-room: trap-doors might be contrived in the floor of the store-room, to throw the dried roots down; and as they ought to be kept dry till they go to the mill, they may be heaped round the furnaces under the reversed pyramids of kilns; for they should be kept dry till they are barrelled up.

On a supposition that the produce of four hundred thousand pounds might be pulverized in the four winter months, some place should be provided to keep it in proper order till the last went to the kiln: it must be spread at most two feet thick, that it may every day be turned. Experience convinces us, that eight cubic feet of green root weigh one hundred pounds. The surface of the granary will give one thousand three hundred and twenty-three square feet, which, divided by four, give three hundred and thirty quintals and a quarter, or thirty-three thousand seventy-five pounds; but this does not come near four hundred thousand pounds. It is presumed, the best way would be to erect some large building, four or five stories high, which might altogether contain, at least, twelve times as much as the store-room above-mentioned; but this expence might be saved, if the root could be taken up in small quantities during the autumn, winter, and part of the spring.

Explanation of the Figures of the Corbeil *Mill.*

Fig. 4. Plate XVIII. is the frame-work of the mill seen in the front: Fig. 3. is the same frame-work seen endwise, the upright and beam being taken off.

A,

A, beams, eight inches ſquare, ſeen end-wiſe (Fig. 4.) and the length of one of them, which is ten feet (Fig. 5.)

B, traverſe quarters, which are fixed into the beams: the length of one of them is ſeen (Fig. 4.) and the ends of both are ſeen (Fig. 5.) they are ſix inches by four.

C, a flooring or ſtage, laid on the grooved edge of the beams, and the traverſe quarter.

D, uprights, fixed to the beams: their thickneſs may be ſeen (Fig. 4.) the top of one of the uprights only is perceivable (Fig. 5.) over the upper keep, N; and the breadth of the bottom is diſtinguiſhed by two pricked lines on the end of the block which covers it, as the remainder of it is concealed by the middle partition. Theſe uprights are twelve feet eight inches high, ſix inches thick, fourteen inches broad, as high as the axle-tree, then reduced to ten inches.

E, braces, which keep the uprights ſteady on the beams; thoſe in the front are mortiſed at the height of two feet, thoſe behind at four and a half: they are ſix inches by four.

F, the block, on which the beetles fall: it is made of elm, four feet and a half long betwixt the uprights, and twenty inches high by eighteen broad: it has at each end a dove-tail two inches thick, and as much deep, which goes into the grooves of the uprights.

G, a ſhelf, level with the upper part of the block, of the ſame length, twelve inches wide, two inches thick, and a ledge four inches high: it reſts on a groove at the edge of the block, and on the brackets H, Fig. 4 and 5.

I, three pieces of wood, which ſupport the block.

K, the brick-work, which is the foundation of the frame-work.

L, a partition which divides the block into two parts: it reaches from the block to the upper keep; it is two inches thick, and the ſame breadth and ſhape as the uprights: it has on the front, and two ſides next the uprights, grooves which run up till it begins to narrow; there are other ſimilar grooves in the uprights. This partition conſiſts of two parts: the lower part is fixed in a groove of the block, and above with a tenon, and is beſides pinned to the back part of the firſt keep, which is fixed: the upper part is tenoned into the upper part of the firſt keep, and the under part of the ſecond: they go into grooves that croſs the whole breadth of the front parts of the keeps, which are moveable.

M, troughs in which the roots are kept: they are four inches and a half wide at bottom, eleven inches and a half at top, and twelve inches perpendicularly: they conſiſt of two boards ſloping before and behind (Fig. 5.) the ſpace between their edges and the firſt keep is boarded up. In the front *d*, are ſliding ſhutters. The fronts of the troughs take off. In Fig. 4. is ſeen one of the troughs open, and the ſliding ſhutter puſhed up: two of the beetles are alſo viſible, one quite, the other half raiſed.

N, are keeps, three inches and a half: their breadth conſiſts of two parts: thoſe behind are entirely fixed to the uprights: they are ſeven inches broad, notched half the thickneſs of the ſtocks of the beetles, in the parts where they paſs: the other two pieces take off at pleaſure, and are notched in the ſame manner to give the beetles room to work: they have each of them two keys, or tongues, four inches broad, four long, and one thick, which go into the mortiſes in the fixed part of the keep, between the ſtocks of the two beetles belonging to each trough, where they are faſtened by two large pins, *g*. They ſlide on the grooves of the uprights: the undermoſt is ſix inches broad, that the ſhutters may ſlide over it: the uppermoſt is four inches, conſequently projects an inch: the edges are rounded off. The under part of the firſt keep is three feet above the block; the under part of the ſecond, ten feet.

O, beetles, ten feet high: they are twelve inches broad at bottom, to the hight of eighteen inches (Fig. 4.) four inches thick (Fig. 5.) with a ſtock eight inches and a half long, and four inches broad, by three thick. At an inch above the firſt keep, they are left ſeven inches broad, for thirty-ſeven or thirty-eight inches, to make room for a large mortiſe, *b*, twenty-four inches long, and three inches wide. The upper part of the mortiſe is lined with copper, the angle being rounded off. Sixteen inches below the ſecond keep, there are, on the ſides of the ſtocks catches, *i*, two inches high, an inch thick, and projecting four inches. The bottoms of the beetles are ſecured with an iron band, *m*, one inch and a half broad, and four lines thick, and armed with ſeventeen cutters, *n*. The order in which they are placed may be ſeen in Fig. 7. and the ſhape of them in Fig. 8.

P, (Fig. 4.) is a bracket ſix inches ſquare, with its brace, both mortiſed and pinned into the upright (Fig. 5.) There is another on the other upright, not viſible in Fig. 4.

Q, (Fig. 4.) a piece ſix inches ſquare, fixed to the brackets. The end of it might have been ſeen in Fig. 5. but it was not pointed out to avoid confuſion.

R, ſhoulders, reſting on, and pinned to the piece Q, notched at *o*, to receive the levers, Fig. 4. and alſo at *p*, Fig. 5. to receive their pivots.

S, levers which ſerve to raiſe the beetles, and keep them up while the troughs are emptied: they reſt on ſhoulders, R, where they play: they are made of a piece of even grained wood ſix inches broad, and two inches and a half thick: the length of the ſhorteſt arm is fifteen inches; that of the longeſt ſixty inches. The center of the point ſhould be on a level with the under part of the catches. At the extremity of the long arm is faſtened a cord, *g*, which is fixed to the pins, *r*, in the block, when the beetles are raiſed thirteen or fourteen inches. Another cord, *s*, is faſtened as near as poſſible to the end of the ſhort arm, which is tied to the ſame pins *r*, when the beetles are at work.

T, the turning axle-tree, ſeen endways, Fig. 5. and in front, Fig. 6. It is round, and fourteen inches diameter. It is furniſhed with twelve lifters, on four planes, ſo diſpoſed, that, when it is at work, the lifters anſwer the mortiſes, *b*, Fig. 4. by which they raiſe the beetles, without touching the ſides: they may all be ſeen in Fig. 5. Thoſe that are on the ſame plane, are diſtinguiſhed by the ſame figures, 1, 2, 3, 4, as well here as in Fig. 6. They are made out of pieces of wood, ſix inches broad, and two inches and a half thick: their tenons, X, Fig. 5. are two inches and a half by two, and as long as poſſible, without touching in the center of the axle-tree. From the center of the axle-tree, to the point of contact of the levers with the mortiſes, *b*, is twelve inches: this point is five or ſix lines under the mortiſes. Great care muſt be taken, that the tenons of the lifters be not made of croſs-grained wood.

V, V, (Fig. 7.) the baſe of a beetle, to explain the manner of placing the cutters, which are repreſented by black lines, as if only their edges were ſeen. The pricked lines make the diviſion of the ſuperficies to arrange them.

Y, (Fig. 8.) one of the cutters, marked *n*, Fig. 4, and 5. The height from the upper part of the ſhoulder to the edge, is four inches; the tongue three inches and a half; its largeſt part half an inch ſquare; the ſhoulder about eighteen lines diameter: the edges twenty-ſeven lines broad; they ſhould be ſteeled and ſhort.

The Fig. 7. and 8. are drawn by a ſcale, four times as large as the reſt, that their parts might be the better diſtinguiſhed.

MADS, earth-worms.

MAIZE, a ſpecies of grain ſo generally uſed for food in America, that it has obtained the name of Indian corn.

The ſize of its ear differs greatly, according to the fertility of the ſoil, and the warmth of the climate in which it is cultivated; but, at a medium, it is about a ſpan long, and commonly has eight or more rows of grain, each of which uſually contains upwards of thirty ſeeds, of various colours, as red, white, yellow, blue, olive, greeniſh, blackiſh, ſpeckled, ſtriped, &c. ſometimes in the ſame field, and the ſame ear: but the white and yellow are the moſt common: nor does this diverſity of colours ever reach beyond the outſide of the grain, the flour of which always is white, with a little tinge of yellow. Theſe ſeeds, which are as big as large peas, are round at their outer ſurface, very ſmooth, and ſet extremely cloſe, in ſtraight lines. The ear is cloathed and armed with ſeveral ſtrong thick huſks, which defend it not only from unſeaſonable rains, and the cold of the night; for it does not ripen fully in ſome places, till towards the latter-end of September, but alſo from crows and other birds, which,

which, being allured by the sweetness of the grain before it hardens, flock to it in great numbers, suck through the top of the outer covering, and devour as far as they can reach. In the northern colonies, the stalk of this plant, which contains a remarkably sweet pith, and is jointed like a cane, does not grow near so high as in the southern parts. It has long leaves, almost like flags, at every joint, and at the top a bunch of flowers, of various colours, highly pleasing to the eye. The northern Indians, far up in the country, have a species of this grain, called Mohawk's corn, which never grows high, and, though planted in June, ripens in due season. The general time of planting it, is between the middle of March and the beginning of June, or, more particularly, from the middle of April to the middle of May.

Mr. Ray was of opinion, that there are only two really distinct species of this plant; but Mr. Miller is certain there are three, which do not alter by culture, and he enumerates them in the following manner:

" The first of these, with yellow grains, grows naturally in the islands of the West-Indies, and has a very large strong stalk, which rises to the height of ten or twelve feet. Its leaves have a broad white mid-rib, are long, broad, and hang downward. The male flowers (for maize has both male and female flowers, situated at remote distances on the same plants) come out in branching spikes at the upper part of the stalks, and are from eight to ten inches long. The female flowers come out from the bottom of the leaves on the side of the stalk, and are disposed in a close, long, thick spike, which is covered closely with their leaves: out of the end of this cover hangs a thin long bunch of filaments or threads, which are supposed to convey the *farina fœcundans* of the male flowers to the germe of the female. When the seeds of this sort are ripe, the spikes or ears are nine or ten inches long, and sometimes a foot: but these rarely ripen in England.

" The second sort, which has white grains, is cultivated in Italy, Spain, and Portugal. The stalks of this species are slenderer than those of the former, and seldom rise more than six or seven feet high. Its leaves are likewise narrower, are hollowed like the keel of a boat, and their tops hang downward. The spikes of the male flowers of this are shorter than those of the former sort, and the ears, or spikes of grain are slenderer, and not more than six or seven inches long. The grains of this sort do not come to maturity in England, unless the season proves very warm, and they are planted early in a warm soil and situation.

" The third species, which has a yellow and white spike, is cultivated in the northern parts of America, and also in Germany. The stalks of this are slender, and seldom rise more than four feet high. Its leaves are shorter and narrower than those of the two former, are hollowed like the keel of a boat, and their tops hang down. The spikes of the male flowers of this sort are shorter than those of the others, and the ears, or spikes of grain, are seldom more than four or five inches long. This sort ripens perfectly well in England, in as little time as barley, and therefore may be cultivated here to advantage."

This plant is seldom cultivated in England for use, tho' it might probably turn to good account, as was lately experienced by a gentleman in Lincolnshire, who planted this corn in an open field, where it ripened perfectly, and yielded an abundant crop; but very great quantities of it are raised in Asia and Africa, in several parts of France, in Italy, Germany, and North America; its culture in the latter is given in the following manner, by a very worthy and ingenious gentleman of that country, who speaks from his own knowledge.

" The English in North America plough the ground thoroughly before the grain is planted. They seldom, if ever, dung the whole face of the field, but sometimes put a little dung in each hill of corn, if they think the ground requires it. Where fish are plenty, in the planting season, they put two or three small fish into each hill, with the grain.

" In order to plant the corn, they make trenches, or furrows, with a plough, across the field, at certain distances from each other, and cross these with others of the same distance, which divide the field into squares; and where the trenches intersect, the grain is put in, and covered. Three or four grains are commonly planted for each hill. The intermediate ground is afterwards ploughed at leisure, as the plants grow, and want more loose earth for the roots to spread in. The hills are made at the time of weeding; some loose earth being then hoed up over the roots, and round the stems or stalks of the corn.

" The corn is planted at different distances in different places. In the northern colonies, the Indian corn grows low; seldom exceeding four or five feet in height; and the leaves being proportionably small, the plants do not require so much ground as in the southern colonies, where they frequently rise to fourteen or fifteen feet. The space generally allowed for the lowest plants, is three feet, and for the highest five or six. This distance may be more necessary in our manner of cultivating this corn; more ground being required to nourish three or four plants than one; for I do not know that we ever pluck up any of the plants. An advantage attending this method is, that the labour is less in hilling; three or four plants being earthed up in the same time as one; and there is more room for passing between the rows when the corn is to be weeded.

" At the same time that the corn is weeded, the ground is loosened round the plants, with a hoe, and the hills are raised and enlarged from time to time, by adding more earth. The morning, before the dew is off, and the evening, are reckoned better for this work, than the middle of the day.

" The hilling of the corn, as it grows, has been the universal practice: the design being to give the plant more nourishment, and to support it better against the winds: but of late, some planters have thought it better to plant in holes: the reason is, that this plant requires a good deal of moisture; and indeed nature, by the form and position of the leaf, appears to have intended the receiving of the rain that falls around, and conducting it to the stalk, and by that down to the roots: but a hill round the stalk, tends to throw the water off to a greater distance: and as to supporting the plants, they say the hills do not affect it, because, by covering the stalks in that part from the air and sun, which would harden and strengthen them, the mould around them keeps them soft and tender, and thereby rather weakens them.

" The panicles, or tossils, contain the *farina fœcundans* of the plant, and therefore should not be cut off till the grain in the ear is filled. If the tossils of a whole field should be cut off before that time, there would be no grain at all in the ears. This has been proved by experiment.

" In the more southern colonies, where hay is scarce, and the leaves of this corn are very large, they cut them off for fodder: but in the northern colonies, where there is plenty of hay, and the leaves of the corn are small, they generally neglect cutting off the tossils, and stripping off the leaves. They are left on the stalks, and the cattle, being turned into the fields, after the corn is gathered in, eat what they like of them: but they are not esteemed so good as what has been cut in season.

" An easy way of taking the grain out of the ears is, to rub one against another, holding one in each hand.

" When the ears are stript of their husks, they are reckoned in the best state for preservation; much better than when the grain is rubbed off from the ear: for then, they say, insects can get at the soft part of the grain, and eat into it, which they cannot do while the soft part is connected with the cob in the ear, and the hard flinty part of every grain turned outward, and the grains close to each other.

" To preserve this corn, they make in North America a sort of bins, or cages, which they call corn-cribs, 15 or 16 feet long, and five or six wide, widening upwards to the top a foot or more. They are made of sapling poles, three or four inches diameter, framed roughly together, by notching the ends where they cross the corners, at such a distance from each other, as but just to keep the ears from falling through, that there may be a free passage for the air. These bins stand abroad, and have a slight moveable covering, or thatch, to keep out the rain. The Indians burry their corn in holes in the ground, lined with mats and dry leaves.

The manner of using this corn in America, is various. It has this advantage over wheat, that subsistance may be drawn

drawn from your corn-fields long before the general harveſt: for the green ears roaſted, are delicate food; and as the corn ripens and grows harder, the ears boiled are good eating, with butter and ſalt. When it is ripe, the corn parched and ground into meal, is the hunting and war proviſion of the Indians, being light to carry, and affording good nouriſhment. They mix a little of it with water, and it needs no other cooking, having already paſſed the fire in the parching. The grain ſoaked in water, will part with its ſkin when beat in a large mortar with a wooden peſtle: then it is boiled, and eaten with milk. Being pounded coarſely, dry, it is alſo boiled and eaten as rice. Bag puddings, and baked puddings made of it properly, are very good. The meal is alſo boiled with water, to make what they call a haſty pudding, which they eat with butter and ſugar, or with milk. This haſty pudding, or boiled meal, being mixed with twice as much dry wheat flour, and worked into loaves, makes much better and pleaſanter bread than flour alone. All creatures fed with Indian corn, have firm and fat fleſh: the pork of corn-fed hogs, is reckoned the fineſt in the world for taſte and goodneſs; their fat is milk-white, and as hard as butter. The horſes of Virginia and Maryland, whoſe chief fodder is the leaves and ſtalks of this corn, are reckoned the hardieſt of the ſpecies, bearing moſt labour, and requiring leaſt care; and the people of thoſe countries where it is the common food of men, are healthy, ſtrong, and hardy."

This corn is thought to keep better than wheat, and has frequently been of infinite ſervice in many countries in times of ſcarcity of other grain. It anſwers all the purpoſes of the white pea, of about the ſize of which its grains are, and would certainly be a better ſubſtitute for the poor, than bean-flour, or ſome other ſorts, which have been uſed even in England, where maize may doubtleſs be cultivated to advantage in light ſandy lands, in which beans and peas do not thrive well. It is excellent for feeding poultry, either given whole to the larger ſort of fowls, or broken a little for the ſmaller. The Breſcians, in particular, who are remarkable for the fatneſs of their capons, uſe a great deal of it for this purpoſe. The Indians reckon it a good remedy in all acute diſorders; and it has been obſerved, that thoſe people are very little ſubject to the ſtone, which ſome aſcribe to their living upon this corn. They extract from its ſtalk, when green, a ſweet ſyrup, which anſwers all the ends of ſugar; and when the ſtems are diveſted of their ears, and dried, they make excellent fences, coverings of ſheds, &c.

The Indians, and ſome Engliſh, particularly where the ground is good, and has been well manured with fiſh, plant with the maize, in every corn hill, a kind of French beans, which run up the ſtem of the corn, and are ſupported by it: others plant potatoes, gourds or pumkins, and others again ſow turneps, in the intermediate ſpaces between the hills.

Some curious perſons, by way of experiment, have planted ſeeds of only one colour in the ſame field, without any other coloured ſeeds near them, and their produce has been intirely of the ſame colour: but when the rows have been planted alternately with grains of different colours, they have interchanged, and produced a mixture of all the ſorts in the ſame row, and frequently, as was ſaid before, on one and the ſame ſpike. It is even affirmed, that they will mix with each other at the diſtance of four or five rods, if no tall fence or building ſtands between, ſo as to intercept their communication.

Mr. Miller, who mentions this, very rightly recommends the horſe-hoeing huſbandry, as, in all reſpects, fitteſt for the culture of maize; and gives the following as a method in which it has ſucceeded beyond expectation.

The land, which was very light and ſandy, and far from being rich, was ploughed deep before winter, and laid up in high ridges till the ſpring, when it was broken fine with the harrow. It was ploughed again in April, laid level, harrowed ſmooth, and then ſowed in drills four feet aſunder, into which the ſeeds were dropped at the diſtance of about eight or nine inches from each other. When the plants were about three inches high, they were thinned with a hand-hoe, by cutting up ſome of them where they grew too cloſe, and the intervals between the rows were ploughed ſhallow, to deſtroy the young weeds: but when the ſtems were advanced, the ground in the intervals was ploughed deep, and the earth laid up to the plants on both ſides; and when the weeds began to grow again, a third ploughing was given, to deſtroy them. This kept the ground pretty clean from weeds till the corn was ripe, as the ſeaſon did not prove wet; for otherwiſe a fourth ploughing would have been neceſſary. Each of the ſtalks of theſe plants produced from three to ſix ſpikes of grain.

Sir Richard Bulkley, who planted ſome of this corn in Ireland, from ſeed which grew in Brandenburgh, had, from each of his grains, which were ſet a foot aſunder in rows about a yard diſtant from each other, from three to ſix ſtems, and upon each ſtem three ſpikes or ears of corn, with two hundred and forty grains in each ſpike. An amazing increaſe!

Some good huſbandmen in France, have cultivated this grain upon nearly the ſame principles as thoſe which Mr. Miller points out. The little differences in their methods may not be un-inſtructing: for which reaſon we ſhall here give the ſubſtance of M. Duhamel's account of their management of this corn.

"Maize thrives better in a light and ſandy ſoil, than in ſtiff and clayey land. It cannot do without dung; and the ground intended for it ſhould receive two good ploughings in March. A third ploughing, which is given towards the end of April, makes the furrows for the ſeed; and what clods remain after this, are broken by hand, the furrows then preventing the uſe of a harrow.

"A fine clear day is choſen in May, to ſow the ſeed, which is done by making at the bottom of the furrows, with a ſtick or other inſtrument, ſmall holes, into each of which two grains of maize are dropped. The furrows are a foot and a half aſunder; and the holes, at the ſame diſtance from each other, are diſpoſed in ſuch manner that they form a kind of quincunx.

"When the corn is riſen, the weakeſt of the two plants is plucked up, where both ſeeds have ſprung; and where neither of them has grown, two new grains are planted.

"Towards the middle of June, the ground is hand-hoed round each plant; and as they ſtand in the bottom of a furrow, the mould which crumbles down, from time to time, lays freſh earth to their roots, and helps to ſupport them. About the end of July, a ſlight hoeing is given them, which is the laſt; and in ſo doing the earth is laid toward the roots of the plants.

"The panicles of the male flowers, which grow at the top of each plant, and are well known not to contain any grain, are cut off about the middle of Auguſt. But care muſt be taken that the grain be impregnated before they are cut off; which may be known by the then turgid appearance of the outward covering of the ears: nor ſhould the panicles be cut off from all the plants at the ſame time; becauſe ſome of the ears are not impregnated till a fortnight after others. Theſe panicles are excellent food for cattle. When they are cut, or ſhortly after, all the leaves are ſtripped off the ſtalks, together with all the blighted and ſmutty ears: for it is ſaid that the good ears would not grow ſo large, nor the grains be ſo well nouriſhed, if they ſhould be left upon the ſtalks. All theſe leaves and ears are given as fodder to oxen; and it is remarkable, that thoſe creatures are fonder of the ſmutty ears than of all the reſt.

"The time for reaping maize is towards the end of September. The ears are then gathered by hand, and put into baſkets, in which they are carried and laid in heaps from ſpace to ſpace in the field; after which they are loaded in carts, carried home, and ſpread upon an even floor prepared for that purpoſe. They are then taken out of their ſheath or hood, and dried in the ſun before they are laid up in the granary; or elſe the grain is taken out at that time. Maize which has been well dried in the ſun will keep ſeveral years, and not be the leſs fit for ſowing. The granary ſhould be very dry, and the corn laid up in it ſhould be turned at leaſt every three months, to prevent its growing muſty, or being attacked by inſects.

"There are two ways of taking out the grain. The firſt, which is the moſt expeditious, is by threſhing it with a flail: but in this method a great deal of the corn is broken or bruiſed. The ſecond, and more common, is by by rubbing the ears hard against the edge of a flat piece of iron. This easily separates the grains from the spike, or cob, without hurting them, and this remainder of the ear is very good food for oxen.

" As soon as the ears are gathered, the stalks remaining in the ground are plucked up, and laid by for winter fodder, for oxen. The field is afterward ploughed up as soon as possible: it being the general opinion of farmers, that the roots of the maize would otherwise continue to suck up the rich particles of the earth. Whether this be true, or not, their notion is, that if this ploughing should be deferred, the next year's crop would certainly suffer by it.

" When maize is planted only for fodder, particularly of cows and oxen, it is sowed very thick, and harrowed in, or covered with a rake, in a good soil, which has been ploughed twice, and well dunged: but it is observed, that in these thick sowings, all the female flowers are barren, and produce no grain: and it likewise is so great an impoverisher of land, that though the ground be dunged every time it is planted, wheat never does so well where this corn has grown, as in the neighbouring fields where it never was."

M. Aimen, M. D. in the province of Guyenne, where great quantities of this corn are raised, observes to M. Duhamel, 1. That it is important to sow maize rather in the beginning than at the latter end of May; because, if it is sowed early, the plants will have acquired sufficient strength before the great heats, to shoot out then with vigour; nor will their ears be burnt, or liable to that barrenness to which they are subject when this corn is sowed late; besides which, the stalks will be stronger, and their ears larger and fuller of grain. 2. That the ears of maize are greatly hurt by cutting the panicles too late; and that they ought to be cut before the hoods are open. By leaving a plant with its male flowers at every twenty feet distance, all the female ears will be impregnated.

In two different, but successive years, this gentleman singled out two rows of maize, the plants of which seemed to him equally strong. He cut off the panicles of the male flowers of all the plants in the first row, before their hoods opened, and let the panicles of the other row remain till the usual time of performing this operation: the consequence was, that the female ears of the first row were much the largest and best filled with grain.

He likewise sowed a row of maize at a distance from any other field planted with that corn, and cut off the panicles of that row before the hoods were opened; leaving only one plant with its male flowers at every twenty feet distance. At harvest, he observed, 1. That all the female ears of all the plants were impregnated. 2. That the female ears of the plants which had lost their male panicles early, were thicker, longer, and fuller of corn than any others. 3. That the female ears of the plants whose panicles had been cut late, were smaller and shorter, and that in some parts of them the grains were abortive.

To satisfy himself whether it be best to sow maize thick, or thin, he planted three different spots of ground with this corn, on the third of April 1753. The seed used for the first, where the grains were placed about a foot and a half asunder, according to the common practice of the country, in which experience had instructed the husbandman, weighed one ounce and one pennyweight: the second, in which the grains were only a foot asunder, was sowed with two ounces and two pennyweights of seed: and the third, in which they were but six inches apart, was sowed with four ounces and a half. The first of these spots produced eighteen pounds and four ounces of grain: the second, fifteen pounds seven ounces: and the third, eleven pounds two ounces. A manifest proof, as M. Duhamel observes, that some sorts of grain will not thrive unless they are sown very thin; and that, for want of this precaution, a great deal of corn is often lost, and the crops are considerably diminished.

As maize is a large plant, and requires much nourishment, it would certainly be right to try the culture of it with the horse-hoe: to this end, it will be proper to plant the rows two feet asunder, and the grains in them twelve or fourteen inches apart. All the necessary hoeings may then be given with the cultivator drawn by one horse; and I believe, with Mr. Miller, M. Aimen, and M. Duhamel, that the corn will thrive the better for it, and the land be afterwards fitted for other grain. It is worth the while of those who live in the countries where maize is cultivated, to try what will be the effect of this method.

MALANDERS, cracks in the bend of a horse's knee, that discharge a sharp indigested matter; they are often the occasion of lameness, stiffness, and the horse's tumbling.

This distemper is cured by washing the parts with a lather of sope warmed, or old chamber-ley; and then applying over the cracks a strong mercurial ointment spread on tow, with which they should be dressed, night and morning, till all the scabs fall off: if this should not succeed, anoint them night and morning with a little of the following, and apply the above ointment over it.

> Take of Æthiops mineral half an ounce; white vitriol one dram; soft green sope six ounces: anoint with this often, but first clip away the hair, and clear the scabs. On their drying up, it may be proper to give a gentle purge or two; or the nitre-balls may be taken advantageously for a fortnight or three weeks. *Bartlet's Farriery.*

MALT, is barley prepared, to fit it for making a potable liquor called beer, or ale, by stopping it short in the beginning of vegetation.

It is said, that the soil on which barley grows makes a considerable difference in the grain, and that the barley fittest for malt is that which grows on a rich, light, or gravelly soil, and which has been raised from seed brought from a farm of a different soil and situation. The fullest and largest grains of such a crop should be chosen for making malt. It should be heavy and perfectly sound, and such as has not suffered any accident in the field. Its being a little heated in the mow, is by some reckoned an advantage, because the grain will be the more equally dried, and will consequently the more equally imbibe water. If it has been so much mow-burnt as to look blackish when broken at the root end, or, as Mr. Combrune says, if it has suffered a heat of 120 degrees, it is unfit to make good malt. It is also found by experience, that barley taken immediately from the field does not malt so kindly as that which has been some time in the house, or mow. Special care should be taken that it be free from the seeds of weeds; for these, in the malting, are apt to give the grain a bad taste, which cannot be afterwards got rid of.

By germination, all the principles of barley are put in action. The heat which it undergoes in malting separates and divides its parts; and the viscidity which it before possessed is removed by the looser texture of its oils, and their intimate union with the salt, which gives malt the sweetish taste that distinguishes it from barley.

In order to its being malted, the barley is put into a cistern lined with lead or stone, and covered with water about six inches deep above the barley, to give room for its swelling. All the good grain will sink in the water; but, after stirring it, the imperfect or distempered grains will rise to the surface. These should be skimmed off, and given to poultry or hogs, for they will never make good malt. By the water's gaining admittance into the barley, a great quantity of the air is expelled; as appears from the number of bubbles which rise on the surface.

The barley is left in the water two or three days, more or less, in proportion to the heat of the weather and the dryness of the barley. A judgment is formed that grain is fully saturated with water, from its appearing turgid, and easily giving way to an iron rod dropped perpendicularly into it. Or, take a corn from the middle of the cistern, and hold it steadily, by the two ends, between the fore-finger and thumb: press it gently, and if it continues firm when so pressed, and the skin does not break, it must soak longer: if it crushes together and feels mellow, and the skin crack, it is watered enough. Nicety in this is a material point, and can be learnt only by experience. If the grain should be suffered to remain too long in the water, it would begin to to lose part of its sweetness. When it has been steeped sufficiently, the water is drawn off.

The water used for this purpose should be that of a clear running stream, or rain water; or, if such cannot be had, pond water, provided it be sweet and clean, will do very well; or pump water, which should be rendered soft if it be naturally hard. If the water made use of is any way tainted, it communicates to the malt a taste which it never loses. Mr. Combrune advises the adding of lime to the water in which the barley is steeped: but this seems to be improper, because it appears from Dr Home's experiments that lime renders water hard.

From the cistern, the barley is laid in a regular heap, or couch, where it must remain thirty hours, or till it contracts a heat. It must then be worked in one or more heaps, and turned every four, six, or eight hours, according as the weather is cold or hot. When it begins to spire, it should be turned every three or four hours, according to the temperature of the air; and as it comes (for so its spiring is commonly termed) the heap must be spread thinner to cool it, lest it be heated too much, and the germination be carried on too fast, by which the oils would be too much consumed. The turning of it must be continued in proportion as it is more or less slow in growth, so that it may be brought tolerably dry to the kiln. When the roots begin to deaden, the couch must be thickened again, and often turned, that the growth of the roots may not revive. At this time, the spire should be near piercing through the outer skin of the barley: for if it grows quite out, the strength of the malt will be too much consumed. After the malt is made thus far, the common practice is to lay it at once on the kiln: but the best way is to gather it all up in one heap, to let it lie in that state twelve hours, and then to turn it every fourth hour, during the space of twenty-four hours.

No person should be suffered to tread on the malt with their shoes, while it is on the floor; because many grains are inevitably bruised thereby, and these, vegetating no longer, afford the roots of the other grains a substance into which they extend their fibres, and are by that means intangled in bunches: and besides this, the bruised corn acquires a degree of putrefaction which taints the liquor made of the malt intermixed therewith. Equal care should also be taken, that the grain be not bruised by any other means.

Mr. Combrune thinks, that the time most proper for malting is when the temperature of the air is such that barley begins naturally to germinate, at which season the thermometer marks from between thirty-two to forty degrees. How far that time may be extended, experience alone can determine. The warmer the weather is, the greater must be the disadvantage under which the maltster labours; because the motion of the fluids is then so strong, that the process goes on too quick, and the finer parts are apt to fly off; the consequence of which is, that instead of a sweet, the malt inclines to a bitter taste, the oils being turned rancid. This is so universally experienced, that brewers carefully avoid purchasing what is termed latter made malt.

The grain thus prepared for drying is spread on the kiln, where, meeting with a heat greater than is suited to vegetation, its farther growth is stopped. It is spread on the kiln three or four inches thick, and turned every three or four hours. The laying of it thicker is attended with inconveniencies, among which is particularly its being unequally dried; and therefore that should be avoided. The strength and duration of the fire is different, according as the malt is intended to be dried, pale, amber, or brown. The pale malt requires more leisure, and less fire, than the amber or brown.

Pale and amber malt are dried with coke or culm, which not emitting any smoke, give the malt a brighter colour, and do not communicate that bad relish which malt has when dried with wood, straw, &c. the smoke of which taints it. Coke is best, because its fire gives a steady and constant heat, whereby the malt is dried uniformly. If wood, or any vegetable fuel is used, it should be extremely well dried, in order that, being as free as possible from moisture, it may yield the less smoke.

The size of the malt kiln is generally proportioned to the quantity of malt for which it is intended. Some build their kiln square, and others make it round; but this last is undoubtedly the best form, because the heat of the fire is more equally diffused therein, and the grain is of course more equally dried. Various substances have been made use of for covering the kiln, such as tiles, plates of tin, and wire: of these, the wire is to be preferred, because it does not contract so great a degree of heat as to parch the grain in contact with it: but, for this very reason, hair cloth is preferable to any other covering; because, when any part of the malt is in immediate contact with a substance much more solid than itself, and therefore capable of receiving a proportionably greater degree of heat, the malt in contact with that heated body is parched or burnt, by heat which is not equally diffused through the whole mass, which mass cannot therefore be all equally heated. The hair cloth is spread upon small wooden rafters, and these are supported by bars of iron laid across the kiln.

An ingenious and attentive maltster marked the degree of heat in the malt whilst on the floor: and the result of his observations in this respect is as follows. During the first ten days that the malt was on the floor, the heat in it was between 50 and 60 degrees. During the next three or four days, the heat was increased from 60 to 65 and 67 degrees; and during the last days of its lying there, to 80, 84, and 87, which last was the degree of heat when the malt was put on the kiln. There cannot be any absolute rule as to the difference of heat during the different times in the process of malting, because it must be suited to the heat of the air: at least we have not yet sufficient data whereon to found such a calculation. The heat of the malt on the kiln when fit for pale malt was 120 degrees, and when it was fit for brown the heat was 147.

This intelligent artist's observation, that the malt was fit for what is called pale malt when its heat was at 120 degrees, suggests a caution which should be most carefully attended to, namely, that whatever colour it be intended to give to the malt, the heat at first should always be the same: thus, for example, malt which is dried to the degree of high brown, should first be rendered pale malt, then amber, and so on progressively; not by a sudden increase of the fire, but by a longer continuance thereof. In this manner, the whole body of the grain is equally and gradually dried; whereas a strong and quicker fire would parch, or as it were singe the outside, while the internal parts remain moist: and as that moisture is afterwards evaporated, it must crack the surrounding hardened crust, whereby the grain is again damaged in another respect.

As soon as the malt is dry, it must be removed from the kiln, and spread thin, that it may cool to the temperature of the air. It cannot be supposed, that any of its parts are capable of retaining the fire in such manner as not to suffer it to escape; though some have conceited that they do. In proportion as malts are dried, their particles are more or less separated, and coming in contact with water, they strongly attract from it particles which fill up their interstices. In mashing, this action between the malt and the water generates a small degree of heat, but no way durable; though from hence arose the opinion, that brown malt is full of fire.

Barley may, at a medium, be said to lose, by malting, one fourth part of its weight, including what is separated from it by the roots screened off: but this proportion varies, according as it is more or less dried.

The condition of the barley, as to its greenness or ripeness, at the time of its being gathered in, is clearly discernable when it is melted. If it was gathered green, it rather loses than gains in quantity, the malt becomes of a smaller body, appears shrivelled, and often is unkindly hard; whilst, on the contrary, that which was cut at full maturity increases in malting, appears plump, bright, and clear, if properly carried through the process, and, on being cracked, readily yields that fine mealy substance so much desired by the brewers.

Malt which has not had a sufficient time to shoot, so that its plume, or acrospire as the adepts in malting call it, may have reached to the inward skin of the barley, remains charged with too large a quantity of it's unattenuated oils. All thoſe parts which have not been put in motion by the act of germination, will, when laid on the kiln to dry, be ſo hardened, as not to be ſoluble in water, and conſequently will be loſt to the ſtrength of the drink.

When malt is ſuffered to grow too much, or until the ſpire has ſhot through the ſkin of the barley; though all that is left be malt, yet, as too large a portion of its oils will have been expended in vegetation, the malt will be greatly diminiſhed in proportion to what it ought to have been, and what remains cannot be fit to brew drink for long keeping, becauſe of the loſs of the oils.

Malt which has been duly worked on the floor, will, if it has not been ſufficiently dried on the kiln, be apt to germinate or ſprout afreſh; perhaps to conceive ſo great a heat as to take fire; and ſhould it continue long with a moderate degree of heat, the leaſt evil that can be expected, is that it will grow mouldy and have an ill flavour.

Malt well worked, but over-dried, will be ſo hardened, or its ſaponaceous quality will be ſo deſtroyed, that it will not imbibe from the air that moiſture which is neceſſary to mellow it, and render it fit for brewing: for when it has been previouſly ſoftened by the moiſture of the air, it mixes more eaſily and more intimately with the water, and by that means yields a more copious extract, than it would otherwiſe do.

Malt juſt, or but lately, taken from the kiln, remains warm a conſiderable time. Until it becomes as cool as the ſurrounding air, it does not mellow by the addition of a due quantity of moiſture from the air: and the wort made of ſuch malt requires a much longer boiling before it breaks, than that which is made of malt ſome months old.

The practice of thoſe maltſters who ſprinkle water on malt newly taken from the kiln, to give it the appearance of having been made a proper time, or, to uſe their own expreſſion, to plump it, is highly blameable. It is, in fact, a downright fraud, practiſed chiefly becauſe leſs grain then fills the buſhel: but a farther evil is, that if it be not uſed ſpeedily, it heats, ſoon grows mouldy, and ſuffers great damage.

Malt dried on a kiln not ſufficiently heated muſt require a proportionably longer time for it to receive the due effect of the fire: for want of which it will be in the ſame ſtate as malt not thoroughly dried. Or if the fire be too quick, or too fierce, inſtead of gently evaporating the water from the corn, it ſcorches the outward ſkin, and ſeparates it from the body of the grain. The malt to which this happens is called blown malt; of which Mr. Combrune obſerves, that, by the internal expanſion of its parts, it occupies a larger ſpace than it ought to do. He adds, that if ſuch a fire be continued, it changes ſome parts of the grain into ſo brittle a ſubſtance, that the malt is ſaid to be glaſſy. The particles which are thus hardened will not diſſolve, or but in ſmall proportion: ſo that they frequently occaſion an almoſt total want of extract, which, in the phraſe of the art, is termed, ſetting the griſt.

The goodneſs of malt may be known by the following marks. Bite a grain of it aſunder, and if it taſtes mellow and ſweet, breaks ſoft, and is full of flour from one end to the other, it is good. If it has a round body, and upon putting ſome grains of it into water, they ſwim on the ſurface, it is good. Barley ſinks in water, and malt that is not well made will do the ſame: but it is to be obſerved that this is not an invariable proof, becauſe, if the malt be broken, or in the leaſt cracked, it will take in water, and ſink. Malt that is rightly made will not be hard, but of ſo mellow a nature, that if drawn over an oak board, acroſs the grain, it will leave a white line upon the board, like a mark of chalk. Its ſmell alſo may be conſulted; for malt, though otherwiſe good, may have contracted an ill ſcent from the fuel, or from the water uſed in the ſteeping.

Before malt is ground, it ſhould be freed from the tails and duſt, which would otherwiſe heighten the colour of the wort, render the liquor muddy, and give it a bad taſte, which could not afterwards be got rid of. The cylindrical ſieve will be of excellent uſe for this purpoſe.

The malt muſt be broken, in order to its communicating its virtue to the water. If it be ground too ſmall, its flour will mix too freely with the water, and cauſe the wort to run thick. Many are of opinion that the beſt way is only to crack it, ſo that none of the grains may come out whole: for the intent is, that the water ſhould draw out an extract, but not be mixed with the mealy part, in the manner of a paſte, or gruel. Some think that malt is better ground by a ſtone mill, than by a ſteel one, becauſe the former bruiſes it, and the latter only cuts the grains.

After the malt is ground, it ſhould lie ſome time to mellow, in a cool room, where no ſun comes. The time for this is different, according to its kind. Brown malt may be ground at from three to fourteen days before it is uſed, in order that the corn, which is rendered uncommonly hard by that degree of drying, may be gradually ſoftened by the moiſture in the air; by which means it will become the more ſoluble in water. The pale malts require only one or two days. After lying thus in the air, leſs maſhing ſuffices; the ſtrength of the malt is more perfectly extracted, and the beer will be conſiderably ſtronger than it would be with the ſame quantity of malt taken directly from the kiln. Care muſt be taken that it get no damage in lying.

Mr. Combrune obſerves, that malt imbibes moiſture more readily by being ground and expoſed for ſome time to the air, than it does when whole; and that as the dampneſs thus abſorbed by the grain is in reality ſo much cold water, malt which has been long ground requires to be maſhed with hotter water than it would otherwiſe be neceſſary to uſe. *See the article* BREWING.

The reader is obliged for the following uſeful obſervations on the art of making malt to a very ingenious gentleman, who has practiſed the art many years.

Experience, and a conſtant obſervation on effects and their cauſes, have, ſays he, made me maſter of ſome pieces of knowledge relative to this ſubject, which your farming readers may probably think worthy their attention: the reſult of this experience I ſhall lay before them.

The firſt thing I ſhall mention, with regard to malt, is the benefit of changing the water whilſt it is ſteeping.

Some maltſters think this change of water no ways neceſſary; others, on the contrary, approve of it, but do it indiſcriminately in the ſame proportion during the whole ſeaſon. They are in both reſpects wrong; for the times when the water requires to be changed ofteneſt are at the beginning and latter end of the ſeaſon, in autumn and ſpring, when the weather is warm; for in the middle of the winter the weather is too cold to admit of the water being at all changed to any advantage. Suppoſe the barley to be left in ſteep forty-eight hours in the ſpring: if the weather is inclinable to be warm, the water may be in that ſpace of time changed three times; in other caſes twice may be enough; but the beſt rule to go by, is that which follows.

Every maltſter muſt know, that in the autumn and ſpring, if barley is left too long on the ſteep in the ſame water, the water will grow ſlimy, and ſometimes ſour: now I would adviſe the maſter to watch the changes of the water, and when he finds that it is ſmooth and oily to the touch, and that it is inclinable either to ſmell or taſte ſour, let him by all means have it inſtantly changed; but he muſt obſerve, if he regards his intereſt, a particular method even in doing this.

The uſual way of changing the water is, firſt to draw off that in which the barley was ſteeping, and afterwards, by pails full, or by pumping, fill the ciſtern again.

This I do not approve of, becauſe the barley when the water is drawn off lies cloſer, and is apt, in a very ſhort ſpace of time, to heat: this is a great damage to the commodity, and, without precaution, a conſiderable loſs enſues. Now my method has always been, firſt to get a hogſhead of water in readineſs near the ciſtern, which I cauſe to be thrown on the barley the inſtant the firſt water is drawn off; and as a hogſhead of water is ſufficient to wet eight buſhels of barley, I add afterwards as many hogſheads, ſave one, as my ciſtern will wet quarters. By theſe means I avoid the danger of the barley heating in the ciſtern.

The conſequences of not changing the water whilſt the barley is ſteeping, are often fatal to the malt, which either forts of water near his houfe with fome white hard fope, fuch as is made at Nayland; and that which lathers fooneft is moft fuited to his purpofe.

I have already obferved, that in the fpring and autumn it is neceffary to change the water often in which the barley is fteeped: it fhould likewife be remembered, that in thefe feafons the making of malt, in all its parts, is a very critical bufinefs; particularly it is then neceffary that the beds, or couches, fhould be frequently turned, or the malt will not come kindly; but the tap root will be apt to fhoot forth vigoroufly, ftarving the other roots, and preventing them from accompanying it in its growth: this muft be checked, and the remedy is, to turn the couch often, fpread it thin, and give it a fufficient quantity of air, at the fame time keeping it cool and temperate. This will ftop the progrefs of the firft root, give the others time to fprout, and the barley will malt kindly and regularly.

A thin fkinned fine-coated barley is beft for making malt, and it is not the worfe for not being very full bodied; yet would I by no means recommend a lean, half-ftarved, unripe grain.

Barley, which has grown on lands highly manured, is not fo good for making malt, as that which has been produced by land of a moderate richnefs without any manure: in fact, a luxuriant foil, whether naturally fo, or enriched by art, is not, in general, beft for yielding barley for the maltfter's ufe.

For the reafons above mentioned, never chufe to buy barley from the farmers who have large crops, as it is moftly a full-bodied grain they have to fell. I prefer, for malting, a grain which is the produce of a foil that is rather poor than rich, rather light than ftrong, and more inclined to a gravel than a clay.

This grain is clean-coated, taper, and elegant in its form, is full of flour, almoft tranfparent when watered, and will be fufficiently wetted in forty-eight hours.

This grain increafes in the malting, fills the bufhel well, and makes a fine, fweet, wholefome, clean, full-bodied malt, from which the beft of beer may be brewed, either brown or pale, according as the malt has been dried higher or lower.

Now I have mentioned drying of malt, a few cautions on that head may not be amifs.

My practice has been to give my malt as much drying as I could on the floor: this is not only a great faving of fuel to me, but is alfo attended with feveral other advantages.

I find that my malt, by being thus gradually divefted of its outward moifture, does not fhrink fo much when it comes to be laid on the kiln; of courfe it meafures to more advantage: it is befides of a better quality, having acquired no foreign tafte in drying.

It may very eafily be obferved, that if malt is laid very damp on the kiln, a thick mift, or fmoky vapour, will immediately arife from the furface of it, which, being repelled and condenfed by the cold circumambient air, falls again on the malt, where, by the heat from the furnace, it is a fecond time rarefied, and afcends in clouds of fteam.

This alternate rarefaction and condenfation of the moifture is of great differvice to the malt, giving it often a difagreeable mufty flavour, and making it befides more unfit for keeping.

Now, by my method of fuffering the malt to receive a part of its drying on the floor, this inconvenience is, in a great meafure, avoided; for the grofs moifture is already evaporated before it is laid on the kiln, and that which remains creates no great degree of fteam, provided the fire in the furnace is not at firft made to burn too fierce.

With this precaution I have often made pale malt as fine as I have any where feen, fuch as fome gentlemen, who long dealt with me frequently, nay, conftantly, praifed. In drying this malt, I took care that there was, during the whole time it was on the kiln, but a very moderate, yet equal, fire in the furnace.

If I had an inclination to have any malt high dried (for fome like brown malt better than pale) when the moifture was nearly evaporated, I caufed the fire to be gradually encreafed till it roared again in the furnace, taking care that the malt fhould be properly ftirred, left it proved kiln-burnt; and by this method I had a fine, fweet, brown malt, fit for making harveft beer, fuch as fome farmers are very fond of brewing.

Many are of opinion, that brown malt, ufed in the fame proportion with the pale, will make the ftrongeft beer; but this is certainly a miftake; for I have often made the experiment with great precifion, but could never find any material difference, and what difference there was at any time, feemed to me to be rather in favour of the pale than the brown malt: this may eafily be accounted for, as the flour in the pale malt always remained found and uninjured in the drying; whereas the brown malt would fometimes, notwithftanding all the care of the maltfter, be injured or parched by the fire, and that part which was parched had of confequence loft its fpirit and virtue.

I muft, however, on this occafion, make one neceffary remark, which is, that fome pale malts are flack dried: thefe, I own, make a raw unwholfome liquor, which will not keep well; but if the pale malt is gradually and flowly dried by an uniform gentle heat, it will certainly anfwer the character I have already given of it, and will, befides, (I have experience for my voucher) keep as well as any brown malt whatever.

Maltfters in general are too little nice in the barley they buy. I have already faid fomething on this head, to which I fhall add, that I would by no means have them ever bargain for mixed grain: what I mean by mixed grain, is barley grown on various foils, and in different fields. There is a fure difappointment in buying fuch grain, as the kerns will fpire at different times, and fome of them not at all; fo that, after the couch is dried, fome part of it will not be half malted, and a great deal of the remainder not malted at all.

In order to avoid this misfortune, for fuch it is, as the maltfter's cuftomers will, with too much reafon, find fault with his commodity, let him by no means attempt to buy tythe barley, for that he is fure is mixed: I experienced myfelf, many years ago, a great lofs by a purchafe of the kind. A neighbouring farmer, with whom I was well acquainted, brought a fample of barley to market: I looked at it, and though it was not very fine, I bought it, on account of his letting me have it fix-pence a quarter cheaper than I could then buy of others: the lot confifted of one hundred quarters; but when it came home, and I had tried fome of it, I think about ten quarters, I was greatly furprifed to find the malt fo bad, when examining the barley with great attention, I foon difcovered the reafon of it. Meeting the farmer, of whom I had bought it, within a day or two afterwards, I afked him how he came to fell me mixed barley, adding, that I always thought he kept his grain with more care feparate: he foon unravelled the myftery, by telling me, that it was the parfon's barley, not his own, which he fold me.

When I heard this, I was not a little difpleafed; however, refolving to make the beft of a bad bargain, I carried a fample of it to market the next day, and fold it to a hog-feeder for eighteen-pence a quarter lefs than I gave for it. This was fome lofs; however I was glad to get off fo well, as I would not have made the whole into malt, and have impofed on my cuftomers for an hundred pounds.

To fhew that I am not felf-interefted, I will inform your readers of a method by which they may difcover whether malt has been made of mixed, or in part unripe barley. Take a bowl of water; throw into it a couple of handfuls of the malt; give it a gentle ftirring, and the barley which has not been malted will fink to the bottom; the half-malted grains will have one end funk, being in a vertical pofition; and the true good malt will fwim. This experiment I have often made, and never found it deceive me.

The fame barley, though ever fo good, will not malt alike well at all times: for inftance, take it as foon as it is houfed, it comes well, but whilft it is in its fweat, by no means; yet after it has done fweating, it comes well again.

In the fame manner, barley which has been got in early in a very dry feafon, makes but indifferent malt; whereas the fame barley, if it is left abroad till rain falls on it to loofen the hufk from the kernel, malts very well, and yields a large increafe.

Alfo, old barley, mixed with that of the laft harveft, does not malt well, for the reafons above mentioned; it does not all fpear, or put forth its beard, at the fame time.

Thefe I know are niceties which few maltfters attend to; yet I am certain that an obfervance of them, and fome few more particulars, would increafe their profits nearly ten per cent.

A great many maltfters in the counties of Hertford and Effex, make prodigious quantities of malt for the London market; and there are often difputes happen between the maltfters and the factors and buyers at Mark-lane, about the malt not holding out meafure; the reafon of which many of the country dealers are unacquainted with, and therefore know no other way of guarding againft it, than by throwing in a bufhel or two extraordinary: this is fome abridgment of their profits, and is befides often unneceffary. One reafon for this deficiency, is the avariciousnefs of the maker, who is willing to have as large an increafe as poffible, to the amount of fix pecks in eight bufhels; whereas, if the malt is intended for the London market, four pecks is all that can, with propriety, be allowed; for it muft not be drawn too long; and this malt requires more cleaning by the fcreen, &c. than that fold in the country.

Malt, if it is not thoroughly cleaned, will heat in the hold of the veffel that carries it; and the tails, being loofened, will fall off; the neceffary confequence of which muft be a deficiency when it comes to be meafured a fecond time at the wharf or ware-houfe: now, to prevent any altercation or difpute, let the maltfter always caufe his commodity to be well fcreened before it is meafured into the facks to be carried on fhipboard: he need then put up no more than the meafure; he will gain himfelf a character as a clean good workman; and I will anfwer for it, that the factors, if he makes his malt according to fample, will readily give him one fhilling a quarter more than his neighbours.

MALT-DUST, the duft, &c. that feparates from the malt in the act of drying.

The following obfervations on the benefit of malt-duft, as a manure for a ftiff foil, with a relation of fome experiments made to afcertain its virtues, appeared in the *Mufeum Rufticum*, *vol.* III. *page* 277.

For the benefit of your farming readers, fays this gentleman, I fhall communicate a few experiments I made fome time fince, in order to try the virtue of malt-duft as a manure for a crop of wheat.

I had often heard it afferted, that malt-duft was much better fuited, as a manure, to barley than wheat; for the latter lying a whole year in the ground, and the malt-duft being fown with it, the virtues of the manure were exhaufted long before the fummer, when the corn principally wants nourifhment; being advanced in its growth, and ferved chiefly to make the wheat winter-proud.

Others, contradicting this affertion, faid it was beft for wheat, and made it appear, that it often caufed very good crops of corn, particularly after a hard winter.

Being determined in my own mind to try fome experiments, in order to determine this matter, I pitched upon a field of ten acres, which had borne a good crop of horfe-beans; after which it was fown with turneps, which being fed off, it was fummer-fallowed, being intended for wheat.

The foil was a ftiffifh loam; it was in good heart, and tolerably clean.

I divided this field by deep furrows into ten equal parts, each containing one acre, numbered 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10.

The whole field, during the courfe of the fallowing, had four ploughings, which reduced it to a fine tilth.

When wheat feed-time came, I fowed number 1. broad-caft, with three bufhels of wheat, and ploughed it in, laying on no manure whatever.

Number 2. I fowed with the fame quantity of wheat, after which I ftrewed over it ten quarters, or eighty bufhels of malt-duft, and ploughed that and the feed in together.

Number 3. I fowed alfo with wheat in the fame manner, except that I deferred ftrewing on the malt-duft, till the latter end of January.

Number 4. had a dreffing of dung in the ordinary way, and was fowed with three bufhels of wheat like the other parts.

Number 5. was dreffed by fheep-folding, and was alfo in like manner fown with wheat.

Number 6. was fown with wheat in the fame quantity; and in February, after fowing, received a half dreffing of very rotten dung, which had been feveral times turned and mixed.

Number 7. after receiving a ploughing in the fpring, was fown with ten pecks of barley, which was harrowed in, and no manure at all applied.

Number 8. was fown with barley, as above, but had ten quarters of malt-duft laid on it.

Number 9. had in the winter a good dreffing of dung, and was in the fpring fown with the fame quantity of barley.

Number 10. was fown with barley, like number 8. only it had five inftead of ten quarters of malt-duft laid on it.

It may be neceffary, perhaps to obferve, that all the pieces of wheat were fown the firft week in October, and all the barley the fecond week in March.

Soon after Chriftmas I went to take a view of my wheat, when I found that the acre marked number 2. looked moft forward and flourifhing; though I muft own there was in appearance but little difference between that and number 4.

The numbers 1, 3, and 6. neither of them looked fo vigorous as thofe already noticed; and number 5. feemed rather thin on the land; but the wheat plants were in good condition and healthy.

In May I took another view of my wheat crops, and found number 1. tolerably clean, and promifed well.

Number 2. gave me hopes of a large crop, and was furprifingly clear of weeds.

Number 3. was greatly improved fince the laying on of the dreffing of malt-duft.

Number 4. looked very vigorous and ftrong, but was very foul, having feveral forts of weeds not to be met with in other parts of the land.

Number 5. was thin of plants, and they did not branch much; however, they ftill feemed healthy and ftrong.

Number 6. was like number 3. greatly improved; but it was foul, and, what appeared ftrange to me, had many weeds of a nature quite different from thofe with which number 4. was infefted, though the dung laid on both thefe parts was taken from the fame heap.

I, at this time, alfo looked at my pieces fown with barley, when I found number 7. promifing and clean.

Number 8. was forwarder, and flattered me with the profpect of a large crop.

Number 9. was forward and fine, but foul with weeds.

Number 10. bore much the fame appearance as number 8. and promifed as well.

At harveft number 2. of the wheat was firft fit to reap, after which fucceeded number 4. the reft were ready nearly at the fame time.

Of my barleys, number 8. and 10. were firft ready to mow.

I fuppofe it is unneceffary to obferve that thofe crops which were cleareft of weeds were the fooneft fit for carrying.

I ordered thefe crops to be all laid feparately; and as I was obliged, juft after Michaelmas, to go up to London, about fome particular bufinefs, I left orders with my bailiff, that they fhould all be feparately threfhed and dreffed as early as might be in the winter.

The produce of the feveral crops was thus diftinctly noted to me, for I had ordered that particular care fhould be taken not to mix one with the other, and my orders were, I found, on enquiry, punctually carried into execution.

	Bufh.	Pecks.
Number 1. unmanured, yielded of wheat –	20	1
Number 2. manured with malt-duft when fown – – – – – – – – – – – –	28	3

 Number

Number 3. manured with malt-duſt after Chriſtmas, by way of top-dreſſing	41	0
Number 4. manured with dung in the ordinary way	32	2
Number 5. folded with ſheep	29	3
Number 6. dreſſed with rotten dung in February	30	0
Number 7. unmanured, yielded of barley	32	3
Number 8. manured with ten quarters of malt-duſt when ſown	48	0
Number 9. manured with dung in the winter	40	2
Number 10. manured, when ſown, with five quarters of malt-duſt	44	0

I muſt, with your leave, treſpaſs upon your reader's patience, till I make a few obſervations on the above ſtate of the produce of my crop.

Firſt, I conclude, that when malt-duſt is uſed as a manure for wheat, it is beſt to lay it on by way of top-dreſſing after the corn is come up, as the crop of number 3. yielded above twelve buſhels more than that of number 2. and I am apt to think that the virtue of the malt-duſt laid on number 2. was exhauſted before it could be of any eſſential ſervice to the crop; whereas, in number 3. the manure began to yield forth its virtues juſt as the wheat plants began to be in want of a freſh ſupply of nouriſhment. It was alſo obſervable, that the grains of wheat which grew on number 2. were thinner, and had leſs ſubſtance, than thoſe of number 3. the grain of which was fine, plump, and heavy.

The produce of number 4. convinces me that malt-duſt is, in many caſes, a better manure for wheat than dung, not only as it gives a larger encreaſe, but alſo becauſe it does not ſtock the land with deſtructive and devouring weeds.

The wheat grown on number 5. was as fine as that of number 3. but conſiderably leſs in quantity, as appears by the account.

I do not much approve of the method purſued in number 6. yet is it a good alternative, if the farmer happens to have too little dung to dreſs all his fallows.

I judge alſo malt-duſt to be a very good and profitable manure for a barley crop; but the yield of number 10. being forty-four buſhels, and of number 8. only forty-eight buſhels, which laſt is not an encreaſe in proportion to the additional quantity of manure laid on, I thence judge that eight quarters, or ſixty-four buſhels, of malt-duſt, is the proper quantity of malt-duſt to lay on an acre for a barley crop, and that at the time of ſowing.

When I ſpeak of malt-duſt, I mean the kiln-d.ſt, which falls from the malt in drying: as to the tail-duſt, which falls through the ſcreen whilſt the malt is cleaning before it is put up in ſacks, that may be applied to a better uſe, being generally given to pigs, and often to cows, in which laſt caſe it makes them give a great deal of milk.

It has been ſuggeſted that the virtue of malt-duſt, as a manure, laſts only for one crop; but this is a miſtake, for when this manure is laid on in January or February, a good crop of barley may be had after the wheat.

It (I mean malt-duſt) is of a very warm nature: this has induced many farmers to think that it will burn a crop; and I will not anſwer for it but it might do ſo on a hot gravelly ſoil; but on clay land, or a ſtiff loam, it ſeldom or never does any damage: and indeed the only danger is a dry time enſuing after it is ſpread on the land, for the firſt ſhower of rain waſhes it in, and ſecures the crop from all hazard of being burnt.

Many of my acquaintance, beſides myſelf, have found that malt-duſt is for a ſtiff ſoil a better manure than dung; but the diſpute among them was, whether it was moſt profitable to lay it on when the wheat was ſown, or by way of top-dreſſing in January or February: however, ſince I made the above experiments, they are all converts to my opinion, and are determined in future always to dreſs their heavy wheat land with it after Chriſtmas.

One thing more in recommendation of this my favourite manure let me add before I conclude, that nothing ſurpaſſes it when laid on cold graſs grounds, to the amount of about eight quarters, or ſixty buſhels, on an acre, but not leſs.

Such as have not ſeen its effects in this way applied, would be ſurpriſed at the large encreaſe of ſweet feed which it occaſions: in ſhort, whoever finds it neceſſary to dreſs ſuch land, and can get malt-duſt in a ſufficient quantity, will do well to uſe it, as they will be puzzled to find any thing in the extenſive circle of manures better adapted to the purpoſe.

MANGER, the place or veſſel in which the horſe's corn is put.

MANURE, a general name for ſoil of all kinds laid upon land to improve it. *See* DUNG.

The following Letter ſent to Dr. Templeman, *Secretary to the Society for promoting Arts, &c. to be by him communicated to the Committee of Agriculture, in Recommendation of a new Manure, is of too much Importance to be omitted here.*

"SIR,

"As a farmer, like a chemiſt, ſhould loſe none of his materials, but make even his waſhings, runnings, and reſiduums, turn out to his advantage, I have ſent you ſome account of an experiment I have made in manuring of land, which I beg you will lay before the committee of agriculture, that they may communicate it to others.

"I am poſſeſſed, Sir, of a farm of near three hundred pounds a year, and have in my yard, what you uſually ſee in moſt farmers yards, two receſſes or pools, as reſervoirs of dung and water. Theſe reſervoirs in wet weather are continually running over; and of courſe part of the matter contained in them is carried off, by the neceſſary drains, into the highways, ditches, and rivers.

"As much of the eſſential quality of the dung is loſt in this manner, (for part of the ſalts, whether fixed or volatile, will be waſhed into the pools, and when they over-run, will be conveyed into the ditches, &c.) I thought it a part of good huſbandry to carry this ſuperabundant water, or manure, (for ſo we may juſtly call it) on my land, which I did by means of a watering-cart, not unlike thoſe with which the roads near London are watered in the ſummer time to allay the duſt.

"That the experiment might be the more obvious and certain, I firſt tried it (in the beginning of March, 1763) on a few acres in the middle of a large meadow, and on ſome lands in the middle of a large field of wheat, where, in a little time, I found a conſiderable encreaſe, in growth, both of graſs and grain; and at hay time and harveſt, both the one and the other were much better crops than what the ſame lands produced that were not ſo manured.

"As a man, or even a boy, with one of theſe carts, and one horſe, may manure a great deal of land in a day, provided it be near the yard, I would recommend the practice to all my brother farmers; for the expence is nothing, but the value of the time of the boy and the horſe; and the encreaſe, by what I have ſeen, will be very great.

"This manure may be alſo laid, to great advantage, on land that is freſh ſown with barley, oats, or any other grain; but on graſs it ſhould be only laid in the winter time, when the rains will waſh the ſalts off the blade; or in the ſpring, when the lands are laid up for hay; as the cattle will not feed on the graſs, while the dung, or ſalt, adheres to the blade of it.

"This dung-water ſhould likewiſe be carried on the land, not at a time when it rains, but in the dry weather, and at a time when the dung-water in the pools is of a deep brown colour, and ſtrongly impregnated with ſalts. By this means the land may be manured from time to time, and the pools kept almoſt empty for the reception of freſh matter every time it rains; and nothing will be loſt.

MARE, the female of the horſe. *See the article* HORSE.

Such mares as are deſigned for breeding, ought to be as free from defects as poſſible, and ſhould, no more than the ſtallions, have either moon-eyes, watery-eyes, or blood-ſhot-eyes; they ſhould have no ſplint, ſpavin, or curb, nor any natural imperfection; for the colts will take after them: but choice ſhould be made of the beſt and ableſt, the moſt high ſpirited, beſt coloured, and fineſt ſhaped; and the natural defects that may be in the ſtallion, ſhould be amended in the mare, as well as that which is amiſs in the mare ſhould be amended in the ſtallion.

As for her age, ſhe may be covered when three years old; but the moſt convenient time is after four, when ſhe will

will nourifh her colt beft; and though fhe may breed till fhe is thirteen, yet fhe is not fit for it when fhe is paft ten, for the colt of an old mare is commonly heavy. Before a mare is covered, fhe fhould be in the houfe about fix weeks, during which time fhe fhould be well fed with good hay and oats well fifted; and in order to render her conception the more certain, near a quart of blood may be taken from each fide of her neck, about five or fix days before covering. Another method to bring a mare in feafon and make her retain, is to give her, for the fpace of eight days before you bring her to the horfe, about two quarts of hemp-feed in the morning, and as much at night; and if fhe refufes to eat it, to mingle it with a little bran or oats, or elfe to let her faft for a while: and if the ftallion alfo eat of it, it will greatly contribute to generation.

Mares go with foal eleven months and as many days as they are years old; and therefore the propereft time for covering them is in the beginning of June, that fhe may foal the May following, when there will be plenty of grafs, which will afford the mares a great abundance of milk for nourifhing their foals: but a mare fhould never be covered while fhe is bringing up her foal, becaufe the foal to which fhe is giving fuck, as well as that in her belly, will be prejudiced by it, and fhe herfelf fooner fpent. After covering, let her, for three weeks or a month, have the fame diet as before, and kept clean in the ftable till the middle of May, with her feet well pared and thin fhod: take her in again about the latter end of September, if not before, and keep her to the end of her foaling. If fhe cannot readily bring forth, hold her noftrils fo as to ftop her taking wind; and if that will not do, diffolve madder, to the quantity of a walnut, in a pint of ale, and give it her warm. In cafe fhe cannot void her fecundine, or after-burden, boil two or three handfuls of fennel in running water, then put half a pint of that liquor into as much fack, or, for want thereof, into a pint of ale, with a fourth part of fallad-oil, mixed together, and pour it luke-warm into her noftrils, holding them clofe for fome time: otherwife give her green wheat, or rye, the laft of which is beft.

If the mare has but little milk, boil as much as you can get from her, with the leaves of lavender and fpike, and bathe the udder with it warm, till the knobs and knots are diffolved. She fhould now drink only white water (which is bran put into water;) give her alfo fweet mafhes: and a month after foaling, let her have a mafh with fome brimftone or favin in it.

MARYGOLD, a flower much ufed as a pot-herb, and therefore planted in moft kitchen-gardens.

Marygolds are raifed from feeds fown in March or April, in the place where the plants are to remain. They require no other culture than keeping them clean from weeds, and thinning them to the diftance of about ten inches afunder, that their branches may have room to fpread. They will begin to bloffom in June, and continue in flower till the froft kills them. Their feeds will ripen in Auguft and September, and, if they are fuffered to fow themfelves, will produce a plentiful crop of young plants in the next fpring: but as thefe will confift of a mixture of good and bad forts, it is moft advifable to prevent this fpontaneous growth, to fave the feeds of the beft flowers only, and to fow each variety, whether fingle or double, by itfelf.

MARLE, a kind of dry, foft, foffile earth, ufed in manuring land.

Marle is either grey, blue, brown, yellow, red, or mixed, and is known by its pure and uncompounded nature: befides which, it is diftinguifhed by feveral other marks, fuch as, its breaking into little fquare bits; its falling eafily to pieces, by the force of a blow, or upon being expofed to the fun or froft; its feeling fat and unctuous; and its looking, when dry, after having been expofed to the weather for fome time, as if it was covered with a hoar-froft, or fprinkled with fine falt. Even when mixed with the land intended to be manured by it, the whole furface of the foil will have that whitifh appearance. But the moft unerring way to judge of marle, and know it from any other fubftance that may refemble it, is, to break a piece as big as a large nutmeg, and, when it is quite dry, drop it into a glafs of clear water, where, if it be the right fort, it will foon diffolve into a foft and almoft impalpable pap, fhooting up many fparkles to the furface of the water. Some marles effervefce but little with acids: but they fhould always be put to that trial; becaufe, the more they effervefce with them, the more valuable they are as manures. In hot weather, good marle will flake with the heat of the fun, like lime; efpecially if any rain follows a hot day.

The farmers in Staffordfhire reckon the foft blue marle, which is moft commonly found under clay, or low black ground, at the depth of feven or eight feet, the beft for arable land, and the grey fort the beft for pafture. That which is of a brownifh colour, with blue veins in it, and little lumps of chalk or lime-ftone, generally lying under ftiff clays, and very hard to dig, is moft efteemed in Chefhire. The marle which is ufually found at the depth of about two feet, or a yard, on the fides of hills, and in wet boggy grounds which have a light fand in them, is very fat and clofe, and reckoned the ftrongeft of all marles; for which reafon it is particularly good for fandy lands. This is commonly called peat-marle, or delving-marle. The paper-marle, as it is fometimes called, frequently lies near coals, and flakes like leaves or pieces of brown paper, than which it is of a fomewhat lighter colour. That which fome writers call clay-marle, becaufe it looks like clay, is very fat, and fometimes mixed with chalk-ftones. Steel-marle breaks of itfelf into fquare cubical bits. Thefe two laft kinds generally lie under fand or clay; fometimes about a yard deep under the former, but often much deeper under the latter.

Stone, flate, or flag-marle, which is a kind of foft ftone, or rather flate, of a blueifh colour, is generally allowed to be the beft. It eafily diffolves with froft or rain, is found near rivers and on the fides of hills, and is a very lafting manure. An ingenious gentleman, paffing lately through Bedfordfhire, obferved, that the people employed to mend the highways, were laying upon them a blueifh kind of ftone. Struck with the novelty of the appearance, he ftopt, took up a lump, and foon found it to be this blue marle, which the ignorant peafants were ufing inftead of real ftone. The confequence was, that, when he returned the fame way fome time after, a heavy fhower having fallen, the whole road where this fubftance had been fo injudicioufly fpread, was become a perfect quagmire.

Mr. Markham reckons four forts of marle, in Suffex; viz. grey, blue, yellow, and red. The blue is accounted the beft, the yellow next, and then the grey. The red is the leaft durable. A great deal of the marle in the north country runs much upon the loam; but that in Suffex is more like fuller's earth, and therefore muft certainly be the fatteft.

Mr. Mortimer fays, he faw a fample of marle from Derbyfhire, which was very fat, though it contained fo much fand, that, when wet, it could not be worked into a ball, or be made to hold together. This marle did very well upon clayey land, becaufe it was of an opening quality.

In many parts of moft counties in England, marle difcovers itfelf to the moft negligent eye; particularly on the fides of broken hills, or deep, hollow roads. Many rivers are bordered with a vaft treafure, which is plundered by every flood. Boggy lands frequently cover it; and, in them, it feldom lies above three feet deep. It is fomewhat lower under ftiff clays, and marfhy level grounds. The loweft parts of moft fandy lands abound with it, fometimes at the depth of three feet, and fometimes at feven, nine, or more. The depth of the marle itfelf can feldom be found; for, when the upper cruft of the earth is removed, all that can be feen, or dug, is marle, to fo great a depth, that there are few, if any, inftances of a marle-pit's having been exhaufted.

Nothing is more common than to find the ditches which inclofe a field, dug fo deep that they have penetrated fix or feven inches into a bed of marle, without the farmer's taking any notice of it; though the extraordinary fhooting and increafe of the grafs which is put forth by the marle thrown up on the fides of the bank, might, one would think, be a means of difcovering it. Where the marle is thus accidentally difclofed, it not only turfs the fides and tops of the banks, and thereby fecures them againft all injuries of the weather, but makes the grafs grow fo long and

thick,

thick, that, when beaten down by winds, it hangs as if it thatched the earth which nourished it, and carries off the rain, without letting any great quantity penetrate through it.

The marquis of Turbilly, in his excellent directions for clearing and breaking up land, recommends, for boring it (in order to know what different layers of earth, ores, quarries, springs, &c. lie underneath, and at what depth, by which means the better judgment may be formed of the plants most proper for the soil), an instrument of his own inventing, as far superior to any thing that has yet been thought of for that purpose. A description of it may be of service to every ingenious improver of land. *See the article* BORER.

Marle is very common in Ireland, where it seldom lies above a foot or two below the surface of the soil; luckily for that country, which is extremely boggy. But in France, though they have marle in many places, they are often obliged to dig for it very deep, particularly in the province of Artois, where it generally lies eighty or ninety feet under ground, in beds about five feet thick, at the bottom of which frequently is water, which breaks in upon the workmen. On account of this great depth of the marle-pits there, extraordinary care is taken to set up marks, and rail them in, to prevent the fatal accidents which might otherwise happen. The same is, indeed, done in England; but not so strictly as it ought to be.

Authors differ widely both as to the quantity and the manner of using almost all the manures they treat of; points which must, in a very great measure, depend on the quality of the soil, and the strength of the manure, of whatever kind it be, and in which experience will ever be the judicious farmer's surest guide. In marling, it is particularly necessary to find the true proportion which the land requires, and better to err in laying on too little, than too much; because, more may be added at pleasure; whereas, by over-doing it, the first year's crop often fails, because the body of the marle has not been sufficiently opened; and, in that case, it will sometimes be two or three years before the ground comes to a proper temper. The best directions that can be given to the farmer in the application of this manure to light soils, is, to lay on the quantity which will give the degree of cohesion wanted in those soils. A general rule cannot be laid down in this respect; because, the quantity of marle requisite to effect the desired end, must be different, in proportion to the degree of lightness of the soil.

Pliny speaks of marle as a species of improvement known to the Greeks, but more peculiar to Britain and Gaul. He calls it, the fat of the earth, and compares it to the glands in the human body, which are lapped in a coat of fat. As this manure, so far as we can find, was not used, and probably not to be found, in Italy, it shews how attentive the Romans were to agriculture, wherever they carried their victorious arms; since, notwithstanding the continual alarms they lived in from the natives here and in Gaul, they found time to discover and perfect a means of improving land, particularly suited to the soil and climate, and, of all others, the cheapest and most lasting.

Before we quit this subject, we must observe, with Dr. Home, that a body very similar to marle in its appearance, but essentially different in its effects, is often found in the same bed with the best marle. It is of a darkish lead-colour. Instead of fertilizing the earth, it renders even the best soils incapable of bearing any kind of vegetables for many after. I have seen, says that gentleman, the spots on which it was laid, entirely barren three years after; and have heard of its bad effects continuing in other places for a much longer time; nor is it certain when they will cease. A body so very destructive to agriculture, deserves to be well characterized, in order to its being shunned; and should be thoroughly examined, that we may know whence proceeds this noxious quality, and how to cure it when it has taken place.

Marle takes a smooth polish from the instrument with which it is wrought. A piece of this taken up, when it has not been much exposed to the influence of the air, differs greatly in taste from marle. Instead of the smooth unctuous taste of the latter, it is acid, and remarkably astringent. It agrees with marle, in crumbling in water, but differs remarkably from it in not raising any effervescence with acids, nor in the least destroying their acidity. It turns the syrup of violets red; which shews that it contains an acid: whereas marle, like all absorbent earth, gives it a green colour. The trying of marle with acids is therefore the more necessary, to guard against using this pernicious substance.

It appears from experiments made by the doctor, that this pernicious substance consists of an earthy body like clay, about an eighteenth part of salt of steel, and a small proportion of the vitriolic acid: from whence he concludes, that good marle is the proper cure where this noxious earth has been inadvertently used; because it corrects the acid, and decomposes the salt.

The following account of marle was sent by a very intelligent gentleman to the editors of the *Museum Rusticum.*

A short Dissertation on Marle.

It is taken out of the bowels of the earth at several depths, is of divers colours as after named, and some sorts have often two or three colours intermixed. It is unctuous, of a slippery nature, and in goodness pure; soon relents after rain, and, when dry, slackens like lime, and at last dissolves into the finest powder.

I intend to leave with you some specimens of two kinds of marle (which you may give to the gentlemen or farmers who desire them): they are what I have collected in Middlesex, which county abounds with good marle; but it is not used by the gentry, or farmers, so much as it ought, because they have so readily dung, soot, ashes, and other composts, from London.

In order to discover marle, the best way is to use the auger, and observe the strata taken up from time to time by it.

I have found, after I have got through the surface, which is about a spade and half deep, that the next earth was a very strong, coarse, bed of clay, five or six feet deep; afterwards, getting through it, the auger brought up marle, viz. that which appears of a fine light-brown colour, and some of it mixed with blue veins (which I will here call pigeon marle, by way of distinction): here was a bed of this pigeon marle of five or six foot deep, and after that followed another kind of marle, which I will call toad marle, by way of distinction; this is heavier, and without any veins of blue.

When either of these marles are dug out of the pit, the spade cuts them like so much soap; and the last-named marle looks very blackish and dark, and may be, and I believe is, in some countries, called toad marle, from its resemblance in colour to that animal; but this marle being exposed to the air alters the colour very much. This appears to me to be the strongest marle.

Marle may be discovered sometimes near the surface, by carefully observing the ditches and fences of your lands.

It is frequently found near rivers, or brooks, and sometimes may be discovered on the banks of such waters.

To know when you have found true Marle, try it by Air, Fire, and Water, or Vinegar.

First, By exposing a large lump of three or four pounds in the air, which, if true marle, will, in a little time, by the nitre, dews, &c. break into small parts; and there will be an hoary, or white, congelation on that part of it which is exposed to the sun.

Secondly, When your marle is dry, break it into small particles, and put an handful into an hot coal fire, and it will crackle as if so much salt had been put therein.

Thirdly, Place a piece of the dried marle in a glass, and thereon gently pour as much water as will cover it. If true marle, it will then gradually moulder, and dissolve into a liquid soap. Let not the glass be shaken, that you may observe the ebullition (which is material); or you may, in like manner, try it with vinegar, where the effervescence, or struggling, will be much stronger than in water.

The Virtues of Marle.

It is the beft manure for fandy, dry, gravelly, or light lands of any kind. It is excellent for moffy lands. It is, indeed, good for all other lands, of what nature foever, even clay, provided care be taken in laying on a proper quantity, and that the fame be well diffolved.

Care muft be taken in the quantity ufed; if too little, you may eafily add; but if too much is laid on the land, you cannot take it away.

