Radifhes are fown in different feafons, according to the time when they are defired for ufe. Thofe fown in September will be fit to eat at Chriftmas, if they are not deftroyed by froft: but they muft be ufed whilft very young, for they foon grow hot and fticky. If fown towards the end of October, which is commonly the time of fowing for the earlieft crops, they will be fit for the table in the beginning of March. Thofe fown at Chriftmas, if the feafon is mild, and the ground in good order, will, if they efcape the froft, be fit for eating about the end of March or beginning of April; and by continuing the fowing once a fortnight, from the middle of January till the beginning of April, always obferving to fow the earlieft crop in the warmeft and beft fheltered fituations, and the later ones in a moift foil and open fituation, without which they will run up, and grow fticky, before they are fit for ufe, a regular fucceffion of thefe roots may be had throughout the feafon. The tendereft, and mildeft to the tafte, are thofe which have been raifed in deep, rich, and light mould.

When the radifhes are come up, and have got five or fix leaves, they muft be thinned wherever they ftand too clofe; for otherwife they will run up in tops, and not increafe in their roots. Some thin them by hand: but it is much better to ufe a fmall hoe, which will ftir the ground, deftroy the weeds, and promote the growth of the young plants. They may be left about three inches afunder, if they are intended for drawing up fmall; but fix inches will be little enough, if they are to ftand till they are pretty large.

The kitchen gardeners about London, who pay great prices for their ground, and therefore are obliged to make it produce as many crops as poffible in the year, fow carrot feed with their early radifhes, in order that if the radifhes are killed foon after their coming up, as they fometimes are, the carrots may remain, for the feeds of thefe laft generally lie in the ground five or fix weeks before they grow, while thofe of the radifhes fprout in about a fortnight: but when both crops fucceed, the radifhes muft be pulled up while very young; or they will weaken the carrots, fo that thefe laft will not be able to fupport themfelves after the former are gone.

It is alfo the conftant practice of thefe induftrious and intelligent men, to fow fpinage with their latter crop of radifhes: for after the radifhes are taken off, and the ground has been cleared between the plants of fpinage, thefe laft will grow up fo prodigioufly as to cover the whole fpace in a fortnight's time: and if this fpinage is of the broad leaved kind, it will be larger and fairer than it ufually is when fown alone; becaufe moft people are apt to fow it too thick, when they do not mix it with any other crop.

The fmall topped, the deep red, the fcarlet, and the long topped ftriped radifh, are the varieties generally cultivated in kitchen gardens. The fmall topped is moft commonly preferred, becaufe it takes up the leaft room: but a fmall fpot of ground will furnifh, from each fowing, as many radifhes of any kind as can be fpent in a family while they are good.

The Naples radifh, which has a very white, round, fmall, and fweet root, may be propagated in the fame manner as the common fort, excepting that it fhould not be fown till the beginning of March, and the plants fhould be allowed a greater diftance. It is not very common in this country; and, indeed, its feeds are apt to degenerate here.

The white and the black Spanifh radifhes will be fit for the table by the end of Auguft, or the beginning of September, if they are fown about the middle of July, or a little earlier, and will continue good till the froft fpoils them. Thefe fhould be thinned to a much greater diftance than any other fort: for their roots will grow as big as common turneps. If they are drawn out of the ground before a hard froft comes on, and laid up in dry fand, in the fame manner as is practifed for carrots, they will keep good all the winter.

To fave the feeds of radifhes, fome of the ftraiteft and beft coloured roots fhould be planted in rows three feet afunder, and at the diftance of two feet from each other in the rows, in deep and well dug ground. If the feafon is dry, they muft be watered from time to time till they have taken root, after which they require no farther care but keeping them clear from weeds; nor need thefe be feared after the branching feed-ftalks of the radifhes have over-fpread the ground, as they will foon do, in fuch manner as to prevent their farther growth.

In this tranfplanting of the radifhes, an allowance fhould always be made for bad feafons; becaufe the very fame plants will not yield a fourth part of the quantity of feeds in dry feafons, that they would do in a moift feafon.

When the feed begins to ripen, it fhould be carefully guarded from birds; and when it is ripe (which is known by the pods turning brown), it fhould be cut, dried in the fun, threfhed out, and laid up in a place where mice cannot come at it.

Horfe-RADISH, a well known plant, cultivated in kitchen-gardens.

Horfe-radifh is propagated by cuttings or buds from the fides of the old roots. The beft feafon for this work is in October or February; the former for dry lands, and the latter for moift. The manner of doing it is as follows: provide yourfelf with a good quantity of off-fets, which fhould have a bud upon their crowns; but it matters not how fhort they are: therefore, the upper part of the roots which are taken up for ufe, fhould be cut off about two inches long with the bud to it, which is efteemed the beft for planting. Then make a trench ten inches deep, in which you fhould place the off-fets at about four or five inches diftance each way, with the bud upward, covering them up with the mould that was taken out of the trench: then proceed to a fecond trench in like manner, and continue the fame until the whole fpot of ground is planted. After this, level the furface of the ground even, obferving to keep it clear from weeds, until the plants are fo far advanced, as to be ftrong enough to over-bear and keep them down. With this management, the roots of the horfe-radifh will be long and ftraight, and free from fmall lateral roots; and the fecond year after planting will be fit for ufe. It is true, they may be taken up the firft year, but then the roots will be but flender; therefore it is the better way to let them remain until the fecond year. The ground in which this is planted ought to be very rich, otherwife the roots will make but a fmall progrefs.

Woollen RAGS, and the nippings of the pitch-marks upon fheep, are a fingularly good manure. The rags fhould be chopped fmall, about an inch or two fquare, and fcattered on the earth at the fecond ploughing; for being thereby covered, they will begin to rot by feed-time. They imbibe the moifture of dews and rain, retain it long, and, as Dr. Home obferves, thereby keep loofe foils in a moift ftate. They coft about four-pence a bufhel at London, from whence many loads are fent every year to Dunftable, which is thirty-three miles, where they are laid even on ftiff-lands, juft after the fowing of the corn, allowing to the acre four facks of fix bufhels each.

RAG-WORT, or as it is called in Yorkfhire, *feagrim*, is a very pernicious weed.

The reverend Mr. Camber, of Eaft-Newton, has obliged the public with the following obfervations on the growth and deftruction of ragwort, or feagrim.

“ This plant, ſays he, has a ſtalk, in its early ſtate, green, but, as it advances in age, inclining to violet or purple, eſpecially downwards. Its flowers are yellow, and thick-ſet, and compoſed each of a number of ſmall-pointed leaves. It runs to ſeed in the latter end of ſummer. The ſmell, both of the ſtalk and leaves, which are jagged, (whence probably it obtains one name) and the flower itſelf, are offenſive to all animals, I think ; for I have obſerved that hardly any creatures feed upon it, except almoſt hungered or ſtarved. I have not indeed obſerved whether or no aſſes reject it.

“ Like moſt other weeds, it thrives beſt in the beſt ſoils, either natural or artificial ; and I took up a plant of it in my orchard, about two years ago, (with the root) which, when in flower, touched my chin, (my height is about five feet eight or nine inches) and its root, which is round, and thick ſet with taws, was much larger than a new-born child's head : but the uſual dimenſions are much leſs than theſe.

“ About four years ago, I obſerved the ſpreading of this weed in that part of this eſtate which was in our own hands. I took notice, that neither cows nor horſes eat it ; and when I ſmelled it, I ceaſed to wonder that they did not. It was obvious to remark, that a weed ſo bulky as this, and ſo groſs, muſt extract much nouriſhment from the earth, and that it was adviſable to get rid of it as faſt as poſſible. The moſt eaſy method was mowing. I therefore ordered a ſervant to mow theſe weeds in the paſtures as near to the ground as he could ; and I hoped that the common mowing in the meadows would be ſufficient to deſtroy them : but I ſoon found my miſtake ; for in a very few weeks theſe offenſive ſtrangers ſhot up again into a ſtalk and leaf, and even flower, though all in much ſmaller ſize than before, but with this diſagreeable circumſtance, that the root was ſo far from being injured with the ſcythe, that for one ſtalk ſeveral aroſe, and the root ſeemed to have gained new vigour from the wound.

“ I now applied myſelf to plucking up by the roots of theſe odious inmates, and found new difficulties ; for while the ground was dry, as it uſually is in the latter end of ſummer, I found the ſtalks of ſuch of the ſeagrims as were longeſt, and afforded the tighteſt graſp, either break in plucking, and leave the root in the ground entirely, or at beſt bring with it only a ſmall part of the root ; and when the wet weather came on, and looſened the ground, and made it poſſible, or even eaſy, to bring away the whole ball of the root, yet the ſeaſon of ſeeding was come on alſo, and the earlieſt ripe ſeeds had diſperſed themſelves, and produced an aſſurance of a larger crop for ſucceeding years than the moſt careful plucking of the preſent crop could deſtroy.

“ But if theſe were the difficulties which attended my attempts to eradicate thoſe ſeagrims, which had happened not to be mowed, I was much more embarraſſed by thoſe which had been ; for here it was impoſſible to get any ſuch faſt hold, as to pluck them up with much, or even any root.

“ I now applied myſelf to enquire what gentlemen or farmers were plagued with this weed, and what methods they had tried with ſucceſs to deſtroy it.

“ I was told by a gentleman in my own neighbourhood, that Sir G. Cayley, of Brompton, near Scarborough, baronet, had been plagued with this weed, and had purſued the method of plucking with ſucceſs.

“ Animated by this aſſurance, I reſolved to purſue this method with great attention ; and as it ſeemed to be a work which required great care, both in the choice of ſeaſon and manner of plucking, I reſolved not to depute the work to others, but to endeavour to clear a ſpot in my cow-paſture with my own hands, that, if my labour ſucceeded, I might employ others to follow the ſame method under my own eye in the reſt of this paſture.

“ Accordingly, in the evenings of the ſummer, or rather autumn, of 1762, after ſhowers, I applied myſelf to this work ; and by help of a pair of ſtrong gloves, and a tight graſp, I brought up almoſt every root, in a ſpace of about two hundred yards ſquare, whole ; ſo that I had good hopes I ſhould ſee this ſpot clear in the ſucceeding ſummer. It is true, I ſaw leaves of the ſpecies of this weed, and of a very vivid green too, around the plants which I pulled up : but as I reaſonably concluded theſe to be fed by the taws which ſpread themſelves from the main root, ſo I (methought reaſonably) concluded alſo, that this main root being deſtroyed, the ſide taws would die, and conſequently theſe young leaves.

“ But how was I diſappointed, when, in the ſummer of 1763, I ſaw this ſpot of ground as much over-run with ſeagrims as any part elſe of the paſture which had been unpulled !

“ Converſing, however, with G. Watſon, of New Malton, Eſq; towards the latter end of ſummer, on this ſubject, I was aſſured by him, that by a repetition of this labour of plucking for ſome years, he thought he had leſſened the number of his ſeagrims, though they were ſtill numerous. Urged by this example, I have gone through the whole of my paſture, which is about ten acres, and keeps five cows, at the latter end of laſt ſummer, of 1763, with the ſame care as was uſed to a ſmall part of it in 1762 ; yet am I not elated with much hope of ſucceſs ; for a little plot before my garden (in which my horſes run, and which was managed with ſtill more accuracy on account of the odious appearance of the ſeagrims from my windows) ſeems to threaten another conſiderable crop.

“ As I did not confine my enquiries about the method of deſtroying this hateful weed to any one rank of men, I was told by an honeſt quaker, a farmer in my neighbourhood, that he had found turning of ſheep in winter into his cow-paſture the only effectual method of deſtroying this hateful weed.

“ I thought this method very likely to ſucceed ; for ſheep are ſuch cloſe eaters, that I have known them deſtroy whole beds of the rankeſt docks, which could not be killed by any other means.

“ I have not been able to try this experiment conſiderably ; for, as I am raiſing quick fences, both in my meadow and paſture, I keep no ſheep. I have, however, occaſionally admitted ſome of my tenants ſheep into the ſmall plot before my garden this winter ; and, upon an accurate examination this morning, I do not entertain any ſanguine hopes of great ſucceſs from this method. I find that many of the young leaves of this weed, now level with the ſurface of the ground, are untouched by the ſheep ; and that ſuch others as appear bitten by them, do not ſeem in a dying condition.

“ The truth ſeems to me, that ſheep, though they may not have the ſame averſion to this weed as horſes and cows, yet are far from being fond of it ; and if any great ſucceſs is to be hoped for from their bite, (which may prepare beds for the water, and ſo decay the root) the ſheep ſhould be folded pretty cloſe upon it, and obliged to eat it near, and at ſuch a ſeaſon that the winter-rains may have time to work its deſtruction. And ſuch a method, if carefully purſued, ſeems to be moſt probable for the extirpation of this pernicious weed.

“ If the method of plucking is followed, I would ſubjoin ſome cautions.

“ Firſt, In order to prevent the large plants from ſeeding, I would adviſe to cut off all the tops, and the tops only, when the flowers begin to die, that then good hold of the ſtalk may be gotten.

“ Secondly, I would defer the plucking till the rains have moiſtened the ground ſufficiently to bring up the whole main root.

“ Thirdly, I recommend ſtriking the root ſo brought up againſt the ground, in order to diſperſe the earth which adheres to it, by way of manure.

“ Fourthly, I always pile the plants thus pulled up and cleanſed from earth, that, if the ſeaſon prove favourable, they may be burnt, and the aſhes ariſing from them ſpread on the ground ; or if this cannot be conveniently done, (though it is much the better method, and may, with a ſufficient fire, be done when they are ever ſo green) left to rot and manure the ſoil.

“ The groſſneſs, and even ſtench, of this weed, is a proof of the great quantity of ſalts it contains ; and in the ſame proportion as any plant exhauſts the ground of its ſalts, it repays when reduced to manure. There can, however, be no queſtion, but whilſt weeds are left to rot, a great quantity of the ſalts, which by burning would mingle with the ſoil, are carried into the air.

“ I

"I ſuppoſe your readers will be curious to know in what manner I account for the ſudden appearance of ſeagrims in vaſt abundance, in this eſtate, where they were hardly ever known before.

"I will give you an account, which, I dare ſay, you will eſteem perfectly ſatisfactory. About eight years ago I undertook to improve a piece of ground of about fourteen acres, which was over-run with thorns of both ſorts, brambles, broom, and furze.

"When I had got it cleared of all this traſh, my next buſineſs was to pare the hills off, and pile them, and, after a winter's mellowing, to break and ſpread them with a mixture of lime, and all other kinds of manure which I could collect. As the ſoil was very poor, having been exhauſted by the great quantity of traſh it had nouriſhed for many years, I was not yet ſatisfied, but reſolved to take the advantage of the firſt dry ſummer, to lead out the riches of a pond of about thirty yards long and half as many broad, which had been occupied by a great number of geeſe, &c. and never thoroughly cleaned during near thirty years. I got through this work, though at a great expence, being obliged to employ a conſiderable number of draughts, leſt the rains ſhould make the mud too thin, or the heat bake it too much, the mud being for a conſiderable ſpace a yard perpendicular.

"All this mud I laid on my newly-improved ground, except a few cart-loads, which were brought and laid by the wall of a kitchen-garden, to be mingled with the other ſoil.

"I had divided my improved ground, reſerving about four acres for meadow.

"Behold! the ſucceeding year gave me a crop of ſeagrims both in my new meadow, my new cow-paſture, and the plot of ground in which the mud for my garden had been ſcattered; and more particularly in thoſe parts where the ground had been broke, either to ſtub the thorns, &c. or to take away the hills, while the adjoining ground on every ſide was free from this pernicious weed.

"As I knew little or nothing of this weed, I ſuffered it to feed before I took any neceſſary precautions for its deſtruction. The ſucceeding year preſented me with a much larger crop, and I have been ever ſince ſtruggling for its extirpation, and have the mortification to ſee its encroachments on adjoining grounds by the ſeeds which winds have carried.

"This fact, and another of the ſame kind, in a piece of ground which I improved ſince, at ſome diſtance from the former, have confirmed me in an opinion, which I before thought very probable, viz. "That all ſoils are originally impregnated with the ſeeds of almoſt all graſſes and weeds, (though of ſome in greater quantities) which only want a proper ſtirring and manure to awaken them to vegetation, though at the expence of one another, ſome being ſuffocated by that proceſs which gives life to the others."

"I will add another ſtriking inſtance in confirmation of this ſentiment, notorious in this neighbourhood.

"A conſiderable quantity of the park at Gilling was over-run with brakes and moſs, and that wretched graſs which grows in ſuch company. Lord Fairfax, the owner, finding that he could not have his veniſon fat as it ought to be, deſtroyed his park, and applied himſelf ſeriouſly to the improvement of it at a vaſt expence. In courſe of time by due tillage he brought this worſt part of it to be not only good corn-land, but even tolerable, though coarſiſh, meadow and paſture; yet both of them thick ſet with ſeagrims, a weed never ſeen there till the quantity of lime which his lordſhip put into that poor ſoil had warmed it ſufficiently.

"I have only to add, on this ſubject, that I am perſuaded ſeagrim does more harm in meadow than paſture land; for in the latter it only exhauſts the ground, on which it ſtands, to no good purpoſe; but in the former it communicates its diſagreeable ſtench in the ſweat to the good hay, and deſtroys its ſweetneſs. I adviſe, therefore, that hay-makers be ordered to throw it with their rake-ſhafts out of the ſwathe whenever they meet with it." *Muſeum Ruſticum, vol.* V. *page* 117.

RAM, the male of the ſheep kind. *See the article* SHEEP.

A correſpondent of the editors of the Muſeum Ruſticum has obliged the world with the following method of gelding rams.

"It was, ſays he, a long time before I came into a proper method of gelding my rams: I uſed, like my neighbours, always to employ a common gelder, who cut and ſeared them; however, I obſerved that this not only put the animal to great pain, but was a conſiderable time before it healed, and the ſheep or lamb always loſt fleſh in no ſlight degree.

"Whilſt I was muſing how to improve this practice, a friend of mine, a farmer, who came accidentally to ſee me, out of Bedfordſhire, adviſed me to leave off gelding my rams in the manner I had practiſed, and, inſtead of it, to have them knitted.

"The method of doing this he deſcribed as follows. Firſt take ſome ſmall, yet ſtrong, twine, not too hard twiſted; add three of theſe together, and ſlightly twiſt them on your knee, as the ſhoemakers do their thread; than wax it well with ſhoemakers wax, and it is ready for uſe.

"When you are thus prepared, take a proper length of this twine; tie each end of it to a ſhort bit of ſtick, as thick as a walking-cane; then put it round the cod, and tying a ſingle knot, do you take hold of one ſtick and draw it, whilſt another man draws the other, as tight as you well both can; for on the tightneſs of the drawing depends the ſucceſs of the operation.

"The animal immediately loſes all ſenſe of feeling in the cod; the circulation of the blood thither is ſtopped; and if it was to be let alone, it would rot off; but this is a bad, as well as a naſty and dangerous practice, for the ſheep ſometimes die of the ſtench.

"The beſt way is, at the end of nine days, to cut off the cod; but then you muſt take a great deal of care you do not cut it too cloſe to the tying; if you do, the ſtring may chance to ſlip off, and the conſequence be dangerous, as by ſuch a neglect many ſheep may be loſt in a ſeaſon.

"Many farmers, I am informed, when they knit their rams, truſt to the ſtrength of one man's arms; and this may ſometimes be well enough, when your workman is ſtrong, attentive, and willing; but if he is failing in any of theſe points, ten to one but an accident happens: I therefore always chuſe to employ two men at this work.

"The ſeaſon I chuſe is the ſpring of the year, though ſome prefer November, after the ramming ſeaſon is over: I have many reaſons for this preference, and, particularly, I think that the warm weather coming on, hinders them from pining, or falling off their fleſh, and ſoon re-eſtabliſhes them in their perfect health. When this operation is performed in November, and the winter is either wet or froſty, the ſheep are pinched by the cold, and pine away conſiderably, not having that heartening food, to keep them in ſpirits, as they meet with in the ſpring of the year.

"I have obſerved, that if the rams are not in good fleſh, or have not been pretty well fed, they do not undergo this operation ſo well: I therefore always take care to keep them particularly well ſome time before, and alſo ſome time after the buſineſs is done. This is an attention by no means thrown away, for without it ſome miſcarriages may happen, which would otherwiſe be avoided.

"When I ſay I prefer knitting my rams in the ſpring, I mean before the hot weather comes on; as to the particular time, I am governed by the ſeaſon: if it is deferred till ſummer, the flies will ſurely be troubleſome." *Muſeum Ruſticum, vol.* IV. *page* 159.

In a ſucceeding number of the ſame work, another correſpondent has laid down the following method, which he thinks preferable to the former. He declares he has practiſed it for ten years, and in that time had not loſt a ſingle one by gelding, out of ſeveral hundreds; neither do they loſe fleſh: on the contrary, ſome of them, that did not thrive before, rather fatten better after, if the paſture does not fail. The ſucceſs he imputes to the evacuation of the humours, by cutting the ſcrotum, &c. may be the occaſion of it.

"What, ſays he, is neceſſary to be obſerved, by way of caution, is as follows. When I am about to have my lambs

lambs gelt, I take dry fresh weather to do it in; for which purpose I defer it until they are about two months old, which brings, at least, the middle of May for that work to be performed in; but, in order to have a settled state of weather, and the moon in decrease, I do it either a little sooner, or a fortnight later, when I judge the work may be done with safety, according to the above caution.

"I have the lambs put into a fold that has a good wall, or dyke, about it, by seven or eight o'clock in the morning, or as soon as the dew is off. A man is appointed to stand within the fold, with his back against the wall or dyke, who may be called the holder: another is appointed to take the lambs, one at a time, taking care not to heat them either in folding or taking them.

"When he has taken a lamb, he brings it to the holder, who takes it by the hinder houghs, and presses its back against his breast, with its head over his shoulder: the operator then, who generally is the shepherd, takes his knife, and cuts about an inch from the lower end of the cod quite off: he then puts one of his hands close up to the creature's belly, while he presses back the cod with the other; and by that means he causes the bare stones to put out, so that he can easily gripe them one at a time with his teeth, and pulls them slowly out.

"He then takes a little salt water, which is prepared on purpose, and set near him, into his mouth, and warms it a little; then he squirts it up the cod, and all is done; the holder handing the lamb over the wall, or dyke, to one that sets it on its feet on the other side, pulling its tail pretty hard when he lets it go, which makes it stretch itself out.

"Thus, in half a minute, a lamb is gelt; and in three or four days all danger is over, if kept from lying on nettles, and the like.

"It is proper to walk the lambs gently about three or four hours after they have been half a day gelt.

"If old rams are to be gelt, I do it about the same season; and the operator takes no other method than that used with the lambs, only putting a bit of salt and butter up the cod instead of squirting up a little salt water: the holder, indeed, must not now stand, but sit on the ground, griping the ram by the houghs, while he lies on his back, with his head over one of the holder's thighs, &c.

"My reasons for letting the lambs be about two months old before they are gelt, besides the reason before given, are, that at that age they are better able to bear the pain of the operation than when they are young and weakly; and the strings, as they are called, are so strong that they do not break, but come entirely out along with the stones, which makes a free passage for matter to issue out by the cod; whereas, when they are gelt very young, as is the practice with some, the *tunica albuginea*, or strings as they are vulgarly called, being but weak, they often break, probably occasioning inflammations, &c. which certainly ought to be avoided, if possible. This occasions more to die, when they are gelt young, by the operation, than when cut at two months old.

"I mentioned having the moon in decrease when I have my lambs, &c. gelt, which by some, perhaps, will be thought a circumstance not worth notice: but let such only attend to the wonderful effects the luminaries have on fluids, as well the juices of the animal œconomy, as others, when they are in the positions that constitute new and full moon; and they will, I dare say, be disposed to think the hint is not quite impertinent.

"The reasonableness of my conclusion is not deduced from argument only, but has the authority of experiment, as follows:

"I attempted to geld my lambs, one year, just at full moon: the first lamb that was cut bled very sorely; the next did the same. I tried as far as half a dozen, and none of them were otherwise. I then apprehended there was danger, so deferred cutting any more for five days, when there was a great abatement in the bleeding: besides, one of the six gelt at full moon dropt, and none of the others that were gelt five days after did, although they were above twenty times the number of the former (the weather and usage were nearly the same.) This, I own, carried conviction enough for me. Those that will not be convinced by my relation of this fact, I, notwithstanding, do heartily wish them no worse luck than I have had in that way; but withal they had as good use circumspection. *Museum Rusticum, vol. IV. page* 331.

RAMPION, the name of a beautiful flower cultivated in curious gardens.

The crimson rampion is greatly prized by the curious, for the beauty of its rich crimson flowers, which exceed all the flowers I have yet seen, in the deepness of its colour: and these commonly, when their roots are strong, produce large spikes of these flowers, which continue a long time in beauty, and make a most magnificent shew amongst other flowers. The time of their flowering is commonly in July and August; and if the autumn prove very favourable, they will sometimes produce good seeds in England. These plants are natives of Virginia and Carolina, where they grow by the sides of rivulets, and make a most beautiful appearance; from whence the seeds are often sent into England. These seeds commonly arrive here in the spring; at which time they should be sown in pots filled with light earth, and but just covered over; for, if the seeds are buried deep, they will not grow. These pots should be placed under a frame, to defend them from cold, until the season is a little advanced; but they should not be placed on an hot-bed, which will also destroy the seeds.

When the weather is warm, towards the middle of April, these pots should be placed in the open air, in a situation where they may have the morning sun till twelve o'clock, observing to water them constantly in dry weather; and, when the plants are come up, and are grown pretty strong, they should be transplanted each into a small pot filled with fresh light earth, and placed in the same situation, observing to water them in dry weather; and, in winter, they should be placed under an hot-bed frame, where they may be sheltered from severe frosts; but, in mild weather, they should be as much exposed to the open air as possible.

The March following these plants should be put into larger pots filled with the same fresh earth, and placed, as before, to the morning sun; observing to water them in dry weather, which will cause them to flower strong the autumn following.

These plants are also propagated by parting of their roots: the best season for which is, either soon after they are past flower, or in March; observing to water and manage them, as hath been directed for the seedling plants both in winter and summer. *Miller's Gard. Dict.*

RANUNCULUS, or *Crowfoot*, the name of a very beautiful flower, greatly cultivated, and much admired.

There are a great variety or species of ranunculus; but that called the Persian ranunculus being universally admired, we shall only give the method of cultivating it.

The beds in which the Persian ranunculus roots are planted, should be made with fresh light sandy earth, at least three feet deep; the best soil for them may be composed in this manner, viz. take a quantity of fresh earth from a rich upland pasture, about six inches deep, together with the green sward: this should be laid in heaps to rot, for twelve months before it is mixed, observing to turn it over very often, to sweeten it, and break the clods: to this you should add a fourth part of very rotten neat's dung, and a proportionable quantity of sea or drift sand, according as the earth is lighter or stiffer; if it be light, and inclining to a sand, there should be no sand added; but if it be an hazel loam, one load of sand will be sufficient for eight loads of earth: but if the earth is strong and heavy, the sand should be added in a greater proportion: this should be mixed six or eight months before it is used; and you should often turn it over, in order to unite their parts well together, before it is put into the beds.