It is ufed in fome countries for arable lands only: yet it is as good for grafs or pafture lands, but does not the firft, and feldom till the fecond year, fhew forth its utility; and then you will obferve the grafs to fhoot out a dark, or blackifh colour, which afterwards turns to the fineft green; and with it come up quantities of white clover-grafs, which hath occafioned me fome difficulty with the farmers to convince them I had not fown the clover-feed.

If lands are properly marled, they will continue good for twelve or fourteen years for the plough; and for pafture, or grafs-lands, much longer.

I would recommend that the plough be not fuffered to enter into the land till the marle is thoroughly diffolved.

Fifh thrive prodigioufly, and grow fatter in marle-pits than any other ponds.

Quantities to be ufed.

A great difficulty this to afcertain the quantity.

In fome countries they will tell you of laying three hundred loads to an acre, others more, others lefs; but they no where afcertain what is a load. In Chefhire and Lancafhire their loads are fcarcely fix bufhels, and they ufe a fmall cart made for the purpofe, drawn by two or three fmall horfes.

If the land is gravelly, fandy, or light, let as much be laid on it as will make a good thick coat to bind and ftiffen the foil.

But let the land be what it will, fo much fhould, in all events, be laid on as will make a thin coat over the entire furface.

Upon my lands, which are grafs and pafture, of a tolerable mould, on a clayey foil, and which were left, about eight years fince, in a bad plight, by the late tenant, I firft attempted to lay ten loads to every acre, (by a load I mean as much as three large, well-fed, ftrong horfes could draw) but found it was too little, and would not meet in the fpreading.

I immediately doubled the quantity, and two years afterwards I added another coat of fifteen loads more to every acre, and find it anfwers very well for hay and pafture. I need not fay horfes and cows are fonder of this hay and grafs than of that wherein the dung may be tafted and fmelt.

A work of this kind fhould be fet about by the end of Auguft, or beginning of September; and the loads fhould be fhot into fmall heaps, as the Middlefex farmers fhoot their dung, viz. two or three bufhels in each heap; and a man muft be ready to feparate it, that the nitre, air, dews, and rain, coming on the large pieces, may act, and caufe them to break, as of themfelves, into fmaller parts.

After the marle has been laid upon the ground, and you fee that the air, nitre, &c. have loofened the great lumps, and they are ready, on a flight touch, to fall into pieces, a perfon fhould be ordered (when the weather and marle are quite dry) to break and fpread the pieces to complete your coat; and you fhould avoid as much as poffible, leaving any large pieces to lie and diffolve without being fpread on the furface, but caufe them to unite therewith.

In the beginning of February, and in dry weather, I caufe an old gate to be well bufhed, and a heavy weight laid on it, to be drawn by one horfe over the whole field, in order that every part may have its due proportion.

If you intend to plough your lands, the preceding cautions are not fo neceffary, as the plough and harrows will fpread and intermix the marle with the foil fufficiently; but if you ufe the drill-plough, the above hints may be ufeful.

It would take a volume to give an exact and full hiftory of marle, its virtues and ufes, and to fhew that it was ufed by the Romans, and many years difcontinued, and efpecially till the houfes of York and Lancafter were united, and then revived in fome few counties; and the great benefits received by marling in Suffolk and Norfolk within a few years paft.

We very well know that gentlemen and farmers are a long while ere they care to venture on the practice of marling from theory, and principally from not having feen or known what is, and what is not, true and genuine marle, and from being unacquainted with the rules or modes to judge and determine upon it: therefore, if this fhort account will obviate their doubts, and in any way contribute to the advancement of agriculture, vegetation, and pafturage, my defign is anfwered.

There are variety of colours in marle, viz. blue, white, yellow, red, and other colours, which make no material difference, provided they be earthy and fat, or flippery as foap, and as free as poffible from a mixtre of fand, gravel, or ftone.

DICE MARLE, a name given by the people of Staffordfhire to a reddifh marle, that breaks into fmall fquare pieces like dice, or into thin flakes, in the manner of lead ore, and looks fmooth on the furface.

MARSHY LANDS, a fort of pafture or grazing grounds, lying near the fea, rivers, or fens.

As to lands lying near rivers, the great improvement of them is their being overflowed, which brings the foil of the uplands upon them, fo that they need no other mending, though kept conftantly mowed. The great inconveniency of thefe lands is their being fubject to floods, which high hills near the fides of rivers, and the long courfe of them, befpeak to be frequent: and, though the richeft land generally lies near fuch rivers, yet there is the greateft danger of the crops being fpoiled, efpecially when they are not inclofed, and therefore cannot be fed with cattle. This, when feeding bears any thing of a price, would be the very beft way of managing thefe uncertain lands; and inclofing them would be highly beneficial on this account. *Mortimer's Hufbandry.*

The marfh-lands in Lincolnfhire, and many other parts of England, produce a fort of grafs, which feed fheep in a bettter manner than that of almoft any other land, in regard to their fize, and the quantity of wool. The fheep about Grimfby, and fome other places in this county, produce fuch lufty wool, or, as they call it, wool of fo large a ftaple, that three or four fleeces ufually make a tod of twenty-eight pounds weight. Several hundred loads of this wool are yearly carried from thefe places to Norfolk, Suffolk, and other parts of the kingdom, for the cloth manufacturers. They fend this in large packs, which they call pockets, each containing about five and twenty hundred weight. *Philof. Tranf.* Numb. 223.

When marfh lands lie flat, it is neceffary for the owner to keep all the water he can from them. The fea-water in particular is to be kept from them as much as poffible; and this is ufually done at a very great expence, by high banks and walls.

Two things greatly wanting in thefe lands, in general, are good fhelter for the cattle, and frefh water. The careful farmer may, however, in a great meafure obviate thefe, by digging in proper places, large ponds to receive the rain water, and by planting trees and hedges in certain places towards the fea, where they may not only afford fhelter for the cattle, but keep off the fea breezes, which often will cut off the tops of all the grafs in thefe places, and make it look as if mowed.

Thefe lands fatten cattle the fooneft of any, and they preferve fheep from the rot. It would be of great advantage to them, if there were raifed, in the middle of every large marfh, banks of earth in a crofs, or in the form of two femi-circles, and thefe planted with trees; thefe would ferve as a fhelter for cattle, let the wind blow from what quarter it would, and would foon repay the expence of making.

There are, in different parts of England, very large quantities of land upon the fea-coafts that would be worth taking in, though no one has yet thought of doing it. The coafts about Bofton, Spalding, and many other parts of Lincolnfhire, give frequent inftances of this, where the ſea falls from the land, ſo that on the outſide of the ſea walls, on the owſe, where every tide the ſalt water comes, there grows a great deal of good graſs, and the owſe is firm to ride upon when the water is upon it.

This owſe, when taken in, hardly ſinks any thing at all, and they dig the walls from the outſide of it, all the earth they are made of being taken from thence, and the ſea, in a few tides, filling it up again: and though the ſea, at high water, comes only to the foot of the bank, yet once in a year or two, ſome extraordinary tides go over the banks, though they are ten feet high. Theſe banks are fifty feet broad at the bottom, and three feet at the top; and the common price of making them is three ſhillings a pole, the earth being all carried in wheel-barrows, and face towards the ſea, where the greateſt ſlope is, being turfed. *Mortimer's Huſbandry.*

MATFELLON. *See* BLUE BOTTLE.

MAY-WEED, a wild ſpecies of chamomile, a trailing pyrennial plant, which puts out roots from its branches as they lie on the ground. By this means, and by ſcattering its ſeeds long before the corn is ripe, it ſpreads and multiplies greatly. It flowers in May, and thence has acquired the name of May-weed.

The means of extirpating it are, ſummer fallows, repeated good harrowing, and burning the collected roots, as before directed, in ſimilar caſes, or, which will be found ſtill more effectual, the frequent hoeings practiſed in the New Huſbandry. What eſcapes theſe clearings ſhould be very carefully pulled up by hand; for the common weeding-hook will not go deep enough to take out the whole of the long ſlender tap root of this plant, of which every remaining bit that has a knot in it will produce new ſhoots. Nor ought the farmer to regret this ſmall additional expence, to get rid of one of the moſt fatal enemies his corn can have. Mr. Liſle aſſures us, that as good a crop of wheat as one would wiſh to ſee all the winter time was, to his knowledge, ſo deſtroyed by the coming up of May-weeds and poppies in the ſpring and ſummer, that it did not at laſt yield ſo much as the ſeed.

MEAD, a liquor made of honey, and held in great eſtimation by moſt of the northern nations, but perhaps not eſteemed here ſo much as it might deſerve, if due care was taken to prepare it properly.

All the writers who have hitherto treated of this ſubject, have given into a capital error with regard to the ſtrength of this liquor, by directing too great a proportion of honey to be diſſolved in the water. The uſual practice of making it ſo ſtrong to bear an egg, is very wrong. The liquor is thereby rendered a meer ſtum, and this bad quality is ſtill increaſed by the long boiling generally practiſed. It is ſcarcely poſſible to procure honey ſo pure, but that ſome bee-bread, wax, or other ſubſtance, is mixed with it; and this cannot be perfectly ſeparated from it, ſo far as I know, but by boiling. On this account the boiling of mead ſeems indiſputably neceſſary. In order the more effectually to ſeparate theſe impurities from the liquor, it will be adviſable to mix ſome whites of eggs with it before it is put on the fire, and it will be particularly neceſſary to ſkim off the thick ſcum that riſes, the moment the liquor begins to boil; and this muſt be attentively continued ſo long as it boils. The only intention of boiling being here to ſeparate the impurities, and to make a perfect union of the water and the honey, both which purpoſes are very ſoon obtained, it evidently appears, that the boiling need be of but very ſhort duration. This becomes here more particularly neceſſary, becauſe the liquor will be the leſs diſpoſed to ferment kindly, the longer the boiling has been continued. It is perhaps owing to the ſingle article of long boiling, that mead has hitherto lain under ſo great diſcredit; becauſe it then never fermented ſufficiently to take off its luſcious ſweetneſs; whereas, had it undergone a due fermentation, that ſweetneſs would have gone off, and the mead would have attained a fine racy flavour.

Some notable houſewives have added hops to their mead. This helps to take off its ſweetneſs, and, as the bitterneſs of the hop goes off, gives it a pleaſant flavour. A ferment is here, as in all liquors that are boiled, generally wanted to bring on a perfect fermentation: but as the leaſt taint in the ferment is communicated to the whole liquor, particular care ſhould be taken that it be very ſweet and good. Mead, judiciouſly managed on theſe principles, will keep for years, and be improved by age. The racking, fining, &c. of this liquor, are the ſame as thoſe of other white wines.

MEADOW, a general name for paſture or graſs-lands, annually mown for hay; but is more particularly applied to lands which are ſo low as to be too moiſt for cattle to graze upon them in winter, without breaking the ſward.

Meadows, being generally enriched with the fine mould waſhed down from the adjacent riſing grounds, are uſually of a good ſoil, and ſeldom require any other improvement, than the removing of temporary imperfections. But they may likewiſe be of ſuch a nature as to ſtand in need of a more particular treatment: as is the caſe when their ſurface is a moſſy looſe earth, or when it is of a binding or clayey quality.

If, through long neglect, a coarſe ſtrong graſs, ruſhes, or other buſhy plants, be ſuffered to remain upon the ground till they rot there, they will, in ſome years, form a looſe ſpongy ſubſtance, ſomewhat reſembling moſs. In this caſe, the firſt neceſſary ſtep is to pare off and burn that looſe ſurface, or at leaſt ſo much of it as to enable the plough afterwards to reach the better ſoil underneath. The manner of doing this has already been explained ſo very amply, that it will be ſufficient to add here, that this looſe upper earth muſt be ſo ſtrengthened as to afford ſufficient ſtability to the roots of whatever plants are ſown on it, by mixing it well, either with the better ſoil underneath, or with marle, clay, or rich loam, brought to it from the neighbouring grounds, or with the compoſts before directed for this purpoſe.

If the ſoil is clay, or a ſtrong binding earth, the treatment of it is much the ſame, whether it be meadow or upland paſture. Such ſoils, by retaining water in every hollow place, become what the farmers call ſour, and produce a coarſe graſs, compoſed, as Mr. Miller obſerves, of bad weeds, of which the ſeveral ſorts of docks make no ſmall ſhare. Although many of the meadows produce a great burden of what the country people call hay, yet this is fit only for ſuch cattle as, by hard labour and hunger, are driven to eat it: for horſes which have been accuſtomed to feed on good hay, will almoſt ſtarve rather than touch this. A plain proof of its being diſagreeable to all cattle, is, that when they are turned in, after it has been mowed, we often ſee the ground covered with rank weeds, which they will not meddle with.

When a paſture is in the ſtate above deſcribed, if there is a ſufficient depth of ſoil to admit of it, the ſurface ſhould be pared off, and burnt: and as ſuch places are uſually over-run with ant-hills, theſe ſhould alſo be burnt; after which, by the addition of proper manure, and by the help of deep plowing, the land ſhould be brought into fine tilth. The deeper this improvement goes, the deeper and more laſting will the graſs be. We have been informed of a particular inſtance of the good effects of this method, by which the gentleman who practiſed it had graſs which continued for years in a ſtrong ſtate of vegetation, and was conſtantly near a month forwarder than that of his neighbours, whoſe ſoil and ſituation were exactly the ſame.

Let not any one be deterred by the expence attending this improvement: for the crops of grain and other plants taken while the ſoil is thus preparing, will nearly repay all the charges, and the ground will afterwards yield much more plentiful crops of graſs; at leaſt for a number of years. But as clayey lands require more frequent and more thorough repairs than other ſoils, the returns of tillage propoſed by Camillo Tarello will be the moſt proper means of managing them.

He would have farmers divide their paſtures in four parts, keep one of theſe parts under grain or pulſe, during five years, and at the expiration of that time lay it down to graſs as before; and ſo proceed with every other part. He propoſes, that the firſt breaking up ſhould be by paring and burning, and thorough plowing. But if we may differ from him in opinion, we think it is needleſs to keep the ground ſo many years in tillage, unleſs this ſhould ſuit the huſbandman's convenience for the culture of particular plants.

plants. In this cafe, the pafture may be divided into five or fix parts. After each part has thus been in tillage, Tarello advifes breaking up again the fpot firft began with; though not by burning now, but only by plowing, in order to fow it as before. "This, fays, he, will be profitable to the hufbandman, and improve the pafture. It will benefit the hufbandman, becaufe he will thereby raife a greater quantity of corn; and it will do good to the paftures, becaufe nothing is more ferviceable to them, than this renewal of their furface, as is attefted by Columella. Let not the hufbandman imagine that he will have lefs hay when only three fourths of his ufual extent of land are under grafs: for, in fact, it is not the quantity of the land, but the care which is taken of it, that gives plenty of hay."

When a foil of this kind is laid down for meadow, great care fhould be taken to flope it down gently, from the middle, in fuch manner that no water may reft on any part of it. If the extent is large, fmall ditches fhould interfect the meadow into as many divifions as fhall be neceffary to form a fufficient drain for the wafte water, and the fpaces between thefe ditches may be gently raifed. In an upland pafture on fuch a foil, ridges fhould be raifed inclining a little from the horizontal, that the furrows may be fo many drains, as before directed in the plowing of fuch foils, to prevent their becoming fpewy or wet: for as the rain cannot defcend beyond the clay, it will glide along it, till, collected in fuch quantities as to form a fmall ftream, it iffues forth at the furface, ufually loaded with fome mineral quality imbibed from the earth underneath.

When the foil is a rich or light loam, the plough will not be fo neceffary; as fuch meadows or paftures may be repaired by the means which will be pointed out in the directions hereafter given for the improvement of the meadows already laid down to grafs. *See the article* GRASS *and* PASTURE.

Black, rich mould, requires but a moderate quantity of water: juft fufficient to give action to the fertilizing particles it contains. The watering here fhould be frequently repeated, rather than long continued.

It is a general rule, that fandy or gravelly foils require watering the moft of any; becaufe whatever moifture they receive, finks through them too fpeedily. But it may be doubted, whether this very reafon for watering them be not one of the greateft of objections againft their being watered, at leaft fo much as is generally directed: for the water not only paffes rapidly through thefe foils, but it may carry down with it through the fand or gravel, the finer and richer particles of the fhallow mould ufually found upon fuch foils, and thereby rather impoverifh their furface. It would therefore feem advifable, to let water in upon fuch foils only occafionally, to refrefh their verdure, when their furface is too dry: and to give it a pretty quick current, that it may reach to a greater extent of furface: for if it runs flow, it finks too faft.

It is a queftion whether paftures newly laid down to grafs, after having been arable land, ought to be watered at all during the firft year. The judicious author of one of the ingenious differtations in the Memoirs of the Berne Society confulted on this fubject an intelligent farmer, who had experienced the effects of watering, and of not watering, thefe new paftures, as fome call them, and was anfwered; that they had yielded the greateft quantity of grafs the firft year, when they had been watered, but that the crops had always dwindled in the fucceeding years: whereas thofe that were left dry till autumn, and then only begun to be watered, had made ample amends during the following years, for the fcantinefs of their produce in the firft. This hufbandman was therefore of opinion, that it is beft not to water thefe meadows before the autumn; and he added a farther very fenfible reafon, namely, that as thefe new meadows ftill retain fome portion of the manure laid upon the land the year before, when it was fowed with corn; the letting in of water upon them, while the mould is yet extremely loofe and light, will be apt to carry off thofe rich remains of manure, which will otherwife incorporate with the foil, as it acquires more confiftence.

A very wrong cuftom which prevails among our farmers, in general, with refpect to low meadows, is, that of flowing them during the whole winter. The roots of all the fweeteft kinds of graffes are thereby deftroyed, and only fuch left as are natives of marfhes, which are coarfe and four, and which no cattle will eat.

The method which Mr. Miller propofes for the management of thefe meadows, is never to flow them till the middle or latter end of March, excepting once or twice in the winter, when fuch floods happen, as bring down a great deal of foil from the upper lands: for then it will be of great fervice to let fuch water in upon the meadows, that the foil may fettle there: but the fooner the wet is drained off after this is lodged, the greater will be the benefit done to the meadows. By letting on the water frequently, from the end of March to the middle of May, the growth of the grafs will be greatly affifted, and there will not then be any danger of deftroying its roots.

River water, which is univerfally acknowledged to be the beft for this purpofe, cannot be fo beneficial when the ftream overflows its banks, and runs rapidly over the paftures, as when its courfe is flow; and ftill much lefs than when it ftagnates. It therefore is advifable to fence in every meadow liable to be thus overflowed, in fuch manner that it cannot be flooded, but at the owner's pleafure, by opening proper fluices. But as the produce of many meadows will not bear this expence, the proprietor, or farmer, fhould, if poffible, prevent the too hafty current of the water, by raifing at their upper end, or wherever elfe it may be neceffary, fuch fences as fhall render the water which flows fidewife upon the meadow, rather a back, or ftanding water. Great advantages will arife therefrom. The finer mould will no longer be carried away by the ftrong current of the river, which, inftead of robbing the foil, will then depofit a rich fediment, and thereby greatly fertilize the land.

The water of mineral fprings fhould not by any means be brought upon paftures; becaufe they are either deftructive of grafs, or produce only a very harfh coarfe kind of it.

We fhall clofe this fubject with the following remarks made by the judicious author of one of the before-mentioned differtations in the Memoirs of the Berne Society, and which deferve the ferious attention of every hufbandman who would water his paftures with due care.

"Many people imagine, that the whole art of watering meadows confifts in making good channels, and in opening and fhutting the fluices at proper times. But this is not enough: for fo long as the water flows in a meadow, the farmer fhould vifit all his channels once or twice a day, with a fhovel, hoe, or three grained fork in his hand, and examine carefully whether any of them want cleanfing or repairing. Sometimes he will find a channel choaked with flime; in other places he will fee the water fpread too far, or not far enough; and in others again he will obferve it not rife high enough to overflow its channel, fo that the neighbouring ground is not watered at all. He will immediately endeavour to remedy thefe defects, according to the exigency of the cafe, whether by clearing away the muddy flime, heightening the banks of the channel, lowering them, giving a freer current to the water in fome places, and checking its courfe in others, according to the nature of the foil; or by cutting new channels in fome places, and laying fods or fluices acrofs others, to divert the ftream from fuch parts as are fufficiently moift, and turn it to others which want watering: for it frequently happens that, even in the fame meadow, though not a large one, there are very different foils, each of which requires the affiftance of water, but in different degrees. In fhort, the careful hufbandman will not ever vifit his paftures without noticing in them things which may be altered and amended."

The farmer who has improved his meadows according to the foregoing directions, may expect abundant recompence in plentiful crops of grafs.

When grafs is to be fed off, it fhould not be permitted to ftand till it grows high, becaufe the cattle will then trample under foot great part of it, which they afterwards will not eat. The prudent hufbandman will alfo vary the kinds of cattle fed upon it. *See the article* HAY.

MEDLER, a fpecies of fruit-trees, and may be raifed by grafting or budding them upon the common white thorn. This is the ufual way of propagating the American forts, which are of the hawthorn kind; but the beft way to raife the other forts is from their feeds. All medlars and will take when they are grafted or budded upon each other. They will alſo take upon ſtocks of pears, or of quinces, and both of theſe will take upon the medlar; ſo that there is a great affinity between them. All the American ſorts will grow twenty feet high, if they are not ſtinted by grafting.

Medlars may alſo be raiſed from their ſeeds, which, if put into the ground in autumn, ſoon after they are ripe, will come up the following ſpring: but if they are not ſet till the next year, they will not ſhoot till the year after.

MELILOT, a plant of the trefoil kind, and grows in ſuch abundance among the corn in many parts of England, particularly in Cambridgeſhire, as to be a moſt troubleſome weed; for it is hardly poſſible to ſeparate it from the corn in reaping, ſo that they are houſed together, and the ſeeds of the melilot, which ripen about the ſame time as the corn, are threſhed out with it, after which, they being likewiſe heavy, it is very difficult to ſeparate them. If but a few of theſe ſeeds are ground with the corn, they will ſpoil the flour; for the bread, or whatever elſe is made with it, will have a ſtrong taſte and ſmell like melilot plaiſter. The roots of this plant are ſtrong and woody, and from them ſpring out ſeveral ſtalks, which riſe from two to four feet high, according to the goodneſs of the land. Theſe ſtalks branch out, and are garniſhed with trifoliate leaves, having oval ſawed lobes of a deep green colour. The flowers are produced in long ſlender ſpikes, which ſpring from the wings of the ſtalks. They are of a bright yellow, ſhaped like the other butterfly flowers, and are ſucceeded by naked ſeeds, which ripen in Auguſt.

MELON, the name of a well-known plant cultivated in kitchen-gardens.

To have a continuation of melons, they ſhould be ſown at two, or rather three, different times. The firſt, if the ſeaſon be forward, ſhould be in the ſecond week in March; but otherwiſe it will be better to defer it for a few days longer; becauſe the ſucceſs of theſe plants depends greatly on their being raiſed ſtrong, which they cannot well be if the weather ſhould prove ſo bad after they are come up, that a ſufficient quantity of freſh air cannot be admitted to them. The ſecond ſowing ſhould be at the end of March; and the third, if there be a third, ſhould be about the tenth or twelfth of April. Theſe are the directions of Mr. Philip Miller, whoſe long experience and excellent obſervations have enabled him to treat this ſubject ſo much better than any other had ever done before him, that we cannot do juſtice to him, or to our readers, but by giving the ſubſtance of his judicious inſtructions on this head; eſpecially as they contain ſeveral new and eſſential improvements.

The melons which beſt deſerve culture are, the Cantaleupe, the Romana, the Succado, the Zatte, the ſmall Portugal, and the black Galloway: for our common ſorts, and thoſe which moſt of the trading gardeners around this metropolis raiſe for the markets, where their ſize is chiefly regarded, are not worth the trouble and expence beſtowed upon them, otherwiſe than as they bring in a profit to the cultivator.

The Cantaleupe, as it is called, by way of pre-eminence, particularly by the Dutch, who cultivate very few other ſorts, and never ſubjoin the word melon when they ſpeak of this, though they apply that diſtinctive appellation to every other kind, is held in the greateſt eſteem by all the curious in Europe. It derives its name from a place (where the pope has a country-ſeat) about fourteen miles from Rome, where it has long been cultivated: but it was firſt brought thither from that part of Armenia which borders on Perſia, where this fruit grows naturally in vaſt abundance. Its outer-coat is very rough, full of knots and wart-like protuberances; and its fleſh, which is generally of an orange colour, though it is green in ſome, but theſe are not ſo good, is ſingularly delicious, when in perfection, and remarkable for the ſafety with which it may be eaten; for it does not offend even the moſt tender ſtomachs.

The Romana is a good melon, when it is well conditioned, and produced by a perfectly healthy plant, in a dry ſeaſon. It may be ripened ſooner than the Cantaleupe, and therefore merits the attention of thoſe who are fond of having early melons.

The Succado is alſo a very good ſort, and will yield early fruit: but neither it, nor the Romana, can be compared to the Cantaleupe, when this laſt is in ſeaſon.

The Zatte melon is likewiſe well taſted; but its fruit is ſo very ſmall (ſeldom exceeding the ſize of an orange), and the fleſh in it ſo little, that it is ſcarcely worth cultivation. It is ſomewhat flat at both ends, and its coat is warted like that of the Cantaleupe.

The ſmall Portugal melon, which ſome call the Dormer melon, may alſo be cultivated for an early crop. It is a pretty good fruit, and grows plentifully; for which reaſon people who chooſe quantity rather than quality, and many whoſe palates are not nice, give it a ſort of preference to moſt other ſorts: but it falls greatly ſhort of the Cantaleupe, in point of flavour.

The black Galloway, which was brought from Portugal, many years ago, by Lord Galloway, is the beſt of all melons for an early crop; for it will ripen in a ſhorter time from the ſetting of it, than any other ſort; and its fruit is by no means bad when it is ſuffered to ripen naturally. This would, therefore, certainly be a very proper ſort to cultivate even in the open field, according to the principles of the New Huſbandry, by a proper application of which to the melon, we have juſt ſeen how well M. de Chateauvieux ſucceeded. The ſeeds of the right black Galloway are, indeed, not eaſily met with now in this country; becauſe it has degenerated by growing among other ſorts, the male duſt (farina) of whoſe bloſſoms has been waſted to, and has impregnated, the flowers of this: for, to preſerve any particular ſort of melon in perfection, no other plant of a different kind, though of the ſame genus, no cucumber, no gourd, nor any ſimilar growth, ſhould be permitted to blow near it.

To the want of care in this important, though too generally unheeded, caution, is owing the complaint of many lovers of this fruit, who, not knowing the true cauſe, have imputed the gradual diminution of the goodneſs of their melons to their having been too long cultivated from ſeeds ſaved in the ſame garden, and have therefore held it to be abſolutely neceſſary to procure a frequent change of ſeeds from diſtant parts. That a change of ſeeds now and then is beneficial, and even adviſable, is readily allowed in regard to this, as well as for all other vegetables; but the great difficulty is, to get them from people who have ſaved them with due care; for all hired, or otherwiſe mercenary, gardeners, are apt to be very blameably negligent in this reſpect. Even Mr. Miller, though a member of the botanic Academy at Florence, and very ſolicitous to have the right ſort, could not, for ſeveral years, procure any good ſeeds of the true Cantaleupe melon, notwithſtanding that ſeveral parcels were ſent to him from Italy, as ſuch, by perſons who, he thought, could not be deceived in their choice, and who lived near the place of their growth. He therefore judiciouſly warns all perſons not to depend upon ſeeds brought from abroad, either by thoſe who import them for ſale, or by gentlemen; and declares his own reſolution, founded on repeated diſappointments to be, never more to try any of them, unleſs he receives them from a ſkilful perſon who has himſelf eaten of the fruit from which he ſaved them: "for, adds he, in Italy, Spain, Portugal, and many parts of France, the gardeners are very careleſs in the choice of all their ſeeds, but of the melons they are remarkably ſo; and as for thoſe which come from Conſtantinople, Aleppo, and other parts of Turky, I have rarely ſeen one melon produced from thoſe ſeeds, which was tolerable."

Melon ſeeds ſhould be at leaſt three years old, and not more than ſix, or at moſt ſeven, when they are ſown: for though they will grow at the age of ten or twelve years, and at leſs than three, yet the fruit produced by them will, like that of light ſeeds which ſwim upon the water when taken out of the pulp, not be near ſo thick fleſhed, ſo firm, ſo moiſt, or ſo well taſted, as what is raiſed from heavy ſeeds kept to a proper time, even though they be taken out of the ſame melons. Mr. Miller has made the trial ſeveral times, and always found this to be the event. The culture of all ſorts of melons, of which there are many varieties beſides the above-mentioned, though not of value enough to be particulariſed here, is exactly the ſame. The two firſt ſowings of them, that is to ſay, thoſe made in March, ſhould be under frames, and therefore

fore these may be placed at the upper side of a cucumber-bed, if there be one in readiness; otherwise a hot-bed must be made on purpose for them, with new horse-dung, in the manner before directed for cucumbers, like which they are to be raised and managed in all respects, till they are planted out where they are to remain. The third sowing, of which the plants are generally reared under bell or hand-glasses, or under frames covered with oiled paper, should not be earlier than the tenth or twelfth of April, lest these plants, if they thrive well, should extend their shoots to the sides of the glasses before it will be safe to let them run out, on account of the sharp morning frosts which are frequent in this country even in the middle of May: nor must they, on the other hand, be cramped in the glasses, because they would then be in equal danger from the heat of the sun in the day-time. If they do grow so as to exceed the limits of their glasses sooner than it may be safe to expose them to the air, the projecting ends of their vines must, in that case, be sheltered with mats, to defend them from the cold. For these reasons it is most advisable to set the seeds of such plants as are to be reared under hand-glasses, a little later than those which are intended for the much more spacious coverings of oiled paper: and likewise for the same reasons, it is best in this climate, not to attempt to have melons ripe earlier than the middle of June, from which time they may be had in plenty till the end of September, if they are rightly managed: nay, when the autumn has continued favourable, Mr. Miller has had them very good, even till the end of October.

When the beds, or, as the gardeners term them, the ridges, in which these plants are to be set to remain, are of a proper warmth (but not before, lest the too great violence of the heat at first should burn the earth laid upon them) a covering of two inches thick of mould will be sufficient to begin with, except in the middle of each light, where a hill of it should be raised eighteen inches high, or more, terminating in a flat cone, in the top of which the plants are to be placed. In two or three days, this will be sufficiently warmed to receive the plants, which always succeed best when they are transplanted young; and the most proper time for removing them is the evening, when a little wind is stirring. They should be carefully taken up with a trowel, so as to preserve all their fibres, and as much earth as possible about them; for these plants are much tenderer than those of cucumbers. The Cantaleupe melon is particularly so: for it will be long before that recovers itself, and after being transplanted, if this is not done soon after it has put out its third, or what the gardeners call its rough leaf. If this happens before the beds are ready, the best way is, particularly for the Cantaleupe, which requires the nicest management, to take up the plants, as soon as they are fit for removing, to put each of them into a separate small garden pot, and then to plunge these into the hot bed where they were raised, or into a cucumber bed, if there be room, in order that they may be brought forward; and when the bed or ridge where they are to remain is ready, they may be turned out of the pots, with all the earth about their roots, so as not to receive any check by the transplanting. This may be the more easily done, as only one melon plant should be suffered to grow in each light, and there will not be any danger of hurting their roots when they are removed in this way. When they are well placed on the top of the little mounts, or hillocks, before mentioned, they should be watered gently, and this should be repeated once or twice, till they have taken good root, after which more water will seldom be wanted, or advisable; because too much wet makes them canker at the root, and then they never produce good fruit. When the plants are well fixed in this new bed, a greater quantity of earth should be laid on it, beginning at the hillocks, that their roots may be enabled to strike out horizontally; and as this earth is added from time to time, it should be pressed or trodden down as close as possible, till it is at last raised at least a foot and a half thick upon the dung all over the bed. The frames should also be raised in proportion, that their glasses may not be so near the plants, as to make the sun scorch them: but in this raising of the frames, great care must be taken to stop every crevice all around, so that no cold air may be able to penetrate through them.

The earth, which the Dutch and German gardeners, who are very exact in that respect, lay upon these beds, consists of one third of hazel loam, one third of the scouring of ponds or ditches, and one third of very rotten dung. They prepare this compost at least one year, but oftener two years, before they use it; frequently turning it during that time, the more thoroughly to blend and sweeten it: but Mr. Miller has found, by experience, that melons succeed best in this country, when they are planted in two thirds of fresh gentle loam, and one third of rotten neats dung, well mixed, and frequently turned over during one year before they are wanted, so as to enable them to enjoy all the benefit of a winter's frost and summer's heat; and of this a sufficient heap should always be kept in readiness, under a shed, well sheltered from heavy rains, which would carry off its goodness.

When the plants have four leaves, and consequently a joint, their tops above that joint should be pinched off with the finger and thumb, to make them put out lateral branches, for these are to produce the fruit; and when there are two or three of these branches, their extremities must also be pinched off, as soon as they have got two or three joints, to force out more, and these again must be treated in the same manner, that there may be runners enough, as the gardeners call them, to cover the bed. Care must be taken not to bruise the plants, when the tips of their shoots are thus pinched off, nor must they be cut with a knife, because the wound will not heal soon in either of these cases. Neither should a greater number of lateral shoots than is necessary to cover the bed properly, be forced out by cropping off their ends, lest more fruit should be produced than the plant can possibly nourish. The farther management of these plants is the same as that of cucumbers, only it is to be observed, that melons require a greater share of air than cucumbers, and very little water; and that when they are watered, it should always be at a distance from their stems.

If the plants raised in frames succeed well, their vines will extend over the bed, and reach to the frames, in about six weeks, at the end of which the alleys between the beds should be dug up; or, if there is but one bed, a trench about four feet wide should be dug on each side of it, as deep as the bottom of the bed. A sufficient quantity of hot dung should then be trodden down closely to it, till this dung is as high as that of the bed, and this additional breadth should be covered with the same sort of earth as was used for the bed. This earth should also be trodden down as close as possible, and the whole bed should by these means be enlarged to the breadth of twelve feet; for the roots of the plants will extend themselves to very near that distance: but if they should reach farther than they are covered, and their extremities be consequently dried by the sun and air, the plants themselves will gradually languish and decay, or at best produce but meagre, mealy, and ill flavoured fruit; whereas those which have a sufficient breadth and depth of well trodden earth for their roots to run in, will remain in vigour till the frost destroy them. Mr. Miller has experienced the benefit of this practice, so far as to have a second crop, even of Cantaleupe melons, upon the same vines as had borne the first; and that second crop has sometimes ripened very well under his judicious inspection. The languishing of the plants, for want of sufficient room to extend their roots, frequently before the fruit is full grown, and even sometimes before it is well formed, may soon be discovered by the drooping of their leaves in the middle of the day, and a then speedy total decay of many of those leaves. It is owing to their not having enlarged the beds, as above directed, or even made them at all wider than they were at first, or increased the original depth of the mould upon them, which perhaps did not exceed the common allowance of about three inches, that many people have seen their plants of Cantaleupe melons pine away, and perish, before they had ripened a single fruit; and then have imputed to their tenderness, too great, say they, for this climade, a miscarriage which was entirely owing to their not understanding the right method of cultivating them.

When the vines have extended so far as to fill the frames, and consequently to want more room, the frames should be raised up about three inches above the surface of the

the bed, and ſet upon a few bricks, at that height, in order that the ſhoots may have room to run out under them: for if the plants are vigorous, theſe branches will reach to the diſtance of ſix or ſeven feet every way from their ſtem. It therefore is evidently beſt, not to put more than one plant under each light; and the more ſo as its fruit will ſeldom ſet well if the vines are crowded, but will drop off when about the bigneſs of an egg. The addition of the warm dung before mentioned, on each ſide of the bed, will indeed, by reviving the heat of the dung in the bed, be of great ſervice to the ſetting of the fruit, eſpecially if the ſeaſon ſhould prove cold, as it ſometimes is with us till the very end of May; and this is ſurely no ſmall advantage accruing from that method. To ſecond it properly, the frames for melons ſhould not be made ſo ſmall as is the general cuſtom; for the wider they are, the better the plants will thrive, and the greater quantity of fruit they will produce.

If the weather ſhould become cold after the plants have extended themſelves from under the frames, it will be right to cover the extremities of their vines every night with mats, during the continuance of the cold; for if they are injured, the growth of the fruit will be retarded, and the plants themſelves may be hurt eſſentially. Care ſhould alſo be taken after this enlargement of the beds, that what water is given to the plants be poured only in the alleys between the beds, or towards the outſide of the ſpace added to them; for their roots will now have extended ſo far as to reap the benefit of any ſuch watering, and their ſtems will continue the ſounder for being kept dry.

This watering ſhould be pretty plentiful when it is given; but it ſhould not be repeated above once a week, even in the drieſt weather: and, on the other hand, the plants ſhould be aired as much as poſſible when the ſeaſon is warm.

The plants of melons intended to be reared under bell or hand-glaſſes, ſhould be raiſed in the ſame manner as the beforementioned; and the beds, or ridges, for them ſhould be made by the latter end of April, if the ſeaſon is forward. A ſufficient quantity of hot dung ſhould therefore be provided for this purpoſe, ſo as to allow eight or nine good wheel-barrow loads of it to each glaſs. When there is but one bed, and that is to be extended in length, the trench for it ſhould be dug four feet wide, and its length ſhould be proportioned to the intended number of glaſſes, which ſhould ſtand at leaſt four feet aſunder: for if the plants are too cloſe to each other, their vines will intermix and entangle, and crowd the bed ſo as to prevent the ſetting of the fruit. This trench ſhould be ſo ſituated, that there may be room for widening the bed two or three feet on each ſide. Its depth muſt depend on the nature of the ſoil, as was before obſerved: but if the ground is ſo dry as to obviate all danger of the bed's being hurt by wet, it cannot well be dug too deep. After the dung is ſpread, trodden down, and flatted in the trench, as already directed, a hill of earth (ſuch as was before adviſed will be the beſt) ſhould be raiſed eighteen inches high, with a flat head, in the middle of each ſpot where a plant is to be ſet; but the reſt of the bed need not yet be covered above four inches thick; for that will be ſufficient to prevent the evaporation of the warmth of the dung. The glaſſes ſhould then be ſet down cloſe, over the hills, that theſe may be warmed ſo as to be fit to receive the plants, which they will be in two or three days, if the bed works kindly, and then the plants ſhould be ſet in the top of the hills, in the manner before directed. If they are taken out of pots, with all the earth about their roots, only one ſhould be ſet under each glaſs, becauſe there will not then be any danger of their growing; but if they are tranſplanted directly from the ſeedling-bed, it will be right to plant two upon each hill, and afterwards to remove one of them, if they both grow. Theſe plants muſt be watered when they are firſt ſet, to bring the earth the cloſer to their roots. They muſt alſo be ſhaded every day, till they have taken new root; and if the nights prove cold, the glaſſes ſhould be covered with mats, the better to preſerve the warmth of the bed.

When ſeveral of theſe beds are made, they ſhould ſtand eight feet aſunder at firſt, that there may be between them a proper ſpace, which is afterwards to be filled up, in order to enlarge them ſo that the roots of the vines may have room to extend themſelves every way, for the reaſons before aſſigned.

When theſe plants have taken good root, their tops muſt be pinched off as before directed for thoſe in the frames; and the glaſſes ſhould be raiſed up in the day time, in warm weather, on the ſide oppoſite to the wind, to let in freſh air to the plants, which will otherwiſe be drawn up weak and ſickly: a ſtate which all poſſible care ſhould be taken to prevent, becauſe their runners cannot ſupply the fruit with due nouriſhment, if they themſelves have not proper ſtrength.

If the weather be favourable, the glaſſes ſhould be raiſed two or three inches high from the ſurface of the beds, and ſet upon three bricks, as ſoon as the plants are grown long enough to touch their ſides, in order to give the vines room to run out from under them; but it is eſſential to obſerve, that, when this is done, the whole bed ſhould be covered with earth to the depth of eighteen inches; that this earth ſhould be trodden down as cloſe as poſſible; and that, if the nights ſhould prove froſty, a covering of mats ſhould be carefully ſpread over the beds, to guard the tender ſhoots of the plants from the cold. It is alſo to be obſerved, with regard to the Cantaleupe melon in particular, that, as the vines of this ſort cannot endure wet, the beds where it grows ſhould be arched over with hoops, to ſupport the mats, and that theſe ſhould be held in readineſs to be uſed at a moment's warning, either againſt cold or rain: for this is the only way to have theſe melons ſucceed in ſo variable a climate as ours is. Mr. Miller gives a ſtriking inſtance of the neceſſity of this precaution, when he ſays, that he had ſome beds of Cantaleupe melons in as fine order as could be deſired, under theſe glaſſes, and that they were totally deſtroyed by one day's heavy rain in June.

If the weather ſhould prove cold after the bed is covered with the proper thickneſs of earth, well trodden down, it will be adviſable to dig a trench along each ſide of it, or, if there are more beds than one, to dig out their intermediate ſpace, then to fill this, or the trenches, with hot dung, up to the height of the dung of the adjoining bed, and to cover this dung with an equal depth of well trodden down earth, as before directed. This new dung will revive the warmth of the former beds, and ſoon make the plants ſhew their fruit. The watering of them, pinching off their tops, and, in ſhort, every other part of their management, muſt be the ſame as before directed for thoſe under frames: but a farther care requiſite here is, to cover them with mats in all hard rains and cold nights. If all this is rightly performed, theſe plants will remain vigorous until the cold in autumn deſtroys them.

The oiled paper coverings are a late invention; but they have been found to ſucceed admirably well when rightly managed. The chief thing to be attended to when they are uſed, is, not to keep them down too cloſe over the plants; for then the melon vines will waſte themſelves by running out in length, and will be ſo weak as rarely to ſet their fruit in any plenty. The beſt way therefore is, where theſe coverings are intended to be uſed, to raiſe the plants under bell or hand glaſſes, as before directed, till they are grown large enough to be releaſed from thoſe glaſſes; and then, inſtead of mats, to uſe this oiled paper covering, which, if it be prudently managed, will anſwer every end that can be deſired.

To make this covering, a number of ſheets of ſtrong, but not too dark coloured, paper ſhould be paſted together ſo as to over-ſpread the frame intended to be uſed; and theſe ſhould then be faſtened to the frame, and rubbed well over with linſeed oil, which will dry ſoon; for all the ſtench ſhould be gone off before it is put over the plants, becauſe they will otherwiſe be hurt thereby. Pan-tile laths put together in the ſhape of the ridge of a houſe, with hinges to each ſlope, whereby any of the pannels may be raiſed at pleaſure, to let air in to the plants, are the beſt materials, and the beſt form, for theſe frames; for when they are made with broad hoops, like the tilts of waggons, they are cumberſome to move, and no air can be admitted to the plants, but by raiſing up one whole ſide of the frame; which is very inconvenient.

When the vines begin to put forth their fruit, which they will do in plenty ſoon after the bearing runners ſhall have been produced by nipping off, in the manner before adviſed, firſt the top of the plant, as ſoon as it has one joint, and then the ends of the earlieſt lateral ſhoots when they have two or three joints, they ſhould be carefully looked over thrice a week, to obſerve the ſetting of the young melons, and ſingle out, upon each runner, that only which ſeems to be the ſtrongeſt fruit, which has the thickeſt foot-ſtalk, and which is ſituated neareſt to the ſtem. All the others ſhould then be pinched off; and the end of the runner upon which a melon has been thus choſen ſhould alſo then be nipped off at the third joint above the ſelected fruit, to ſtop the ſap and ſet the melon: but none of the ends of theſe bearing runners ſhould ever be broken off before the particular fruit has been culled out, becauſe that would only make them produce more ſhoots, which would weaken the plant, and draw away the nouriſhment neceſſary for the fruit. For this reaſon, if any new ſhoots do break out, or any young fruit appears, after the above precautions in favour of that which is intended to remain have been taken, they ſhould be nipped off immediately; for if many of them are ſuffered to grow, they will abſolutely impoveriſh the plant to ſuch a degree, that it would not be ſurprizing to ſee all the fruit drop off when it comes to be about as big as a man's thumb. One young melon is as much as ought to be left upon any one runner; for, if but half of theſe ſtand, they will be full as many as the plant can nouriſh. Six or eight of the Cantaleupe's, whoſe fleſh is thick, are full enough for the ſtrongeſt plant of that kind; and though ſome ſmaller ſorts may be ripened in greater numbers, even unto fifteen or twenty upon one plant, they will be thinner and poorer than if they were leſs numerous.

For plants which are ſo confined under frames, that the wind requiſite to convey the farina from the male flowers to the female is excluded, it is the practice of ſeveral gardeners, and perhaps it may there be even a neceſſary one, to take off ſome of the male flowers whoſe farina is juſt ripe and fit for the purpoſe, and, inverting them over the female flowers ſituated on the crown of the young fruit, to ſtrike the former gently with the tip of a finger, ſo as to ſhake its farina into the latter; for by this means the female flower will almoſt ſurely be impregnated, and if it is, its fruit will ſwell ſoon after, and ſhew manifeſt ſigns of being perfectly ſet: but, from the time that the fruit appears on the vines, the glaſſes ſhould be conſtantly taken off in good weather, or the fruit will ſeldom form in any plenty.

As the melons draw towards ripening, (long before which all the ſuperfluous fruit and weak runners will have been pinched off, if they are properly managed,) they ſhould be turned gently twice a week, that every part of them may receive equal benefit from the ſun and air; for if the ſame ſide is ſuffered to lie continually downward, in which ſituation it will be deprived of both thoſe advantages, that ſide will become pale, or whitiſh, as if it were blanched.

Beſides airing the plants as much as poſſible when the weather will permit, they will alſo require to be watered in very dry weather, and perhaps moſt particularly after they have been pruned: but this, as was before obſerved, ſhould be done with great care not to wet their ſtems, by pouring the water only in the alleys, at a diſtance from them: nor ſhould it be repeated oftener than once in a week or ten days. Then, indeed, the alleys ſhould be well ſoaked, to forward the growth of the fruit, and render it thick fleſhed: though it is eſſentially neceſſary not to over-water the plants.

The goodneſs of all melons depends greatly on their being cut at a proper degree of maturity. The Cantaleupe, in particular, is ſo very nice in this reſpect, that it will loſe much of its delicacy if it be left but a few hours too long upon the vines. The beds ſhould therefore be looked over at leaſt twice every day when the fruit is ripening; and if thoſe which are intended for the table are cut early in the morning, before the ſun has warmed them, and laid by in a cool place till they are uſed, their flavour will be much better than if they are gathered later in the day, and ſerved up directly. Such as are cut afterwards, when the heat of the day has affected them, ſhould be put into a pail of cold ſpring water, or ice, to cool them, before they are ſet upon the table.

A ſure ſign of maturity in the Cantaleupe melon is, its beginning to crack at the foot-ſtalk, and to emit a fragrant ſmell. Whenever this happens, the fruit ſhould be cut directly; for this ſort ſeldom changes its colour as the others do, and only a few hours delay will render it too ripe, as was before obſerved.

The beſt ſeeds of melons are thoſe which are taken from the firmeſt and higheſt flavoured fruit; and if they are ſcooped out with the entire pulp, ſo as not to diſplace them, and left in it for two or three days before they are waſhed out, they will be benefited thereby. None but the heavy ſeeds, which ſink in the water, are worth ſaving. *Miller's Gard. Dict.*

MESLIN-CORN, wheat and rye mixed together.

MET, a ſtrike, or four pecks.

METEYARD, or METERWARD, a ſtaff of a certain length for taking meaſures.

MIDDING, a dunghill.

MIDGE, a knat.

MILDEW, a diſtemper very deſtructive to corn.

"This diſtemper, ſays M. Duhamel, attacks the blades and ſtems of corn, which it covers with a powder of the colour of ruſt of iron, when at the height of their vegetation. This ſubſtance does not adhere ſtrongly to the blades; for I have ſeen the hair of white ſpaniels full of this powder, after they have run through a field attacked with this diſeaſe. It is likewiſe known, that if the infected wheat is waſhed by a plentiful rain, the ruſt diſappears almoſt entirely, and the grain ſuffers little from it. The French give it the name of ruſt, from the colour of the powder; and it ſeems to be the ſame diſtemper which the Roman writers call *rubigo*.

"The cauſe of this diſtemper is uſually imputed to dry gloomy weather, happening while the corn is at the height of its vegetation: and in effect I have many times obſerved, that when a hot ſun has ſucceeded ſuch dry hazy weather, the corn was ruſted within a few days after.

"This diſtemper is not common in clear and dry hot years: but when the ſpring is wet, the fineſt fields of wheat run great hazard of being deſtroyed by the mildew, which generally appears upon the breaking out of the ſun in the morning, after cloſe and ſultry weather, during which there has not been any dew. The ruſty powder then gathers upon the blades in ſuch quantities as to cover the earth two feet around. M. de Chateauvieux cut off the mildewed blades, and found the trial anſwer: the ſame plants produced new blades, and throve much better than thoſe on which this operation had not been performed: but this cannot be done except when the corn is very young.

"This diſtemper is very fatal: for the fineſt wheat is ſuddenly brought almoſt to nothing, when it is entirely attacked with it.

"If it attacks the plants while they are young, and before their ſtems begin to riſe, the miſchief is ſometimes not very great, provided there comes on a ſeaſon favourable to their farther growth. In this caſe, they are only weakened, as if they had been fed or mowed. They ſhoot out anew, and produce ears: though their ſtraw is ſhorter, and thoſe ears are ſmaller, than they would otherwiſe have been. But if both blades and ſtalks are mildewed at the ſame time, the farther growth of the plant is ſtopt, and the grain gets ſcarce any more nouriſhment; ſo that the crop is exceedingly diminiſhed.

"This grievous diſtemper well deſerves the ſerious attention of every inquirer into nature, who intereſts himſelf in the progreſs of agriculture; and I cannot too ſtrongly exhort all ſuch, to endeavour to inveſtigate its cauſes and remedies.

"Several authors have, very improperly, confounded this diſtemper with others to which corn is ſubject. M. Tillet imputes it to a ſharpneſs in the air in dry cloudy weather, which breaks the veſſels interwoven with the ſubſtance of the blades and ſtem, and makes them diſcharge a thick oily juice, which, drying by degrees, is turned into that ruſty powder. In effect, if we examine with a microſcope, or only with a good magnifying-glaſs, plants of wheat, whoſe ſtems and leaves are covered with ruſt, we ſhall ſee diſtinctly ſmall crevices in the places where this powder lies, and ſhall diſcern, from ſpace to ſpace, in the membrane of the plant, openings through which it ſeems probable that the juices, afterwards converted into this ruſty powder, iſſues, and over which one may perceive ſome ſlight fragments of the membrane imperfectly covering thoſe cracks and openings.

"In

" In ſupport of this opinion, M. Tillet quotes a memoir of M. de Renéaume, publiſhed in the Tranſactions of the Academy of Sciences, on the extravaſation of the nutritive juice of the walnut trees in Dauphiny: of the manna of Calabria, which is not a dew, but the extravaſated juice of the leaves of a kind of aſh; and what M. Muſchenbroek relates in his Phyſical Eſſays of thick and oily juices which iſſue out at the excretory veſſels of leaves, and ſtop there in the conſiſtence of honey.

" However this may be, the ruſt of corn is the conſequence of a diſtemper of which the firſt cauſe is not yet ſufficiently known. It is a miſtake to think, that the ruſt and mealy powder which may be ſeen on many plants are a collection of eggs laid there by inſects, and that this is a ſource of other innumerable inſects very fatal to vegetables. By admitting the extravaſation of the nutritive juices, as the cauſe of theſe diſtempers, we ſhall conceive that the ruſt of corn, the honey-dew, the mealy-dew, and all the unctuous ſubſtances which are found upon gramineous plants, depend on the quality of the juice concentrated in the plants, upon the outſide of which it manifeſts itſelf by evaporation, and is converted ſometimes into an impalpable powder, and ſometimes into that thick ſubſtance which is red on garden-beans, of a ruſty colour on all kinds of corn, greeniſh on the plum-tree, yellowiſh on the aſh, white on the larch-tree, &c.

" Theſe obſervations and reflections ſtill leave undoubtedly much room to wiſh for farther information. They will, however, help to point out the path to a careful obſerver, and ought to excite philoſophers to exert themſelves in a matter of ſo great importance to the public. We confeſs that we have tried to produce the ſame effects as the dry hazy weather, which occaſions the ruſt, by applying to the leaves of many plants, acid and corroſive liquors, to others alkaline or ſpirituous, and frequently ſuch clammy glutinous ſubſtances as might ſtop the perſpiration without hurting the texture of the plants: but none of theſe trials have produced any thing like ruſt. However, who can tell how far experiments may lead the judicious and attentive? Some little circumſtances which may have eſcaped us, might perhaps, if duly remarked, have led us to the object of our ſearch. The public welfare calls on all attentive obſervers, to exert themſelves on this very intereſting ſubject.

" Count Ginanni, in a memoir printed in the *Journal Economique*, for October 1761, treats expreſsly of this diſtemper, and ſays, he has obſerved, with the help of a microſcope, ſmall worms lodged between the two membranes of the blades.

" If we had any certain knowledge of the cauſes of the ruſt, we ſhould probably be enabled the more eaſily to find preſervatives againſt it: but in the mean time it will be right to collect every obſervation made by lovers of agriculture; becauſe they will certainly afford uſeful lights at one time or other.

" M. de Chateauvieux obſerved, in the autumns of 1753 and 1754, that when the corn was ruſted, the ſecond crop of hay was ſo likewiſe. The graſs turned from a fine green, to the ugly ruſty colour of the corn: it was covered with the ſame kind of powder, and its quantity diminiſhed ſenſibly every day; and as the whole of a field of corn is not uſually affected at the ſame time, ſo this diſtemper extended only to ſome parts of the meadow.

" The cauſe of this diſtemper is undoubtedly the ſame in corn and in graſs; but its effect is not exactly ſimilar. It may deſtroy annual plants, ſuch as corn, entirely; but in perennials, like graſs, it deſtroys only the leaves or blades. May not the preſervation of theſe laſt be owing to the taking off of thoſe leaves or blades, when they are cut for hay? But this is only conjecture; for I own that I have not yet made any obſervation on this head.

" As the ſtraw of ſmutty, mildewed, or ruſted corn, and by the ſame rule graſs, in a ſimilar condition, may poſſibly give diſeaſes to cattle fed with it; it were to be wiſhed, for the public good, that a parcel of fodder, the moſt infected with either of theſe diſtempers, ſhould be ſet apart for the food of a certain number of beaſts. If cows or oxen, for example, remain ſound and healthy after having been fed with this growth for two or three months, we may afterwards give it them with confidence and ſafety: but if, on the contrary, they are viſibly diſordered by it, the remedy is eaſy and at hand, by feeding them with good wholeſome hay, which will carry off the diſeaſe, then known to proceed from the bad quality of the food."

The air in England ſeldom is ſo dry as to exhale all the moiſture of the glutinous exſudations, and thereby convert them into the ruſty powder above deſcribed. The extravaſation of the ſap ſeems to account for this diſtemper of plants in a much more rational manner, than the thick clammy dews which ſome of our authors ſpeak of, as falling in cloſe weather, ſtopping the perſpiration of vegetables, and hindering their juices from aſcending to nouriſh the flowers, &c.

Mr. Miller takes the true cauſe of the mildew's appearing moſt upon plants which are expoſed to the eaſt, to proceed from a dry temperature in the air when the wind blows from that point; in which caſe it ſtops the pores of plants, and prevents their perſpiration, whereby their juices are concreted upon the ſurface of their leaves; and that concretion being of a ſweetiſh nature, inſects are incited thereto. Thoſe inſects, finding their proper nutriment, depoſit their eggs, and multiply ſo faſt as to cover the whole ſurfaces of plants, and, by corroding their veſſels, prevent the motions of the ſap. He thinks it very probable, that the excrements of theſe inſects may enter the veſſels of plants; and, by mixing with their juices, may ſpread the infection all over them; for it is obſervable, that whenever a tree has been greatly infected by this mildew, it ſeldom recovers in two or three years, and many times never is entirely clear from it after. But he by no means allows theſe inſects to be the firſt cauſe of this diſtemper, as ſome have miſtakenly imagined.

It is obſervable, that mildews and blights frequently attack only one ſort of corn, or fruit, and leave the other ſpecies unhurt.

Count Ginanni diſtingiſhes two principle kinds of mildew, one of which ſpots the blades and ſtems of corn, and dries upon them, without ever producing any powder; but penetrates through their outward covering, and entirely dries them up. This is generally of a pale colour, either reddiſh, yellowiſh, purpliſh, or blackiſh; and ſometimes a variegated mixture of many colours. The other ſpeedily covers the plant with a moiſt and thickiſh ſubſtance, which afterwards becomes dry, and turns into a powder, of one or other of the abovementioned colours, but moſt commonly reddiſh or yellowiſh. This, ſays he, always fades, corrodes, and ſeparates the outer ſkin from the plant. The former extends to every ſpecies of corn; but the latter is almoſt peculiar to wheat in the blade; though it is ſometimes ſeen upon oats and barley. Some may perhaps reckon, as a third ſpecies of mildew, a yellowiſh ſubſtance, or powder, ſometimes ſeen under the membrane of the blades of corn, where it raiſes bliſters, makes many little holes and craks, and corrodes the fibres; and perhaps they may not be wrong in accounting it ſuch.

He is confident that this diſtemper is the rubigo of the Latins.

" For the vegetation of ſeeds," continues count Ginanni, " after they have been properly depoſited in the earth, for their fecundity, their ſprouting, and the increaſe and well-doing of the plants produced by them, it is neceſſary that the action of the fluid which pervades them be duly regulated: for that fluid is operated on in them by the ſame cauſes which affect the liquor in a thermometer and barometer, or influence the hygrometer; ſo that whenever its due courſe is obſtructed or weakened, or its quantity too much increaſed or diminiſhed, or its quality injured in any manner whatever, a diſtemper will enſue. This fluid is ſubject to two laws of motion; the one, ſimply as a fluid, which conſiſts in an inteſtine agitation of its minuteſt particles; and the other, as a fluid whoſe progreſs is through the various ducts of the plant. By the firſt of theſe motions it aſſimilates to itſelf all the homogeneous particles, and expels the heterogeneous; and by the ſecond, it penetrates into the various parts where thoſe functions are to be performed. When both theſe motions proceed naturally, equally, and juſtly, the ſecretions are duly made, and every part of the plant continues ſound and healthy: but when that harmony is interrupted, the fluid degenerates from its natural ſtate, and the ſecretion becomes vitiated and depraved.

"Now, if the ſeveral diſtempers to which plants are ſubject are owing to the various ways in which the regular action of this fluid may be hurt; and no one diſtemper can, in my opinion, happen to corn, which will not fall under one or other of theſe circumſtances; we ought to ſearch after, and endeavour to diſcover them, in order to be thereby enabled to prevent, or to cure them, that mankind may be the leſs expoſed to the injuries reſulting therefrom. But as the knowledge of theſe particular things depends on an adequate conception of thoſe which are univerſal; and as the univerſal cauſes of diſtempers are external or internal, and the diſtempers themſelves ſeem particularly to depend on the conſtitution of the air, or an alteration of food, or on both; ſo when we have diſcovered the genus of the cauſe, it will not be very difficult afterwards to find out the ſpecies, and the efficient cauſe. So many and various have been my reſearches, obſervations, and experiments, and ſuch the lights which they have afforded me, that, if the love of truth did not oblige me to be diffident of myſelf, and if I was not thoroughly perſuaded, with that great philoſopher and mathematician Gallileo, that we cannot in general underſtand how nature acts, becauſe ſhe makes uſe of means frequently beyond the reach of our comprehenſion, I ſhould, perhaps, flatter myſelf with thoughts of having diſcovered the origin of ſome of the diſtempers to which corn is ſubject whilſt in the blade."

He then gives his opinion of mildews, which is, that they come on very early in the morning, and cover the corn almoſt inſtantaneouſly, after a cold night, which has been preceded by a hot day; and that the ſap or moiſture which then iſſues out of the plant, is gradually exhaled, and forms the ruſty powder which characteriſes this diſtemper.

After trying in vain all the boaſted remedies of the ancients (highly commended by ſeveral modern writers) ſuch as burning of ſtraw and weeds in a ſerene night, when not a breath of air is ſtirring, or the wind, if any does blow, comes only from the weſt, ſticking up branches of laurel, &c. ſprinkling the corn with tobacco, and with pepper; and ſtrewing among it, as Dr. Hales adviſes, woollen rags ſteeped in a ſtrong ſolution of ſalt of tartar, or ſea-ſalt, or in good white-wine vinegar, and afterwards well dried, even from which laſt he cannot ſay that he has found much benefit; the method long ago directed in this caſe by Mr. Worlidge, of making two men go at a proper diſtance from each other in the furrows, holding a cord ſtretched ſtrait between them, and carried ſo as to ſhake off the dew from the tops of the corn, before the heat of the ſun has thickened it, ſucceeded beſt of all; to which he adds, as an excellent preſervative, keeping the ground perfectly free from weeds, and ſtirring the earth frequently between the plants. I ought not to omit here M. Worlidge's farther obſervation, that "the ſowing of wheat early has been eſteemed, and doubtleſs is, the beſt remedy againſt mildews; for by this means the corn will be well filled in the ear before thoſe dews fall, and the increaſe will conſequently be the greater. For curioſity ſake, wheat was ſowed in all the months of the year: that ſown in July produced ſuch an increaſe as is almoſt incredible. In France, they generally ſow before Michaelmas.

"Bearded wheat is not ſo ſubject to mildews as the other, its awns keeping the dew from the ear."

MILKNESS, a dairy. *See* DAIRY.

MILLET, the name of a plant which grows naturally in India, from whence it was firſt imported into Europe, is greatly cultivated in Italy, Spain, and the ſouthern parts of France, for the food of men, as well as for that of poultry: and we alſo raiſe it in ſeveral places in England; though we have our annual ſupply of this grain from the Eaſt-Indies, which makes ſome people erroneouſly call it Eaſt-India wheat.

It delights in a light ſandy ſoil, prepared in the ſame manner as for maize; and in ſuch land it branches out into many ſtalks, ſometimes thirty or forty, not unlike reeds either in their ſhape or leaves, of which there is one at each joint. The top of each ſtalk is terminated by a large looſe panicle, which hangs on one ſide, with a chaffy flower, which is ſucceeded by a ſmall round ſeed, about the bigneſs of turnip or cabbage-ſeed, of a yellowiſh white colour in one ſort, and of a dark red, inclining to black, in another. The ſmall millet, and the large, a diſtinction which ſome writers make, are only varieties of the ſame ſort. It is likewiſe ſaid to thrive extremely well in ſtrong land: but will not do in ſtony ground, or where the bottom is either chalk or clay.

Mr. Miller directs ſowing this grain in the beginning of April, which may be very right in this country, that it may be ripe in Auguſt: but in warmer climates, the general rule is to ſow it either between the middle and the end of May, or at Midſummer. The former is reaped at the end of September, and the latter about the end of October.

The ſeed is ſowed in furrows, very thin, and covered with the plough or rake. The largeſt ſort ſhould be ſowed thinneſt, becauſe it branches moſt. When the plants are about a month old, the ground ſhould be ſtirred round them with a hand-hoe, as well to lay freſh earth to their roots, for they require a great deal of nouriſhment, as to clear them from weeds, of which they will afterwards prevent any great increaſe, by over-topping them. At the ſame time, the millet ſhould be thinned wherever it grows too cloſe, ſo as to leave, in general, about ſix inches between each plant. The huſbandman has nothing more to do to this grain till harveſt, exceptiug that, when it begins to ripen, he muſt take great care to protect it from birds, which would otherwiſe ſoon devour it. If preſerved from them, the returns are very great; for it is not eaſily hurt by drought or rain, nor is it ſubject to blight. Frequent ſhowers of rain are of great ſervice to it whilſt growing.

When the millet is ripe, its panicles are cut off near the uppermoſt joint of the ſtalk, with a knife, and put into baſkets or ſacks, in which they are carried home. They are then laid up in heaps, covered over with cloths, and, after remaining in that ſituation five or ſix days, are ſpread upon the barn floor, threſhed out with a flail, and cleanſed, like other grain. Great care muſt be taken to dry it well in the ſun, before it is laid up in the granary: for it would ſoon ſpoil if the leaſt moiſture were left in it; this being of all grains the moſt difficult to keep, unleſs it be thoroughly dry: and, on the other hand, none keeps longer or better, after it has been well dried. It is not liable to the weevil: and though it ſhould be turned from time to time in the granary, yet if that happens now and then to be neglected, it ſtill keeps perfectly well.

It has been a conſtant obſervation, that the late ſown millet, I mean ſo late as Midſummer, had always had the greateſt number of abortive grains; that its panicles are ſmaller than thoſe of the ſame grain ſowed earlier; and that the crop is leſs plentiful.

The ſmall white millet, which is by far the moſt delicate, and of which excellent puddings, &c. are made, is the ſort chiefly cultivated in this country. The red, which is much larger and coarſer, is not uſed here, except, perhaps, for pigeons, poultry, and ſwine, for which laſt it ſhould be ground to meal: but the peaſants about Bourdeaux, where a great deal of it is raiſed in the poor light lands near that city, make of it a reddiſh, heavy, ill-taſted bread, difficult to digeſt. The culture of this ſort, which is Mr. Miller's *ſorgum*, is, in all reſpects, the ſame as that of the white; excepting that, as it grows much larger, the plants require more room.

Millet, either green, or after its grain is threſhed out, is very good fodder for cattle, for which uſe it may be ſowed thicker than for a crop of grain. Its many roots, large ſize, and quick growth, are ſaid to render it a great impoveriſher of the earth; for which reaſon ſome people pull up the roots, and plough the ground immediately, as ſoon as the crop is reaped: but others, more judicious, plough in the ſtubble and roots, which rot, and greatly enrich the ſoil: and indeed all other ſucculent plants, inſtead of being ſuch robbers as is commonly ſuppoſed, return to the earth, by the inſpiration of their leaves and perſpiration of their roots, even while they grow, perhaps as much as they borrow from it: for how ſhould it be poſſible for them to pierce into the very drieſt and hardeſt ground, as we frequently ſee they do, unleſs they perſpire moiſture through their roots? As this plant requires a great deal of nouriſhment, it would probably thrive beſt in the horſe-hoeing huſbandry.

The

The following account of the culture and amazing produce of the African millet, was fent by the ingenious Mr. Burton, to the editors of the Mufeum Rufticum.

" I cannot help mentioning to you, for the fake of your practical readers, the African millet, *forghum, milium nigrum*, the culture of which is ftrongly recommended by M. Tfchiffeli, who has written a paper on the fubject, publifhed in the Tranfactions of the Berne Society. There is fomething fo very extraordinary in this paper, that I am fure you will think a fhort abftract of it worthy to be inferted in your work.

" Monf. Tfchiffeli obferves, that this millet is a plant which merits the hufbandman's utmoft attention, and that for the following reafons: 1. It thrives in all forts of foils. 2. It neither requires much dung, nor a great deal of tillage. 3. It is not fubject to the depredations of birds, which are very fond of panic and common millet. 4. It yields very large returns. 5. Laftly, it does not exhauft the land in proportion to the largenefs of the crops.

" He farther fays, that the feed of this fort of millet comes originally from Africa, where it fupplies the inhabitants with food; but that they are miftaken who thence conclude it will thrive only in hot countries: for providence has endowed it with fuch excellent qualities, that it may, with fuccefs, be cultivated in countries much colder than Switzerland.

The firft feed of it M. Tfchiffeli received was from Mr. Engel, magiftrate of Efchalens, who procured it from Pomerania, it being fent to him by the celebrated doctor Schreber, in the fpring of the year 1760. M. Tfchiffeli had from him about a fpoonful.

" In the month of May of the fame year, he fowed it on a gravelly foil, hard and ftony, very much expofed to the north wind, and which the year before had borne fome very indifferent bere. In the month of February preceding, fome human ordure had been laid on this land; and in May the clods were all broken before the feed was fpread: having fo fmall a quantity of feed, he took care to fpread it very thin; and to this does he afcribe the ftalks running to the height of eight feet or more. The ears were above ten inches long; and if a fhower of hail had not fallen on it, the fpoonful would probably have produced him at leaft a peck. This accident occafioned the lofs of half his feed: he had, however, enough left to divide with his friends in Switzerland, as well as elfewhere.

" In the month of May, 1761, he fowed about a quart of feed, or near a pound, on fome land, from which he had firft pared off the turf, and afterwards burnt it. The fpace on which the feed was fown might be about twenty paces long, and ten broad.

" Some time before harveft, M. Tfchiffeli perceived he fhould have allotted three times as much ground for that quantity of feed. The ftalks, which were very clofe, were interwoven one with the other, like the hairs of a brufh. They were fcarcely five feet in height, and the ears alfo were much fhorter than the preceding year: this, however, did not prevent his reaping about feven pecks, or above fifty for one. In the year 1762, he fowed about four pounds of feed, or about half a peck, on fome pretty good land, being in quantity about thirty fquare rods or perches. The year before, the fame land bore potatoes; and as he had laid on no frefh manure for the millet, and had neglected to plough it before the winter (for it was only turned over with a fpade before fowing) he imagined he had not fown the feed too thick: but in this he was greatly miftaken; the millet came up almoft as thick as the year before, and as he had not the courage to thin it, which would have been right, the ftalks and ears were fhorter than the firft year.

" Notwithftanding this, he was enabled to reap twenty bufhels, being fix hundred and forty pounds; of courfe, a return of an hundred and fixty for one.

" There can then be no reafon to doubt, but that land of a moderate quality, fown thin, and properly prepared, will produce, one year with another, one hundred bufhels of millet per acre; for our hufbandman got as much in proportion, though his land was but flightly tilled, and he manifeftly fowed his feed too thick. This is certainly a moft wonderful increafe, in what light foever we behold it.

" What grain is there which in the open field will yield a return of one hundred and fifty for one, and which, at the fame time, will fell fo well, for in price it is on a footing with wheat? It is true, it yields a heavy, crumbly, and indifferent bread; but if it is made into pottage, it is excellent, very nourifhing, and of exquifite flavour. Not only M. Tfchiffeli's fervants and workmen were very fond of millet thus prepared; but he himfelf prefers it to the beft rice, which will not grow in Switzerland, and comes at a much higher price.

" The millers in Switzerland, whofe reputation is not of the beft, return a good third of a bufhel of millet-meal for every bufhel fent to them, after deducting toll, bran, wafte, &c. Now this ingenious writer knows by experience, that fuch a quantity, when made into pottage with milk, will ferve at leaft fifty men for a meal. Surely they cannot be fed at a cheaper rate. In times of fcarcity millet muft be of great ufe, as with potatoes the poor might live comfortably.

" An acre of land requires, at moft, but ten pounds of feed; and M. Tfchiffeli fays he can, from his own experience, venture to affert, that millet does not impoverifh land in proportion to its produce. The land he fowed in 1760 and 1761, yielded, the following year, fine plants of Dutch clover, and rye-grafs in as great plenty, with refpect to the crops, as the neighbouring land."

MILL-HOLMS, watery places about mill-dams.

MISLIN, the fame with maflin, or maflin-corn. *See* MASLIN-CORN.

MINT, the name of a well-known herb, propagated in the kitchen-garden.

There are feveral fpecies of mint; but all of them are very eafily propagated by parting the roots in the fpring, or by fetting cuttings of it during any of the fummer months, in a moift foil. If the feafon fhould prove dry, thefe cuttings muft be watered often till they have taken root, and after that they will not require any farther trouble, except good weeding. If any quantity of thefe plants is raifed (for example, for diftilling) they fhould be fet in beds about four feet wide, with a path a foot and a half or two feet broad, to go between the beds, in order to water, weed, and cut the mint; and the diftance between the plants fhould be at leaft five inches every way, that their roots may have room to fpread; for this they do to fo great a degree, that they will mat together, and rot each other, if they are fuffered to ftand above three years in the fame bed.

When mint is cut for diftilling, or for any medicinal ufe, this fhould be done in very dry weather, when the plants are juft coming into full bloom; for they are fulleft of fap, and higheft in flavour, at that point of time. What is then cut fhould be hung up to dry in a fhady place, till it is wanted for ufe: but care muft be taken not to hang it againft a wall, becaufe this will make it turn black and mouldy. The fame will alfo happen to mint that is cut in wet weather.

If the foil be fit for this plant, it will afford three general cuttings every year: but thofe fhoots which come out after July, are feldom good for much. Thefe fhould therefore be let ftand till Michaelmas, when it will be right to cut the whole down clofe to the ground, and, after carefully clearing away all the weeds, to fift a little fine rich earth all over the beds, to the thicknefs of about an inch. This will give vigour to the roots left in the ground, and will make them fhoot out finely the next fpring.

MIST, a meteor confifting of grofs vapours floating near the furface of the earth.

The bluifh mift, which we fometimes fee on our fields and paftures in a morning though often innocent, yet has been in fome places found to be the actual caufe of murrain, and other fatal difeafes among the horned cattle.

Dr. Winklar gives, in the Philofophical Tranfactions, an account of a murrain affecting the cattle in Italy and other places, which was evidently feen to fpread itfelf over the countries in the form of a blue mift. Wherever this was perceived, the cattle were fure to come home fick; they appeared dull and heavy, and refufed their food; and many of them would die in four and twenty hours. Upon diffection there were found large and corrupted fpleens, fphacelous and corroded tongues; and in fome places thofe people who were not careful of themfelves, in their management of the cattle, were infected and died as faft as themfelves. The principal caufe of this difeafe feemed to to be the exhalation of ſome unwholeſome ſteams from the earth; and it was obſervable that there had been three earthquakes in Italy the year before it happened. The method of cure which ſucceeded beſt, was this: as ſoon as any beaſt appeared to be ſick, they examined the tongue, and, if apthæ, or little bliſters, were found on it, they ſcraped it with a ſilver inſtrument made with ſharp teeth at the ſides, till it bled in all thoſe parts where the apthæ were; the blood was then wiped away with a cloth, and the whole tongue waſhed ſeveral times with vinegar and ſalt. After this, the following medicine was given internally: take of ſoot, brimſtone, gun-powder, and ſalt, of each equal parts; mix theſe in as much water as will make them thin enough to be ſwallowed, and let a ſpoonful be given for a doſe three or four times a day. The cattle which were in health had this medicine given them, as well as the ſick; and the conſequence was, that very few died in Switzerland, while almoſt all died in other places.

It was very remarkable that the contagion, on this occaſion, ſeemed to travel ſlowly and regularly on: it came at the rate of about two German miles in twenty-four hours: this it kept regularly to, during the whole time of its raging, and never appeared in very diſtant places at the ſame time.

The whole ſurface of the earth emitting theſe effluvia, no cattle eſcaped them in the courſe of their way; but thoſe which were kept within doors at rack and manger fell ill at the ſame time, and in the ſame manner with theſe in open fields. Dr. Slare was of opinion, that it was owing to certain inſects which could not fly faſter than at the rate of two German miles a day; and that they travelled regularly, and ſpread the miſchief where they paſſed; but there wanted ſome judicious perſons, verſed in theſe obſervations, to have examined both the ſtate of the air, and the beaſts, on this occaſion. *Philoſ. Tranſactions*, Numb. 145.

MIXEN, a dung-hill.

MIZZY, a bog, a quagmire.

MOAR-LOVRE, a term uſed to expreſs a peculiar diſtemperature of corn, generally comprehended under the common term of a blight. In this caſe the earth ſinks away from the roots of the corn, and leaves the plant ſtanding in great part above ground with naked roots; theſe being too weak to ſupport the ſtalks, the plants fall, and the ears become light. This a diſtemperature peculiar to corn growing on light and looſe lands. *Tull's Horſehoing Huſbandry.*

The remedy is this: turn a ſhallow furrow againſt the rows, when they are ſtrong enough to bear it, and the mould is fine and dry; the motion of the ſtalks with the wind will draw in this looſe powder, and it will ſpread itſelf equally among all the rows, ſettle about the roots, and cover them.

MOLE, a ſmall animal too well known to the huſbandman, from the miſchief it does in the fields, by looſening of the earth, and deſtroying the roots of corn, graſs, and other vegetables.

The common method of deſtroying them is by traps, made in the following manner:

Take a ſmall board, about three inches and a half broad, and five inches long: on one ſide thereof raiſe two ſmall round hoops or arches, one at each end, like the two hoops or bails of a carrier's waggon, capacious enough for a mole to creep through eaſily: in the middle of the board make a hole about the bigneſs of a gooſe-quill, and have in readineſs to put into it a ſtick about two inches and a half long, fitted at one end to the hole, and a little forked at the other. Cut alſo a hazel or other ſtick, about a yard, or a yard and a half long, which will riſe with pretty ſtrong elaſticity, when it is ſtuck into the ground; and to the end of this ſtick faſten a very ſtrong nooſe of horſe-hair, made ſo as to ſlip eaſily. Have likewiſe in readineſs four ſmall hooked ſticks: then go to the furrow or paſſage of the mole, and after you have opened it, fit in the little board with the bended hoops downward, ſo that when the mole paſſes that way, it may go directly through the two ſemi-circular hoops. But before you fix the board in this manner, put the hair ſtring through the hole in the middle of it; place the nooſe in a circular form, ſo as to make it anſwer to the two hoops; put the ſmall ſtick before mentioned gently into the hole in the middle of the board, ſo as juſt to ſtop the knot of the hair ſpring, without entering ſo far as abſolutely to tighten it. Then faſten the board down with four hooked ſticks, and cover it with earth. When the mole, paſſing in its furrow, comes into this trap, it will diſplace the ſmall ſtick that hangs perpendicularly downward, the knot will then be drawn through the hole, and the nooſe, inſtantly ſtreightened by the riſing of the end of the hazel ſtick to which it is faſtened, which will catch the mole round the neck.