The depth which this should be laid in the beds, must be about three feet; this should be below the surface, in proportion to the dryness or moisture of the place where they are situated; which, in dry ground, should be two feet eight inches below the surface, and the beds raised four inches above; but in a moist place they should be two feet four inches below, and eight above the ground; and, in this case, it will be very proper to lay some rubbish and stones at the bottom of each bed, to drain off the moisture; and if, upon this, at the bottom of the beds,

beds, some very rotten neat's dung is laid two or three inches thick, the roots will reach this in the spring, and the flowers will be the fairer. This earth I would by no means advise to be skreened very fine: only, in turning it over each time, you should be careful to break the clods, and throw out all large stones, which will be sufficient; for if it is made very fine, when the great rains in winter come on, it will cause the earth to bind into one solid lump, whereby the moisture will be detained, and the roots, not being able to extend their tender fibres, will rot.

The beds, being thus prepared, should lie a fortnight to settle, before the roots are planted, that there may be no danger of the earth settling unequally after they are planted; which would prejudice the roots, by having hollow places in some parts of the bed, to which the water would run and lodge, and so rot the roots in such places. Then having levelled the earth, laying the surface a little rounding, you should mark out the rows by a line, at about six inches distance each way, so that roots may be planted every way in straight lines; then you should open the earth with your fingers at each cross, where the roots are to be planted, about two inches deep; placing the roots exactly in the middle, with their crowns upright; then with the head of a rake, you should draw the earth upon the surface of the bed level, whereby the top of the roots will be about an inch covered with earth, which will be sufficient at first. This work should be done in dry weather, because the earth will then work better than if it were wet; but the sooner after planting there happens to be rain, the better it will be for the roots, for if it should prove dry weather long after, and the earth of the beds be very dry, the roots will be subject to mould and decay; therefore, in such a case, it will be proper to give a little water to the beds, if there should no rain happen in a fortnight's time, which is very rare at that season of the year; so that they will seldom be in danger of suffering that way.

When the roots are thus planted, there will no more be required until towards the end of November; by which time they will begin to heave the ground, and their beds appear; when you should lay a little of the same fresh earth, of which the beds were composed, about half an inch thick all over the beds, which will greatly defend the crown of the root from frost: and when you perceive the buds to break through this second covering, if it should prove a very hard frost, it will be very proper to arch the beds over with hoops, and cover them with mats, especially in the spring, when the flower buds will begin to appear; for if they are exposed to too much frost, or blighting winds, at that season, their flowers seldom open fairly, and many times their roots are destroyed: but this happens more frequently to the Persian kinds, which are tenderer, than to those sorts which are pretty hardy; for which reason they are commonly planted in open borders, intermixed with other flowers, though in very hard winters these are apt to suffer, where care is not taken to guard off the frost.

In the beginning of March the flower stems will begin to rise, at which time you should carefully clear the beds from weeds, and stir the earth with your fingers between the roots, being very careful not to injure them; this will not only make the beds appear handsome, but also greatly strengthen their flowers. When the flowers are past, and the leaves are withered, you should take up the roots, and carefully clear them from the earth; then spread them upon a mat to dry, in a shady place; after which they may be put up in bags or boxes, in a dry room, until the October following, which is the season for planting them again. *Miller's Gard. Dict.*

RAPE, the name of a plant much cultivated for its seed, and also as a food for cattle. *See the article* COLE.

RASPBERRIES, the name of a shrub, of which there are three different kinds; the common, or wild; the large red garden raspberry; and the white. They all ripen about the beginning of July.

These plants are generally propagated by slips, or suckers, but layers are far preferable, because they will be much better rooted. Their fibres should be shortened when they are transplanted; but the buds, which are placed at a small distance from the stem of the plant, must not be cut off, because they produce new shoots the following summer. A fresh strong loam in a shady situation is that in which they thrive best, and produce the fairest fruit, especially if they are planted two feet asunder every way, in borders of a moderate breadth: for if there be not room for the air to pass freely between them, they never produce their fruit in so great a quantity, nor does it grow so large, or ripen so kindly, as when they stand at sufficient distances from each other. To promote this they must be kept clear from weeds; and to let the sun in among them to ripen their fruits, their heads should be cut off just above the bearing part, a fortnight or three weeks before the fruit begins to ripen. It is upon this principle that Mr. Miller advises setting them about two feet asunder in the rows, and leaving a space of four or five feet between row and row. March is the usual time for planting them.

When they are dressed, the season for which is in October, all the old wood, which produced fruit the preceding summer, should be cut down below the surface of the ground, and the young shoots of the same year must be shortened to the length of about two feet. The intervals between the rows should then be well dug, to lay fresh earth to the roots; and if a very little rotten dung is buried therein, the plants will shoot the more vigorously in the following summer, and produce the finer fruit. During the summer, they will require no other culture than keeping them clear from weeds.

These plantations should be renewed every third or fourth year; after that their fruit dwindles greatly, both in quality and in quantity.

RAT, the name of a well known animal, very troublesome to the farmer, &c.

We shall here give the two following receipts, as they are said to be effectual, for destroying rats.

The first has the sanction of the Dublin society, who on the 19th of November 1762, ordered a premium of five guineas to one Laurence O'Hara, for this discovery; which is "one quart of oat-meal, four drops of rhodium, one grain of musk, and two nuts of nux vomica finely rasped." This mixture is to be made up in pellets, and laid in the holes and places which the rats frequent.

The other receipt is thus: "Take of the seeds of staves-acre, or louse-worth, powdered, one fourth part, and of oatmeal three parts; mix them well and make them up into a paste with honey. Lay pieces of it in the holes, and on the places frequented by rats or mice, and it will kill such of those vermin as eat thereof." *Gent. Mag. March* 1763.

The first step taken by rat-catchers, in order to clear a house, &c. of those vermin, is to allure them all together to one proper place, before they attempt to destroy them; for there is such an instinctive caution in these animals, accompanied with a surprising sagacity in discovering any cause of danger, that, if any of them be hurt, or pursued, in an unusual manner, the rest take the alarm, and become so shy and wary, that they elude all the devices and stratagems of their pursuers for some time after. This place, where the rats are to be assembled, should be some closet, or small room, into which all the openings, but one or two, may be secured: and this place should be, as near as may be, in the middle of the house, or buildings. It is the practice, therefore, to attempt to bring them all together to some such place, before any attempt be made to take them; and, even then, to avoid any violence, hurt, or fright to them, before the whole be in the power of the operator.

The means used to allure them to one place are various: one of those most easily and efficaciously practised is, the trailing some piece of their most favourite food, which should be of the kind that has the strongest scent, such as toasted cheese, or broiled red-herring, from the holes or entrances to their recesses in every part of the house, or contiguous buildings, whence it is intended to allure them. At the extremities, and in different parts of the course of this trailed tract, small quantities of meal, or any other kind of their food, should be laid, to bring the greater number into the tracks, and to encourage them to pursue it to the center place, where they are intended to be taken: at that place, where time admits of it, a more plentiful repaſt is laid for them, and the trailing repeated for two or three nights.

Beſides this trailing, and way-baiting, ſome of the moſt expert of the rat-catchers have a ſhorter, and perhaps more effectual, method of bringing them together; which is, the calling them, by making ſuch a kind of whiſtling noiſe as reſembles their own call; and by this means, with the aſſiſtance of the way-baits, they call them out of their holes, and lead them to the repaſt prepared for them at the place deſigned for taking them. But this is much more difficult to be practiſed than the art of trailing; for the learning the exact notes, or cries, of any kind of beaſts or birds, ſo as to deceive them, is a peculiar talent, not eaſily attained to in other caſes.

In the practiſing either of theſe methods, of trailing or calling, great caution muſt be uſed, by the operator, to ſuppreſs and prevent the ſcent of his feet and body from being perceived; which is done by overpowering that ſcent by others of a ſtronger nature. In order to this, the feet are to be covered with cloths rubbed over with aſſa fœtida, or other ſtrong ſmelling ſubſtances; and even oil of rhodium is ſometims uſed for this purpoſe, but ſparingly on account of its dearneſs, though it has a very alluring, as well as diſguiſing effect, as will be obſerved below. If this caution of avoiding the ſcent of the operators feet, near the track, and in the place where the rats are propoſed to be collected, be not properly obſerved, it will very much obſtruct the ſucceſs of the attempt to take them; for they are very ſhy of coming where the ſcent of human feet lies very freſh, and intimates, to their ſagacious inſtinct, the preſence of human creatures, whom they naturally dread. To the above-mentioned means of alluring by trailing, way-baiting, and calling, is added another of very material efficacy, which is, the uſe of oil of rhodium, which, like the marum lyriacum in the caſe of cats, has a very extraordinary faſcinating power on theſe animals. This oil is extremely dear, and therefore ſparingly uſed. It is exhaled in a ſmall quantity in the place, and at the entrance of it, where the rats are intended to be taken, particularly at the time when they are to be laſt brought together, in order to their deſtruction; and it is uſed alſo, by ſmearing it on the ſurface of ſome of the implements uſed in taking them by the method below deſcribed: and the effect it has in taking off their caution and dread, by the delight they appear to have in it, is very extraordinary.

It is uſual, likewiſe, for the operator to diſguiſe his figure as well as ſcent; which is done by putting on a ſort of gown or cloak, of one colour, that hides the natural form, and makes him appear like a poſt, or ſuch inanimate thing; which habit muſt likewiſe be ſcented as above, to overpower the ſmell of his perſon: and beſides this, he is to avoid all motion, till he has ſecured his point of having all the rats in his power.

When the rats are thus enticed and collected, where time is afforded, and the whole in any houſe and out-buildings are intended to be cleared away, they are ſuffered to regale on what they moſt like, which is ready prepared for them, and then to go away quietly for two or three nights; by which means thoſe, which are not allured the firſt night, are brought afterwards, either by their fellows, or the effects of the trailing, &c. and will not fail to come duly again, if they are not diſturbed or moleſted. But many of the rat-catchers make ſhorter work, and content themſelves with what can be brought together in one night or two; but this is never effectual, unleſs where the building is ſmall and entire, and the rats but few in number.

The means of taking them, when they are brought together, are various. Some entice them into a very large bag, the mouth of which is ſufficiently capacious to cover nearly the whole floor of the place where they are collected: which is done by ſmearing ſome veſſel, placed in the middle of the bag, with oil of rhodium, and laying in the bag baits of food. This bag, which before lay flat on the ground with the mouth ſpread open, is to be ſuddenly cloſed when the rats are all in it. Others drive, or fright them, by ſlight noiſes or motions, into a bag of a long form, the mouth of which, after all the rats are come in, is drawn up to the opening of the place by which they entered, all other ways of retreat being ſecured. Others, again, intoxicate or poiſon them, by mixing with the repaſt prepared for them, the coculus Indicus, or the nux vomica. A receipt for this purpoſe has appeared, which directed four ounces of the coculus Indicus, with twelve ounces of oatmeal, and two ounces of treacle or honey, made up into a moiſt paſte with ſtrong beer; but if the nux vomica be uſed, a much leſs proportion will ſerve than is here given of the coculus. Any ſimilar compoſition of theſe drugs, with that kind of food the rats are moſt fond of, and which has a ſtrong flavour, to hide that of the drugs, will equally well anſwer the end. If, indeed, the coculus Indicus be well powdered, and infuſed in the ſtrong beer for ſome time, at leaſt half the quantity here directed will ſerve as well as the quantity before-mentioned. When the rats appear to be thoroughly intoxicated with the coculus, or ſick with the nux vomica, they may be taken with the hand, and put into a bag or cage, the door of the place being firſt drawn to, leſt thoſe which have ſtrength and ſenſe remaining eſcape.

By theſe methods, well conducted, a very conſiderable part of the rats in any farm, or other houſe, and the contiguous buildings, may be taken. *Muſeum Ruſticum, vol. I. page* 395.

RAT-TAILS, excreſcences which creep from the paſtern to the middle of the ſhanks of a horſe, and are ſo called from the reſemblance they bear to the tail of a rat. Some are moiſt, others dry; the former may be treated with drying ointment and waſhes, the latter with mercurial ointment. If the hardneſs does not ſubmit to the laſt medicine, it ſhould be pared off with a knife, and dreſſed with turpentine, tar, and honey, to which verdigreaſe or white vitriol may occaſionally be added; but before the uſe of the knife you may apply this ointment.

> Take black ſope, four ounces, quick-lime, two ounces, vinegar enough to make an ointment. *Bartlet's Farriery, page* 296.

RED-CLOVER. *See the article* CLOVER.

RED-GAME, an Engliſh name of a bird, common in the mountainous parts of Yorkſhire, and ſome other of our northern counties. It is of the ſhape of a partridge, but much larger, and of a mixed colour of red and black, and is feathered down to the ends of the toes.

RED-LAND, a term much uſed by huſbandmen to expreſs a ſandy ſoil of a reddiſh hue, interſperſed for the moſt part with pieces of ſand-ſtone of the ſame colour, or ſomewhat deeper.

There are ſeveral varieties of this ſoil, one of which is almoſt entirely made up of ſand; another with an admixture of clay with the ſand, the whole making a looſe loamy earth; and a third, full of fragments, of a poor ſandy iron ore, and often containing ſhining ſpecks of ſelenitæ. *Moreton's Northamptonſhire.*

RED-WORM, the name of an inſect very deſtructive to young corn.

" I have often (ſays Mr. Baker, in his report to the Dublin Society) heard of the havock which red-worms make in young wheat, barley, and oats; and in ſome few writers upon huſbandry have read of them: but never ſaw them till May 1764; when to my great mortification, in a few days, they deſtroyed, almoſt totally, nine acres of my wheat, for I did not reap above half a barrel per acre. This misfortune induced me to propoſe to the conſideration of the Dublin Society, whether the offer of a premium might not probably produce a diſcovery of ſome effectual method for deſtroying ſo injurious an inſect, to the infinite advantage of the public: and the ſociety were pleaſed to offer a premium accordingly.

" I now have the honour to lay before them, what has occurred to me upon that ſubject.

" The moſt ingenious M. de Chateauvieux ſpeaks of an inſect, which is certainly the ſame kind, if it be not the very inſect which I have now under conſideration. This gentleman, after ſaying, " our wheat, in the month of May, 1755, ſuſtained a loſs, which even that cultivated according to the New Huſbandry did not eſcape, deſcribes the worm thus: we found in it many little white worms, which afterwards became of a cheſtnut colour. They poſt themſelves between the blades, and eat the ſtems. They are uſually found between the firſt joint and the roots; every ſtalk, which they attacked, grew no more, but became yellow, and withered. The fame misfortune happened to us in the year 1732. The infects appeared about the middle of May, and made fuch havock, that the crops were almoft deftroyed."

" It perhaps might be expected, that this great man fhould have made the very enquiry which we are now upon, as the lofs appears to have been very great in Geneva, at the two periods which he mentions: but when we confider, how much the high office, which he held in the city and republic of Geneva, muft have engaged his attention, it is rather aftonifhing, that he could oblige the world fo much as he hath done, by his repeated experiments in hufbandry, and his judicious obfervations upon them: it is therefore lefs to be wondered at, that this circumftance efcaped him.

" The ingenious Mr. Benjamin Stillingfleet alfo, in the fecond edition of his Mifcellaneous Tracts, in a note, p. 175-6, fpeaks of an infect, which is probably the fame as that which we are feeking to deftroy. His words are,

" Thus in Suffolk, and in fome parts of Norfolk, the farmers find it their intereft to encourage the breed of rooks, as the only means to free their grounds from the grub, from which the tree or blind-beetle comes, and which in its grub ftate deftroys the roots of corn and grafs, to fuch a degree, that I myfelf have feen a piece of pafture-land, where you might turn up the turf with your feet.

" Mr. Matthews, a very obferving and excellent farmer, of Wargrove in Berkfhire, told me, that the rooks one year, whilft his men were houghing a turnep field, fate down in part of it, where they were not at work, and that the crop was very fine in that part, whereas in the other part there were no turneps that year.

" We fee, that M. de Chateauvieux defcribes this worm as being firft white, and afterwards becoming of a cheftnut colour. I have carefully fought them at different periods during the paft year, but always found them of the fame cheftnut colour, never varying in any particular, except that of fize, which I find to be the cafe at all feafons, in which I have feen them.

" The infect which Mr. Stillingfleet fpeaks of, he calls a grub, which, he fays, deftroys corn and grafs: this induces me to believe, that it is the fame infect (though the report which he relates from Mr. Matthews feems to contradict it) becaufe I have obferved, that the red or cheftnut worm, never appears voluntarily upon the furface; but, when the earth is turned up, either with plough or fpade, the rooks and crows are very bold in their approach to pick them up; a circumftance, which I own has in fome degree abated my enmity to thefe birds: I therefore never deftroy nor frighten them off my land whilft I am ploughing it; but when I fow, when the corn rifes, and when it is ripe, I deftroy or banifh them as well as I can, becaufe the mifchief which they do at thofe times is intolerable.

" A member of the Dublin Society informed me laft fummer, that fome of his turneps were deftroyed by a worm; I had fome few which decayed in their leaves, and became of a lemon colour, preceding the putrefaction which followed, and deftroyed the turneps: I examined their roots, but could not difcover any infect which had injured them, and therefore I cannot pronounce that it is the red-worm which deftroyed this gentleman's turneps; but I fhall be very watchful with refpect to this circumftance, upon every opportunity which may prefent itfelf.

" I have obferved my lucerne to decay in its tops, foon after it has been up; and upon examining the roots, I have found the red-worm, which had cut them off.

" This infect feems to be every where in Ireland called the red-worm; by fome of the Englifh writers who have fpoken of an infect, which deftroys corn in the manner already mentioned; which I think is undoubtedly the fame: it is called a grub, by others the large maggot, and the rook worm, becaufe the rooks eat it; but as none of the writers have given any other defcription of it, than the name by which they refpectively call it, I fhall endeavour to defcribe it.

" Red-worms are about half an inch long, and about one tenth of an inch in diameter: they are jointed in their fkins, and are of a very firm texture: they have many fhort legs, two fmall black fpecks, which appear to be their eyes; and two fmall points fpringing from their heads, with which I believe they cut the corn; and which, in that work, I apprehend, act like forceps: and all that I have feen of this fpecies, are of a bright cheftnut colour. For this reafon, I fhould conceive it would be more defcriptive to call them the cheftnut worms.

" When they are expofed to the air, by turning up the earth which is infefted with them, they will very foon cover themfelves again in the foil, which they are very capable of doing, by the ftrength which their make gives them, although they appear to be a fluggifh infect, and have not the advantage of a fliminefs upon their fkins, which the common large creeping worm has, which enables that inoffenfive worm to penetrate the earth, and get under timber and ftones with eafe.

" The red-worm, immediately endeavouring to cover itfelf from the air, is certainly from natural inftinct, as it will foon die, when expofed to the air; as will appear by the experiment, Numb. 10, hereafter mentioned.

" Thefe worms deftroy wheat, barley, oats, and lucerne, whilft in an infant ftate, in the months of March, April, and May. Late-fown barley and oats, they will deftroy as late as June. I have not yet experienced, that they deftroy any other crops.

" The mifchief done by them is in dry weather. Rain fufficient to penetrate the ground, makes them defift from deftroying the corn; and, I fuppofe, every thing elfe which they at any time injure.

" They cut wheat off, juft above the crown of the roots; barley and oats in the fame place, and alfo higher up, upon any part of the ftem, which is below the furface of the earth.

" Thefe worms feem to abound more in ground which is lightly tilled, than in fuch as hath been well tilled; but, in lay ground, they feem to be more numerous than any where elfe: and the fields upon my farm, in which I have found them, are wetter than other fields where they are not; whether that circumftance contributes to their increafe, I cannot fay; but the following experiments prove, that they will live longer in water than they can, when expofed to the open air.

" *Experiments on Red-worms.*

" Numb. 1. I put ten red-worms into a wine-glafs with common falt in it. They were all dead in four hours.

" Numb. 2. Into a glafs with brine in it I put ten red-worms. They were all dead in fix hours.

" Numb. 3. Into a glafs with lime in it, which had been flaked for a long time, and expofed to the weather, I put the like number. They were all dead in forty-four hours.

" Numb. 4. Into a glafs with the above lime, and fome water in it, I put the like number. They were dead in twenty hours.

" Numb. 5. Into a glafs with lime newly flaked, and when cold, I put the like number. They were dead in fourteen hours.

" Numb. 6. Into lime-water, made with cold water, I put the like number. They were dead in ten hours.

" Numb. 7. Into a glafs with foot in it, I put the like number. They were dead in four hours.

" Numb. 8. Into foot and water, I put the like number. They were dead in four hours.

" Numb. 9. Into fair water, I put the like number. They were dead in fifty-two hours.

" Numb. 10. Into a glafs, without any thing in it, I put the like number. They were dead in thirty-two hours.

" By thefe experiments we fee all the articles ufed will kill this infect in a fhort time, particularly the falt and foot. I thought it neceffary to confider different articles, the better to fuit different parts of the kingdom.

" Where lime can be conveniently had, and that it is ufed as a manure, I am apt to believe, from the experiments, that no injury can be fuftained from thefe worms; but I am afraid a fmall quantity will not effectually deftroy them; befides, I fhould fear, if it were not put on before the fowing of the corn, that it might finge the blades of the corn; for, from the experiments, it appears, that lime

lime newly ſlaked, is more ſuddenly deſtructive to them than old lime, and therefore it is to be preferred.

"Where lime is uſed for no other purpoſe than to deſtroy this worm, I ſhould conceive, that about eight barrels, regularly ſown by hand on an acre of ground, might be ſufficient: it muſt be firſt ſlaked and cold before a man can poſſibly caſt it upon the ground with his hand, lime being a very ſtrong cauſtic; and, even when it is cold, the man ſhould have a thick glove upon his hand.

"Where ſalt ſhall be uſed to deſtroy this worm, it muſt always be ſown upon the ground, before the intended crop; for, although corn will vegetate, and receive benefit from ſalt as a manure, when it is uſed antecedent to the ſowing the corn, yet, if it be added after the corn is growing, it will certainly deſtroy it: and therefore, it ſhould never be uſed for this purpoſe, but before the corn is ſown, or at leaſt before it vegetates.

"I conceive that where ſalt is uſed for this purpoſe only, about four hundred and a half to an acre will anſwer the purpoſe, which is a trifle more than one ounce to every ſquare yard.

"We ſee by the experiment, that ſoot kills this worm as ſoon as ſalt; and, as in moſt places it is to be had at a much leſs price than ſalt, I think there can be no doubt about preferring of it; beſides which, it may be ſafely uſed after the corn is up.

"I had ſome ſmall parcels of barley under experiments, which theſe worms began to deſtroy; and in order to convey the ſoot as ſoon as poſſible to the roots of the plants, I mixed a little of it in water, and poured it on the plants with a garden watering-pot; the conſequence was, that I did not loſe one plant afterwards.

"It will hardly be imagined, that I mean that the ſame method is to be purſued upon a whole farm: no; the method I would recommend to the practice of the farmer is this, to ſpread or caſt by hand, as he ſows his corn, about ſix or eight barrels of ſoot on an acre, and let him be careful to chooſe a calm day for the work, otherwiſe the wind will carry away great part of it: and as what remains cannot be regularly diſpoſed, let him be careful to do it early enough in the ſpring, that the rain may waſh the ſoot and convey it to the roots of the plants, before the worm begins the miſchief; if he does this, I am perſuaded his crop will be preſerved.

"We ſee by the experiments, that this worm will live longer in water, by twenty hours, than when expoſed to the open air; but at length, i. e. in fifty-two hours, they died in the water; perhaps this might be from the effect of drowning; but if ſo, I might have expected they would have been totally deſtroyed in my two fields in the winter of 1763 and 1764, by the immoderate rains which fell at that ſeaſon for a long continuance, by which the land was often flooded. But they ſurvived that winter, as appeared by the great loſs I afterwards ſuſtained, by their deſtroying my wheat; and therefore, whether water be an enemy to them or not, it ſeems not eaſy to determine: but if theſe which died in the glaſs of water were really drowned; yet, I think we may conclude, that water is neceſſary to their exiſtence in the earth, and propably aids them in getting their food from it: and what ſeems to confirm this notion is, that when the land is wet, they do not touch the corn, but as ſoon as ever the land is dry, they begin their miſchief. However, this ſpeculation I muſt ſubmit to the conſideration of perſons more capable of diſcuſſing it than I am.

"We ſee by the experiment, Numb. 10, that they cannot live in the open air; which ſeems to prove, that, where they abound in land, the oftener it is ploughed, particularly in the ſummer, when they cannot penetrate the ground ſo eaſily as when it is moiſt, they muſt be, by ſuch ploughing, greatly diminiſhed; beſides which, the frequent ploughing gives the crows more opportunities of picking them up, in which, as I before ſaid, they are very watchful.

"Frequent ploughing has been recommended by ſome writers, as the only means of deſtroying this worm; and they have recommended the ploughs being ſtuck with nails, urging, that by thoſe nails the worms are cut to pieces; others have recommended walnut leaves being ſoaked in water, to ſprinkle the land; and ſteeping ſeed-corn in various liquors, as infallible remedies: but ſuch methods as theſe are founded upon miſtaken principles; they only miſlead the farmer, and muſt diſappoint him.

"Worlidge recommends a ſtrong lye made of fixed ſalts, but that would be impracticable. Mortimer recommends ſea-water, for ſuch lands as are near the ſea-coaſt, which I believe would anſwer very well. He ſays he uſed ſoot once with ſucceſs, but that it did not ſucceed with him afterwards. I am perſuaded he did not uſe the ſoot early enough to have it waſhed into the ground by rain, or perhaps he uſed too ſmall a quantity.

"I would not be thought to arrogate any merit to myſelf, on account of what I have here offered, on this ſubject, ſince it appears, that other perſons have uſed the articles which I have recommended, againſt this common enemy; but many perſons have been diſappointed in their expectations from theſe remedies, which muſt have ariſen from their either having uſed too ſmall a quantity, or not having obſerved the neceſſary precautions; if thoſe, which I have recommended, ſhall be put in practice, and found to anſwer, I ſhall think myſelf amply rewarded."

REEK. *See the article* STACK.

REEK-STAVEL, *or* REEK-STAFFOLD, a frame of wood placed on ſtones, on which the mow or ſtack is raiſed.

REED, the name of an aquatic plant, infeſting low paſture lands.

The beſt method of deſtroying reeds, is by draining the land; for if the drains be cut deeper than their roots, it will take away their nouriſhment, and, conſequently, deſtroy them. Aſhes, or ſoot, will likewiſe kill them; and ſo will ploughing up the land, and laying it in high ridges. They always indicate a good ſoil, for a bad one will not nouriſh them.

RESERVOIR, a baſon, or receptacle for water. *See the article* BASON.