Others, watching their motions in the morning and evening, which are their uſual times of ſtirring, dig them out in a moment with a ſpaddle: and about March, which is their time of breeding, numbers of their young ones may be deſtroyed by turning up their neſts, which are generally in the greateſt hills; and the old ones who come to ſeek their young will preſently be taken.

Some commend the pot-trap, which is a deep earthen veſſel ſet in the ground with the brim even with the bottom of the mole tracks. The ſeaſon for uſing this is when the moles couple, which is about the beginning of March, or perhaps ſomewhat earlier.

Mr. Worlidge ſays, they may be driven from the gardens, meadows, and other places where one would not chooſe to dig, by fuming their holes with brimſtone, garlick, or other unſavoury things; and that the putting a dead mole into a common haunt, will make them abſolutely forſake it: to which Mr. Mortimer adds, but only upon report, that white hellebore and the roots of palma-chriſti, dried, powdered, and ſifted through a fine ſieve, then mixed with barley-meal and eggs, and worked into a paſte with wine and milk, will kill them, if laid in little pellets under their hills.

The writers of the Memoirs of the Society of Agriculture at Angers, recommend hazle-nuts boiled in an infuſion of hellebore, as a ſure method of deſtroying moles. Two or three of theſe nuts are to be laid under each mole's hill, and the creatures, by being fond of that fruit, will be poiſoned by eating them.

The way to remove mole-hills and ant-hills, which are not only diſagreeable to the ſight, but detrimental to the paſture, and a great hindrance to the mowing of the graſs, eſpecially where they are numerous, is particularly in regard to the latter, either to divide the turf which grows over them, into three parts, with a ſpade, or other inſtrument, then to pare it off each way, to dig out the middle or core of the hills, to ſpread this mould over the other ground, to leave the holes open all the winter, that the ants may be killed, to lay the turf down again in the ſpring, and to roll thoſe ſpots after the re-inſtated turfs are ſettled, and their graſs has taken freſh root; or, which is a more expeditious method, to ſcoop them out at once, with what Mr. Bradley calls a ſcolloped mole-hill plough, made in the following manner.

From *a* to *a* (Fig. 1. Plate XX.) is an iron plate, about five inches over, and above an inch thick at the back. *b b* is the ſcolloped ſpade, or tongue, of the plough, and about a foot over at the wideſt part. This, from the ſharp point, grows thicker by degrees, till it comes to the back, which ſhould be a full inch thick. The iron muſt be well hardened, and very ſharp at the edges. *c c* is the paring plate, which ſhould be very ſharp on the fore edge, and, with the ſcolloped ſpade, ſhould be four feet long from *a* to *a*. *d d* are iron ſockets, in which are fixed the plough handles, or ſtilts, *e e*. At *a a* are foot-links to ſet the harneſs on, for one horſe, or two horſes lengthwiſe, to draw by.

When this plough is uſed, the point of the ſcolloped ſpade muſt be ſet to the bottom of the hill, by raiſing the plough ſtilts, ſo that it may go into the ground; and when the hill is near cut through, the point ſhould be raiſed up again, by weighing a little on the ſtilts.

The hollow left by this plough will receive the rain as it falls, and this will drown the remaining ants.

After the mole and ant-hills, and other inequalities have been thus taken off, the beſt way is to carry them to a corner of the field, there to break them well to pieces, and mix them with a conſiderable portion of lime, or other manure ſuited to the ſoil, which will effectually deſtroy every remains of the ants, and convert the whole to good manure, which may then be profitably ſpread all over the ſurface of the ground. The ſpots on which the mole, or ant-

ant hills stood, should be loosened with a spade, then mixed with lime or other manure, and afterwards be laid down with clean grass seeds.

This method is the most advisable of any, because a fine grass will be raised in those places, instead of the coarse benty growth which occupied them before.

MOLTEN-GREASE, a fat or oily discharge with the dung, and arises from a colliquation, or melting down of the fat of the horse's body, by violent exercise in very hot weather.

It is always attended with a fever, heat, restlessness, starting and tremblings, great inward sickness, shortness of breath, and sometimes with the symptoms of a pleurisy. His dung will be extremely greasy, and he will fall into a scouring; his blood will have a thick skin of fat over it when cold, of a white or yellow hue, but chiefly the latter; the congealed part, or sediment, is commonly a mixture of size and grease, which makes it so extremely slippery, that it will not adhere to the fingers, and the small portion of serum feels also slippery and clammy. The horse soon loses his flesh and fat, which probably is dissolved and absorbed into the blood; and those that survive this shock commonly grow hide-bound for a time, their legs swelling both before and behind, and continue in this state till the blood and juices are rectified; and if this is not done effectually, the farcy, or some obstinate surfeit, generally follows, very difficult to remove.

In the first place bleed plentifully, and repeat it two or three days successively in smaller quantities; two or three rowels should also be immediately put in, and cooling emollient glysters, daily thrown up to abate the fever, and drain off the greasy matter from the intestines. By the mouth give plenty of warm water, or gruel, with cream of tartar, or nitre, to dilute and attenuate the blood; which in this case is greatly disposed to run into grumes, and endanger a total stagnation.

When the fever is quite gone off, and the horse has recovered his appetite, gentle aloetic purges should be given once a week, for a month or six weeks, in order to bring down the swelled legs; but if the purgative ingredient does not exceed half an ounce, or six drams of fine aloes, it only opens the belly gently; and, with the other medicines joined with it, passes into the blood, acts as an alterative, and operates both by urine and perspiration; as will appear by the horse's staling plentifully; and the kindly feel of his skin. To this end give the following, which, repeated for some time, will intirely remove this disorder.

> Take of succotrine aloes six drams, of gum-guaiacum powdered half an ounce, of diaphoretic antimony, and powder of myrrh, of each two drams: make into a ball with syrup of buckthorn.

Or it may be prepared with an ounce of aloes, six drams of diapente, and a spoonful of oil of amber.

These will seldom take a horse from his business above two or three days in a week; neither will he lose his flesh or appetite with them, which cannot be obtained by any other method of purging, and gives this greatly the preference in many cases.

Two ounces of nitre mixed up into a ball with honey, and a dram of camphire, will also be found an excellent medicine for this purpose, as it will powerfully attenuate the blood, and promote the due secretions; to which end it should be given every day for a fortnight, or three weeks. *Bartlet's Farriery*, p. 168.

MOLTER, the toll of a mill.

MOOR, a very fine black mould, sometimes found under a pretty thick sward of grass, but more frequently under moss, or straggling plants of heath.

It differs from peat, in that it does not stick together, nor has the fibrous roots, or bituminous viscous quality of this last. Peat, when dry, becomes hard and firm: this falls into powder. It cannot be better described, than by comparing it to that substance which is found in hollow rotten willows, and other trees of that kind; which gives room to think that it arises from rotten plants. It is of a spungy nature, and ready to imbibe moisture, which adds considerably to its weight. There is generally underneath it, as under most earths of this kind, a bed of clay, or some substance impervious to water: so that the particles of bodies decayed on their surface, not being admitted into the soil, remain upon that surface, dry there, and increase its thickness, according to the continuance of the cause.

If this kind of soil is collected in a place where running water, in rainy seasons, brings with it clay, or other fat soils, from the neighbouring grounds, it then acquires a greater degree of cohesion, hardens when dry, and resembles the cleansing of ponds, more than the former.

The most considerable soil of this kind is the sort called peat. This is usually full of roots of weeds, and even of trunks and branches of trees and other plants. It always contains a bituminous oil, which renders it very inflammable when dry; at which time it also becomes very hard, though it is quite soft when in the mine, if we may be allowed to give that name to the bed in which it lies; for there it is easily cut in the form of bricks, as we see it when used for fuel.

"The whole mass and body of this soil, says Mr. Maxwell, is a dung-hill, made up of rotten timber, grass, weeds, and often mud washed from the higher grounds about it, by the land-floods; than which there are few richer composts: only by age, and its cold situation in water, pent in about it by the neighbouring rising grounds, its salts are weakened, and its spirits become languid. The same will happen to the richest dunghill that can be made of any composition whatever, if too long kept. It will even become such as not to be distinguished, by the eye, from ordinary moss; nor will it be more useful, as dung, except either in proportion to the shorter time it has been kept, or the better situation of the place where it has stood. I believe the qualities of mossy grounds differ very little from one another in any other respect, than with regard to the better or worse quality of the mud which makes a part of their composition. They are more or less spungy, in proportion as this rich mud fills up the cavities of the component vegetables, which are preserved from putrefaction by the acid in the water. The less spungy, and the more rotten the moss is, the fitter it is for the vegetation of any thing planted in, or sown on it."

The first thing to be done, in order to the improvement of moors, is to divide them into proper inclosures; not only to secure their future produce, but also to be a means of procuring rich earth to cover the otherwise insipid useless mould on their surface, and give root to the plants which may afterwards be cultivated in them. Then, as the natural produce of this earth is of no value, its surface should be pared off, in order to be burnt. But as this subject, of burning earth, has been before fully treated of, we shall only observe here, that the husbandman should be very careful not to make the clods too dry, or light his fires in too dry a season, lest they should extend farther and deeper than was intended.

If the depth of the moorish earth be not very considerable, the surrounding ditches, which make the inclosure, will afford a rich strong soil, which should be spread about three or four inches thick all over the surface. When the clods are burnt, their ashes should be mixed with this new soil. If no proper earth can be got from the ditches, sand or gravel may be used with success, as was practised by the ancients. Gravel is singularly beneficial to such lands, as has been shewn under the article Bog.

The Berne society, who recommend this method of improvement as founded on repeated experience, very properly observe, that the good effects of the sand and gravel will be considerably increased by a moderate mixture of dung, and that, especially if the ground be intended for plowing, this covering should be at least a hand's breadth in thickness. Dung alone would undoubtedly be extremely efficacious on all such soils, in which it is remarked to be of longer service than in any other; but the farmer can seldom spare a sufficient quantity of it to go far enough unmixed, nor indeed for mixing. In this case, other ingredients must be recurred to; though the sand, or gravel, will generally do great things without any mixture. Well preserved ashes will be of excellent service, and so will the rubbish of old buildings, or any other similiar substance, when mixed with the sand or gravel, even of the coarser kind, and incorporated with this naturally rich earth, which, were its real value known, and the proper method of treating it rightly understood, might claim a preference before any other foil. Loam is ftill better than either fand or gravel. This fhould be brought on before the fires are lighted to burn the furface of the mofs, and fhould remain in heaps till it can be equally mixed with the afhes. Lime, where it can be had, will alfo contribute to the meliorating of moffy grounds. The moorifh earth, thus covered, is fitted for various kinds of crops.

Mr. King, who obferved that the places in bogs in Ireland, where a little earth had chanced to fall as the peafants were carrying it to mend the ways acrofs them, became a green fod, covered with a fine fcutch grafs, does not doubt but that the fame expence as fands or gravels land, would bring a dried bog even to be arable; and as to the common opinion that gravelling is bad for grafs, the contrary, he fays, is apparent; efpecially in bogs. Another method of reducing barren boggy land, in Ireland, is by laying upon it a little dung or ftraw, and covering this with fhells.

A ftrong proof of the propriety of covering mofs with earth, refults from a fact which happened to Mr. Græme, near Stirling. Two years after this gentleman had earthed his mofs, which he had not yet fowed, it was as full of natural white clover, and other grafs, as any field generally is in twice that time.

In the province of Groninguen, they pare off the upper furface of the foil, which is a light loofe earth, and lay it by till they have dug out the peat underneath, when they mix it with the fand which lies under the peat, and fow it with rye and hay-feed the firft year; after which they let it run to grafs, and have amazingly fine crops. In Sweden, a drained bog was remarkably improved by a peafant who burnt upon it a parcel of ufelefs wood and limeftones; and another converted his drained bog into a fine meadow, by covering it with lime and tanner's bark.

Mr. Eliot, after draining a very remarkable fwamp, fowed it with grafs-feed, fuch as red clover, fpear-grafs, fowl-meadow grafs, and herd grafs; none of which came up fo well as the red clover, which he found to be the boldeft and moft hardy. Though this came up well, yet, where the fward was ftrong, what with the toughnefs of the ground and the over-topping growth of the wild natural grafs, it made but flow progrefs till the fall of the year, and then it mended confiderably. The other forts of grafs came up but poorly, the land being, as Mr. Eliot judges, too new and tough for them. In September, he ploughed up a piece of this ground, where he had not fowed any grafs. It ploughed very tough, and the cattle mired in fome places; but he kept them as much as poffible upon the grafs; notwithftanding which there was a neceffity of leaving many baulks. About a month after, he ordered thefe baulks, to be hoed up, and was agreeably furprifed to find how eafily this was done. He found the meadow rotted and mellowed more in one month in the fall, than it had been in the whole fummer; but thinks the ploughing would have been performed with much greater eafe, if it had been deferred till a month later. In July, he fowed a little piece with turnips, which came up, but did not grow well till the ground began to rot in the fall of the year, when they throve perfectly, and were good and fweet, inftead of being rank, as he expected.

This gentleman found by experience, that fuch drained land muft have one fummer to ferment and rot, fo as to become proper foil, before it will be fit for grain or every fort of grafs. "If, fays he, I had fowed red clover inftead of the other forts of grafs, I had faved five pounds in feed. Clover out-did my expectation, and the other forts fell fhort of it. If others fave where I loft, and mend wherein I was miftaken, it anfwers my defign in writing.

"By a little experience which we have had of thefe drained lands, we find they will produce Indian corn, fixty or feventy bufhels to an acre, and flax. If life and health be continued, I defign to try liquorice-roots, barley, Cape-Breton wheat, cotton, indigo-feeed, wood for dying, and the water melon. But what I have principally in view is hemp. New-England doth not, I fuppofe, expend lefs than feveral hundred thoufand pounds worth of foreign hemp yearly. If we can raife more than to fupply our own occafions, we may fend it home. It is not a mere conjecture, that the drained lands will produce hemp. I am informed by my worthy friend Benjamin Franklin, Efq; of Philadelphia, that they raife hemp there upon their drained lands.

"Hemp requires fuch very ftrong land to produce it, that it would confume all our dung to raife it in any great quantities; fo that we fhould not be able to raife bread-corn: therefore, how inviting foever the trade is, and how great foever the encouragements have been, both from home and by our own government, we have not as yet engaged in that affair. We have now a promifing profpect of fuccefs in thefe drained lands: what may be the iffue, time and experience muft determine. A meadow of drained land, which could be laid under water, and this drawn off at pleafure, would probably be of great value. I have heard that a man in the Jerfies hath fuch a meadow, which thotugh only half an acre in exent, yields him as much hemp yearly, as fells for fifty pounds, York money: but this feems incredible."

Whatever advantages are reaped from hemp, may alfo be received from flax, if rightly managed, upon moffy grounds. Some improvers in Scotland have already tried it with fuccefs, and though, a new attempt, doubt not its anfwering well in that kind of foil. The moft approved method of cultivating and dreffing each of thefe fingularly beneficial plants, are given under the articles HEMP and FLAX.

"It is common in fwamps, continues Mr. Eliot, to find the mofs two or three feet deep. At firft, I was perplexed how to get rid of it, and fomewhat doubtful whether the land would be worth any thing, if this furface was removed. When the water was drawn off by ditches, the mofs grew fo dry, that in a hot fummer feafon, it would burn quite down to the ground. To burn this, or any other trafh you would confume upon land, fet fire to it when the weather is clear, the fun hot, and a ftrong foutherly wind blows, which makes fire rage more fiercely, and do much more execution, than a northerly or wefterly wind. In a northerly wind the air is thin and light, fo that the fire is not ftrongly compreffed: the moift heavy fouth wind prevents the diffipation of the fire, and renders it more compact. Thus we fee a fmith fwab and wet his coals, by which means the heat is greatly increafed. Whether this reafoning be juft or not, the fact is certain, and that is the chief concern of the farmer.

"Deep fwamps are preferable to thofe which are fhallow: for experience fhews, that a deep foil bears extreme drought better than any other land, in the hot feafon. The cold drought in the fpring will hurt fuch land, fo that the firft crop of grafs will not be very great; but the fecond crop will be extraordinary good.

"The red clover in my drained land above-mentioned, looked in the cold drought at the latter end of the fpring, as if it would not come to any thing: but it recovered a good colour, and grew up well, when hot weather came on, though the drought continued. This is fuch an advantage as will always recommend a foil eight or ten feet deep.

"Our ditching and draining dry only the top of the ground, not more than three feet deep in the hot and dry feafon; I fuppofe that the moifture from the mud and water underneath is drawn up by the force of the fun, fo that the roots of the grafs are furnifhed with fufficient moifture to bring forward the vaft burthen they frequently bear. But this is not to be expected till the land be concocted, changed, and altered by the fun and air: for at firft, foon after it is drained, it is pinched with the drought more than any other land.

"Thofe fwamps which are thick overgrown with mofs, prove as good as any other drained land, when they are fo far dried by draining, that the mofs will rot, or burn off. I mention this, becaufe it is beft that the farmer work as free from difcouragement as poffible.

"Our drained land, though in all other refpects well adapted for producing Indian corn, is of fo loofe a texture that the plants become an eafy prey to crows and other birds, which, if not prevented, will pull up a great part of them, and deftroy the crop. To guard againft this great difcouragement in all fuch land, "Take the roots of swamp hellebore (known in different places by the several names of skunk-cabbage, tickle-weed, bear-root) and boil them in so much water as to keep them covered an inch deep: by two hours boiling, the liquor will be of sufficient strength: strain it off; put your corn into it while the liquor is warm, and let it steep twenty hours. It will then be fit for planting.

"This is found to be an effectual security. The Rev. Mr. Todd observes, that after meeting with much trouble and loss, by having his corn repeatedly pulled up, he planted his ground with corn steeped in this liquor; but not having enough of that, he ordered the planting to be finished with unsteeped corn. The event was, that the birds pulled up but two or three hills of the soaked corn, but left not one in ten of those which were planted with unsoaked corn. He planted anew, with steeped corn, the hills where the plants had been thus pulled up, except a few of them in the middle of the field, which were planted a second time with unsteeped corn, upon a supposition that the birds would not find them out: but the result was as before: all the unsoaked was pulled up, and the hills planted with the steeped corn were spared.

"Upon the whole," says Mr. Todd, "I think this experiment a full proof that corn so prepared when planted, is secure from the birds; the knowledge of which may be of great service to husbandmen, as the preparation is cheap and easy, and our swamps seem to be the best land we have for Indian corn. My little swamp this year yielded after the rate of above ninety bushels to the acre, and was easier and cheaper tilled than the same quantity of upland." *See the article* BOG.

MORES, or *Moars*, hills.

MORGAN, the same with May-weed. *See the article* MAY-WEED.

MOSS, a name given to moory or boggy grounds, in many parts of England. These sorts of land consist of a turfy surface, below which is a black, moist, spongy earth, which being dug up with spades, almost in the form of bricks, and dried, is what they call peat, and used as fuel in several parts.

The shortest method of all for the improvement of moss, if the ground be designed only for grass, and its situation be such as admits of it, is this: first drain the moss, and if there be heath upon it, burn that off, and make the surface even. Then make a dam at the lowest part, and a sluice, and work the water upon it through the winter. The mud which comes with the land flood will bring a fine sward upon it in two or three years, and be afterwards a yearly manure; so that it will bear annual cutting, and, besides, be good pasture for cattle, after the sward is become strong enough to bear them.

Mr. Græme found that the improvement of moss may be endangered by draining it too much; for his crops were best where the surface of the water in the surrounding ditches was not above three feet lower than the level of the moss. It will, undoubtedly, be a vast advantage to an improved moss, if the farmer is able to flood it at proper times, by means of a sluice in the lowest part of the surrounding ditch, as mentioned before. This will greatly promote the growth of plants; but should be used with the caution of not letting the water remain too long at a time upon the ground, because, though there will be no danger of its re-converting the soil into a bog so long as there are channels to carry it off, it will be apt to chill, and thereby hurt the plants. *See the article* BOG, *and* MOOR.

MOSS *on Trees*, is a distemper of very bad consequence to their increase, and much damages the fruit of the trees of our orchards.

The present remedy is the scraping it off from the body and large branches, by means of a kind of wooden-knife, that will not hurt the bark; or with a piece of rough hair-cloth, which does very well after a soaking rain. But the most effectual cure is, the taking away the cause. This is to be done by draining off all the superfluous moisture from about the roots of the trees, and may be greatly guarded against in the first planting of the trees, by not setting them too deep.

If trees stand too thick in a cold ground, they will always be covered with moss; and the best way to remedy the fault, is to thin them. When the young branches of trees are covered with a long and shaggy moss, it will utterly ruin them; and there is no way to prevent it, but to cut off the branches near the trunk, and even to take off the head of the tree, if necessary, for it will sprout again; and if the cause be in the mean time removed by thinning the plantation, or draining the land, the young shoots will continue clear after this.

If the trees are covered with moss, in consequence of the ground's being too dry, as this will happen from either extreme in the soil, then the proper remedy is, the laying mud from the bottom of a pond or river, pretty thick about the root, opening the ground to some distance and depth to let it in; this will not only cool it, and prevent its giving growth to any great quantity of moss, but it will also prevent the other great mischief which fruit-trees are liable to in dry grounds, which is, the falling off of the fruit too early. *Mortimer's Husbandry.*

False MOTH, an insect which proceeds from a small caterpillar, the body of which is smooth and whitish. It has sixteen legs, does not lodge in the grains of corn, but contrives to fasten several of them together with a web which it spins, and with which it makes itself a dwelling place like that of common caterpillars. This dwelling place, or sheath, in which the caterpillar of the false moth usually abides, is generally in the middle of the little heap of grains which it has collected for its food: but, which distinguishes it from the caterpillar of the true moth, it can quit this sheath at any time, to eat the grains around it, one after another. It generally attacks several grains at once, and always without order, eating sometimes of one, and sometimes of another; so that several are gnawn, when not one is wholly consumed. When these insects are very numerous in a granary, all the grains upon the surface of the corn are linked together by a web, so as to form a crust, which is sometimes three inches thick. This caterpillar turns into a chrysalis, or aurelia, in a grain which it has hollowed, or in the sheath of its web, and issues from thence, in the month of June, in the form of a butterfly. When a heap of corn is stirred in which there are many caterpillars of the species of this false moth, those insects crawl up the walls; but they soon return to the heap, and, by the very next day, cover it all over with a new web.

In its state of moth, it is grey, has six legs, and is frequently seen in vast numbers fluttering about the eaves of the windows of granaries, in the spring and summer, when the weather is very hot. The females lay their eggs upon the heaps of wheat, and these eggs produce the caterpillars, or corn worms, as some call them, which feed on the grain, and envelop it with their silky web, so as to form over the whole surface a crust that is sometimes three or four inches thick. This entirely spoils the corn within that depth, besides communicating a bad smell to all the rest. These worms, or rather caterpillars, for they have sixteen legs, are smooth, whitish, and seldom exceed a quarter, or at most the third part of an inch when at their full growth. Breaking of their webs avails but little, for they are woven again by the next day: for which reason some have been of opinion, that it is best to let them enjoy undisturbed the surface of the corn of which they have taken possession. But it should be considered, that three inches are a sixth part, and four inches upwards of a fifth, of any quantity of corn spread eighteen inches deep, which is the medium thickness at which it is laid; and that, independant of the bad smell with which the rest is tainted, this is a very considerable object, though it extend no farther. When this crust is broken, most of the grains which compose it are found to be either gnawn in their inside, or full of live worms, or of aureliæ, according to the season; or one sees only the empty sheaths of the catterpillars, if the aureliæ have been transformed into moths.

It is said, that strewing the corn with powdered lime, so as to form a crust over it, will preserve it from the ravages of these insects: but as the surface would still be spoiled, and as that surface may be a considerable part of the small provision of wheat allotted for a family only, M. Duhamel did not try this expedient. Covering

vering it with hay, which he did try, anſwered no end whatever.

Theſe obſervations, and the reflections conſequent thereon, made him ſuſpect that this inſect, as it delights in none but very warm places, would not be able to live in the cold air of his ventilating granaries.

Accordingly, in the winter of the year 1746, he collected all the wormy cruſts which theſe caterpillars had formed in his common granaries, where they were very thick, the moths having been extremely numerous the preceding ſummer. Theſe cruſts were broken and ſcreened; and what grain could be got from them, which undoubtedly was impregnated with the eggs of the moths, was put into one of his granaries of preſervation, which contained ſeventy-five cubic feet, and was ventilated from time to time during all the winter.

Towards the end of May, when the vent-holes at the top of this granary were opened, a prodigious number of moths flew out, which ſhewed that they did not like their ſituation.

When the wheat was thought to have been ventilated ſufficiently, the holes were ſhut cloſe, and nothing more was done to it for a month: for as this corn (which had not been ſtove-dried) was old and dry enough, it was but ſeldom ventilated.

In June 1747, this granary was emptied: all the moths and worms were dead, and there remained only a thin cruſt, not above a twelfth part of an inch thick, on the top of the corn, which had ſo far loſt the bad ſmell it had when put into the granary, that it ſold for the current market price.

Not ſatisfied with this ſingle method, M. Duhamel tried the effect of the ſtove upon another parcel of wheat known to be full of theſe worms. A heat from 45 to 50 degrees of Réaumur's thermometer (from 115 to 124 of Farenheit's) killed them all. This corn was then laid up in a common granary, where it remained two years without being attacked by any of theſe moths; and even in the third, but very few of them appeared.

Theſe experiments remove all doubt of the poſſibility of deſtroying the corn moth, or worm, without hurting the grain, which would otherwiſe be ſpoiled by it; and as that grain, generally is wheat, which the inſect prefers to any other, this diſcovery is of great importance to the huſbandman, as well as to the public.

MOULD, a looſe kind of earth, every where obvious on the ſurface of the ground, called by ſome mother earth, and by others loam.

The goodneſs of a mould for the purpoſes of agriculture and gardening, &c. may be known, according to Mr. Miller, by the ſight, ſmell, and touch. 1. Thoſe moulds that are of a bright cheſnut or hazely colour, are counted the beſt: of this colour are the beſt loams, and alſo the beſt natural earth; and this will be the better yet, if it cut like butter, and does not ſtick obſtinately, but is ſhort, tolerably light, breaking into ſmall clods, is ſweet, will be tempered without cruſting or chopping in dry weather, or turning to mortar in wet. Next to that the dark grey and ruſſet moulds are accounted the beſt: but the light and dark aſh coloured the worſt, ſuch as is uſually found on common heathy ground: the clear tawney is by no means to be approved; but that of a yellowiſh red colour is the worſt of all: this is commonly found in wild and waſte parts of the country, and for the moſt part produces nothing but goſs, furze, and fern, according as their bottoms are more or leſs of a light and ſandy, or of a ſpewey gravel, or clayey nature. 2. All lands that are good and wholeſome, will, after rain, or breaking up by the ſpade, emit a good ſmell. 3. By the touch we may diſcover whether it conſiſts of ſubſtances entirely erenaceous, or clammy; or, as it is expreſſed by Mr. Evelyn, whether it be tender, fatty, deterſive, or ſlippery; or more harſh, gritty, porous, or friable.

MOULDINESS, a term applied to bodies which corrupt in the air, from ſome hidden principle of humidity therein; and whoſe corruption ſhews itſelf by a certain white down, or lanugo, on their ſurface, which, viewed through a microſcope, appears like a kind of meadow, out of which ariſes herbs and flowers, ſome only in the bud, others full blown, and others decayed, each having its root, ſtalk, and other parts.

MOUND, a bank or fence of earth. *See the article* BANK.

MOW, the pile or collection of corn in the ſtraw, placed in a bay of a barn. *See the article* BARN.

MOW-BURNT, over-heated in the mow for want of being dry.

MOWING, the art of cutting down corn, graſs, &c. with a ſcythe.

M. de L'Iſle lately introduced the mowing of wheat. The method is this: the ſcythe he uſes is at leaſt ſix inches ſhorter in the blade than the common ſcythe, and inſtead of a cradle has two twigs of ozier put ſemicircular-wiſe into holes made in the handle of the ſcythe, near the blade, in ſuch a manner, that one ſemicircle interſects the other: this method is frequently practiſed by the men who mow our meadows, as they think a cradle unneceſſary and cumberſome, unleſs the ſcythe is to carry over a large and very heavy ſwarth.

In mowing barley, or oats, the corn is always on the right-hand of the workman: but by M. de L'Iſle's method of mowing wheat the corn is at his left-hand: he mows it inward, bearing the corn he cuts on his ſcythe, till it comes to that which is ſtanding, againſt which it gently leans. After every mower follows a gatherer, which may be a lad of twelve or fourteen years of age, or a woman. The gatherer keeps within five or ſix feet of the mower, and being provided either with a hook or ſtick about two feet long, gathers up the corn, makes it into a gavel, and lays it gently on the ground: this muſt be done with ſpirit, as another mower immediately follows; for to every mower there is a particular gatherer.

To do this work properly, the mower ſhould form but one track with his feet, advancing in a poſture nearly as if he was going to fence, one foot chaſing the other. In this manner the ſtanding corn is mowed; but the workman muſt take care to have the wind at his left, as it bears the corn towards the ſcythe, and cauſes it to be cut nearer the ground. If the wind is behind the mower, it is no great inconvenience: it only occaſions the ſcattering of a few ears; and the cut corn, which ſhould lean againſt the ſtanding corn, is ſometimes thrown down; which makes the work go on ſlower, and encreaſes the gleanings. The wind in front is very bad; the corn cannot be cut cloſe, and there is a great loſs: but the wind on the right-hand is worſt of all; the ſtubble is left long, and ſuch a quan- of gleanings, that one would imagine no crop had been taken off. When wheat is bent, the workman takes the corn as it preſents itſelf to him, which has the ſame effect as if the wind was at his left-ſide. When wheat is laid, it is more troubleſome to the gatherer, becauſe the cut corn is apt to be mixed with that which is ſtanding; but a good mower takes the advantage of the wind, and cuts it againſt the way it is laid. No particular directions can be given for corn that is lodged and tangled, unleſs it is to take it as it is inclined, as if the wind was in the back of the mower.

This method of mowing wheat was tried in Northamptonſhire, and the following account of it ſent to the editors of the Muſeum Ruſticum.

" A gentleman, a foreigner, ſays this writer, came down here to a neighbour's of mine, in order to put us into a method of going about this work.

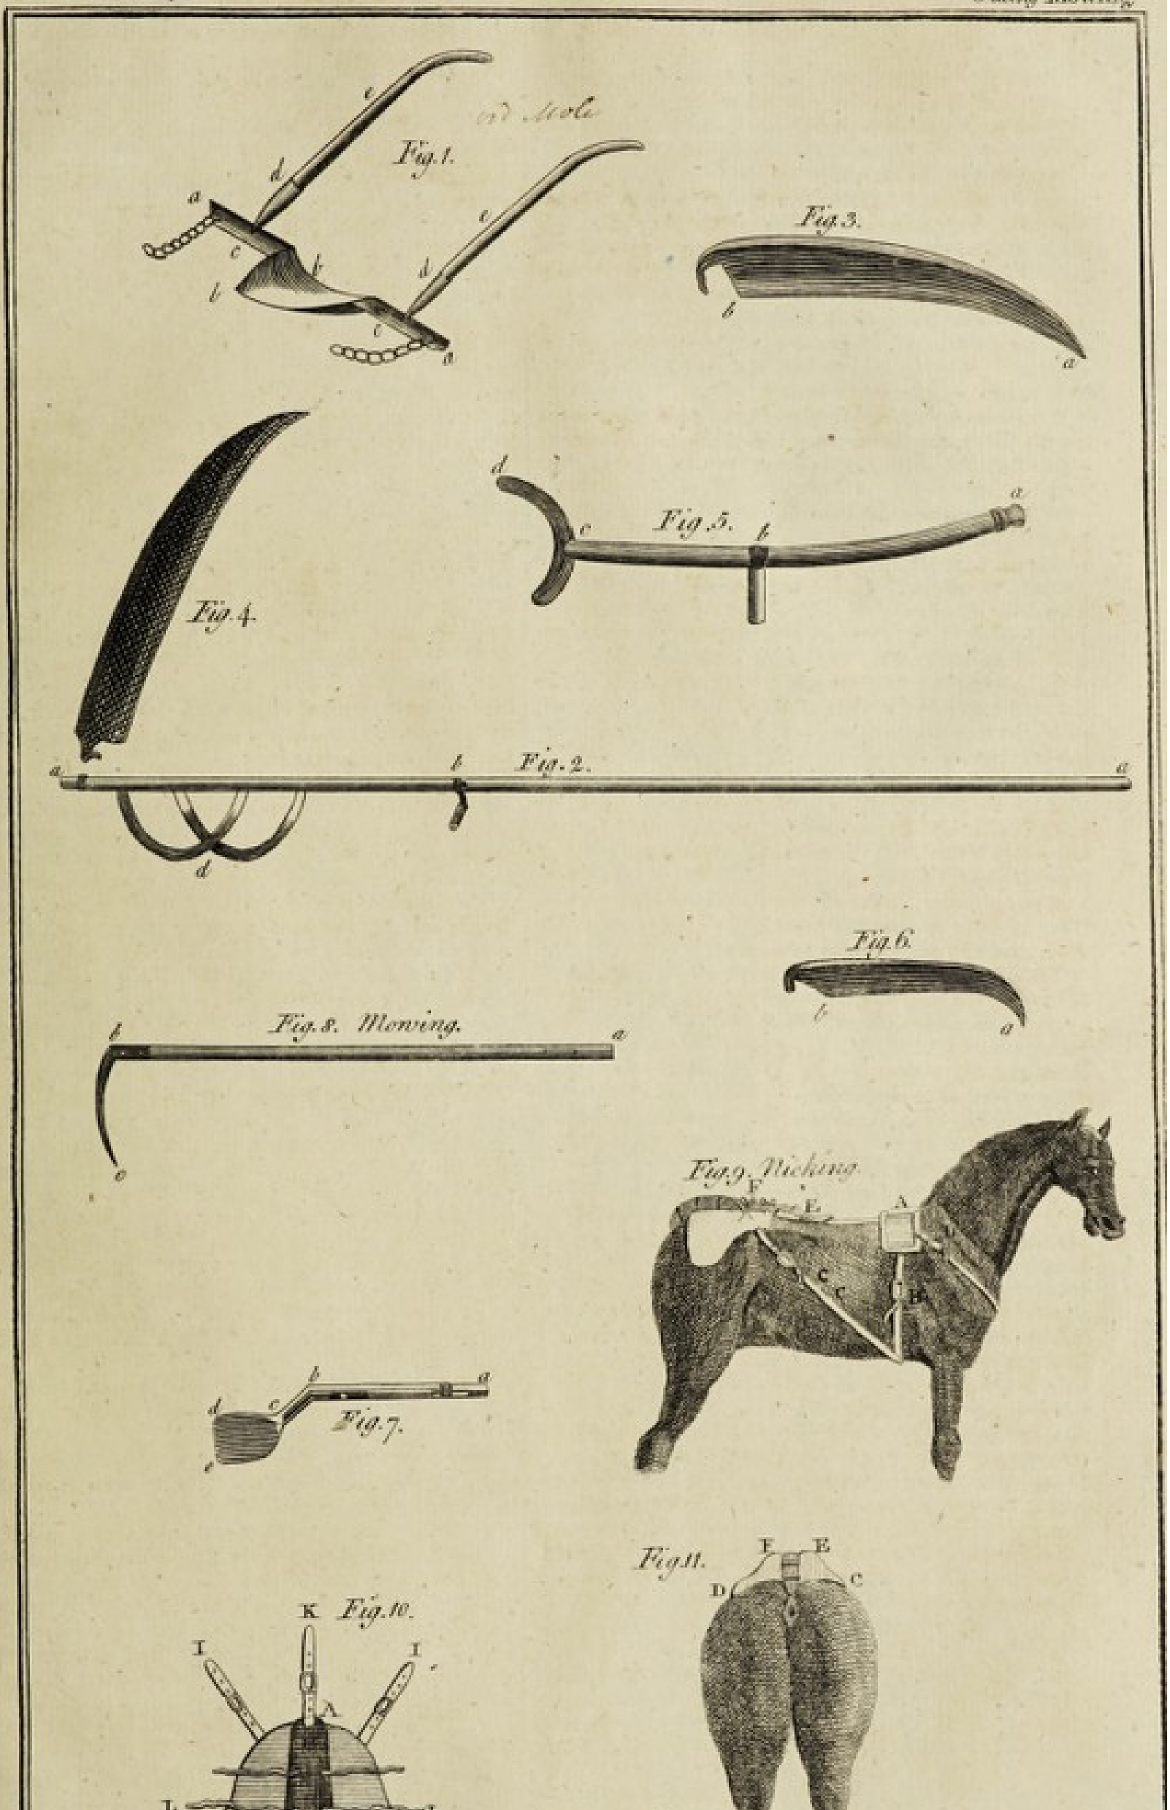
" Many trials were made in the preſence of myſelf, and a great number of others: the ſcythes did their work well; they cut the corn within two inches of the ground: and though our workmen were of courſe a little aukward, ſcarcely any ears were ſcattered: but the greateſt advantage is, that a man with one of theſe ſcythes can cut down at leaſt double the quantity of wheat in the day he can with a ſickle or hook.

" The chief objections made to the introduction of this method were, that the ſtubble is left too ſhort, and on that account is not fit for thatching; that the weeds are cut with the corn, and will be apt to mould or heat, and the ſeeds to mix with the corn in threſhing; and that the poor are deprived of their gleanings, as none of the corn is ſcattered.

" But theſe objections muſt ſoon fall to the ground, when we reflect that, by mowing, the ſtraw is much longer, and certainly ſtraw is much better for thatching than ſtubble.

" As

PLATE XX. *Facing* Mowing.



"As to the weeds being cut with the corn, it is of no consequence; for they are easily shaken out of the bottoms of the sheaves, after drying a day or two; and the sheaves may be safely left to dry, if they are laid in the following manner.

"Suppose three tobacco pipes to represent three sheaves, the bowls to be the feet of the sheaves, and the small part the ears: lay one of these on the ground; then take another, and lay the bowl of it under the small end of the first; take afterwards a third, and disposing them in form of a triangle, lay the bowl of the third under the small end of the second, and the bowl of the first under the small end of the third: by disposing them in this form, the ears are always kept from the ground, and will endure a great deal of wet without damage.

"As to the seeds of the weeds being threshed, and mixing with the corn, that may easily be avoided; for the wheat, by this method of mowing it, is so regularly disposed in the sheaf, that the sheaves need only to be threshed on the ear, without being unbound.

"The objection, that the poor would be deprived of their gleanings, is a mere farce: their time might be much better employed; and by the same parity of reason, the more corn the farmer left for them in the field, the more justice he would do them; and this few would venture to assert, as custom might in time extend it to half the crop: besides, as by this new method, a great deal more corn will be inned, it will of course be cheaper the year round, and easier purchased by the poor.

"The foreign gentleman was of great use to us: he is intelligent and communicative, and we all of us acknowledge ourselves much obliged to him.

"Many in this county propose making more extensive trials of it next harvest, and there is no doubt but that in the space of a few years it will be brought into constant use.

"A short certificate of the advantages resulting from the practice of this method, was some time ago drawn up: it was presently signed by a number of gentlemen, farmers, gardeners, labourers, &c. and transmitted to Dr. Templeman, secretary to the Society of Arts in London, to be, if necessary, published for the benefit of the kingdom. This new method will doubless be introduced to the knowledge of the English world with a better grace, coming under the sanction and recommendation of so respectable and useful a society."

The authors are happy, that, as members of the society, they have an opportunity of conveying to the readers of this Dictionary, a perfect idea of the form of the scythes lately tried in Northamptonshire: for this purpose they have annexed a plate engraved from a drawing taken from the three scythes now deposited in the Society's machine-room, for the inspection of the curious. The parts are represented separate, that they might be more distinct: the dimensions and proportions follow. Plate XX. Fig. 7. is the handle, or mounting of the largest scythe: the length of it from *a* to *c* is eight feet, from *a* to *b* five feet, from *b* to *c* three feet: at *c* is the part whereon the blade is fixed, *d* shews the two bends which serve instead of a cradle. Fig. 3. is the blade to this scythe: from the heel *a*, to the point *b*, measures three feet, and it is two inches and a half broad: when the scythe is mounted, from the point of the blade *b*, to the end of the long handle *a*, measures an angle of seven feet. Fig. 4. is the blade of another scythe, the length and breadth the same as the last blade. Fig 5. is the handle to this second scythe: from *a* to *d*, it measures three feet ten inches, from *a* to *b*, two feet, and from *b* to *c*, one foot seven inches: the blade is fixed at *a*, and when the scythe is mounted, the angle from the point of the scythe-blade to the end of the handle, measures three feet nine inches. Fig. 6. is the blade of the smallest scythe: from *a* to *b*, it measures one foot nine inches, and is two inches and a half broad. Fig. 7. is the handle or mounting to this last scythe: at *a* the blade is fixed: from *a* to *b* is one foot five inches and a half; the angle from *b* to *c*, four inches and a half; from *c* to *d*, five inches; from *d* to *e*, three inches and three quarters. Fig. 8. is the gathering-hook: the length of its handle, from *a* to *b*, is three feet nine inches; the hook from *b* to *c*, is ten inches long.

MUCK, dung, or straw that lies rotting.

MUD, the sediment at the bottom of rivers, ponds, ditches, &c. *See the article* DUNG.

MUGWORT, a very troublesome weed; for its roots creep far under the surface of the ground, so as soon to overspread a large space, if they are not stopped; and its seeds, being light, and easily carried to a distance by the wind, will produce numbers of new plants the next spring. It has plain cut leaves, ending in many parts, woolly underneath, and single spikes of pale yellow oval flowers, which blow in June.

MULBERRY, the name of a tree, of which there are several species, but two only are generally cultivated, called the black and white mulberry.

The black mulberry grows naturally in Persia, from whence it was first brought to the southern parts of Europe; but is now become common in every part of Europe, where the winters are not very severe: for in the northern parts of Sweden, these trees will not live in the open air; and in several parts of Germany they are planted against walls, and treated in the same way as peach and other tender fruits are here.

These trees are generally of both sexes, having male flowers or katkins, on the same tree with the fruit; but it often happens, that some of the trees which are raised from seeds, have only male flowers, and produce no fruit; so that those who plant these trees for their fruit, should never make choice of such as have been propagated by seeds, unless they have seen them produce fruit in the nursery. It is also the surest way to mark such trees as are fruitful in the nursery, at the time when their fruit is upon them, because those trees which are propagated by layers, are sometimes of the male sort.

The old mulberry trees are not only more fruitful than the young, but their fruit are much larger and better flavoured; so that where there are any of these old trees, it is the best way to propagate from them, and to make choice of those branches which are most fruitful. The usual method of propagating these trees, is by laying down their branches, which will take root in one year, and are then separated from the old trees; but as the most fruitful branches are often so far from the ground as not to be layed, unless by raising of boxes or baskets of earth upon supports for this purpose; so the better way is to propagate them by cuttings, which, if rightly chosen and skilfully managed, will take root very well; and in this method there will be no difficulty in having them from trees at a distance, and from the most fruitful branches. These cuttings should be the shoots of the former year, with one joint of two years wood to their bottom; the cuttings should not be shortened, but planted their full length, leaving two or three buds above ground. The best season for planting them is in March, after the danger of hard frost is over; they should be planted in light rich earth, pressing the ground pretty close about them; and if they are covered with glasses, it will forward their putting out roots; but where there is no such conveniency, the ground about them should be covered with moss, to prevent its drying; and where this is carefully done, the cutting will require but little water, and will succeed much better than with having much wet. If the cuttings succeed well, and make good shoots, they may be transplanted the following spring into a nursery, where they should be regularly trained to stems, by fixing down stakes to each, to which the principal shoots should be fastened; and most of the lateral branches should be closely pruned off, leaving only two or three of the weakest to detain the sap, for the augmentation of the stem; for when they were quite divested of the side shoots, the sap is mounted to the top, so that the heads of the trees grow too fast for the stems, and become too weighty for their support. In about four years growth in the nursery, they will be fit to transplant where they are to remain; for these trees are transplanted with greater safety while young, than when they are of a large size.

The white mulberry is commonly cultivated for its leaves to feed silk-worms, in France, Italy, &c. though the Persians always make use of the common black mulberry for that purpose; and it is said that the worms fed with those of the black produce much better silk than those fed with the white; but it is to be observed, that the leaves of the black sort should never be given to the worms,

worms, after they have eaten for fome time of the white, left the worms fhould burft, which is often the cafe when they are thus treated.

The trees which are defigned to feed filk-worms fhould never be fuffered to grow tall, but rather kept in a fort of hedge; and inftead of pulling off the leaves fingly, they fhould be fheared off, together with their young branches, which is much fooner done, and not fo injurious to the tree.

This white fort may be propagated either from the feeds or layers, as the black mulberry, and is equally hardy; but the moft expeditious method of raifing thefe trees in quantity, is from the feeds, which may be procured in plenty from the fouth of France and Italy. The beft way to fow thefe feeds, in England, is to make a moderate hot bed, which fhould be arched over with hoops, and covered with mats; upon this bed the feeds fhould be fown in the middle of March, and covered over with light earth about a quarter of an inch deep: in very dry weather, the bed muft be frequently watered, and in the heat of the day fhaded with mats, and alfo covered in the nights when they are cold. With this management the plants will come up in five or fix weeks, and as they are tender when they firft appear, fo they muft be guarded againft frofty mornings, which often happens in May. During the fummer they muft be kept clean from weeds, which is all the culture they require: but there muft be care taken of them the firft winter, efpecially to cover them in autumn, when the firft frofts come, which will kill the tender plants to the ground, if they are not protected; the following March, thefe plants fhould be tranfplanted into the nurfery, to get ftrength, where they may remain two or three years, and then fhould be removed where they are to continue.

MULE, a mongrel kind of quadruped, ufually generated between an afs and a mare, and fometimes between a horfe and a fhe-afs.

The mule is a fort of a monfter, of a middle nature between its parents, and therefore incapable of propagating its fpecies; fo careful is nature to avoid filling the world with monfters. Mules are chiefly ufed in countries where there are rocky and ftony roads, as about the Alps, Pyrenees, &c. Great numbers of them are kept in thefe places; they are ufually black, ftrong, well-limbed, and large, being moftly bred out of the fine Spanifh mares.

In Spain there is great encouragement for breeding and training mules to every kind of bufinefs: in Portugal they are eftimated at a high price, and are not a little valued in the fouthern parts of France.

I own, fays a writer in the Mufeum Rufticum, I have often been aftonifhed (the ufeful nature of this creature confidered) that we do not more encourage the breed in England. This inattention may perhaps proceed from mules being thought naturally more vicious than horfes: I doubt the fact; yet be it as it will, they are, to my knowledge, equally capable of being made ufeful, docile, and gentle.

I affert not this merely from opinion, having had many years experience of what may be done in this way.

During the courfe of the war, in which his royal highnefs the duke of Cumberland commanded the army of the allies in Flanders, the emprefs queen made him a prefent of above fifty fine mules to carry his baggage: thefe mules, at the end of that war, were brought to England, at which time I had an opportunity of feeing and admiring them. They were, I think, the fineft and largeft I ever before beheld; and one, nearly white, particularly attracted my attention, being almoft fixteen hands high.

This circumftance of feeing his highnefs's ftring of mules, it was firft induced me to think of breeding them, in which I have fince had uncommon fuccefs.

I had many encouragements to make the attempt: my fortune was fuch as could not be hurt by the experiment; my park was extenfive, and very proper for the purpofe; and I had many fervants, who had fo little to do, as to have leifure time enough to obey my orders in this matter.

My great difficulty at firft fetting out was to procure a he afs or two to cover my mares; for I found none were to be got of any fize bred in England.

It is true, I met with fome Spanifh affes; but they were fluggifh, and not likely to get mettled colts: befides, I could not buy two of them, of any fize and fhape, under feven hundred pounds, which I thought too much money to throw away, if I could by any other means get my end eafily anfwered.

Senfible that perfeverance does much in all things, I bought a ftrong-boned, fine-fhaped he afs, and two fhe affes of a large fize, confidering they were bred in England, determined to try if I could not by a little care and attention mend the bred, before I attempted to get any mules.

Thefe coft me only four pounds, and my two fhe affes foon afterwards dropped a foal each.

I continued to breed from them for feveral years; but it is the manner in which I managed the afs colts, that the great fuccefs I have lately had in breeding mules muft be afcribed.

I took care that the fhe affes fhould be well fed, and be kept in order, both before they dropped their foals, and afterwards whilft they fuckled.

As foon as the colts were weaned, I had them as carefully attended and fed as if they had been got by Childers or Babram: every winter they ftood under cover, defended from the injuries of the weather, and were regularly fed, cleaned, and littered, the door of the ftable being always left open two or three hours in the middle of the day, for them to exercife themfelves as they thought proper, which they feldom failed to do, if the weather was fine, to fome purpofe, returning, without compulfion, when the hour of feeding approached.

In this manner I always managed them till they were three years old, when I permitted my ftone colts to cover, and my females to breed.

You would indeed be furprifed to fee how much, by this plain and fimple management, my breed of affes is improved; for I have now in my ftables feveral he affes, which I keep as ftallions, that are, I believe, as large, and as well fhaped, as any that were ever heretofore bred in thefe iflands.

I fhall now proceed to defcribe to you the manner in which I breed my mules. For this purpofe I chufe mares that are of a very large breed, fuch as are fometimes ufed to draw the brewers drays in London.

My next care is that they are young, full of life, large barrelled, but fmall limbed, with a moderate fized head, and a good forehand. At the proper feafon my mares are covered by my afs ftallions, and they feldom mifs. During the time the mares are in foal, I take care to have them fed with nourifhing fodder, fuch as I imagine will moft contribute to the fize of the foal.

My expectations, after this management, are generally anfwered, for in due feafon my mares drop foals, which I could often fell for ten, and fometimes for twenty guineas a piece at three months old; and their future value is more than in proportion encreafed afterwards.

I always houfe my mule colts the firft winter; otherwife the hard frofts, and fharp, cold, long nights, would ftint them in their growth, befides making them unfhapely and rough.

From the time of their being dropped, I caufe them often to be handled, to make them gentle: this prevents their hurting themfelves by fkittifhnefs, and fudden frights: they are befides much eafier broke at the proper age, and become docile and wonderfully harmlefs, having nothing of that vicioufnefs which is fo commonly complained of in thefe animals.

I have them for the moft part broke at three years old, but never permit them to do much work till four: they are thus fecure from being hurt by hard labour, till they have acquired ftrength enough to bear it without injury.

I have now feveral mules which I conftantly employ in various kinds of labour; two, which are indeed very fine, I ride myfelf after my harriers; two more I keep for my huntfman, and one for my whipper-in: thefe are black, forrel, and grey.

I have alfo four fine mules, but ftronger and heavier than thofe above mentioned, which I drive occafionally in a four-wheel chaife, befides feveral others lefs valuable, ufed for ploughing and carting.

Some of my neighbours fmile at my tafte; yet they cannot at the fame time help acknowledging, that they are

are cheaper animals, when bred at home, as has been my practice, than horses.

Perhaps some of your readers, from the hints above thrown out, may be inclined to try the experiment: if so, I would caution them against some errors I at first setting out fell into.

I thought at first I could not keep my colts too well during the winter months: accordingly I ordered that they should have the sweetest hay, which I had before ordered to be reserved for my cows, and as many oats as they could eat.

This way of feeding them, it is true, made them very fat; but it was far from being an advantage to them; for I afterwards found by experience, that it was not only incurring a much larger expence than was any ways necessary, but also made them wonderfully nice and delicate in their appetites ever after, and also by encreasing their weight of flesh, made them more subject to strains and hurts in their morning gambols.

Finding this to be the case, I altered my method entirely, and contented myself with giving them food enough to prevent their losing flesh, and keep up their growth, without palling their appetites with delicacies, or making them over fat: as to the rest, I took the same care of defending them from the injuries of the weather as ever, by allowing them stable room, and good litter to sleep on, besides causing them every day to be well rubbed down with a hard wisp of straw by an active groom, whose peculiar province it was to attend them; and this was scarcely ever omitted, particularly in cold, raw, wet weather, when they were least inclined to exercise themselves in the park. *Museum Rusticum, vol.* II. *page* 162.

MULCH, straw half rotten.

MULLOCK, dirt, or rubbish.

MULLEIN, the name of a biennial plant, which perishes soon after it has perfected its seeds. The leaves spread on the ground, are nine or ten inches long, and six broad, very woolly, of a yellowish white colour, and very little footstalk. The stem rises four or five feet high, and the upper part of it is garnished with yellow flowers, which sit very close, and form a thick spike. These flowers have an agreeable odour, appear in July, and the seeds ripen in autumn.

This plant commonly grows by the sides of highways, and on banks: but if it once gets into the fields in a warm exposure, and is suffered to seed there, it will soon overrun the whole ground. It may be easily destroyed by cutting off the stem, when it is in flower.

MURE, the cake of apples, grapes, &c. left in the press, after extracting the juice.

MURRAIN, or *Gargle*, a contagious disease among cattle.

The most remarkable murrain is that mentioned in the Philosophical Transactions, which spread through Swisserland, Germany, into Poland, &c.

The contagion seemed to propagate itself in form of a blue mist, which fell on the grass where the cattle grazed, when whole herds, forbearing their food, almost died away in twenty-four hours. Upon dissection were found large corrupted spleens, sphacelous and corroded tongues, &c. And even the persons who managed them were infected, and died like the beasts.

Some imagined it had its rise from noxious vapours thrown out of the earth, in three earthquakes perceived in the neighbourhood of the place where it began; though Dr. Slare thinks it rather owing to swarms of volatile insects.

The antidote for the sound, and medicine for the sick, was equal parts of soot, gunpowder, brimstone, and salt, with as much water as would wash it down: a spoonful was the dose.

The common signs of this disease are a hanging down of the head, gum at the eyes, as big as your finger, growing weakly, staggering, the head swelling very much, the breath short, the heart beating with rattling in the throat; and if you put your hand into the creature's mouth, and find his breath very hot, and his tongue shining, the distemper is very strong.

As soon as you find any of your cattle infected, take a pretty large quantity of blood from them immediately, and give them a drench. Madder root is highly commended for this distemper.

MUSHROOM, a genus of imperfect plants, composed of a pedicle crowned with a broad head, convex and smooth at the top; and hollow, foliated, lamellated, or pistulous underneath.

It is of the utmost importance to distinguish the right eatable sort, from several noxious kinds that have been productive of even fatal accidents: the true sort appear at first with a roundish head, not unlike to a button. The outside of this head is then very white, as is likewise the stalk on which it grows; but its under part, when it is taken off that stalk, from which it separates pretty easily, is of a livid flesh colour. Its flesh is also very white within. If this sort remains undisturbed, its head will spread to a considerable size, and open at the bottom, so as to form an almost flat surface, the under part of which will then be changed to a dark colour.

Most of the writers upon gardening have spoken so confusedly, not to say, of most of them, so unintelligibly, of the means of propagating this plant, that excepting the authors of the *Maison Rustique*, and Mr. P. Miller, one is sometimes puzzled to guess at their meaning. The account which this last has given in his Dictionary, is the most practical, being the method of the gardeners near London, who raise annually great quantities of mushrooms for sale. The substance of it is to the following effect.

The spawn of mushrooms, from which only they are propagated, looks like a white mouldiness shooting out in long strings. It is frequently found among the dung of old hot-beds, or in old dunghills, especially when much litter has been mixed with these last, or the wet has not penetrated so as to rot it; or it may be procured by mixing some long stable dung, which has not been thrown up in a heap to ferment, with strong earth, and then laying this mixture under cover, where it cannot be wet, and where the air may be excluded from it as much as possible; for, the more effectually it is kept from air, the sooner the spawn will be produced. It will generally appear in about two months, if the heap has not been laid so close together as to heat (for that will destroy the spawn) and especially if it has been well covered with old thatch, or litter which has lain so long abroad as to have lost the power of fermenting. These are expedients by which the spawn of mushrooms may be procured at almost any time, by those who have not already had mushroom-beds in their gardens, and therefore cannot collect it from their remains: for there are but two months of the year in which it can be gathered from downs or pastures. These are August and September; when plenty of mushrooms spring up naturally in many of those places. To propagate them from thence, the ground should be opened about their roots, and such earth as is there found full of small white knobs, which are the offsets, or young mushrooms, should be attentively gathered up, with as much care as can be not to break the lumps, or the earth about them. This seed, or rather this spawn (for if mushrooms have seeds, they are imperceptible to the eye) should be kept very dry till it is used; for the drier it is, the better it will take to the bed, as has been remarkably experienced by Mr. Miller, who declares, that he never saw these plants produced so soon, or in so great quantity, as from a parcel of their spawn which had lain near the oven of a stove for upwards of four months, and was become so dry, that he despaired of its success.

The beds for mushrooms should be made of dung plentifully intermixed with litter, but not thrown in a heap to ferment. The best dung for this purpose is that which has lain spread abroad for a month, or longer. Their breadth should be about two feet and an half at bottom, their length proportioned to the desired quantity of mushrooms, and they should be made on dry ground, by spreading upon it, first a layer of dung about a foot thick, and upon this about four inches deep of strong earth; then a couch of dung about ten inches thick, and upon that another layer of earth, contracting the surface of the bed all the way up, till it terminates like the ridge of a house. This may be done with three layers of dung, and as many of earth. When it is finished, it should be covered with litter, or old thatch, as well to prevent its drying, as to keep out wet, and after it has remained eight or ten days in this situation, it will be of a proper temperature to receive the spawn, for which its warmth should be but moderate. The thatch, or litter, ſhould then be taken off, the ſides of the bed ſhould be ſmoothed, and a covering of light rich earth, by no means wet, ſhould be laid all over it, about an inch thick. Upon this the ſpawn ſhould be placed, by laying its lumps about two or three inches aſunder, in ſuch manner as to prevent their ſlipping down, and then the whole ſhould be covered gently with about half an inch thick of the ſame light earth as was uſed before. The covering of litter ſhould then be replaced over the bed, ſo thick as to ſecure it from wet, and to prevent its drying. If theſe beds are made in the ſpring or autumn, when the weather is temperate, the muſhrooms will frequently come up in a month's time: but thoſe which are made in ſummer, when the ſeaſon is hot, or in winter, when it is cold, will not produce them near ſo ſoon. Sometimes too it happens that neither of theſe beds, but moſt particularly thoſe made in the ſummer or winter, yield any muſhrooms before the end of five or ſix months; and that they then produce uncommon quantities, and continue in perfection for a long time.

The great art in managing of theſe beds is, to keep them conſtantly in a due degree of moiſture, and, above all, not to ſuffer them ever to receive too much wet; for that would inevitably deſtroy the ſpawn of the muſhrooms. During the ſummer, they may be uncovered, to admit gentle ſhowers of rain to them at proper times; and if the weather continues dry for a long while together, it will be right to water them gently now and then, but by no means to overdo it. During the winter, they muſt be kept as dry as poſſible, and cloſely covered, leſt the cold air of the ſeaſon ſhould injure them. It will even be right in froſty or very cold weather, to lay over them a covering of dry litter, for it muſt not incline to ferment, and upon that ſome warm litter ſhaken from out of a heap of dung. This covering ſhould alſo be renewed as often as it is found to decay, and, if the cold grows more ſevere, its thickneſs ſhould be increaſed.

The muſhrooms thus produced have a finer flavour than any that are gathered in the fields; and if the above directions are obſerved, they may be had in plenty during the whole year: for each ſingle bed will continue good for ſeveral months, and yield great quantities if the ſpawn takes kindly.

When theſe beds are deſtroyed, the ſpawn for a freſh ſupply ſhould be taken from them, and laid up in a dry place till the proper ſeaſon for uſing it, which ſhould not be ſooner than five or ſix weeks, in order that it may have time to dry well, before it is put into the new bed; for otherwiſe there will be ſome danger of its ſucceeding.

MUST, new wine, or wort, before it is fermented.

MUSTARD is an annual plant raiſed from its ſeed only. The white muſtard, as it is commonly called, is the ſort chiefly cultivated in gardens, for a ſallad herb in the winter and ſpring. The ſeeds of this are ſown very thick in drills, either upon a border warmly ſituated, or if the weather be very cold, upon a gentle hot-bed, in the ſame manner as creſſes and other ſmall ſallading, and in about ten days or a fortnight after the time of ſowing, the plants will be fit for uſe; for when they are large and have rough leaves, they are too ſtrong to be mixed with ſallads.

The beſt way to ſave the ſeeds of this plant, is to ſow a ſpot of ground with it in the ſpring, to thin the plants when they have about four leaves, and at the ſame time to hoe down the weeds, as is practiſed for turnips. This hoeing is to be repeated in about a month after, and the plants are then to be left about eight or nine inches aſunder, which will be a ſufficient ſpace for the growth of this ſpecies. If theſe hoeings are well performed, in dry weather, they will keep the ground clean till the muſtard ſeeds are ripe. The ſtalks of this plant, which are branched and hairy, will then be about two feet high, and the ripening of its ſeed is indicated by the pods changing to a brown colour; immediately after which they ſhould be cut down, dried upon cloths, for two or three days, and then threſhed out for uſe.

The larger ſorts of muſtard, the ſeeds of which are uſed chiefly for ſauce, are to be treated in the ſame manner; excepting that, as they grow much larger, a proportionably greater ſpace muſt be left between their plants; and as their ſeeds will not ripen ſo ſoon as thoſe of the ſmaller kind, three hoeings, or rather good deep ſtirrings, of the ground may be requiſite for them. One of theſe large ſorts, which is the common muſtard, grows naturally in many parts of England; but is cultivated in the fields for its ſeeds, of which the ſauce called muſtard is made; and another ſort, which naturally grows in our arable lands, and is alſo cultivated for uſe, produces the ſeeds which are commonly ſold under the appellation of Durham muſtard-ſeed. The ſtalks of the laſt ſort ſeldom riſe above two feet high; but thoſe of the former generally run up to the height of four or five feet.

N.

NAIL, or *Naile*, the weight of eight pounds.

NAPE, or *Neap*, a piece of wood with two or three feet, with which they fupport the fore-part of a loaded wain.

NASTURTIUM. *See the article* CRESS.

NAVE *of a Wheel*, is that fhort thick piece in the center of the wheel, which receives the end of the axletree, and in which the ends of the fpokes are fixed; it is bound at each end with hoops of iron, called the nave-bands; it has likewife, in each end of the hole, through which the end of the axletree goes, a ring of iron, called the wifher, which faves the hole of the nave from wearing too big.

NEAT, black cattle, oxen.

NEAT-HERD, a herd or company of black cattle: alfo a perfon who looks after horned cattle.

NECTARINE, a fruit greatly efteemed for its delicious flavour, and fuppofed to have its name from the nectar of the gods, in heathen ftories.

It differs in nothing from the peach, but in having a fmoother fkin, and a firmer pulp. *See* PEACH.

We have ten kinds of nectarines cultivated by the curious in gardening.

1. Fairchild's early nectarine; this is a fmall fruit of a red colour, and very well tafted, and ripens in July, the earlieft of all this kind.

2. The Elruge nectarine; this is a larger fruit of a purple colour, on that fide which was towards the fun, and of a greenifh yellow on the other parts. This is a very well flavoured nectarine, of a foft, melting juice, and parts from the ftone: it ripens towards the end of July.

3. The Newington nectarine; this is a fair large fruit, of a fine red toward the fun, and of a yellowifh green towards the wall. It has a very rich juice, but the pulp adheres to the ftone: this ripens in Auguft.

4. The fcarlet nectarine; this is of a fine glowing red towards the fun, and of a pale red towards the wall; it ripens in the end of July.

5. The Brugnon, or Italian nectarine; this is a fair, large fruit, of a deep red next the fun, but of a foft yellow next the wall. The pulp is firm, and of a rich flavour, but clofely adheres to the ftone, and is red in that part: this ripens in the middle of Auguft.

6. The Roman red nectarine; this is a fair large fruit, of a deep purple towards the fun, and of a greenifh yellow next the wall. The pulp is very firm and well tafted, but it is red about the ftone, and adheres firmly to it: this is ripe in the middle of Auguft.

7. The murry nectarine; this is a middle-fized fruit, of a dirty red next the fun, and of a greenifh yellow next the wall. The pulp is tolerably well flavoured, and ripens in the middle of Auguft.

8. The golden nectarine; this is a fair handfome fruit, of a foft red next the fun, but of a gold yellow next the wall; and its pulp is very yellow, but of a faint red about the ftone, to which it adheres: it is a very well flavoured kind, and ripens at the end of September.

9. Temple's nectarine; this is a very fine kind; it is of a foft red towards the fun, and of a yellowifh green next the wall. It parts from the ftone, and is of a very rich flavour; the pulp is white in other parts, but yellowifh about the ftone: this ripens in the middle of September.

10. The Peterborough nectarine, called by fome the late green nectarine; this is a middle-fized fruit, of a pale green colour towards the fun, and of a whitifh green toward the wall; the pulp is firm, and well flavoured: it ripens towards the end of September.

Nectarine trees generally produce their fruit either upon the young wood of the preceding year, or, at moft, upon fhoots of two years old, and thefe ceafe to bear after that age. The branches of thefe trees muft therefore be fhortened, according to their ftrength, in order to make them put out annually new fhoots for the fucceeding year. When the knife is ufed for pruning them, care fhould always be taken to cut them a little floping behind a wood bud, which may be eafily diftinguifhed from the bloffom buds; thefe laft being fhorter, rounder, and more turgid than the former; for if the fhoot have not a leading bud where it is cut, it is very apt to die down to the next leading bud. This leading bud, or wood-bud, is always neceffary, to preferve a circulation of the juices in the branch. The length at which the pruned fhoots are left, fhould be proportioned to the ftrength of the tree: thus, in a healthy ftrong tree it may be ten inches, or more; but in a weak one, it fhould not exceed fix inches: however, this muft alfo be determined, in fome meafure, by the pofition of a fine wood bud; for it is better to leave a fhoot three or four inches longer, or to cut it two or three inches fhorter, than one might otherwife choofe to do, for the fake of fuch a bud; it being abfolutely neceffary for the future welfare of the tree. It is alfo neceffary to cut out entirely all weak fhoots, though there may be many bloffoms upon them; for thefe have not ftrength enough to nourifh the fruit, but will weaken the other parts of the tree. It is to the neglecting of this, and to the not difplacing of all luxuriant fhoots as foon as they are produced, that half the blights we hear complained of are (though wrongly termed, and miftaken as to the caufe) in Mr. Miller's opinion, owing.

In nailing the fhoots to the wall, care muft be taken to place them, as nearly as poffible, at equal diftances, in order that their leaves, when come out, may have room to grow, without fhading the branches too much. So far as the nature of the tree will permit, they fhould never be nailed upright, becaufe they are very apt to fhoot from the

the uppermoſt eyes, and the lower parts of the ſhoots become thereby naked, when they are trained in that manner.

When the fruit is ſet, and grown to the bigneſs of a ſmall nut, it ſhould be looked over, and thinned ſo as to be left at leaſt five or ſix inches aſunder; for no tree can afford ſufficient nouriſhment to perfect ſo great a crop as it ſometimes produces; and it is evidently better to pull off early ſuch fruits as over-burden it, and therefore are not to remain on the tree, than to let them impoveriſh the reſt by ſtanding longer; eſpecially as, in this laſt caſe, the tree itſelf is frequently ſo weakened thereby, as to be diſabled from bearing well for three or four years after.

If the ſeaſon ſhould prove hot and dry, it will be proper to draw the earth round the ſtem of each tree, ſo as to form a baſon of about ſix feet diameter, to cover the ſurface of the ground in the baſon with mulch, and once in a week or fortnight, according to the heat and drought of the ſeaſon, to pour down eight or ten gallons of water to the root of the tree: or where there is an engine, which will diſperſe the water in eaſy gentle drops like rain, if the ſame, or a larger, quantity of water is ſprinkled all over the branches of the trees, this ſoaking down to the roots, will keep the fruit conſtantly growing, and prevent its falling off the trees, as it is very apt to do where this method is not practiſed. The fruit thus conſtantly nouriſhed will alſo be much improved in its taſte, and the trees thus treated will be maintained in vigour. But this watering ſhould not be continued longer than while the fruit is growing; becauſe it will afterwards be hurtful to the trees and fruit; for a dry autumn ripens both wood and fruit better than a moiſt latter ſeaſon.

Mr. Miller, who recommends this practice from his own long and extenſive experience, blames, upon the authority of the ſame unerring guide, the too frequent cuſtom of pulling off the leaves of the trees, in order to admit the ſun to the fruit; becauſe, as the leaves are abſolutely neceſſary to cheriſh the bloſſom buds, which are always formed at their footſtalks, theſe buds muſt be greatly injured by pulling off the leaves before they have performed the office aſſigned them by nature.

After diſproving the common opinion, that theſe trees are not long lived, and that they ſhould therefore be renewed every twenty years, by declaring that he has eaten ſome of the fineſt peaches of various kinds, which grew on trees upwards of fifty years old, and then aſcribing this miſtaken notion to the wrong practice of the French, who generally bud their peaches upon almond ſtocks, which are of ſhort duration; he recommends dunging the borders where fruit trees grow, every other year, with well rotted dung dug into the ground in November, that the rain may waſh down its fertilizing particles before the ſpring comes on: and to confirm this opinion, he inſtances the practice of the gardeners at Montreuil, near Paris, who have for ſome generations been famous for this practice, and are as careful to dung the borders where their peach trees grow, every other year, as the kitchen-gardeners are for their legumes. He thinks neats or hogs dung, mixed with loam, ſix or eight months before it is uſed, and mellowed by frequent turning during that time, the beſt for a looſe or ſandy ſoil, becauſe this dreſſing is cooler than any that is made with horſe-dung; and he thinks this laſt, mixed with light ſandy earth, or ſea-coal aſhes, the moſt proper for ſtrong land.

NETTLE, the name of a weed well-known, and which may be eaſily deſtroyed by cutting the roots, before the plant has perfected its ſeed.

NEWING, yeaſt, or barm.

NICKING, the name of an operation often performed on the tails of ſaddle-horſes, and by which means they carry them in a more beautiful manner.

Before we deſcribe the operation of nicking, it may be neceſſary to enquire how the effect of it (the elevation of the tail) is brought about; and in order to know this, and judge with propriety of the operation, we muſt conſider the tail as elevated, or lifted up, by one ſet of muſcles, and depreſſed or pulled down by another.

It is ſomewhat remarkable, that Snape, Saunier, and Gibſon, who are in general pretty exact in their anatomical deſcriptions, ſhould omit, in their account of the muſcles of a horſe, to deſcribe thoſe of the tail: for which reaſon, as a proper opportunity has not offered, to ſupply this omiſſion, by making a complete diſſection, with that accuracy we could have wiſhed, it is hoped the ſubſequent imperfect deſcription will be excuſed, as it was taken only from a tail that was diſſected after docking.

Here we obſerved, that the muſcles which elevate the tail, are more numerous, large, and ſtrong, than thoſe that depreſs it; that they are cloſely connected to the bones of the tail by fleſhy fibres, and terminate in ſtrong tendons at the extremity: but the muſcles of the latter ſoon form into tendinous expanſions, and three large tendons, which are inſerted into the latter bones of the tail: there are ſeveral other ſmall tendons, which run laterally, whoſe uſe moſt probably is to move the tail ſideways. The arteries are four in number, and run ſometimes above the bones of the tail, conſequently eaſily avoided by a dextrous hand, as they cannot readily be wounded by the knife, in dividing the tendons neceſſary to be cut in this operation.

The art of nicking horſes then chiefly conſiſts in a tranſverſe diviſion of theſe depreſſing tendons of the tail, and ſuch a poſition afterwards as will keep their extremities from coming again into contact; ſo that an intervening callus fills up the vacuity: by theſe means an additional power is given to the antagoniſt muſcles, viz. the elevators; the counteraction of the depreſſors being manifeſtly abated by the diviſion of the tendons, and the intervention of the callus.

The uſual method of ſupporting the tail by a pulley and weight, is liable to many exceptions, the extremities of the divided tendons not being by that method kept ſufficiently aſunder; the ſituation of the tail being rather inclined to a perpendicular than a curved direction: this poſition too is liable to many variations, from the different movements of the horſe, and is the reaſon that the tail frequently inclines to one ſide, as the nick may heal up faſter on one ſide than the other; the diſagreeable ſituation the horſe muſt ſtand in, with a weight conſtantly hanging to his tail, is another material objection, beſides the neceſſity of removing it when the horſe is exerciſed, or taken out to water.

To remedy theſe inconveniencies, and perfect this operation, a very ingenious gentleman, who had thoroughly conſidered it, has been ſo kind as to favour us with a draught and deſcription of a machine he contrived for that purpoſe, which has frequently been practiſed with the expected ſucceſs, and indeed at firſt view appears in every reſpect calculated to correct all the defects in the old one: as we doubted not its reception being perfectly agreeable to the public, we have ordered a plate to be engraved, which, with the annexed deſcription, will, we hope, make it very familiar and intelligible to every capacity.

In regard to the operation, it is worth notice, that the extremities of the tendons, which jut out in the operation, need not here be cut off, as is cuſtomarily done; the number of the inciſions muſt be in proportion to the length of the tail, but three in general are ſufficient. The moſt approved method of dreſſing at firſt, is with powdered roſin, and ſpirit of wine, applying a ſoft doſſil of lint or tow, dipped in the ſame, between each nick, and lapping the tail up with a linnen cloth and broad fillet; which the next morning ſhould be cut open down the back part of the tail, and the morning after be gently taken off: when it will be proper to plat the hairs, in order to keep them clean, and to ſet the tail, as will be directed in the plate and references.

Every two or three days, the tail ſhould be let down, and the upper part next the rump bathed with hot vinegar; and if it begins to crack, and the hair comes off, a little tincture of myrrh will ſoon put a ſtop to it. To obviate any threatening ſymptoms that may ariſe in regard to the wounds, have recourſe to the remedies uſed on docking.

After ſix or eight days, it will be proper to let the horſe ſtand without the machine for a few hours, and then be rode about, in order to obſerve how he carries his tail; by which means you will the better judge how to faſten it down, whether to confine it cloſer, or give it more ſcope: after the wounds are healed up, it may be neceſſary to keep

keep the tail fufpended, till the callus is confirmed, at leaft for fome hours in the day; though a greater liberty may now be allowed it.

Thus this machine anfwers every intention, is far preferable to the pulley, as it keeps the tendons properly feparated, and the tail in a certain pofition; fo that the wounds heal up uniformly, without any rifk of its being caft to one fide; the horfe alfo is more at eafe, having no weight conftantly pulling and teazing him, and may be taken out to water or exercife without any inconveniency, or difturbance.

Directions for the Application of the Nicking Machine; and Explanation of the Plates.

When the hair of the tail is properly platted, and tied with a knot or two at the end, the pad, &c. as defcribed in Plate XX. Fig. 9. muft be put on, and the machine, as in Fig. 10. buckled to them, letting the part G. in the machine lie over the part of the tail that joins to the horfe's rump; then let an affiftant, ftanding on the fide rail of the brake, or any other conveniency that may place him above the horfe, raife the horfe's tail very gently, till the knot of the tail gets fo far beyond the ftrings L L in Fig. 10. that it may be tied down; which being done, the tail may be let down lower, or taken up higher at pleafure. It is to be obferved, that the ligature is not made on the tail itfelf, but on the plated hair, at the extremity of the ftump.

The machine, Fig. 10. muft be made of a piece of tough wood, about a foot long, viz. from A to B, and about nineteen inches broad from C to D, and feven or eight inches thick. The under part muft be hollowed, fo as to let in the horfe's rump, and that the wings C D may reft on his buttocks. To receive the tail, a groove muft be cut from G to H, about three inches wide, and three deep at G, leffening gradually both in height and breadth to H. Holes muft be made at certain diftances in the groove, as at H for the ftring, and a nick cut to receive the billet from the ftrap K. Two buckles fixed to the machine as at I I.

The pad, &c. are fufficiently defcribed in Fig. 9. and its references; the wood muft be floped off from E to C and A, and fo on the other fide, to lighten the machine, and hollowed at B, G, and F.

Fig. 9. reprefents a horfe, with his tail in the frame or machine. A is a pad, to which is faftened a circingle B. C C two fide ftraps, one on each fide the horfe, faftened to the circingle, to keep the machine from going to either fide; D, a breaft-plate, to prevent the pad, &c. flipping back. E, a ftrap fixed to the pad, and buckling to the machine, to keep the tail on the ftretch at pleafure. F, the ftring tied on the hair, to confine the tail down to the machine.

Fig. 10. from A to B is twelve inches; from C to D, meafured with a ftring drawn over E F, is nineteen inches. From the top of the groove at E to the bottom G, is three inches. From E to F, the wideft part of the groove, is three inches, gradually narrowing, as a tail leffens to its extremity. The dots about H are holes in the groove, through which a piece of tape or pack-thread muft be put, according to the length of the dock, and the diftance of the knot, to tie the tail down behind the knot. I I, the buckles to receive a ftrap from the circingle on each fide, as defcribed in Fig. 9. which keeps the machine from turning to either fide. K, the ftrap with a billet and buckle, which comes along the back from the pad, and is faftened to the machine, through a nick cut juft above H. L L, the ftrings to tie down the tail. B, G, F, the hollow to let in the rump.

Fig. 2. reprefents the horfe with the machine on, ftanding directly before you, where the depth of it is fhewn, being three inches.

C D, the extremities of the wings. E F, the upper part. *Bartlet's Farriery, page* 325.

NIGHT-FALL, the beginning of night.

NOPE, a bull finch, or red-tail, a fmall finging bird, well known.

NURSERY, or NURSERY GARDEN, a piece of land fet apart for the raifing and propagating of all forts of trees and plants, to fupply the garden and other plantations.