REY-*graſs*, a hardy ſort of graſs, much eſteemed among the farmers for that quality. It will grow on any land, and therefore produces crops where nothing elſe will. It thrives beſt of all on ſour, clayey, and weeping grounds, and equally endures the ſevereſt droughts of ſummer, and froſts of winter, ſuffering no damage from either. It is the beſt of all winter foods for cattle, the ſhorter it is eaten the better, and it ſprings the earlieſt of any. There is no danger of over-ſtocking it, for, if it be left to grow too much, the ſtalk becomes hard and ſticky. It is beſt for horſes and for ſheep, and very much prevents the rotting of the latter. The beſt way of ſowing it is with clover. The common quantity of ſeed is two buſhels to an acre, but three buſhels is much better; though in ſome lands, where the clover is likely to ſucceed very well, they ſow eight pounds of clover ſeed and one buſhel of rey-ſeed to an acre, and this makes a crop that will laſt ſeven or eight years.

Some mow it as hay, and thraſh it for the ſeed, which, about London, ſells from half-a-crown a buſhel to three ſhillings. Four or five quarters of this ſeed will be ſometimes produced from an acre of the graſs. If at any time a field of this graſs is found to grow thin, it is only neceſſary to ſtrew on a buſhel of the ſeed, and roll it with a wooden roller, and the plants riſing from this addition will make the whole crop ſufficiently thick. Rey graſs has this great advantage, that it kills weeds without any other ſown plant; even thiſtles cannot grow among it. When the rey-graſs is cut for hay before perfectly ripe, the hay is the better; but the ſeed will not grow ſo well. When the ſeed is newly thraſhed, it muſt not be laid too thick, for it is very apt to heat and ferment, and the whole will be ſpoiled. *Mortimer's Huſbandry, vol.* I. *pag.* 40.

RICE, the name of a plant cultivated in many parts of the eaſt, in South-Carolina, and alſo in Spain, Italy, and Piedmont.

The plant grows to the height of about two feet and a half, with a ſtalk not unlike that of wheat, but fuller of joints, and with leaves reſembling thoſe of a leek. It branches out into ſeveral ſtems, at the top of which the grains grow in cluſters, and each of them is terminated with an arum or beard, and incloſed in a yellow rough huſk. When ſtripped of this they appear to be of an oval ſhape, of a ſhining white colour, and almoſt tranſparent.

The following account of the culture of rice in China, is taken from M. Duhamel's Husbandry.

" 1. To hasten the sprouting of the rice, it is put into baskets, and soaked for some days in a standing water.

" 2. When their rice grounds are so soaked with water as to be quite like mud, they plow them with a buffalo yoked to a plough very simple in its make, having but one share, one handle, and no wheels.

" 3. After a gentle rain, they break the clods with a kind of large hurdle, drawn by a buffalo; the driver sitting upon it, to increase the weight.

" 4. The ground is cleared of all stones, and whatever roots are in it are pulled up by a strong harrow, with great iron teeth. This instrument is drawn by a buffalo, and a man guides it with the help of two handles, like those of a plough, upon which he leans hard. The earth is like mud, and partly covered with water during all this operation.

" 5. The earth is afterwards smoothed with a harrow, which has several rows of teeth. A man guides this harrow by its two handles, whilst a buffalo draws it; and as fast as its teeth form little channels in the ground, the water runs in, and fills them up.

" 6. When the rice that was laid to soak has sprouted, the seed is known to be good; and it is then sown by hand, very thick, and as equally as possible. Only part of the ground is sown in this manner, to furnish plants for the rest.

" The day after it has been sown, the points of the plants appear above the surface of the water: for the ground is overflowed all this time with just enough water to cover it.

" 7. When the plants have acquired a little strength, they are sprinkled with lime water, to destroy the insects and some of the weeds that would hurt them. For this purpose a small basket is fastened to the end of a long handle, and dipt in the lime-water, which runs through it, as it is conveyed over the plants.

" The Chinese have a great veneration for the first inventor of this method, which answers to our custom of steeping wheat in lime-water, or manuring land with quick-lime.

" 8. Towards April, when the plants are grown strong enough to cover the whole field, and look very green and even, the greatest part of them is pulled up by handfuls, all the mud is carefully washed off their roots, and, being held all this time as even as possible with one another, they are planted in tufts, pretty far asunder, and in a quincunx form, in fields prepared on purpose for them. A serene day is chosen for this operation, which must be performed as quick as possible.

" This practice of the Chinese is with respect to the common culture of rice, what the new husbandry is with respect to the common culture of wheat.

" 9. The rice must be watered: which is always done in China, by overflowing it. To this end, the rice grounds are always near a rivulet, pond, or great pool of water, from which they are separated only by a bank or causey.

" If the water was higher than the rice ground, a trench cut through the causey would overflow it at once: but as it is generally lower, or on a level with the rice ground, the necessary quantity is conveyed in pails or buckets, which are worked chiefly by the help of ropes.

" 10. Though a man cannot step in these rice grounds without being up to his knees, the Chinese weed them three times in a summer; and that with such care, that they pull up even the roots of every weed.

" 11. When the rice is ripe, which is known by its turning yellow like wheat, it is cut down with a sickle, made into sheaves, and carried to a barn, where it is threshed with flails pretty much like ours: the straw is removed with pitch-forks and shovels, and the outer husk of the grain is taken off by beating it with great wooden pestles, or a kind of mallet, after which it is sifted and winnowed: and, lastly, to get off the under husk, the grain is put between two mill-stones, which are worked by a lever fastened to the upper one.

" The two most remarkable circumstances of this culture are, 1. The care which the Chinese take not to let their plants be too close together, lest they should rob one another of their food. 2. Their weeding their rice grounds three times in a summer, which answers the end of the hoeings recommended for the alleys between the beds of other grain, cultivated according to the new husbandry." *Culture des Terres, Tom. II. p.* 180.

RICK, a pile of corn, hay, straw, &c. regularly heaped up in the open air, and sheltered from wet. *See* STACK.

A practical farmer has given the following account of the benefits arising to the farmer from keeping his wheat-straw in ricks, to be used when occasion requires it.

" Experience will, they say, make a fool wise: I took the hint, and have ever since guarded against a misfortune of the like nature.

" I constantly, says he, every year make a rick of wheat straw, unless it happens to be very short, when I keep my rick two years, instead of making a new one the second year.

" This may, and doubtless will, by some of your readers, be thought an unnecessary expence; yet, as I find it answer, I am determined to continue the practice. I not only rick the straw, but I also slightly thatch the rick to keep out the weather; yet, after all, I save by it.

" As I keep a very regular account of my farming expences, I find that in the space of ten years I am a gainer of fifty-three pounds, by saving in this manner a rick of straw for thatching, besides what I saved by not threshing my wheat at an improper season. When I say I am a gainer of so much money in the time, I mean a clear gain: after deducting the expences of making up the rick, thatching it, &c. my expences in thatching for the last ten years have been fifty-three pounds less than they were the ten preceding years; and this I can easily account for, and will, for the satisfaction of your readers, at least in part, do it.

" I now always do my thatching work at the most convenient season, being never in want of straw; and, for the same reason, as soon as any part of my thatching is deficient, I have it immediately repaired, which is a great saving.

" My thatching now lasts longer than it used to do, for I never thatch with short straw, having always, as I observed before, long straw to use; for in the years when the straw is long, I save the largest rick, which I have sometimes kept two or three years, till the wheat straw has been again long.

" In the space of the last ten years I had two accidents happened, which would have proved very expensive to me, if I could not have resorted to my straw rick.

" The first was, that one of my sons (a boy about ten years of age at the time) set fire to the thatch of a large barn, by means of a squib. It burnt furiously for some time, and so far damaged the roof, that I was obliged to have it new thatched; for which purpose I made use of a part of my straw rick, and it was finished in a few days; whereas, if I had not had this rick, I must have bought short straw, for there was scarcely any other to be had, at a large price, and the thatching could not have been finished so soon; by which means I should have had a considerable quantity of barley, that was in the barn, damaged, for it rained very hard, for a considerable time, in a few days after the thatch was repaired.

" The other accident was occasioned by a gust of wind which stripped off a good deal of thatch; but it was soon repaired, without any damage to the corn that was in the barns at the time.

" All this, perhaps, will not be enough to persuade your practical readers to rick their long straw. If this is the case, they must even continue their old practices: yet I hope I may be permitted to say one thing, which I know to be true; what I mean is this, that farmers, if they would attend to matters which they generally think beneath their consideration, would get more money than they do: profits arise from what appear to be trifles at first sight, and the merest trifle should be by a farmer attended to.

" A habit of industry, frugality, œconomy, and perseverance, is absolutely necessary to the occupier of land, if he does not mean soon to shift his quarters. *Museum Rusticum, vol.* III. *page* 245.

RIDDLE, an oblong sort of sieve used to separate dust, and the seeds of plants from corn.

RIDE, a clufter of fprigs of hazel, or the underwood, fhooting out of the fame root.

RIDGE, a long piece of rifing land between two furrows.

Mr. Tull obferves, that the method of ploughing lands up into ridges is a particular kind of tillage, the chief ufe of which is the alteration it makes in the degrees of heat and moifture. But the principal advantage this gentleman propofes from ridges is the draining wet hills, where the upper ftratum is mould, and the fecond ftratum clay. Thefe ridges he obferves fhould be plowed acrofs the hill, almoft horizontally, that their parting furrows lying open, may each ferve as a drain to the ridge next below it; for when the plough has made the bottom of thefe horizontal furrows a few inches deeper than the furface of the clay, the water will run to their ends very fecurely, without rifing into the mould, provided no part of the furrows be lower than their ends. Thefe ridges and their parting furrows muft be made more or lefs oblique, according to the form and declivity of the hill; but the more horizontal they are, the fooner the rain-water will run off the lands: for in that cafe, it will run to the furrows, and reach them at right angles. Every one of thefe horizontal trenches receives all the water from the rills, or little gutters, which in thefe quagmire-hills run betwixt the mould and the clay; thefe are all cut off by the trenches, which receives the water at their upper fides, and carry it away, as the gutters of lead, placed under the eaves of a houfe, carry away the rain-water. Thefe ridges fhould be plowed in pairs, without throwing any earth into the trenches; and at every time of ploughing, the pairs muft be changed, fo that the furrow which had two ridges turned towards it one time, muft have two turned from it the next. *See the article* PLOUGHING.

RIDGES *in a Horfe's Mouth*, are wrinkles or rifings of flefh in the roof of the mouth, running acrofs from one fide of the jaw to the other, with furrows between them.

RIDGLING, the male of any beaft that has been half caftrated.

RING-BONE, a hard fwelling on the lower part of the paftern of a horfe, and generally reaches half round the forepart. It has its name from the refemblance to a ring.

It often arifes from ftrains, &c. and, when behind, from putting young horfes too early upon their haunches; for in that attitude a horfe throws his whole weight as much, if not more, upon his pafterns, than on his hocks.

When it appears diftinctly round the paftern, and does not run downwards toward the coronet, fo as to affect the coffin-joint, it is eafily cured; but if it takes its origin from fome ftrain or defect in the joint originally, or if a callofity is found under the round ligament that covers that joint, the cure is generally dubious, and fometimes impracticable; as it is apt to turn to a quittor, and in the end to form an ulcer upon the hoof.

The ring-bones that appear on colts and young horfes, will often infenfibly wear off of themfelves, without the help of any application; but when the fubftance remains, there needs no other remedy befides bliftering, unlefs when by long continuance it is grown to an obftinate hardnefs, and then it may require both bliftering and firing.

To fire a ring-bone fuccefsfully, let the operation be performed with a thinner inftrument than the common one, and let the lines or razes be made not above a quarter of an inch diftant, croffing them obliquely, fomewhat like a chain; apply a mild blifter over all, and when quite dried up, the rupture plaifter; and then turn the horfe to grafs for fome time. *Bartlet's Farriery, page* 264.

RIPPLING *of Flax*, the operation of taking off the feed from the flax by drawing it through a ripple, or large comb. *See the article* FLAX.

RISING, yeaft, or barm.

RIVER, a current, or ftream of frefh water flowing in a bed, or channel, from its fource into the fea.

RIVULET, a little river or fmall ftream of water.

ROD, a meafure in length, confifting of fixteen feet and a half.

ROLLER, a large piece of wood turning on its axis, and drawn over the furface of the ground to break the fmall clods, and render it fmooth and even.

Spiky ROLLER. *See* SPIKY ROLLER.

ROLLING, the operation of drawing a roller over the furface of the ground.

"Rolling, as well as ploughing and harrowing, fays Mr. Clarke, if admitted in the culture of fallow-lands, would, I prefume, much facilitate eradicating of weeds, and promote the prolific capacity; for it often happens, that after land has been ploughed and worked with the great harrow, &c. there ftill are grafs and weeds remaining, that will the next ploughing caufe the furrows to be ropy, and then much labour and time is required to make it to the mind of the judicious hufbandman, which rolling in the following order will be found to elude.

"Thus, when the land has been once ploughed, bracked, and harrowed, immediately give it a double rolling with a ftone cylinder about four feet long and three feet radius, which, with its furniture, is a roller about one ton weight: the preffure of fuch roller, when there is little moifture in the land, fixes it fo much, that no weeds nor grafs can vegetate: next, in about a month after, put in manure by another ploughing, viz. dung or compoft, whereof dung is the major part; but lime is at this time very improper, as it refifts putrefaction: then give the land a ftroke with the great harrow, and roll it as before: this puts the manure, foil, and juices in contact; by which, together with the vivifying heat of the fun, (that muft be greater on rolled land than on loofe, rough, unfteady particles of earth, becaufe it thereby becomes quiefcent, and the furface acquires a kind of polifh) fermentation and putrefaction muft be ardently excited.

"That thefe are falubrious and moft powerful agents in the fertilifing of land, by loofening the compaffes, and fetting at liberty the more fubtile parts of the manure and foil, and generating that fort of air which is found fo neceffary to animal as well as vegetable life, none converfant in thefe matters can make the leaft doubt.