Of this fort there are great numbers in the different parts of this kingdom, but particularly in the neighbourhood of London, which are occupied by the gardeners, whofe bufinefs it is to raife trees, plants, and flowers for fale; and in many of thefe there is at prefent a much greater variety of trees and plants cultivated than can be found in any other part of Europe. In France, their nurferies (which are but few, when compared with thofe in England) are chiefly confined to the propagation of fruit-trees, from whence they have the appellation of pepinier: for there is fcarce any of thofe gardens, where a perfon can be fupplied either with ever-greens, flowering fhrubs, or foreft-trees. And in Holland, their nurferies are principally for flowers; fome few of them indeed propagate tender exotic plants. But thofe nurferies in the neighbourhood of London do, feveral of them, include all thefe; and from hence moft of the curious perfons abroad are fupplied with furniture for their gardens. But we do not propofe, in this place, to treat of thefe extenfive nurferies, or to give a defcription of them; therefore fhall confine ourfelves to treat of fuch nurferies only as are abfolutely neceffary for all lovers of planting to have upon the fpot, where they defign to make their plantation: for if thefe are large, the expence of carrying a great number of trees, if the diftance is greet, will be no fmall article, befides the hazard of their growing; which, when plants have been trained up in good land, and removed to an indifferent one, is very great. Therefore it is of the utmoft confequence to every planter, to begin by making of a nurfery. But in this article we muft beg leave to obferve, that a nurfery fhould not be fixed to any one particular fpot: we mean by this, that it would be wrong to continue the raifing of trees any number of years upon the fame fpot of ground: becaufe hereby the ground will be fo much exhaufted by the trees, as to render it unfit for the fame purpofe. Therefore all good nurfery-gardeners fhift and change their land, from time to time; for when they have drawn off the trees from a fpot of ground, they either plant kitchen herbs, or other things, upon the ground for a year or two, by which time, as alfo by dunging and trenching of the land, it is recovered, and made fit to receive other trees. But this they are obliged to from neceffity, being confined to the fame land; which is not the cafe with thofe gentlemen, who have a large extent of ground in the country. Therefore all fuch perfons we would advife to make nurferies upon the ground which is intended for planting, where a fufficient number of the trees may be left ftanding, after the others have been drawn out, to plant in other places; which, for all large growing trees, but particularly fuch as are cultivated for timber, will be found by much the moft advantageous method: for all thofe trees which come up from the feed, or which are tranfplanted very young into the places where they are defigned to remain, will make a much greater progrefs, and become larger trees than any of thofe which are tranfplanted at a greater age. Therefore the nurferies fhould be thinned early, by removing all thofe trees which are intended for other plantations, while they are young; becaufe hereby the expence and trouble of ftaking, watering, &c. will be faved, and the tree will fucceed much better. But in expofed fituations, where there are nurferies made, it will be neceffary to permit the trees to ftand much longer, that, by growing clofe together, they may fhelter each other, and draw themfelves up: and thefe fhould be thinned gradually, as the trees advance; for by taking away too many at firft, the cold will check the growth of the remaining trees. But then thofe trees which are taken out from thefe nurferies, after a certain age, fhould not be depended on for planting; and it will be prudence rather to confign them for fuel, than by attempting to remove them large, whereby, in endeavouring to get them up with good roots, the roots of the ftanding trees will be often much injured.

What has been here propofed, muft be underftood for all large plantations in parks, woods, &c. but thofe nurferies which are only intended for the raifing of evergreens, flowering fhrubs, or plants which are defigned to embellifh embellish gardens, may be confined to one ſpot, becauſe a ſmall compaſs of ground will be ſufficient for this purpoſe. Two or three acres of land, employed this way, will be ſufficient for the moſt extenſive deſigns; and one acre will be full enough for thoſe of moderate extent. And ſuch a ſpot of ground may be always employed for ſowing the ſeeds of foreign trees and plants; as alſo, for raiſing many ſorts of biennial and perennial flowers, to tranſplant into the borders of the pleaſure garden; and for raiſing many kinds of bulbous-rooted flowers from ſeeds, whereby a variety of new ſorts may be obtained annually, which will recompenſe for the trouble and expence, and will moreover be an agreeable diverſion to all thoſe perſons who delight in the amuſements of gardening.

Such a nurſery as this ſhould be conveniently ſituated for water; for where that is wanting, there muſt be an expence attending the carriage of water in dry weather. It ſhould alſo be as near the houſe as it can with conveniency be admitted, in order to render it eaſy to viſit at all times of the year; becauſe it is abſolutely neceſſary, that it ſhould be under the inſpection of the maſter; for unleſs he delights in it, there will be little hopes of ſucceſs. The ſoil of this nurſery ſhould alſo be good, and not too heavy and ſtiff; for ſuch land will be very improper for ſowing moſt ſorts of ſeeds; becauſe, as this will detain the moiſture in the ſpring and winter, ſo the ſeeds of moſt tender things, eſpecially of flowers, will rot in the ground, if ſown early. Therefore, where perſons are confined to ſuch land, there ſhould be a good quantity of ſand, aſhes, and other light manures buried, in order to ſeparate the parts, and pulveriſe the ground; and if it is thrown up in ridges, to receive the froſt in winter, it will be of great uſe to it; as will alſo the frequent forking or ſtirring of the ground, both before and after it is planted.

The many advantages which attend the having ſuch a nurſery, are ſo obvious to every perſon who has turned his thoughts in the leaſt to this ſubject, that it is needleſs for us to mention them here; and therefore we ſhall only beg leave to repeat here what we have frequently recommended, which is, the carefully keeping the ground always clear from weeds; for if theſe are permitted to grow, they will rob the young trees of their nouriſhment. Another principal buſineſs is, to dig the ground between the young plants at leaſt once a year, to looſen it for the roots to ſtrike out; but if the ground is ſtiff, it will be the better to be repeated twice a year, viz. in October and March; which will greatly promote the growth of the plants, and prepare the roots for tranſplanting.

The ground you intend for the flower nurſery ſhould be well ſituated to the ſun, but defended from ſtrong winds by plantation of trees, or buildings; and the ſoil ſhould be light and dry, which muſt always be obſerved, eſpecially for bulbous-rooted flowers, which are deſigned to be planted therein.

In this nurſery ſhould be planted the off-ſets of all your bulbous-rooted flowers, where they are to remain, until they become blowing roots; when they ſhould be removed into the pleaſure garden, and planted either in beds or borders, according to the goodneſs of the flowers, or the management they require.

You may alſo, in this ground, raiſe the ſeveral ſorts of bulbous-rooted flowers from ſeeds, by which means new varieties may be obtained; but moſt people are diſcouraged from ſetting about this work, from the length of time before the ſeedlings will come to flower: however, after a perſon hath once begun, and conſtantly continued ſowing every year, after the parcel firſt ſown has flowered, the regular ſucceſſion of them, coming annually to flower, will not render this method ſo tedious as it at firſt appeared.

The ſeedling auriculas, polianthus's, anemonies, carnations, &c. ſhould be raiſed in this nurſery, where they ſhould be preſerved until they have flowered; when you ſhould mark all ſuch as are worthy of being tranſplanted into the flower garden; which ſhould be done in their proper ſeaſons: for it is not ſo well to have all theſe ſeedling flowers expoſed to public view in the flower garden; becauſe it always happens, that there are great numbers of ordinary flowers produced among them, which will make but an indifferent appearance in the pleaſure garden. *Miller's Gard. Dict.*

NUSHED, ſtarved in bringing up.

OAK,

O.

OAK, a tree well known, and one of the principal materials in building ſhips, &c. being ſtrong in all poſitions.

All the ſorts of oaks are propagated from acorns, which ſhould be ſown as ſoon as poſſible after they are ripe; for if they are kept too long out of the ground, they ſeldom grow.

The manner of ſowing theſe acorns, if deſigned for a ſmall plantation, or to be removed, is, to prepare ſome beds of freſh earth, neither too ſtrong and heavy, nor too light and dry; in theſe beds you ſhould place the acorns in rows one foot aſunder, and about two inches diſtance in the rows, covering them about two inches thick with the ſame freſh earth; obſerving to leave none of them uncovered, to entice the vermin, which may, in a ſhort time, deſtroy all the ſeeds.

In the ſpring, when the plants begin to appear, you muſt carefully clear them from weeds; and if the ſeaſon proves dry, you ſhould refreſh them now and then with a little water, which will greatly promote their growth. In theſe beds the plants ſhould remain until the following autumn, obſerving conſtantly to keep them clear from weeds; at which time you ſhould prepare a ſpot of good freſh earth, in ſize proportionable to the quantity of plants, which ſhould be trenched and levelled: then towards the middle or latter end of October, you ſhould carefully take up the plants, ſo as not to injure their roots, and plant them out in rows three feet aſunder, and eighteen inches diſtance plant from plant; obſerving never to ſuffer the plants to abide long out of the ground, becauſe their roots would dry, and endanger the growth of the plants.

When they are planted, you ſhould lay a little mulch upon the ſurface of the ground, near their roots, to prevent the earth from drying too faſt; and if the ſeaſon ſhould prove very dry, you ſhould give them a little water to ſettle the earth to their roots.

When the plants have taken root in this nurſery, they will require little more care than to keep them clear from weeds, and dig the ground between the rows every ſpring; in doing of which, you ſhould cut off ſuch roots as extend very far from the trunk of the trees, which will render them better for tranſplanting again: you ſhould alſo prune off ſuch ſide-branches as extend themſelves very far, and would retard the upright ſhoot; but you ſhould by no means cut off all the ſmall lateral branches, ſome of which are abſolutely neceſſary to be left on, to detain the ſap for the augmentation of the trunk; for I have often obſerved, where trees have been thus cloſely pruned, that their heads have over-grown their bodies, ſo that they have bent downward and become crooked.

When theſe trees have remained in the nurſery three or four years, they will then be large enough to tranſplant to the places where they are to remain; for it is not proper to let them grow very large before they are planted out; becauſe theſe are very hazardous trees to remove when old, or after they have taken deep root.

The ſeaſon for this work is, as I ſaid before, in the autumn; at which time, if they are carefully taken up, there will be little danger of their ſucceeding. When they are planted, the ſurface of the ground ſhould be mulched about their roots, to prevent its drying too faſt; and if the ſeaſon is very dry, they ſhould be watered, to ſettle the earth to their roots, which may be repeated two or three times in very dry weather; but you muſt carefully avoid giving them too much water, which is very injurious to theſe trees, when newly removed.

You ſhould alſo ſtake them to prevent their being ſhaken and diſturbed by the winds, which would retard their rooting. In tranſplanting of theſe trees, you ſhould by no means cut their heads, which is too much practiſed: all that ſhould be done, muſt be only to cut off any bruiſed or ill-placed branches, which ſhould be taken off cloſe to the place where they are produced: but there can be no greater injury done to theſe trees than to ſhorten their roots; for when the leading bud, which is abſolutely neceſſary to draw and attract the nouriſhment, is taken off, the branch often decays entirely, or, at leaſt, down to the next vigorous bud.

The trees, thus raiſed and managed, will, if planted in a proper ſoil, grow to a conſiderable magnitude, and are very proper for a wilderneſs in large gardens, or to plant in clumps in parks, &c. but if they are deſigned for timber, it is much the better method to ſow the acorns in the places where they are to remain; in order to which, you ſhould provide yourſelf in autumn with a ſufficient quantity of acorns, which ſhould be always taken from ſtraight, upright, vigorous-growing trees; theſe ſhould be gathered from under the trees as ſoon as may be after they are fallen, and, if poſſible, in a dry time, laying them thin in ſome open room to dry; after which they may be put in dry ſand, and preſerved in a dry place until the end of November, when you ſhould prepare the ground for planting them.

The directions here given are deſigned only for ſmall plantations in a garden or park, which are only for pleaſure: but where theſe trees are cultivated with a view to profit, the acorns ſhould be ſown where the trees are deſigned to grow; for thoſe which are tranſplanted will never grow to the ſize of thoſe which ſtand where they are ſown, nor will they laſt near ſo long ſound: for in ſome places, where theſe trees have been tranſplanted with the greateſt care, and they have grown very faſt for ſeveral years after, yet they are now decaying, when thoſe which remain in the place where they came up from the acorns, are ſtill very thriving, and have not the leaſt ſign of of decay: therefore, whoever designs to cultivate these trees for timber, should never think of transplanting them, but sow the acorns on the same ground where they are to grow; for the timber of all those trees which are transplanted, is not near so valuable as that of the trees from acorns. I shall therefore add some plain directions for the sowing of acorns, and managing of the young trees, during their minority, until they are out of danger, and require no farther care.

The first thing to be done is that of fencing the ground very well, to keep out cattle, hares, and rabbits; for if either of these can get into the ground, they will soon destroy all the young trees. Indeed, they will in a few years grow to be out of danger from the hares and rabbits; but it will be many years before they will be past injury from cattle, if they are permitted to get into the plantation; therefore, durable fences should be put round the ground. If, in the beginning, a pale fence is made about the land, which may be close at the bottom, and open above; and within the pale a quick-hedge planted; this will become a good fence, by the time the pale decays, against all sorts of cattle; and then the trees will have got above the reach of hares and rabbits, so that they cannot injure them; for the bark of the trees will be too hard for them to gnaw.

After the ground is well fenced, it should be prepared, by ploughing of it three or four times, and, after each ploughing, to harrow it well, to break the clods, and cleanse the ground from couch, and the roots of all bad weeds. Indeed, if the ground is green sward, it will be better to have one crop of beans, pease, or turnips, off the ground, before the acorns are sown, provided these crops are well hoed to stir the surface, and destroy the weeds: for if this is observed, the crop will mend and improve the land for sowing; but in this case the ground should be ploughed as soon as possible, when the crop is taken off, to prepare it for acorns; which should be sown as soon as may be after the acorns are ripe: for although these may be preserved in sand for some time, yet they will be apt to sprout; and, if so, the shoots are in danger of being broken and spoiled; therefore we would advise the sowing early, which is certainly the best method.

In making choice of the acorns, all those should be preferred which are taken from the largest and most thriving trees: and those of pollard-trees should always be rejected, though the latter are generally the most productive of acorns; but those of the large trees commonly produce the strongest and most thriving plants.

The season for the sowing of the acorns being come, and the ground having been ploughed, and levelled smooth, the next work is to sow the acorns; which must be done by drawing of drills across the ground, at about four feet asunder, and two inches deep; into which the acorns should be scattered, at two inches distance. These drills may be drawn either with a drill-plough, or by hand, with an hoe; but the former is the most expeditious method, therefore in large plantations should be preferred. In the drawing of the drills, if the land has any slope to one side, these should be made the same way as the ground slopes, that there may be no stoppage of the wet by the rows of plants crossing the hanging of the land. This should be particularly observed in all wet ground, or where the wet is subject to lie in the winter. When the acorns are sown, the drills should be carefully filled in, so as to cover the acorns securely; for, if any of them are exposed, they will entice the birds and mice; and if either of these once attack them, they will make great havock with them.

The reason of my directing the drills to be made at this distance, is for the more convenient stirring of the ground between the rows, to keep the young plants clean from weeds; for if this is not carefully done, it cannot be expected, that the young plants should make much progress; and yet this is generally neglected by many who pretend to be great planters, who are often at a large expence to plant, but seldom regard them after: so that the young plants have the difficulty to encounter the weeds, which frequently are four or five times the height of the plants, and not only shade and draw them, but also exhaust all the goodness of the ground, and consequently starve the plants: therefore, whoever hopes to have success in their plantations, should determine to be at the expence of keeping them clean for eight or ten years after sowing, by which time the plants will have obtained strength enough to keep down the weeds: the neglecting of this has occasioned so many young plantations to miscarry, as are frequently met with in divers parts of England.

About the end of March, or beginning of April, the young plants will appear above ground; but before this, if the ground should produce many young weeds, it will be good husbandry to scuffle the surface over with Dutch hoes, in a dry time, either the latter end of March, or the beginning of April, to destroy the weeds, whereby the ground will be kept clean, until all the plants are come up so as to be plainly discerned; by which time it may be proper to hoe the ground over again; for by doing it early, while the weeds are small, a man will perform more of this work in one day than he can in three or four, when the weeds are grown large: besides, there will be great hazard of cutting off or injuring the young plants, when they are hid by the weeds; and small weeds, being cut, are soon dried up by the sun; but large weeds often take fresh root, and grow again, especially if rain should fall soon after, and then the weeds will grow the faster for being stirred; therefore, it is not only the best method, but also the cheapest husbandry, to begin cleaning early in the spring, and to repeat it as often as the weeds are produced.

The first summer, while the plants are young, it will be the best way to perform these hoeings by hand; but afterwards it may be done with the hoe-plough; for as the rows are four feet asunder, there will be room enough for this plough to work; and as this will stir and loosen the ground, it will be of great service to the plants; but there will require a little hand labour where the plough is used, in order to destroy the weeds, which will come up in the rows between the plants; for these will be out of the reach of the plough, and, if they are not destroyed, they will soon over-grow and tear down the young plants.

After the plants have grown two years, it will be proper to draw out some of them, where they grow too close; but in the doing of this, great care should be had not to injure the roots of those left; for as the plants which are drawn out are only fit for plantations designed for pleasure, so these should not be so much regarded in their being removed, as to sacrifice any of those which are designed to remain. In the thinning of these plantations, the plants may, at the first time, be left about one foot asunder, which will give them room enough to grow two or three years longer; by which time it may be easy to judge which are likely to make the best trees. Therefore these may be then fixed on, as standards, to remain; though it will be proper to have a greater number at this time marked than can be permitted to grow, because some of them may not answer the expectation: and, as it will be improper to thin these trees too much at one time, so the leaving double the number intended at the second thinning will not be amiss. Therefore, if they are then left at about four feet distance in the rows, they will have room enough to grow three or four years longer; by which time, if the plants have made good progress, their roots will have spread over the ground; therefore it will be proper to take up every other tree in the rows. But, by this, I do not mean to be exact in the removing, but to make choice of the best plants to stand, which ever rows they may be in, or if they should not be exactly at the distance here assigned: all that is designed here, is, to lay down general rules, which should be as nearly complied with as the plants will permit: therefore every person should be guided by the growth of the trees in the performance of this work.

When the plants have been reduced to the distance of about eight feet, they will not require any more thinning. But in two or three years time, those which are not to remain will be fit to cut down, to make stools for underwood; and those which are to remain, will have made such progress as to become a shelter to each other; for this is what should be principally attended to, whenever the trees are thinned; therefore, in all such places which are much exposed to the wind, the trees should be thinned with great caution, and by flow degrees; for if the air is let too much at once into the plantation, it will give a fudden check to the trees, and greatly retard their growth, but, in fheltered fituations, there need not be fo great caution ufed as in thofe places; the plants will not be in fo much danger of fuffering.

The diftance which I fhould chufe to allow to thofe trees which are defigned to remain for timber, is, from twenty-five to above thirty feet, which will not be too near, where the trees thrive well; in which cafe their heads will fpread, fo as to meet in about thirty, or thirty-five years: nor will this diftance be too great, fo as to impede the upright growth of the trees. This diftance is intended that the trees fhould enjoy the whole benefit of the foil. Therefore, after one crop of the underwood, or, at the moft, two crops are cut, I would advife the ftubbing up the ftools, that the ground may be intirely clear, for the advantage of the growing timber, which is what fhould be principally regarded: but, in general, moft people have more regard for the immediate profit of the underwood than the future good of the timber, and, frequently, by fo doing, fpoil both: for, if the underwood is left after the trees have fpread fo far as that their heads meet, the underwood will not be of much worth; and yet by their ftools being left, they will draw away a great fhare of nourifhment from the timber-trees, and retard them in their progrefs.

The foil in which oak makes the greateft progrefs, is a deep rich loam, in which the trees grow to the largeft fize; and the timber of thofe trees which grow upon this land, is generally more pliable than that which grows on a fhallower or drier ground; but the wood of the latter is much more compact and hard. Indeed there are few foils in England in which the oak will not grow, provided there is proper care taken in their cultivation; though this tree will not thrive equally in all foils: but yet it might be cultivated to a national advantage upon many large waftes in many parts of England, as alfo to the great profit of the eftates where thefe tracts of lands now lie uncultivated, and produce nothing to the owner. And, fhould the prefent temper of deftroying the timber of England continue in practice fome years longer, in the fame degree which it has for fome years paft, and as little care be taken to raife a fupply, this country, which has been fo long efteemed for its naval ftrength, may be obliged to feek for timber abroad, or be content with fuch a naval ftrength as the poor remains of fome frugal eftates may have left growing: for, as to the large forefts, from whence the navy has been fo long fupplied, a few years will put an end to the timber there: and how can it be otherwife, when the perfons to whofe care thefe are committed, reap an advantage from the deftruction of the timber? *Miller's Gard. Dict.*

OAK-BARK. *See the article* BARK *and* TAN.

OATS, the name of a well known fpecies of grain, and of which Mr. Miller reckons four forts, cultivated in England, viz. the white, the black, the brown or red, and the naked oat, in which, though fuppofed to be only accidental varieties, he has never obferved any alteration where they have been cultivated feparately for many years. Their principal difference is in the colour of their grain.

The white fort, which is moft common about London, makes the whiteft meal, and is chiefly cultivated where the inhabitants live much upon oat-cakes. The black oat is more cultivated in the northern parts of England, and is efteemed a very hearty food for horfes. Red oats are much cultivated in Derbyfhire, Staffordfhire, and Chefhire, but are feldom feen in any of the counties near London; though, as they are a very hardy fort, and yield a good increafe, they will be well worth propagating, efpecially in all ftrong lands. The ftraw of thefe oats is of a brownifh red colour, as is alfo the grain, which is very full and heavy, and efteemed better food for horfes than either of the other forts. The naked oat is leaft common in the fouthern parts of England; but in the northern counties, in Scotland, and in Wales, it is pretty much cultivated, and is particularly efteemed, becaufe its grain threfhes clean out of the hufk, and need not be carried to the mill, to be made into oat-meal or grift.

As oats are very hardy, and will thrive in almoft any foil, they have been a great improvement to many eftates in the northern parts of this kingdom, where, though fown even fo late as April, and in ftiff ground, they have ripened early, and yielded a good crop. However, February, or March, according as the feafon proves early or late, is a more common and better time for fowing this corn, of which it will always be right to fow the largeft grain fort earlieft.

Oats are often fown after a crop of wheat, rye, or barley; in which practice the common method is to turn in the ftubble, with one ploughing, about the beginning of February, and fow the feed with a broad-caft at twice, harrowing it in, once after the firft fowing, and five or fix times after the fecond, obferving to draw the harrow once or twice acrofs the furrows, to break the clods and cover the feeds; but at the other times to harrow in the fame direction as the furrows, left the ftubble fhould be raifed on the furface. But it would be much better hufbandry to plough in the ftubble in autumn, that it may rot in winter, and to give the land another ploughing, and a good harrowing, juft before the oats are fown. This will render the ground finer, and fitter to receive the grain, the increafed produce of which will amply repay the extraordinary expence of tillage. M. Duhamel, after obferving that every farmer knows, though but few practice it, that all crops of fpring-corn are greatly bettered by this method, inftances the example of M. d'Elu, one of his correfpondents, who having given three ploughings to fome of his oat-lands, had, in 1759, a year remarkably dry, and unfavourable to fpring-corn, a plentiful crop of oats, which held up well till they were perfectly ripe, and yielded excellent grain.

Another thing, which I muft alfo infift on, is, that if farmers were to follow the directions before given, in regard to the changing of crops, by which means oats, which impoverifh the ground, would always fucceed fome one of the meliorating crops, the return would be much more plentiful than in the common way, becaufe the earth would be in a much loofer ftate.

When oats, as it frequently happens, are fown upon a lay, or on ground newly broken up, after only one ploughing, which is given in January, when the earth is moift, to turn down the fward; the harrowing muft be in the fame direction as the furrows, or but very little acrofs, for fear of raifing the turf. But this again is bad hufbandry: for the ground would be brought to a much better tilth for other grain, as a preparation for which this fowing is chiefly intended, by giving the fward time to rot before the oats are fown; becaufe the roots of the grafs will prevent thofe of the corn from ftriking downward.

Black oats delight in a moifter foil than the white fort, and, being a hardier plant, may be fown a month earlier. The white, which prefer a dry land, and will do well on gravel and fand, are the beft of all corn for ground fubject to quick-grafs or weeds, becaufe it may be ploughed later for them, and they rife fooner, and top the weeds better than black oats. The weather cannot be too dry when white oats are fown; though the ground may then be moifter for them than barley will endure; becaufe this laft, having a thinner coat, is fooner chilled by imbibing the wet, which may perhaps burft many of its veffels; whereas white oats, being protected by a double hufk, better refift the entering of the moifture. Mr. Lifle, who makes thefe remarks, adds, that, according to the beft of his obfervations, white-oats require a rich feeding foil; becaufe their haulm, or ftraw, running to a great largenefs, cannot be fupported without good juices and moifture; that white chalky ground, though in never fo good heart, will be unfruitful with white oats; and that a mixed mould, between white earth and red clay, of which there is a great deal in the hilly parts of Hampfhire, is not feeding enough for them. The red and the white clays, when in good heart, carry moifture enough, and are very fit for this grain.

The common allowance of feed oats is four bufhels to an acre; but Mr. Miller rightly thinks three bufhels more than enough: and the ufual produce is about twenty-five bufhels from an acre; though he obferves, that he has fometimes known more than thirty bufhels reaped from that

that extent of ground; and we can ſay with truth, from an accurate account now in our poſſeſſion, that a gentleman, who is indeed an excellent huſbandman, has had, for a continuance, forty-eight buſhels of oats from off each acre of his land ſown with that grain. I do not mean forty-eight buſhels of naked oats; for the produce of that ſort is the leaſt of any in bulk, becauſe its grains are ſmall, and lie very cloſe together: but they make up in value, for what is wanting in meaſure. White oats always produce a greater increaſe than black oats. Mr. Liſle threſhed a ſtack of twenty-eight loads of the former, and found it yield more grain than a ſtack of thirty-eight loads of the latter; and farmers in general account an ordinary crop of white oats as good as a middling crop of black oats. This laſt ſort is alſo moſt liable to blight, eſpecially if a hot ſummer follow a dry cold ſpring, and the grain has been ſown on lay ground. Their culture is alike; and the manner of mowing and ordering them at harveſt exactly the ſame. Only it is to be obſerved, that white oats are apt to ſhed moſt as they lie, and black oats as they ſtand.

In the year 1709, M. Liſle ſowed, in the beginning of May, in ſome of his wheaten ground, where the corn had been killed by the preceding hard winter, rath-ripe barley in one part, and ſhort grained white oats, which he diſtinguiſhes by the name of white Poland oats in another. Both grains were ſown on the ſame day, in an equally fertile, moiſt and well tilled ground. He made no doubt but that the Poland oat would be firſt ripe, and was therefore ſurpriſed to ſee the rath-ripe barley ſpring up ſooneſt, by four or five days: but reflecting on the nature of each grain, he ſoon concluded the reaſon to be, that the oat, having a double hull, and being conſequently better guarded from moiſture, could not imbibe the vegetable water ſo ſoon as the barley; but that, the texture of the flour of the oat, and the infolded fibres of the incloſed plant being ſofter, it would conſequently grow faſter. From hence he infers, that, to ſecure the growing of Poland oats without rain, they muſt be committed to the earth before it becomes ſo dry as is proper for the ſowing of barley, not only becauſe the oats require more moiſture to make them grow, but alſo becauſe they lie ſo many days longer in the ground, before they come up, than the barley does.

When oats are about four inches high, intelligent huſbandmen run a wooden roller over them, after a ſhower of rain has ſoftened the clods, by the breaking of which in this manner, freſh earth is laid to the roots of the plants, their tillering is conſiderably increaſed, if they have not been ſown too thick, and the ſurface of the field is ſmoothed; ſo that the mowers, at harveſt, are able to cut cloſe to the ground, as it is very fit they ſhould, becauſe oats ſeldom grow high. Both oats and barley ſhould be carefully weeded.

Oats are ripe when the ſtraw turns yellow, the grain becomes hard, and the chaff begins to open and ſhew the ſeed. When mowed, they are generally let lie ſome time for the due and rain to plump them, and make them threſh well, and, if weedy, to kill the weeds: but if rain wet them much, they ſhould be carried off as ſoon as they can be got tolerably dry again, or they will ſhed; for oats may be inned the wetteſt of any corn, if the weeds among them be but dead. Even in very rainy harveſts, when other grain is ſpoiled, this will receive little or no damage, the ſurface of its ſtraw and ears being ſo ſmooth and compact as to turn off water, and of ſo dry a nature, that, though houſed wet, they will not heat in the mow, or become mouldy, as other grains uſually do. This is a vaſt advantage in northern climates, where the harveſt is generally late, and the autumn wet.

M. Duhamel is ſtrongly of opinion, that farmers, eſpecially thoſe who keep many cattle, would find their account in houſing their oats directly, without letting them lie out after they are cut, as is the common way, that rain and dews may moiſten, and conſequently ſwell their grain. He earneſtly adviſes huſbandmen to try the experiment upon a part of their crop; "becauſe," ſays he, "the fodder will, by this means, certainly be much better for cattle, and much leſs grain will be loſt in the field. It may be objected, that theſe oats will be difficult to threſh; to which I anſwer, that if this be the only inconvenience, the ſuperior quality of the fodder, and the ſaving of a quantity of grain, which would otherwiſe be ſhed, will probably more than pay the extraordinary wages of the threſher.

"But allowing that the oats thus houſed cannot be threſhed quite clean, and that ſome grain will neceſſarily remain in the ears, I ſay, that this will not be loſt to the farmer; for he is obliged to give his cattle unthreſhed oats, and they will eaſily find the grains remaining in the ſtraw, which will not perhaps exceed the quantity that would have been dropped in the field: and even granting, though it will not happen, that the greateſt part of the grain be left in the ear, ſtill it will not be loſt in the hands of an intelligent farmer; for what ſhould hinder him from giving it to his horſes? ſuppoſing that four ſheaves yield a buſhel of oats, he need only give his horſes thoſe ſheaves inſtead of a buſhel of corn. They will certainly be longer in feeding upon four ſheaves, than upon a buſhel of cleared oats; and at the ſame time they will eat ſome ſtraw with the corn, which will ſupply the place of other fodder, and probably prove a more healthy food." This method may be particularly beneficial to ſuch as live in very hot countries, or in very dry ſeaſons.

Mr. Liſle, refuting the opinion of thoſe who think that oats cut green will ripen while they lie in ſwarth, ſays, "If, by ripening be meant ſhrinking, drying, or withering, I muſt allow the poſition; but if the countryman will have it, that the greeniſh oat, cut a fortnight or ten days, or be it but a week, before it is ripe, will proceed in its vegetable increaſe, and ſwell as well as harden by lying in ſwarth, I muſt deny it. This year (1707) I made a full experiment of this matter; for when the ſpring corn was ſown, the ground being generally dry, half the oats and barley came not up till the latter end of May, when rain came, whereby in moſt places half the crop was edge-grown. The forward oats being then in danger of ſhedding, we were forced to cut down the greeniſh corn with the ripe, when otherwiſe we ſhould have waited ten days longer. I let them lie in ſwarth above a week, and, when I carted them, I found the hull of the greeniſh oat had got a riper colour, and the pith was well hardened, but pitifully lean and ſhrunk; ſo that though this is to be done on neceſſity, yet it ought not to be practiſed with ſuch indifference as is uſual among farmers. Note, the pith of theſe green oats was well paſt the milk, and came to a floury ſubſtance."

The ſame gentleman adds, that oats are the worſt of all grain to keep, becauſe of the great moiſture in them, and their conſequent aptneſs to heat when laid in a heap; and that when the heat has been ſuch as to ſpoil them for growing, their hulls look as red as a fox.

The meal of oats makes tolerably good bread, and is the common food of the country people in the north. In ſome places beer is made with this grain: in Ruſſia in particular the poorer ſort make with it a drink, which they call *quas*; but its principal uſe is for the food of horſes, for which purpoſe it is reckoned very wholſome, being ſweet, and of an opening nature: but it muſt not be given them before it has ſweated in the mow, or been otherwiſe dried, leſt it ſhould prove too laxative.

The very long drought of the ſummer 1762, ſhewed another very profitable uſe of oats on ſuch occaſions; and probably it will anſwer equally well in the winter. Some milk-men near London boiled oat-meal in the water which they gave their cows to drink, and found that the expence was abundantly repaid, by the additional quantity of milk which theſe cows yielded more than thoſe which had not this maſh.

The following Letter from Mr. Lamb, *on the beſt Method of cultivating Black Oats, and recommending more frequent Ploughings than are uſually afforded them, will, we are perſuaded, be acceptable to our Readers.*

Gentlemen,

"Having been for many years a practical farmer in the eaſtern part of the county of Eſſex, you will not, I hope, think me impertinent in troubling you on the culture of black oats, which I have very often to great advantage ſown.

Moſt

"Most of my neighbours prefer the white Poland oat, which may, I own, in some circumstances of soil and situation, be best. I prefer the black oats because they are hardiest, for which reason they suit best with my convenience; for, as a considerable tract of the farm I occupy is light land, I am under a sort of necessity of sowing this soil early, or, if a dry summer followed, I should have no return at harvest.

"Few people allow more than one ploughing for a crop of oats; but such as follow this practice are very wrong-headed; for they may assure themselves, that no crop pays better for ploughing than oats; and it is on this account that I generally give my land designed for oats three tilths; whence I am morally certain arises the largeness of my crops, for I have seldom under five, oftener six, and very frequently seven quarters from an acre, throughout a field

"Your readers will not be surprised at my having such good crops, when I observe, that I almost every year sow some oats on a fallow that has been well dunged; and this I aver to be good husbandry, as it abates the rankness of the soil, kills many of the weeds, and prepares the land in an excellent manner for a succeeding crop of sweet wheat; but I must observe, that I always clear my land of the stiff oat-stubble before I attempt to plough for the wheat.

"I have already said that I sow black oats early on my light land: by early, I mean as early as the first week in February, by which time I have generally an opportunity of getting the land in proper order, for a light soil is soon wet, soon dry.

"Let me mention once more to your readers, that it is on a light soil, which is apt to burn a crop, that I sow my black oats so early as the beginning of February; for should any of them attempt to sow them so early in a moist, cold, stiff soil, and a hard frost should follow, the young blade would, in all probability, be killed.

"I must also remark, that when I sow oats thus early, it is generally under furrow; yet I sometimes sow them broad-cast, and plough them in.

"The quantity of seed I, for the most part, use, is about three bushels, which I find to be enough; nay, I have sometimes from only two bushels had a good crop; but then I have been particularly careful and attentive to the goodness of the seed, without which precaution I should not, unless the season had been very favourable indeed, have succeeded.

"I have found it a very good way to sow first half my quantity of seed under furrow, and afterwards, sowing the remainder broad-cast, harrow it in; and this is often my practice when I sow the latter end of February, or the beginning of March.

"When I sow oats after wheat, which however is not very frequently, I turn up the stubble as soon as I conveniently can after harvest, and leave it rough through the winter. The first fine weather after Christmas, I lay it down smooth with the harrows, and immediately give it a cross ploughing.

"As soon as February comes in, if it is not a hard frost, I make the land as fine as I possibly can by the harrows, raising a fine loose mould to the surface, which is to be the bed for the oats to lie in; for I sow my oats directly under furrow; after which I pass a moderate-sized roller over the field, and then give it a slight scratch with a pair of light harrows.

"This husbandry generally produces me a crop I have no reason to complain of.

"My chief reason for troubling you with this letter is, to endeavour to persuade my brother farmers that they do not, in general, allow their oats a sufficient number of ploughings, one being the stated quantity.

"If they would plough twice for this crop, they would receive more than twenty shillings an acre for their trouble; but if they would consult their own interests, and allow three ploughings, it would often make fifty pounds difference to them in a field of twenty acres: this they will, perhaps, think wonderful; but it is no less true.

"The black oats require particularly to be sown early, especially if the farmer wishes to have them of a fine glossy ebon colour, and that the crop should corn well; for if they are sown late, and wet weather follows soon after sowing, they will be apt to run all to straw; and if dry weather, and the soil is gravelly, it is a chance but they are burnt up.

"I have found by experience, that black oats will yield a very large crop after turnips; and this I believe is simply owing to their being sown in a fine tilth; for the mould cannot but be reduced to very small particles if a crop of turnips has been well husbanded, especially if it is in a light soil.

I am, &c.

East of Chelmsford, Essex. J. LAMBE."

Wild OATS, a species of oats difficult to be extirpated where they have once taken possession; for ripening before harvest, and scattering their seed round them, they will remain in the ground till it is ploughed up again, though it be for a whole year, some say four or five years, and will then come up with the corn. The surest way to destroy them, is to lay the ground down to clover, and to mow the oats and clover together before the oats are ripe.

OILS, the beards, or prickles of barley, &c.

OLITORY, a kitchen-garden.

OLIVE-TREE, the name of a tree much cultivated for its fruit in the warmer climates, and which will grow in almost any soil, provided the situation be very warm, and the exposure to the south or east, especially on the side of a hill, or other rising ground; for it never bears well in a flat, or valley. It grows to the largest size when planted in rich moist ground: but its fruit is best, either for eating, or for making oil, when produced on a poorer soil. That which grows on chalky land mixed with coarse sand, and lying upon a bed of gravel, is thought to yield the finest and best keeping oil: but a watery, oozy, or quite chalky soil, is not fit for the olive.

This tree seldom rises higher than from twenty to thirty feet; nor is it often seen with a single stem, but generally with two or three, which rise from the same root, and put out from their sides, for almost their whole length, branches which are covered with gray bark, and garnished with stiff leaves about two inches and an half long, and an inch broad in the middle, gradually diminishing to both ends. They stand in opposite pairs, and are of a lively green on their upper side, and hoary on the under. The flowers, which are produced in small bunches from the wings of the leaves, are small, white, and have short tubes, spreading open at the top; and these are succeeded by oval fruit, which ripens in the autumn.

It would be at least very tedious to raise olive-trees from the stones of their fruit: but they may be easily enough propagated by layers, cuttings, or offsets from their roots.

The layers, which are formed by laying down the tender branches, in the same manner as is practised for other trees, must be allowed two years to take root, before they are cut off from the mother-tree, in order to their being planted in the nursery; for a nursery is as necessary for the raising of these, as it is for any other sort of fruit-trees. This nursery should be in a free air, in land that is moderately strong, but rather light than heavy, and somewhat moist, though by no means wet or watery. It should be ploughed well, and repeatedly, or rather thoroughly dug, to the depth of at least three feet, so long before the time of planting, as that it may be well mellowed by the influences of the air, &c.

The cuttings, or rather truncheons, for they should be full two inches in diameter, and not above a foot and an half long, should be taken from the straitest, roundest, and most fruitful branches of young trees, the bark of which is smooth, and perfectly sound. They should be sawed off with care not to hurt the bark or any other part of them, and with eyes towards each end, to produce shoots at the one, and roots at the other. Both the cut extremities should then be smoothed with a sharp knife; and after that the wounds have been covered with the grafting clay or cement, or says Columella, with dung mixed with ashes, these truncheons should be set in the nursery, so deep as that the upper end may be covered with four fingers depth of earth. Care must be here taken to place that end uppermost, which was uppermost on the tree; and in order to be sure of this

this, they ſhould be marked with chalk, or ſome other ſoft ſubſtance, as ſoon as they are cut: for if they were put under ground inverted, it would be long before they would ſtrike out roots, and even though they ſhould afterwards produce ſtrong trees, they would be for ever barren. A mark ſhould alſo be ſtuck upon each ſide of the cutting thus planted, in order that the digger of the nurſery may not injure it with his ſpade or hoe. The beſt way therefore is to ſet them in ſtrait rows, and at regular diſtances from each other.

When the offsets from the roots, which are generally moſt numerous when the head of the tree has been hurt by froſts in the winter, are grown pretty ſtrong, they are ſeparated from the tree with a ſharp axe, ſo as to preſerve a few roots to them, and they are planted about two feet deep in the ground. This is the moſt uſual method of propagating the olive-tree in Languedoc and Provence.

November is the moſt proper ſeaſon for either of the above ways of planting in very warm countries; but February and March are preferable for milder climates.

The holes for planting theſe layers, cuttings, or offsets, but eſpecially for the cuttings, or truncheons, ſhould be four feet large every way, and ſhould remain open for at leaſt two months before the plants are ſet in them, in order that the earth may be the better mellowed. The mould which is to be returned into them ſhould alſo be mixed with well rotted dung and wood-aſhes; and when the plants are ſet, it ſhould be trodden down gently about them.

The young trees muſt remain in this nurſery five years, during the firſt of which the ground ſhould be well hoed with a hand-hoe, and in the courſe of the others it ſhould be dug with a ſpade, or carefully horſe-hoed, at leaſt every ſpring and autumn, and it ſhould be kept conſtantly clear from weeds. The ſoil ſhould alſo be well manured every autumn with thoroughly rotted dung, and the plants ſhould be watered now and then in very dry ſeaſons. They ſhould not be pruned at all during the two firſt years: in the third, two branches only ſhould be left upon each of them; and in the fourth, the weakeſt of thoſe two branches ſhould be cut off. When the trees thus reared are five years old, they will be fit to tranſplant into the places where they are to remain. This is beſt done in November, if the ground intended for their future growth is dry, and the climate hot: but the ſpring, a little before their time of budding, is beſt for ſuch lands as are rich and moiſt. The trenches, or holes, for this new planting ſhould be laid open for a year before they are uſed; or if ſo much time cannot be allowed, let ſtraw be burnt in them, that the heat of the fire may bring the mould to that looſe and crumbling ſtate, which it would otherwiſe have derived, ſtill more effectually, from the ſun, air, and froſts. Care ſhould alſo be taken, that there be no wet at the bottom of them when they are planted; and the earth with which they are filled up after the trees are ſet (being that which was before dug out of them, and ſpread abroad to mellow) ſhould be mixed with well rotted dung, and trod down gently about the ſtems, as above directed for the nurſery. The rows of theſe trees ſhould be from about thirty to thirty-five feet aſunder in land which is rich enough to bear corn; but about twenty or twenty-five feet will be enough for ground of an inferior quality, where their growth will, of courſe, be leſs luxuriant. The diſtances between the trees in the rows ſhould be in proportion; and, both here and in the nurſery, they ſhould be carefully fenced from cattle, eſpecially whilſt they are young. The trees ſhould be taken up with as much earth as can be about their roots: the rows ſhould be directed towards the weſt, that the ſummer breezes may have the freer paſſage through them; and Columella is again of opinion here, that the trees thus tranſplanted ſhould be ſet to the ſame aſpect as they had in the nurſery.

The olive grounds in the ſouth of France are carefully dug, or ſtirred pretty deep with a hoe, twice a year, viz. at Midſummer and at Michaelmas. Channels are likewiſe cut to convey the rain, and the fine mould which is waſhed down with it, from the higher parts of the ground to the ſtems of the trees on the lower; and in the autumn, about ſix pounds of goats-dung are laid around the foot of each olive-tree, with ſometimes a ſmall quantity of the lees of oil of olives, to fatten the land, and kill the worms which breed in it. The roots of the olive-tree are laid bare every year from October till February; all young ſhoots which have ſprung out of the lower part of the ſtock are extirpated every year, unleſs it be an old tree which is to be renewed thereby, in which caſe one or two of the fineſt ſhoots are left; and all the dead wood is pared off very cloſe.

The olive-tree is not pruned till it is eight years old, nor, after that, oftener than once in eight years. This is moſt uſually performed at the end of the winter, a little before the buds begin to ſwell. It ſhould be done in fine weather; and the people of Provence and Languedoc, who may poſſibly have experience on their ſide, and therefore we ſhall not pretend to contradict them, hold, that the moon ſhould always be in the decreaſe when theſe trees are pruned. They heal the wounds made in pruning, by rubbing them with lees of oil drawn without ſalt, or covering them over with the ſubſtance which remains of the olives after their oil has been preſſed out.

Skilful huſbandmen manure their olive grounds every third year, generally with well rotted dung, whether they be, or be not, ſown with corn in the intervals between the trees; which laſt practice Columella recommends, becauſe, as the olive-tree does not produce an equal plenty of fruit in any two ſucceſſive years, the other crop will help to make amends for the deficiency, and the ſtirring of the ground, by ploughing it, will always be of ſervice to the trees.

An olive-tree which thrives well, and does not produce fruit, may be made to bear by cutting off one of its principal roots; or by laying to its roots lees of unſalted oil, mixed with ſtale urine of men or ſwine: but the ſureſt way is to engraft it with a good cion of its own kind, taken from a fruitful branch of a well bearing tree. This is generally done in May, and the method is that of ſcutcheon-grafting; but no part of the ſtock is cut off till a year after. Then, indeed, its head is cut off cloſe to the graft.

In Provence, when an olive-tree is decayed, and therefore condemned to be grubbed up, the following method is uſed in order to force it to yield a good final crop. The breadth of an inch of bark is peeled off all around its youngeſt branches, and the place thus bared is covered with an equal ſlip of other bark taken from the branch of a young tree of the ſame ſpecies. The wound is then dreſſed in the ſame manner as is practiſed for grafing, and the branches of the old tree thus ſpliced in the rind yield an uncommon quantity of fruit. Nearly the ſame thing is done in Languedoc, by grafting old olive-trees in the month of May, and then cutting the bark off circularly to the breadth of about three fingers, juſt above the graft, ſo as to lay bare the wood of the ſtem or branch which has been engrafted; the conſequence of which is found to be, that the tree produces a double quantity of bloſſoms and of fruit. The trees thus forced die indeed the ſame year: but as this operation is not performed till they are no longer worth cultivating, it is thought beſt to kill them in this manner, becauſe an extraordinary crop of fruit is obtained thereby.

In Spain, the olive-trees are not ſuffered to grow ſo high as they do in France: on the contrary, they are kept low, like ſhrubs, and are found then to yield the moſt fruit, which is alſo leaſt apt to be blown off or injured by high winds, and likewiſe the eaſieſt to be gathered. Theſe trees are therefore cut low when they are pruned: for their nature is to produce either a great deal of wood, or a great deal of fruit. The Spaniards give the preference to their large olives, becauſe they are moſt fleſhy, and yield the greateſt quantity of oil: but neither the fruit nor the oil of that country is at all comparable to the product of France or Italy.

The olive-tree is long lived, and its wood, which has an agreeable ſmell, and is prettily veined, is eſteemed by the turners.

The antients looked upon the olive as a maritime-tree, and ſuppoſed that it would not thrive far from the ſea: but, though it does bear the ſpray of the ſea better than moſt other ſorts of trees, experience has ſhewn that it it will fucceed perfectly well in any country where the air has a proper degree of heat.

The fruit of this tree is gathered by hand, either in June or July, while the olives are green, if they are intended for pickling; or in November and December, or even January, when they are thoroughly ripe, which is known by their beginning to turn to a blackifh red, if they are defigned for oil.

OLLET, fuel of any kind.

OMY, mellow; fpoken of land.

ONION, the name of a well-known plant propagated in kitchen-gardens.

Onions intended for the general winter crop fhould be fown in the latter end of February, or beginning of March, on rich light ground, well dug and levelled, and cleared from the roots of all weeds. The weather fhould be dry, and the furface of the ground not moift, at the time of fowing. The common allowance of feed is after the rate of fix pounds to an acre of land: but the generality of gardeners fow more, in order to allow for drawing out a crop, which they call cullings. However, they ought not to be fown too thick.

The way of fowing thefe feeds alone in the garden is, to ftrew them as equally as poffible over the ground intended for them, then to tread or beat it down flat, in order to fix them in their places, and as foon as they begin to fhoot, to fift a little fine earth over them, to the thicknefs of fomewhat lefs than a finger's breadth: for they muft not be buried deep.

In about fix weeks from the time of fowing, the onions will be forward enough to be hoed. This fhould be done in dry weather, with a hoe about two inches and an half wide; carefully cutting up all weeds, and thinning the plants themfelves, till they ftand at leaft two or three inches afunder. In about a month after, they muft be hoed again, and thinned till they are four or five inches from each other; and in about a month or fix weeks more, they muft be hoed for the third and laft time, and thinned to the diftance of at leaft fix inches. If this hoeing (which may be performed with a wider hoe, for the fake of greater riddance) be well executed, and the weather proves dry, the ground will remain clean till the onions are fit to pull up, which will generally be towards the middle of Auguft. But if the feafon be wet, a careful perfon fhould go over the ground, about a fortnight or three weeks after this laft hoeing, and pluck up by hand all weeds that may chance to have taken frefh root, or to have fprung up fince the former clearing: for the onions fhould not be difturbed with a hoe after they have begun to bulb.

Onions have attained their full growth when their blades fall to the ground, and fhrink: but before their necks are withered off, the bulbs fhould be taken up, and, after cutting off the extremity of their leaves, be fpread upon a dry fpot of ground, and there turned every other day at leaft, to accelerate their drying, and prevent their taking frefh root; which laft they will otherwife quickly do, efpecially in moift weather. With this management, they will be fit to houfe in about a fortnight. But at the time of hoeing them, which fhould be done in perfectly dry weather, particular care fhould be taken to rub off all remaining earth, to feparate the faulty roots, which would foon decay and fpoil the reft, and not to lay them up in too thick heaps, leaft this fhould make them fweat, and confequently rot. A loft, or garret, is therefore preferable to a lower room, or ground-floor, for keeping them in; and the lefs they are expofed to the air, the better they will be preferved. It will be right here to look them over at leaft once a month, and to pick out all fuch as are found to be decaying: though, with all the care that can poffibly be taken, many of them will fprout in the loft, efpecially in mild winters, which are generally moift, unlefs their roots have been flightly finged with a hot iron. This, indeed, will effectually prevent their growing: but great caution muft be ufed not to fcorch the pulp of the onions; for that would foon deftroy them.

To fave the feeds of onions, fome of the firmeft, largeft, and beft fhaped bulbs fhould be replanted, in the beginning of March, in well dug beds of fine good mould, about three feet wide, and two feet afunder. Each of thefe beds will confequently be wide enough to contain four rows of plants, at the diftance of near a foot from each other. To make thefe rows, a channel, for each, fhould be opened all along the bed, to the depth of about fix inches, and the onions intended for feed fhould be placed therein, with their roots downward, at about nine inches afunder. They fhould then be covered, by raking the ground fmooth, and in about a month's time their leaves will appear. Many of thefe roots will produce three or four ftalks. Care muft be taken to keep them clear from weeds; and towards the beginning of June, when the heads of the flowers begin to fhew themfelves upon the tops of the ftalks, ftakes, about four feet long, fhould be fixed in the ground, at fuch diftances, that ftrings may be faftened from one to the other, fo as to fupport thofe heads, which would otherwife foon be broken down by wind and rain, or even by their own weight. Thefe ftrings fhould therefore run clofe under the heads that are to be fupported by them.

About the end of Auguft, the heads of the onions will turn brown, and the cells which contain the feeds will begin to open. This is a fure fign of their being ripe, and no time fhould then be loft to cut them, leaft they fhould fall to the ground. The heads thus cut fhould be immediately fpread upon coarfe cloths, and expofed to the fun: but they fhould be fheltered at night, and alfo in wet weather. When they are quite dry, the feeds muft be beaten out, which is very eafily done, and after clearing them from their hufks, &c. and expofing them again to the fun, for one day, to complete their drying, they may be put up in bags, and kept for ufe.

The Spanifh onion is moft efteemed for its mildnefs as well as fize; but it foon degenerates in this country. The next place is given to the Strafburgh, and the third to the white, fometimes called the Egyptian, which is the fpecies that furnifhes the general winter crop, of which only we have hither to fpoken. But the gardeners about London generally raife two other crops from this fame fort. One of thefe crops, known by the name of Michaelmas onions, is fown in Auguft, and fupplies the markets after the winter onions are over: the other is fown in the fpring, and is drawn up for fallads, after the Michaelmas onions are grown too large for that purpofe.

Welch ONIONS, a fort of onions propagated by gardeners for the ufe of the table in fpring; they never make any bulb, and are therefore only to be eaten green with fallads.

They are propagated by fowing their feeds towards the end of July, in beds of a dry but rich foil; and in three weeks after fowing, they will appear above ground; when they muft be kept very free from weeds. About October all their leaves die away, which has occafioned fome to think all the plantation loft, and to dig up the ground for fome other ufe; but if they are fuffered to ftand, they will fhoot up again very ftrong in January, and from that time will grow very vigoroufly, refift all weathers, and be fit to draw in March, when they will be extremely green and fine. They are much ftronger than any other fort of onions, and have much of the tafte of garlic.

OPE-LAND, ground that is loofe or open, from its being ploughed up every year.

ORANGE, the name of a delicious fruit of the apple kind, too well known to need defcription.

This fine tree not being natural to our climate, we muft quicken the nature of our foil with a compofition that may caufe it to correfpond as much as poffible with the temperament of warmer countries. It delights greatly in a foil that is compofed of an equal quantity of fheep's dung that has refted two years; old compoft, or the foil of a fewer; and fat land taken either from a marfh or hemp-clofe.

When the proper feafon is arrived for lodging your young ftems in boxes, thefe latter fhould always be proportioned to the heads of the plants. The ftems, even when they are become vigorous, will accommodate themfelves to a box of about fifteen inches diameter; but they muft be placed more at large in others, when the tree ceafes to augment its foliage, and informs you, by its languid air, that its foil and fuftenance are infufficient. At the end of feven or eight years, they may be tranfplanted, with all the earth, into their laft boxes, whofe diameters

may

may be about twenty-four inches. All thefe boxes fhould be made of entire heart of oak, and cafed over with a double coat of green paint liquified with oil, as alfo on the infide, in order to preferve the wood from rotting by frequent waterings, as it is on the outfide, to fecure it from rain and fun.

The large boxes fhould have a door with double hinges, and two iron-bars to admit the proper renovations of foil, and to enable you to clear the box of that liquid fediment that is collected and thickened at the bottom; and likewife to pare off the extreme parts of the mould, that it may afterwards be taken out with eafe, when it is neceffary to transfer it into a new box.

In order to place fome fhrubs, and more efpecially orange trees, in boxes, after a proper manner, the firft proceeding is to cover the bottom of the boxes with large pieces of brick and potfherds, which afford the water an eafy flow through the cavities that are opened at the bottom. Were it not from this precaution, the humidity collected by the fediment would rot the box, and deftroy the tree by an immoderate chilnefs. When this provifion has been made for the fecurity of the tender plant, the bottom and fides of the box muft be lined with good foil, prepared in the manner already mentioned: in this foil the tree fhould be inverted in an upright pofition, and the ball of earth at its roots muft be leffened, not with an intention to ftrengthen the tree, but rather to prevent its requiring a large quantity of earth, and to confine it by a moderate vigour to a juft proportion with the box. A new mafs of earth muft then be heaped up on every fide, and preffed with a due compactnefs, in order to fecure the ftem from violent winds, and caufe the earth to fettle round the root with as much exactnefs as poffible.

When the tree is to be placed in the box, care fhould be taken to raife the upper part of the clod of the earth at its roots higher than the rim of the box, becaufe the weight of the tree and the action of the roots will afterwards lower the clod by degrees to a level with the edge of the box. If this precaution be neglected, the tree in procefs of time will fink too low. And, that the upper part of the clod may not be expofed to the air, it fhould be covered over with earth, and the whole fuftained by fmooth ftaves difpofed round the edges of the box.

When fruit-trees are to be pruned, care fhould be taken to preferve the fmall branches in a thriving ftate, in order to promote their fertility; but they are retrenched in an orange-tree, that a vacancy may be opened within. The fame method is taken with the branches that fhoot downwards in a perpendicular direction; and alfo with thofe that are divefted of their leaves, which only happens, when the tree is weak or diftempered: but we carefully preferve all the vigorous branches, whofe advantageous fituation contributes to the regularity of the head.

Oranges are brought from feveral parts. The beft and moft in efteem for a good tafte are thofe which grow in hot countries; not only becaufe the foil of the places, having ftore of exalted fulphur and volatile falts in it, communicates a great quantity of the fame to thefe fruits, and gives them an agreeable fmell, but becaufe the heat of the fun there digefts, and more completely ripens their juice, and gives them a more delicious tafte. *Miller's Gard. Dict.*

ORCHARD, a plantation of fruit-trees.

It is a rule among gardeners, that thofe orchards thrive beft which lie open to the fouth, fouth-weft, and fouth-eaft, being fcreened from the north, and have the foil dry and deep.

In planting of an orchard, great care fhould be had to the nature of the foil, that fuch trees as are adapted to grow upon the ground intended to be planted, may be chofen, otherwife there can be little hopes of their fucceeding; and it is for want of rightly obferving this method, that we fee, in many countries, orchards planted which never arrive to any tolerable degree of perfection, their trees ftarving, and their bodies either covered with mofs, or the bark cracks and divides; both which are evident figns of the weaknefs of the trees; whereas, if inftead of apples, the orchard had been planted with pears, cherries, or any other fort of fruit to which the foil had been adapted, the trees might have grown very well, and produced great quantities of fruit.

As to the pofition of the orchard, if you are at full liberty to chufe, a rifing ground, open to the fouth-eaft, is to be preferred; but we would by no means advife to plant upon the fide of an hill, where the declivity is very great; for in fuch places the great rains commonly wafh down the better part of the ground, whereby the trees would be deprived of proper nourifhment; but where the rife is gentle, it is of great advantage to the trees, by admitting the fun and air between them, better than it can upon an entire level; which is an exceeding benefit to the fruit, by diffipating fogs, and drying up the damps, which, when detained amongft the trees, mix with the air, and render it rancid: if it be defended from the weft, north, and eaft-winds, it will alfo render this fituation ftill more advantageous; for it is chiefly from thefe quarters that fruit-trees receive the greateft injury: therefore, if the place be not naturally defended from thefe by rifing hills, which is always to be preferred, then you fhould plant large growing timber-trees at fome diftance from the orchard, to anfwer this purpofe.

You fhould alfo have a great regard to the diftance of planting the trees, which is what few people have rightly confidered; for if you plant them too clofe, they will be liable to blights; and the air, being hereby pent in amongft them, will caufe the fruit to be ill-tafted, having a great quantity of damp vapours from the perfpiration of the trees, and the exhalations from the earth mixed with it, which will be imbibed by the fruit, and render their juices crude and unwholefome.

Wherefore we cannot but recommend the method which has been lately practifed by fome particular gentlemen with very great fuccefs; and that is, to plant the trees fourfcore feet afunder, but not in regular rows. The ground between the trees they plough and fow with wheat and other crops, in the fame manner as if it were clear from trees; and they obferve their crops to be full as good as thofe quite expofed, except juft under each tree, when they are grown large, and afford a great fhade; and, by thus ploughing and tilling the ground, the trees are rendered more vigorous and healthy, fcarcely ever having any mofs, or other marks of poverty, and will abide much longer, and produce better fruit.

If the ground in which you intend to plant an orchard has been pafture for fome years, then you fhould plough in the green fward the fpring before you plant the trees: and, if you will permit it to lie a fummer fallow, it will greatly mend it, provided you ftir it two or three times, to rot the fward of grafs, and prevent weeds growing thereon.

At Michaelmas you fhould plough it pretty deep, in order to make it loofe for the roots of the trees, which fhould be planted thereon in October, provided the foil be dry; but, if it be moift, the beginning of March will be a better feafon.

When you have finifhed planting the trees, you fhould provide fome ftakes to fupport them, otherwife the wind will blow them out of the ground; which will do them much injury, efpecially if they have been planted fome time; for, the ground at that feafon being warm, and for the moft part moift, the trees will very foon pufh out a great number of young fibres; which, if broken off by their being difplaced, will greatly retard the growth of them.

In the fpring following, if the feafon fhould prove dry, you fhould cut a quantity of green turf, which muft be laid upon the furface of the ground about their roots, turning the grafs downward; which will prevent the fun and wind from drying the ground, whereby a great expence of watering will be faved: and, after the firft year, they will be out of danger, provided they have taken well.

Whenever you plough the ground between thefe trees, you muft be careful not to go too deep among their roots, left you fhould cut them off, which would greatly damage the trees: but, if you do it cautioufly, the ftirring of the furface of the ground will be of great benefit to them; though you fhould obferve never to fow too near the trees, nor fuffer any great rooting weeds to grow about them, which would exhauft the goodnefs of the foil, and ftarve them.

If, after the turf which was laid round the trees be rooted, you dig it in gently about the roots, it will greatly encourage them. There are some persons who plant many sorts of fruit together in the same orchard, mixing the trees alternately; but this is a method which should always be avoided; for hereby there will be a very great difference in the growth of the trees, which will not only render them unsightly, but also the fruit upon the lower trees ill-tasted, by the tall ones overshadowing them; so that, if you are determined to plant several sorts of fruit on the same spot, you should observe to place the largest growing trees backwards, and so proceed to those of less growth, continuing the same method quite through the whole plantation; whereby it will appear at a distance in a regular slope, and the sun and air will more equally pass through the whole orchard, that every tree may have an equal benefit therefrom.

The soil of your orchard should also be mended once in two or three years with dung, or other manure, which will also be absolutely necessary for the crops sown between; so that where persons are not inclinable to help their orchard, where the expence of manure is pretty great; yet, as there is a crop expected from the ground besides the fruit, they will the more readily be at the charge upon that account.

In making choice of trees for an orchard, you should always observe to procure them from a soil nearly a-kin to that where they are to be planted, or rather poorer; for, if you have them from a very rich soil, and that wherein you plant them is but indifferent, they will not thrive well, especially for four or five years after planting; so that it is a very wrong practice to make the nursery, where young trees are raised, very rich, when the trees are designed for a middling or poor soil. The trees should also be young and thriving; for, whatever some persons may advise to the contrary, yet it has always been observed, that though large trees may grow, and produce fruit, after being removed, they never make so good trees, nor are so long-lived, as those which are planted while young.

These trees, after they are planted out, will require no other pruning but only to cut out dead branches, or such as cross each other, so as to render their heads confused and unsightly: the too often pruning them, or shortening their branches, is very injurious; especially to cherries and stone-fruit, which will gum prodigiously, and decay in such places where they are cut: and the apples and pears, which are not of so nice a nature, will produce a greater quantity of lateral branches, which will fill the heads of the trees with weak shoots, whenever their branches are thus shortened; and many times the fruit is hereby cut off, which, on many sorts of fruit-trees, is first produced at the extremity of their shoots.

It may, perhaps, seem strange to some persons, that we should recommend the allowing so much distance to the trees in an orchard, because a small piece of ground will admit of very few trees, when planted in this method: but they will please to observe, that, when the trees are grown up, they will produce a great deal more fruit than twice the number when planted close, and will be vastly better tasted; the trees, when placed at a large distance, being never so much in danger of blighting as in close plantations, as hath been observed in Herefordshire, the great county for orchards, where they find that when orchards are so planted or situated, that the air is pent up amongst the trees, the vapours which arise from the damp of the ground, and the perspiration of the trees, collect the heat of the sun, and reflect it in steams so as to cause what they call a fire-blast, which is the most hurtful to their fruit; and this is most frequent where the orchards are open to the south sun.

But, as orchards should never be planted, unless where large quantities of fruit are desired, so it will be the same thing to allow twice or three times the quantity of ground; since there may be a crop of grain of any sort upon the same place, as was before said, so that there is no loss of ground: and, for a family only, it is hardly worth while to plant an orchard; since a kitchen-garden well planted with espaliers will afford more fruit than can be eaten while good, especially if the kitchen garden be proportioned to the largeness of the family: and, if cyder be required, there may be a large avenue of apple-trees extended cross a neighbouring field, which will render it pleasant, and produce a great quantity of fruit; or there may be some single rows of trees planted to surround the fields, &c. which will fully answer the same purpose, and be less liable to the fire blasts before-mentioned. *Miller's Gard. Dict.*

ORCHARD-GRASS, the name of a small, coarse, but very sweet grass. It is of very quick growth, and may possibly hereafter be cultivated to advantage.

ORE-WEED, a general name for weeds growing at the bottom of the sea, and also on the muddy and rocky parts of the shore.

Sea-weeds are so beneficial a manure, that farmers ought not to grudge the expence of carrying them a few miles. In Devonshire, Cornwall, and other maritime parts of England, these weeds are laid in heaps till they are rotten, and then spread upon the land, about a load to three rods: but this lasts only one year, unless sand, or a stiff earth, according to the quality of the soil intended to be improved, be laid on or mixed with them; and then they become a lasting manure. In some places, these weeds are gathered in heaps, and burnt as soon as they are dry; after which about a bushel of their ashes is laid on upon three rods of ground. But these, like all other ashes, should be mixed with sand, or stiff earth, if you would have the land last good: otherwise, they are only an improvement for a year. These ashes are particularly good for grass grounds over-run with moss. Loose sandy soils are likewise peculiarly benefited by this weed: but, being a sub-marine plant, the wind and sun soon exhale its moisture; so that the more speedily it is taken from the shore, where storms often throw it up in great quantities, the better it is. When spread on the ground, and afterwards covered over, it soon dissolves into a salt oily slime, proper to fertilize and bind light soils. This is the most approved way of applying it: though some lay it naked and fresh from the sea, upon their barley lands, towards the end of March and beginning of April, and have a good crop of corn: but such quantities of rank weeds are apt to shoot up afterwards, that no wholesome plant is to be expected that year.

The value of the lands all along the coast of Scotland has been more than doubled by the use of this excellent manure. It is chiefly used there for barley; and the farmers watch every opportunity when it is thrown in by the sea, and lay it on at all seasons, in autumn, winter, and spring. But if they could choose their time, it would probably do best about the month of March; for being then ploughed into the ground, and afterwards ploughed up again to the seed, it would be incorporated and blended with the soil; whereas, if it be laid on in autumn, before the fallowing or first ploughing, it is too much wasted before the spring; and if it be laid on to the seed-furrow, it is apt to burn the ground in a dry season, though it will do very well in this method in a wet summer. Its effects are but just felt the second year; though it is laid on thicker upon strong clay land, which receives no other manure for three crops, viz. barley, oats, pease, and beans; a method which might, perhaps, be altered for the better by omitting the oats, and sowing alternately barley, and pease and beans, and laying on the sea-ware, as these weeds are commonly called, for every second crop of pease and beans.

We see by the abridgement of Mr. Scott's account of the manner of using sea-ware in Scotland (published by Mr. Maxwell in his Miscellaneous Papers) that much of this valuable manure must necessarily be lost through want of proper management: for they have no reservoirs to keep it in, when thrown ashore at a season in which they cannot use it, or where there is no ground in tilth, as is generally the case in winter, and during the busy part of their hay and corn harvest. It should be collected on these occasions, and lodged in a place free from any running water; and, as it is equally beneficial to strong or light lands, it might be there covered with sand or clay, according to the nature of the soil for which it is intended. This will prevent its being parched by the sun, or its dissolving into a putrid mass, which, if not secured in this manner, would either be washed away by rains, or fly off into the air: whereas, when thus covered, it would greatly enrich the

the clay or sand, and render them good manures for their opposite soils. If it be thrown ashore at a time when it can be ploughed in directly, that is certainly the best manner of using it.

Mr. Scott observes, that there is a kind of land all along the coast, which is gravelly, and covered over so thick with sea-stones, that, to look at it, one would not think corn could spring through them; and another sort of land, which is a deadish sand. To both these grounds sea-ware is the only manure; for dung of all kinds has been often tried, but with no success; and yet sea-ware makes them bring excellent crops of barley. This kind of ground is seldom ploughed more than twice, and the sea-weed is generally laid on before the first ploughing. Barley is sowed during two years, and pease the third; a fresh manure of sea-weed being laid on each year that barley is sown. As little wheat is cultivated in the country where Mr. Scott lived, the farmers there might probably improve their practice of raising barley and pease, by sowing them alternately, and laying the sea-ware to the pease. In the summer, it is carried to a distance from the sea, and laid upon ley-ground (arable land under grass) which, though in very ill heart, will bear a good crop of oats with only once ploughing, or of barley, if ploughed again in the spring.

Another kind of sea-ware, of a much stronger nature than that which is thrown up by the waves, is cut from the rocks at low water, and will last three years. It costs more labour, but brings greater recompence. Mr. Scott thinks the best time of laying this on the ground would be in autumn, before the land is ploughed rough for a spring crop.

The farmers on the coast of Scotland (and I believe the same may be said, in general, of those in most of the maritime parts of England) prefer this manure to any other, especially for their light grounds; and it has the advantage of being much more easily transported, because one load of it will go as far as two of dung.

It does very well in kitchen-gardens, where Mr. Scott says he has seen pot-herbs and roots of an extraordinary size produced by its help; to which he adds, that he has known fruit-trees, perfectly barren before, rendered extremely fruitful by laying this manure about their roots.

Mr. Duhamel likewise informs us, that these sea-weeds are used with great success in the maritime provinces of France.

OST, *Oost*, or *Oust*. *See* OUST.

OVER-REACH, a wound in the fore-heel of a horse, made by the point of the hind-shoe.

When this wound is only slight or superficial, it is, in general, very easily cured by washing it clean, and applying the wound ointment: but it should be observed from the nature and manner of the injury, where the blow has been smart, that it differs widely from a common cut; the part here being both torn and bruised, and consequently it requires to be properly digested, in order to lay a good foundation for healing.

For this purpose, after washing out any dirt or gravel with sope-suds, &c. let the wound be digested, by dressing it with dossils of lint dipped in an ounce of Venice turpentine, divided with the yolk of an egg, to which half an ounce of tincture of myrrh may be added; over this dressing it would be advisable to apply the turnip poultice, or that with strong beer grounds and oatmeal, three or four times, or oftener, till the digestion is procured, and then both these dressings may be changed for the precipitate medicines, or the lime-water mixture; observing always to apply the dossils carefully to the bottom, to fill up the sore with the same even to the surface, and to bind all on with a compress and roller: and if any cavities appear that cannot conveniently be dressed to the bottom, they should always be laid open, or no proper foundation for healing can be obtained. The hoof also should be kept supple, or pared away, when the growth of it interrupts this end, as is sometimes the case. *Bartlet's Farriery, page* 244.

OUGHTS, leavings.

OUST, a kiln, generally applied to that used in drying malt.

It is built with fire-places in the nature of malt-kilns; and at a proper distance over the fire is an hair-cloth strained upon laths; and thereon the hops are laid, and raked even to the depth of about six or seven inches, for the better conveniency of drying them equally; and when they are properly cured on the under side, they are carefully turned; and by that means the upper side becoming the under, the whole shares the fire alike. The person that performs this part is called the dryer, whose business it is to manage the fires.

The fuel commonly made use of is charcoal, for its freeness from smoke, and affording a steady heat. Great nicety is required in this part; a small fire being to be made, at first, that they may heat gradually, and so raised as they dry, that it may be done without scorching; and the fire is to be lowered by degrees, against they are ready to be taken off: the time required is about eight hours.

But as charcoal is very dear, being three or four pounds per load, many people have adopted the method of drying with sea-coal, upon what they call cockle-ousts, which are square iron-boxes placed upon brick-work, and a flue and chimney in the back part of the building for the smoke to go off. The computation is, that a chaldron of sea-coal, at about twenty-four shillings, will dry a load of hops, and that a load of charcoal will do no more. It is indeed expensive to erect such ousts, as there must be no timber near them; and an iron-beam and iron-laths are to be used, and they covered with plates of tin or iron properly fastened together.

A gentleman has lately claimed the merit of having invented a new method of drying hops with sea-coal, or any kind of fuel whatever, by means of a moveable iron furnace: it is in form of an horizontal cylinder, stopped at both ends: it lies on an iron carriage, which rolls on four iron-wheels: in the fore-end of the cylinder is the furnace door, and a hollow iron flue runs in an horizontal direction along the upper surface of the cylinder from the back till it reaches the fore-end of it, when it takes a vertical direction, and is carried as high as is necessary to convey the smoke out of the oust. We cannot pretend to say what are the particular advantages resulting from the use of this rolling furnace, never having seen it at work.

OUST-HOUSES, out-houses, or such as belong to, and are adjoining to the dwelling-houses.

OX, the name of an animal well known, being a bull castrated.

Oxen, like other domestic animals, vary in colour, though the dun seems the most common; and the redder it is, the more it is esteemed. A black coat is also valued; and bay oxen are said to be vigorous and long lived; whereas the brown soon decay. The grey, the dappled, and the white, are proper only for the slaughter; no care can render them fit for labour; but whatever be the colour of an ox's coat, it should be glossy, thick, and smooth to the touch; for if it be harsh, rough, or thin, there is reason to suppose that the animal is out of order, or at least not of a strong constitution. A good ox for the plough must be neither too fat nor too lean; the head short and thick; the ears large and shaggy; the horns strong, glossy, and of a middling size; the forehead wide, the eyes full and black; his muzzle large and flat; the nostrils wide and open; the teeth white and even; the lips black; a fleshy neck, large and heavy shoulders; the breast broad; the dew-lap hanging down to the knees; the reins very broad; a spacious descending belly; the flanks firm; the haunches large; and the rump thick; large and nervous thighs and legs; the back straight and full; the tail reaching to the ground, and well covered with thick and fine hair; the feet firm; the hide thick and pliable; the muscles raised; the hoof short and broad: he must also answer to the goad, be obedient to the voice, and well trained; but it is only gradually, and by beginning early, that the ox can be brought willingly to bear the yoke, and be easily governed. At the age of two years and a half, or three at the latest, you must begin to tame him, and bring him under subjection; if delayed longer, he becomes froward, and often ungovernable. The only method of succeeding is, by patience, mildness, and even caresses, for compulsion and ill-treatment will only disgust him irreclaimably; stroaking him gently along the back, clapping him, giving him occasionally boiled barley, ground beans, and such other aliments as please him best, all of

them

them mingled with salt, of which he is very fond, will prove of the greatest use. At the same time his horns should be often tied, and some days after the yoke is to be put on his neck, and fastened to a plough, with another ox of the same size ready trained; these are to be tied together at the manger, and in the same manner led to the pasture, that they may become acquainted, and accustomed to have one common motion. The goad is never to be made use of in the beginning, as that would only render him more untractable; he must also be indulged, and labour only at short intervals; for till he is thoroughly trained, he tires himself very much; and for the same reason he is to be fed more plentifully than at other times.

An ox is to draw the plough only from his third to his tenth year, when it will be advisable to fatten and sell him, as being then of a better flesh than if he was kept longer. The age of this creature is known by his teeth and horns. The first fore-teeth, which he sheds at the end of ten months, are replaced by others, larger, but not so white; at six months the teeth next to those in the middle fall out, and are also replaced by others; and in three years all the incisive teeth are renewed. They are then equal, long, and pretty white; but as the ox advances in years, they wear, become unequal, and black. It is the same in the bull and cow: so that the growth and shedding of the teeth are not affected by castration, or the difference of sexes. Nor is the shedding of the horns affected by either; as both bull, ox, and cow, lose them alike at the end of three years; and these also are replaced by other horns, which, like the second teeth, remain; only those of the ox and cow are larger and longer than those of the bull. The manner of the growth of these second horns is not uniform, nor the shooting of them equal. The first year, that is the fourth year of the ox's age, two small pointed horns make their appearance, nearly formed, smooth, and towards the head terminated by a kind of button. The following year this button moves from the head, being impelled by a corneous cylinder, which also lengthening, is terminated by another button, and so on; for the horns continue growing as long as the creature lives. These buttons become annular joints, which are easily distinguished in the horn, and by which the age of the creature may be readily known; counting three years for the point of the horn to the first joint, and one year for each of the other intervals.

OX-BOOSE, an ox-stall, or cow-stall, where these creatures stand in the winter.

OX-HARROWS, very large harrows, called, in some counties, drags.

OX-GANG, or *Ox-gate*, a quantity of land measuring fifteen acres, being as much ground as a single ox is supposed to be capable of ploughing in a year.

P.

PACK-SADDLE, a saddle adapted to the carriage of heavy packs or burdens.

PAD, the road, a foot-path; also an easy paced horse: likewise a low saddle.

PADDLE STAFF, an instrument used by the ploughman to free the share from stubble, clay, &c. which hinder its action.

PADDOCK, a small field or inclosure. It also signifies a large frog or toad.

PAIGLE, a cowslip.

PAIL, a wooden vessel in which milk or water is commonly carried.

PALISADE, a row of handsome pales set up by way of ornament or defence. The gardeners use this word to denote a row of trees, which bear branches and leaves from the bottom, cut and spread in the manner of a garden wall, along the side of an alley or the like, so as to appear like a wall covered with leaves.

PALMS, the male flowers of the willow.

PALSY, a disease common to horses, wherein the body or some of its members, lose their motion, and sometimes their sensation of feeling.

In paralytic disorders, where the use of a limb or limbs is taken away, the internals (recommended under the article STAGGERS) should be given in order to warm, invigorate, and attenuate the blood; and the following stimulating embrocation should be rubbed into the parts affected.

> Take oil of turpentine four ounces, nerve ointment and oil of bays, of each two ounces; camphor rubbed fine, one ounce; rectified oil of amber three ounces, tincture of cantharides one ounce.

With this liniment the parts affected should be well bathed for a considerable time, to make it penetrate; and when the hind parts are chiefly lame, the back and loins should

ſhould be well rubbed with the ſame: to the nervous medicines above recommended, may be added ſnake-root, contrayerva, muſtard-ſeed, horſe-radiſh root, ſteeped in ſtrong beer, or wine where it can be afforded. Take the following for an example, which may be given to the quantity of three pints a day alone, or two horns full may be taken after the nervous balls.

> Take ſnake-root, contrayerva and valerian, of each half an ounce, muſtard-ſeed and horſe-raddiſh root ſcraped, of each two ounces, long-pepper two drams, infuſe in three pints of ſtrong beer or wine.

When the horſe is recovering from any of the above diſorders, the following alterative purge may be repeated two or three times, as it operates very gently.

> Take ſuccotrine aloes one ounce; myrrh half an ounce; aſſa fœtida and gum ammoniacum, of each two drams; ſaffron one dram: make into a ball with any ſyrup.