"Now, indeed, may a quantity of quick-lime be applied to great advantage, by being fpread on the furface; for the weeds that are harrowed up, will not only foon be diffolved by it, and converted into nourifhment for vegetables; but the very principle of vegetation, which is going off in exhalations by the effervefcence within, is by it abforbed, and retained for the nutrition of the crop, which it will communicate when it is ploughed in; and that may be done about fourteen or twenty days after, fooner or later, as the weather anfwers, or the experimentor fees it neceffary: and if it is a foil fit to grow turneps, and the feafon proper, the feed may be fown immediately, either in the drill or common way; but the drill, on many accounts, in fowing turneps, deferves precedency; or, if it is to be winter corn, one ploughing more, which is the third only, makes it in fine order for the feed.

"The utility of rolling does not end here neither; for to roll wheat, rye, barley, &c. with a roller about twice the length, and half the weight of the one above defcribed, may be advantageous, as it preffes down the foil, that has been raifed by the frofts, about the minute ramifications of the attracting ducts, and augments the quantity of mould upon them by breaking the little lumps of foil, which, indeed, were very ferviceable in winter, by affording fhelter, but in fpring will be of ftill greater ufe, by fuch imminution, in filling up the fiffures, and preventing, in a great meafure, the ill effects droughts have on light foils, by retaining and filtering rain water; whereby the foil imbibes whatever is nutritive, what is fuperfluous of the fimple fluid only efcapes.

"Thefe are fome of the many advantages rolling produces in agriculture; notwithftanding which, it amounts to more than mere conjecture, that in general rolling corn may do more damage than it can do good, if fuch as the following cautions be not carefully attended to, viz. Never to roll corn but in dry, frefh weather; by no means ufe heavy rollers, nor roll too early, i. e. before the blades be pretty ftrong, for the wounds that the blades may receive, the roots, being then tender, will be unable ever to recover; nor too late, i. e. when the ftalks are hardened and grown any height, for the roller will break them, which injury hardly can be repaired, and the crop is thereby hurt; that none but light lands are proper to be be rolled, and those only which have been manured that or the preceding year with dung: in short, none but rich, light soils, in general, can be improved by rolling; for in poor lands it opposes the most active primogeneous agents, and undoes all that has been done for the crop by ploughing, &c.

"Thus the soil, the condition, the growth of the corn, the weather, and the weight of the roller, are all to be most scrupulously regarded: when all coincide, the advantages of rolling will be great; but when they do not, the disadvantages may be insuperable.

"Rolling, then, is neither the least critical, nor most insignificant piece of the husbandman's profession; therefore ought not to be performed at random and without circumspection. *Museum Rusticum, vol.* IV. *page* 5.

Rolling it also of use to land in grass, by pressing down mole-hills, &c. It also makes the grass tiller, and grow thicker.

There is a sort of land, which, when clover is sown upon it, throws out the young plants after a frost. Rolling in the beginning of winter, and immediately after the frost is gone, will, in some measure, prevent this. The first rolling hinders the frost from penetrating so deep as it would otherwise do; and the second makes the land firm, after having been loosened by the change from frost to open weather.

ROOD, a quantity of land equal to forty square poles or perches, that is, a quarter of an acre.

ROOK, a well-known bird, resembling a crow; but feeds on grain, insects, &c.

Great care should be taken to guard against these mischievous birds at the time when the wheat is just shooting up; for they perceive its shooting much sooner than the farmer can, and are led by the shoot to pick it up. They must, therefore, be carefully kept off the ground about a week or ten days after this season; for at the end of that time the blade will be grown up, and the grain so exhausted of its substance, that they will not give themselves any trouble about stealing it. They never molest the wheat which is sown about Michaelmas; because so much grain of the late harvest then lies scattered about the fields, that they find it much easier to pick up that, than to search for corn under ground in new-sown lands. They do most harm when the snow is first going off from the green wheat, towards the end of winter; for having been pinched for food during that season, they then greedily pluck up the young plants, in order to come at the remainder of the seeds still adhering to their roots; and are greatly assisted in this by the loose state of the earth at that time.

Among the many contrivances to frighten them away, such as feathers stuck up, the limbs of rooks scattered about the ground, dead rooks hung on sticks, the gun, a boy to halloo and throw his hat, or to toss a dead rook up in the air, Mr. Tull says he found this last to be the most effectual. They will immediately quit their usual places of abode, if the earth is turned up around the trees, in which they have built their nests, and will not return to them till the grass is grown again; as was lately experienced in the repairing of Fountain-court in the Temple: Mr. Lisle assures us, that the taking down of their nests, with their young ones in them, and burning under the trees they were built in, will effectually make all the old ones desert that place. However, it has been doubted, and perhaps with reason, whether they do not, upon the whole, compensate pretty fully, for the mischief they do to corn, by destroying vast quantities of grubs, worms, and other pernicious insects, in the spring: as crows are also of service in the neighbourhood of populous towns, by devouring a great deal of carrion.

It is a common proverbial saying of the countrymen, that at whatsoever farm a colony of rooks plant themselves, and make a rookery, it is a sign of prosperity to the occupier of that land; and that, on the contrary, their deserting it, betides misfortunes and poverty: for both which remarks, Mr. Lisle accounts very rationally, by observing, that where a man is a good husbandman to his land, and improves it, the worms, which are a great food to these creatures, especially at certain times of the year, multiply, and grow to a much greater bulk and fatness, than in a poor neglected soil; the strength of land being as discernable by the large size of worms, as from the growth of plants; and that the grubs or maggots of the beetle kind in particular, on which the rooks feed greatly, as is apparent from their following the plough, in order to pick them up, not only grow fattest and largest in rich well tilled ground; but that the beetles themselves, while in their state of flies, always choose to lay their eggs in such land as will best nourish and provide for their young. The contrary to this soon happens under a bad husbandman.

ROOKERY, a nursery of rooks, or place where they build their nests.

ROOP, hoarseness.

ROOT, the lower part of a plant, by which it adheres to the earth, and by which it draws its nourishment, and transmits the juices to the other parts. For the method of clearing land from the roots, *see the article* GRUBBING.

ROSIL, or *Rosills*, land neither light nor heavy, being a medium between sand and clay.

ROSACEOUS, an epithet applied to such flowers, as are composed of several petals or leaves, disposed in a sort of circular form, like those of the rose; of this kind are the flowers of the piony, ranunculus, unquefoil, &c.

ROSE, the name of a well known beautiful plant, and of which there are numerous varieties.

All sorts of roses are propagated either by suckers or layers; the best season for laying is in October, which is also the proper time for planting, though in moist land the spring is nearly as proper.

ROSEMARY, the name of an odoriferous plant very common in almost every garden.

Rosemary may be raised from seeds; but it is more commonly, and more easily propagated by planting slips or cuttings of it in a spot of fresh light earth, in the spring of the year, just before its buds begin to open. When these plants have taken root, till which they must be watered gently from time to time, and shaded if the sun be too powerful, they should be transplanted into the places where they are to remain. This should be done early in September, that they may have time to strike out new roots before they can be in danger of being hurt by frosts; for those which are set too late in the autumn seldom live thro' the winter, especially if the weather prove very cold. Rather than do this, it is better to let them stand till the next ensuing March, and then to remove them after the hard weather is over: but in whatever season they are transplanted, it should not be during a cold drying easterly wind; because this would soon shrivel up their leaves, and kill them. If a few warm showers fall soon after they are set, they will soon take root, and after that they will require no farther care, than keeping them free from weeds. The distances between the plants should be full sufficient to allow for their utmost growth, so that they may not touch one another. That growth will be most luxuriant, especially in the summer, if they are set in a rich mould: but then they will be most subject to be injured by frosts; nor will their odour be near so strongly aromatic, as when they are raised on a poor gravelly soil.

ROT, a disease incident to sheep, arising frequently from wet seasons, and too moist pasture.

"But the rot in sheep, says an ingenious and practical writer, does not always proceed either from moisture alone, or the nature of the soil alone; for all moist grounds do not cause the rot in sheep, and there are some lands which rot sheep in wet years only.

"The rot, in fact, arises from a certain putrefaction, both in the air, and in the grass or herbs that usually grow in such moist years: these, together with their moist food, corrupt their livers, and bring on the disease.

"It is indeed very difficult to cure this disorder, unless it is attempted before the liver is too much wasted: where there is a convenience of doing it, the best remedy is, an immediate removal to salt-marshes; but this is far from being in every farmer's power: I shall endeavour therefore, from my own former experience, to supply the deficiency.

"In such cases as these, a prevention of the evil is to be recommended to the practice of every rational farmer.

"Some grounds naturally yield a soft, spungy grass, which is, more than any other, subject to breed the rot in sheep; I would therefore advise, that other cattle be fed in these grounds, and the sheep kept in the driest, hardest, and healthiest pastures.

"I have known land that has kept ſheep in health for many ſucceſſive years, yet afterwards, when the months of May and June have proved wet, a frim and frothy graſs has ſuddenly ſprung up, which, together with the bad air that muſt of courſe follow, has cauſed a rot in the ſheep that were then on it: the evil was obſerved in time, the ſheep were removed to a dry and almoſt barren heath, and in the ſucceeding winter they were foddered with good, dry, ſweet hay, and a great loſs was prevented: this happened to an old friend of mine, ſince dead.

"This unwholſome graſs is moſt apt to grow in cold land, and in the ſummer-time; and it is a general opinion, and well founded on experience, that if the ſummer does not rot ſheep, the winter will not, the power of the winter alone not being ſtrong enough to begin a rot.

"A very ſenſible writer, whoſe book I have juſt turned to, I mean Mr. Liſle, ſays, that broom is very good for the rot; and indeed I have often experienced it; for in a farm I occupied ſome years ago there were ſeveral broom-fields, and I have often obſerved that ſuch of my ſheep as were part of the year fed in them were never infected with the rot, whilſt others in my poſſeſſion had it to a great degree. I profited however by experience, for I took care thenceforward that all my ſheep ſhould, by turns, enjoy the advantages to be derived from their feeding on the young ſhoots of the broom.

"As to what Mr. Liſle ſays, on the authority of Mr. Ray, that the marſh-trefoil will cure the rot, I cannot, from experience, corroborate it: I have heard its efficacy in this diſorder often mentioned, but never yet heard any particular fact related ſo circumſtantially as to induce me to depend on its effects.

"That ſalt is good, I agree with the above gentleman and Mr. Boyle; and this gives me an opportunity of communicating a receipt which I know to be a good one.

"When you perceive, by the colour of your ſheep's eyes, that the rot has taken them, drive your flock into a barn, a covered fold, or ſome ſuch convenient place: around this place let there be wooden troughs, like mangers, in which you ſhould feed your ſheep with good, dry, clean oats, for forty-eight hours: then have ready ſome bay ſalt finely powdered and ſearced, of which you are to ſprinkle a little among the oats, encreaſing the quantity till it diſguſts the ſheep, and you perceive they fall off their appetites: afterwards, for the two following days, give them again clean oats; and then mix your ſalt with them as before, continuing this proceſs till their eyes have recovered their natural colour, when you will find them perfectly cured; and to be convinced, it will only be neceſſary to kill one or two out of the flock.

"To this I ſhall add a receipt for the rot in ſheep, which was communicated to me by a friend, a man of credit and veracity, who ſays he has often tried it with ſucceſs.

> "Steep ſome regulus of antimony in ale, adding thereto ſome grains of paradiſe, and a little ſugar to ſweeten it. Of this infuſion ſomewhat leſs than a gill is to be given to every one of your affected ſheep; they are to have two or three doſes, according as they are more or leſs affected by the diſtemper, allowing two days intermiſſion between each doſe."

"This is ſaid, as I have already obſerved, to be a cure almoſt certain.

"I juſt now take notice, that when rain falls in the months of May and June it is apt to cauſe the rot in ſheep: it will be neceſſary to add, that folding them in the above months encreaſes the diſorder; for after having been deprived of their liberty during the whole night, they bite the noxious graſs the more greedily in the morning, having leſs ceremony in their choice of herbs than if they were not folded. This is a matter of ſome conſequence, therefore worthy of being attended to.

"One thing more I muſt, on the authority of Mr. Liſle, communicate to your readers, viz. an obſervation of a Leiceſterſhire farmer; that ſheep, when firſt touched with the rot, will thrive mightily in fatting for ten weeks; but if they are not diſpoſed of when they are come up to a pitch, they will, in ſeven or eight days time, fall away to nothing but ſkin and bone. The ſame farmer obſerved, that he had often had them die in the height of their pitch, in half an hour's time, with twenty-ſeven pounds of tallow in their bellies." *Muſeum Ruſticum, vol.* I. *pag.* 434.

To this account we ſhall add a receipt communicated to Mr. Mills by a gentleman of Lincolnſhire.

> "Steep a handful of rue in a pail of water all night, and at morning put in as much ſalt as will make it bear an egg. Give each ſheep half a pint of this liquor, and repeat it thrice, every other morning.

"A farmer who kept four hundred ſheep tried this receipt in the laſt general rot (about five years ago), and did not looſe any, though his neighbours loſt almoſt all theirs. For the ſake of the experiment, he ſet apart about twenty, and did not give them this drink. Many of theſe were rotten." *Mills's Huſbandry, vol.* III. *p.* 416.

Buck-bean, or marſh-trefoil, is alſo excellent in this diſtemper. *See the article* BUCK-BEAN.

ROUGHINGS, latter-graſs, aftermaths.

ROUP, the name of a filthy diſeaſe in poultry, conſiſting of a boil or ſwelling upon the rump, and is known by the ſtaring, or turning back of the feathers.

The roup, if not ſoon remedied, will corrupt the whole body of the fowl; to prevent which the feathers ſhould be plucked away, the ſwelling laid open, and the matter preſſed out; after which the part is to be waſhed with brine, or ſalt and water.