Where a retention of dung is the cauſe of this diſorder, the great gut ſhould firſt be raked thoroughly with a ſmall hand, after which plenty of emollient oily clyſters ſhould be thrown up, and the opening drink given, till the bowels are thoroughly emptied of their impriſoned dung. Their diet ſhould for ſome days be opening, and conſiſt chiefly of ſcalded bran, with flower of brimſtone, ſcalded barley, &c.

PANIC, a plant reſembling millet in its ſtalks, leaves, and roots; but differing in its ſpikes, or ears, which are about the thickneſs of a man's finger at their baſe, and growing taper toward their points. They are about eight or nine inches long, and cloſely ſet with a ſmall roundiſh grain, ſometimes white, ſometimes red or purple, and ſometimes yellow. It is raiſed and reaped in the ſame manner as millet, but does not require ſo much rain. This plant grows naturally in both the Indies, and is cultivated in ſeveral parts of Europe for the food of men. Cakes and bread are made of it in Germany, Italy, and the ſouthern parts of France; but it is not reckoned ſo good nouriſhment as millet: nor is the German ſort ſo much eſteemed as the Italian; though the former ripens beſt in cold countries, where it is frequently ſowed in land which will not produce better grain. It thrives moſt in a dry ſtiffiſh ſoil, ſuch as the ſides of hills, and even in ſtony ground; grows to the height of about four feet, and branches very much; for which reaſon the horſe-hoeing huſbandry is by far the fitteſt for it. The plants, if managed rightly, ſhould ſtand at leaſt eighteen inches aſunder, in rows three feet apart, that there may be room to hoe the ground between them, and to keep them clear from weeds. When grown pretty tall, they ſhould be ſupported by ſtakes, leſt the wind break them down, and particular care muſt be taken to guard againſt birds when their ſeeds begin to ripen.

PANNAGE, the food which ſwine feed upon in woods, as acorns, and the maſt of beech. It alſo ſignifies the money taken by the king's agiſtors, for the privilege of feeding hogs in the king's foreſts.

PANNEL, a low ſaddle.

PARING *the ſole. See the article* SHOEING HORSES.

PARSLEY, the name of a well-known herb, which is cultivated in gardens for culinary purpoſes, it being more uſed in the kitchen than any other herb whatſoever; it will tolerably endure cold, but is apt to be deſtroyed in very ſevere winters, eſpecially where the land is moiſt; it is commonly ſown in the ſpring, and ſends forth a ſtalk the year after, which flowers in June or July, and the ſeeds ripen in Auguſt.

The common parſley is, by ſome ſkilful people, cultivated in fields for the uſe of ſheep, it being a ſovereign remedy to preſerve them from the rot, provided they are fed twice a week, for two or three hours each time, with this herb: but hares and rabbits are ſo fond of it, that they will come from a great diſtance to feed on it; ſo that whoever has a mind to have plenty of hares in their fields, by cultivating parſley, will draw all the hares off the country to them.

PARSNEP, the name of a plant propagated for the ſake of its roots.

Parſneps require a rich, mellow, and deep ſoil; in order that their roots, according to the bigneſs and length of which they are eſteemed, may have full room to thicken and run downward. The ſeeds of theſe plants ſhould be ſown in February or March, either alone, or with carrots, eſpecially if it be intended to draw theſe laſt very young; becauſe parſneps ſeldom ſpread much before the latter end of ſummer, by which time the carrots will, in this caſe, be gone. The practice of thoſe gardeners who ſow leeks, onions, and lettuces with their parſneps, is very wrong; becauſe ſo many different growths muſt impoveriſh one another.

The young parſneps muſt be hoed and weeded, or, if they were ſown in rows, the ground between thoſe rows muſt be dug, three or four times in the ſpring, or whenever elſe many weeds appear. By the latter end of the ſummer, their leaves will cover the ground, and prevent the farther growth of weeds; ſo that they will not require any more care after that ſeaſon.

When their leaves begin to decay, their roots may be dug up for uſe: but they are ſeldom well taſted before that time; nor are they good for much late in the ſpring, after they have ſhot out again. They, therefore, who would preſerve them for ſpring uſe, ſhould dig them up in the beginning of February, and bury them in ſand in a dry place, where they will remain good until the middle of April, or later.

To ſave the ſeeds of this plant in the moſt advantageous way, ſome of the longeſt, ſtraiteſt, and largeſt roots, ſhould be ſingled out, and planted about two feet aſunder, in a place where they will be defended from the ſtrong ſouth and weſt winds: for the ſtems of the parſneps generally grow to a great height, and are very apt to be broken by ſtrong guſts of wind, if they are expoſed thereto. This ground ſhould alſo be kept clear from weeds; and if the ſeaſon ſhould prove dry, watering of theſe plants moderately, twice a week, will increaſe the quantity, and improve the quality, of their ſeeds, which will be ripe about the end of Auguſt or beginning of September, when the heads ſhould be carefully cut off, and ſpread upon a coarſe cloth for two or three days, to dry. The ſeeds ſhould then be beaten off, and put up for uſe. But neither theſe, nor carrot-ſeeds, ſhould be depended on after they are above a year old.

Parſneps are an excellent, wholeſome, and very nouriſhing food for cattle. Their culture, as I have juſt obſerved, is exactly the ſame as that of carrots, with which they may therefore be ſown in the ſame ground. Their leaves will decay at nearly the ſame time, when the roots may be dug up, and laid by for uſe, likewiſe buried in dry ſand, in a dry place.

Parſnep-ſeeds ſeldom grow after they are above a year old.

It has long been a cuſtom in ſome parts of Britany, to ſow parſneps in the open field for the food of cattle; as we are informed by the firſt volume of the tranſactions of a Society inſtituted in that province, for the encouragement of the economical and commercial intereſts of their country. "It is of great importance," ſay they, "that parſneps ſhould be univerſally cultivated; becauſe they afford an excellent and wholeſome food for all kinds of cattle, during the winter, and may be uſed to great advantage to fatten them. Our hogs have no other food in all that ſeaſon, and our bullocks and oxen thrive well upon it. Our cows fed with parſneps give more milk than with any other winter fodder, and that milk yields better butter than the milk of cows nouriſhed with any other ſubſtance. Our horſes fatten with this food; though ſome pretend that it renders them leſs mettleſome, and hurts their legs and eyes.

"Cattle eat theſe roots raw at firſt, ſliced lengthwiſe; and when they begin not to reliſh them, they are cut in pieces, put into a large copper, preſſed down there, and boiled with only ſo much water as fills up the chaſms between them. They then eat them very greedily, and continue to like them."

PARTERRE, a level diviſion of ground, which, for the moſt part, faces the ſouth and beſt front of the houſe, and is generally furniſhed with greens, flowers, &c.

There are ſeveral ſorts of parterres, as plain graſs with borders, and parterres of embroidery, &c.

Plain

Plain parterres are more beautiful in England than in any other country, by reason of the excellency of our turf, and that decency and unaffected simplicity that it affords to the eye of the spectator. Other parterres are cut into shell and scroll work, with sand alleys between them; which sort of parterres are esteemed finest in France.

As to the general proportions of parterres, an oblong, or long-square, is esteemed the best: therefore, a parterre should not be less than twice as long as it is broad; twice and a half is accounted a very good proportion; and it is very rare that three times is exceeded. As to the breadth of a parterre, it is to take its dimensions from the breadth of the front of the house; if the front of the house is one hundred feet long, the breadth of the parterre should be one hundred and fifty feet; and if the front of the house be two hundred feet, the parterre should be fifty feet broader: but where the front exceeds the breadth of this parterre, it will be a good proportion to make the parterre of the same dimensions with the front.

There should be a terrace-walk on each side of the parterre, for an elevation proper for view; and therefore, there should never be the flat of a parterre between terrace-walk and terrace-walk, above three hundred feet; nor can it be well made less than one hundred and forty. As to the adorning and furnishing these parterres, whether it be plain or with embroidery, that depends much upon the form of them, and therefore must be left to the judgment and fancy of the designer.

PARTRIDGE, a timorous and simple bird, and is so valuable at the table, that there are a great many ways of taking it invented by the sportsmen, all of which succeed from the folly and fear of the animal.

The places that partridges most delight in, are corn fields, especially while the corn grows; for that is a safe retreat, where they remain undisturbed, and under which they usually breed. They frequent the same fields after the corn is cut down, and that with another intent; for they then feed on the corn that has fallen from the ears, and find a sufficient shelter for them under covert of the stalks, especially of those of wheat stubble. When the wheat stubble is much trodden by men or beasts, they retire to the barley stubble, and will there hide themselves in coveys of twenty or thirty. When the winter comes on, and the stubble fields are trodden down or ploughed up, they then retire to the upland meadows, where they lodge in the high grass, and among rushes; sometimes they resort to the low coppice woods, especially if there be corn lands near them.

PASSION-FLOWER, the name of a very beautiful plant, having long slender stalks, which run a great length, and require support; they are covered with a purplish bark, and are furnished at each joint with a digitated leaf, composed of five smooth entire lobes, connected with the stalk by pedicles, about two inches long, having two small leaves embracing the stalks at their base; and from the same point comes out a long tendril, which twists round the neighbouring support; the flowers come out at the same joints as the leaves, supported on footstalks almost three inches long; these flowers have a faint smell, and continue but one day; they come out in July, and there is a diurnal succession till the frost in autumn puts a stop to them.

This plant may be propagated either from seeds, layers, or cuttings; they require a good aspected wall; where they may have height for their shoots to extend, which should be properly trained against it; and in the spring the plants must be pruned, when all the small weak shoots should be cut off, and the strong ones shortened to about four or five feet long, which will cause them to put out strong shoots for flowering the following summer.

PASTURE, or *Pasture Land*, a general name for all sorts of land reserved for the purposes of feeding cattle.

Pasture ground is of two sorts: the one is low meadow land, which is often overflowed; and the other is upland, which lies high and dry. The first of these will produce a much greater quantity of hay than the latter, and will not require manuring or dressing so often: but then the hay produced on the upland is much preferable to the other; as is also the meat which is fed in the upland more valued than that which is fatted in rich meadows: though the latter will make the fatter and larger cattle, as is seen by those which are brought from the low rich lands in Lincolnshire. But where people are nice in their meat, they will give a much larger price for such as hath been fed on the downs, or in short upland pasture, than for the other, which is much larger. Besides this, dry pastures have an advantage over the meadows, that they may be fed all the winter, and are not so subject to poach in wet weather; nor will there be so many bad weeds produced; which are great advantages, and do, in a great measure, recompense for the smallness of the crop.

We have already mentioned the advantages of meadow land, or such as is capable of being overflowed with water, and given directions for draining and improving low pasture land, under the article LAND; therefore shall not repeat that here, but just mention some methods for improving of upland pasture.

The first improvement of upland pasture is, by fencing it, and dividing it into small fields of four, five, six, eight, or ten acres each, planting timber trees in the hedge-rows, which will screen the grass from the dry pinching winds of March, which will prevent the grass from growing in large open lands; so that, if April proves a dry month, the land produces very little hay; whereas in the sheltered fields the grass will begin to grow early in March, and will cover the ground, and prevent the sun from parching the roots of the grass, whereby it will keep growing, so as to afford a tolerable crop, if the spring should prove dry. But, in fencing of land, it must be observed, as was before directed, not to make the inclosures too small, especially where the hedge-rows are planted with trees; because, when the trees are advanced to a considerable height, they will spread over the land; and, where they are close, will render the grass sour; so that, instead of being an advantage, it will greatly injure the pasture.

The next improvement of upland pasture is, to make the turf good, where, either from the badness of the soil, or for want of proper care, the grass hath been destroyed by rushes, bushes, or mole-hills. Where the surface of the land is clayey and cold, it may be improved by paring it off, and burning it in the manner before directed: but, if it is an hot sandy land, then chalk, lime, marle, or clay, are very proper manures to lay upon it: but this should be laid in pretty good quantities, otherwise it will be of little service to the land.

If the ground is over-run with bushes or rushes, it will be a great advantage to the land to grub them up towards the latter part of summer; and after they are dried, to burn them, and spread the ashes over the ground just before the autumnal rains; at which time the surface of the land should be levelled, and sown with grass-seed, which will come up in a short time, and make good grass the following spring. So, also, when the land is full of mole-hills, these should be pared off, and either burnt for the ashes, or spread immediately on the ground, when they are pared off, observing to sow the bare patches with grass seed, just as the autumnal rains begin.

Where the land has been thus managed, it will be of great service to roll the turf, in the months of February and March, with an heavy wood roller; always observing to do it in moist weather, that the roll may make an impression: this will render the surface level, and make it much easier to mow the grass, than when the ground lies in hills; and will also cause the turf to thicken, so as to have what the people usually term a good bottom. The grass, likewise, will be the sweeter for this husbandry, and it will be a great help to destroy bad weeds.

Another improvement of upland pastures is, the feeding of them: for, where this is not practised, the land must be manured at least every third year; and where a farmer hath much arable land in his possession, he will not care to part with his manure to the pasture. Therefore every farmer should endeavour to proportion his pasture to his arable land, especially where manure is scarce, otherwise he will soon find his error; for the pasture is the foundation of all the profit which may arise from the arable land.

Whenever the upland pastures are mended by manure, there should be a regard had to the nature of the soil, and a proper sort of manure applied: as, for instance, all hot sandy land should have a cold manure; neat's dung and swine's dung are very proper for such lands; but, for cold lands, horfe-dung, afhes, and other warm manures, are proper. And, when thefe are applied, it fhould be done in autumn, before the rains have foaked the ground, and rendered it too foft to cart on; and it fhould be carefully fpread, breaking all the clods as fmall as poffible, and then harrowed with bufhes, to let it down to the roots of the grafs. When the manure is laid on at this feafon, the rains in winter will wafh down the falts, fo that the following fpring the grafs will receive the advantage of it.

There fhould alfo be great care had to the deftroying of weeds in the pafture every fpring and autumn: for, where this is not practifed, the weeds will ripen their feeds, which will fpread over the ground, and thereby fill it with fuch a crop of weeds as will foon overbear the grafs, and deftroy it; and it will be very difficult to root them out, after they have gotten fuch poffeffion; efpecially ragwort, and fuch other weeds as have down adhering to their feeds.

Thefe upland paftures feldom degenerate the grafs which is fown on them, if the land is tolerably good: whereas the low meadows, which are overflowed in winter, in a few years turn to an harfh rufhy grafs, though the upland will continue a fine fweet grafs for many years without renewing.

There is no part of hufbandry, of which the farmers are in general more ignorant than that of the pafture: moft of them fuppofe, that when old pafture is ploughed up, it can never be brought to have a good fward again: fo their common method of managing their land, after ploughing, is, to fow, with their crop of barley, fome grafs feeds, as they call them; that is, either the red clover, which they intend to ftand two years after the corn is taken off the ground, or rye-grafs, mixed with trefoil: but as all thefe are, at moft, but biennial plants, whofe roots decay foon after their feeds are perfected; fo, the ground, having no crop upon it, is again ploughed for corn: and this is the conftant round which the lands are employed in, by the better fort of farmers; for I never have met with one of them, who had the leaft notion of laying down their land to grafs for any longer continuance; therefore, the feeds which they ufually fow, are the beft adapted for this purpofe.

But, whatever may have been the practice of thefe people, I hope to prove, that it is pooffible to lay down land, which has been in tillage, with grafs, in fuch a manner, as that the fward fhall be as good, if not better, than any natural grafs, and of as long duration. But this is never to be expected, in the common method of fowing a crop of corn with the grafs feeds: for, wherever this has been practifed, if the corn has fucceeded well, the grafs has been very poor and weak; fo that, if the land has not been very good, the grafs has fcarcely been worth faving: for the following year it has produced but little hay, and the year after the crop is worth little, either to mow or feed. Nor can it be expected to be otherwife; for the ground cannot nourifh two crops: and, if there were no deficiency in the land, yet the corn, being the firft, and moft vigorous of growth, will keep the grafs from making any confiderable progrefs; fo that the plants will be extremely weak, and but very thin, many of them, which came up in the fpring, being deftroyed by the corn; for, whenever there are roots of corn, it cannot be expected there fhould be any grafs. Therefore, the grafs muft be thin, and, if the land is not in good heart, to fupply the grafs with nourifhment, that the roots may branch out after the corn is gone, there cannot be any confiderable crop of clover: and, as their roots are biennial, many of the ftrongeft plants will perifh foon after they are cut; and the weak plants, which had made but little progrefs before, will be the principal part of the crop for the fucceeding year: which is many times not worth ftanding.

Therefore, when ground is laid down for grafs, there fhould be no crop of any kind fown with the feeds; and the land fhould be well ploughed, and cleaned from weeds; otherwife the weeds will come up the firft, and grow fo ftrong, as to overbear the grafs, and, if they are not pulled up, will entirely fpoil it. The beft feafon to fow the grafs feeds upon dry land is about the middle of September, or fooner, if there is an appearance of rain: for, the ground being then warm, if there happen fome good fhowers of rain after the feed is fown, the grafs will foon make its appearance, and get fufficient rooting in the ground before winter; fo will not be in danger of having the roots turned out of the ground by the froft, efpecially if the ground is well rolled before the froft comes on, which will prefs it down, and fix the earth clofe to the roots. Where this hath not been practifed, the froft has often loofened the ground fo much, as to let in the air to the roots of the grafs, and done it great damage; and this has been brought as an objection to the autumnal fowing of grafs: but it will be found to have no weight, if the above direction is practifed: nor is there any hazard of fowing the grafs at this feafon, but that of dry weather, after the feeds are fown; for, if the grafs comes up well, and the ground is well rolled in the end of October, or the beginning of November, and repeated again the beginning of March, the fward will be clofely joined at bottom, and a good crop of hay may be expected the fame fummer. But, where the ground cannot be prepared for fowing at that feafon, it may be performed the middle or latter end of March, according to the feafon's being early or late; for, in backward fprings, and in cold land, we have often fowed the grafs in the middle of April, with fuccefs: but there is danger, in fowing late, of dry weather, and efpecially if the land is light and dry; for we have feen, many times, the whole furface of the ground removed by ftrong winds at that feafon; fo that the feeds have been driven in heaps to one fide of the field. Therefore, whenever the feeds are fown late in the fpring, it will be proper to roll the ground well foon after the feeds are fown, to fettle the furface, and prevent its being removed.

The forts of feeds which are the beft for this purpofe, are, the beft fort of upland hay-feeds, taken from the cleaneft paftures, where there are no bad weeds: if this feed is fifted to clean it from rubbifh, three bufhels will be fufficient to fow an acre of land. The other fort is the *trifolium pratenfe album*, which is commonly known by the names white Dutch clover, or white honeyfuckle grafs. Eight pounds of this feed will be enough for one acre of land. The grafs feed fhould be fown firft, and then the Dutch clover-feed may be afterwards fown: but they fhould not be mixed together; becaufe the clover-feeds, being the heavieft, will fall to the bottom, and confequently the ground will be unequally fown.

When the feeds are come up, if the land fhould produce many weeds, thefe fhould be drawn out before they grow fo tall as to overbear the grafs: for, where this has been neglected, the weeds have taken fuch poffeffion of the ground, as to keep down the grafs, and ftarve it; and, when thefe weeds have been fuffered to remain until they have fhed their feeds, the land has been fo plentifully ftocked with them, as intirely to deftroy the grafs: therefore it is one of the principal parts of hufbandry, never to fuffer weeds to grow on the land.

If the ground is rolled two or three times, at proper diftances after the grafs is up, it will prefs down the grafs, and caufe it to make a thicker bottom: for, as the Dutch clover will put out roots from every joint of the branches which are near the ground, fo, by preffing down of the ftalks, the roots will mat fo clofely together, as to form a fward fo thick as to cover the whole furface of the ground, and form a green carpet; and will better refift the drought. For, if we do but examine the common paftures in fummer, in moft of which there are patches of this white honeyfuckle grafs growing naturally, we fhall find thefe patches to be the only verdure remaining in the fields. And this, the farmers in general acknowledge, is the fweeteft feed for all forts of cattle; yet never had any notion of propagating it by feeds: nor has this been long practifed in England; for, till within a few years, that fome curious perfons imported the feed from Brabant, where it had been long cultivated, there was not any of the feeds faved in England: though now there are feveral perfons who fave the feeds here, which fucceed full as well as any of the foreign feeds which are imported.

As the white clover is an abiding plant, fo it is certainly the very beft fort to fow, where paftures are laid down to remain: for as the hay-feeds which are taken from the beft paftures, will be compofed of various forts of grafs, fome of which may be but annual, and others biennial; fo, when thofe go off, there will be many and large patches

patches of ground left bare and naked, if there is not a sufficient quantity of the white clover, to spread over and cover the land. Therefore, a good sward can never be expected, where this is not sown: for in most of the natural pastures we find this plant makes no small share of the sward; and it is equally good for wet and dry land, growing naturally upon gravel and clay, in most parts of England: which is a plain indication how easily this plant may be cultivated, to great advantage, in most sorts of land throughout this kindom.

Therefore, the true cause why the land which has been in tillage, is not brought to a good turf again, in the usual method of husbandry, is, from the farmers not distinguishing which grasses are annual from those which are perennial: for, if annual or biennial grasses are sown, these will of course soon decay; so that, unless where some of their seeds may have ripened and fallen, nothing can be expected on the land but what will naturally come up. Therefore this, with the covetous method of laying down the ground with a crop of corn, has occasioned the general failure of increasing the pasture in many parts of England, where it is now much more valuable than any arable land.

After the ground has been sown in the manner before directed, and brought to a good sward, the way to preserve it good is, by constantly rolling the ground with an heavy roller, every spring and autumn, as hath been before directed. This piece of husbandry is rarely practised by farmers: but those who do, find their account in it; for it is of great benefit to the grass. Another thing should also be carefully performed; which is, to cut up docks, dandelion, knapweed, and all such bad weeds, by their roots every spring and autumn: this will increase the quantity of good grass, and preserve the pastures in beauty. Dressing of these pastures every third year is also a good piece of husbandry; for otherwise it cannot be expected the ground should continue to produce good crops. Besides this, it will be necessary to change the seasons of mowing, and not to mow the same ground every year; but to mow one season, and feed the next: for, where the ground is every year mown, it must be constantly dressed, as are most of the grass grounds near London, otherwise the ground will be soon exhausted. *Miller's Gard. Dict.*

The following Methods of improving wet Pastures, will, we doubt not, be very acceptable to our Readers, as they are founded on Experience, and consequently have no tendency to deceive the Husbandman.

"As I have, says our ingenious husbandman, within a few years, not only had some experience in my own farm, but observed the methods employed by many neighbouring gentlemen and farmers in mending their pastures, I shall communicate a few of my remarks to you on the improvement of wet pastures; a subject which may prove, perhaps, of some little utility, as I shall speak of nothing but what I have either performed myself, or seen hereabouts.

"The particular lands of which I speak are loose, woodcock, brick-earth soils for about eighteen or twenty inches, and under that, clay to a great depth.

Some that I have improved myself were exactly level, so as to be quite poisoned with the wet, which could not drain off.

"From the best observations I could make on many experiments, the following is the method which answers best to improve them. I shall also give you the expence with us.

"The first thing to be done is, to make large, deep ditches round every field, and, if the fields are large, to divide them into smaller, of five, six, or seven acres each, by new ditches; nothing is attended with a more sudden improvement of all the ground near the borders of the fields, than good ditches.

"I generally make mine six feet perpendicular deep, seven wide at top, and three at the bottom. I never pay for them by the rod (which is customary) but give twopence halfpenny per load, of thirty bushels, for all the clay, &c. that is thrown out of them, and two shillings and sixpence a score loads for filling and spreading it.

"These ditches should be made in such a manner that no water can remain in them, but a descent from one to another to carry it quickly off.

"It may be easily imagined how much these must drain the land, besides the quantity of excellent manure (clay) which arises out of them. Add to this the great convenience of having such fences about a farm, that the farmer is sure to find his cattle wherever he turns them, instead of their breaking perpetually into his corn or hay fields, which, in multitudes of farms, is so often the case: it is sometimes the work of a boy, only to be hunting after hogs and sheep that go astray for want of good fences.

"In the banks of new ditches we always lay white thorn, fifty roots to a rod (the workmen are allowed sixpence per hundred for gathering them;) but I always avoid intermixing any thing with it, especially hasel, for in the nut season fences are pulled in pieces for the fruit by all the boys and girls in the neighbourhood; and oak, ash, &c. only give an opportunity to get over the hedge with greater ease. Sallow, willow, elder, &c. are to be avoided in the hedge, or by way of hedge stake for the dead hedge, as they grow so fast as quite to overshadow the quick, and even destroy it. After frequent cuttings, to render the plants thick and strong, I keep the quick regularly clipped, which, in a few years, renders the fence impenetrable to man or beast, considering the largeness of the ditch.

"If an old fence is grown bad and thin, or composed of improper plants, I never yet observed it improved by planting quick in the gaps: the best way is, to reverse the bank, and plant fresh quick.

"One advantage arising from good fences is not apparent at first sight. To the disgrace be it spoken of most of the gentlemen of large fortunes round Bury, the game is wretchedly destroyed by poachers, who take it with night-nets. These vermin, who are generally labourers, swarm in every village round me. Their method is this: they take the farmer's horses out of his fields, and, after their doing a hard day's work, ride them all night, as fast as they can make them go, over the stubbles, to catch the partridges, blundering over every hedge (except such as I have described) in their way, oftentimes staking the horses (of which two instances have I seen this season) making gaps in the fences, riding over standing corn, clover for seed, or any thing that is a cover for birds, and, after damaging the farmer in a most shameful manner, carry the produce of their infamous labour to many, who, to their great dishonour, encourage these rascals for their conveñience. The money they get is spent at the next alehouse, and instead of doing the farmer a good day's work, they are drunk, asleep, or idle, the whole day.

"Now there are very few farmers horses that will leap a gate; but most will plunge through such hedges as are common hereabouts: none could pass such ditches as I always make and recommend. A farmer in this parish has so effectually fenced in his fields with prodigious ditches, that I have heard him declare, that not a single night-netter has been on his grounds on horse-back; and were they to attempt it, they would lose more time in passing one ditch than was necessary to drag some whole farms.

"The pernicious effects, to farmers, of this abominable practice, are notorious, and cry aloud for redress: if they would ease themselves, I know of no way but such ditches as I have described.

"But to return.

"When the ditching is done, the next work is to land-drain the whole fields in such a manner that every part of them may be laid dry. In a pasture of six acres I did two hundred rod. If there is the least fall in any part, or any place more wet than others, the drains should be cut through them. If the surface is exactly level, the depth of the drains should vary, so that the water may every where have a descent.

"These drains are made here, in general, thirty-two inches deep, twenty inches wide at the top, and four wide at the bottom. They are filled eight inches deep with either stones or wood; but I should ever recommend

mend the former, as the moſt effectual and laſting, to thoſe who are not deſirous of ſaving the difference of the expence. However, I know many fields in this pariſh and neighbourhood that are drained with wood, and which anſwer extremely well; and I have been aſſured that they will laſt twenty or thirty years. Nay, in ſome parts of Eſſex I hear they do it with ſtraw alone; but this muſt be of ſervice for only a few years: if ſtone be uſed, there can be no doubt of its laſting. The labour of the whole is three-pence per rod; ſometimes it is done for two-pence halfpenny.

" If with ſtone of the farmers, a load of thirty buſhels will do three rods, which coſts one ſhilling and a halfpenny ſtubbing and picking; ſo the expence of a rod is ſeven-pence, beſides carriage of the ſtone, which will not be much: but if he buys his ſtone, as is much the moſt probable in this country, we may ſuppoſe he muſt go two miles to fetch it, and give a ſhilling for eighteen buſhels ready picked: the carriage is worth a ſhilling more, and reckoning the eighteen buſhels to do a rod and half (which is near the matter) the ſtone of it will coſt per rod one ſhilling and four-pence.

" If buſhes are uſed, a load of forty faggots will coſt if he buys them, or be worth if he has them, five ſhillings, and coſt cutting one ſhilling. They will do ten rods; ſo that the whole expence of doing a rod with them will be ten-pence, and of ſtone one ſhilling and ſevenpence.

" The very firſt year the prodigious advantage of theſe drains appears, eſpecially if the ſeaſon proves wet. The graſs (or corn if in ploughed fields, for it anſwers in all) will be freſh, vigorous, and ſweet, wherever the paſtures are drained.

" I have a field of ſix acres (mentioned above) which by land-draining, ditching, and manuring, is an exceeding good paſture, and has produced two tons and ten hundred weight of hay per acre, in a very good year, and generally thirty-five hundred weight per acre; whereas the paſtures adjoining are ſcarce worth the farming, and let but at ſeven ſhillings per acre, producing ſcarce any thing but a little feed for lean cattle. The ſoil is the ſame in both; the ſix acres, about twelve years ago, being full as bad as the reſt.

" To improve ſuch wet land, nothing can be more advantageous than the clay which is thrown out of the ditches. Eighty loads per acre is the quantity I have laid on, and have been told by ſeveral ſenſible farmers (who clay a good deal) that it is a proper covering; but if nothing is mixed with it, ninety-five or one hundred. I know a piece of graſs-land greatly improved, on which were ſpread one hundred and fifty loads.

" My method is to make a large hill of manure, by firſt laying a quantity of clay regularly on a heap; then placing a thin layer of muck, ſuch as I have, upon it, either my ſtable or rack-yard dung, or bringing it of any kind in my waggon from Bury; on this layer, another thick one of clay; then the ſecond of dung, and ſo on; letting the proportion be about twenty loads of dung to fifty of clay. Theſe heaps, after remaining ſix months without ſtirring, I mix well together by turning them over, which a workman will do at the rate of eight ſhillings for one hundred loads. Let it lie ſix months longer in this ſtate, and then carry it on to the land, paying two ſhillings and ſixpence per ſcore loads for filling and ſpreading. This I take, from experience, to be by much the beſt way of manuring with clay, as it works and impregnates the ſoil much ſooner than alone.

" Whenever I clay arable land, I do it on clover paſtures after the crop of corn is off, managing it in the ſame manner as for paſtures. If it is ploughed in directly, it is ſeveral years before it works; but having a winter and ſummer to diſſolve and powder it, it waſhes into the ſoil more equally, and in a properer ſtate for improvement. *See the article* CHALK.

" Theſe are the principal points to be obſerved in improving ſuch wet, cold, looſe, paſtures as I have deſcribed: ſome that I have quite changed by theſe means were half over-run with moſs and ruſhes; but draining them thoroughly, and claying them, kills all rubbiſh of this ſort, and preſents the farmer with ſo admirable a view of good paſture for dairy or grazing, where ſo lately nothing could live, as is to be equalled in ſcarce any thing of the kind.

" But as all improvement ceaſes to be ſuch when more money is ſpent in it than the advantages will repay, I ſhall in a few words diſplay how far this is from being the caſe here. I will ſuppoſe two or three fields are improved, amounting in the whole to twenty acres.

	l.	s.	d.
" Sixty loads of clay per acre thrown out of the ditches, twelve hundred loads, at two-pence halfpenny per load – – – – –	12	0	0
" I will ſuppoſe ſixty rod of new ditching done, which, before clay is thrown out by the load, will coſt one ſhilling per rod – – –	3	0	0
" Three thouſand quickſets, at ſixpence per hundred – – – – – – –	0	15	0
" Land-draining ſeven hundred rod with buſhes (this is the quantity I have now marked out in a field of twenty acres) at ten-pence per rod	29	3	4
" N. B. I had a great part of my laſt crop of barley killed in this field with the wet: I had therefore a fine opportunity of marking exactly where the drains ſhould be made, which ought, on ſuch occaſions, never to be omitted, were it only for the common water-furrows which are made for every crop. In ſome fields, unleſs ſuch a guide offers, it is very difficult to tell exactly where to make the land-drains.			
" Turning and mixing one thouſand ſix hundred loads of manure – – – –	6	8	0
" Filling and ſpreading one thouſand ſix hundred loads, at two ſhillings and ſixpence per ſcore	10	0	0
" I will ſuppoſe that the work may be done the ſooner if the farmer brings one hundred loads of the four hundred of dung from the neareſt town; and as I have not reckoned the horſes and driver for the clay cart, I ſhall not in the bringing the dung: therefore the expences per waggon load will be, the coſt three ſhillings, boy ſixpence, and turnpike ſixpence. A waggon load is two tumbrel loads (in this country) ſo fifty loads, at four ſhillings, are	10	0	0
Total	71	6	4

" This is three pounds eleven ſhillings and three-pence per acre: and ſuppoſing the profit to laſt but twenty years, although the draining and ditching part will laſt twice that time, and the clay five and twenty as good as at firſt; and the farmers hereabouts ſeldom change their farms, if tolerable ones, living in them their lives, and their ſons after them, with leaſes of ſeventeen, twenty-one, and twenty-five years: ſuppoſing twenty years profit, I ſay, the expences will then be, per acre per annum, three ſhillings and ſixpence halfpenny.

" So ſmall is the expence divided. But now let us conſider the profit.

" Such land as I have deſcribed never lets here for more than ten ſhillings per acre, by far oftener for eight ſhillings, or eight and ſixpence; and it is from my own experience, as well as various obſervations, that I aſſert the ſame land, after the improvements, will let to any tenant for ſeventeen, eighteen, and twenty ſhillings per acre.

" I will ſuppoſe it only ſixteen ſhillings, though I am certain that is conſiderably under the mark: he then gains, in point of rent, ſix ſhillings per acre; and the whole calculation is abſurd, if we do not add his whole proportional profit on the acre: ſuppoſing his profit on it before improvement was a rent, ten ſhillings; afterwards, it will undoubtedly be the ſame at leaſt; which adds ſix ſhillings more to the profit; ſo that the whole will be twelve ſhillings per acre per annum, or eight ſhillings and ſixpence clear, after the improvement is paid.

	l.
" Twelve ſhillings per acre is per annum, for twenty years – – – – – – – –	240
" Expences of improvement – – – –	71
" Clear profit – – – – – – –	169

" Or

"Or eight pounds nine shillings per annum: and if we reckon five per cent. interest for the seventy-one pounds, that is, three pounds eleven shillings per annum, which, deducted from eight pounds nine shillings, leaves four pounds eighteen shillings per annum absolute profit.

"Thus, I think, I have stated the case of this improvement clearly; and I must repeat it, that I speak from experience. The sum to be expended on twenty acres will appear large to most farmers, whose property is not considerable; but the proportion holds for a single acre, and those who cannot afford to improve twenty, may three, four, or five; and I make no doubt but such as attempt it will find their account in it greater than I have stated it.

"As I have mentioned a tumbrel-load to be thirty bushels, and a waggon load to be but two tumbrels, I should observe that we carry away of muck fifty bushels at a time in our tumbrels, and so agree with our men in proportion to the thirty bushel loads.

"I have observed, that in making new ditches, or enlarging old ones, I never pay by the rod, but by the load: however, to those who chuse the former way, I would recommend that they have them worked by a frame of small fir deal, nailed into the exact size of the intended ditch, and agree with the workmen to do their work by it: this will prevent disputes which frequently arise."

PATE, a brock or badger.

PEACH-TREE, a genus of fruit-trees well known, and said to be natives of Persia.

This tree, in England, grows to a tolerable size; is generally trained against walls, &c. being too apt to miscarry of its fruit when planted as a standard; when grown old it has a pretty thick stem, with many brittle branches, and a redish and brownish bark; the leaves are thin, oblong, acuminated, and for the most part crenated on their edges, having a bitter taste; the flowers appear in the beginning of the spring before the leaves, and are without pedicles, for they adhere to the tubercles of the branches, and are rosaceous, consisting each of five oblong oval petals inserted in the cup; they are of a light pink colour, and in the middle are many stamina; the flower is succeeded by a well known globular, furrowed fruit, covered with a thick soft whitish down. In England there are several sorts or varieties cultivated, as 1. The white nutmeg peach, this is ripe in July. 2. The red nutmeg, this ripens about the beginning of August. 3. The early purple, this is ripe by the middle of August. 4. The French mignon; this is a most excellent melting peach, and ripens about the middle of August. 5. The red magdalen; this peach is ripe about the end of August. 6. The early Newington ripens the end of August. 7. The noblest; this is a fine melting peach, and ripens the end of August. 8. The chancellor, a good melting peach, and ripens the end of August. 9. The admirable; this peach parts from the stone, and ripens the beginning of September. 10. The old Newington; this peach adheres to the stone, and is reckoned one of the best sort. 11. The Portugal peach; this has a rich juice, and adheres to the stone, these ripen about the middle of September. 12. The nivette; this is a melter, and ripens in September. 13. The pavy of pomponne, is a very large fine peach, and ripens in October. 14. The Catherine; this adheres to the stone, is a high flavoured peach, and ripens in October: there are various other sorts, which might be enumerated; but the above-mentioned being of the best and richest flavour, we think it will suffice. The French distinguish those we call peaches into two sorts, viz. pavies, and peaches; those are called peaches which separate from the stone, and those whose flesh closely adheres to the stone are called pavies; these are much more esteemed in France than the peaches, though in England the latter are preferred to the former by many persons.

The best expositions for peach trees, are the south, south-east, and south-west, but they will do tolerably well on a west wall, which ripens its fruit just as those of the south are gone; they should not be planted in a cold wet soil, the fruit in such places are always watery, and insipid; the best soil for these, is fresh untried earth, which is neither too stiff nor too moist, but of a kind loamy nature; and if the earth in the borders is exhausted where the trees are intended to be planted, it should be taken away, and its place supplied with fresh; all the sorts of peaches are propagated by inoculation on plumb-stocks, and trained in the nurseries for planting against walls, &c. but it is certainly best to make choice of such trees, which are of one year's growth from the budding, as they will soon overtake in growth those which are called trained trees; the best time to transplant them is in autumn, when the leaves are turned yellow, when they will have time to form fresh roots, before winter, and thereby be better prepared to shoot more vigorous in the spring; but the head should not be cut off at that time of planting; but if the soil is very moist, it is better to plant in the spring just as the sap begins to be in motion: in February the tops of the trees should be cut off within four or five eyes of the place of inoculation; and when the weather becomes hot and dry, it may be necessary to water the trees: in May the young shoots will have made some progress; those which have a fore-right direction, should be displaced, and the others nailed horizontally to the wall; this must be repeated as often as it is necessary: in October, the branches should be shortened in proportion to the strength of the tree, a vigorous branch may be left nine inches or a foot long, but if the shoots are weak, half that length is sufficient; observing to train them horizontally, as the middle of the tree will easily furnish itself with branches: the second summer, they are to be managed as the first, displacing all fore-right shoots as they are produced, and nailing in the others close to the wall horizontally; but the shoots should not be shortened in the summer, unless in those places where there happens to be vacancies: in October, shorten the shoots as before directed, and the following year's management, is much the same as the preceding. The time for pruning is at the above-mentioned time, where the trees are planted in a dry soil; but if the land is moist, it is better to defer it till the spring.

When peach-trees hasten to bear very soon, it is a sign of decay, or weakness, the best help for them is to disburthen the tree of its bloom, pruning it short, and keeping it well watered in hot weather; but when the trees are vigorous, cut out such large branches as appear to be useless, and nail in the remainder at a good length; and in making choice of shoots, always choose the middling wood as are full of swelling double buds, for those produce fruit, which the flat single ones do not, their product being wood and leaves only; the distance these trees should be planted, may be about sixteen feet: when the fruit is set and grown to the bigness of a small nut, they should be thinned, leaving them at least five or six inches asunder, for when they are permitted to remain in bunches, as they are often produced, the nourishment which should be employed wholly to the fruits designed to stand, will be equally spent amongst the whole number, a great part of which must be afterwards pulled off, so that the sooner this is done, the better it will be for the remainder; and if it should sometimes happen, that a part of those left, by any accident should be destroyed, yet the remaining ones will be much the larger, and better flavoured for it, and the trees will gain more strength; for a moderate crop of fruit, is always preferable to a great crop; for when the trees are overcharged with fruit, it is always small, ill tasted, and the trees are generally so much weakened thereby, as not to be in a condition for bearing well for two or three years afterward.

The following curious and useful observations on the pruning of peach-trees, are extracted from a French treatise, entitled, *Traite de la Culture de Peches*; and will, we hope, prove agreeable to our readers.

"The best time, says this author, for pruning is when the blossom-buds first begin to smell; for then you may discover which blossom promises the fairest for producing a fruit.

"That you may not run the hazard of breaking off such buds as you should wish to preserve, do not offer to prune a twig till the tree is entirely unnailed from the wall.

"Your method of pruning must be regulated by the age, health, and vigour of the tree, and in some sort must humour what has been already done.

"I will begin with the tree in its first year: if it has made but weak shoots, you first reduce its shoots, leaving from two to four on each ſide, oppoſite to each other, and prune them to the length of five or ſix inches. If you find a ſmall bearing branch that looks exceedingly flouriſhing in the middle, you may leave it; but unleſs it is remarkably promiſing, cut it off, for the middle of the tree is ſure to be filled if you prune the ſides properly: and the whole beauty and goodneſs of the tree abſolutely depends upon your right treatment of it for the two firſt years.

"If your tree has thrown out in a good place, on each ſide, one ſtrong branch, prune it to eight or ten inches, leaving here and there a bearing branch.

"It is the way with many gardeners, who look on theſe ſtrong ſhoots as blood-ſuckers, to lop them off without mercy; but this ought to be done with diſcretion, for it is not uncommon for a tree, ſo ſeverely handled, to languiſh and pine away, and from that luxuriant ſtate to dwindle to nothing: the reaſon I take to be this, that, as in all trees the root bears a proportion to its head, the ſap, being here repelled, becomes ſuperfluous and putrid in the root.

"Experience has taught me, that by pruning ſuch kind of trees with judgment, they will, in two or three years, be brought into order: but if they ſtill continue to throw out ſuch ſtrong wood, I ſhould adviſe the ſtopping all ſuch ſmaller branches of the year, which have been thrown out on the ſides, in order more effectually to ſpend the ſap: by this means the exceſſive luxuriance of the tree will be moderated, and much good bearing wood procured.

"The only inconvenience to be apprehended from this practice, and what ſhould be carefully guarded againſt, is, that the lower part of the tree is apt to become bare; but this may be remedied by an attention to pinch off the tops of the ſhoots in the month of May, and to lighten the head well when you prune it.

"If there is one of theſe woody branches on the ſide, and one in the middle of the tree, they muſt both be taken entirely off, or the weak ſide will be totally overpowered, and the tree can never be brought into any handſome form: you muſt then likewiſe prune the leſſer branches, that the two ſides may be kept as equal as poſſible. Here I muſt obſerve, that none of theſe ill-placed branches would be ſeen, for by lightening the ſtrong ſide, the ſap would naturally find its way to the other; but, as few people will take this trouble, we muſt find ſome means of repairing the damage incurred by ſuch neglect.

"This is the method to be followed for the firſt year. Let us now proceed to the ſecond, and ſo on.

"I have ſpoken ſufficiently of ſuch trees as run into wood, whoſe redundancy muſt be moderated before they will throw out any bearing branches, and by what means it may be done: as to thoſe that are moderate, they muſt be treated proportionably; but, above all things, care muſt be taken to keep the middle of the tree ſhort, and the ſides perfectly equal: let no flattering promiſe of fruit induce you to deviate from this rule.

"In regard to the good management of the tree, let two or four proper branches be, as it were, the parents of the reſt; over theſe you muſt be particularly watchful: let them ſpread, and have all the ſpace you can think they will poſſibly cover: they may be allowed from twelve to fifteen inches when you find them of a reaſonable ſtrength. As to the leſſer, they ſhould be left ſix or eight inches long, as you think the vigour of the tree will bear, and the ſpace to be occupied requires; and according as the bloſſom-buds are more or leſs diſtant from the foot of the branch, your own prudence muſt direct you to leave the ſhoot longer if neceſſary.

"Take care to preſerve ſuch bloſſom-buds as come out with a leaf-bud between them: thoſe which come ſingle, though with a leaf-bud by the ſide, will rarely ſet, or come to perfection: notwithſtanding they look very promiſing, never ſuffer yourſelf to be tempted, by a proſpect of abundance of fruit, to allow too many to remain on the tree; for by this means you waſte the ſtrength of it, and, in the end, ruin both the middle and ſides.

"As to ſlender, ill-ripened branches, I reject them all; as alſo thoſe tender twigs which are ſo much reſpected by the generality of gardeners; that is, ſuppoſing I have well-ripened wood of a moderate ſize (not too large) ſufficient for my uſe, it being inconteſtibly proved, that ſuch good wood will nouriſh the fruit beſt, and bring it to the higheſt perfection. I would not be underſtood here to reject thoſe little ſpurs which are only an inch or two long, and are cluſtered like noſegays; no, theſe are to be preſerved with the utmoſt care, as they generally produce the fineſt of fruit.

"There is a good uſe to be made of the branches which I here condemn, namely, to prune them down to the laſt eye, when they are in a place which may poſſibly become bare in future time: one of theſe branches, ſo pruned, may, in the next year, produce a better, which, if it is not wanted, may again be reduced, and ſo on, till it ſhall be deſirable to make uſe of it.

"It will be always found uſeful to have ſome of theſe branches in reſerve in all parts of the tree for a ſupply, in caſe of blight, or when a branch has bore too much fruit the year before; and for that reaſon I ſhould adviſe the cutting even a good branch for this purpoſe, when others are wanting.

"As all trees naturally ſhoot upwards, you muſt uſe your utmoſt diligence to keep the bottom part full of wood, which is only to be effected by proper pruning, and laying the branches exactly even, and quite horizontal: great attention muſt be given to this; for a crooked, or bent branch, or one laid over another, will never produce good fruit.

"On the art of pruning depends the duration of the tree; and it conſiſts in not overcharging it, and keeping it in all parts full: this may appear very eaſy, but it is attended with difficulty, as to the choice of what is to be preſerved, and what rejected, and as to the keeping of promiſing bloſſom-buds, and not preſſing the tree too much if it has bore greatly the preceding year.

"Now let us paſs on to the time when the tree ſhall be found in its full beauty and vigour.

"Suppoſing it has been managed after the method I preſcribe, after it is unnailed, examine into the branches which bore the laſt year: theſe are eaſily diſcovered by their leanneſs, and the poor ſhoots which they have made. I cut them quite cloſe to the large branch from which they ſpring, unleſs they have by chance thrown out ſome very promiſing wood, which may be worthy of preſervation, eſpecially if there is nothing in the neighbourhood to take up the place; then I go to the ſhoots of the year, and cut out all the very ſtrong woody ones, and the very ſmall ones, preſerving only thoſe of a moderate ſize, and the little cluſters or noſegays, before-mentioned.

"If I muſt, out of neceſſity, keep any of the weak ſhoots, I juſt top them about the thickneſs of a crown-piece: this done, there remains nothing but branches of equal ſtrength and goodneſs, and I can ſee clearly what I have to do.

"My only buſineſs now is, to make choice of what I ſhall preſerve of the remainder; and this is my rule:

"Of all the ſhoots which are made from the wood pruned laſt year, I leave only one lower ſhoot; and by the precaution I have uſed in the month of May, by nipping the tops of the others, that will be found by far the beſt, or rather the only good one.

"As for ſuch as neglect this operation, they muſt make the beſt choice they can.

"After this I go over it a third time, and examine whether the tree has borne much fruit the laſt year, that I may prune accordingly. The magdalene is generally a vigorous tree, and will bear a greater burthen than ſome others.

"If my trees of every ſort have not been too much exhauſted, I prune to the length of eight inches, if the place will allow it; but if I am confined, and have nothing below to ſupply the place of a waſted branch, I ſhorten it to three or four inches.

"It will generally be found, that half my branches are ſhort, and half long, according to their ſituation; by which I am enabled to keep the tree always full of good wood without preſſing it to its hurt.

"I have ſaid, that I never leave more than one ſhoot on the laſt year's branch; but in caſe a blight has killed the neighbouring branch; or there appear two ſhoots on the lower part, ſo very equal in goodneſs that there can be no choice between them, I then prune to the length of five or ſix inches: but if I have not an abſolute neceſſity for both for preſent uſe, I prune the higheſt of the two to the length, and cut the loweſt quite down to its firſt eye, in order to inſure to myſelf a proviſion for the next year."

Our author next treats of budding, or nipping off the buds; from which we ſhall ſelect a few paſſages, which cannot, we think, fail giving pleaſure to our readers.

"What I ſhall here call nipping of trees, is an operation of all others the moſt important, and at the ſame time one the moſt of all neglected: when I ſay the moſt important, I mean to except the pruning. The uſe of nipping is this, that it helps and forwards all other operations, and gives to the fruit theſe three advantages, their certainty, beauty, and goodneſs.

"The proper time for nipping is the month of May, when the buds are ſufficiently formed for you to aſcertain your choice, and ſtill tender enough for you to nip them off with your finger and thumb, without any other inſtrument. This nipping is uſually confounded with two other operations, which are called pinching and ſtopping, becauſe they are generally all performed together; but I ſhall diſtinguiſh them, the one from the other.

"All the management of peaches (as I have ſaid before) may be determined in theſe two objects, namely, the good figure of the tree, and its abounding with good fruit: to accompliſh this, all your work ſhould tend.

"With this view therefore you are to diveſt it of all that may be uſeleſs or hurtful; and I muſt call all uſeleſs which is ill ſituated, though in itſelf good, and all hurtful which is ill in itſelf.

"Theſe two evils we muſt guard againſt, and they will be particularly found on the branches, which are pruned the year before; and theſe branches, according to my method, are moſt of them ſix or eight inches long, there will be found on them from eight to ten eyes, which are as many branches: ſuch a number of branches cannot poſſibly be equally well nouriſhed, and muſt, of courſe, breed confuſion.

"I reduce them, according to their ſituation, to two or three, which I chuſe on the loweſt ſide, oppoſite to each other, and the end one, provided the fruit is there, and that it is not lower.

"If the fruit is only ſet on the lower ſide, or if it is ſet all the way along it, where the number of eyes may be from eight to ten, in both caſes I reduce them to half their number, and preſerve only three or four of the moſt promiſing, always obſerving to leave at the end a fair young branch of the year.

"At the ſame time I pinch off with my nail ſuch branches as accompany the fruit, to the thickneſs of about two crown-pieces, which I call ſtopping: and if there are others which have not fruit, I pull them quite off, reducing the number to two or three.

"If the branch has not thrown out any fruit, I prune it down to the ſecond bud; that is to ſay, I only preſerve the two loweſt buds, unleſs the tree is too luxuriant, and it becomes neceſſary to leave more in order to conſume the ſap.

"With reſpect to ſuch branches as I have pruned ſhort, I preſerve only two of the new ſhoots, the uppermoſt and its oppoſite: I ſuppreſs all others which have not fruit by them; ſuch as have, I pinch them; but if the fruit fall off, I ſerve them all after the ſame faſhion: ſometimes, however, I leave only one of theſe new ſhoots, and it muſt be always the loweſt.

"If I find a woody, ſtrong ſhoot on the branch pruned laſt year, or even if it ſhoots from the body of the tree, I conſider whether it will weaken the tree, be detrimental to its neighbour, or not of immediate ſervice: if it anſwers no purpoſe, I take it entirely off.

"But if it may hereafter be found uſeful, either to fill a vacant place, or to waſte the ſap which too much abounds, I pinch it down to four or five leaves; and as there comes a new ſhoot from every leaf, I ſhall find preſently as many free ſhoots, of a moderate ſize, out of which I may chuſe, in the firſt nailing, ſuch as promiſe beſt. As to the weak ſhoots which come from the old wood, I ſuppreſs them entirely, unleſs they come opportunely to fill a preſent vacancy, or are deſirable for a future reſource; but the little cluſters, or noſegays, I always preſerve, let them be where they will.

"Great regard ſhould be paid to the bottom part of the tree, as it often puts forth good ſhoots, which will be found very convenient to ſupply ſuch wood as is exhauſted with bearing: theſe I preſerve with the utmoſt care, and, if they are ſtrong, pinch them off to five or ſix eyes. As for thoſe craving ſhoots which are to be known by their bright-green colour, with here and there red ſpots, and by their ſize, they muſt be wholly taken off, unleſs they are abſolutely neceſſary to fill a vacancy, and that you are without other reſource: if ſo, you muſt pinch them now, and again in the month of June.

"It generally happens, that from one eye, eſpecially that at the extremity of the laſt year's pruning, three ſhoots will come forth of nearly the ſame ſtrength: chuſe only one of them, and let it be that which is beſt placed.

"When you meet with twin fruit, take off the leaſt of them with all poſſible care not to ſhake the other: by this means you have a chance of having one good fruit, and if both are preſerved, neither will be ſo.

"Theſe are the chief points which relate to the nipping. The next thing is to ſhew the advantages it produces.

"It may eaſily be comprehended that theſe retrenchments, made in the proper time, are likely to ſtrengthen ſuch as are left, both fruit and branch, as, from a moderate ſhare of nouriſhment, they will by this means enjoy a better, till they are made perfect.

"Nay, more, it is poſſible that what you have retrenched of the ill-placed branches, which you muſt have cut off at the firſt nailing, might have been more favoured by the ſap, and have robbed the well-placed branch, which, by being left alone, now enjoys the whole of the nouriſhment, and becomes ſtrong and vigorous.

"By theſe retrenchments you reap this further advantage, that when you come to the nailing, inſtead of being obliged to clear with the pruning-knife, you have theſe branches ready cleared to your hand; by which you are ſaved an infinite deal of trouble, which the confuſion of ſuch a multitude of ſhoots occaſions, and are ſpared the diſagreeable ſight of abundance of ſtumps, which the ſummer-pruning muſt neceſſarily produce, and occaſion a deal of buſineſs when you come to the winter-pruning, unleſs you unadviſedly leave them on.

"It often happens likewiſe, that theſe naſty ſtumps, left at the time of nailing, throw out two or three ugly ſhoots, which waſte the ſap, breed confuſion, and ruin the fruit.

"It farther happens, that by your efforts to take off theſe ſuperfluous and ill-placed branches with the pruning-knife, and the uncertainty you work in, you rub off many of thoſe fruits which you would wiſh to preſerve, they being then paſt danger.

"By this nipping, which I ſo much recommend, you avoid the following inconveniencies, which the fruit hid, ſtifled, and, as it were, buried in leaves, would be ſubject to, namely, being made too tender, which may plainly be diſcerned by its whitiſh colour; and when it comes to be expoſed ſuddenly to the free air, joined to the ſtrong rays of the ſun, which are new to it, it is moſt probable that the greateſt part of them will wither and fall; for you muſt obſerve, that, as the ſap always puſhes forward to the extremity of the branch, and as only theſe extremities enjoy the benefit of the free air, the lower part of the branch, being ſmothered, caſts its leaves, or ſo great a part of them, that the fruit at beſt is but covered by halves.

"None of theſe inconveniencies will happen, if your branches have enjoyed the free air, in their whole length, and your fruit hath been early enured to the little inclemencies of the weather; for by making them hardy, by the time they arrive at the ſize of a wall-nut, you will ſcarcely find any fall, unleſs they are too many for the tree to nouriſh: you have this further advantage by an early expoſure of the fruit, which is, that the inſects, particularly ſnails, will not be ſo fond of it, as when made ſo tender by being covered with leaves.

"Regard muſt be always had to ſet ſuch fruit and branches at liberty as are confined by the nail; for if once a fruit is become deformed, no art will then reduce it, and a deformed fruit will never be well flavoured.

"It

"It will here be neceſſary to ſpeak of blights, which, by knotting the branches, and enlarging them improperly, ſwallow up the ſap you want to nouriſh the tree.

"When the trees are ſo attacked, you ſhould not only take off all the infected leaves, but likewiſe cut away the branch beyond the infected place: by this you give the ſap the power of going into new ſhoots, which will be equally uſeful another year.

"If your tree be infected to a great degree, your expectation of fruit for that year muſt not be great, for they will fall by degrees before they come to perfection.

"The ants and lice will ſometimes occaſion the ſame diſorder among the leaves and branches; and in that caſe you muſt uſe the ſame means as directed above; but generally theſe inſects are inveterate in poiſoning the eyes of branches, ſo that the ſap is obſtructed.

"If the tree ſhould be attacked with the gum, you ſhould prune it at leaſt an inch beyond the grieved part, which will prevent the deſtruction of the whole in cutting off the communication: from this you will have a ſhoot or two which will ſupply the place, and your loſs will be but trifling.

"The laſt and greateſt advantage of nipping is, that you will find an ample compenſation for all the time you have ſo employed when you come to nailing, as you will ſee your work clearly before you, and every branch will naturally take the place that you would deſire to put it into, and you will ſcarce need to make uſe of the knife.

"I have experienced, that I can ſooner nail three trees which have been nipped than one which hath not.

"Notwithſtanding this operation may have been carefully performed, your work muſt be reviewed every eight or days, as well to deſtroy the vermin, as to take off any ſuperfluous or ill-placed ſhoots, which may put forth after a ſhower of rain; or when the morning-dew is on the tree, is the moſt likely time to find the ſnail at work.

"Regard muſt alſo be had to ſtop the ravages of the gum, and you will find that time ſo employed is by no means thrown away.

"For thoſe that are maſters of their time, it is as well to divide the operation of nipping in this manner: in the end of April I would take off ſuch ſhoots as come behind and before the branch; and in the latter end of May, when the fruit is ſet, I would perform the reſt.

"Theſe rules which I have now laid down, for the well-pruning by the hand, ſtill demand that I ſhould make ſome diſtinction as to their ages.

"For trees in their firſt year, I begin by taking off the backward and fore-right ſhoots at the latter end of April, and only leave ſuch as come on the ſides; and if one ſide has put forth more ſhoots than the other, I diſcharge that ſide in order to drive the ſap to the other: and at the end of May I make a ſecond review, and if I find one branch a great deal ſtronger than the other, I cut or pinch it off.

"Nearly the ſame method may be purſued for the two or three following years, obſerving this difference, that if the tree be vigorous, I relieve it much leſs in nipping than if it is weak; for I would only diſcharge a vigorous tree of the ill placed and fore-right ſhoots which are put forth on the ſtrong branch left at the laſt pruning, preſerving always ſuch as come on the ſides, as many, at leaſt, as I can poſſibly find room for on my wall.

"As for an old tree, I not only take off the ill-placed ſhoots, but likewiſe all ſuch as are weak to a certain degree; and, in order to ſtrengthen the reſt, I confine myſelf to a ſmall number of the beſt ſhoots, on which I leave but a ſmall quantity of fruit.

"I nip ſuch trees the laſt of all, becauſe they are later in coming out."

PEAR, a genus of fruit-trees, ſaid to have been originally brought from Alexandria, Numidia, Greece, &c.

As the ſpecies are very numerous, we ſhall only mention a few of the beſt, viz. 1. the little muſk-pear, which ripens in July; 2. the jargonelle, this is one of the beſt ſummer-pears; 3. the Windſor-pear; 4. the blanquette-pear; 5. the red orange-pear; 6. the royal-pear; 7. the ſummer-boncretien; 8. the rouſſellet; 9. the princes-pear; 10. the ſummer-bergamot; 11. the autumn-bergamot; 12. the brown-beurré; 13. the monſieur John; 14. the flowered-muſcat; 15. the green ſugar-pear; 16. la marquiſe; 17. the craſſan; 18. the colmar; 19. the vert-longue; 20. the virgoulé; 21. the winter-thorn; 22. the St. Germain; 23. the winter-rouſſelet; 24. the Eaſter-bergamot; 25. the Hollands-bergamot; 26. the winter-boncretien; 27. the Chaumontelle. (The following are baking-pears) 28. the pound-pear, or black-pear of Worceſter; 29. the winter citron-pear; 30. the francreal; 31. the double flowering-pear, with many other ſorts: they are all propagated by budding or grafting upon ſtocks of their own kind (commonly called free-ſtocks) or upon quince-ſtocks; the latter are uſed for low walls, dwarfs, or eſpaliers; and eſpecially in wet lands, theſe ſtocks doth effectually prevent the too great luxuriancy of the plant, and cauſe it to produce fruit much ſooner than on a pear ſtock; but then, on the other hand, it has this evil attending it, that the tree is but ſhort-lived, and moſt of the ſorts of hard baking-pears are rendered ſtony and good for little: on the contrary, moſt melting ſoft pears are greatly improved by being grafted on quince-ſtocks, particularly if the ſoil is of a moiſt ſtrong nature.

The beſt ſeaſons to prune pear-trees is at the fall of the leaf, though it may be deferred till the ſpring, obſerving to cut out all luxuriant branches, which are known by the great diſtance of their buds, and to lay in no more wood than the roots may be reaſonably ſuppoſed capable of ſupplying with ſufficient juices, leaving them at a diſtance from each other, in proportion to the ſize of the fruit; ſuch ſorts whoſe fruit are ſmall may be allowed five or ſix inches, but the larger ones muſt be not leſs than ſeven or eight inches aſunder, always remembring to train the branches horizontally as they are produced, without topping them, by which means there will be little occaſion for much pruning theſe trees; for it appears, that pear-trees have their bearing-buds in three different ſtates, continually ſucceeding each other; the blowing-buds of three years old diſcover themſelves at the fall of the leaf, which, whilſt the fruit preceding them was growing and ripening, they were preparing to ſucceed them the enſuing year: theſe buds are produced upon curſons or ſpurs, and are known by their being very full and larger than the others, in a ſeeming ſwelling impatient ſtate of breaking out into its beautiful dreſs of delightful bloom, which is enwrapped within it: the preparative buds of two years are of a ſharp conic figure, and red ruſſet colour, growing very near the fruitful buds before deſcribed: the junior buds of one year are very ſmall, but full above the bark, and always break out near the buds of two years growth; to which may be added, there is a continued ſucceſſion of buds in embryo, ad infinitum.

The diſtance pear-trees ſhould be planted, either againſt walls or eſpaliers, ſhould not be leſs than thirty feet, for if they have not room to ſpread on each ſide, it will be impoſſible to preſerve them in good order, eſpecially thoſe on free ſtocks, for the more theſe trees are pruned the more they will ſhoot: many ſorts of pears produce their bloſſom-buds at the extremity of the ſhoots; ſo that when they are ſhortened the fruit will be cut away, which cannot be avoided where the trees have not room allowed in their firſt planting.

The beſt ſeaſon for planting pear-trees in a dry ſoil is at autumn, but if the land be moiſt the ſpring is to be preferred.

PEASE, a genus of plants cultivated in every part of England both in the field and kitchen-garden. We ſhall lay down the beſt methods for cultivating them in the kitchen-garden, from Mr. Miller's Gardener's Dictionary, and then proceed to give the beſt inſtructions in our power for obtaining large crops in the field.

With regard to the kitchen.—The diſtance between the rows of peas ſhould be proportioned to the ſize to which they grow. The channels in which they are ſown ſhould be about two inches deep; and the quickeſt and moſt regular way to perform this work is, to draw a ſmall hoe, directed by a line, along the ſurface of the ground, ſo as to open a drill, then to ſcatter the ſeeds in this furrow, and to earth them over with the help of a rake. By this means they will be well and equally covered; which is eſſentially neceſſary, becauſe if any of them lie above ground, they will attract mice, rooks, pigeons, and other birds, which will then ſoon find out the reſt, and

deſtroy

deſtroy the whole plantation. The chief trouble after ſowing them is, to ſtick the larger ſorts which require ſupport, to keep the plants clear from weeds, and to earth them up; both which laſt parts of their culture are very eaſily, readily, and effectually executed when a ſmall plow can be introduced between the rows.

The names of the principal ſorts of garden peas now cultivated in England, and the order in which they naturally become fit for gathering, are as follow, viz. the golden hotſpur, the Charlton hotſpur, the Reading hotſpur, the maſter's hotſpur, the Eſſex hotſpur, the dwarf pea, the ſugar pea, the Spaniſh morotto, the nonpareil, the ſugar dwarf, the ſickle pea, the marrowfat, and the roſe, or crown pea: for the rouncival, the common white pea, the gray pea, the pig pea, and ſome other large winter peas, as they are commonly called, ſeldom find a place but in the field. But I muſt here obſerve, that ſeveral of the above-mentioned, which gardeners and ſeed-men have diſtinguiſhed by different appellations, are, in fact, only ſeminal variations, which will degenerate into their original ſtate in a few years, if they are not very carefully managed. The only way to prevent this, is to rogue them, as the gardeners term it, that is to ſay, to examine attentively thoſe which are intended for ſeeds, at the time of their beginning to flower (but before the flowers are open,) and to draw out all the bad plants from among the good ones, that the farina of the former may not impregnate the latter, and thereby make them change. It is chiefly owing to this particular care, and to the ſelecting of thoſe plants which bloſſom earlieſt, that the culture of peas has been very greatly improved of late years around this metropolis, and that, from a continuation of the ſame induſtrious endeavours to bring it to ſtill greater perfection, we may hope to ſee yet forwarder varieties of this moſt uſeful ſpecies of pulſe.

The hotſpur pea is, naturally, the earlieſt of all, and therefore I have named it firſt: but the gardeners about London raiſe, by art, from the dwarf pea, tranſplanted into a hot-bed, a crop which anticipates the ſpontaneous growth of the other. To effect this, they ſow their dwarf peas in warm borders, under walls or hedges, about the middle of October; and when the plants are riſen, they draw the earth up gently around their ſtems, to protect them from the froſt. They let them remain where they were ſown till the latter end of January, or the beginning of February (ſtill continuing to earth them up from time to time, as they advance in growth, and covering them with dry haulm, or ſtraw, in caſe of ſevere froſt,) and then remove them into a hot-bed made of good, new, well fermenting dung, properly mixed, that the heat may not be too great. This dung is laid from two to three feet thick, according as the ſeaſon is more or leſs advanced; it is covered with ſix or eight inches deep of light and freſh, but not too rich, earth; the frames, about two feet high at their back, and fourteen inches deep in front, are then put on, and covered with their glaſſes, which are propped up every day, during three or four days, to let the riſing ſteam paſs off; and when the bed is become of a moderate temperature, the plants are taken up as carefully as poſſible, to preſerve the earth about their roots, and planted in it about an inch aſunder in rows two feet diſtant from each other. They are then watered a little and ſhaded, till they have taken root, and aired whenever the ſeaſon is favourable, leſt they ſhould be drawn up very weak, grow mouldy, and decay. Their ſtems are alſo earthed up as they advance in height, and they are kept perfectly clear from weeds. This firſt watering ſhould be gentle, and dealt out ſparingly; for too much of it would make them grow rank, and ſometimes rot them off at their ſhanks, juſt above the ground. If the weather becomes very hot, the glaſſes are covered with mats in the day-time, to ſcreen the plants from the too great violence of the ſun; and when they begin to fruit, they are watered oftener and more copiouſly than before; for they have nearly done growing by that time, and refreſhing of them frequently will make them produce the greater number of pods.

The dwarf pea is preferred for this purpoſe, becauſe it is more eaſily confined within frames, than any other ſort. The reaſon for ſowing it in the common ground, and afterwards tranſplanting it into a hot-bed, is, to check its growth, and thereby make it bear the more in a ſmaller compaſs.

The hotſpur, of which the ſorts before enumerated differ very little from each other, except in the forwardneſs of their fruit, in which the golden and the Charlton are earlieſt, ſucceeds the hot bed crop of the dwarf pea. But it is neceſſary to obſerve here, that both theſe kinds of hotſpur peas are particularly apt to degenerate, and become later in their podding, if they are cultivated in the ſame ground for three or four years running: wherefore the beſt way is to change their ſeeds annually, and always to prefer ſuch as come from a colder ſituation and a poorer ſoil, than the place where they are to be ſown, for theſe will be earlieſt in the ſpring; and if they are procured from a diſtant part, it will be ſo much the better.

Theſe peas muſt alſo be ſown in warm borders, about a fortnight after the former, that is to ſay, towards the end of October. When the plants are a few inches high, they ſhould be earthed up as before directed, to defend their ſtems from froſt; and if the winter be very ſevere, they ſhould be covered with haulm, or ſome other light covering: but this muſt be taken off as ſoon as the weather grows mild, leſt it ſhould draw them up weak and tender; and the weeding and earthing up ſhould be repeated as they advance in growth, but with care not to bury their leaves, for that might rot their ſtems, eſpecially in wet ſeaſons. Both of theſe works muſt be very carefully performed in the ſpring: and this is likewiſe the moſt proper time to kill the ſlugs, which, of all vermin, do the greateſt injury to peas. They lie all day in the hollows of the earth, near the ſtems of the plants, and come out in the night, to the ſometimes total ruin of the crop. They abound moſt in wet ſoils, and in neglected grounds over-run with weeds: for which reaſon they have the leaſt chance of finding ſhelter where the new huſbandry is well practiſed. Mr. Miller recommends, as the beſt method he could ever find to deſtroy them, to clear the ground thoroughly well around the plants, and there, very early in a fine mild morning, when theſe inſects are got abroad, to ſlake a quantity of lime and ſtrew it over the ground hot, and pretty thick. This will kill the ſlugs wherever it falls upon them, and will not do much hurt to the peas, if they be not over-loaded with it.

If this crop does well, it will immediately ſucceed that of the dwarf peas on the hot-bed: but leſt it ſhould miſcarry, it will be right to ſow two other crops, at the diſtance of about a fortnight or three weeks from each other. Theſe will ſuffice till the ſpring, when more crops of the ſame ſort may be ſown every fortnight, and by this means the early peas will be continued through the ſeaſon.

About the middle of February, ſome of the Spaniſh morotto, which is a great bearer, and a hardy pea, may be ſown in a clear open ſpot of ground, for the next uſe of the family. The rows of theſe, which are a larger kind, ſhould be four feet aſunder, and the peas ſhould be dropped at about an inch from each other in the drills.

To ſucceed theſe, another ſpot of ground ſhould be ſown about the end of February, either with the ſame, or any other large ſort of pea, and theſe ſowings ſhould be continued every fortnight, till the middle or latter end of May; only obſerving to allow diſtances proportioned to the ſize of the pea at it's full growth. Thus marrowfats, for example, ſhould not ſtand nearer than four feet and an half from row to row, and the roſe pea ſhould be at leaſt eight or ten inches aſunder in the rows: for all peas, (and the caſe is exactly the ſame in regard to every other plant) will run up in height, and yield but little fruit, if they are too much crowded.

When theſe larger ſorts of peas (which muſt be carefully weeded and earthed up as before directed) are grown about eight or ten inches high, ſome bruſh-wood ſhould be ſtuck up cloſe to them, to prevent their trailing upon the ground, which is very apt to rot theſe kinds in particular, eſpecially in wet ſeaſons: and another great advantage ariſing from their being thus ſupported, is that the air has then a free current between them, which will keep their bloſſoms from falling off before their time, and they will conſequently bear much better than they could if left trailing upon the ground. There will alſo, by this means, be proper room to hoe between the rows, and to paſs between them in order to gather the peas when they are ripe.

The marrowfat is the beſt taſted of all the large kinds of peas, and it will continue good till the end of Auguſt, if it be planted in a ſtrong ſoil. The other large growing ſorts may be raiſed for the common uſe of the family, becauſe they yield the moſt plentifully, and can endure the greateſt drought: but the early kinds are by far the ſweeteſt. It will therefore be well worth the maſter's while to ſee that a crop of theſe, and particularly of the early hotſpur, is ſown every fortnight, to ſupply at leaſt his own table during the ſeaſon.

All the dwarf peas yield plentifully, if the weather be not over dry; but they ſeldom continue to bear long. As they rarely ſurpaſs the height of one foot, or ſpread wider than ſix inches, about two feet and an half may be a ſufficient ſpace for weeding and ſtirring of the ground between their rows, in which they need not be ſet above an inch aſunder. Among theſe may be claſſed the ſickle pea, or ſugar pea, which is much cultivated in ſeveral foreign countries, but is ſeldom propagated here, except by curious gentlemen, for their own table. The pods of this pea, are crooked and ill-ſhaped, but extremely ſweet when boiled with their unripe fruit in them, as is the general way of dreſſing them; for they have not any tough inſide ſkin, like the pods of other peas. I wonder that this ſort is not yet to be met with in our markets; unleſs the reaſon be, that the trading gardeners, who furniſh them, find that their profit will not pay for the trouble and expence of defending theſe peas from birds, which are ſo exceſſively fond of them, that they will ſoon devour a whole crop, if they are not very carefully kept off. If theſe peas are planted in April, they will be fit for gathering at Midſummer. Their pods, when they are very young, and their tendrils, have an agreeable acid flavour in ſallets; as have alſo the young tendrils of the hop and the vine.

A general rule to be obſerved in the planting of peas, is that the later they are ſown, the ſtronger and moiſter the ſoil ſhould be.

Having thus delivered the beſt method for cultivating peas in the kitchen-garden, we ſhall proceed to make ſuch obſervations as may be of uſe for obtaining large crops in the open field.

Mr. Liſle, for the greater eaſe and more certain guidance of country people, who are apt to be perplexed by a long liſt of particular names of different ſorts of field-peas, and of their ſeveral numerous varieties, judiciouſly ranges them under two general heads, viz. the tender and the hardy ſmall ſort, and the tender and the hardy great ſort; under the one or the other of which claſſes he thinks all kind of peas may properly he ranked, becauſe they equally agree or diſagree with the ſame ſoil. The tender pea, for example, is improper for a cold country, or, which amounts to the ſame, for cold ground in a warm country; and the large pea, by reaſon of its great haulm, is not proper for ſtrong rich land, becauſe its haulm will there increaſe to ſo great a length, that it will not be able to bear pods. His own experience in the year 1704, ſatisfied him fully that the beſt way to make peas pod well, is to ſow them on a mellow mould, rendered light by plowing: and he thinks it right to roll the ground ſoon after they are ſown.

Even the moſt general directions, and therefore theſe cannot but be of ſervice to the huſbandman: but more particular obſervations and actual experiments properly diverſified, are ſtill much wanted in the culture of this, and indeed of all other podded grains, and ſucculent plants, whoſe importance, as deſtroyers of weeds, improvers of land, and excellent preparers of it for other crops, is eſtabliſhed beyond diſpute. It is even a rule with farmers, not to ſow the ſame land a ſecond time with peas, till ſix, or at leaſt five years after the former crop of the ſame kind; becauſe, till then, the ground on which they grew will continue ſo rich as to make them run luxuriantly to haulm, in a manner inconſiſtent with the bearing of much fruit.

The common white pea does beſt on light ſandy land, or on a rich looſe ſoil. It is generally ſown with a broad caſt, and only harrowed in. Three buſhels of theſe peas are the uſual allowance of ſeed for an acre of ground; and the common time for ſowing them is about the latter end of March, or the beginning of April, on warm land: but a fortnight or three weeks later than this, will be early enough on cold ground. If ſown in drills, which is by far the beſt way, a buſhel and a half of ſeed will be full enough for an acre; and, when they are thus ſet regularly, the ground may be ſtirred with a hoe, to deſtroy the weeds, and earth up the plants, by which they will be greatly improved, and the peas will be much eaſier to cut in autumn, when they are ripe.

The green and the maple rouncivals require a ſtronger ſoil than the white, and ſhould be ſown a little later in the ſpring, alſo in drills, but farther aſunder, that is to ſay, at the diſtance of at leaſt two feet and a half, or three feet from each other, becauſe they are apt to grow rank, eſpecially in a wet ſeaſon. The ground between theſe rows ſhould be ſtirred two or three times with a hoe, which will not only deſtroy the weeds, but, by earthing up the peas, will greatly improve them, and alſo render the land fitter to receive whatever crop is put on it the following ſeaſon.

The gray and other large winter peas, as they are called, are ſeldom cultivated in gardens, becauſe they require a great deal of room. The beſt time for ſowing of theſe is about the beginning of March, when the weather is pretty dry; for if they are ſown in a very wet ſeaſon, they are apt to rot, eſpecially if the ground be cold. The diſtance between the rows ſhould here be at leaſt three feet, and theſe peas ſhould be ſown very thin in the rows: for if they are ſown too thick, their haulm will ſpread ſo as to fill the ground, and they will ramble over each other; by which means many of the plants will be rotted, and hindered from bearing. The common allowance of theſe large peas, is two buſhels to an acre: but that is certainly more than conſiſts with the very thin ſowing which is beſt for them.

The gray peas, in particular, thrive beſt on a ſtrong clayey land, in which they are commonly ſown under furrow. But by this method of ſowing, large peas, eſpecially, are always planted too thick, and at unequal depths, which prevent their coming up regularly. For this reaſon, among many others, all rank-growing plants, ſhould undoubtedly be ſown in drills, in which their ſeeds will be diſtributed much more equally in all reſpects.

If only a ſmall ſpot of ground be planted with theſe peaſe, a channel about two inches deep may be made with a hoe, guided by a line, the ſeeds may be dropped therein, and the earth may be drawn over them with a rake. By this means they will be covered equally, and with tolerable diſpatch, though not ſufficient for large fields, where, for this reaſon, a ſhallow furrow is commonly made with the plough, the ſeeds are ſcattered in it, and the earth is harrowed over them. The greateſt trouble then remaining is to keep the plants clear from weeds, and lay the earth up to their roots, which, in countries where labour is dear, is very expenſive to have done with the hand-hoe, but may be eaſily effected by drawing a horſe-hoe between the rows. This will entirely eradicate the weeds, ſtir the ſoil, render it mellow, and greatly promote the proper growth of the plants.

All ſorts of peaſe love limed or marled land: but when they are ſown late in the ſeaſon, the ſoil ſhould be ſtrong and moiſt; for they will then burn up and periſh in hot light land, or at leaſt not produce a crop worth taking off the ground. The authors of the *Maiſons Ruſtiques* approve of ſteeping them twenty-four hours in water before they are ſown, as well as to ſeparate the bad and faulty from the good, to enable theſe laſt to riſe the ſooner by being thus moiſtened. In general, the larger the pea is, and conſequently the later its uſual time of ripening, the earlier it ſhould be ſown, as experience has directed, and as Mr. Liſle rightly infers from the following curious obſervation, which, if duly attended to, may be of ſervice to huſbandmen and gardeners, and perhaps productive of ſome improvement in the culture of this plant.

In 1708, when the field and garden peaſe were near a foot high, he obſerved on the very top of them a purſe or neſt of buds of bloſſoms, lying in a bag together; and perceiving at the ſame time that there was no ſhew of bloſſoms putting forth at the lower joints, he concluded that the crops of peaſe would miſcarry that year, that they would

would not only have ſome top-kid, and that it would be vain to expect any on the lower joints, becauſe they are always forwarder in bloſſoming and kidding than the upper joints, and had not then the leaſt appearance of doing either. This afforded him ſome amuſements in reaſoning: but, not being ſatisfied, in a day or two after looked again into theſe upper pods or bags of bloſſoms, and, upon diſſecting a number of them, found ſometimes in a ſingle one near thirty bids of bloſſoms, two or three of which ſeemed uſually to have got the ſtart of the reſt, and to be bigger in bulk, and taller: moſt of the reſt ſeemed to lie in a huddle, without making any gradations: but as he had never ſeen, excepting the crown pea (which carries all its bloſſoms in a tuft at top, like a noſegay) other peaſe put forth above two bloſſoms and kids at top, which ſeldom come to any good, he ſuſpected that the many bloſſoms in this pod, muſt form the ſucceſſive gradations of bloſſoming joints, ariſing from that ſtock as from a common root, and that every bloſſom ſhot forth in order, as it grew forwarder than the reſt, while the main ſtem, advancing higher and higher, left behind the ſubaltern bloſſom of a lower joint. To be clear in this, he tied ſcarlet threads juſt under ſeveral of theſe pods, that he might know them again, and, as he expected, found in four or five days time a gradation of bloſſoms ariſing from joints with lobous leaves above his ſcarlet threads, and the pod of bloſſoms ſtill advanced on to the end, leaving behind farther joints of bloſſoms, till the whole ſtock was ſpent.

From this obſervation Mr. Liſle infers, 1. That by looking into this pod, or purſe of buds, while it is yet ſo much in its infancy as only to be viewed by a magnifying glaſs, we may judge what hopes there are of a future crop, provided the ſucceeding months prove favourable: and, 2. That we may learn from thence what ſort of peaſe to adapt to every ſort of ground: " but, continues he, before I enter on this part and uſe of the above-mentioned obſervation, I muſt, for the better underſtanding thereof, premiſe, that the farmers vary in their judgment in no one point ſo much as in the nature of the pea. Several ſorts of peaſe are commonly ſown within the limits of the ſame pariſh, and each of the perſons who ſow them generally has a great prejudice to any other ſort than that which he ſows, having perhaps been diſappointed of his expected return from other peaſe, when he has ſowed them, and being, for the ſame reaſon, equally diſpoſed as readily to alter his opinion of his laſt favourite kind; for the produce of a crop of peaſe is always very uncertain. But if the farmer would conſider, from the foregoing obſervation, how early or rath-ripe a pea is, or how late in ripening, in its nature; and that (as all its ſtock or power to put forth bloſſoms lies within the foliage of one pod) the art muſt reſult from thence, ſo to ſow the peaſe, in ſuch ground, and at ſuch time, that each ſort of pea, according to its nature, may, before autumn and cold weather come to check them, ſend forth all its gradations of joints or bloſſoms, ſo that none may become abortive for want of ſummer enough to enable nature to bring her embrios to maturity, and carry the bud-bloſſoms into kids; then it is apparent (as all large peaſe ripen late, and run to great haulm or ſtalks, and ſmall peaſe have leſs haulm and ripen earlier) that the great or late ripe peaſe ſhould be ſowed as early as the climate will permit; for thereby ſuch pea will get ſo forward as to have time to put forth all its gradations of bloſſoms and kids, and to perfect them before a rainy autumn comes, and puts a ſtop to farther vegetation. Again, great peaſe ought to be ſowed on a white, or ſome mixed land, not too groſs of juice; but not on a cold clay: for the moiſture of this laſt will keep feeding the haulm, and be inconſiſtent with the main deſign of ſowing them early, which is, that they may bring all their fruit to maturity in due time. The white or mixed mould muſt be in good heart; for otherwiſe it cannot maintain a great pea. On the other hand, it is evident from hence that a pea which ripens early ſhould be ſowed in a ſtrong feeding land, becauſe ſuch land will nouriſh it more vigorouſly, without danger of too great an increaſe of its haulm, which is naturally ſhort; and, notwithſtanding the coldneſs of the ſoil, there need be no doubt but that all the kids will ripen."

Moderate rains are of ſingular ſervice to peaſe while they grow, and particularly at their time of bloſſoming and filling up their pods; but a continuance of cold rain for many days, is perhaps as prejudicial as too much heat or drought. The blueiſh bloom upon their leaves, and their expending backward the two outermoſt and largeſt leaves of their bloſſoms, are undoubted ſigns of great health and vigour. Mr. Liſle is of opinion, that they neither ripen nor harden ſo well upon high grounds, as in the vallies, and conſequently that the former are not ſo fit for keeping as the latter.

Among the very few experiments on the culture of peaſe in field, the following, which M. Duhamel has given, afford a pretty ſtrong conviction of the benefits which ariſe from horſe-hoeing between their rows.

In April 1753, M. de Villiers, one of that ingenious gentleman's correſpondents, ſowed a ſmall field in Champagne, with peaſe, in double rows. Not being provided with a proper inſtrument to hoe the intermediate ſpaces, he made uſe of a narrow angular kind of ſhare, which ſtirred only three or four inches on the out ſide of the rows. Almoſt all the peaſe in his neighbourhood were deſtroyed that year by a kind of vermin called vine-fretters. His were hurt the leaſt of any; which was probably owing to the greater vigour of the plants, or the inſects being killed by the ſtirring of the ground. By a compariſon which he made of the produce of this ſpot, he found that it yielded ſix times as much as the ſame extent of the beſt land in the ſame country. " In a good year, ſays M. Duhamel, the difference would not have been ſo great; but ſtill this experiment ſhews that plants cultivated in the new or horſe-hoeing way, are better able to reſiſt the inclemencies of the ſeaſons, and other accidents, than thoſe which are cultivated according to the old method."

The next year, M. de Villiers, being provided with M. Duhamel's drill and horſe-hoe, ſowed peaſe again in rows, in ſome places two feet, and in others two feet and a half aſunder. But this diſtance was ſo narrow that it rendered the horſe-hoeing very difficult in many places, and quite impracticable in others. He was therefore obliged to contrive other means of ſtirring the ground, in which, notwithſtanding this, his peaſe flouriſhed extremely, and yielded more than any others on the very beſt land in the ſame diſtrict.

The ſame gentleman drilled peaſe again, in 1755, in a ſtrong heavy ſoil, in which no one had ever ventured to ſow any in the common huſbandry. They grew as high as if the ground had been ever ſo fit for them, and yielded half as much again as any ſown in the common way, beſides the ſaving in the ſeed, which in peaſe thus drilled, is about one half. They were ſown in double rows, with a ſpace about two feet and a half wide between the outmoſt rows of one range and the next outmoſt row of another, and this ſpace was ſtirred with the horſe-hoe.

When any particular ſorts of peaſe are intended for ſeed, they ſhould be carefully looked over whilſt in flower, in order to draw out all ſuch plants as are not of the right ſort; for there will always be, in every ſort, ſome roguiſh plants, as the gardeners term them, which, if left to mix, will degenerate the kind. As many rows as may be thought ſufficient to furniſh the deſired quantity of ſeed, ſhould then be marked out, and left till their pods turn brown and begin to ſpilt, when they ſhould immediately be gathered up, with the haulm; and if the huſbandman has not room to ſtack them till winter, they may be threſhed out as ſoon as they are dry, and put up in ſacks for uſe: but particular care ſhould be taken not to let theſe remain too long abroad after they are ripe, becauſe wet would rot them, and heat, after a ſhower of rain, would make their pods burſt in ſuch a manner that the greater part of their ſeeds would be loſt.

When peaſe are reaped, or hacked, as they call it in ſome parts of England, they are laid up in ſmall wads, and left in the field till their haulm and pods are dry: but during this time they ſhould be frequently turned, and raiſed as much as poſſible from the earth, that they may lie hollow for the wind to dry them, eſpecially when any rain happens to wet and beat them down. In Leiceſterſhire they ſet all their peaſe abroad in ſtacks, being perſuaded that they thence acquire a much better colour, than when houſed in a barn.

An ingenious farmer has obliged the public with the following method of preparing peaſe for hog-meat; and which we ſhall here give in his own words.

" A

"A few years ago, fays he, I had a plentiful crop of peafe on a ten acre piece, which lies near my houfe: when they were full podded and nearly ripe, I had them hooked in the ufual manner; but before I could get them in, there came a heavy fhower of rain, which wetted them through and through; and the dull heavy weather, with quent fhowers, which followed, prevented their drying for a confiderable time.

"I caufed the wads to be from time to time turned, to prevent the haulm from rotting; and at length a few days funfhine dried them enough to be inned; for as they lay hollow, the wind was greatly affiftant to the operation.

"Before I got them in, on examining fome of the pods, I found that the peafe were all fprouted to a confiderable length: this was what I had expected, as I gave my crop over for loft, till after a little recollection, as the weather ftill continued fine, I determined to threfh them in the field.

"This was accordingly done; and the corn, after it was caft and riddled to feparate it from the rubbifh, was dried on my malt-kiln.

"When this operation was over, I began to refleċt in what manner I fhould difpofe of my peafe, being fenfible that they could not be proper for feed, and ftanding no chance of difpofing of them to any advantage in the market.

"At length, as it was then a time of war, and of courfe there was a great demand for pork for the ufe of the navy, I determined to buy in a confiderable number of lean hogs, that I might by their means confume this crop on my own premifes, and in that manner make the moft of it.

"My expectations were more than anfwered, for I found, by repeated experience, that three bufhels of the peafe I have mentioned went nearly as far in fattening the hogs I bought, as four bufhels got in dry and hard in the manner ufually practifed.

"This difcovery I made feveral years ago, and it has turned out to my advantage; for, fince that time, I have been quite indifferent as to the weather in which my peafe are hooked, being rather better pleafed, as far as relates to them, with wet, than dry weather: but if the weather happens to be dry at the time they are ripe, I always caufe as many as I want for feeding my hogs, which are not a few in a year, to be regularly malted in the fame manner, nearly, as my barley: this management has, of late fucceeded very well with me, and I therefore intend to continue it.

"Befides feeding my hogs with thefe malted peafe, I have befides often given them to my horfes, with which they agree very well, and are heartening food.

"Turkeys will fatten apace on them alfo, and be fine meat.

"I have applied my malted peafe to many other ufes, which I have not, at prefent, time to enumerate: but were they only ufed for feeding hogs and horfes, it is ftill worth while to prepare fome in this manner every year." *Mufeum Rufticum, vol.* I. *page* 109.

PEASE-BOLT, peafe haulm.

PEAT, a fpecies of earth ufed in many countries for firing.

Under the article ASHES we have given fome account of the ufes of thofe made from peat; and fhall here add the obfervations of a very intelligent hufbandman, with regard to the value of thofe afhes, and the feveral crops to which they may be profitably employed as a manure.

"The more general, fays he, a manure is in its ufes, of fo much the more value is it to the farmer; and, of all forts of manures, perhaps afhes agree with the greateft variety of foils and crops: afhes, therefore, fhould, one would imagine, be had in univerfal requeft, for the purpofe of dreffing land; but the misfortune is, no great plenty can be procured, and the few that are to be got fetch a large price: this deters the farmer for making ufe of them often as manure.

"I muft, however, except one fort of afhes, which are on all accounts valuable; I mean peat or turf-afhes: thefe are, in moft places, eafy to be procured, coft no great matter, and have a wonderful effect on almoft every foil and crop. You may believe what I fay, as I have had many years experience of their good qualities.

"The fulphureous and faline particles with which thefe afhes abound, have a moft happy effect in promoting vegetation; and if ufed with difcretion, the increafe procured by them is truly wonderful.

"I fuppofe few of your readers will be at a lofs to know what peat or turf is, moft people having feen a kind of it burnt as fuel.

"The ordinary peat is dug from wet bogs and moraffes; but that which is of a much fuperior quality and virtue in its afhes, is dug from moory wettifh lands, which will bear cattle: as to the peat that is pared from the furface of heaths and commons, for firing for the poor cottagers, the afhes of it are of very little value, when compared with thofe above-mentioned.

"Peat is found in moft low grounds that lie betwixt hills, efpecially if timber has formerly ftood on the fpot. It lies at various depths, being often near the furface, and fometimes fix, eight, or ten feet deep, having a ftratum of black moory earth over it, fuch as is the foil of many of our low meadows near the banks of rivers: it fometimes even lies under a bed of gravel.

"Peat may be burnt, for the fake of procuring its afhes for manure, all the fummer feafon: as foon as it is dug, fome of it is mixed in a heap regularly difpofed with faggot wood, or other ready burning fuel: after a layer or two of it mixed in this manner, peat alone is piled up to complete the heap. A heap will confift of from one hundred to a thoufand loads.

"After fetting fire to it at a proper place, before on purpofe prepared, it is watched in the burning, and the great art is to keep in as much of the fmoke as poffible, provided that as much vent is left as will nourifh and feed the fire.

"Whenever a crack appears, out of which the fmoke efcapes, the labourer in that place lays on more peat; and if the fire flackens too much within, which may eafily be known by the heat on the outfide, the workman muft run a ftrong pole into the heap in as many places as is neceffary to fupply it with a quantity of frefh air. When managed in this manner, the work goes on as it fhould do. It is to be noticed, that when once the fire is well kindled, the heavieft rain does it no harm whilft it is burning.

"Having procured a fufficient quantity of afhes, the farmer's next care fhould be to apply them properly to ufe; and to do this, he muft be made well acquainted with the nature of the manure he is to lay on his land.

"All afhes are of a hot, fiery, cauftic nature; they muft therefore be ufed with caution. With refpect to peat-afhes, almoft the only danger proceeds from laying them on in too great quantities at improper feafons.

"Nothing can be better than peat-afhes for dreffing low damp meadows, laying to the quantity of from fifteen to twenty Winchefter bufhels on an acre: it is beft to fow them by hand, as they will then be more regularly fpread.

"This work fhould be done in January or February at lateft, that the afhes may be wafhed in towards the roots of the grafs by the firft rains that fall in the fpring.

"If they were fpread more forward in the year, and a fpeedy rain fhould not fucceed, being hot in their nature, they would be apt to burn up the grafs, inftead of doing it any fervice.

"It is to be remembered, that the damper and ftiffer the foil, the more peat-afhes fhould be laid on it; but in grafs lands the quantity fhould never exceed thirty Winchefter bufhels, and on light warm lands lefs than half that quantity is fully fufficient.

"On wheat crops thefe afhes are of the greateft fervice, but they muft be laid on with the utmoft difcretion. Were they to be fpread in any quantity before the winter, after the fowing the corn, they would make the wheat too rank, and do more harm than good; was the fpreading this manure, on the contrary, deferred till the fpring, the corn could not poffibly during the winter feafon be benefited by it. After due reflection and repeated experience, my method of management in this cafe is as follows:

"About the beginning of November, before the hard frofts fet in, I fow on every acre of my heavy clayey wheat land about eight Wincher bufhels of thefe afhes on my lighter

lighter warmer lands in wheat, I ſow only four buſhels at this ſeaſon.

" The winter-dreſſing is, I imagine, of great ſervice: trifling as the quantity may ſeem, it warms the roots of the plants, brings it moderately forward, preſerves its verdure, and diſpoſes it to get into a growing ſtate the firſt fine weather after Chriſtmas.

" About the latter end of February, or the beginning of March, on the above-mentioned heavy lands in wheat I beſtow another dreſſing of aſhes, by ſowing of them on every acre eight buſhels more: on my light lands, in this ſecond dreſſing, I allow only ſix buſhels.

" Theſe aſhes laid on in the ſpring are of the greateſt ſervice, without any probability of danger: if rain falls within a few days after the dreſſing is laid on, it is waſhed in, and has a happy effect on the ſucceeding crop, co-operating with the manure that was laid on in November: if, on the contrary, dry weather for a long continuance ſucceeds, the firſt winter-dreſſing has its full effect, and the quantity laid on in the ſpring is in fact ſo ſmall, that there is very little probability of its burning or hurting the crop.

" This method has ſucceeded very well with me, and I have no reaſon to think it can fail with any one elſe.

" This excellent manure is, I find, of great uſe in the turnep-huſbandry on many accounts, particularly as it much contributes to preſerve the young crop from being devoured by the fly.

" When I ſow my turneps, before I harrow in the ſeed, I have eight buſhels of theſe aſhes ſtrewed by hand on every acre, and when the plants ſhew their firſt leaves above ground, I ſow on every acre four buſhels more: by this management my crops ſeldom fail, when at the ſame time ſome of my neighbours ſow their turnep-land three or four times over.

" But one of the principal advantages derived from theſe aſhes I have not yet mentioned, which is the very great ſervice they are of to every kind of artificial paſture.

" Saintfoin receives great benefit from this manure, and ſo does clover, ray-graſs, and trefoil, provided it is laid on with diſcretion: the proper ſeaſon is about the month of February: the quantity muſt be regulated by the nature of the crop and ſoil; but, in my opinion, it ought ſcarcely in any inſtance to exceed thirty Wincheſter buſhels. Clover, with the help of this manure, grows with great luxuriance, inſomuch that I have often had two large crops of hay from the ſame field in a year, and good autumn feed afterwards.

" But the effect of it is moſt ſeen in tares or vetches, and on them it is I beſtow moſt of this manure, as they will bear it, being a very ſucculent plant. I had laſt ſummer a crop of tare-hay that was aſtoniſhing, by the help of theſe aſhes, being above three large loads on an acre. The field contained ſix acres; it was a dryiſh loam, and not very rich. In the beginning of February I cauſed ten buſhels, Wincheſter meaſure, to be ſtrewed on each acre: immediately after the firſt rains had waſhed them in, the ſame quantity was in like manner ſpread, and about the middle of March I beſtowed on each acre ſix buſhels more for the laſt dreſſing. I am fond of dividing my entire quantities, thinking my crops are thereby leſs expoſed to the danger of being burned, and the manure is beſides more gradual and laſting in its effects.

" My tares came on amazingly, but they run chiefly to haulm, which was what I wiſhed, not having any deſire of ſaving the ſeed, but intending to make the crop in hay: my only fear was, that it would rot on the ground before it was in a proper condition to cut; but this I luckily eſcaped, by the ſoil being tolerably dry, and by the fineneſs of the weather. It was ſo heavy in the ſwarth, that I was obliged to pay an extraordinary price for mowing it.

" I have obſerved above, that I was fearful my tares would have rotted on the ground before they were fit to cut; this was owing entirely to the invigorating quality of the aſhes, which by their ſalts, &c. promoted the growth of the plants even to luxuriance.

" Before I well knew the great fertilizing quality of theſe aſhes, I loſt, by improper management, a fine three acre piece of hog-peaſe. I laid on this field, ſoon after the peaſe came up, threeſcore Wincheſter buſhels of theſe aſhes at one dreſſing: this brought them forward a great pace, but at harveſt I found, to my grief, I had ſcarcely any corn, for I had overdone it in laying on ſo much, and the peaſe were run all to haulm.

" Ever ſince this accident I have declined uſing them as a common dreſſing for my peaſe; and this I have been the more induced to do, as, in ſeveral little experiments I have ſince made, I have found it extremely difficult to apportion the ſeveral quantities which ought to be laid on various ſoils when ſown with peaſe; for the quantity that has one year ſucceeded very well with me, has the next, owing to the difference of ſeaſons, on the ſame ſoil, in another part of the ſame field, totally diſappointed me; ſo that, for peaſe, I eſteem it a very critical manure, therefore very cautiouſly to be uſed.

" The effects of this manure will be viſible at leaſt three years, and it does not, like ſome others, leave the land in an impoveriſhed ſtate, when its virtues are exhauſted and ſpent.

" Peat-aſhes are not ſo certain a manure for barley and oats as for the winter-corn: for as theſe are quick growers, and occupy the land but a few months, this warm manure is often apt to puſh them forward too faſt, and make them run too much to coarſe ſtraw, yielding only a lean immature grain. Oats, however, are not ſo apt to be damaged by it as barley.

" To get a good crop of barley, I often ſow it after turneps, which have two light dreſſings of aſhes, in the manner above deſcribed.

" When the turneps are fed off, or drawn, I give the field, if the ſeaſon permits, a good ploughing: if they were fed off, the land will want no more aſhes; but if they were drawn, and either carried into another ground to feed ſheep, or given to my ſtall-fed oxen, I ſtrew on each acre, after this ploughing, five Wincheſter buſhels of aſhes, leaving them to be waſhed in by the firſt rain. In this manner I let the land lie till I give it the ſecond and laſt ploughing before it is ſown. The manure has by this management the deſired effect, and the barley generally produces full and heavy ears.

" When I ſow my barley after turneps, I give the land only two ploughings, becauſe the ſoil was before much looſened by the hoeings beſtowed on the turneps; but in other caſes I am fond of allowing three, and ſometimes four ploughings to my lands deſtined for barley; and I generally find it anſwer very well; for many years experience has convinced me, that upon a fine tilth barley always thrives beſt, and yields moſt: in fact, the crop is almoſt always governed by the condition of the land, and a well-tilled ſoil is leſs expoſed to danger in an untoward ſeaſon.

" Peat-aſhes approach, in their effects on the ſeveral crops on which they are laid, to coal-ſoot; but two-thirds of the quantity that is uſed of ſoot, will be ſufficient of the aſhes, as they are in a much ſtronger degree, impregnated with a vegetative power; and they are, beſides, in moſt places eaſier procured in quantities, and at a cheaper rate.

" It may poſſibly be objected, that this manure requires great nicety in the application: I allow it does; yet every intelligent farmer, who knows the nature and qualities of the ſoils of his ſeveral fields, will ſoon be able, with great preciſion, to judge how much he ought to lay on each acre: his chief care at firſt ſhould be not to overdo it; for therein conſiſts the principal danger; though, after all, theſe aſhes will, at the worſt, unleſs laid on in very great exceſs indeed, only occaſion the inexperienced farmer the perhaps partial loſs of a ſingle crop; for the ſucceeding year they will, in all probability, have a very ſalutary effect on the land, and ſometimes even repay the preceding loſs.

" When the error is in the exceſs, it is very eaſy for a farmer to avoid falling into it; for, independent of every other conſideration, the ſole view of leſſening his expences will, it is imagined, ſufficiently induce him to be attentive to this particular.

" When peat is burnt for the ſake of its aſhes in ſummer time, it is neceſſary that ſome care ſhould be taken to defend them from the too powerful influence of the ſun, air, dews, rains, &c. or great part of their virtue would be exhaled and exhauſted. If the quantity of aſhes procured is not very great, they may be eaſily put under cover in a barn, cart-lodge or hovel; but large quantities muſt neceſſarily, to avoid expence, be kept abroad; and when this is the caſe, they ſhould be ordered as follows.

" A dry ſpot of ground muſt be choſen; and on this the aſhes are to be laid in a large heap, as near as poſſible in the form of a cone ſtanding on its baſe, the top as ſharp pointed as poſſible: when this is done, let the whole be covered thinly over with a coat of ſoil, to defend the heap from the weather: the circumjacent earth, provided it is not too light and crumbly, will always ſerve for this purpoſe.

" When thus guarded, the heap may very ſafely be left till January or February, when it is in general the ſeaſon for ſpreading it: but, before it is uſed, it is always beſt to ſift the aſhes, that the cinders, ſtones, and half burnt turf, may be ſeparated from them.

" This may, perchance, by many be eſteemed an unneceſſary trouble; but experience, which is the beſt guide, has convinced me, that by this means I can better aſcertain the quantity that ought to be ſown on the ſeveral ſorts of land; for the ſmall powdered aſhes, being equal in quality, are of courſe equal in effect; whereas, when there has been any other mixture with them, the effect has often been greater or leſs than I could have wiſhed. Thus, when I mentioned the number of buſhels I ſtrew on an acre, it is always to be underſtood of ſifted aſhes: ſhould any farmer be inclined to try them rough as they are firſt produced after burning, the quantity to be allowed for an acre muſt be more in proportion to the mixture of other matter that is in them.

" Theſe peat-aſhes are almoſt, as I have already obſerved, a general manure ſuited to every ſoil. On cold clay they warm the too compact particles, diſpoſe it to ferment, crumble, and of courſe fertilize, and, in fine, not only aſſiſt it in diſcloſing and diſpenſing its great vegetative powers, but alſo bring to its aid a conſiderable proportion of ready prepared aliment for plants.

" On light lands theſe aſhes have a different effect: here the pores are too large to be affected, or farther ſeparated by the ſalts or ſulphur contained in them; but, being cloſely attached to the ſurfaces of the large particles, of which this earth is generally compoſed, this manure diſpoſes them, by means of its ſalts, to attract the moiſture contained in the air: by this operation, the plants which grow on theſe porous ſoils, are prevented from being ſcorched up and burnt; and if they want, which they generally do, more nouriſhment than the land is of itſelf capable of affording, this is readily and abundantly ſupplied by this uſeful manure.

" In large farms it is very uſual to ſee all the home-fields rich and well-mended by the yard-dung, &c. whereas the more diſtant lands are generally poor, impoveriſhed, and out of heart, for want of proper manure being applied in time.

" Whilſt the farmers depend almoſt entirely on their yard-dung, this cannot fail being the caſe; for dung is of very heavy carriage: they are willing, therefore, to drop it as near home as poſſible, being in this way able to do a great deal more work in the ſame ſpace of time: but would they once try the virtue of peat-aſhes, all their lands might be alike improved, though at a very conſiderable diſtance from the home-ſtall; for ſo few of them are required, and they are ſo light of carriage, that a ſingle tumbril will hold as many as ought, in moſt caſes, to be laid on two acres of land; by which means, when theſe aſhes are uſed as a dreſſing for the diſtant fields, it coſts the farmer leſs in carriage than does that of the ſtable-dung for his home-fields." *Muſeum Ruſticum, vol.* I. *page* 222.

PENNY-ROYAL, the name of an herb, that propagates itſelf very faſt by its numerous trailing branches, which faſten themſelves to the ground at every joint, and from thence put forth roots and new ſhoots. Nothing therefore is requiſite in order to its culture, but to cut off ſome of thoſe rooted branches, and to tranſplant them into other beds. This ſhould be done in September, that the young plants may have time to fix, and gather ſtrength before the winter comes on: for by this means they will yield a much larger crop the next ſummer, than they would do if removed in the ſpring. They ſhould be ſet, at leaſt, a foot aſunder every way, that they may have ſufficient room to grow in: for the roots of this plant multiply ſo exceedingly, that if planted at a ſmaller diſtance, they will meet together in the ſpace of a year, and afterwards ſoon rot one another in the winter.

Their favourite ſituation is moiſt, and ſomewhat ſhady; and if planted in ſuch places they will flouriſh amazingly. *Miller's Gard. Dict.*

PENNY-*earth*, a term uſed by the farmers for a hard, loamy, or ſandy earth, with a very large quantity of ſea ſhells intermixed in it; ſome of which being round and flat, and in ſome meaſure reſembling pieces of money, have occaſioned the earth's being called by this name. It is an earth not eaſily dug, but is uſually undermined with pickaxes, and then falls in large lumps; which, with the froſts, break to pieces, and leave the ſhells looſe. It is prepared by breaking and mixing well with water, and then makes very deſirable floors. The Jerſey combers comb-pots are alſo made of it, and the ſides and roofs of ovens are plaiſtered with it; and, being rightly managed, it combines into a flower almoſt as ſtrong as plaiſter of Paris. *Moreton's Northamptonſhire.*

PERRY, the name of a very pleaſant and wholeſome liquor extracted from pears, in the ſame manner as cyder is from apples. *See the article* CYDER.

The beſt pears for perry, or at leaſt the ſorts which have been hitherto deemed the fitteſt for making this liquor, are ſo exceſſively tart and harſh, that no mortal can think of eating them as fruit; for even hungry ſwine will not eat them, nay, hardly ſo much as ſmell to them. Of theſe the Boſbury pear, the Bareland pear, and the horſe pear, are the moſt eſteemed for perry in Worceſterſhire, and the ſquaſh pear, as it is called, in Glouceſterſhire; in both which counties, as well as in ſome of the adjacent parts, they are planted in the hedge-rows and moſt common fields.

There is this advantage attending pear trees, that they will thrive on land where apples will not ſo much as live, and that ſome of them grow to ſuch a ſize, that a ſingle pear tree, particularly of the Boſbury and the ſquaſh kind, has frequently been known to yield, in one ſeaſon, from one to four hogſheads of perry. The Boſbury pear is thought to yield the moſt laſting and moſt vinous liquor. The John pear, the Harpary pear, the Drake pear, the Mary pear, the Lullum pear, and ſeveral others of the harſheſt kinds, are eſteemed the beſt for perry, but the redder or more tawny they are, the more they are preferred. Pears, as well as apples, ſhould be full ripe before they are ground.

Dr. Beale, in his general advertiſements concerning cyder, ſubjoined to Mr. Evelyn's Pomona, diſapproves of Palladius's ſaying, that perry will keep during the winter, but that it turns four as ſoon as the weather begins to be warm; and gives, as his reaſons for being of a contrary opinion, that he had himſelf taſted at the end of ſummer, a very briſk, lively, and vinous liquor, made of horſe pears; that he had often tried the juice of the Boſbury pear, and found it both pleaſanter and richer the ſecond year, and ſtill more ſo the third, though kept only in common hogſheads, and in but indifferent cellars, without being bottled; and that a very honeſt, worthy, and ingenious gentleman in his neighbourhood aſſured him, as of his own experience, that it will keep a great while, and grow much the ſtonger for keeping, if put into a good cellar, and managed with due care. He imputes Palladius's error to his poſſibly ſpeaking of common eatable pears, and to the perry's having been made in a very hot country: but he would have aſcribed it to a more real cauſe, perhaps, had he pointed out the want of a thorough regular fermentation, to which it appears plainly that the ancients were entire ſtrangers; for all their vinous liquors were medicated by boiling, before they were laid up in order to be kept. *See the article* CYDER.

PHEASANT, a bird ſo nearly allied to our common poultry, that it would naturally appear a very eaſy thing to breed them up from young; but the proper food of them is not ſufficiently enquired into. Though they eat corn when full grown and in health, yet they have recourſe in their young ſtate, and when ſick, to another ſort of food, preying

preying on ſeveral inſects, and that in a very voracious manner.

The young pheaſants and partridges prey upon ants; and they will never ſucceed with us, if they have not a proper quantity of ants to have recourſe to, as ſoon as they leave their rooſt in a morning. When muſty corn, or want of due care in cleaning their houſes, has made them ſick, a repaſt of ants will often recover them. When that fails, they may be offered millepedes or earwigs, or both together, which will always do much better than either ſingly. To this medicine muſt be added a proper care that their common food of corn be very ſweet, their habitation kept nicely clean, and their water ſhifted twice a day. They muſt not be let out of the houſe in a morning till the dew is off the ground; and after ſun-ſet they muſt be immediately taken in again: in the heat of the day they muſt be allowed to baſk in the ſun in a dry ſandy place. With theſe regulations the birds of this kind will ſucceed much better than they uſually do. The pheaſant is a bird of a ſullen diſpoſition, and, when the coupling time is over, there are ſeldom found more than one in a place. *Philoſ. Tranſ.* Nº 23.

PIGEON, the name of a well known bird, and of which here are two kinds, the wild and the tame; the latter differ from the former only in bigneſs and familiarity: the wild uſually perch upon trees, being ſeldom ſeen on the ground. Pigeons are of various ſorts, ſuch as carriers, powters, runts, turbets, &c. *See* CARRIERS, &c.

There are two ſeaſons when you may eaſily procure a ſufficient ſtock of pigeons, viz. May and Auguſt: for at theſe ſeaſons there are a great number of young pigeons, which may then be purchaſed very reaſonably.

PIGEON HOUSE, a houſe erected full of holes within for the keeping, breeding, &c. of pigeons, otherwiſe called a dove-cote.

Any lord of a manor may build a pigeon-houſe on his land, but a tenant cannot do it without the lord's licence. When perſons ſhoot at or kill pigeons within a certain diſtance of the pigeon-houſe, they are liable to pay a forfeiture.

In order to erect a pigeon-houſe to advantage, it will be neceſſary, in the firſt place, to pitch upon a convenient ſituation, of which none is more proper than the middle of a ſpacious court-yard, becauſe pigeons are naturally of a timorous diſpoſition, and the leaſt noiſe they hear frightens them. With regard to the ſize of the pigeon-houſe, it muſt depend entirely upon the number of birds intended to be kept; but it is better to have it too large than too little; and as to its form, the round ſhould be preferred to the ſquare ones; becauſe rats cannot ſo eaſily come at them in the former as in the latter. It is alſo much more commodious; becauſe you may, by means of a ladder turning upon an axis, eaſily viſit all the neſts in the houſe, without the leaſt difficulty; which cannot ſo eaſily be done in a ſquare-houſe.

In order to hinder rats from climbing up the outſide of the pigeon-houſe, the wall ſhould be covered with tin plates to a certain height, about a foot and a half will be ſufficient; but they ſhould project out three or four inches at the top, to prevent their clambering any higher.

The pigeon-houſe ſhould be placed at no great diſtance from water, that the pigeons may carry it to their young ones; and their carrying it in their bills will warm it, and render it more wholeſome in cold weather.

The boards that cover the pigeon-houſe ſhould be well joined together, ſo that no rain may penetrate through it. And the whole building ſhould be covered with hard plaſter, and white-waſhed within and without, white being the moſt pleaſing colour to pigeons. There muſt be no window, or other opening, in the pigeon-houſe to the eaſtward; theſe ſhould always face the ſouth, for pigeons are very fond of the ſun, eſpecially in winter.

The neſts or covers in a pigeon-houſe, ſhould conſiſt of ſquare holds made in the walls of a ſize ſufficient to admit the cock and hen to ſtand in them. The firſt range of theſe neſts ſhould not be leſs than four feet from the ground, that the wall underneath being ſmooth, the rats may not be able to reach them. Theſe neſts ſhould be placed in quincunx order, and not directly over one another. Nor muſt they be continued any higher than within three feet of the top of the wall: and the upper row ſhould be covered with a board projecting a conſiderable diſtance from the wall, for fear the rats ſhould find means to climb the outſide of the houſe.

M. Duhamel thinks that pigeons neither feed upon the green corn, nor have bills ſtrong enough to ſearch for its ſeeds in the earth; but only pick up the grains that are not covered, which would infallibly become the prey of other animals, or be dried up by the ſun. "From the time of the ſprouting of the corn, ſays he, pigeons live chiefly upon the ſeeds of wild uncultivated plants, and therefore leſſen conſiderably the quantity of weeds that would otherwiſe ſpring up; as will appear from a juſt eſtimate of the quantity of grain neceſſary to feed all the pigeons of a well-ſtocked dove-houſe." But Mr. Worlidge and Mr. Liſle alledge facts in ſupport of the contrary opinion. The latter relates, that a farmer in his neighbourhood aſſured him he had known an acre ſowed with peas, and rain coming on ſo that they could not be harrowed in, every pea was fetched away in half a day's time by pigeons: and the former ſays, "It is to be obſerved, that where the flight of pigeons falls, there they fill themſelves and away, and return again where they firſt roſe, and ſo proceed over a whole piece of ground, if they like it. Although you cannot perceive any grain above the ground, they know how to find it. I have ſeen them lie ſo much upon a piece of about two or three acres ſown with peas, that they devoured at leaſt three parts in four of the ſeed, which, I am ſure, could not be all above the ſurface of the ground. That their ſmelling is their principal director, I have obſerved; having ſown a ſmall plat of peas in my garden, near a pigeon-houſe, and covered them ſo well that not a pea appeared above ground. In a few day, a parcel of pigeons were hard at work in diſcovering this hidden treaſure; and in a few days more I had not above two or three peas left out of about two quarts that were planted; for what they could not find before, they found when the buds appeared, notwithſtanding they were hoed in, and well covered. Their ſmelling alone directed them, as I ſuppoſed, becauſe they followed the ranges exactly. The injury they do at harveſt on the peas, vetches, &c. is ſuch that we may rank them among the greateſt enemies the poor huſbandman meets withal; and the greater, becauſe he may not erect a pigeon-houſe, whereby to have a ſhare of his own ſpoils; none but the rich being allowed this privilege, and ſo ſevere a law being alſo made to protect theſe winged thieves, that a man cannot encounter them, even in defence of his own property. You have therefore no remedy againſt them, but to affright them away by noiſes, or ſuch like. You may, indeed, ſhoot at them; but you muſt not kill them; or you may, if you can, take them in a net, cut off their tails, and let them go; by which means you will impound them: for when they are in their houſes, they cannot bolt or fly out of the tops of them, but by the ſtrength of their tails, after the thus weakening of which, they remain priſoners at home."

Mr. Worlidge's impounding the pigeons reminds me of a humourous ſtory of a gentleman who, upon a neighbouring farmer's complaining to him, that his pigeons were a great nuiſance to his land, and did ſad miſchief to his corn, replied jokingly, Pound them, if you catch them treſpaſſing. The farmer, improving the hint, ſteeped a parcel of peas in an infuſion of coculus indicus, or ſome other intoxicating drug, and ſtrewed them upon his grounds. The pigeons ſwallowed them, and ſoon remained motionleſs on the field: upon which the farmer threw a net over them, incloſed them in it, and carried them to an empty barn, from whence he ſent the gentleman word that he had followed his directions with regard to the pounding of his pigeons, and deſired him to come and releaſe them.

PIGGIN, a little pail or tub, with an erect handle.

PIKE, a name given in ſome counties to what is generally called a fork, uſed for carrying ſtraw, &c. from the barn, cocking of barley, &c.

PINE, the name of a foreſt tree, of which there are various ſpecies, but two only that deſerve cultivating; namely, the Scotch-pine, and the white pine, commonly called in England lord Weymouth's, or New England pine.

The

The Scotch-pine, ſo called from its growing naturally on the mountains of Scotland, is the tree that affords the red or yellow deal, which is the moſt durable of any of the kinds yet known. The leaves of this tree are pretty broad and ſhort, of a greyiſh colour, growing two out of each ſheath; the cones are ſmall, pyramidal, and end in narrow points; they are of a light colour, and the ſeeds are ſmall.

This ſort grows well upon almoſt every ſoil; I have planted numbers of the trees upon peat bogs, where they have made great progreſs. I have alſo planted them in clay, where they have ſucceeded far beyond expectation; and upon ſand, gravel, and chalk, they likewiſe thrive as well; but as they do not grow near ſo faſt upon gravel and ſand, as upon moiſt ground, ſo the wood is much preferable; for thoſe trees which have been cut down upon moiſt ſoils, where they have made the greateſt progreſs, when they have been ſawn out into boards, have not been valuable, the wood has been white, and of a looſe texture; whereas thoſe which have grown upon dry gravelly ground, have proved nearly equal to the beſt foreign deals; and I doubt not but thoſe plantations, which of late years have been made of theſe trees, will, in the next age, not only turn greatly to the advantage of their poſſeſſors, but alſo become a national benefit.

The white pine is one of the talleſt trees of all the ſpecies, often growing a hundred feet high, as I have been credibly informed. The bark of this tree is very ſmooth and delicate, eſpecially when young; the leaves are long and ſlender, five growing out of each ſheath; the branches are pretty cloſely garniſhed with them, ſo make a fine appearance; the cones are long, ſlender, and very looſe, opening with the firſt warmth of the ſpring: ſo that if they are not gathered in winter, the ſcales open and let out the ſeeds. The wood of this ſort is eſteemed for making of maſts for ſhips; it is in England called lord Weymouth's, or New England pine, as hath been already obſerved. As the wood of this tree was generally thought of great ſervice to the navy, there was a law made in the ninth year of queen Anne, for the preſervation of the trees, and to encourage their growth in America; and it is within forty years paſt theſe trees began to be propagated in England in any plenty, though there were ſome large trees of this ſort growing in two or three places long before, particularly at lord Weymouth's, at Longleet, Sir Wyndham Knatchbull's in Kent; and it has been chiefly from the ſeeds of the latter that the much greater number of theſe trees now in England have been raiſed; for although there has annually been ſome of the ſeeds brought from America, yet thoſe have been few in compariſon to the produce of the trees in Kent: many of the trees, which have been raiſed from the ſeeds of thoſe trees, now produce plenty of the ſeeds, particularly thoſe in the gardens of the late duke of Argyle at Whitton, which annually produce large quantities of cones, which his grace, when living, moſt generouſly diſtributed to all the curious.

All the ſorts of pines are propagated by ſeeds, which are produced in hard woody cones; the way to get the ſeeds out of theſe cones, which are cloſe, is to lay them before a gentle fire, which will cauſe the cells to open, and then the ſeeds may be eaſily taken out. If the cones are kept entire, the ſeeds will remain good ſome years, ſo that the ſureſt way to preſerve them, is to let them remain in the cones, until the time for ſowing the ſeeds: if the cones are kept in a warm place in ſummer, they will open, and emit the ſeeds; but if they are not expoſed too much to heat, many of the ſorts will remain entire ſome years, eſpecially thoſe which are cloſe and compact; and the ſeeds, which have been taken out of cones of ſeven years old, have grown very well, ſo that theſe may be tranſported to any diſtance, provided the cones are well ripened, and properly put up.

The beſt time for ſowing the ſeeds of pines, is about the end of March; when the ſeeds are ſown, the place ſhould be covered with nets to keep off birds, otherwiſe, when the plants begin to appear with the huſk of the ſeed on their tops, the birds will pick off the heads of the plants, and deſtroy them.

Where the quantity of ſeeds to be ſown is not great, it will be a good way to ſow them either in boxes or pots filled with light loamy earth, which may be removed from one ſituation to another, according to the ſeaſon of the year; but if there is a large quantity of the ſeeds, ſo as to require a good ſpace to receive them, they ſhould be ſown on an eaſt or north-eaſt border, where they may be ſcreened from the ſun, whoſe heat is very injurious to theſe plants at their firſt appearance above ground. Thoſe ſeeds, which are ſown in pots or boxes, ſhould alſo be placed in a ſhady ſituation, but not under trees; and if they are ſcreened from the ſun with mats, at the time when the plants firſt come up, it will be a good method to preſerve them.

When the plants appear, they muſt be conſtantly kept clean from weeds, and, in very dry ſeaſons, if they are now and then gently refreſhed with water, it will forward their growth; but this muſt be done with great care and caution, for if they are haſtily watered, it will waſh the tender plants out of the ground, or lay them down flat, which often rots their ſhanks; and when this is too often repeated, it will have the ſame effect; ſo that unleſs it is judiciouſly performed, it will be the beſt way to give them none, but only ſcreen them from the ſun.

If the plants come up too cloſe, it will be a good method to thin them gently about the beginning of July. The plants, which are drawn up, may then be planted on other beds, which ſhould be prepared ready to receive them, for they ſhould be immediately planted as they are drawn up, becauſe their tender roots are ſoon dried and ſpoiled at this ſeaſon of the year. This work ſhould be done, if poſſible, in cloudy or rainy weather, and then the plants will draw out with better roots, and will ſoon put out new fibres again; but if the weather ſhould prove clear and dry, the plants ſhould be ſhaded every day from the ſun with mats, and now and then gently refreſhed with water. In drawing up of the plants, there ſhould be great care taken not to diſturb the roots of the plants left remaining in the ſeed-beds, &c. ſo that if the ground be hard, the beds ſhould be well watered ſome time before the plants are thinned, to ſoften and looſen the earth; and if, after the plants are drawn out, the beds are again gently watered to ſettle the earth to the roots of the remaining plants, it will be of great ſervice to them; but it muſt be done with great care, ſo as not to waſh out their roots, or lay down the plants. The diſtance, which ſhould be allowed theſe plants, is four ur five inches row from row, and three inches in the rows.

In theſe beds the plants may remain till the ſpring twelve-months after, by which time they will be fit to tranſplant where they are to remain for good; for the younger plants are, when planted out, the better they will ſucceed; for although ſome ſorts will bear tranſplanting at a much greater age, yet young plants planted at the ſame time will in a few years overtake the large ones, and ſoon outſtrip them in their growth; and there is an advantage in planting young, by ſaving the expence of ſtaking, and much watering, which large plants require. I have ſeveral times ſeen plantations of ſeveral ſorts of pines, which were made of plants ſix or ſeven feet high, and at the ſame time others of one foot high planted between them, which in ten years were better trees than the old ones, and much more vigorous in their growth; but if the ground, where they are deſigned to remain, cannot be prepared by the time before mentioned, the plants ſhould be planted out of the beds into a nurſery, where they may remain two years, but not longer; for it will be very hazardous in removing theſe trees at a greater age.

The beſt ſeaſon to tranſplant theſe pines, is about the latter end of March, or the beginning of April, juſt before they begin to ſhoot; for although the Scotch pine, and ſome of the moſt hardy ſorts, may be tranſplanted in winter, eſpecially when they are growing in ſtrong land, where they may be taken up with balls of earth to their roots, yet this is what I would not adviſe for common practice, having frequently ſeen it attended with bad conſequences; but thoſe which are removed in the ſpring rarely fail.

Where theſe trees are planted in expoſed ſituations, they ſhould be put pretty cloſe together, that they may ſhelter each other, and, when they have grown a few years, part of the plants may be cut down to give room

for

for the others to grow; but this muſt be gradually performed, leſt by too much opening the plantation at once, the air ſhould be let in among the remaining trees with too great violence, which will ſtop their growth.

Wherever large plantations are deſigned to be made, the beſt method will be to raiſe the plants either upon a part of the ſame land, or as near to the place as poſſible, and alſo upon the ſame ſort of ſoil; a ſmall piece of ground will be ſufficient to raiſe plants enough for many acres; but, as the plants require ſome care in their firſt raiſing, if the neighbouring cottagers, who have many of them ſmall incloſures adjoining to their cottages; or, where this is wanting, a ſmall incloſure ſhould be made them for the purpoſe of raiſing the plants, and they be furniſhed with the ſeeds and directions for ſowing them, and managing the young plants, till they are fit for tranſplanting, the women and children may be uſefully employed in this work, and the proprietors of land agreeing with them to take their plants, when raiſed, at a certain price, it would be a great benefit to the poor, and hereby they would be engaged to have a regard for the plantations when made, and prevent their being deſtroyed.

The Scotch pine, as was before obſerved, being the hardieſt of all the kinds, and the wood of it the moſt uſeful, is the ſort which beſt deſerves care. This will thrive upon the moſt barren ſands, where ſcarce any thing elſe except heath and furze will grow; ſo that there are many thouſand acres of ſuch land lying convenient for water carriage, which at preſent is of little benefit to any body, that might, by plantations of theſe trees, become good eſtates to their proprietors, and alſo a national benefit; and as the legiſlators have taken this into their conſideration, and already paſſed ſome laws for the encouraging theſe plantations, as alſo for their preſervation and ſecurity; ſo it may be hoped that this will be undertaken by the gentlemen who are poſſeſſed of ſuch lands in all the different parts of the kingdom, with proper ſpirit; for although they may not expect to receive much profit from theſe plantations in their own time, yet their ſucceſſors may with large intereſt, and the pleaſure which theſe growing trees will afford them, by beautifying the preſent dreary parts of the country, will in ſome meaſure recompenſe them for their trouble and expence, and by creating employment for the poor, leſſen thoſe rates which are now, in many parts of England, ſcarce to be borne.

The expence of making theſe plantations is what moſt people are afraid of, ſo would not engage in it; but the greateſt of the expence is that of fencing them from the cattle, &c. for the other is trifling, as there will be no neceſſity for preparing the ground to receive the plants, and the charge of planting an acre of land with theſe plants will not be more than thirty ſhillings where labour is dear, excluſive of the plants, which may be valued at forty ſhillings more. I have planted many acres of land with theſe trees, which was covered with heath and furze, and have only dug holes between to put in the plants, and afterward laid the heath or furze, which was cut upon the ſurface of the ground about their roots, to prevent the ground drying, and few of the plants have failed. Theſe plants were moſt of them four years old from ſeed, nor was there any care taken to clean the ground afterward, but the whole left to ſhift, and in five or ſix years the pines have grown ſo well, as to over-power the heath and furze, and deſtroy it.

The diſtance which I have generally planted theſe plants in all large open ſituations, was about four feet, but always irregular, avoiding planting in rows as much as poſſible; and in the planting, the great care is not to take up the plants faſter than they can be planted, ſo that ſome men have been employed in digging up of the plants, while others were planting. Thoſe who take up the plants, muſt be looked after to ſee they do not tear off their roots, or wound their bark; and as faſt as they are taken up, their roots ſhould be covered to prevent their drying, and put into their new quarters as ſoon as poſſible. In planting them, care ſhould be had to make the holes large enough for their roots, as alſo to looſen and break the clods of earth, and put the fineſt immediately about their roots, then to ſettle the earth gently with the foot to the roots of the plant. If theſe things are duly obſerved, and a proper ſeaſon choſen for performing it, there will be very little hazard of their ſucceeding; but I have ſeen ſome plantations made with plants, which were brought from a great diſtance, and had been ſo cloſely packed up, as to cauſe a heat, whereby moſt of the plants within had their leaves changed yellow, and few of them have grown, which has diſcouraged others from planting, not knowing the true cauſe of their failure.

After the plantations are made, the only care they require for five or ſix years, will be to ſecure the plants from cattle, hares, and rabbits; for if theſe are admitted to them, they will make great deſtruction in a ſhort time, for if the branches are gnawed by hares or rabbits, it will greatly retard the growth of the plants, if not deſtroy them.

In about five or ſix years after planting, the branches of the young trees will have met, and begin to interfere with each other, therefore they will require a little pruning; but this muſt be done with great caution. The lower tier of branches only ſhould be cut off; this ſhould be performed in September, at which time there will be no danger of the wounds bleeding too much, and the turpentine will harden over the wounds as the ſeaſon grows cold, ſo will prevent the wet from penetrating of them. Theſe branches ſhould be cut off cloſe to the ſtem of the plants, and care ſhould be taken in the doing of this, not to break any of the remaining branches of the young trees. This work ſhould be repeated every other year, at each time taking off only the lower tier of branches; for if the plants are much trimmed, it will greatly retard their growth, as it does in general that of all trees; but as theſe trees never put out any new ſhoots where they are pruned, ſo they ſuffer more from amputation than thoſe which do.

In about twelve or fourteen years theſe will require no more pruning, for their upper branches will kill thoſe below where they have not air; but ſoon after this, if the plants have made good progreſs, it may be neceſſary to thin them; but this ſhould be gradually performed, beginning in the middle of the plantation firſt, leaving the outſide cloſe to ſcreen thoſe within from the cold, ſo by degrees coming to them at laſt, whereby thoſe, which were firſt thinned, will have had time to get ſtrength, ſo will not be in danger of ſuffering from the admiſſion of cold air. When theſe plantations are thinned, the trees ſhould not be dug up; but their ſtems cut off cloſe to the ground, for their roots never ſhoot again, but decay in the earth, ſo there can no harm ariſe by leaving them, and hereby the roots of the remaining plants are not injured. The trees which are now cut, will be fit for many purpoſes; thoſe which are ſtrait, will make good putlocks for the bricklayers, and ſerve for ſcaffolding poles, ſo that there may be as much made by the ſale of theſe, as will defray the whole expence of the planting, and probably intereſt for the money into the bargain.

As the upright growth of theſe trees renders their wood the more valuable, they ſhould be left pretty cloſe together, whereby they will draw each other up, and grow very tall. I have ſeen ſome of theſe trees growing, whoſe naked ſtems have been more than ſeventy feet high, and as ſtraight as a walking cane, and from one of theſe trees there were as many boards ſawed, as laid the floor of a room near twenty feet ſquare. If theſe trees are left eight feet aſunder each way, it will be ſufficient room for their growth; therefore, if at the firſt thinning a fourth part of the trees are taken away, the other may ſtand twelve or fourteen years longer, by which time they will be of a ſize for making ladders, and ſtandards for ſcaffolding, and many other purpoſes; ſo that from this ſale, as much may be made, as to not only pay the remaining part of the expence of planting, if any ſhould be wanting in the firſt, but rent for the land with intereſt, and the ſtanding trees for fortunes of younger children. This may be demonſtrated by figures, and there has been ſeveral examples of late years, where the profits have greatly exceeded what is here mentioned. *Miller's Gard. Dict.*

Pitch, tar, reſin, and turpentine, are all made from theſe trees by a very familiar proceſs. In the ſpring time, when the ſap is moſt free in running, they pare off the bark of the pine-tree, to make the ſap run down into

a hole

a hole which they cut at the bottom to receive it: in the way, as it runs down, it leaves a white matter like cream, but a little thicker: this is very different from all the kinds of refin and turpentine in ufe, and it is generally fold to be ufed in the making of flambeaux, inftead of white bees wax. The matter that is received in the hole at the bottom, is taken up with ladles, and put in a large bafket; a great part of this immediately runs through, and this is the common turpentine. This is received into ftone or earthen pots, and is ready for fale. The thicker matter, which remains in the bafket, they put into a common alembic, adding a lage quantity of water; they diftil this as long as any oil is feen fwimming upon the water; this oil they feparate from the furface in large quantities, and this is the common oil or fpirit of turpentine; the remaining matter, at the bottom of the ftill, is common yellow refin. When they have thus obtained all that they can from the fap of the tree, they cut it down, and, hewing the wood into billets, they fill a pit dug in the earth with thefe billets, and, fetting them on fire, there runs from them, while they are burning, a black thick matter; this naturally falls to the bottom of the pit, and this is the tar. The top of the pit is covered with tiles, to keep in the heat; and there is at the bottom a little hole, out at which the tar runs like oil: if this hole be made too large, it fets the whole quantity of the tar on fire; but, if fmall enough, it runs quietly out.

The tar, being thus made, is put up in barrels, and, if it be to be made into pitch, they put it into large boiling veffels, without adding any thing to it: it is then fuffered to boil a while, and, being then let out, is found, when cold, to be what we call pitch. *Phil. Tranf.* Numb. 243.

PINE-APPLE, the name of a very curious plant, of which Tournefort has enumerated three, and Mr. Miller fix, fpecies.

The pine-apple, fo called from its refembling the cones of the European pine-tree, is a native of the torrid zone; but has for fome years been cultivated here in tolerable perfection. The plant that produces it nearly refembles the aloe, except that the leaves of the pine-apple are much thinner, longer, and moft of them near the ground ftand in a horizontal pofition; but as they approach nearer the fruit, diminifh in length, and become lefs expanded. The plant, in its native climate, feldom grows to above three feet in height, and terminates in a flower refembling a lilly, but of fo elegant a crimfon as to dazzle the eye. The pine-apple makes its firft appearance in the center of the flower, about the fize of a nut; and as this increafes, the luftre of the flower fades, and the leaves expand themfelves to make room for it, and ferve it at once for a bafe and ornament. On the top of the apple itfelf is a crown or tuft of leaves, like thofe of the plant, and of a very lively blue-green colour. This crown grows in proportion with the fruit, till both have attained their utmoft magnitude. As foon as this happens the fruit begins to ripen, and its green changes into a bright ftraw-colour; during this alteration of colour, the fruit exhales fuch a fragrancy as to difcover it, though concealed from fight. While it continues to grow, it fhoots out, on all fides, little thorns or prickles, which, as it approaches towards maturity, dry and foften, fo that the fruit is gathered without the leaft inconvenience.

The fingularities that concenter in this product of nature cannot fail of ftriking a contemplative mind with admiration. The crown which formed a kind of apex, while growing, becomes itfelf a new plant; and the ftem, after the fruit is cut, dies away, as if fatisfied with having anfwered the intention of nature in fuch a production; but the roots fhoot forth frefh ftalks, or fuckers, for the farther increafe of fo váluable a fpecies.

Thefe plants are propagated by planting the crowns which grow on the fruit, or the fuckers which are produced either from the plants, or under the fruit, either of which I have found to be equally good; although, by fome perfons, the crown is thought preferable to the fuckers, as fuppofing it will produce fruit fooner than the fuckers, which is certainly a miftake; for by conftant experience I find the fuckers (if equally ftrong) will fruit as foon, and produce as large fruit as the crowns.

The fuckers and crowns muft be laid to dry in a warm place for four or five days, or more (according to the moifture of the part which adhered to the old plant or fruit) for, if they are immediately planted, they will rot. The certain rule of judging when they are fit to plant, is by obferving if the bottom is healed over, and become hard; for, if the fuckers are drawn off carefully from the old plants, they will have a hard fkin over the lower part; fo need not lie fo long as thofe which by accident may have been broken. But whenever a crown is taken from the fruit, or the fuckers from the old plants, they fhould be immediately divefted of their bottom leaves, fo high as to allow depth for their planting; fo that they may be thoroughly dry and healed in every part, left, when they receive heat and moifture, they fhould perifh, which often happens when this method is not purfued. If thefe fuckers or crowns are taken off late in the autumn, or during the winter, or early in the fpring, they fhould be laid in a dry place in the ftove, for a fortnight or three weeks before they are planted; but in the fummer-feafon they will be fit for planting in three or four days.

As to the earth in which thefe fhould be planted, if you have a rich good kitchen-garden mould, not too heavy, fo as to detain the moifture too long, nor over light and fandy, it will be very proper for them without any mixture: but, where this is wanting, you fhould procure fome frefh earth from a good pafture, which fhould be mixed with about a third part of rotten neats-dung, or the dung of an old melon or cucumber-bed, which is well confumed. Thefe fhould be mixed fix or eight months at leaft before they are ufed; but if it be a year, it will be the better; and fhould be often turned, that their parts may be the better united, as alfo the clods well broken. This earth fhould not be fcreened very fine; for, if you only clear it of the great ftones, it will be better for the plants than when it is made too fine. You fhould always avoid mixing any fand with the earth, unlefs it be extremely ftiff; and then it will be neceffary to have it mixed at leaft fix months or a year before it is ufed; and it muft be frequently turned, that the fand may be incorporated in the earth, fo as to divide its parts: but you fhould not put more than a fixth part of fand; for too much fand is very injurious to thefe plants.

In the fummer feafon, when the weather is warm, thefe plants muft be frequently watered; but you fhould not give them large quantities at a time. You muft alfo be very careful that the moifture is not detained in the pots by the holes being ftopped; for that will foon deftroy the plants. If the feafon is warm, they fhould be watered every other day; but, in a cool feafon, twice a weak will be often enough: and, during the fummer feafon, you fhould once a weak water them gently all over their leaves, which will wafh the filth off them, and thereby greatly promote the growth of the plants. There are fome perfons who frequently fhift thefe plants from pot to pot; but this is by no means to be practifed by thofe who propofe to have large well-flavoured fruit; for, unlefs the pots be filled with the roots, by the time the plants begin to fhew their fruit, they commonly produce fmall fruit, which have generally large crowns on them; fo that the plants will not require to be new potted oftener than twice in a feafon; the firft time fhould be about the end of April, when the fuckers and crowns of the former year's fruit (which remained all the winter in thofe pots in which they were firft planted) fhould be fhifted into larger pots, i. e. thofe which were in half-penny or three farthings pots, fhould be put into penny, or at moft three halfpenny pots, according to the fize of the plants; for you muft be very careful not to over-pot them, nothing being more prejudicial to thefe plants. The fecond time for fhifting them is towards the latter end of Auguft, or the beginning of September, when you fhould fhift thefe plants which are of a proper fize for fruiting the following fpring into two-penny pots, which are full large enough for any of thofe plants. At each of thefe times of fhifting the plants, the bark-bed fhould be ftirred up, and fome new bark added, to raife the bed up to the height it was at firft made; and, when the pots are plunged again into the bark-bed, the plants ſhould be watered gently all over the leaves, to waſh off the filth, and to ſettle the earth to the roots of the plants. If the bark-bed be well ſtirred, and a quantity of good freſh bark added to the bed, at this latter ſhifting, it will be of great ſervice to the plants; and they may remain in the tan until the beginning of November, or ſometimes later, according to the mildneſs of the ſeaſon, and will not require any fire before that time. During the winter ſeaſon theſe plants will not require to be watered oftener than every third or fourth day, according as you find the earth in the pots to dry: nor ſhould you give them too much at a time; for it is much better to give them a little water often, than to over-water them, eſpecially at that ſeaſon. You muſt obſerve never to ſhift thoſe plants which ſhew their fruit into other pots; for, if they are removed after the fruit appears, it will ſtop the growth, and thereby cauſe the fruit to be ſmaller, and retard its ripening; ſo that many times it will be October or November before the fruit is ripe: therefore you ſhould be very careful to keep the plants in a vigorous growing ſtate from the firſt appearance of the fruit, becauſe upon this depends the goodneſs and ſize of the fruit; for, if they receive a check after this, the fruit is generally ſmall and ill-taſted.

The method of judging when the fruit is ripe, is by the ſmell, and from obſervation; for, as the ſeveral ſorts differ from each other in the colour of their fruit, that will not be any direction when to cut them; nor ſhould they remain ſo long as to become flat and dead, as they alſo do when they are cut long before they are eaten: therefore, the ſureſt way to have this fruit in perfection, is to cut it the ſame day it is eaten; but it muſt be early in the morning, before the ſun has heated the fruit, obſerving to cut the ſtalk as long to the fruit as poſſible, and lay it in a cool, but dry, place, preſerving the ſtalk and crown to it, until it is eaten. *Miller's Gardener's Dictionary.*

The following Method of cultivating the pine-apple Plants, was communicated by the late Mr. Allen, of Bath; and has been practiſed with great Succeſs:

Let the pine-apple plants be planted as ſoon as poſſible, in pots of about eight or nine inches diameter, and plunged into a bed of tanner's bark, about three foot and a half thick; and let the laſt half foot on the top of the bed be old tan that has loſt its heat, which will prevent the plants being ſcorched at the roots. In September ſhift them into large pots with all the earth about them: at the ſame time ſhaking up the tan to the bottom of the pit, adding ſome freſh to keep it up to its proper height; ſtill obſerving to keep about ſix inches of old tan at the top. This will be ſufficient to keep them till they ſhew their fruit, which will probably be in February or March; when being prepared with a bed of freſh tan, cover it over about two inches thick with earth; then turn the plants out of the pots, without diſturbing the roots, and place them on the bed at proper diſtances, filling up the interſtices with good earth; where they may remain till the fruit is ripe: water them about twice a week all over the bed, but not on the fruit.

There may be few objections raiſed againſt this method, the principal of which is, That thoſe plants which do not ſhew when they are turned out of the pots, there is a great probability of their paſſing the ſummer without fruiting; or, if there ſhould be any that ripen late, the houſe cannot be at liberty to receive the plants for the ſucceeding year; and if it is all new tan, as propoſed, it is apt to cake and want freſh ſtirring when the fruit is three parts grown, in order to ſwell the fruit out to a large ſize.

There are two ſorts of the ananas principally cultivated in England; one called the queen-pine, the other the Montſerrat. The queen is moſt eſteemed among the gardeners, as being more regular and certain in their bearing; whereas the Montſerrat ſort frequently miſs the proper ſeaſon; and many that are brought from that iſland, though fine plants to look at, are apt to produce but trifling fruit. One cauſe of this, perhaps, may be, the ill choice that is made in promiſcuouſly taking the ſuckers from the plants that have produced but indifferent fruit.

It generally happens that pine plants which are brought from the Weſt-Indies, have a white inſect adhering to them, and which, if not deſtroyed, may infect a whole houſe of plants to their great prejudice, as they never thrive while theſe inſects prey on them. Some gardeners infuſe the plants in tobacco water, in order to deſtroy theſe inſects, but this often rots the plants: a much better method therefore is, when the plants arrive, to ſtrip the ſmall leaves from the roots, and clean them dry; for it is in that part theſe inſects moſtly harbour. While the bottoms of the plants are hardening, make a hot-bed with dung, and lay ſeven or eight inches of old tan on it, which cover with glaſſes. When the violence of the heat is a little abated, ſtick the plants in the tan, and let them remain there about three weeks; by which time they will be fit for potting, and the inſects intirely deſtroyed by the ſteam of the dung. As for plants that do not immediately come from abroad, they are never troubled with theſe inſects, unleſs the waterings have been neglected, or the plants by ſome other means are become unhealthy; for they will not prey upon any perfectly healthful plant.

The following Eſtimate of the Expence of building a Stove for raiſing Pine-apples; together with the annual Charges for Tan, Labour, &c. appeared in the Muſeum Ruſticum, *Vol. III. Pag.* 142.

A ſtove, forty feet long, and twelve wide, is the proper ſize for one fire-place, and contains as much air as one fire will properly warm: I ſhall therefore calculate my expences for one of that ſize, and particularly as it will produce about one hundred and fifty pines a year, which is fruit enough for a moderate-ſized family.

The height in front is three feet, and the back part about ſeven feet.

The front, one end, and roof to be of glaſs, the other end brick, where ſhould be a room about twelve feet ſquare, and it ought not to be leſs, for the convenience of laying the fuel, and for making the fire.

As to the dimenſions of the flues, &c. it is not neceſſary here to inſert them; but I will beg leave to refer any gentleman, who wants to build one, to that ingenious bricklayer, Mr. Salter Field, of Walton upon Thames, who has ſhewed great ſkill and judgment in building ſeveral.

The expence of building ſuch a ſtove will be about eighty pounds, ſuppoſing all the materials to be new, and at the prices given in London and its neighbourhood; but if you have the conveniency of a wall ready built to erect it againſt, it will ſave about fifteen pounds.

The price of the plants will be according to their ſizes, from two or three ſhillings each to ten or twelve, and entirely depends on how long you will wait for fruit, and whether you will buy ſuch as will produce fruit of only one pound weight each, or two or three pounds; but about fifty pounds will ſtock it properly at firſt, to have fruit immediately.

The yearly Expences as follows.

	l.	s.	d.
Eight hundred buſhels of tan to fill the pit at firſt, at three half-pence per buſhel	5	0	0
Sixteen loads carriage	0	16	0
Three chaldrons and a half of coals, at thirty-ſix ſhillings per chaldron	6	6	0
Two hundred buſhels of tan more, to keep the bed level with its former height, at three half-pence per buſhel	1	5	0
Four loads carriage	0	4	0
Filling the pit with tan, and planting the pots, two days, two men, at two ſhillings a day each	0	8	0
Stirring the tan up, and adding freſh four times more, at ditto	1	12	0
The time in attending the fires, watering, &c. is worth at the moſt eighteen-pence a week, which comes to	3	18	0
Repairing the windows, painting, and white-waſhing	1	11	0
Total	21	0	0

The

The ashes from your house, and rubbish from your garden, or, where you can get peat or turf cheap, will abate something in coals; and I think there are few places in England where all the articles together will cost so much: thus you will have one hundred and fifty pines of one pound and a half weight each, one with another, for less than three shillings a-piece; and with good management most of them will weigh two or three pounds a-piece, especially if you plant only your prime crowns and suckers.

Besides pines, you may have vines come through the walls, and nailed to the roofs, and on the flues French-beans, strawberries, and cucumbers.

PIP, *or* PEP, a disease among poultry, consisting of a white thin skin, or film, which growing under the tip of the tongue, hinders their feeding. It usually arises from their drinking puddle-water, or eating filthy meat; and is cured by pulling off the film with the fingers, and rubbing the tongue with salt.

PLEURISY, and inflammation of the lungs, &c. are disorders in horses, though they have scarce been mentioned by any writer in farriery before Mr. Gibson; who, by frequently examining the carcases of dead horses has found them subject to the different kinds of inflammations here described.

He has often discovered matter on the pleura (or membrane which lines the chest internally) making its way into the chest; he has found in some horses the whole substance of the lungs black, and full of a gangrened water; and in others abscesses of various sizes; and in short, inflammations in every bowel. He has frequently seen the blood vessels so over-loaded, that the blood has burst out of the smaller vessels, and run over their carcasses in many places, while the collar-maker was fleaing off their hides, and on cutting open the larger vessels, the blood has gushed out as from a fountain, filling all the cavity of the body; an evident proof, that plentiful evacuations had been neglected. In order to distinguish these disorders from others, we shall describe the symptoms in Mr. Gibson's own words.

"A pleurisy then, which is an inflammation of the pleura; and a peripneumony, which is an inflammation of the lungs; have symptoms very much alike; with this difference only, that in a pleurisy a horse shews great uneasiness, and shifts about from place to place; the fever, which at first is moderate, rises suddenly very high; in the beginning he often strives to lie down, but starts up again immediately, and frequently turns his head towards the affected side, which has caused many to mistake a pleuritic disorder for the gripes, this sign being common to both, though with this difference:

"In the gripes a horse frequently lies down, and rolls, and when they are violent, he will also have convulsive twitches, his eyes being turned up, and his limbs stretched out, as if he was dying; his ears and feet sometimes occasionally hot, and sometimes as cold as ice; he falls into profuse sweats, and then into cold damps, strives often to stale and dung, but with great pain and difficulty; which symptoms generally continue, till he has some relief: but in a pleurisy, a horse's ears and feet are always burning-hot, his mouth parched and dry, his pulse hard and quick; even sometimes when he is nigh dying, his fever is continued and increasing; and though in the beginning he makes many motions to lie down, yet afterwards he reins back as far as his collar will permit, and makes not the least offer to change his posture, but stands panting with short stops, and a disposition to cough, till he has relief, or drops down.

"In an inflammation of the lungs, several of the symptoms are the same, only in the beginning he is less active, and never offers to lie down during the whole time of his sickness; his fever is strong, breathing difficult, and attended with a short cough; and whereas in a pleurisy, a horse's mouth is generally parched and dry, in an inflammation of the lungs, when a horse's mouth is open, a roapy slime will run out in abundance; he gleets also at the nose a reddish or yellowish water, which sticks like glue to the inside of his nostrils.

"In a pleurisy, a horse heaves and works violently at his flanks, with great restlessness, and for the most part his belly is tucked up; but in an inflammation of the lungs, he always shews fullness, and the working of his flanks is regular, except after drinking and shifting his posture; and his ears and feet are for the most part cold, and often in damp sweats.

"The cure of both these disorders is the same. In the beginning a strong horse may lose three quarts of blood, the next day two quarts more; and if symptoms do not abate, the bleedings must be repeated, a quart at a time; for it is speedy, large, and quick repeated bleedings that are in these cases chiefly to be depended on. But if a horse has had any previous weakness, or is old, you must bleed him in less quantities, and oftener. Mr. Gibson recommends rowels, on each side the breast, and one on the belly; and a blistering ointment to be rubbed all over his brisket upon the foremost ribs.

"The diet and medicines should be both cooling, attenuating, relaxing, and diluting; and the horse should have warm mashes, and plenty of water or gruel. The following balls may be given thrice a day.

> "Take of spermaceti and nitre, of each one ounce; oil of anniseed thirty drops; honey enough to make a ball.

"A pint of barley-water, in which figs and liquorice-root have been boiled, should be given after each ball; to which the juice of lemons may be added; and if the lungs are greatly oppressed with a dry short cough, two or three horns full of the decoction may be given three or four times a day, with four spoonfuls of honey and linseed oil. A strong decoction of the rattle-snake root is also much recommended in pleuritic disorders, and may be given to the quantity of two quarts a day, sweetened with honey. It remarkably attenuates the blood, and disperses the inflammation, and in some parts is deemed a specific for this complaint.

"An emollient clyster should be injected once a day, to which may be added two ounces of nitre, or cream of tartar.

"In two or three days he will probably run at the nose, and begin to feed; but should he not, and continue hot and short breathed, you must bleed him again, and give the following clyster:

> "Take senna and marshmallows, of each two ounces; fennel and bay-berries, each one ounce: boil in five pints of water to two quarts, pour off the clear, and add four ounces of purging salts, two or three of syrup of buckthorn, and half a pint of linseed, or any common oil.

"If by these means he grows cooler, and his pain moderates, repeat the clyster the next day, unless it worked too much; then intermit a day; and when he comes to eat scalded bran and picked hay, leave off the balls, and continue only the decoction, with now and then a clyster.

"But let it be observed, that a horse seldom gets the better of these disorders, unless he has relief in a few days; for if the inflammation is not checked in that time, it usually terminates in a gangrene, or collection of matter, which for want of expectoration, soon suffocates him.

"But as pleuritic disorders are apt to leave a taint on the lungs, great care should be taken of the horse's exercise and feeding, which should be light and open for two or three weeks. Thus a quartern of bran scalded, with a spoonful of honey and flour of brimstone, may be given every day, with two or three small feeds of oats, sprinkled with chamber-lye. Instead of the bran, for a change, give about a quart of barley scalded in a double infusion of hot water, that it may be softened, and the water given to drink. His exercise should be gradual, in an open air and fair weather; and when his strength is recovered, a gentle purge or two should be given; that of rhubarb, when it can be afforded, is best, or the purging drink already recommended for this purpose.

"There is also an external pleurisy, or inflammation of the muscles between the ribs, which when not properly treated, proves the foundation of that disorder, called the chest-founder; for if the inflammation is not dispersed in time, and the viscid blood and juices so attenuated by internal medicines, that a free circulation is obtained; such a stiffness and inactivity will remain on these

these parts, as will not easily be removed, and which is generally known by the name of chest-founder.

"The signs of this inflammation, or external pleurisy, are a stiffness of the body, shoulders, and fore-legs; attended sometimes with a short dry cough, and a shrinking when handled in those parts.

"Bleeding, soft pectorals, attenuants, and gentle purges are the internal remedies; and externally the parts affected may be bathed with equal parts of spirit of sal armoniac, and ointment of marshmallows, or oil of chamomile.

"These outward inflammations frequently fall into the inside of the fore-leg, and sometimes near the shoulder; forming abscesses, which terminate the disorder.

"The membrane which separates the lungs, and more particularly the diaphragm, or midriff, is often also inflamed; which is scarce to be distinguished from the pleurisy, only in this, that when the midriff is greatly inflamed, the horse will sometimes be jaw-set, and his mouth so much closed, that nothing can be got in: but the method of cure is the same." *Bartlet's Farriery, page* 51.

PLOUGH, a well known machine for breaking up the ground.

The advantage of digging with the spade, or such other instrument, very naturally led men to the invention of the plough, a greatly more expeditious way of doing the same thing; that is, cutting and breaking the earth into small pieces; but in this the spade has the advantage of the common plough, as it goes deeper, and divides the earth more minutely; but the improvement of the common plough into the four-coultered one, shews that it is easy to make the plough perform this office as much better, as it usually does it worse than the spade.

The plough described by Virgil had no coulter; and at this time, the ploughs of Italy and the south of France, have none; and the ploughs in Greece, and in the eastern nations in general, are of the same kind. Neither is it indeed possible to use a coulter in such a plough; because the share does not cut the bottom of the furrow horizontally, but obliquely: in going one way it turns off the furrow to the right-hand, but in coming back it turns it off to the left; therefore if it had a coulter, it must be on the wrong side every other furrow.

It is a great mistake in those who say that Virgil's plough had two earth-boards, for it had really none at all; but the share itself always going obliquely, served instead of an earth-board; and two ears, which were the corners of a piece of wood lying under the shares, did the office of ground-wrists. This fashion of the plough continues to this day in those countries; and in Languedoc this sort of plough performs tolerably well when the ground is fine, and makes a shift to break up light land. This is the sort of land that is common in the east, and the arable lands about Rome, being never suffered to be fallow so long as to come to turf: this plough succeeds very well in such places, but it would be wholly impossible to turn up what in England we call strong land, with it.

The English ploughs are therefore different from these, as the soil is different. Our ploughs, where well made, cut off the furrow at the bottom horizontally; and therefore, it being as thick on the land side as on the furrow side, the ploughs cannot break it off from the whole land at such a thickness, being six times greater than what the eastern ploughs have to break off, and for this purpose it must have, of necessity, a coulter to cut it off: by this means the furrow is turned perfectly whole, and no part of the turf of it is broken; and if it lie long without new turning, the grass from the edges will spread, and form a new turf on the other side, which was the bottom of the furrow before the turning; but is now become the surface of the earth, and will soon become greener with grass than it was before ploughing.

If whole, strong, turfy furrows are ploughed cross ways, as is too commonly practised, the coulter cannot easily cut them; because, being loose underneath, they do not make a proper resistance or pressure against its edge, but are apt to be drawn on heaps, and turned in all directions, but without cutting.

Some of our ploughs have heavy drags, with long iron tines in them; and though these broken pieces of furrows, being now looser than before, require keener edges to cut them, these tines have no edges at all. Thus the clods of earth are tossed into heaps again, and the surface left bare between them, and great labour and expence is used to very little purpose: all this is owing to the one coulter.

If the soil be shallow, it may be broken up with a narrow furrow, which will the sooner be brought into tilth; but if it be a deep soil, the furrows must be proportionably enlarged, or else a great part of the good mould will be left unmoved, and so be lost. The deeper the land is, the worse it is broke by one coulter; that is, it is broke into larger furrows, and it requires such repeated labour to conquer this, that, often, the best land will scarcely pay the tillage.

This gives an opportunity to servants to cheat their masters. They plough such deep land with a small furrow, and shallow, to the end, that the turf and furrows may be broken the sooner, and the superficial part made fine. They pretend the plough will go deeper the next time; but this is never the case.

This sort of land must not be ploughed the second time in wet weather; for this will cause the weeds to multiply, and the earth will be formed into thick and heavy clods where trodden: and in dry weather, the resistance of the untouched earth below, and the slight pressure of the plough above, will always be reasons why the plough will enter no deeper the second time than it did the first.

Another way to conquer a strong turf, is to plough it up first with a breast plough, very thin; and when the sward is rotten, then it is to be ploughed to the proper depth: but this method is liable to great objections; it is very troublesome and expensive, and if the turf be pared off in the winter, or early in spring, it is a chance but the rains come on, and set it to growing faster than before: if, on the other hand, it be pared later in the year, though the turf be thoroughly killed by the succeeding dry weather, yet the time is lost, and the farmer loses the sowing season for wheat, which is the proper corn for such strong land.

Paring PLOUGH, an instrument used in several parts of England, for paring off the surface of the ground, in order to its being burnt. *See the article* BURN-BAKING.

One of the best and simplest instruments of this kind is that which Mr. Bradley gives, with the following description.