ROWEL, a kind of iſſue made in horſes for the cure of various diſorders, as inward ſtrains, hard ſwellings, &c.

The operation is performed in the following manner:

A little ſlit being made through the ſkin, about a handbreadth below the part aggrieved, big enough to put a ſwan's quill in, the ſkin is raiſed from the fleſh, the end of the quill put in, and the ſkin blowed from the fleſh upwards, and all over the ſhoulder; then, the hole being ſtopped with the finger, the part blown is beat with a hazle-ſtick, and the wind ſpread with the hand all over, and then let go; this done, a ſkain of horſe-hair, or red ſarſenet, half the thickneſs of the little finger, is put in a rowelling-needle, ſeven or eight inches long, and the needle is put into the hole, and drawn through again, ſix or ſeven inches higher; then the needle is drawn out, and the two ends of the rowel tied together, anointing it every day, as well as before the putting it in, with ſweet butter and hog's greaſe, and drawing it backwards and forwards in the ſkin, to make the putrid matter diſcharge itſelf more plentifully.

Others, diſliking theſe rowels, as making too large a ſore and ſcar, uſe the French rowel, which is a round piece of ſtiff leather, with a hole in the midſt, laying it flat between the fleſh and ſkin, the hole in the rowel juſt againſt that in the ſkin, ſewing it with a needle and thread drawn through the hole and the ſkin, cleaning it once in two or three days, and then anointing it afreſh.

"The general and abſurd reaſoning of farriers, ſays Mr. Bartlet, on the effects and uſe of rowelling, makes the following obſervations the more neceſſary, as it is too notorious how impertinently they talk on this ſubject: for in ſhort with them, a rowel is to draw off all the bad and corrupt humours from the blood, by a ſort of magick.

"It is neceſſary to obſerve that the matter generally diſcharged by a rowel, is nothing more, than an ouzing from the extremities of the veſſels divided in the making of it; in fact then, it is blood, which loſes its colour, by being ſhed out of the veſſels, the warmth of the part, and its confinement.

"If this is granted, it will evidently appear, that the good effects enſuing this operation, muſt be owing to a gradual depletion, or emptying of the veſſels in general; by which means the ſurchage or load on a particular part, is taken off and removed; and impurities or bad juices (generally called humours) run off with the good, in proportion to their quantity in the blood.

"To imagine particular humours are thus ſeparately, and alone diſcharged from the blood, through theſe orifices, is an opinion but too generally received, though a very abſurd one; and muſt be very pernicious in its conſequences, from the bad effects it may have in practice; as muſt the ſame reaſoning alſo in regard to purging.

"The

"Thus to lean hide-bound horfes, and thofe of a dry hot conftitution, the difcharge, by depriving the conftitution of fo much blood, and fluids, is daily exhaufting the ftrength of the animal; and may be productive of bad confequences, by defrauding the conftitution of a neceffary fluid.

"But in diforders from fullnefs, attended with acrimony, or fharpnefs of the juices, and with defluxions on the eyes, lungs, or any part of confequence; the gradual difcharge brought on by thefe means, will contribute to leffen the fullnefs on the parts affected, and give the veffels an opportunity of recovering their tone, while evacuating and alterative medicines are doing their office.

"It may be neceffary however to obferve, that there is a wonderful communication between the veffels of the cellular membrane under the fkin, which remarkably appears, by inflating thofe of fheep, calves, &c. by the butchers; hence probably it is that fome diforders of this integument, are fo apparently relieved by iffues, or rowels, without our having any recourfe to that general depletion of the veffels we have juft obferved, to account for it; and hence alfo may be deduced their utility, fometimes in draining off any extravafated fluids, which may lodge between the interftices of the mufcles, after violent ftrains of the fhoulder; alfo in difcharging fuch vicious, or fharp fluids, as are thrown on the membranes, and occafion thofe flying pains and lameneffes, which we find are often removed by this local remedy." *Bartlet's Farriery, page* 220.

ROWEN, *or* ROWET, winter-grafs.

ROWTY, over-rank, too ftrong.

RUDDLE, a fort of red earth, of a lax texture, and very eafily reduced to powder. It is found in feveral parts of England, efpecially in Derbyfhire; and is much ufed in marking fheep.

RUNCHES, charlock when dry and withered.

RUE, the ftem of a well-known plant, cultivated in moft kitchen-gardens.

It may be propagated either by fowing its feeds, or by planting flips or cuttings of it in the fpring.

RUNNEL, pollard wood.

RUNNET, the acid juice found in the ftomachs of calves, that have fed on nothing but milk, and are killed before the digeftion is perfect. It alfo fignifies a liquor made by fteeping of the ftomach of a calf in hot water. The latter is the runnet ufed in making cheefe, &c.

RUNNING-THRUSH, *or* FRUSH, is an impofthume that fometimes gathers in a horfe's frog; or a fcabby and ulcerous difpofition, which fometimes caufes it to fall off.

When this difcharge is natural the feet fhould be kept clean, but no drying wafhes made ufe of, it being thought as unfafe to repel fome of thefe difcharges, as to cure fome fweaty feet.

When an impofthume, or gathering appears, the fafeft way is to pare out the hard part of the frog, or whatever appears rotten; and wafh the bottom of the foot two or three times a day with old chamberlye; this is the fafeft and beft way of treating them. But when a horfe has been neglected, and there is a ftrong flux to the part, it is apt to degenerate into a canker, to prevent which, ufe the following:

> Take fpirit of wine and vinegar, of each two ounces, tincture of myrrh, and aloes one ounce; Ægyptiacum half an ounce; mix together.

Bathe the thrufh with this, wherever there appears a more than ordinary moifture, and lay over the ulcer a little tow dipped in the fame. The purges and diuretics recommended in the greafe, fhould be given at this time, to prevent the inconveniencies that the drying up thefe difcharges frequently occafion *See the article* CANKER. *Bartlet's Farriery, pag.* 312.

RUNT, a name given to the fmall black cattle brought out of Wales and Scotland.

RUNT, is alfo an epithet applied to feveral fpecies of pigeons; as the Leghorn, Spanifh, and Friefland runt, &c.

The Leghorn runt is a ftately large pigeon, feven inches or better in the legs, clofe-feathered and faft-flefhed, extremely broad-breafted, and very fhort in the back. He carrries his tail, when he walks, fomewhat turned up like a duck's; his neck is longer than any other pigeon's, and he carries it bending like a goofe or fwan. He is goofeheaded, and his eye lies hollow in his head, with a thin fkin round it, like that of the Dutch tumbler. His beak is very fhort for fo large a bird, and has a fmall wattle on it, and the upper chap falls a little over. It is a very valuable pigeon, but is tender, and requires care.

The Spanifh runt is the longeft-bodied of all the pigeons; it is fhort-legged and loofe-feathered, and does not walk fo upright as the Leghorn runt. Thefe are of a great variety of colours, but are apt to have accidents in fitting, from their fitting too heavy, and often breaking their eggs.

The Friefland runt is a large pigeon, and has all its feathers reverted, or looking as if placed the wrong way.

The Roman runt is a pigeon of the fame general make with the common kind, but fo large and heavy that it can hardly fly.

The Smyrna runt is middle-fized, and is feather-footed, and that to fuch a degree fometimes, as to look as if there were wings upon the foot; the feathers of thefe are fometimes four or five inches long, and often pull the eggs and young out of the nefts. The common runt is the common blue pigeon kept for the table, and known to every body. *Moore's Columbarian.*

RUPTURE, a preternatural eruption of the guts or caul.

In regard to ruptures, though they are generally divided into particular claffes, we fhall only obferve, that by violent efforts of the horfe, or other accidents, the guts or caul may be forced between the mufcles of the belly at the navel, and through the rings of the mufcles into the fcrotum or cod. The fwellings are generally about the fize of a man's fift, fometimes much larger, defcending to the very hock; they are frequently foft, and yield to the preffure of the hand, when they will return into the cavity of the belly with a rumbling noife; and in moft the vacuity may be felt, through which they paffed.

On their firft appearance, endeavours fhould be made to return them by the hand; but if the fwelling fhould be hard and painful, in order to relieve the ftricture, and relax the parts, through which the gut or caul has paffed, let a large quantity of blood be immediately taken away, and the part fomented twice or thrice a day, applying over it a poultice made with oatmeal, oil and vinegar, which fhould be continued till the fwelling grows foft and eafier, or the gut is returned. In the mean time it would be proper to throw up emollient oily glyfters twice a day, and to let the horfe's chief diet be boiled barley, fcalded malt, or bran.

Should the fwelling afterwards return, we apprehend the reftringent applications ufually recommended on thefe occafions, will avail little without a fufpenfory bandage; fo that an ingenious mechanic in that art is chiefly to be relied on, for any future affiftance; though it has been obferved, that with moderate feeding, and gentle exercife, fome horfes have continued to be very ufeful under this complaint. *Bartlet's Farriery, page* 334.

RUSH, the name of a well known plant, too common in wet lands.

Rufhes always intimate a good foil; and may be deftroyed by lime, even after it has been flaked, by fea-coal afhes, and by draining the land.

RUST, a diftemper incident to corn, and generally called mildew. *See the article* MILDEW.

RYE, a fpecies of corn, greatly cultivated in the northern parts of England.

Mr. Miller is of opinion that all the rye fown in England is of the fame fpecies, though diftinguifhed by farmers into two varieties of winter and fpring rye, as he has not been able, by the moft fedulous experience, to find any difference.

The winter rye, which has the largeft grain, is what the generality of farmers cultivate. It is ufually fown in autumn, or at the fame time as wheat; and in many of our northern countries, as well as in Wales, they are often mixed and fown together; though as Mr. Miller rightly obferves, this muft be very bad hufbandry, becaufe the rye will always ripen fooner than the wheat; fo that if the latter be fuffered to ftand till fully ripe, the grain of the former will fhed; nor can this be practifed where the people are not accuftomed to eat rye-bread: for though fome account it good when mixed, it is fo very clammy that few who have been ufed to wheaten bread will ever relifh it.

Rye is generally fown on poor, lime-ftone, dry, gravelly, or fandy foils, where wheat will not thrive, and in fuch places it does very well. The ground fhould be dry when it is fown: for if much rain falls, even after the fowing, before the rye is come up, it often rots in the earth. It indeed rifes in a much fhorter time than wheat.

When fown upon light land, it ripens much earlier than a cold ftiff ground, and by continuing to fow it in fuch a foil during two or three years, it will be forwarded fo much as to ripen a month earlier than that which has been long raifed upon ftrong cold ground. For this reafon, thofe who are obliged to fow rye toward fpring, generally provide themfelves with this early feed. A little fprinkling of dung or mud, though it be but half the quantity commonly ufed for other corn land, will, if laid upon the rye ground, greatly advance the crop. The ufual allowance is two bufhels of feed to a ftatute acre, or, if it be new broke up ground, or land fubject to worms, about a peck more; and the produce commonly is about twenty bufhels upon an acre.

In the fummer of the year 1699, which was uncommonly dry, Mr. Mortimer reckoned ninety grains apiece in feveral ears of rye.

The fmall rye may be fown in the fpring, about the fame time as oats, and ufually ripens as foon as the other fort: but if the feafon prove wet, it is apt to run much to ftraw, and the grain is generally lighter than the other. The chief ufe of this fort is to re-fow lands where the autumnal crop has failed.

This corn is ripe when its ftraw turns yellow, its ear hangs, and its grain is hard. It is not very apt to fhed; and therefore, if it be weedy (though this ought never to be the cafe with any corn), it fhould be let lie upon the ground, or gavel, as fome call it, a week or ten days after it is cut, if the weeds do not dry fooner, before it be bound up; for otherwife thofe weeds will give in the barn, make the rye not thrafh well, and render it mufty. But as this grain will grow in the ear fooner than any other, if it be wet, particular care muft be taken, efpecially if rain comes on, to turn it at leaft once in two or three days, and lay the ears upon the ftubble, as high above the ground as can be. This will help to preferve it from hurtful moifture: but if it be cut in perfectly dry weather, and without weeds, it may be houfed as it is reaped.

The general ufe of rye is for bread, either alone, or mixed with wheat, in which ftate it is called meflin corn. It alfo yields a ftrong fpirit when diftilled; and, if fowed only for dreffing of land, is of vaft fervice to the ground where it is plowed in green and fucculent. The truly worthy, and reverend Dr. Eliot informs us, that he has not only been told, but knows by his own obfervation, that if rye be fowed fucceffively every year upon the fame land, both the crop and the land will be greatly improved; infomuch that fome grounds which would yield but five bufhels to the acre at firft, have, in time, afforded a crop of fifteen bufhels to the acre, without the charge of dung, or any manure. But it fhould be remembered that the land fown by Dr. Eliot, was newly broke up.

This plant is likewife fown in autumn to great advantage, purpofely for green feed for cattle, particularly for ewes and lambs in the fpring, before there is plenty of grafs. When this is intended, the rye fhould be fown early, that it may have ftrength to furnifh early fodder. In this light, it fupplies the want of turnips where they have failed, or where their feafon is over: fo that, in fuch cafes, it is very good hufbandry to fow the land with rye, efpecially where there are ftocks of fheep, which cannot be well fupported without green food early in the fpring. The farmer who has many fheep fhould confider, that turnips are always a very precarious crop; and therefore he fhould, befide fowing fome places with cole-feed, in order to have green fodder, fow rye in others, to guard againft accidents. If fome of the ground fowed late with turnips, which have failed, be fown in the autumn with rye, he will find it turn to good account. To have green fodder for cattle in April, which is the fcarceft time of all the year, fome fplit the ridges of their wheat-ftubble, and fow them with rye, allowing about a bufhel to an acre, which they harrow in, and feed about April, or when they want it; and in May they plough it up for a fallow.