From A to A, Fig. 1. Plate XXI. is the plough-beam, about seven feet long, mortised and pinioned into the block B, which is of clean timber, without knots. CC are the sheaths or standards, made flat on the inside, to close equally with the paring-plate, and be fastened to it with a bolt and key on each side, as is marked at D.

E is the paring-plate, of iron laid with steel, about four inches wide, and from twelve to eighteen inches long, as the business may require. This plate must be made to cut on the sides, which are bolted to the standards, as well as at the bottom part.

FF are two iron braces, to keep the standards from giving way. These standards must be mortised near their outsides, and through the block.

GG are the plough handles, which must be fixed slopewise between the beam and the standards.

The pin-holes in the beam, the use of which is to make this plough cut more or less deep, by fixing the wheels nearer to or farther from the paring-plate, should not be above two inches asunder.

Rotherham, or *Patent* PLOUGH, the name of a plough, very simple in its construction, easily worked, and therefore deserves the husbandman's particular attention.

Fig. 2. Plate XXI. represents the left or land side of this plough, of which AB is the beam, CD the sheath, EBD the main handle, FR, the smaller handle, GH the coulter, KI the sock or share, NP the bridle, S the fly-band, ML a piece of wood in place of a head. The forms of all these different parts, as they appear on this side of the plough, are here represented, and their sizes and distances may be measured by the annexed scale of feet and inches.

Fig. 3. represents the right-hand side of this plough, with all the parts that can be seen on that side, in which TV is the mould-board, &c.

Fig. 4. shews the under part of this plough turned up, in which may be seen the shape and size of the share, and the

the manner in which it is fixed on the ſheath, mould-board, and ground-reſt, with the angle which they make.

Fig. 5. repreſents the hind-part of the plough, in which are ſeen the two handles EF, with the hinder-part of the mould-board VT, and a piece of wood in the place of the head LM, in their proper ſhapes and ſizes by the ſcale.

Fig. 6. repreſents an upper view of this plough, as it appears while it works, with the bridle NP extended, the mould-board TV, fixed in its proper poſition, and all the other parts as they appear in this ſituation, in their ſeveral ſhapes and ſizes according to the ſcale.

Fig. 7. is the upper part of the ſock or ſhare.

Fig. 8. ſhews the opening of the ſhare, as it is fixed on the end of the ſheath and mould-board.

Fig. 9. is a perſpective view of the bridle.

The whole of this plough ſhould be made of aſh or elm; the irons ſhould be ſteeled and well tempered; and that part of the plough which is under ground in tilling, ſhould be covered with plates of iron.

The difference betwixt this and the common ploughs, ſeems to conſiſt in the bridle at the end of the beam, by which the ploughman can give the plough more or leſs land by the notches at N in Fig. 4, and 6. or make it cut deeper or ſhallower by the holes at P in Fig. 2, and 3. in the coulter and ſhare, which are made and ſet ſo as to cut off the new furrow without tearing; and in the mould-board, which is ſo ſhaped at firſt to raiſe a little, and then gradually turn over the new cut furrow with very little reſiſtance. But the greateſt advantage of all is, its being ſo eaſy of draught, that it will do double the work of any common plough, as experience has proved; and, with only one man and two horſes, will perform, even in ſtiff land, as much as two men and ſix horſes can do in a moderately light ſoil with any of the wheeled ploughs generally uſed, or indeed known in this country, where their great defect is, that they are too complex, and weigh too much upon the fore-carriage, ſo that the friction of their wheels becomes a conſiderable addition to the draught: for the beſt plough certainly is that which is the moſt ſimple in its make and tackle; which requires the leaſt ſtrength to draw it, in proportion to the ſtiffneſs of the ſoil; which can be made always to cut to a proper depth; and which, by the ſhape of its mould-board, is beſt adapted to turn the furrow upſide down. The principle of the Kentiſh plough, with the ſhifting mould-board, is very good, where the land is dry, and will admit of it.

Meſſieurs de Chateauvieux and Duhamel, ever ſtudious to promote the welfare of mankind, have endeavoured to remedy theſe inconveniencies in wheeled ploughs, by the following improvements, which, with their uſual ſpirit of univerſal benevolence, they have moſt obligingly communicated to the world. We ſhall begin with the invention of the former of theſe gentlemen, becauſe it was rather prior, in point of time, to that of M. Duhamel.

The fore-part of M. de Chateauvieux's plough is compoſed of a wheel thirty-two inches in diameter, which may be extended to thirty-four inches, or reduced to thirty: but to fall ſhort of, or to exceed theſe meaſures, would be attended with inconveniencies. This wheel may be made very light, eſpecially if it be encircled with a thin hoop of iron. The plough itſelf is repreſented in Plate XXII. Fig. 1, 2, and 3. where Fig. 2. is the plan, and Fig. 1. the profile.

The frame in which the wheel is placed, is formed by two ſhafts AB, CD, Fig. 2. diſtant from each other eighteen inches, from inſide to inſide; which fixes the length of the nave of the wheel. Theſe ſhafts are four feet eight inches long, and may be reduced to four feet four inches, by ſhortening them at the ends C and A. They are about two inches and a quarter ſquare: but the edges ſhould be rounded off. Theſe two pieces are faſtened together by the two croſs ſtaves EF, GH, which are two inches and a half wide, and about an inch thick. They are riveted to one of the ſhafts, at E and G, where they are not to be looſened at all; and at their other ends F and H, the ſhaft muſt be moveable, ſo as to be taken off, to let the two croſs ſtaves through two mortiſes in the beam IK of the plough; after which the ſhaft CD is put in its place, and fixed with two iron pins, *a*, *b*. Between the two ſhafts is placed the wheel LM, the nave of which is pierced through its center, with a hole proportioned to the thickneſs of the iron pin or ſpindle NO, which ſerves for an axle-tree, and is repreſented by the two pricked lines. This ſpindle, or axle-tree, the diameter of which is about three quarters of an inch, ought not to project beyond the outſide of the ſhafts, leſt it ſhould lay hold of or hurt the ſtalks of the corn, when this plough is uſed for ſtirring the earth between the rows in the New Huſbandry, as will hereafter be more particularly mentioned. To fix it at N, that end is flattened, and bent over the ſhaft to the middle of its upper ſide, where it is faſtened at *d*, by a ſmall pin driven through it and the ſhaft.

On the upper ſurface of each of the ſhafts, at the ends A and C, are the hooks AC, to which the harneſs is faſtened: and at the other ends B and D, are two rings, the uſe of which will be explained hereafter.

The ſhafts AB, CD, ſhould be pierced with four or five holes, to ſet the wheel more or leſs forward or backward, in order to make the plough ſtrike more or leſs deep into the earth, as may be ſeen in Fig. 1. at *a*, *b*, *c*, and *d*. The ſame holes are indicated by the pricked lines on the two ſhafts of Fig. 2. from A to N, and from C to O.

The hind part of this plough conſiſts of the beam IK, Fig. 1, and 2. the ground-reſt CD, Fig. 1. which is covered by the ſhare LD; the handles KP, KQ, Fig. 2. and KP, Fig. 1. the ſheat EF, Fig. 1. of which part is pricked in Fig. 1. and the end appears at X in Fig. 2. the mould-board RS, Fig. 2. part of which is ſeen at N in Fig. 1. the coulter GH, Fig. 1. and TV, Fig. 2. and the ſhare LD, Fig. 1. part of which is ſeen at Y, in Fig. 2.

The beam is four feet eight inches long, excluſive of the tenon which traverſes the handles. Three inches and a quarter ſquare are very ſufficient in its thickeſt part, which is from X to V, Fig. 2. The mortiſes in the beam, which are under *g*, *h*, and through which the two croſs-ſtaves EF, GH, are ſlipt, ſhould be ſo fitted, that the croſs-ſtaves may not ſhake or be looſe in them, at the ſame time that the beam ſhould, by their help, ſlip with eaſe over the croſs-ſtaves, either to the right towards EG, or to the left towards FH, according as the intended ploughing may require. The beam ſhould be faſtened, either by two nuts ſcrewed on at *m*, *n*, which will fix it tight to the croſs-ſtaves EF, GH; or by two iron pins ſtuck through the holes *p* and *q* in the two croſs-ſtaves, one to the right in the croſs ſtaff EF, and the other to the left in the croſs-ſtaff GH. Theſe pins will keep the beam ſteady in its place.

The lower part of the ground-reſt ſhould be ſomewhat concave, as is repreſented at CD, Fig. 4. in order to leſſen its friction againſt the earth.

The beam IK, Fig. 1, and the ground-reſt CD, are faſtened together by the ſheat FE, and the handles PK, both of which laſt are riveted to the ground-reſt by two ſtrong iron pins, the heads of which are ſeen at *g* and *h*; and to the beam, as alſo to the tenon of the beam which traverſes the handles at *m*, *n*; and by the two wedges, *p*, *o*, and *q*, another uſe of which will be explained hereafter.

Wood naturally crooked is beſt to make the handles of, that they may be all of one piece, which ſhould be ſo diſpoſed, that one third of the ſpace between the two handles, ſhould be left on the left ſide, and the two other thirds on the right ſide, in order to facilitate the plowman's walking in the furrow. This diſpoſition is ſhewed in Fig. 2. in which a line *e*, *f*, drawn from the middle of the beam, between the two handles, gives to the left ſide a third P*f*, of the diſtance PQ between the two handles, and the two other thirds *f*Q to the other ſide.

For want of wood naturally bent to a proper ſhape, theſe handles may be made of two pieces firmly riveted and faſtened together; and if it ſhould be more convenient to the plowman, the whole ſpace between the handles may be on the right-ſide, as in Fig. 6.

The ſheat EF, Fig. 1, ſhould be very ſtrongly and cloſely faſtened by its tenon to the ground-reſt, at *g*. An intelligent

intelligent workman will eafily make it of a proper fize, which is about two inches and a half wide, and a full inch thick. The inclining of this piece with the ground-reft, gives it greater ftrength to refift, than if it was faftened to it at right angles.

The mould-board, reprefented by RS, Fig. 2, and AB, Fig. 7, is from thirty to thirty-one inches long, and ten inches high or deep. It ought to be placed as in Fig. 8, where its end A forms an acute angle, terminating at the junction of the fin of the fhare: its other end B extends beyond the length of the ground-reft, againft which it fhould incline, in fuch manner that, fuppofing the ground-reft to be lengthened out as far as C, the line CB would be twelve or thirteen inches long, reckoning from the fartheft lateral furface of the ground-reft to the fartheft lateral furface of the mould-board, which, being thus placed, will form the width of a furrow.

The lower part of this mould-board is floped a little inward, as is expreffed by the fhade in Fig. 7: and the part *b* Fig. 7, fhould jet out at leaft two inches beyond the part *a*. To this end, the mould-board fhould be made of a plank about three inches thick, which will bear being fcooped on one fide and rounded off on the other, in order to give it the concavity without, and the convexity within, reprefented in Fig. 3. and 7.

The mould-board fhould be well faftened, to prevent its being difplaced by the refiftance of the earth. The upright piece CD Fig. 7, which joins to the handles at its end D, and to the mould-board at its other end C, fupports it ftrongly. It is highly neceffary to cover the part of the mould-board which bears upon the earth, with a thin plate of iron, in order to preferve it; for otherwife it would foon be worn out.

The coulter GH, Fig. 1. fhould be made of good iron well fteeled. A notch is cut in the beam to receive it, as in Fig. 9 and 10; and as the corners of that notch, C and B, againft which the coulter bears hardeft when the plough works, would foon be worn away if the wood was left bare, it is proper to fecure them with two fmall pieces of iron AB, CD, about the fixth part of an inch in thicknefs, fcrewed on with flat-headed fcrews. Thefe pieces of iron will keep the coulter fteady in its place.

The coulter fhould be pierced with feveral holes from E to F, Fig. 10, to take it higher up, or let it lower down, as occafion may require. It is faftened to the beam, which is pierced at E, Fig. 9, by a ftrong iron pin with a fquare flat head, which is let into the beam and lies even with it, as in Fig. 10. The other end of this pin, E, Fig. 10, is a fcrew, fitted with its nut, by which the coulter is faftened tight to the beam. Upon this fcrew hangs the handle A, Fig. 1, which ferves to turn it, and at the end of which is the key that faftens on the nuts of the iron pins which fecure the fhare. By this means, the key to turn the fcrews is always carried with the plough.

M. de Chateauvieux's coulters weigh but five or fix pounds a-piece at moft, and frequently not more than three pounds.

He places his coulter fo that its point G, Fig. 1. projects about an inch beyond the outfide of the fhare LC.

Fig. 12 reprefents the fhape of the fhare, with its dimenfions, as do alfo Fig. 13 and 14. The point of this fhould be made of good fteel, and the reft of good iron, neither too foft, nor too high tempered, that it may not be fubject to break or bend. The tail of the fhare, AB, Fig. 12, fhould be thickeft from A to C, becaufe that is the part which bears the greateft ftrefs. Its thicknefs diminifhes gradually to B, where the fhare is faftened to the ground-reft. This tail is pierced with two round holes at A and B, Fig. 13, through which are put the iron pins DE, FG, Fig. 12. which have fquare flat heads, lying even with the tail of the fhare. Thefe pins pafs through the ground-reft, where they are faftened on the other fide by the nuts EG. A third round hole may be added at *x*, Fig. 13, in order to faften the fhare ftill more firmly to the ground-reft, with a fhort flat headed fcrew.

M. de Chateauvieux has likewife made fome ploughs with the round holes *ab*, Fig. 13, near A and B; that the iron pins DE, FG, Fig. 12, might not traverfe the tenons of the fheat and handles; and inftead of thofe iron pins, he has riveted them with wooden pins, and found them keep the whole tighter together than the iron ones.

To the left fide of the plough fhould be faftened the thin board N, Fig. 1 and 7, the ufe of which is to prevent the earth from tumbling over between the fhare and the mould-board. As plowing wears the point of the fhare, though it will not hurt this fo much as it does that of the common plough, it muft be new pointed from time to time, always obferving to make the point incline a little towards the earth, as is reprefented by the pricked line DL, Fig. 1; that the fhare may fcarcely touch the ground at any other part than D and L, in order to leffen the friction.

The hind part of the plough, thus formed, is joined to the fore carriage, by running the crofs ftaves EF, GH, Fig. 2. through the mortifes of the beams, *gh*; and is fixed there, either by the fcrews *mn*, or the pins *p*, *q*. The traces of the firft and fecond horfe are faftened to the hooks AC; and if a third horfe be ufed, the traces of that third horfe are faftened to thofe of the fecond. Horfes will do better for this plough, than oxen, unlefs thefe laft have been ufed to be harneffed one before the other.

The plough thus equipped, may eafily be carried to the field, if its hind part is laid upon the little carriage ÆW, Fig. 2. confifting of an iron axle-tree ÆW, two fmall wheels *ki*, *lr*, and the two pieces B*t*, D*v*, at the end of which are the hooks B and D. Thefe wheels are about twenty-one inches, or two feet in diameter; and three feet fix inches, or even four feet afunder. They are very light, having but a fmall weight to bear. The hooks of thefe two pieces B*t*, D*v*, are inferted in the rings B and D at the end of the fhafts; and by this means the plough will be carried upon three wheels, of which Fig. 1 and 2 fhew fufficiently the arrangement and ufe. Fig. 5, fhews the flope that fhould be given to the upper furface of the middle of the axle-tree of this fmall carriage, on which the reft of the plough is to be loaded in order to remove it from one place to another, that the ground-reft and other pieces may lie flat and fteady upon it.

To open the firft furrow with this plough, the wheel muft be placed at the laft hole, towards the extremity of the fhafts. This makes the fhare incline the more, and confequently cut the deeper. But as it would be fomewhat troublefome to change the pofition of the wheel, at every firft cut of the plough, a very little attention will remedy that inconvenience. It is only inclining the handles of the plough to the right or left, inftead of holding them even. The whole plough will incline with the handles, and the fhare will then enter into the ground with eafe, and open the firft furrow. The other furrows are plowed without any fort of difficulty; and for them, the plough is to be held even, or inclined but very little, either to the right-hand or the left, as the fituation of the land may require.

M. de Chateauvieux generally refts the beam on the left-hand fide of the fore-carriage. It is eafy to place it fo as to leave whatever diftance is thought proper between the outmoft row of corn and the furrow that is actually plowing.

The forwarder the wheel is fet, the deeper the plough cuts; and fo on the contrary. But if one would have it cut ftill deeper, or fhallower, than it can be made to do by altering the pofition of the wheel, that too may eafily be effected. By loofening a little the wedge above the beam *p*, *o*, Fig. 1. and driving farther in the wedge *q*, the plough will cut lefs deep: as, on the other hand, the fhare will be more inclined, and therefore cut deeper, if the wedge *q* under the beam is loofened, and the wedge *p*, *o*, over it is driven in tighter.

The chief differences between M. de Chateauvieux's plough, and that of M. Duhamel, are as follow.

1. The beam of this laft, ABC, Fig. 1. Plate XXIII. bends from C to B; whereas that of M. de Chateauvieux's is nearly ftrait all along.

2. In confequence of this bending, the hindmoft extremity of M. Duhamel's beam is joined at B to the hindermoft part of the ground-reft E, after paffing through a mortife F, in the lower part of the handles: fo that this beam is joined to the ground-reft by its extremity B, the bottoms of the handles F, and the fheat G; whilft that

of

of M. de Chateauvieux's plough, is joined to the ground-rest by this sheat, another which this plough has not, and the lower part of the handles: for the beam does not answer to the ground-rest.

3. The mould-board HI, Fig. 2, of this plough, is lighter than that of M. de Chateauvieux's, and differently shaped.

4. The two handles KK, are at equal distances from the beam, and are joined together by a cross staff M.

5. The share N, Fig. 3, is pretty much like that of M. de Chateauvieux's plough, but shorter and narrower; so that it cuts less wide furrows, which M. Duhamel rightly thinks the best way of plowing.

6. The coulter O of this plough passes through a mortise in the beam, which is there strengthened by hoops of iron, to prevent the beam's being split by the driving in of the wedges PP which fix the coulter.

M. Duhamel thinks this hind part of his plough preferable to that of M. de Chateauvieux's, for light lands: but it would not do so well in stiff soils, because the earth would be apt to clog about the sheat at Q; whereas it is thrown off by M. de Chateauvieux's plough. M. Duhamel likewise approves of making the beam strait as M. de Chateavieux's is, instead of giving it the bending from C to B, especially for stiff lands.

7. The beam CA, is fixed to the cross staves RR of the fore-carriage of this plough, by the screws and nuts SS.

8. The shafts TT, are fastened before by a cross staff V, which gives great solidity to the fore-carriage, and cannot be added to M. de Chateauvieux's plough; not only because the wheel is too large, but likewise because it must be set forwarder or backwarder, in order to make the share cut more or less deep.

The wheel of this plough is not so large as that of M. de Chateauvieux's, because the axle-tree, instead of being inserted in the shafts TT, is let into the side pieces X, Fig. 4, which are fastened to the shafts by the screws and nuts YY.

The advantages of having the wheel smaller, are, 1. That the plough is less apt to lean too much on its side, and is more easily held upright; 2. That the cross-staff V may be added to the fore-carriage, by which it is rendered more solid; and 3. That the fore-carriage may be made shorter than it otherwise could be.

The bare inspection of the draught of this plough, shews that it is made to cut more or less deep, by screwing the nuts Y more or less tight, and putting a thicker or thinner wedge between the side piece X and the shaft; which is an easier and quicker way, than changing the situation of the wheel. But still, a readier method is, to have under the shafts TT, a false shaft ZZ, Fig. 5, fixed with hinges, &c. for then, by only sticking the peg *a*, into one of the holes *b*, the beam is raised or lowered, in a moment, to whatever degree is thought proper, without altering the position of the wheel.

It is likewise evident, that in order to give the share a greater or less degree of entrance into the earth, nothing more is requisite than to place the beam nearer to, or farther from, the right-hand shaft: for the horses, which are harnessed one before another, go, as does also the wheel, in the last made furrow, and the plowman goes in the furrow actually making.

dd. Are hooks to fasten on the harness of the horses.

ee. Cramps to fasten the fore-carriage.

ff. Pins to fix the beam to the sheat.

gg. Pegs to fasten the cross staves.

h. A strong pin which goes through the hole *i*, to keep the mould-board steady.

Four coultered PLOUGH, an instrument invented by Mr. Tull, being an improvement on the common plough, that makes it cut the pieces of earth into four; that is, it thus divides the earth four times as small as the common plough.

The common two-wheeled plough has of late years become universally used in many countries, and is found greatly preferable to the ploughs they used before; there is an objection to it, indeed, in regard to some stiff and miry lands, in which the wheels become clogged up, and cannot turn. This, however, is easily remedied by twisting thumb ropes of straw about the iron circle and spokes of the wheels; these spreading as they turn, and, as the circle twist bears upon the ground, throw off the dirt, and never clog. The two principal parts of this plough are the head and the tail: the plough-head contains the two wheels and their axis, or spindle, passing through a box, and turning round both in it and in the wheels.

There are fixed perpendicularly in this box two crow-staves, as they are called, which are flat and narrow boards, each having on it two rows of holes, whereby to raise or sink the beam of the plough, by pinning up or down the pillow, to increase or diminish the depth of the furrow. Behind are a pair of gallows, through which the crow-staves pass at the top by mortises, into which they are pinned; and to these are fastened what are called the wilds, which are rings and crooks of iron, by which the whole plough is drawn in the working. From the box to the center of the beam there is carried an iron-chain, consisting of four, five, or more long links, and called the tow-chain: this fastens the plough-tail to the plough-head. It is fixed to an iron collar, fastened in the beam at one end, and at the other passes through a hole in the middle of the box, and is pinned in with a wooden pin.

From the same iron-collar to which the tow-chain is fixed, there is also another chain fastened, called the bridle-chain: this runs above the beam, as the tow-chain does below it, and is composed of smaller and more numerous links. At the upper end, as the tow-chain enters the box of the plough, this bridle-chain is fixed to the top of what is called the stake of the plough: this is a perpendicular stick, carried up parallel with the left crow-staff, and pretty near it, and fastened to it by a wyth or rope, or by the end of the bridle-chain itself, when that is long enough. This stake is also fastened in its lower part, under the gallows, to the same crow-staff, by another wyth or piece of rope.

These are the parts of which the head-part of the plough is composed. The plough-tail consists of the beam carried from the head to the very extremity, and serving as the support and base of all the rest. A little below the collar to which the tow-chain and bridle-chain are fastened, this beam is pierced with a large hole, which lets through the coulter: this is a long and narrow piece, terminating in an edge, and reaching just to the share; and it is fixed immoveably in its place by means of a wedge which is driven into the hole of the beam with it: the office of this coulter is to cut the earth as it is thrown up by the share. Behind these, the same beam is pierced with two more holes, one very near its end: these give passage to two oblong pieces, called the fore-sheat and hinder-sheat, by which the plough-share is supported in its place. To the top of the hinder-sheat there is fastened a short handle by a wooden pin. Parallel to the hinder-sheat there runs up a piece of wood of much the same form, called the drock; and to this is fastened another horizontal piece, called the ground-wrist: these are all on the right-hand side of the plough, and parallel with the fore-sheat. There runs another piece of much the same form with it, on the right-hand; and the bottom of this is the earth-board. The long handle of this, which reaches as far as that of the sheat, is fastened to the drock by a pin, the other end of which goes into the beam. Near the lower end of the fore-sheat, there are two flat pieces of iron, which pass from the two sides of it up to the beam; and being let through it, are fastened to the upper part by screws and pins. These keep the sheat in its place.

The structure of the four-coultered plough is different, in some respects from this, though in general founded on it. Its beam is ten feet long, whereas that of the common plough is but eight. The beam is straight in the common plough, but in this it is arched in one fourth part of its length, near the plough-head. At the distance of three feet two inches from the end of the beam at the plough-tail, the first coulter, or that next the share, is let through; and at thirteen inches from this, a second coulter is let through: a third at the same distance from that; and, finally, the fourth at the same distance from the third, that is, thirteen inches.

The crookedness of the upper part of the beam in this plough is contrived to avoid the too great length of the three foremost coulters, which would be too much, if the beam was straight all the way; and they would be apt to bend

bend and be displaced, unless they were vastly heavy and clumsy. Ash is the best wood to make the beam of, it being sufficiently strong, and yet light.

The sheat in this plough is to be seven inches broad. The fixing of the share in this, as well as in the common plough, is the nicest part, and requires the utmost art of the maker; for the well going of the plough wholly depends upon the placing of this. Supposing the axis of the beam, and the left side of the share, to be both horizontal, they must never be set parallel to each other; for, if they are, the tail of the share, bearing against the trench as much as the point, would cause the point to incline to the right-hand, and it would be carried out of the ground into the furrow. If the point of the share should be set so, that its side should make an angle on the right side of the axis of the beam, this inconvenience would be much greater; and if its points should incline much to the left, and make too large an angle on that side with the axis of the beam, the plough would run quite to the left-hand; and, if the holder, to prevent its running quite out of the ground, turns the upper part of his plough toward the left-hand, the pin of the share will rise up, and cut the furrow diagonally, leaving it half unploughed. To avoid this and several other inconveniencies, the straight side of the share must make an angle upon the left side of the beam; but that must be so very acute a one, that the tail of the share may only press less against the side of the trench than the point does.

The great thing to be taken care of, is the placing the four coulters; for on this the success of the whole depends. These must be so set, that the four imaginary planes described by their four edges, as the plough moves forward, may be all parallel to each other, or very nearly so; for if any one of them should be very much inclined to, or should recede much from either of the other, then they would not enter the ground together. In order to the placing them thus, the beam must be carefully pierced in a proper manner. The second coulter-hole must be two inches and an half more on the right-hand than the first: the third must be as much more to the right of the second, and the fourth the same measure to the right-hand of the third: and this two inches and an half must be carefully measured from the center of one hole to the center of the other. Each of these holes is a mortise of an anch and a quarter wide, and is three inches and an half long at the top, and three inches at the bottom. The two opposite sides of this hole are parallel to the top and bottom, but the back is oblique, and determines the obliquity of the standing of the coulter, which is wedged tight up to the poll. A perspective view of this curious plough the reader will find in Plate XXI. Fig. 9.

The coulter is two feet eight inches long, before it is worn; the handle takes up sixteen inches of this length, and is allowed thus long, that the coulter may be driven down as the point wears away. *Tull's Horse-hoeing Husbandry.*

Double PLOUGH, an instrument invented by Mr. Randal, which, by putting the share point to the middle of the interval left by the horse-hoe, throws the mould on each side of it, at the same time, towards the rows, and earths them up to what degree the ploughman pleases, in order to nourish them on to perfection. If a common plough, instead of the single hough, was used, the furrows would be turned into the middle of the interval, and appear in the form of a single ridge: and if the plough went twice in a place, to deepen the soil, the ridge in the middle would be proportionably higher, and the ground strangely improved by such operations, and the vegetables surprisingly promoted in their growth. In either of these cases, of the plough's going once or twice in a place, the double plough, by taking fast hold of the mould, throws all back again; and if the vegetables are not effectually earthed up, which may be the case after double spitting the intervals; then running the double plough over again, compleats the business, and strangely tosses about and mellows the mould. This, in general, is the use of this plough in earthing up vegetables, that have three feet intervals.

But under the name of this double plough, we are to understand another of the same form, but much narrower in the tail, to perform what is called ridge-work, which is either single, or double: if single, this double plough works alone, throws up the ridges, and, at a proper time, splits them, and throws them back into the trenches; and this tosses the mould backwards and forwards, which, by these agitations, and other operations, is made ready for cropping, as is particularly mentioned in my Treatise. If these ridges are to be double, that is, if there is to be double spitting, then the double plough performs as before, and goes as deep as is consistent with the interest of the man's arms, and the horse's ease. Here the worthy ploughman is requested to keep his hands even, that the plough may run flat upon its sole, and clear the trench of mould, as far as necessary, which it is made to do in that posture, to make way for the lifting-plough, of the same breadth in the tail. *See* Plate XXI. Fig 10.

Double Lifting-PLOUGH. My earnest desire, says Mr. Randal, to imitate gardeners, in preparing the soil, by their always going a good depth, and which, to be sure, is the true bias of nature, in regard that vegetables, in general, require a looser habitation, beneath the soil, to a greater depth than farmers will allow them: this desire produced the lifting-plough, to raise the generous mould that lies far beneath the reach of common ploughing, into general use. This I have practised to very great effect, and never failed doing it, in all the going ground of the tenures of near a thousand acres, where the stratum, below the usual soil, would give me this desireable and encouraging advantage. Hence it was, that I was always extremely fond of this lifting-plough, which never fails of success in the hands of an honest, worthy ploughman; and, no doubt, there are many such to be found. I was very imprudent, in my first construction of this plough, in having it made too large, in order, through a covetous disposition, to have much work done in a day. The draught was so fatiguing to the horses and men, that the invention was under a good deal of disrepute, and I was in danger of having all the servants leave the service, and of killing the horses: for these reasons, I was obliged to sit down with that loss, great as it was, in the purchase of this plough, and contract all the proportions of it, to make the draught quite easy to the team and men; and then there was not the least complaint heard, but only a backwardness to proceed, which use effectually removed.

Here, then, this lifting-plough is to go into all the trenches made by the double plough, as mentioned before; and as the ploughman deepens the trenches as far down as is consistent with his own and horses ease, the irons, running up on each side of the plough, will lift up the mould, which will be thrown, by the motion, upon the old ridges. The ground now lies in deep trenches, and high ridges, and this is what is called, in my Treatise, double ridges; and how the soil is to be afterwards reduced to a level, and receive farther management, is therein particularly mentioned. Now, from the construction of these two ploughs, the soil beneath will, if the ploughman keeps his hands even, be cut level, instead of leaving there hills and dales, but too often practised, to the discouragement of the growth of the vegetables. *See* Plate XXI. Fig. 11. *Randal's Semi-virgilian Husbandry.*

PLOUGHING, the action of breaking up, and loosening the soil.

" The principle, says M. de Chateauvieux, of thoroughly dividing and loosening the soil, is so generally received, that there is not a farmer, who does not know, that one ploughing more than ordinary is of as much service to his ground, as dunging it would be. Experience must have shewn them, that his crops are increased by this extraordinary ploughing: but he is not sufficiently sensible, that of all the ways of improving his land, no one is more effectual, or less expensive than this. Were its full value known, it would be more generally practised, and every husbandman would give all his lands at least one ploughing extraordinary.

" To satisfy myself of what might be done with the plough alone, I resolved to make a trial on a spot of ground which I knew to be incapable of naturally producing any thing. Some years before, I had dug away the earth, three feet deep, from a space of sixty square perches. Nothing remained in it but a white clay, like that which potters use. This spot, thus circumstanced, seemed to me a proper one for my experiment. As the space

ſpace was too ſmall for a plough to work in, I had recourſe to the ſpade and hoe. The ground was laid out in beds, which were afterwards ſowed with wheat, and the ſpaces between them were frequently ſtirred. The firſt year, my plants were very poor, and branched into only two, three, or four ſtalks apiece. In the ſecond year, they did much better; and in the third, they were as large and fine as any my garden could have produced. This ſpot ſtill continues to produce equally well; the ſoil is now like fine mould; and, which is very remarkable, it has loſt its former white colour, and is become black. We have here a ſtrong inſtance of what may be done by pulverizing the earth. Let us but do the ſame with any of our bad lands, and perſevere in ploughing and ſtirring them a ſufficient time; the ſucceſs will not be doubtful.

"To be ſtill farther convinced of the truth of this important maxim in huſbandry, that the earth ſhould be thoroughly looſened by deep and frequent ploughings, I examined very carefully, whether my lands which had been prepared by repeated ploughing only, without the aſſiſtance of any dung or manure, were more looſened and rendered lighter, than thoſe which were under the common management. All my obſervations proved that they were. The firſt glance of my eye ſhewed me, that their ſurface was ſmoother; on ſounding the furrows, I found them deeper; and much leſs ſtrength was required to plough them; two horſes, or ſometimes only one, or a ſingle ox, doing here with eaſe, what would otherwiſe have employed double that number of cattle: a manifeſt proof that my grounds were in excellent tilth; whereas the common fields offered nothing pleaſing or ſatisfactory to the eye; the earth there was extremely hard, cloſe, and compact, and its ſurface almoſt as firm as that of a beaten road. The ground which had been well and often ploughed remained ſo light and ſoft, after its crop of wheat was taken off, that I thruſt a ſtick of green willow eight or ten inches deep into it without the leaſt difficulty, though I could not by any means puſh it at all into the land cultivated in the common way."

Camillo Tarello, a native of Lonato in the Venetian territories, concerned to ſee the neglected and dreadful miſmanaged ſtate of huſbandry in his country, wrote his ſmall, but highly valuable treatiſe of Agriculture, and preſented it to the ſenate of Venice under the title of *Ricordo d'Agricultura*. The ſenate, in juſtice to the excellency of this work and the patriotic intentions of its author, granted him, on the 29th of September 1566, not only the ſole right of vending his book, but alſo ordered at the ſame time that all ſuch as adopted his new method of huſbandry, ſhould pay to him, and afterwards to his deſcendants, four marchetti (about three halfpence of our money) for every acre of corn land, and two marchetti for every acre of other land, planted according to his direction. The Berne Society have favoured the public with the firſt part of Tarello's excellent treatiſe; and we ſhall take from thence the following extract as a farther proof of the neceſſity of thorough ploughing.

"When we conſider, ſays that good patriot and intelligent huſbandman, Camillo Tarello, that every ear of wheat yields fifty grains (we will ſuppoſe that to be the medium number), we may infer, that if all theſe were ſowed and grew, we ſhould reap fifty times as much as was ſown: but our crops are far from being ſo abundant. This failure cannot proceed from any other cauſe than that all theſe grains do not riſe and proſper; nor can any but one, or all, of the ſeven following reaſons be aſſigned for it, if we except bad ſeaſons and extraordinary accidents.

"The deficiency ariſes either 1, from the ſeed; or 2, from rain, when the corn is in bloom; 3, from winds, when its ſtalks are large; 4, from birds, which eat up the grains that have been ſown; 5, from worms and inſects; 6, from the earth; or, 7, from the cultivator himſelf.

"The cauſe of this defect is not in the ſeed: for, either the ſeed is good, or it is not: if it be not good, the grains will not riſe at all; but if it be good, as we ſuppoſe it to be, each grain may, and ſhould, produce at leaſt one ear. Another proof is, that if a parcel of ſeeds are planted at a proper depth, one by one, in holes made on purpoſe for them, and an equal number of the ſame kind of ſeeds are ſowed at random in the ſame ſort of ground, all the former will riſe, but not all the latter.

"Neither ought it to be aſcribed either to rain or winds, at the time of the bloſſoming of the corn: becauſe we do not reap fifty for one, even when the weather is then very fine; and even when each ear bears fifty grains, we do not reap fifty times the ſeed.

"Nor ought we to accuſe the birds of the air: it being well known that lupins, which they never touch on account of their bitterneſs, do not all riſe; for if they did, the crop would be ſtill more conſiderable, as each of theſe plants bears from fifty to ſixty ſeeds. Beſides, what the birds eat is not conſiderable.

"Worms and inſects are not the cauſe, for three reaſons, firſt, our crops are very little better even when neither worms nor inſects are to be ſeen; ſecondly, the caſe here is the ſame as that of the lupins; and, thirdly, the worms would ravage whole fields (as they ſometimes do) in ſo viſible a manner, that it would be eaſy to diſtinguiſh the cauſe of the miſchief. However, this is an extraordinary and pretty rare event.

"The ſame may be ſaid of fogs, cold, bad weather, reptiles, and other miſchievous creatures. Though theſe enemies do not injure our fields every year, we nevertheleſs conſtantly reap leſs corn than they might be made to produce.

"Laſtly, the earth is not in itſelf the cauſe of this ſcantineſs of increaſe: for the Creator has endowed it with perpetual youth and fruitfulneſs, as Columella juſtly and prettily obſerves in the firſt chapters of his firſt and ſecond books. The earth and nature are always the ſame.

"Now, if the uſual cauſe why we do not reap fifty for one cannot be imputed to either of the things above-mentioned, it muſt of neceſſity be ſought for in the ignorance, negligence, and indolence of the huſbandman: for our practiſe is diametrically contrary to that of the ancient Romans. They plowed often, and ſowed little; yet every family lived upon the produce of its ſmall farm: but we who plow little and ſow a great deal, are always diſappointed."

The Romans were not only extremely attentive to the thorough culture of their land, but alſo, even in the latter time of the republic, laid it down as a maxim to be followed by all good huſbandmen, "to ſow but little and plow much." This is ſtrictly enjoined by Virgil; and Pliny, who inſtances the huſbandry of Creſinus, as an example of the good effects of this practice, laments the deplorable condition of Italy, when rich men, with the help of their numerous ſlaves, farmed large diſtricts of land; becauſe it diminiſhed the number of Roman citizens, and rendered the country leſs fruitful: for, as both he and Columella obſerve, the Romans then became dependant on other nations for the means of ſubſiſtance.

May not this naturally lead us to caſt an eye upon our own country, where, of late years, gentlemen throw their eſtates, as much as poſſible, into large farms, which, in the language of Mago the Carthaginian, muſt, in general, render the farm ſtronger than the farmer, whereby it neceſſarily becomes leſs fruitful? This practice is attended with another moſt fatal conſequence to a manufacturing and trading people: it leſſens the number of inhabitants in the country, from whence only the ſupply of population ariſes; for cities and large towns are always an expence of men.

Whilſt we beſtow this due commendation on plowing, we do not mean to recommend it on Mr. Tull's principles, "that dividing and pulverizing the earth is all in all." When the earth is in fine tilth, ſo that the roots of plants can eaſily extend themſelves every way, an advantage ariſes, which is thus deſcribed by the ingenious M. J. J. Biberg, in his Œconomy of Nature.

"Plants, as well as living creatures, muſt ſubmit to death. They ſpring up, they grow, they flouriſh, they ripen their fruit, they wither, and at laſt, having finiſhed their courſe, they die, and return again to the duſt, from whence they firſt took their riſe. Thus the black mould which we ſee upon the ſurface of the earth, is chiefly owing to dead vegetables. For all roots deſcend into the earth by their branches, and after a plant has loſt its ſtem, the root remains; but this too rots at laſt, and changes into mould. By this means, this kind of mould is mixed with the earth, by the contrivance of nature; nearly in

 the

the ſame way as dung thrown upon fields is wrought into the earth by the induſtry of the huſbandman.

" The earth thus prepared offers again to plants from its boſom, what it had received from them. For when ſeeds are committed to the earth, they draw to themſelves, accommodate to their nature, and turn into plants, the more ſubtile parts of this mould, by the co-operation of the ſun, air, and moiſture; ſo that the talleſt tree is, properly ſpeaking, nothing but mould wonderfully compounded and modified by a virtue communicated to a ſmall ſeed by the Creator. From theſe plants, when they die, juſt the ſame mould is formed, as give birth to them originally; but in ſuch a manner, that it is in greater quantity than before, if the earth be kept looſe to admit of the free extenſion of the roots. Vegetables therefore increaſe the black mould; whence fertility remains continually uninterrupted: whereas the earth would not make good its annual conſumption, if it were not conſtantly recruited by new ſupplies."

The illuſtrious M. Lullin de Chateauvieux, to whom the world in general is infinitely indebted for ſome of the moſt judicious and beſt executed experiments ever made in Agriculture, as is his native country in particular for his excellent adminiſtration in the high office of chief magiſtrate of the republic of Geneva, is the firſt writer who has attended to the advantages of ſtubble as a manure.

Towards the latter end of the year 1753, walking over his grounds after harveſt, he was ſtruck with the difference which he found in the ſtubble of his own experiments, and that of the corn which had been raiſed in the common way. This laſt was ſo poor and weak, that it ſcarcely oppoſed the motion of his feet, while the other reſiſted greatly. " I often felt it break, ſays he, under my feet, and frequently met with tufts of twenty, thirty, forty and ſometimes more ſtalks, which ſtopt me ſhort, like ſo many little buſhes. I am the more particular in my account of this ſtubble, becauſe it ſhews the great ſtrength of the plants, which they would not have had if the earth had not been well prepared. Beſides, it has its real uſe: for thorough plowing ſupplies the want of dung, not only by keeping the earth conſtantly in a looſe ſtate, but likewiſe by the quantity of ſtrong ſtubble which it produces, and which affords a moſt excellent manure attended with no expence. It lies ready upon the ſpot; the plowing of the earth buries it; and as it is a long time in rotting, it helps to keep the ſoil looſe and light, and is repeated every year. I have found ſtubble almoſt whole at a year's end, and have ſeen ſome not quite conſumed at the end of two years. From what I have ſeen of its effects, I will venture to ſay, that it contributes greatly to increaſe the productions of the earth. I have very often plucked up plants remarkable for their beauty, and have frequently found their roots interwoven with tufts of ſtubble, which ſhewed me the cauſe of their extraordinary growth."

" It is often, ſays Mr. Duhamel, more advantageous to increaſe the fertility of land by plowing, than by dung: 1, Becauſe, in general, only a certain quantity of dung can be had, the product of twenty acres being ſcarcely ſufficient to produce enough for four or five; whereas the particles of the earth may be divided and ſubdivided almoſt to infinity. The help derived from dung is therefore limited; whilſt no bounds can be ſet to the benefits that may accrue from plowing.

" 2, Few plants raiſed in dung ever have the fine flavour of thoſe which grow in a good ſoil moderately dunged. Our kitchen gardens and our other grounds afford daily inſtances of this truth. Pulſe, pot-herbs, and fruit, are ſeldom ſo good in the neighbourhood of great cities, where dung abounds, as in country gardens, where but little of it is uſed. The corn raiſed in thoſe exceſſively dunged lands, yields a great deal of bran, and not much fine flour, and is difficult to keep. Nice horſes will not eat oats of the growth of fields manured with human ordure. But nothing is ſo ſtriking as the difference between the wine of an undunged vineyard, and that of vines which have been greatly dunged.

" 3, Dung, which is ſuppoſed to act by fermentation, cauſes indeed an inward diviſion of the particles of the earth, which muſt be very uſeful, as well as the food which it furniſhes to plants: but the plough, beſides dividing thoſe particles, changes their ſituation, and turns the ground upſide down, ſo that the part which was expoſed to the influences of the air and dews, takes the place of another part, which is brought from within the earth, up to its ſurface. The conſequence of this is, that well-plowed land is not exhauſted by weeds, and that it admits the moiſture of rains and dews, together with the rays of the ſun, all of which contribute greatly to render it fertile, as has been proved by very many experiments.

" 4, Dung attracts inſects, and thoſe inſects gnaw plants. It is well known that the roots of trees planted in dunged ground, are very liable to be damaged by inſects; and this is one of the chief reaſons why floriſts baniſh dung from their gardens. Worms, grubs, and other ſuch like vermin, make dreadful havock in their beds of flowers; and I have ſeen meadows where the graſs has been entirely deſtroyed, by their eating its roots.

" I muſt add, that moſt ſorts of dung contain a great many ſeeds, which fill the land with weeds.

" 5, It is true that dung is equally ſerviceable to light lands, and to ſtrong; but the ſame may be ſaid of plowing.

" Land is too ſtrong when its particles lie ſo cloſe together, that the roots of plants cannot extend between them, without great difficulty, in queſt of their neceſſary food, for want of which they will remain poor and ſickly. But when the ground has been well looſened by repeated plowings, and its particles are ſet at greater diſtances from each other, thoſe roots will be able to ſpread freely on all ſides, to pervade every minute chaſm, and to collect ſuch quantities of food, as will make the plants grow ſtrong and vigorous. The friendly influences of the atmoſphere will then penetrate to them. What plainly proves the good effects of looſening ſuch ſoils, is, that their fertility is ſometimes increaſed by a mixture of ſand, inſtead of dung. Now ſand does not afford any nutritive ſubſtance; but only hinders the particles of the earth from re-uniting too cloſely.

" Plowing is equally beneficial to light lands, for the very contrary reaſon; though theſe do not require ſo much of it as the other. There is no danger of their being exhauſted by any expoſure to the ſun; but, on the contrary, they acquire an additional degree of fertility by the ſtirring and grinding of their particles, and are thereby the better fitted to receive the moiſture of rains and dews, and the ſalutary influences of the air and ſun; whilſt their inward pores are at the ſame time better adapted to the proper extenſion of the roots of plants, by their being leſſened.

" But, let the benefits ariſing from dung be ever ſo great, let the means of obtaining enough of it be ever ſo eaſy, and let even its defects be corrected as much as can be; ſtill it will not be the leſs true, that frequent plowing is of infinite ſervice to land.

" For this reaſon it is, that land intended for wheat is plowed three or four times before the grain is ſowed. Some farmers, who could not dung all their lands, plowed part of them double the uſual number of times, and reaped greater crops from theſe, than from thoſe which were dunged. The expence of three plowings extraordinary will be much leſs than the price of the dung neceſſary for the land, if the farmer is obliged to purchaſe it.

" In 1759, M. Delu gave three plowings to ſome of his fields intended for oats; and though that year was very dry and unfavourable to ſpring-corn, his oats kept up well till they were perfectly ripe, and yielded a full crop of excellent grain.

" He gave five plowings to a piece of wheat-land, which had not been dunged, and, at harveſt, had taller and finer corn there, than in the neighbouring grounds which had been dunged and cultivated in the uſual way.

" In ſhort, the advantage of thorough tillage, while the plants are growing, is ſo great, that, in many places, it has been found amply to repay even the expence of digging between the rows of corn."

PLOUGH-WRIGHT, a perſon whoſe buſineſs it is to make ploughs, and other implements of huſbandry.

PLUM-TREES. All the ſpecies of plums have within their fruit a hard ſtone, within which there is contained a ſoft and tender kernel: this kernel contains the ſeminal plant, from which would be produced another tree of the ſame kind, if it were ſet in the ground; and it is very

natural

natural to ſuppoſe, that the only uſe of the thick ſtone or huſk of this was only to preſerve its tender ſubſtance from rotting too ſoon in the earth, and to give it a proper time for developing its parts, to preſerve its natural oilineſs during that time, and to furniſh from its own ſubſtance a proper nouriſhment to the growing plant; for obſervation ſhews, that it finally breaks into a very fine powder.

There has not been found any ſpecies of plum which had not its kernel contained in a ſtony coat of this kind, from whatever grafts they have been propagated; nor is there any art known by which the kernel of this ſort of fruit can, while growing, be deprived of its coat.

Mr. Marchand, however, in the year 1735, ſhewed, before the academy of ſciences at Paris, certain plums, whoſe kernels had no ſtone or ſhell round them; and found that they grew upon a tree which never had produced any others, and which had been known to produce ſuch for twenty years. The kernel in theſe was covered with a reddiſh ſkin, which was rough to the touch; and, within that, with another, which was thinner and white. The kernel had nothing particular in it, except that it carried on one ſide of its outer ſurface, and that always in the ſame place, a little ſtony prominence, more or leſs dented on its convex part: this is uſually a twelfth of an inch broad, and two thirds of an inch long, and has no other appearance but that of a diſtempered part of the kernel, only that all the kernels have it.

The thick wrinkled ſkin which ſurrounds the kernel, ſeems in this caſe to ſupply the place of the ſtone or hard ſhell; and in this alſo it reſembles it, that the pulp of the fruit parts eaſily and readily form it: and the hard oblong body, which is placed on one ſide of the kernel, is by no means proper for this purpoſe. *Mem. Acad. Sciences, Par.* 1735.

All the ſorts of plums are propagated by budding, or grafting them upon ſtocks of the muſcle-plum, the white pear plum, the St. Julian, or the *bonum magnum.*

Budding is much properer than grafting for theſe trees, as they are apt to throw out a great deal of gum from the wound: and the trees ſhould be no more than one year's growth from the bud, when they are tranſplanted; for, if they are more, they ſeldom ſucceed well, being very ſubject to canker; and if they eſcape that, they uſually produce only two or three luxuriant branches. The whole management of planting and pruning them is the ſame with that of peaches. *See* PEACH.

If the walls againſt which they are planted are low, they ſhould be ſet eighteen feet aſunder; if they are higher, then fourteen or ſixteen.

Plums ſhould have a middling ſoil, for they ſeldom ſucceed well in too moiſt or too dry a one; and, when planted againſt walls, ſhould have an eaſt or a ſouth-eaſt proſpect. If they have one at full ſouth, they are apt to ſhrivel up, and become mealy. Plums in general ſucceed very well with proper care on eſpaliers; they will alſo bear very well as ſtandards, but the fruit will not be ſo well taſted. Plums do not only produce their fruit on the laſt year's wood, but alſo on ſpurs that come out of the wood at two or three years old. It is a common error to be too free with the knife in the winter pruning, cutting off the extremities of all the branches; the conſequence of which is, that there is an over quantity of young ſhoots produced, and the fruit is ſmall and poor. *Miller's Gard. Dict.*

POA, meadow graſs, or that common ſpecies of graſs, that principally forms the green covering of our fields.

POCKET, a large ſort of bag in which wool is packed up, in order to be ſent from one part of the kingdom to the other.

POD, a term uſed to expreſs a pericarpium, conſiſting of two valves, which open from the baſe to the point, and are ſeparated by a membranaceous partition from which the ſeeds hang by a kind of minute ſtalk.

POKE, a ſack, or bag.

Hop POLES, the upright poles, or pieces of wood, round which they bind, twiſt, and ſupport themſelves. *See the article* HOP.

POLLARD, or *Pollanger*, a tree that has been frequently polled or lopped, and its top taken off.

POLL-EVIL, an abſceſs near the poll of a horſe, formed in the ſinuſes between the noll bone, and the uppermoſt vertebræ of the neck.

If it proceeds from blows, bruiſes, or any external violence, at firſt bathe the ſwelling often with hot vinegar; and if the hair be fretted off with an oozing through the ſkin, make uſe of two parts of vinegar, and one of ſpirit of wine; but if there be an itching with heat and inflammation, the ſafeſt way is to bleed, and apply poultices with bread, milk, and elder flowers: this method, with the aſſiſtance of phyſic, will frequently diſperſe the ſwelling, and prevent this evil.

But when the tumor is critical, and has all the ſigns of matter, the beſt method then is to forward it by applying the ripening poultices already taken notice of, till it comes to maturity, and burſts of itſelf; or if opened with a knife, great care ſhould be taken to avoid the tendinous ligament, that runs along the neck under the mane: when matter is on both ſides, the opening muſt be made on each ſide, and the ligament remain undivided.

If the matter flows in great quantities, reſembles melted glue, and is of an oily conſiſtence, it will require a ſecond inciſion, eſpecially if any cavities are diſcovered by the finger or probe; theſe ſhould be opened by the knife, the orifices made depending, and the wound dreſſed with the common digeſtive of turpentine, honey, and tincture of myrrh, and after digeſtion with the precipitate ointment; or waſh the ſore with the following, made hot, and fill up the cavity with tow ſoaked in it.

> Take vinegar or ſpirit of wine, half a pint, white vitriol diſſolved in ſpring water, half an ounce, tincture of myrrh, four ounces.

This may be made ſharper by adding more vitriol; but if the fleſh is very luxuriant, it ſhould firſt be pared down with a knife before the application; with this waſh alone Mr. Gibſon has cured this diſorder without any other formality of dreſſing, waſhing with it twice a day, and laying over the part a quantity of tow ſoaked in vinegar and the white of eggs beat together. This laſt application will ſerve inſtead of a bandage, as it will adhere cloſe to the poll, and come off eaſy when there is occaſion to dreſs. Some waſh with the phagædenic water, and then fill up the abſceſs with looſe doſſils of tow ſoaked in Ægyptiacum and oil of turpentine made hot, and continue this method till the cure is effected.

But the moſt compendious method of cure, is found by obſervation to be by ſcalding, as the farriers term it, and is thus proſecuted when the ſore is foul, of a bad diſpoſition, and attended with a profuſion of matter.

> Take corroſive ſublimate, verdigreaſe in fine powder, and Roman vitriol, of each two drams; green copperas half an ounce; honey or Ægyptiacum two ounces, oil of turpentine and train oil, of each eight ounces; rectified ſpirit of wine four ounces: mix together in a bottle.

Some make their ſcalding mixture milder, uſing red precipitate inſtead of the ſublimate; and white vitriol inſtead of the blue; the following has been ſucceſsfully uſed for this purpoſe, viz. half an ounce of verdigreaſe, half a pint of train oil, four ounces of oil of turpentine, and two of oil of vitriol.

The manner of ſcalding is firſt to clean the abſceſs well with a piece of ſponge dipped in vinegar; then put a ſufficient quantity of the mixture in a ladle with a ſpout, and when it is made ſcalding hot, pour it into the abſceſs, and cloſe the lips together with one or more ſtitches. This is to remain in ſeveral days, and if good matter appears, and not in an over great quantity, it will do well without any other dreſſing, but bathing with ſpirit of wine; if the matter flows in great abundance, and of a thin conſiſtence, it muſt be ſcalded again, and repeated till the matter leſſens and thickens.

Theſe liquid corroſive dreſſings agree well with horſes, whoſe fibres are ſtiff and rigid, and whoſe juices are oily and viſcid; in this caſe they contract the veſſels of the tendons on the hind part of the head and upper part of the neck, which are continually ſpewing out a matter or ichor that can hardly be digeſted, or the profuſion abated without ſuch applications as theſe.

POND, a reſervoir or receptacle for collecting and preſerving water.

The neceffity of water, in all paftures, is felf-evident; as cattle cannot live without it, and the driving of them far for it is known to be prejudicial to their health, in hot weather, befides being attended with great trouble, and a confiderable lofs of time. This is fo fenfibly felt in many parts of England, that people are obliged to dig wells, even to fuch a depth as, frequently, to require the affiftance of a horfe to draw up the water. The means of rendering it eafily come at, muft therefore inhance the value of the land where it can be fo procured, and are of very effential confequence to the hufbandman.

Where the furface of the ground is fand or gravel, there feldom is occafion to dig deep for water; becaufe fuch foils generally lie upon marle, or fome other rich earth, through which the water cannot defcend. Beds of clay are moft commonly thicker than thofe of fand or gravel; and chalk is, too often, the thickeft of all. But wherever water is wanting, the farmer fhould bore through the incumbent earth, if he intends to fit his land for pafture: and if he finds the expence of obtaining it too great, his beft way will be to convert the ground fo circumftanced into arable, or to plant it with timber-trees fuited to the nature of the foil.

Wherever water ftagnates in a fandy or gravelly foil, the hufbandman fees at once at what depth is the furface of the earth which retains it. But in other foils, and when this does not happen, Palladius, and the authors of the *Maifon Ruftique*, give the following directions how to feek for water, with the greateft probability of fuccefs.

Where rufhes, reeds, flags, willows, or other aquatic plants grow fpontaneoufly, or where frogs are obferved to lie fquatted down clofe to the ground, in order to receive its moifture, there generally is water underneath. Perfons who make it their bufinefs to find out fprings for fountains, cafcades, &c. look upon it as an infallible fign of fubterranean water, when they fee a vapour arife frequently from the fame fpot of ground. Others affure, that wherever fwarms of little flies are feen conftantly flying in the fame place, and near to the ground, in the morning, after funrife, there certainly is water under that fpot. Again, where water is wanted on land apparently dry, let a man, before fun-rife, lie down flat upon his belly, refting his chin upon his fift placed clofe to the ground, that his view may be directed quite horizontally, and not rife too high, and in that fituation let him look ftedfaftly toward the eaft. If he then fees a tremulous vapour arife from any particular fpot, let him mark the place, by noticing fome neighbouring tree, fhrub, or other indication, and he will find water underneath it. But this experiment is to be made only on ground whofe furface is dry; becaufe other exhalations, from a damp furface, would be apt, in this cafe, to miflead the enquirer.

Another way is thus. Dig a hole three feet wide, and at leaft five feet deep, and place at the bottom of it, when the fun is about to fet, a pan, or bafon, rubbed with oil on the infide: let the bottom of this veffel be uppermoft; cover it with dry hay, fern, or rufhes, and over that with earth; and if any drops of water are found ftanding on its infide the next day, a fpring is probably not far off. Or, put a new, unbaked, but well dried, earthen veffel into fuch a hole, and cover it as before; and if there be water in that place, this veffel will be found foft and wet the next day. Likewife if wool be left all night in a trench of this kind, and water can be fqueezed out of it the next day, little doubt remains but that of plenty of water may be met with there.

The month of Auguft is generally looked upon as the moft proper time to fearch for water; becaufe, we apprehend, as the heat of the preceding fummer will have warmed the earth to a confiderable depth, any fteam arifing from water refting on an impervious foil underneath, and particularly in hollows on the furface of that impervious foil, will then be moft exhaled by this warmth. Now it is this fteam, or vapour, which produces the before-mentioned figns.

By whatever method water is found, the means of coming eafily at it are the next confideration. If it be on a plain, there is no other way than digging a well. In doing this, the fubftance under the fand or light foil muft be dug into, to form a refervoir of water for occafional wants; and this refervoir fhould be made deep and large, in proportion to the quantity wanted. If there were no fuch refervoir, the water, after having rifen a little above the impervious body underneath, would glide along its furface, as ufual, and very little of it could then be obtained, either by pumps, buckets, or any other way employed to raife it. If the well is made in a floping ground, and the declivity is fufficient to give it an horizontal vent, it will be worth the hufbandman's while to dig fuch a paffage, and, by means of pipes, or any other conveyance, to carry the water acrofs the light foil, through which it would otherwife fink. The greateft quantity of water will be obtained in this manner, becaufe there will then be a continual ftream.

If the foil is very deep, and its furface has inequalities in which rain water runs in any quantity; this may be collected in ponds made in the loweft parts of fuch grounds.

If a body of clay is found near the furface, it is worth the farmer's while to bore, that he may know at what depth a bed of fand or gravel may be met with: for he will be fure to find plenty of water in this laft. If this be in a declivity, he need only cut an horizontal paffage, and the water will flow fo freely as even to double the value of his land.

Here again the farmer needs not ever to be at a lofs, becaufe it cannot be very difficult to make a pond in a clayey foil, which is, of itfelf, retentive of water. But it may, perhaps, be advifable, even in this, to cover the bottom of the pond with a coat of gravel, in order to prevent its being poached by cattle, whofe feet would otherwife be apt to fink deep into clay. Some farmers judicioufly pave the declivity by which the cattle enter into the pond, and this renders it much more lafting than it would otherwife be, and preferves the water clean.

When ponds are made in a loofe foil, much more care is neceffary. The bottom and fides there muft be covered with a thick coat of the tougheft clay, from a foot to two feet thick, well rammed down. Some have added hair and loam to the outer part of this covering, with a view of rendering it lefs liable to chap: but a thick coat of gravel is more neceffary here, that the feet of the cattle may not pierce through the clay. Perhaps the expence of paving the whole infide of a pond, might, in the end, be money well laid out.

The greateft difficulty of finding water is in chalky foils, becaufe thefe are not, of themfelves, very retentive of it, and generally lie in fuch thick beds, that it is expenfive to dig through them. However, it fhould be tried; and if fand or gravel be found underneath, water may be depended on. Even here, ponds are eafily made, by digging into the chalk, and lining them with a coat of clay, as before directed. If there is a fupply of proper manure, fuch as clay, or marle, this fituation is well adapted to grain, which loves to ftand dry; and as this kind of ground produces more forward crops than clayey or ftrong foils, it may be fowed early with corn, which will not, in that cafe, be fo apt to be parched up as grafs is, by the fummer's drought. If a good foil can be made here, a foot deep, it will yield plenty of various forts of pafture, either roots or graffes, as the farmer fhall judge moft proper: or it may be planted with different kinds of timber-trees. For the method of making ponds in gardens, *fee the article* GARDEN.

POPLAR, a genus of trees, of which botanifts enumerate four fpecies; viz. the common white poplar, with large leaves: the common white poplar, with fmaller leaves: the common black poplar, and the poplar with trembling leaves, called the afpen-tree. The poplar, whether black or white, may be eafily propagated, either by layers, cuttings, or fuckers, of which the white kind always produces a great many from the roots. The beft feafon for the tranfplanting thefe fuckers is in October, when the leaves begin to decay; and they fhould be removed into a nurfery for two or three years, at the end of which time they will have got ftrength enough to be tranfplanted into the places where they are to remain.

When they are to be propagated by cuttings, it is beft to do that in February, cutting off large truncheons of eight or ten feet long; which, being thruft down a foot deep in the ground, will take root very quickly, and, if the foil be moift, will grow to a confiderable fize in a few years.

The black poplar is not so easily raised from these large truncheons, but should be planted in cuttings, of about a foot and a half long, planting them a foot deep in the ground. This will grow on almost any soil, but does much better on a moist one than on any other. They are the fittest of all trees for raising a shade quickly, as they will grow fourteen feet in height sometimes in one season, and in four or five years will be large trees.

A considerable advantage may be obtained by planting these trees upon moist boggy soils, where few other trees will thrive: many such places there are in England, which do not, at present, bring in much money to their owners; whereas, if they were planted with these trees, they would, in a very few years, over-purchase the ground, clear of all expence: but there are many persons in England, who think nothing, except corn, worth cultivating: or, if they plant timber, it must be oak, ash, or elm; and, if their land be not proper for either of these, it is deemed little worth; whereas, if the nature of the soil was examined, and proper sorts of plants adapted to it, there might be a very great advantage made of several large tracts of lands, which at this time lie neglected.

The wood of these trees, especially of the white, is very good to lay for floors, where it will last many years; and, for its exceeding whiteness, is, by many persons, preferred to oak; but, being of a soft contexture, is very subject to take the impression of nails, &c. which renders it less proper for this purpose: it is also very proper for wainscotting of rooms, being less subject to swell or shrink, than most other sorts of wood: but for turnery-ware, there is no wood equal to this for its exceeding whiteness, so that trays, bowls, and many other utensils, are made of it; and the bellows-makers prefer it for their use; as do also the shoemakers, not only for heels, but also for the soles of shoes: it is also very good to make light carts; the poles are very proper to support vines, hops, &c. and the lopping will afford good fuel, which in many countries, is much wanted. *Miller's Gard. Dict.*

POPPY, the name of a plant, of which several species are cultivated in gardens for the beauty of the flowers. They are all easily propagated by sowing the seeds in autumn. When the young plants come up, they are to be cleared from weeds, and thinned to a proper distance by pulling some up, where they stand too thick; for they never thrive well, if they are to be transplanted. They are to be left, according to their sizes, at six, eight, or ten inches distance.

They are very showy flowers, and make a splendid appearance in gardens; but they are but of a short duration, and are of an offensive smell, which makes them less valued at present than they have been.

Some sow these plants in spring, but it is not so well; because they then have not time to get strength before autumn, when they are to flower; and, for that reason, those sown in spring usually flower weakly. *Miller's Gard. Dict.*

Red POPPY, or *Red-weed.* The common wild red poppy is one of the most mischievous weeds the farmers are plagued with among their corn, and it is the most difficult to thoroughly destroy of almost any other. Its seed will lie a long time in land unploughed, without ever shooting; but they will be sure to grow with every crop of corn. Mr. Tull gives an instance of the seeds of this plant being buried four and twenty years in a field of saintfoin, and at the end of that time, the land being ploughed for wheat, they all grew up among the corn, though they had lain dormant so long before. *Tull's Horse-hoeing Husbandry.*

POTATOE, or POTATO, the name of a well known plant, the roots of which make a very nourishing food.

Mr. Houghton describes the potato to be a bacciferous herb, with esculent roots, bearing winged leaves and a belled flower; and says, that, according to his information, which is allowed to be very right in this respect, it was first brought from Virginia, by Sir Walter Raleigh, who, stopping at Ireland, about the year 1623, gave away a number of these roots, which were planted there, and multiplied so exceedingly, that, in the wars which happened afterwards in that country, when all the corn above ground was destroyed, potatoes became the chief support of the people: for the soldiers, unless they had dug up all the ground where they grew, and almost sifted it, could not have extirpated them. The Philosophical Transactions observe likewise, that the Irish were relieved from their last severe famine, which lasted two years, during which all their corn failed, merely by the help of this root. From Ireland it was brought to Lancashire, now famous for its potatoes: and the culture of this plant has, within these last thirty years, been extended to almost every part of England. The rich, who, at first, deemed them fit for none but the meaner sort of people, now esteem them so much, that Mr. Miller thinks the quantity of them which is cultivated around London only, exceeds that of any other part of Europe.

The red rooted potatoes have purplish flowers, and the white rooted (for Mr. Miller distinguishes only these two general varieties) bear white flowers.

The potatoe seldom perfects its seeds in England; and if it did, the raising of it from them would be much more tedious and uncertain than propagating it by its roots, as is the general and right method: for these multiply exceedingly, and may be made to yield vast crops, with little cost or labour.

"The Irish husbandman, says Mr. Switzer, after blaming the English for planting this root uncut, because it often contains five or six eyes, or perhaps more, from which the produce of the ensuing year is to spring; and also for not allowing that bulb, or rather the great number of shoots and bulbs that proceed from it, a space of earth sufficient for their nourishment, which is the reason why so many poor, stinted, unserviceable potatoes are dug up in the autumn, relates the practice of his country, which is to chuse middle sized roots, for the largest are generally eaten, to single out the eyes that seem strongest and most vigorous, and to cut them out in squares of at least half an inch every way: so that one root will sometimes furnish three or four good pieces to set.

"The ground, prepared for planting, is marked out for beds four or five feet wide, with intermediate alleys of two or three feet. It is then trenched, only a single spit deep, and the bottom of this trench, made as in common garden-trenching, is covered with dung, long and short, taken out of a wheel-barrow which stands at the labourer's elbow. The potatoe-eyes cut as before directed, are placed upon this dung, at about five or six inches asunder; and this trench is filled up with the mould taken out of the next, which is marked by a line at the distance of two or three feet. This trench is again filled with the mould of the next, and so on to the last, which is filled from the alley.

"The use of the dung thus laid at the bottom of the trenches, is not only to make the roots grow single, for not above one root, or at most two, will in this case be produced by each eye, and these will be large and well fed; but it is attended with the farther advantage of making the potatoes run, and spread themselves to a certain determinate depth, which is no small help to their growing large.

"The last thing to be done to them is, in April or May (for they are planted in February or March,) as soon as they begin to rise, to dig the earth out of the alleys, as is done for asparagus, and to cover the potatoe bed with it, about five or six inches thick. This will give new life and vigour to the roots, will keep the green from running too much to haulm, and will make the bulbs grow much the larger. By this means the crop of fine large potatoes will be almost the double of what is obtained when they are planted promiscuously in the common way: nor will any farther culture be requisite till they are fit to be dug up; except the pulling out of some of the largest weeds."

Mr. Miller's reasons for disapproving of the planting, either of the small offsets entire, or the eyes cut out of larger roots, are, that though the former generally produce a greater number of roots, these roots are always small; and that the cuttings of the larger roots are apt to rot, especially if wet weather happens soon after they are planted. He therefore recommends, to make choice of the fairest roots for setting, and to allow them a larger space of ground, both between the rows, and between the plants in the rows; and he assures us that he has observed, when this method has been followed, that the roots, in general, have been large the following autumn. M. Duhamel, in his Elements of Agriculture, does not object at all to the planting of the cuttings.

The soil in which this plant thrives best, is a light sandy loam, neither too dry nor over moist, but brought to a fine tilth, and ploughed very deep: for the deeper the earth is loosened, the finer and larger the roots will grow. In the spring, just before the last ploughing (according to Mr. Miller's method,) a good quantity of rotten dung should be spread on the ground, and this should be ploughed in early in March, if the season be mild; otherwise it had better be deferred until the middle or latter end of that month; for if a hard frost should come on soon after the roots are planted, they may be greatly injured, if not destroyed, thereby; but if they can be planted in the spring, without that danger, the better it will be.

The last ploughing should lay the ground even, and then furrows should be drawn three feet asunder, and seven or eight inches deep. The roots should be laid at the bottom of these furrows, about a foot and a half asunder, and they should then be covered in with earth.

After all the ground intended for potatoes is planted in this manner, it must remain in the same state till near the time when the shoots are expected to appear: then it should be well harrowed both ways, as well to loosen the surface and render it smooth, as to tear up the young weeds which will have begun to grow by that time. If much wet has fallen after the planting, it may have caked the surface of the earth, so as to retard the sprouting of the plants; and this harrowing will, in such case, almost answer the intent of a first hoeing.

I have placed the rows of potatoes at three feet distance, continues Mr. Miller, in order to introduce the hoe-plough between them; because that will greatly improve their roots: for by twice stirring and breaking of the ground between these plants, not only weeds will be destroyed, but the soil will be so loosened, that every shower of rain will penetrate to the roots, and greatly quicken their growth. But these operations should be performed early in the season, before the stems or branches of the plants begin to fall and trail upon the ground: for after that, it cannot be done without injuring the shoots.

If these hoe-ploughings are carefully performed, they will prevent the growth of weeds, till the haulm of the plants cover the ground; and after that there will be little danger of their growing so as to injure the crop; for the haulm will keep them under: but as the horse-hoe can only go between the rows, it will be necessary to make use of a hand-hoe to stir the ground, and destroy the weeds in the rows, between the plants. If this is well done, in dry weather, immediately after each of the two horse-hoeings, it will be sufficient to keep the ground clean until the potatoes are fit to be taken up; which will be, very soon after the first frost in the autumn has killed the haulm. They should not remain much longer in the earth, lest the roots themselves be frost-bitten, which spoils them. A four or five pronged fork is better to dig them up with, than a spade, because it is less apt to cut them: but a principal thing to be considered here, is the clearing of the ground thoroughly of them: for if any are left, they will shoot up among the next crop, whatever it be, and do considerable damage, especially if it be wheat, as is generally the case, sown in the common broad-cast way.

The best way of keeping these roots during the winter, is to lay them up in a dry place in very dry sand, or in fine and perfectly dry earth.

The method of laying dung only at the bottom of the furrows in which the roots are planted, " is a very poor one, says Mr. Miller, because, where the potatoes begin to push out their roots, they are soon extended beyond the width of these furrows, and the new roots are commonly formed at a distance from the old: so will be out of the reach of this dung, and consequently will receive little benefit from it." But rather the contrary would seem to be the case, according to the Irish husbandman, who, seems to speak from experience, when he says, he had intended expressly to answer this very objection, that " the dung is placed at the bottom of the furrows on purpose to make the roots grow single; and that its being so placed is attended with the farther conveniency of making the potatoes run, and spread themselves at a certain determinate depth, which is no small help to their growing large." Facts must here determine which is right: as they also must in regard to some parts of what Mr. Miller adds in the following words. " As most farmers covet to have a crop of wheat after the potatoes are taken off the ground, so the land will not be so thoroughly dressed in every part, nor so proper for this crop, as when the dung is equally spread, and plowed in all over the land, nor will the crops of potatoes be so good. I have always observed, where this method of planting the potatoes has been practised, the land has produced a fine crop of wheat afterward, and there has scarce one shoot of the potatoe appeared among the wheat, which I attribute to the farmers planting only the largest roots: for when they have forked them out of the ground the following autumn, there have been six, eight, or ten large roots produced from each, and often many more, and scarce any very small roots; whereas, in such places where the small roots have been planted, there has been a vast number of very small roots produced, many of which were so small, as not to be discovered when the roots were taken up; so have grown the following season, and have greatly injured whatever crop was on the ground."

Will not a thorough plowing and good harrowing, after the crop of potatoes has been taken off the ground, intermix the dung laid in the furrows, and the contiguous earth most impregnated thereby, with the rest of the soil; perhaps almost as well as if the dung had been spread equally over the whole field, at the very first? If it will, the presumption seems strong in favour of the Irish method. For certain it is, that the land ought to be well plowed and harrowed after the potatoes are removed, before it is sown with any other crop; unless the seed for that crop, which generally is wheat, be sprinkled by hand between the rows, as they are dug up, and there covered with the earth then turned over. This is practised in some parts of France: but, as M. Duhamel observes, the grain is so apt to be distributed unequally in this method, that it is better to plow the ground, and sow it, in the regular way.

If the farmer apprehends that his land has not been thoroughly cleared of the potatoes, and is therefore afraid of their damaging his ensuing crop; his best way will be to lay it up very rough against winter; because the frosts of that season are known to kill and rot all potatoes in the ground exposed to them, and it will at the same time be thereby finely prepared for spring corn; especially as it will have been well enriched by the haulm of the potatoes lying upon it.

Though potatoes delight most in a light sandy loam, neither too dry, nor over moist, as was observed before; yet Mr. Maxwell says he has seen them thrive well on ground that seemed to be very bad; even in deep moss, which could not bear horses to plow it, but which is considerably bettered by them; and on coarse heath, where they were succeeded by grain, without more dung than was laid on at first. Of so improving a nature are they, and so much is the land enriched by the rotting of their stalks among it, and the digging it gets in raising them.

Several experiments communicated to M. Duhamel concur to prove the extraordinary increase of potatoes cultivated with the horse-hoe: but as this will always be the consequence of the new husbandry, wherever it is properly used, I shall only borrow from him, on this occasion, M. de Villier's account of his method of practice, because it is the clearest and most concise.

" There are, says he, several sorts of potatoes. That which I cultivate is the middle sized. It is planted about the end of April, or the beginning of May, and it ripens in October. My beds are five feet wide. I give them two plowings in the spring; at the second of which I half fill the main furrow. Before I plant, I cut a small furrow with the single cultivator, which likewise loosens the earth; but if it be moist, I put a double spring-tree bar to the cultivator, to avoid the poaching of the horses. I then plant the potatoes a foot asunder in the row; choosing for this purpose such as are about the size of a walnut. They are thrust in by hand, two or three inches deep; and if the mould does not then cover them

sufficiently

ſufficiently of its own accord, a little more is puſhed down upon them.

"A ſlight hand-hoeing can hardly be avoided afterwards, to deſtroy the weeds which ſpring up at the ſame time as the potatoes: but this hoeing need not extend farther than three or four inches on each ſide of the row; becauſe the plow will do the reſt.

"I give the firſt hoe-plowing in the ſpring, as for wheat; but earlier or later, according to the condition of the ground.

"My ſecond hoe-plowing is given as ſoon as the plants are tall enough to be earthed up; that is to ſay, when they are eight or ten inches high. I then turn the earth up towards them as much as poſſible.

"As this plant ſpreads greatly, and ſhoots out very faſt, it would be impoſſible to give more than two of theſe hoeings, if one ſhould neglect to take advantage of the time when its leaves and branches do not entirely cover the bed.

"The roots are dug up in October or perhaps ſomewhat earlier or later, according to the ſeaſon, with a ſtrong iron prong; ſhaking and clearing them well from the mould. They are then left to dry for ſome hours, and are afterwards laid up in a place where the froſt cannot reach them.

"This fruit, which yields ſurpriſingly, is of great ſervice to feed and fatten cattle, eſpecially when it has been boiled a little. They like it very well raw, after it has been kept a few months above ground: but it is beſt for them after it has been boiled."

The reader is obliged to the ingenious Mr. Irwin for the following account of cultivating potatoes in Ireland, and which we ſhall give in his own words.

"The potato, ſays he, is become a root of ſuch immenſe utility, eſpecially to the poorer ſort, within this century, that too much, methinks, cannot be ſaid towards improving, and extending the culture of it.

"In Provence, Dauphiny, Switzerland, and ſeveral other parts of Europe, and even in America, it yields commodious, abundant relief to the more indigent, as being eaſily and plenteouſly propagated in almoſt every kind of ſoil.

"In Ireland particularly it is the principal food of the poor during the greater part of the year, without which, ſince the late unproportionable riſe of lands in that kingdom, to the trade of it, they could not well ſubſiſt. And, indeed, it ſeems a particular favour of providence ſent to them on this account.

"In times, not very remote, lands were cheap there, and the peaſantry, conſequently, lived on nouriſhment ſomewhat more luxurious, and diverſified: their labour alſo was leſs burthenſome. But now, being obliged to work hard at four-pence and ſix-pence a day, and their rents conſiderably augmented, it will not ſeem ſurpriſing that this root alone has become the ſtaple of their ſupport, and that they have been the firſt people in Europe, or, perhaps, in the world, that have led the example in an extenſive improvement of it. This may naturally be ſuppoſed to ariſe from cloſe-preſſing neceſſity, the moſt cogent and inſpiriting of all motives.

"In truth with much reaſon; for a poor labourer, in that ill-fated country, is driven to ſeek his ſole refuge for ſubſiſtence in this root, from the inexorable impoſition of a hard-hearted landlord, (ſorry I am to have it to ſay, too many of them grind the poor; but hope it will not be long the caſe) who thinks he cannot get too much for his land out of the perſons, or purſes, of his dependents, and who hath ſo inverted the old cuſtoms, that a hewer of wood, and drawer of water, (and many of theſe perhaps deſcendants of former proprietors) can afford himſelf but a miſerable ſcanty platter of potatoes, ſeaſoned with a palatable grain of ſalt, and waſhed down with a draught from the next rivulet, to ſupport the fatigue of thirteen hours (ſtatute quantity) of unceaſing labour, about his ancient manſion-houſe, or in his elegant gardens, well-laid-out cloſes, or refreſhing bog-holes.

"The potato is a root, a little of which is very filling, quickly appeaſing hunger; but by no means a laſting ſolid nouriſhment for a labourer, as evidently teſtify the ſqualid looks of numbers of the poorer Iriſh; though at the ſame time it is in general whole ſome, agreeing with moſt ſtomachs that can vary their food; but, like other productions of the earth, forbid in many caſes by the medicinal tribe.

"There are ſeveral ways of breeding potatoes in Ireland, which partly ariſe from the difference in ſoil, and kinds of ſeed. The different ſoils for this purpoſe in uſe in my neighbourhood, for about twenty years paſt, and which, I believe, are pretty general, are the following, wherein they are abundantly propagated, viz.

"Firſt, On rich clay land without any manure, vulgarly called graſs potatoes.

"When a leaſe is near being expired, that is, during the laſt ſeven years of it, if there be no covenants grounded on the ſtatute againſt waſte, &c. the tenant, finding no hopes of a renewal, ſets conſiderable tracts in this way, where the ſoil will admit of it.

"Secondly, On good ley land well gravelled, (otherwiſe ſanded) which ought to be done a year before planting. But the poorer ſort, who are the chief cultivators of this root, are obliged to ſand and plant at the ſame time, or nearly thereabouts; which is very deſtructive to themſelves, their potatoes not having the proper benefit of the manure; at leaſt one part in three of the return are on this account exceeding ſmall, and are from hence called poreens by them, being a diminutive expreſſion. Whole fields are ſet in this way, (commonly called ſpaddane, in which a conſiderable trade is driven; eſpecially in the provinces of Munſter and Connaught.

"Had it been properly and moderately done, it would be a fine preparation for the encreaſe of corn, and the laying down and bringing in, or, in other terms, the reclaiming of land; but the poor do it ſo negligently, and mangle it ſo intolerably, having but a ſhort temporary uſe in it, beſides paying near double the worth for it, that this manufacture, which might otherwiſe be of conſiderable benefit to Ireland, is, as now carried on, rather the contrary.

"Thirdly, On ground previouſly gravelled (that is, perhaps ſix months before) and dunged at ſetting time. There is but little done in this way, except by the gentry, and renters of land for their private uſe; it being as yet out of reach of the peaſantry, unleſs in a few inſtances.

"Fourthly, On the ley with dung alone. Marle is not in uſe in my neighbourhood, though there is plenty of it in ſeveral parts of it; therefore cannot yet inform you how it would do for the potatoes in that diſtrict. As to potatoes ſet in the ley with dung alone, this manufacture alſo is done, as you may judge, moſtly by the more opulent. I have, however, often ſeen large fields ſet in this way to the public; but it is not of late years ſo much the cuſtom, this ſort of land being commonly kept for grazing: this hurts the land; and any preparation out of the ley for potatoes will, if not previouſly gravelled.

"Fifthly, In arable or ſtubble land (vulgarly called ſticking or thruſting of potatoes, becauſe they are ſown with a ſtick, pointed at the end, about an inch diameter and two feet long, with the loy (otherwiſe the Iriſh ſpade.) In this method dung is alſo uſed, which ſhall be noticed in loco.

"Theſe are the moſt general methods that now occur to me, or I believe that are in uſe. There are, however, ſome others ariſing from the quality of the ſeed, practiſed only by the curious, in which the plants are put down at nine or twelve inches aſunder every way, in little hillocks, (like the hop plant) as practiſed in ſeveral counties in England; and, if you land them at certain proper ſtated times while vegetation continues, you will have a handſome neſt of large oblong potatoes at every landing.

"I made the experiment of one ſort in my garden; and out of half a dozen potatoes cut into ſeveral pieces, each having an eye, I had, to the beſt of my remembrance, without exaggeration, a quantity nearly equal to twelve Wincheſter buſhels.

"This kind of potato is introduced into Ireland but of late years: it is however well known there.

"A potato entirely black is alſo in uſe in Fingal, near Dublin, fructifies abundantly, and eats exceeding dry, which principally marks the goodneſs of this root in almoſt every inſtance.

2

"There

" There are ſeveral kinds of potatoes. Mr. Maxwell, of Arkland in Scotland, a very judicious gentleman, has particularly noticed ſix ſorts, viz. The long red, the round red; the long white, the round white, or Spaniſh potato; the blue, the leather-coat, and an early kind that comes in a month ſooner than the common ſort, though planted at the ſame time.

" This root being greatly manufactured in Ireland, they mix moſt of the better ſorts promiſcuouſly, both for uſe and ſeed.

" I remember, about twenty-five years ago, the large red potato, then called the Caſtonian, (perhaps from Caſtile) as alſo the oblong Spaniſh white potato, to be chiefly in uſe; but now a leſſer ſort, ſuch as the Munſter or kidney potato, of a whitiſh or lightiſh yellow colour, the leather-coat, or round red Cronian potato, with a rough thick ſkin, and particularly that ſtiled the Spaniſh white potato, are moſtly in uſe.

" All theſe ſorts are cut for ſeed, according to the number of eyes on them, and thrive generally well with very little care; ſo that all ſorts being now ſo plenty, and anſwering ſo well, there are (as we may eaſily judge) no over nice diſtinction made about them there. The poorer Iriſh, who affect not to plant this root in bottom lands, or wet ſwampy grounds, unleſs hard preſſed for ſoil, are even in this caſe ſeldom attentive about the kind of potato they put down, the return being commonly wet, unfit for eating, and only proper for ſeed, which (from my little experience) I think makes but indifferent, though ſown in the beſt prepared upland; for too much moiſture, as well as too much dung, makes a potato wet: and plant it when you will, I am apprehenſive it never loſes this quality, which is the worſt it can have, except being rotten, or froſt-bit: nor will any eat ſo well, raiſed from dung, as without.

" As the potato thrives in different ſoils, ſo there are different methods of cultivating it: I will therefore now proceed to that moſt generally in uſe in my neighbourhood, (and indeed all over the kingdom) called graſs potatoes or ſpuddane, and by ſome (improperly) conacres, which ſeems to be the natural culture, but doubtleſs not ſo good to make the land ſtand long proof, (notwithſtanding the graveling) as if artificial manures were added, ſuch as dung, compoſt, lime, &c. for marle, lime-ſtone, gravel, ſea-ſand, ſhells, &c. I conſider in the claſs of natural manures and the beſt; and providence hath kindly given them in every ſpot, (even in the unpromiſing deſerts of Zara, &c.) had we known how to come at them.

" Land in the ley, (as I ſaid before) and that which requires no manure, the Iriſh ſeek moſt greedily after; ſome of which has not been ploughed perhaps within this century: ſo that you can only juſt diſtinguiſh that it has been tilled, and the tilth generally curved, the old people inclining the plough with the caſual ſhape of the field, ſo as to let the water in the furrow have a drip or fall.

" When a peaſant has the good luck to get a bit of ſuch choice ground, (for two or three of them will be concerned in an acre, and few take more than one) he follows the old ridge with his *loy*, or Iriſh ſpade, unleſs compelled by the poſſeſſor of the land to make his ridges ſtraight, which he moſt unwillingly does, and at beſt but aukwardly, with a rope made of hay or ſtraw, or ſome of his wife's worſt tow; neither of which ſtretching right, and often breaking, ſeldom admit well-looking ridges: theſe he makes from one end of his ground to the other, the beds being about three, or at moſt four feet wide, and the furrows, or trenches, about two. When he depoſits the ſeed on his bed, at about four or ſix inches at moſt aſunder, he divides the turf of his furrow in two equal parts, which he turns alternately in ſods on the edge or verge of each bed, the green ſide on the potatoes, cutting the ſods on three ſides or angles, leaving that next the bed uncut. This laborious work the poor fellow does ſurprizingly quick: two more men follow him, one digging the under ſtratum, and throwing up on the middle of the bed as much of the earth as he conveniently can with his *loy*: the remainder the third man caſts on with his ſhovel, ſettling the bed in the form, or manner, in which it is to remain.

" Some cover their potatoes at firſt (through want of time) with only the ſod, and about four or five inches of earth, and finiſh them perhaps, that is, caſt the laſt covering on them, not for a month, or ſix weeks after; which poſſibly may greatly check their growth. Many account this the beſt way, and it is become common; but I attribute the neglect of not finiſhing their potatoes, (as the term is) in due time, to no want of proper knowledge in the common Iriſh, but their inability to give the proper attention to their own little affairs, occaſioned by the greedy ſeverity of their maſters, as before obſerved.

" Others there are (and many) who, making the furrows unproportionably narrow to the beds, throw up a third ſpit or ſtratum, and perhaps not until two months after the firſt ſetting.

" This pernicious method may poſſibly deſtroy, or check the weeds; but certain I am, it will not contribute to the increaſe or largeneſs of the root, in the unphyſical or over heavy manner in which I have ſeen it done; becauſe this lower ſtratum, which is moſtly ſand, remains on the top of the richeſt part of the ſoil, and being thus unmixed with it, prevents it from receiving the proper benefits of the air, &c. beſides, too great a covering on the potato is highly prejudicial to it.

" In other caſes, theſe ſtratums thrown up, and mixed into a good tilth, would anſwer wonderfully, mixing well, being the life of good tillage. I would therefore in this place recommend to our farmers (who are too penurious of their land) to make their potato trenches ſo wide, as not to require throwing up much of the third or ſandy ſtratum on the laſt covering, or landing, of their potatoes: and they will find a much greater return, and one half (or more) leſs of *poreens*, or ſmall potatoes: which is an object highly worthy of their notice. The experiments I have made, I purpoſe repeating on my return to Ireland, and hope to prove this ſimple method to exceed that in the hillock, or in the drill way.

" In this manner all ley land is ſown with potatoes by the common people, and moſt others, whether manured or not. If dunged, the dung is laid out as the ridges are to be, but the ſand is ſpread all over the ſurface. Commonly little boys and girls precede the ſetters on the ridges, laying down the ſeedlings or potato eyes, which they do very quick, and tolerably well, at the appointed diſtance. This ſeems a giddy part of the buſineſs, and well ſuited to their years; but cuſtom makes them perfect in it.

" The next general method is planting potatoes in ſtubble ground, which is, in the common way above-mentioned, by dunging it well, and ſometimes by ploughing it in, and then ſhovelling up the ridges, a man going before, lightly digging them, that there may be a ſufficient quantity of mould to cover them; but this the poorer ſort cannot well compaſs to do, and always avoid it when they can get a freſh or ley ſurface.

" Nor do they ſow them to chuſe, the ſecond year, in the ſame ground, without dung or ſome other artificial manure, (for the natural, ſuch as ſand, marle, &c. would not do) unleſs it be exceeding good.

" Lime, indeed, in this caſe would very probably anſwer, but it is rarely tried.

" There is alſo a cuſtom a good deal in uſe, which is by ſticking or thruſting potatoes in ſtubble land freſh ploughed, which is done in this manner: a man (but ſeldom two) goes on the crown of a narrow ploughed ſet, and ſticks his *loy*, or *Iriſh ſpade*, in it, every here and there, with his right foot, holding it in his left hand, and with it puſhing the ſpade once, and ſometimes twice from him, to make an opening, (which I have ſeen done with a good deal of dexterity) and with the right hand, that contains the ſeed, (a convenient quantity of which he carries in an apron, or cloth, tied round his middle, ſo as to let the contents be eaſily come at) he throws one, and ſometimes two ſets, or eyes, into the opening which the *loy* makes behind; and on his drawing it away, the looſened earth falls in and covers them. Soon after he dungs the ridges, and covers them up, as in the preceding method, with mould out of the furrows.

" Sometimes alſo they do this work with a ſtick about eighteen inches long, and an inch or ſo diameter, pointed at one end, and ſomewhat curved at the other. By this eafy means hufband, wife, children, and fervants, (if they have any) and a friendly neighbour or two, (who may be helped in return) affift at it for greater expedition, efpecially when the feafon happens to be advanced.

" In Scotland they do this work fomewhat differently.

" In Ireland alfo there are many, who fow potatoes after the plough, the ploughman letting the fets drop in as he goes along; and a harrow matched to the fame plough, following him clofe behind, covers them in. There is no great difficulty in this, the land being in tilth. Over all they put dung; but they fhould mind to give it a light covering, that the fubftance of it might impregnate with the adjacent earth, which it would not do, but evaporate by being left expofed to the air, &c. yet this precaution many are very negligent in.

" The other methods, as in the drill, or hillock, or horfe-hoeing way, &c. are little ufed there, except among the more curious; but they being well known in England, it is needlefs to mention them in this place.

" The next thing requifite is the fencing, which fhould be done, at fartheft, before the ftalk begins to appear; for, if the cattle, that are in that feafon greedy for frefh vegetables, get at them, the roots of fuch as they nip will never come to the fize they otherwife would.

" This is well known in Ireland; and yet the poor, chiefly I believe from inability, and partly from a fort of careleffnefs, or rather lazinefs, they ftill inherit (notwithftanding the mixture of Englifh and Norman blood, &c.) from their Spanifh anceftors, are very remifs in this refpect; efpecially in the chiltern, or more fertile parts of the country; where, in moft matters of hufbandry, they leave too much to chance, relying on the bounty of the foil.

" About me, and in many other parts, they very commonly do not put on the firft covering till about the middle of May; and the fecond, perhaps, not for a month after; fo that it is often July before they fence them properly: and where many of them are concerned in a plantation (as is ufually the way) it is moft troublefome and difficult to get each man to do his part of the ditching, which commonly is but a forry mound of fods, with fome bufhes fodded down on top, to keep out fheep, that fmell this plant when it rifes (as cattle do corn) and are very dexterous in getting at it.

" Some of thefe poor people are fo heedlefs, they never can be brought to make their fences; and then the owner of the ground, in his own defence, is obliged to get it done at an advanced price, and they to pay for it, or their potatoes to remain.

" Many of them, efpecially in cheap years, leave them on the landlord's hands; and, unlefs a farmer collects himfelf, or has a good fervant to do it, the rent is not had without immenfe trouble, and fome of it never. Notwithftanding thefe difficulties, many farmers have made eafy fortunes in this way.

" Thus it happens, at the time they are often finifhing the fencing, they ought to be weeding their potatoes. The weed that moftly annoys them is the Scotch thiftle: this fhould be cut away in June, and if the foil fhould be fo rich as to require a fecond weeding (which is very often the cafe) it fhould be done in Auguft. There will be no other trouble with them till digging time.

" The beft time for this work is in the latter end of October, or beginning of November, to avoid the early frofts, which are mortal to them: but if, by bad hufbandry, they have been planted late, they fhould be left longer in the ground, and covered with litter, or haulm, to prevent being loft in this way.

" About Michaelmas the cattle are let through them, the roots not being then affected by the nipping, or beating down, of the ftalk: this the peafants know by the colour of it, which becomes a dark brown, lofing its verdure; as alfo by the apple and root.

" The more needy begin to dig them for ufe in Auguft, though they are not then near fo long in ground as they are in England; which demonftrates the excellence and ftrength of the Irifh foil.

" When gentlemen farmers dig their potatoes, they fet on a great number of hands at once, two to a ridge: boys and girls gather them promifcuoufly, big and little, into bags containing about two Winchefter bufhels; and thus they are carried to the farm-houfe, and thrown into a room, in one heap, part of which is deftroyed by the froft, a great part by the kitchen, alfo by the hogs, who deftroy them much while in ground, there being hardly any fencing againft them; a great part are alfo ftole by the followers, or hangers-on; and the remainder rarely fuffices for feed, of fo little value is this eftimable root confidered in thofe parts: and yet I have often known them at a very high price, from ten to twenty fhillings, and upwards, the big barrel, which is the ufual meafure in the weftern parts of Ireland; that is, above two barrels, or eight bufhels, Winchefter meafure.

" Had they fuch places as Covent-Garden near them, the cafe would be far different: but where there are no convenient and brifk markets, the wafte in farms is always great.

" Though, as I remarked before, low or fwampy grounds do not anfwer well for potatoes, yet they fometimes thrive, and are large, the meat being generally fcabby, clofe, wet, and heavy, from the too great impregnation of the water, which renders them unpalatable, and not the beft for feed; however, fuch are chiefly ufed in this way: yet I have feen them planted in red bogs, which are the wetteft and worft; and the bog being previoufly fanded and dunged, the ftalk looked green and healthy, and fome of the roots might perchance have eat dry; but thofe planted in black, or drier bogs, have been found to fucceed well.

" There is no culture perhaps, yet known, will better reclaim wafte and unprofitable lands, than that of the potato. Ireland can well prove the truth of this affertion in a numberlefs variety of inftances.

" I have feen feveral tracts of woodland ftubbed up, and brought into fine tilth, by means of the potato hufbandry. America, I believe, can fay the fame.

" Of late years the hard-hearted fky-farmers, that is, the inferior fort, and even fome of our gentlemen-farmers, drive the poor into the mountains, moory grounds, wooded and ftony lands, and even into the bogs; and when, by the culture of the potato principally, they have reclaimed them, fo as to be fit to admit cattle, they are turned out without ceremony. I have in fuch places feen as fine crops of potatoes, and afterwards flax, and different kinds of corn, as ever I met with any where.

" The mountain and other furfaces, except bog, feldom fail being bleffed by nature with lime-ftone, gravel, (which is the commoneft) or fome other manure, adapted to them; fo that it is nothing but hands, money, and a proper limitation of the grazing-farming, that are wanting to make almoft the whole kingdom look like a garden, or like England; I need go no higher with the comparifon.

" It is true, in fome few counties of Ireland, in particular diftricts, nature either has not been fo bountiful, or the farmers have not found out the internal manures; being obliged to carry fea-fand, and other forts, many miles; in which however they find their account, notwithftanding the impolitically too much limited trade of the kingdom.

" Before I difmifs this fubject, it may be proper to obferve, that a fecond crop of potatoes is fometimes taken out of the fame land fucceffively; but this is not common, at leaft about me, though I believe the land is as good as any in the province. On the contrary, the ufual way is, after the firft crop of potatoes is taken off, if the foil is ftrong, they immediately fow bere in it, or keep it till the following fpring for flax, which requires an equally ftrong foil: or if the ground be but of a middling good fort, they fow it, juft after the potatoes are taken out, with wheat; or keep it till the April following for barley.

" The fky-farmer generally takes the land into his own hands after the firft crop of potatoes, and fows it with bere, wheat, or barley, for two or three feafons; after which, if he refrefhes it with a fummer, or a winter fallow, he fows the faid kinds of grain in it for two or three feafons more; then he takes two or three crops of oats; and when it is well impoverifhed, or drawn (as they call it there) he lets it for feveral years together, in con-acres, to the poor people, for at leaft one third more than the real value.

" From hence we may judge how much an alteration of method in hufbandry is wanting in thofe parts."

Mr.

Mr. Irwin is certainly right in ſaying, that lime would very probably anſwer; for in the Iſle of Man, though they are no farmers, yet they cultivate exceeding fine potatoes, as they are their principal food.

Some bring in different ſorts of land by the means of them: in moory ground, after the heath is burnt off it, they mark out the beds, upon which they ſpread out the lime in near about the ſame quantity that is required in liming ground, or rather more; upon which they lay the ſeed in the uſual manner, and, after cutting the turf in the furrow, lay it on the verge of the bed with the heathy ſide undermoſt, and cover them over with the mould out of the furrow in the common method.

After coming up, they weed, or give them a ſlight covering, to keep down the weeds.

When they raiſe them, it takes a little more labour; yet while they are digging a crop of very fine dry potatoes, they are gaining a piece of ground, which was before uſeleſs, and making it fit for ploughing and bearing corn the year following.

Lime is found alſo to be of excellent ſervice to potatoes in cold ſour land, which they manage after the ſame manner, and reap potatoes greatly excelling thoſe without lime, on the ſame ground.

Lime is certainly a very fine manure for potatoes: they uſe it in the iſle above-mentioned, without any other thing, on all ſorts of land, even upon a light, rich, limeſtone ſoil; and it betters the quality of the potatoe ſurpriſingly: beſides fermenting and meliorating the ſoil, it has the property of attracting and abſorbing any cold ſour matter which may be prejudicial to vegetation.

About Caſtletown, in the ſame iſle, they take a great deal of care in their culture of potatoes, and their product pays them very well for their trouble.

After marking out the bed with their ſpade, and ſpreading on the dung, or lime, they begin at one end, and dig acroſs the bed, making it a ſpadeful, all along, higher than the neighbouring ground.

Then they dig and caſt the mould out of the furrows upon the bed, in the common method; and after finiſhing it, they, with a kind of dibble, or ſhaft of a ſpade ſhod with iron, ſome round and ſharp, others ſquare, about three or four inches broad, plant in the ſeed, about ſix or more inches diſtance one from another; and when they come up above ground, they weed them as clean as a garden, and after they are ſtronger and higher, with a hoe earth up the mould about the ſtalks; by which they kill the weeds, and have exceeding fine potatoes.

PREGNANT, teeming, breeding, fruitful.

PRICKING, a term uſed by farriers, &c. to ſignify the driving a nail into the ſoft part of a horſe's foot.

If a lameneſs proceeds from pricking in ſhoeing, the foot ſhould be pared thin on the wound ſide; and after dreſſing with tar and turpentine, let it be ſtopped with two ounces of common turpentine, melted down with four of lard.

If the nail penetrates to the joint of the foot, where matter may be formed, and by its long continuance putrify, ſo as to erode the cartilages of the joint, the caſe is incurable.

If the nail has paſſed up to the nut-bone, it is incurable, becauſe this little bone cannot exfoliate; and becauſe the cartilaginous part of it is deſtroyed, as ſoon as injured.

If the nail has not paſſed to the tendon, the horſe will do well, without a neceſſity for drawing the ſole; but if the tendon is wounded, the ſole muſt be carefully drawn, becauſe a ſinovia and gleet is diſcharged.

When gravel is the cauſe, it for the moſt part follows the nail-holes, and if it gets to the quick, cannot return, unleſs it is ſcraped out; for the make of the hoof, which is ſpiral like an ear of corn, favours its aſcent, ſo that the gravel continues working upwards towards the coronet, and forms, what the farriers call a quittor-bone.

The nature of this diſorder points out the method of cure, which is to be as expeditious and careful as poſſible, in getting out the gravel: if it is found difficult to effect this let the ſole or hoof be pared thin, and if neceſſary, the wound inlarged to the bottom, and then dreſſed up as uſual. Should the coffin-bone be affected, remember always to bathe the hoof with vinegar, or repellers, in order to allay the heat and inflammation, which often happen on ſuch occaſions; and ſhould the pain and anguiſh affect the legs, treat them in the ſame manner, or charge the leg and paſtern with a mixture of wine lees and vinegar.

PRONG, an implement much uſed in huſbandry, conſiſting of two or three pieces of iron, inſerted into a handle, for taking up corn, ſtraw, dung, &c.

PRONG-*hoe*, a term uſed to expreſs an inſtrument uſed to hoe or break the ground near, and among the roots of plants.

The ordinary contrivance of the hoe in England is very bad, it being only made for ſcraping on the ſurface; but the great uſe of hoeing being to break and open the ground, beſides the killing the weeds, which the ancients, and many among us, have thought the only uſe of the hoe, this dull and blunt inſtrument is by no means calculated for the purpoſes it is to ſerve.

The prong-hoe conſiſts of two hooked points of ſix or ſeven inches long, and, when ſtruck into the ground, will ſtir and remove it the ſame depth as the plough does, and thus anſwer both the ends of cutting up the weeds and opening the land. The ancient Romans had an inſtrument of this kind, which they called the bidens; but they were afraid of its uſe in their fields and gardens, and only uſed it in their vineyards. The prong-hoe comes into excellent uſe, even in the horſe-hoeing huſbandry; in this the hoe-plough can only come within three or four inches of the rows of the corn, turneps, and the like; but this inſtrument may be uſed afterwards, and with it the land may be raiſed and ſtirred, even to the very ſtalk of the plant. *Tull's Huſbandry*

PROPAGATION, the continuance or diffuſion of ſucceſſive production.

The ingenious Mr. Barnes has given us the following method of propagating trees by the bud and branch.

"Every leaf, ſays he, upon the branch of a tree, or ſhrub, has uſually a young bud in its boſom; and it is certain each of theſe buds has in it the rudiment of a tree of the ſame kind: therefore it appeared reaſonable to think that every branch might afford as many new plants as there were leaves upon it; provided it were cut into ſo many pieces, and a proper dreſſing was found to prevent the raw ends of each piece from decay. The beſt mixture for this purpoſe, upon careful and repeated experience, I have found to be this.

"Melt together, in a large earthen veſſel, two pounds and a half of common pitch, and half a pound of turpentine. When they are melted, put in three quarters of an ounce of powder of aloes; ſtir them all together; and then ſet them on fire: when it has flamed a moment, cover it up cloſe, and it will go out: then melt it well, and fire it again in the ſame manner: this muſt be done three times. It muſt be in the open air, for it would fire a houſe; and there muſt be a cover for the veſſel ready. After it has burnt the laſt time, melt it again, and put in three ounces of yellow wax ſhred very thin, and ſix drachms of maſtich in powder. Let it all melt together till it is perfectly well mixed; then ſtrain it through a coarſe cloth in a pan, and ſet it by to cool.

"When this is to be uſed, a piece of it muſt be broke off, and ſet over a very gentle fire; it muſt ſtand till it is juſt ſoft enough to ſpread upon the part of the cutting where it is wanted; but it muſt not be very hot. It is the quality of this dreſſing, to keep out wet intirely: the part which is covered with it will never decay while there is any principle of life in the reſt; and, this being ſecured, nature will do the buſineſs of the growing.

"This I have found true in practice; and by repeated trials, in more kinds than one, I have found that I could raiſe from any piece of a branch as many good plants as there were leaves upon it."

PRUNIFEROUS *trees*, thoſe which bear a pretty large and fleſhy fruit, with a nucleus in the middle.

PRUNING, the operation of lopping off the ſuperfluous branches of trees, in order to make them bear better fruit, grow higher, or appear more regular.

There is not any part of gardening, which is of more general uſe than that of pruning; and yet it is very rare to ſee fruit-trees ſkilfully managed: and almoſt every gardener will pretend to be a maſter of this buſineſs, though there are but few who rightly underſtand it; nor is it to be learned by rote, but requires a ſtrict obſervation of the different manners of growth of the ſeveral ſorts of fruit-trees; ſome requiring to be managed one way, and others muſt be treated in a quite different method, which is only to be known from carefully obſerving how each kind is naturally diſpoſed to produce its fruit: for ſome ſorts produce their fruit on the ſame year's wood, as vines; others produce their fruits, for the moſt part, upon the former year's wood, as peaches, nectarines, &c. and others upon curſons or ſpurs, which are produced upon wood of three, four, or five, to fifteen or twenty years old, as pears, plums, cherries, &c. therefore, in order to the right management of fruit-trees, there ſhould always be proviſion made to have a ſufficient quantity of bearing wood in every part of the trees, and, at the ſame time, there ſhould not be a ſuperfluity of uſeleſs branches, which would exhauſt the ſtrength of the trees, and cauſe them to decay in a few years.

The reaſons which have been laid down for pruning of fruit-trees, are as follow: firſt, to preſerve trees longer in a vigorous bearing ſtate; the ſecond is, to render the trees more beautiful to the eye; and, thirdly, to cauſe the fruit to be larger, and better taſted.

1. It preſerves a tree longer in an healthy bearing ſtate; for by pruning off all ſuperfluous branches, ſo that there are no more left upon the tree than are neceſſary, or than the roots can nouriſh properly, the root is not exhauſted in ſupplying uſeleſs branches, which muſt afterwards be cut out; whereby much of the ſap will be uſeleſsly expended.

2. By ſkilful pruning of a tree, it is rendered much more pleaſing to the eye: but here I would not be underſtood to be an advocate for a ſort of pruning which I have ſeen too much practiſed of late; viz. the drawing a regular line againſt the wall, according to the ſhape or figure they would reduce the tree to, and cutting all the branches, ſtrong or weak, exactly to the chalked line; the abſurdity of which practice will ſoon appear to every one who will be at the pains of obſerving the difference of thoſe branches ſhooting the ſucceeding ſpring. All therefore that I mean by rendering a tree beautiful, is, that the branches are all pruned according to their ſeveral ſtrengths, and are nailed at equal diſtances in proportion to the different ſizes of their leaves and fruit; and that no part of the wall, ſo far as the trees are advanced, be left unfurniſhed with bearing wood. A tree well managed, though it does not repreſent any regular figure, yet will appear very beautiful to the ſight, when it is thus dreſſed, and nailed to the wall.

3. It is of great advantage to the fruit; for the cutting away all uſeleſs branches, and ſhortening all the bearing ſhoots, according to the ſtrength of the tree, will render the tree more capable to nouriſh thoſe which are left remaining, ſo that the fruit will be much larger, and better taſted. And this is the advantage which thoſe trees againſt walls or eſpaliers have to ſuch as are ſtandards, and are permitted to grow as they are naturally inclined; for it is not their being trained either to a wall or eſpalier which renders their fruit ſo much better than ſtandards, but becauſe they have a leſs quantity of branches and fruit for their roots to nouriſh; and, conſequently, their fruit will be larger, and better taſted.

There are many perſons who ſuppoſe, that if their fruit-trees are but kept up to the wall or eſpalier, during the ſummer-ſeaſon, ſo as not to hang in very great diſorder, and, in winter, to get a gardener to prune them, it is ſufficient: but this is a very great miſtake; for the greateſt care ought to be employed about them in the ſpring, when the trees are in vigorous growth; which is the only proper ſeaſon to procure a quantity of good wood in the different parts of the tree, and to diſplace all uſeleſs branches, as ſoon as they are produced, whereby the vigour of the tree will be intirely diſtributed to ſuch branches only, as are deſigned to remain; which will render them ſtrong, and more capable to produce good fruit; whereas, if all the branches are permitted to remain, which are produced, ſome of the more vigorous will attract the greateſt ſhare of the ſap from the tree, whereby they will be too luxuriant for producing fruit, and the greateſt part of the other ſhoots will be ſtarved, and rendered ſo weak, as not to be able to produce any thing elſe but bloſſoms and leaves, as hath been before mentioned; ſo that it is impoſſible for a perſon, let him be ever ſo well ſkilled in fruit-trees, to reduce them into any tolerable order by winter pruning only, if they are wholly neglected in the ſpring.

There are others, who do not intirely neglect their trees during the ſummer ſeaſon, as thoſe before mentioned; but yet do little more good to them by what they call ſummer pruning; for theſe perſons neglect their trees at the proper ſeaſon, which is in April and May, when their ſhoots are produced, and only about Midſummer go over them, nailing in all their branches, except ſuch as are produced fore-right from the wall, which they cut out; and at the ſame time often ſhorten moſt of the other branches; all which is intirely wrong practice; for thoſe branches which are intended for bearing the ſucceeding year, ſhould not be ſhortened during the time of their growth, which will cauſe them to produce two lateral ſhoots from the eyes, below the place where they were ſtopped, which ſhoots will draw much of the ſtrength from the buds of the firſt ſhoot, whereby they are often flat, and do not produce their bloſſoms; and if thoſe two lateral ſhoots are not intirely cut away at the winter pruning, they will prove injurious to the tree, as the ſhoots which theſe produce will be what the French call water-ſhoots: and in ſuffering thoſe luxuriant ſhoots to remain upon the tree until Midſummer, before they are diſplaced, they will exhauſt a great ſhare of the nouriſhment from the other branches, as was before obſerved; and by ſhading the fruit all the ſpring-ſeaſon, when they are cut away, and the other branches faſtened to the wall, the fruit, by being ſo ſuddenly expoſed, will receive a very great check, which will cauſe their ſkins to grow tough, and thereby render them leſs delicate. This is to be chiefly underſtood of ſtone-fruit and grapes; but pears and apples, being much harder, ſuffer not ſo much, though it is a great diſadvantage to thoſe alſo, to be thus managed.

It muſt alſo be remarked, that peaches, nectarines, apricots, cherries, and plums, are always in the greateſt vigour, when they are the leaſt maimed by the knife; for, where theſe trees have large amputations, they are very ſubject to gum and decay; ſo that it is certainly the moſt prudent method carefully to rub off all uſeleſs buds when they are firſt produced, and pinch others, where new ſhoots are wanted to ſupply the vacancies of the wall; by which management trees may be ſo ordered, as to want but little of the knife in winter pruning, which is the ſureſt way to preſerve theſe trees healthful, and is performed with leſs trouble than the common method.

The management of pears and apples is much the ſame with theſe trees in ſummer; but in winter they muſt be very differently pruned: for, as peaches and nectarines do, for the moſt part, produce their fruit upon the former year's wood, and therefore muſt have their branches ſhortened according to their ſtrength, in order to produce new ſhoots for the ſucceeding year; ſo pears, apples, plums, and cherries, on the contrary, producing their fruit upon curſons or ſpurs, which come out of the wood of five, ſix, or ſeven years old, ſhould not be ſhortened, becauſe thereby thoſe buds which were naturally diſpoſed to form theſe curſons or ſpurs, would produce wood-branches, whereby the trees would be filled with wood, but never produce much fruit; and as it often happens, that the bloſſom-buds are firſt produced at the extremity of the laſt year's ſhoot, ſo, by ſhortening the branches, the bloſſoms are cut away, which ſhould always be carefully avoided.

There are ſeveral authors who have written on the ſubject of pruning in ſuch a prolix manner, that it is impoſſible for a learner to underſtand their meaning: theſe have deſcribed the ſeveral ſorts of branches, which are produced on fruit-trees; as wood-branches, fruit-branches, irregular branches, falſe branches, and luxuriant branches; all which they aſſert, every perſon who pretends to pruning, ſhould diſtinguiſh well: whereas there is nothing more in all this but a parcel of words to amuſe the reader, without any real meaning; for all theſe are comprehended under the deſcription already given of luxuriant or uſeleſs branches, and ſuch as are termed uſeful for fruit-bearing branches; and, where due care is taken in the ſpring of the year, to difplace thefe ufelefs branches, as was before directed, there will be no fuch thing as irregular, falfe, or luxuriant branches, at the winter pruning; therefore it is to no purpofe to amufe people with a cant of words, which, when fully underftood, fignify juft nothing at all.

The following hints will be of great ufe in pruning ftandard trees.

Firft, you fhould never fhorten the branches of thefe trees, unlefs it be where they are very luxuriant, and grow irregular on one fide of the tree, attracting a great part of the fap of the tree, whereby the other parts are unfurnifhed with branches, or are rendered very weak; in which cafe the branch fhould be fhortened down as low as is neceffary, in order to obtain more branches, to fill up the hollow of the tree: but this is only to be underftood of pears and apples, which will produce fhoots from wood of three, four, or more years old; whereas moft forts of ftone fruit will gum and decay, after fuch amputations.

But from hence I would not have it underftood, that I would direct the reducing of thefe trees into an exact fpherical figure, fince there is nothing more deteftable than to fee a tree, which fhould be permitted to grow as it is naturally difpofed, with its branches produced at proportionable diftances, according to the fize of the fruit, by endeavouring to make it exactly regular at its head, fo crouded with fmall weak branches as to prevent the air from paffing between them, which will render it incapable to produce fruit. All that I intend by this ftopping of luxuriant branches, is only when one or two fuch happen on a young tree, where they intirely draw all the fap from their weaker branches, and ftarve them: and then it is proper to ufe this method, which fhould be done in time, before they have exhaufted the roots too much.

Whenever this happens to ftone fruit, which fuffer much more by cutting than the former forts, it fhould be remedied by ftopping or pinching thofe fruits in the fpring, before they have obtained too much vigour; which will caufe them to pufh out fide branches, whereby the fap will be diverted from afcending too faft to the leading branch, as hath been directed for wall-trees; but this muft be done with caution, as before.

You muft alfo cut out all dead or decaying branches, which caufe their head to look very ragged; efpecially at a time when the leaves are upon the tree, thefe being deftitute of them, have but a defpicable appearance; befides, thefe will attract noxious particles from the air, which are injurious to the trees; therefore the fooner they are cut out the better: in doing of this you fhould obferve to cut them clofe down to the place where they were produced, otherwife that part of the branch left will decay, and prove equally hurtful to the tree; for it feldom happens, when a branch begins to decay, that it does not die quite down to the place where it was produced, and, if permitted to remain long uncut, does often infect fome of the other parts of the tree. If the branches are large which you cut off, it will be very proper, after having fmoothed the cut part exactly even with a knife, chiffel, or hatchet, to put on a plafter of grafting clay, which will prevent the wet from foaking into the tree at the wounded part.

All fuch branches as run acrofs each other, fhould alfo be cut out; for thefe not only occafion a confufion in the head of the tree, but by lying over each other, rub off their bark by their motion, and very often occafion them to canker, to the great injury of the tree; and on old trees, efpecially apples, there are often young vigorous fhoots from the old branches near the trunk, which grow upright into the head of the trees: thefe therefore fhould carefully be cut out every year, left, by being permitted to grow, they fill the tree too full of wood; which fhould always be guarded againft, fince it is impoffible for fuch trees to produce fo much, or fo good fruit, as thofe trees whofe branches grow at a farther diftance; whereby the fun and air freely pafs between them, in every part of the tree. *Miller's Gard. Dict.*

PUCKBALL, a fpecies of mufhroom, full of duft.

PUDDOCK, or PURROCK, a fmall inclofure.

PULSE, a term applied to all leguminous plants, as tares, peafe, &c.

All the fpecies of pulfe afford great abundance of excellent manure, in the ftate in which nature prefents them. The cuftom of ploughing in green fucculent plants, is very ancient. All the Roman writers commend it highly, and with much reafon. Columella recommends particularly lupins, as a manure, which, if cut down and turned in while green, will have as good effect as the beft and ftrongeft dunging whatever. They may be fown upon poor land about the middle of September, and will enrich it greatly if ploughed in before they attain their full growth. In gravelly foils, they fhould be cut down after they have put forth their fecond flower; and in ftrong lands, after the third. In the former of thefe grounds they are turned in while young and tender, that they may quickly rot; and in the latter, they are let ftand till they grow ftronger, that they may bare up the more folid and ftiff clods of earth, and keep them the longer fufpended; by which means the air has freer accefs to the foil, and thefe clods, being heated and dried with the fummer funs, are the more eafily opened, and refolved into duft. Thus fays this judicious author, juftly remarkable for his fuperior fkill in hufbandry. But Mr. Miller is of a contrary opinion.

The *Maifon Ruftique*, a work of very high repute, as is evident from the great number of editions it has gone through, ftrongly and rightly recommends peafe, beans, lupins, vetches, and other fucculent plants, as excellent manures, efpecially for fandy ground. Thefe plants enrich the earth greatly if ploughed in, either green, or when in bloom. In ftrong land, they fhould not be turned down till the pods begin to harden.

In Piedmont and other places where they fatten their land with this manure, lupins are fown upon the fallow ground towards the end of June, immediately after the fecond ploughing, fo that they are ftill green when the third ploughing is given, and the corn is fown. Experience fhews the hufbandmen in thofe countries, that this method of ufing thefe plants for manure makes them ample amends for the lofs of the pulfe or fodder they might otherwife reap from them: but thofe who do not like to lofe any thing, plough in the hufks after they have taken out the grain.

Dr. Lifter likewife recommends for the improvement of fandy, light ground, or any clay well fanded, all plants of the pulfe or pea kind, and particularly, "upon experience, the wood vetch, which, befides its being perennial (at leaft with refpect to its roots) and its thriving even in woods and among bufhes in almoft every country, has thefe farther qualifications, that it fhoots out a thoufand roots far and wide, and fpreads itfelf under ground like quick-grafs; whilft it is fo rampant above ground, that it will climb a fathom and a half upon meafure, and preferve itfelf in fpite of weeds or drought. It may be fet, as well as fown, in furrows. For the former of thefe purpofes the roots may be dug up in September, which is alfo the time for gathering the ripe feed. The growth of the plants will be greatly advanced by fetting their roots; for the older they are, the ftronger, more numerous, and fuller of buds their fhoots will be. I fowed in the latter end of March the feeds which I had gathered in September, and had that year a very great increafe, the bed being thick covered over with grafs above two feet high: but it did not flower that year. I reckoned that one pea had put forth above thirty fhoots in Auguft of the firft year. In the fecond year, it flowered by the middle of June, and bore a wonderful crop, the roots being innumerable. I have obferved this pea very common in all the mountains, as well as plains of England, where bufhes or hedges are. Both the pea and grafs are very fweet, and very agreeable to cattle, as I have tried."

Buck-wheat and vetches are the two plants moft commonly fown in England, for manure. The beft time for ploughing them in, is when they are in bloom; being then in their moft fucculent ftate. Some farmers turn down their fecond crop of clover, to enrich the land for wheat in the autumn. This fhould be done early enough to give the plants fufficient time to putrefy thoroughly before the grain is fowed: otherwife it might prove prejudicial, by bringing on a heat which would hurt the corn.

The reverend and ingenious Mr. Eliot, of New England, prefers millet to every other plant for green-dreffing of land, on account of the cheapneſs of the ſeed, and the largeneſs of the ſtalks and leaves, which muſt afford a good coat to turn in when ploughed. An old farmer, who had long been in the practice of green-dreſſing, aſſured this gentleman, that he had increaſed the ſtrength of his land to a great degree, in a few years, by the following method. After his oats were harveſted, he added a little ſeed to the ſcattered grains, and then ploughed them in. Towards the end of September, he ploughed in the green oats, and ſowed rye; and the next ſummer, when the rye was well grown and full of ſap, he ploughed that in at the uſual ſowing ſeaſon, then ſowed wheat, and always had a large crop.

PURGING, the operation of evacuating the impurities of an animal body by ſtool.

Purging is often neceſſary in groſs full horſes, in ſome diſorders of the ſtomach, liver, &c. but ſhould be directed with caution. Before a purge is given to any horſe, it is neceſſary ſome preparation ſhould be made for it, in order to render the operation more ſafe and efficacious: thus a horſe that is full of fleſh ſhould firſt be bled, and at the ſame time have his diet lowered for a week, eſpecially thoſe that have been pampered for ſale; ſeveral maſhes of ſcalded bran ſhould alſo previouſly be given, in order to open the bowels, and unload them of any indurated excrement; which ſometimes proves an obſtacle to the working of the phyſic, by creating great ſickneſs and griping.

Let it be remembered, that a horſe is purged with difficulty; that the phyſic generally lies twenty-four hours in the guts before it works; and, that the tract of bowels it has to paſs through, is above thirty yards; and lying horizontally, conſequently reſinous and other improper drugs may, and often do, by their violent irritations, occaſion exceſſive gripings and cold ſweats, ſhave off the very mucus or lining of the guts, and bring on inflammations, which often terminate in mortifications, and death.

It is remarkable too, that the ſtomach and guts of a horſe are but thin, compared to ſome other animals of the ſame bulk, and therefore muſt be more liable to inflammation and irritation.

Horſes kept much in the ſtable, who have not the proper benefit of air and exerciſe, in proportion to their food, ſhould in ſpring have a mild purge or two, after a previous preparation by bleeding, lowering their diet, and ſcalded maſhes.

Horſes that fall off their ſtomach, whether it proceeds from too full feeding, or ingendering crudities and indigeſted matter, ſhould have a mild purge or two.

Horſes of a hot temperament, will not bear the common aloetic purges; their phyſic therefore ſhould be mild and cooling.

Purging is always found very beneficial in ſtubborn dry coughs; but mild mercurials joined with them, make them yet more efficacious.

Horſes that have thoſe ſorts of lameneſſes, that are ſaid to proceed from humours flying about (which are of the rheumatic kind, and in young horſes proceed from ſizy blood, and occaſion lameneſs in every limb) require frequent purging; and ſhould alſo have between whiles, medicines that attenuate and thin the fluids.

Horſes of a watry conſtitution, who are ſubject to ſwelled legs, that run a ſharp briny ichor, cannot have the cauſes removed any ways ſo effectually as by purging.

The firſt purge you give to a horſe ſhould be mild, in order to know his conſtitution.

It is a miſtaken notion, that if a proper prepared purge does not work to expectation, the horſe will be injured by it; for though it does not paſs by ſtool, its operation may be more efficacious, as an alterative to purify the blood, and it may paſs by urine, or other ſecretions.

Purging medicines are very ſucceſsfully given in ſmall quantities, mixed with others; and act then as alteratives.

If mercurial phyſick is given, care ſhould be taken that it be well prepared; and warmer cloathing, and greater circumſpection is then required.

Purges ſhould be given early in the morning upon an empty ſtomach; about three or four hours after the horſe has taken it, he ſhould have a feed of ſcalded bran; and a lock or two of hay may then be put in his rack. The ſame day give him two more maſhes; but ſhould he refuſe warm meat, he may be allowed raw bran.

All his water ſhould be milk warm, and have a handful of bran ſqueezed in it; but if he refuſes to drink white water, give it him without bran.

Early the next morning, give him another maſh; but if he refuſes to eat it, give him as much warm water as he will drink: let him be properly cloathed, and rode gently about. This ſhould be done two or three times a day, unleſs he purges violently, once or twice will then be ſufficient: at night give him a feed of oats mixed with bran.

During the working, a horſe ſhould drink plentifully; but, if he will not drink warm water, he muſt be indulged with cold, rather than not drink at all.

We ſhall here inſert ſome general forms of purges.

> Take ſuccotrine aloes ten drams, jallap and ſalt of tartar each two drams, grated ginger one dram, oil of cloves thirty drops; make them into a ball with ſyrup of buckthorn.

Or,

> Take aloes and cream of tartar each one ounce, jallap two drams, cloves powdered one dram, ſyrup of buckthorn a ſufficient quantity.

Or,

The following, which has an eſtabliſhed character among ſportſmen.

> Take aloes, from ten drams to an ounce and a half, myrrh and ginger powdered each half an ounce, ſaffron and oil of anniſeed each half a dram.

Mr. Gibſon recommends the following.

> Take ſuccotrine aloes ten drams, myrrh finely powdered half an ounce, ſaffron and freſh jallap in powder, of each a dram, make them into a ſtiff ball with ſyrup of roſes, then add a ſmall ſpoonful of rectified oil of amber.

The ſuccotrine aloes ſhould always be preferred to the Barbadoes, or plantation aloes, though the latter may be given to robuſt ſtrong horſes, but even then ſhould always be prepared with the ſalt, or cream of tartar; which by opening its parts, prevents its adheſion to the coats of the ſtomach, and bowels; from whence horrid gripings, and even death itſelf has often enſued. This caution is well worth remaking, as many a horſe hath fell a ſacrifice to the neglect of it.

Half an ounce of Caſtile ſoap, to a horſe of a groſs conſtitution, may be added to any of the above; and the proportions may be increaſed for ſtrong horſes.

When mercurial phyſick is intended, give two drams of calomel over night, mixed up with half an ounce of diapente and a little honey, and the purging ball the next morning.

The following, when it can be afforded, is a very gentle and effectual purge, particularly for fine delicate horſes; and if prepared with the Indian rhubarb, will not be expenſive.

> Take of the fineſt ſuccotrine aloes one ounce, rhubarb powdered half an ounce or ſix drams, ginger grated one dram; make into a ball, with ſyrup of roſes.

The following purging drink may be given with the utmoſt ſafety; it may be quickened, or made ſtronger, by adding an ounce more ſenna, or two drams of jallap.

Take fenna two ounces, infufe it in a pint of boiling water two hours, with three drams of falt of tartar; pour off, and diffolve in it four ounces of glauber falts, and two or three of cream of tartar.

This laft phyfick is cooling, eafy, and quick in its operation; and greatly preferable in all inflammatory cafes to any other purge, as it paffes into the blood, and operates alfo by urine.

When horfes lofe their appetites after purging, it is neceffary to give them a warm ftomach drink, made of an infufion of chamomile flowers, annifeeds and faffron: or the cordial ball may be given for that purpofe.

Should the purging continue too long, give an ounce of diafcordium in a pint of Port wine, and repeat it once in twelve hours, if the purging continues. Plenty of gum arabic water fhould alfo be given, and in cafe of violent gripes, fat broth glyfters, or tripe liquor, fhould be often thrown up, with an hundred drops of laudanum in each.

The arabic folution may be thus prepared.

Take of gum arabic and tragacanth of each four ounces, juniper berries and carraway feeds of each an ounce, cloves bruifed half an ounce; fimmer gently in a gallon of water, till the gums are diffolved: give a quart at a time in half a pail of water; but if he will not take it freely this way, give it often in a horn.

When a purge does not work, but makes the horfe fwell, and refufe his food and water, which is fometimes the effect of bad drugs, or catching cold, warm diureticks are the only remedy; of which the following are recommended

Take a pint of white wine, nitre one ounce, mix with it a dram of camphor diffolved in a little rectified fpirit of wine; then add two drams of oil of juniper, and the fame quantity of unrectified oil of amber, and four ounces of honey, or fyrup of marfhmallows.

Or,

Take Venice turpentine one ounce, incorporate with the yolk of an egg; nitre one ounce, then add juniper berries, and frefh annifeeds pounded, each half an ounce, unrectified oil of amber two drams; make into a ball with fyrup of marfhmallows.

PURSLANE, the name of an herb, commonly propagated in the kitchen-garden.

Purflane is raifed upon a hot bed by thofe who would have it among their early fallets; for it is too tender a plant to be fown in the open air before the month of April, and even then it muft be placed in a warm fituation: but it is of fo very cold a nature, that it cannot be fafely eaten in this country, except in the heat of fummer, during which a fupply may be eafily had by fowing it upon common beds of light rich earth, at three or four different times, about a fortnight or three weeks diftant from each other; fay, by fowing it upon thefe beds, becaufe its feeds, which are very fmall, fhould be fprinkled extremely thin over the ground, and then only patted down gently with the back of a fhovel, fo as juft to prevent their being blown away. The plants, which will rife in a few days, will require no other culture than keeping them free from weeds, and watering them two or three times a week in dry weather; for purflane delights in fomewhat more than ordinary moifture. In about fix weeks after fowing, they will be fit for ufe.

The green leaved, and the red or yellow leaved, commonly called golden purflane, are but varieties of the broad leaved, or garden purflane, which is the only fpecies cultivated in our kitchen gardens.

The feeds of purflane are faved from fome of the earlieft and fineft plants, which are left for this purpofe, whilft all the weak or fmall leaved ones about them are rooted out. When they are ripe, the ftalks which bear them fhould be cut down, fpread upon cloths, and dried in the fun during three or four days, houfing them each night. They fhould then be beaten out, fifted, cleaned, and laid up in a dry place. Some are of opinion, that the feeds of purflane are beft when they are about three years old; but that feems to be a miftake.

Q.

QUEEN-BEE, a name given by late writers to what ufed to be called the king-bee, or king of the bees; a large and long-bodied bee, of which kind there is only one found in every fwarm, and which is always treated with the greateft refpect by the reft. *See the article* BEE.

This is, indeed, the parent of the fwarm, and from the fœcundity of this one female, a whole hive is eafily and foon repeopled.

It is to be obferved, that the autumn and winter feafons deftroy a great number of the bees; fo that a hive, which was full in the fummer, is often found fo thinly peopled before the end of winter, that the bees feem only a few inhabitants in a very large city: by Midfummer again this fame hive fhall, however, be found fo well filled with inhabitants, that there fhall be a neceffity of fending out a colony in the name of a new fwarm, and yet the hive will remain as full as it can well hold. This increafe might well appear very amazing, if all the remaining bees of the hive were fuppofed to be females, and to join in it; but how much more fo when it muft be acknowledged, that it is all owing to one female, and that this queen-bee, or bee-mother, alone, has given origin to fuch an immenfe progeny?

The form of this bee, and there being only one fuch in a hive, naturally led all who faw it into an opinion of fomething fingular in its nature, and the antients determined that it muft be the king over the reft: they made it an abfolute monarch, and have fuppofed that all the bufinefs of the hive was done by its immediate orders; and that the feveral parties of bees allotted to work in the making the combs, in the filling their cells, in the ftopping the crevices of the hives, and in carrying away the filth, &c. had all their feveral ftations allotted them by this wife and provident monarch. This was giving great talents to the monarch-bee; but this was mere fancy, and it is plain, that, if this creature rules, it is over a people who all perfectly well know their feveral bufinefs: but it rather appears, that there is no fovereignty at all, but that this creature is refpected in a very high degree by the reft, as the common parent of the whole nation.

There were not wanting among the antients, however, fome who believed this large bee to be a female, and thefe pretend that fhe brought forth only females like herfelf, which fucceeded her in her reign. They had a very different opinion as to the origin of the common bees, not fuppofing them generated of animal parents like themfelves, but produced out of corruption, and born of the flefh of a bull or cow. Among the later writers this opinion, notwithftanding the fanction of the poet Virgil, has been laughed out of the world; yet it was long before the true origin of bees, even after this, was known. The author of the Female Monarchy, though well apprized of this great bee being of the female fex, yet fuppofed that fhe only produced young ones like herfelf; and pretended that the common bees copulated together for the production of other bees like themfelves: this, however, has been fince found to be wholly erroneous, the female, or queen-bee, giving birth to all, and thefe common bees being of no fex at all. Many of the authors who have not given into the idle opinion of the bees being bred of putrid flefh, have yet given them an origin not lefs idle and ridiculous. They pretend that the bees are exempted from the pain of producing either eggs or young; and that their offspring are formed of the juices of flowers, the different kinds, as the drones, females, &c. owing their rife to juices of different kinds. Thefe, and a number of other falfe notions, have been propagated in regard to bees; but their true origin could not well be found till we were in a condition to fee what paffes at certain times within the receffes of the hive, which is done by the ufe of that excellent invention, the glafs hive. By this, and by the help of diffections, we may eafily inform ourfelves perfectly of the true ftate of the cafe. The parts of generation are the fubjects of our enquiry for this purpofe, and, though the bodies of thefe animals are fo fmall, thefe are ufually fufficiently large to be diftinguifhed, often taking up more room in the abdomen than all the other parts together. Thus, if the large long-bodied bee be opened, the abdomen will be found to contain vaft numbers of oblong bodies, which any one acquainted with infects will eafily diftinguifh to be eggs: vaft numbers of thefe are large enough to be obfervable by the naked eye, but, when the affiftance of glaffes is called in, there are difcerned a vaft number of other fmaller eggs, which exceed all computation. It is eafy to determine from this, that this creature, fo long efteemed a male, is in reality, a female, and is in condition to give birth to a very numerous pofterity.

In order to diftinguifh this, however, a proper time muft be chofen for the diffection, and the moft proper of all is when the creature is juft ready to depofit her eggs. This is in the months of April and May, and the moft certain time of all is when fhe is in a hive where a new fwarm have been received about ten days before: if fhe be diffected at other times, the eggs are lefs vifible; and, particularly in winter, there requires a good glafs to fhew the rudiments of them. This is a difagreeable experiment, indeed, becaufe it is always the deftruction of a future fwarm; all the eggs we fee in the diffected female being what would have produced bees to labour for our benefit.

When the body of one of the drones is opened, there is found, inftead of thefe vaft numbers of eggs, a part feeming proper for a male organ of generation: and in the abdomen a number of veffels running in feveral windings and contortions, and filled with a milky humour. Thefe feem deftined for the important ufe of impregnating the

the eggs in the belly of the female, and it is very natural to determine from this that thefe are the males.

The common bees, when diffected, at whatever time of the year never fhew the leaft marks of any fex at all. The inteftines of thefe bees are found at times to be more or lefs diftended with honey, and with rough wax; but there are never difcovered any eggs, nor any of the winding feminal veffels, fo that it is plain they have no fhare in propagating the fpecies: and the obfervation of the fwarms from time to time, with the affiftance of glafs hives, gives proof to what the diffections feem to make fufficiently certain without this evidence.

The female bee refides within the center of the hive, always living in one of the fpaces between the combs; if fhe occafionally comes out to the furface, and is feen walking over the edge of a comb, fhe is to be well obferved at thofe times; for her only bufinefs is the laying her eggs in fome of the empty cells of that part of the comb, which done, fhe always retires again.

In order to fee the female, or mother bee, employed in this operation, we are to obferve in the morning hours, between feven and ten, what paffes in a glafs-hive into which a fwarm have been received a few days before. The fpeed with which the common bees labour in making their combs on this occafion is almoft incredible, and they feem not only to labour to have cells to depofit their honey in, but to know that the parent bee is at this time loaded with eggs for the production of a numerous progeny, and that fhe has an immediate neceffity of cells for the depofiting them in. This neceffity is fo urgent, that fhe is often forced to depofit them in cells not yet finifhed; though the bees labour fo vigoroufly, that they often will erect a whole large comb in one day. If the hive be narrowly watched at thefe times in the morning hours, the female bee will be foon found employed in her work, and will be feen dropping her tail by turns into feveral cells every day. If the combs be examined a day or two after this, they will alfo be found to contain the eggs; one of thefe is placed in each cell, and appears in form of an oblong white body, fixed either to the folid angle of the bafe, or to one of the angles compofed by the rhombs which form the triangular bafe of the cell, and is always attached in fuch a manner, that it lies nearly in an horizontal pofition.

The flat glafs hives are the moft favourable for the making thefe obfervations, fince in thofe the combs are fo narrow and fo numerous, that the whole is taken in view at a time, from one fide or the other; and there are always feveral combs to be made choice of for the operation; in the morning hours of April and May, the female mother-bee will be ufually feen walking very foberly over one or other of thefe combs, attended by a guard of about twenty of the common bees, all placing themfelves in fuch a manner, that their faces are turned towards her, and all paying her the greateft marks of homage and adoration. As fhe walks along in this ftate, fhe examines every cell as fhe paffes over, and fuch as fhe finds yet empty, and fit for her purpofe, fhe refts at: and, introducing the hinder part of her body at the top, plunges it fo deep in that her tail touches the bottom. Then fhe depofits one egg and no more, and this is at that time covered with a glutinous matter, which faftens it to the place where it is laid: from this cell the female paffes to feveral others, where fhe depofits her eggs in the fame manner.

Some authors who have written of the polity of bees, have reprefented the time of the female bee's laying her eggs as a feafon of feftivity and rejoicing in the hive; but this does not at all appear to be the cafe; the few bees which attend her on this occafion feem the only ones that know any thing of the matter, and their behaviour favours more of homage and refpect than of joy: they are continually ftroking and brufhing her clean with their legs and with their trunks, and offer her from their own mouths the fineft honey, when fhe has occafion for food. The reft are all employed in their proper offices, and the work of the hive goes on as ufual; and, indeed, it is well that it does fo, for this time of rejoicing would be of very bad confequence to the affairs of the hive, if carried on as fuppofed, fince the female bee is thus employed, more or lefs, during the whole fummer months.

When the female bee has laid fix or feven eggs, fhe always takes a time of refpite or repofe; and, during this time, the bees which form her levee are doubly bufy in their careffes, fome brufhing her head and breaft with their trunk, but feveral being always employed together to cleanfe the hinder rings of the body, which have been fouled by being thruft into the cells. When this is done, fhe begins again; but Mr. Reaumur obferves, that he never could fee a female lay more than ten or twelve eggs at one time: he fuppofes that his prefence difturbed the creature, and finally drove her into the inner parts of the hive, where fhe might continue her works in cells lefs expofed. It is not difficult to compute the number of eggs which the female lays every day, from the fwarm which is ready to leave the hive at the end of May: this fwarm ufually amounts to at leaft twelve thoufand, and as the hive out of which thefe depart is not lefs peopled by the their lofs, it is evident that they were all the produce of the eggs depofited by the female in the preceding months of April, with a part of March, and a few of the firft days of May. On a moderate computation, on thefe principles it will appear, that the female bee cannot lay lefs than two hundred eggs every day, for a long fpace of time together; and this, though feemingly a monftrous increafe, is yet much lefs than that of fome other of the winged infects, in one of which, a two-winged fly, that author counted no lefs than twenty thoufand living worms, all ready to be depofited by the parent, and to become flies of the fame kind.

It has been ftrongly objected againft this fyftem, that, though the female bee lays eggs, fhe is not the only one that lays; and many will not give up the opinion of the common bees alfo laying fome eggs, though but a few in number; obferving, that, if each of thefe lay only four or five eggs, it would be enough to give birth to a whole fwarm, without fuppofing that this prodigious fœcundity belonged to the female bee alone: but this is running into the old error of the female producing only females like herfelf; whereas, if we obferve the cells in which we fee the female depofit her eggs, we fhall in the fequel find the common bees produced from thefe eggs, and iffuing out of thefe cells: this is a fufficient proof to any fair reafoner, fince it appears very plain, that, if the female produces them, they do not produce one another. It is alfo evident, that not only thefe common or working bees, but alfo the drones, or male bees, are produced from the eggs of this fame female; and there is this remarkable forecaft in the female, that fhe always depofits the eggs which are to give origin to thefe, in peculiar cells, proper for the reception of the worms which are to be hatched from them. It is obferved, in examining a hive, that there are always fome combs, or fome parts at leaft of combs, the cells of which are much larger than thofe of the other parts or combs: thefe large cells are deftined for the refidence of the larger worms, which are to produce the drones or male bees. It has been obferved as a miraculous fingularity by fome, that the female bee always knows before-hand, whether the egg fhe is going to lay will produce a male or a common bee; and that, according to this knowledge, fhe never depofits the eggs for a male in a fmaller cell, nor that of a common bee in a large one; but there is, in reality, lefs wonder in this than is fuppofed, for the eggs of which the drones are to be hatched are much larger while in the body of the female than thofe of which the common bees are to be produced, and the whole occafion of this choice in regard to the placing of them is, that, when the creature finds a large egg coming forth, fhe feeks one of the large cells to depofit it in; and when the common fmall eggs are coming, fhe contents herfelf with the common cells.

It is very natural to believe, that the female bee lays a third kind of eggs; and that, befides producing many thoufand common, or working bees, and many hundreds of the males or drones, fhe ought to lay one egg at leaft capable of producing a female like herfelf, which is to be the mother of a future progeny, and the queen of the prefent race; fince, without fuch a one for their leader, the young brood would never leave the hive in the nature of a colony, and fettle themfelves elfewhere. What we thus perceive ought to be the cafe, is alfo found in reality to be be ſo, and the female, beſides the other kinds of eggs, is found by a ſtrict obſervation to lay alſo eggs of this kind. We might perhaps only expect one female bee to be produced for each ſwarm, but, as nature has ſeemed every where prodigal in the manner of the increaſe of her works, ſo it is in this caſe alſo. What millions of ſeeds are produced on a common elm-tree, for one that ſtrikes and ſucceeds ſo well as to grow up to be a tree? And, of the number of young produced from the ſpawn of a carp, how few live to the ſize of a parent? Thus it alſo is in regard to the female bees: nature, though it has allotted only one of this kind, as abſolutely neceſſary to the new ſwarm, yet has given abundance of chances for that one to ſucceed, by the female's uſually laying at leaſt ten eggs for the production of the female offſpring, and often not leſs than twenty: there are, indeed, ſome ſeaſons when not one female is produced; but in theſe ſeaſons there is no ſwarm going out from the old hive, the creatures being informed by nature, that they have no buſineſs for combs and cells when they can have no offſpring to rear in them.

The working bees are not only very obedient to, and very careful of their queen, or female parent; but they are alſo very ſollicitous about her progeny. This is very evident in the ſtructure of the cells, which they prepare for the reception of thoſe eggs which are to be hatched into females. It has been before obſerved, that they prepare larger cells for the eggs which are to become drones, or male bees, than for thoſe which are to produce workers like themſelves. The large cells deſtined for the drones are, however, of the ſame ſhape and figure with the others, differing only in ſize; but this is not the caſe with thoſe deſtined for the female offſpring: theſe are not only very large, but very clumſily contrived, for the ſake of ſtrength; their ſides being much thicker than thoſe of the reſt, and their figure oval. The bees are extremely ſparing of their wax on all other occaſions, but for the conſtruction of theſe royal cells, as they may not improperly be called, they are as remarkably profuſe: one of the royal cells will weigh more than an hundred and fifty of the common kind. The bees are no more ſparing of the room than of the materials in the conſtruction of theſe royal habitations: they are often placed near the center of a comb, and a vaſt number of other cells are deſtroyed for their baſe; often alſo they hang down from the reſt of the comb, in form of ſtalactitæ from the roofs of ſubterraneous caverns.

A cell of this kind, when firſt formed, repreſents an acorn cup; but it is ſoon lengthened beyond the poſſibility of retaining that figure, and it remains thus till the creature is hatched from the chryſalis or nympth ſtate, and comes out of it; after which the bees, to loſe no room in the hive, form other common cells upon it, and the only remaining mark of the female cell, is the appearance of a knot in the place where it once ſtood.

The number of cells deſtined to receive the eggs which are to produce female bees are ſo few, and they are commonly placed in ſuch cloſe parts of the hive, that there is no great probability of ſeeing the female employed in laying her eggs in them: there is no reaſon to doubt the fact, however, ſince, when we know that ſhe lays eggs for the production of the male and the working bees, there is no wonder that ſhe ſhould alſo lay ſome for the production of females like herſelf.

It might ſeem much harder to conceive how ſo vaſt a number of bees ſhould be produced from this one, as we know are produced from her; but, when one of the females is opened, the vaſt number of eggs diſcovered in each of her ovaries makes the prodigious increaſe no way wonderful.

Swammerdam obſerved, that the number of veſicles in the ovary of the female bee was aſtoniſhingly great; he eaſily counted an hundred and fifty in each ovary, and could count about ſeventeen eggs in each veſicle large enough to be diſtinctly viſible; each ovary contains, therefore, two thouſand five hundred and fifty eggs, and both ovaries five thouſand one hundred. When we find ſo many eggs at once diſtinguiſhable by their ſize, it will be eaſy to conceive, according to the common courſe of nature in the propagation of inſects, that there may be more than as many too ſmall to be yet diſtinguiſhable; and, at that rate, the number of twelve thouſand bees, which is the quantity that compoſes a moderate ſwarm, is not wonderful for the product of the eggs of one female for one ſeaſon. *Reaumur's Hiſt. Inſ.*

QUICK, or *Quickſet-hedge*, a general name for all hedges, of whatever ſorts of plants they are compoſed, to diſtinguiſh them from dead hedges; but, in a more confined ſenſe of the word, it is applied to the white or hawthorn, the ſets or young plants of which are raiſed by the nurſery gardeners for ſale. *See the article* FENCE.

QUICKSILVER, a very ponderous fluid mineral, generally called mercury.

In the year 1765, a diſcovery was made (or rather revived, for it is mentioned by Mr. Bradley) that quickſilver was a ſovereign remedy for deſtroying inſects on trees.

The narrative of this diſcovery was contained in a letter written by Dr. R———, to Dr. P———, in which the former begs the aſſiſtance of the latter "in laying before the learned world an account of ſome experiments, that have been tried with ſucceſs, and which, when fully known, will, he believes, be of very great ſervice to the vegetable part of the creation, by totally deſtroying thoſe pernicious inſects, that are apt to infect the tender leaves and young ſhoots of our choice fruit-trees: and for which, no remedy, that he had ever heard, or read of, has been as yet propoſed, that is either adequate to the diſeaſe, or effectual to the cure." Dr. R———, therefore, in the following part of the letter, deſires Dr. P——— "to lay before the Society for the Encouragement of Arts, &c. the following experiment, that was tried laſt ſpring, with ſucceſs, by one George Bradford, a clothier in the city of Hereford, and a very ingenious young man: in order, after the experiment has been fully tried, they may reward him in proportion as he may ſeem intitled to it." But Dr. R——— adds, that "whether he may be thought worthy of any recompence, or not, he very chearfully ſubmits it to the trial of the curious; and hopes, they may reap the ſame advantages, he did laſt year, by clearing their trees of theſe pernicious inſects." The doctor then proceeds as follows, to give the relation of Mr. Bradford's invention and ſucceſs. "The firſt tree he tried the experiment upon, was a favourite plum-tree: I think a green gage. He was afraid of trying it on the whole body of the tree at firſt: as he did not know, but that it might kill it at once: and therefore he ſelected out a particular branch, that was deſigned to be cut quite away, at the winter pruning, for the ſubject of his firſt eſſay. The method of the experiment is this: he took a ſmall awl, and pierced, ſloping, through the rind, and into part of the wood of the branch, but not to the heart or pith of it; and poured in a ſmall drop or two of quickſilver; and ſtopt it up with a ſmall wooden plug made to fit the orifice: and the reſult of this experiment was, that the inſects all dropt off, from that very branch, the next day; and, in a day or two more, from off the other branches of the tree, without any other puncture: and the tree continued in full vigour; and throve well all the ſummer after. Encouraged by this ſucceſs of the firſt eſſay, he next tried it upon a honey-ſuckle; the leaves of which were quite covered with them: and here he ſcraped away the top of the ground with a trowel; and run his awl, in the ſame ſloping manner, into the main ſtem juſt above the roots; but, with the ſame caution as above, not quite to the inner pith; and the ſucceſs was the ſame as before. The inſects all dropt off dead the next day after the experiment was made. The above facts you may ſafely depend upon: and I ſaw both the trees, on which the experiments were made, ſince Chriſtmas laſt; and they then ſeemed to be both very healthy and well. I did not, indeed, ſee the operation performed, as I was at that time on my reſidence at L———; but the method, manner, and ſucceſs, as above related, I had from Mr. Bradford's own mouth."

This letter from Dr. R———, was dated March 11, 1765, though the delivery of it to the ſociety was deferred from accident till February laſt. But Dr. P———, in his letter to the preſident, deſiring him to lay the other before the ſociety, remarks, that experiments have been ſince made, which confirms the firſt obſervations. He ſays, "the advantage, however, hath ariſen from this delay, that Dr. R——— hath had fuller proof of the ſucceſs of this diſcovery."

We

We ſhall only add, that this method has ſince been tried by ſeveral members of the ſociety, and found fully to anſwer the intended purpoſe.

QUINCUNX, a diſpoſition of trees originally formed into a ſquare, conſiſting of five trees, one at each corner, and a fifth in the middle; which diſpoſition often repeated forms a regular grove, and then viewed by an angle of the ſquare or parallelogram, repreſents equal and parallel alleys.

QUINCE-TREE, a fruit-tree well known, and of which there are ſeveral kinds, as the pear-quince, the apple-quince, and the Portugal quince, &c.

Quince-trees are eaſily propagated, either by ſuckers, or cuttings, planted in a moiſt ſoil. Suckers are the worſt to raiſe them from; and cuttings are generally preferred to layers, becauſe they are of more ſpeedy growth. Theſe cuttings ſhould be ſet early in the autumn, and ſhould be watered often, to encourage their rooting. In the ſecond year after planting, they will be fit to remove into the nurſery, where, after being ſet a foot aſunder in rows three feet diſtant from each other, they ſhould be managed as before directed for apples. After two or three years growth in the nurſery, they will be large enough to tranſplant into the places where they are to remain. A moiſt ſituation, ſuch, for example, as the ſide of a river, pond, or ditch, will make them produce the moſt, and the largeſt, fruit: but that which grows on a dry ſoil will be better taſted, and earlier ripe. Theſe trees require no other pruning, than keeping their ſtems clear from ſuckers, cutting away all croſs branches, and diſplacing all upright luxuriant ſhoots from the middle of the tree, that its head may not be too much crowded with wood: for that is of bad conſequence to all fruit-trees. A ſure way to have the beſt ſorts, is to graft or bud them upon ſtocks of their own kind raiſed from cuttings. The trees ſo managed will bear fruit much ſooner, and more plentifully, than thoſe which are raiſed from ſuckers or layers. The Portugal quince is the moſt valuable.

QUIT-RENT, a ſmall rent payable by the tenants of moſt manors, whereby the tenant is quit, or free, from all other ſervices; and is ſaid to be an acknowledgement of their ſubjection to the lord of the manor.

QUITTOR, an ulcer formed between the hair and hoof, uſually on the inſide quarter of a horſe's foot; it often ariſes from treads and bruiſes, ſometimes from gravel, which by working its way upwards, lodges about the coronet: if it is only ſuperficial, it may be cured with cleanſing dreſſings, bathing the coronet every day with ſpirit of wine, and dreſſing the ſore with precipitate medicine.

But if the matter forms itſelf a lodgment under the hoof, there is no way then to come at the ulcer, but by taking off part of the hoof; and if this be done artfully and well, the cure may be effected without danger.

When the matter happens to be lodged near the quarter, the farrier is ſometimes obliged to take off the quarter of the hoof, and the cure is then for the moſt part but palliative; for when the quarter grows up it leaves a pretty large ſeam, which weakens the foot: this is what is called a falſe-quarter, and a horſe with this defect, ſeldom gets quite ſound.

If the matter, by its confinement, has rotted the coffin-bone, which is of ſo ſoft and ſpongy a nature, that it ſoon becomes ſo, you muſt enlarge the opening, cut away the rotten fleſh, and apply the actual cautery, or hot iron pointed pyramidically, and dreſs the bone with doſſils of lint, dipped in tincture of myrrh, and the wound, with the green, or precipitate ointment. When the ſore is not enlarged by the knife, which is the beſt, and leaſt painful method, pieces of ſublimate are generally applied, which bring out with them cores, or lumps of fleſh: blue vitriol powdered, and mixed with a few drops of the oil, is uſed alſo for this purpoſe, and is ſaid to act as effectually, and with leſs pain and danger. *Bartlet's Farriery, page* 303.

R.

RABBIT, a well known animal of the hare kind, with a very ſhort tail.

The female or doe rabbit goes with young thirty days, and then ſhe kindles; and if ſhe take not buck preſently ſhe loſes her month, or at leaſt a fortnight, and often kills her young and eats them.

In England they begin to breed at a year old, but in ſome places much ſooner; and they continue breeding very faſt from the time when they begin, four, five, ſix, or ſeven times a year being common with them. They have uſually from four to ſeven in a litter, and hence its is that a ſmall number at firſt will ſoon ſtock a whole warren, if left to breed a little while undiſturbed. The does cannot ſuckle their young till they have been at buck again: this therefore is to be done preſently, elſe there is a fortnight loſt of the time for the next brood, and the preſent brood alſo probably loſt. When the buck goes to the doe, he always beats and ſtamps very hard with his feet, and, when he has copulated with her, he falls backwards, and lies as it were in a trance; in this ſtate it is eaſy to take him, but he ſoon recovers from it.

The buck rabbits, like our boar-cats, will kill the young ones, if they can get at them; and the does in the warrens prevent this, by covering their ſtocks, or neſts, with gravel or earth, which they cloſe ſo artificially up with the hinder part of their bodies, that it is hard to find them out. They never ſuckle the young ones at any other time than early in the morning, and late at night, and always, for eight or ten days, cloſe up the hole at the mouth of the neſt, in this careful manner, when they go out. After this, they begin to leave a ſmall opening, which they increaſe by degrees, till at length, when they are about three weeks old, the mouth of the hole is left wholly open, that they may go out: for they are at that time grown big enough to take care of themſelves, and to feed on graſs.

People who keep rabbits tame for profit, breed them in hutches, but theſe muſt be kept very neat and clean, otherwiſe they will be always ſubject to diſeaſes. Care muſt be taken alſo to keep the buck and does apart till the latter have juſt kindled, then they are to be turned to the bucks again, and to remain with them till they ſhun and run from them.

The general direction for the chooſing of tame rabbits is, to pick the largeſt and faireſt; but the breeder ſhould remember, that the ſkins of the ſilver-haired ones ſell better than any other. The food of the tame rabbits may be colewort and cabbage leaves, carrots, parſnips, apple-rinds, green corn, and vetches, in the time of the year; alſo vine leaves, graſs, fruit, oats, and oatmeal, milk-thiſtles, ſow-thiſtles, and the like; but with theſe moiſt foods they muſt always have a proportionable quantity of the dry foods, as hay, bread, oats, bran, and the like, otherwiſe they will grow pot-bellied, and die. Bran and grains mixed together have been alſo found to be very good food. In winter they will eat hay, oats, and chaff, and theſe may be given them three times a day; but when they eat green things, it muſt be obſerved that they are not to drink at all, for it throws them into a dropſy. At all other times a very little drink ſerves their turn, but that muſt always be freſh. When any green herbs or graſs are cut for their food, care muſt be taken that there is no hemlock among it, for, though they will eat this greedily among other things, when offered to them, yet it is ſudden poiſon to them.

Rabbits are ſubject to two principal infirmities. Firſt, the rot, which is cauſed by the giving them too large a quantity of greens, or from the giving them freſh gathered, with the dew or rain hanging in drops upon them. It is over moiſture that always cauſes this diſeaſe; the greens therefore are always to be given dry, and a ſufficient quantity of hay, or other dry food, intermixed with them, to take up the abundant moiſture of their juices. On this account the very beſt food that can be given them, is the ſhorteſt and ſweeteſt hay that can be got, of which one load will ſerve two hundred couples a year; and out of this ſtock of two hundred, two hundred more may be eat in the family, two hundred ſold to the markets, and a ſufficient number kept in caſe of accidents.

The other general diſeaſe of theſe creatures is a ſort of madneſs: this may be known by their wallowing and tumbling about with their heels upwards, and hopping in an odd manner into their boxes. This diſtemper is ſuppoſed to be owing to the rankneſs of their feeding; and the general cure is the keeping them low, and giving them the prickly herb, called tare thiſtle, to eat.

The general computation of males and females is, that one buck rabbit will ſerve for nine does; ſome allow ten to one buck, but thoſe who go beyond this always ſuffer for it in their breed.

The wild rabbits are to be taken either by ſmall cur dogs, or by ſpaniels bred up to the ſport; and the place of hunting thoſe who ſtraggle from their burrows is under cloſe hedges, or buſhes, or among corn-fields and freſh paſtures. The owners uſe to courſe them with ſmall greyhounds, and, though they are ſeldom killed this way, yet they are driven back to their burrows, and are prevented from being a prey to others. The common method is by nets, called purſe-nets, and ferrets. The ferret is ſent into a hole to force them out, and the purſe-net, being ſpread over the hole, takes them, as they come out. The ferret's mouth muſt be muffled, and then the rabbit gets no harm. For the more certain taking of them, it may not be improper to pitch up a hay net or two, at a ſmall diſtance from the burrows that are intended to be hunted: thus very few of the number that are attempted will eſcape.

Some

Some who have not ferrets fmoak the rabbits out of their holes with burning brimftone and orpiment. This certainly brings them out into the nets; but then it is a very troublefome and offenfive method, and is very detrimental to the place, as no rabbit will, of a long time, afterwards come near the burrows which have been fumed with thefe ftinking ingredients.

RACK, a wooden frame made to hold hay or fodder for cattle.

RADIATED *Flowers*, fuch as have feveral femi-flofcules round a difk, in form of a radiant ftar: thofe which have no fuch rays, are called difcous flowers.

RADICLE, that part of the feeds of plants, which upon vegitating becomes its root, and is difcoverable by the microfcope.

RADISH, the name of a well known vegetable, and which is commonly cultivated in the kitchen-garden for its root.