The ingenious Mr. Camber of Eaft Newton, in Yorkfhire, has given us the following obfervations on this grain, which is greatly cultivated in his neighbourhood.

" Rye, fays he, is very excellent for giving a good fkin to horfes, as it is loofening, and carries off foul humours, which hard exercife and bad provender may have left in them. It is alfo a moft excellent feed for geefe. I cannot fay the fame with refpect to hogs, for which animal it feems to me to be too loofening; infomuch that I have given a great deal of it to them when put up to feed, both dry and boiled, without perceiving any advance in their flefh.

" Rye is very generally liked for bread by the people of countries in which it grows commonly, and who are therefore much ufed to it; infomuch, that many of them fcruple not to prefer it to wheat, the bread of which prefently grows dry. There are, however, numbers of perfons, who, though ufed to it from their youth, can never relifh it. Some object to the fournefs of it when made with leven, and others to the natural fweetnefs of the grain, which is difagreeable, efpecially with the favourinefs of flefh meat; and, indeed, I am myfelf of this number.

" I agree entirely with Mr. Miller, that it muft be very bad hufbandry to fow wheat and rye together, as the latter will ripen much ealier than the former, and feveral obvious inconveniences enfue. They who like meflin, may mix them to their mind when carried to the mill, without any inconvenience.

" Many incidents may hinder the fowing of rye in autumn; the ground fhould, by all means, be dry when it is fown, and heavy rains after it is fown may rot it in the ground before it come up: fo that the fowing of fpring-rye becomes an object well deferving our attention: and all the directions and cautions which can be given about it fhould be nicely attended to.

" As drynefs is effential to the fuccefs of rye, it feems adviseable to delay the fowing of fpring-rye as long as can be, with any profpect of fuccefs, rather than not have both the ground dry for fowing, and the fucceeding weather for fome time after fowing likely to be fair; efpecially as rye foon rots in the ground, if wet.

" The ground defigned to be fown with rye in fpring, fhould be laid in winter with high ridges, and have good drains to carry off the water, that it may be as dry as poffible when fown.

" Hot manures fhould be ufed, and particularly lime, which will bring on a fpeedy fhooting. It was long a prevailing opinion, that lime was not a proper manure for the foil in which the lime-ftone was found; but experience has fhewn the vanity of this notion.

" Rolling may be more neceffary to fettle the earth about the roots of plants of rye fown in fpring than in autumn; for the winter frofts will have broke down the clods on to the roots of the autumn-fown rye, though indeed the rains may have partly wafhed that earth away.

" A moderare fowing of foot, after the plants are come up and rolled, may be of great advantage." *Mufeum Rufticum, vol.* IV. *pag.* 225.

The fame ingenious gentleman has obliged the world with the following obfervations on a courfe of crops; by which it appears that rye-land is nearly, if not quite, as valuable as wheat-land.

" The lands of Nether Dunsforth, in the weft riding of this county, are, in general, a ftrong clay, and bear good wheat. The lands at Helperby, a few miles diftant, are, in general, a good black loam, which bear good rye, but, on repeated trials, prove too light for wheat, as the moft fenfible farmers there affirm. Be this as it will, the lands let at the fame prices in both places, viz. at ten fhillings per acre; and we fhall fee that it may be as well afforded, according to the courfe of their crops, &c. which I learned only yefterday from two fenfible farmers, one of them living at the former place, on an eftate of my father's, and the other at the latter, and defirous to fucceed his companion as tenant to my father.

" At

"At Dunsforth they have a wheat-crop, a crop of blendings, as they are called; that is, beans and peas, then a fallow, and fo round again.

"At Helperby they have a crop of rye, then a crop of barley, then a crop of peas, then another crop of barley, and fo round again; and they obferve that the peas fo mellow the ground, that their fourth crop is better than their fecond.

"To bring thefe crops to a fair comparifon, we muft fay, that the Dunsforth men have five crops of wheat, and five of blendings, in fifteen years; and that the Helperby men have three crops of rye, three crops of peas, and fix crops of barley, in the fame fpace.

"To eftimate the real value of thefe crops, without too much nicety, we may fuppofe that the wheat is, one year with another, worth one fhilling and fix-pence per bufhel more than the rye; and that there are twenty-five bufhels of wheat and thirty of rye on an acre. We will take the medium price of wheat to be four fhillings and fix-pence, and of rye three fhillings.

	l.	s.	d.
An acre's crop of wheat then would be ——	5	12	6
Ditto of rye —— ——	4	10	0
Difference —— —— —	1	2	6
But as the ftraw of rye is known to be much more valuable, and of greater quantity, and the expence of manure and feed to be lefs, we may fafely deduct —— ——	0	10	0
So that the real difference of profit, on one acre, will be —— —— —	0	12	6
The crops of blendings and of peas may be reafonably confidered as on a par.			
The difference of profit then betwixt three crops of wheat and blendings on one fide, and three crops of rye and peas on the other, will be	1	17	6

We are now, gentlemen, to confider the difference betwixt the two remaining crops of wheat and two additional crops of blendings on one fide, and the fix crops of barley on the other.

	l.	s.	d.
Suppofing the charge of both fides to be the fame, (and there will be no confiderable difference) the two crops of wheat will be worth —	11	5	0
A crop of blendings ufually falls betwixt fifteen and twenty bufhels to the acre, and the medium price is three fhillings per bufhel: the value of a crop then, at an average, will be feventeen bufhels and an half, at three fhillings; that is, two pounds twelve fhillings and fix-pence, and of two crops of an acre ——	5	5	0
A crop of barley is ufually thirty-two bufhels to the acre at the place in queftion; and the medium price per quarter is one pound: the value therefore of the corn of an acre of barley is four pounds, or of fix crops ——	24	0	0
But the ftraw of barley is fo valuable, that it may be reckoned to exceed the expence of reaping by at leaft five fhillings; that is, for fix crops ——	1	10	0
I did not enquire whether the men of Helperby fow clover with their fourth crop; but they certainly may, and reap one good crop in the fallow year, and turn in all their ftock for a fortnight or three weeks to feed it down, and have time enough to plough in the roots of the clover, and the manure made by the cattle which eat it, and get their fallow into order; fo that we cannot reckon lefs profit hence than one pound per acre; that is, for three crops	3	0	0
Nay, when one confiders, that rye is, of choice, fown late in this country, we may allow a fecond crop of clover and feeding, which cannot be worth lefs than fifteen fhillings per acre; that is, for three crops —— —	2	5	0

The whole account then will ftand as follows.

For the wheat-growers.

	l.	s.	d.
By balance of three crops of wheat againft ditto of rye, and two of blendings againft ditto of peas —— —— —	1	17	6
Brought over	1	17	6
By two crops of wheat —— ——	11	5	0
By ditto of blendings —— ——	5	5	0
Total ——	18	7	6
For the rye-growers:			
By the corn of fix crops of barley ——	24	0	0
By the ftraw —— —	1	10	0
By clover —— —— —	5	5	0
Total ——	30	15	0
Balance of the fifteen years, in favour of the latter	12	7	6

"That is, for one year on one acre, fixteen fhillings and fix-pence; that is a profit more than the rent of the ground, and half as much again above the profit of the wheat-grower.

"Some inexperienced people may think that I have thrown more advantage into the fcale of the rye-growers than I ought: yet, on the ftricteft review, I cannot think fo; but that, on the contrary, I have reckoned their advantages too low. I am fure I am not partial, for I own a wheat-crop my favourite one, (I having a natural diflike to rye-bread) though I own the rye-ground more advantageous to the farmer. Let us review my account.

"Am I thought to deduct too much, when I take off ten fhillings for the faving in feed, and gaining in ftraw, of rye? furely I ought not; for, as wheat is confiderably larger than rye, fewer grains fill the bufhel, confequently more fhould be allowed to an equal portion of land: and farmers who fow nine pecks of rye, fow twelve of wheat to the acre. Now the price of the former (according to the reafonable ftate above) is fix fhillings and nine-pence; of the latter, thirteen fhillings and fix-pence; confequently the faving, feven fhillings and three-pence. And whoever confiders the greater length and finenefs of rye-ftraw than that of wheat, muft think two fhillings and nine-pence per acre a very fmall allowance for it.

"Is it thought that more labour in ploughing attends the production of twelve crops than ten? Be it confidered, rye-land is lighter, and therefore much eafier ploughed, than wheat land; and that in the courfe of this wheat-hufbandry, the fallow is to be ftirred nearly as often as it would be to prepare it for the additional crops; and that, the oftener any ground is ftirred, the more eafily it is ftirred; and that the crops of peas and clover mellow the ground, and make it more eafily ftirred for the fowing down with hard corn; alfo, that it lies unftirred every fourth year, from the fowing down of barley to the eating off the clover, about fifteen months. From all which confiderations it feems moft evident, that the fame team and ploughman will, with more eafe, work the fame quantity of rye-land, to produce its twelve crops of corn, and the clover too, than they could wheat-land to produce the ten corn-crops.

"Am I imagined to reckon the expences of feed and manure for two crops of wheat and two of blendings too high, when I put them on a par with thofe of fix crops of barley? As this feems the moft exceptionable, I will ftate the matter fomewhat more particularly.

"The feed for wheat is three bufhels to an acre, which, at four fhillings and fix-pence, come to thirteen fhillings and fix-pence; for two crops, to one pound feven fhillings. The feed for blendings is four bufhels to an acre, which, at three fhillings the bufhel, come to twelve fhillings per acre; for the two crops, to one pound four fhillings. The feed for the four crops cofts then two pounds eleven fhillings.

"Four bufhels of barley fow an acre, and, at two fhillings and fix-pence per bufhel, come to ten fhillings per acre, or, for the fix crops, to three pounds. The difference then in the value of the feed in the two methods, is only nine fhillings. Now, let it be confidered, that the ground is prepared, as to manure, by the rye-crop for the former barley-crop, and by the crop of peas for the latter barley-crop; fo that nothing need be charged on this account: whereas, to prepare the ground for the two crops of wheat, the farmer muft be at great expence in manure, either in burning, or (which is generally much worfe) buying

buying of lime, and leading it, or at least in leading his own or bought dung; so that the nine shillings saved in the seed will go a very little way in this great expence. Besides, the clover so opens and mellows the ground, and the dung occasioned by eating of it, either at home or in the field, so enriches the soil, that much, if not all, the expence of manure for a crop of rye is saved; and this allows the farmer to lay his manure, otherwise needless, on to his barley-ground, and improves it for that crop, and the succeeding crops of clover and rye too; and on this account great deductions should be made from the expence of the three rye-crops compared with the three of wheat at the head of this account; so that I am clearly of opinion, that, instead of there being any balance therein in favour of the wheat-growers, it would fall considerably on the side of the rye-growers.

"In the last place, am I supposed to take the quantity of wheat on an acre too low? I answer, I take it from the course of the country where the comparison is made; and if greater crops are reaped elsewhere of wheat, so are there also of rye.

"I was lately assured, by a farmer on the estate adjoining to this, that he has frequently reaped fifty-five bushels of rye off an acre, and his father has reaped as much or more off the land in this estate. I am fully persuaded it will be found, on enquiry, that one sixth in quantity, as I state it, is too little in favour of rye. A stook of good rye usually yields five pecks, or more, while a good stook of wheat, whose stalks are thicker, and bed less close, and make much less bands, seldom yields so much as a bushel; so that, if there be an equal number of stooks, as large as can be made, of each sort, on an acre, there will be one fifth, or six bushels in thirty more of rye than wheat, cæt. par. as philosophers speak." *Museum Rusticum, vol. IV. pag.* 345.

RYE-GRASS. *See the article* RAY-GRASS.

S.

SAFFRON, a genus of plants with narrow grass-like leaves, which have a white line running along the middle: the stalk is short and undivided, and bears on the top a purplish blue flower, deeply cut into segments: in the middle of the flower arises, among the stamina, a whitish pistil, divided at the top into three chives or fleshy filaments, the lower part of which is slender and pale coloured, the upper broader, of a deep orange red, and very finely indented about the sides: these filaments, carefully picked, and pressed together into cakes, are the saffron of the shops. The plant is perennial, and flowers in autumn.

As saffron grows at present most plentifully in Cambridgeshire, and has grown formerly in several other counties of England, the method of culture does not, I believe, vary much in any of them; and therefore I judge it sufficient to set down here the observations which I employed proper persons, in different seasons to make, in the years 1723, 1724, 1725, and 1728, up and down all that large tract of ground that lies between Saffron-Walden and Cambridge, in a circle of about ten miles diameter.

In that county saffron has been cultivated; and therefore it may reasonably be expected, that the inhabitants thereof are more thoroughly acquainted with it than they are any where else.

I shall begin with the choice and preparation of the ground: the greatest part of the tract already mentioned is an open level country, with few inclosures; and the custom there is, as in most other places, to crop two years, and let the land be fallow the third. Saffron is always planted upon fallow ground, and, all other things being alike, they prefer that which has borne barley the year before.

The saffron grounds are seldom above three acres, or less than one; and, in choosing, the principal thing they have regard to is, that they be well exposed, the soil not poor, nor a very stiff clay, but temperate dry mould, such as commonly lies upon chalk, and is of an hazel-colour; though, if every thing else answers, the colour of the mould is pretty much neglected.

The ground being made choice of about Lady-day, or the beginning of April, it must be carefully plowed, the furrows being drawn much closer together, and deeper, if the soil will allow it, than it is done for any kind of corn; and, accordingly, the charge is better.

About five weeks after, during any time in the month of May, they lay between twenty and thirty loads of dung upon each acre; and, having spread it with great care, they plow it in as before; the shortest rotten dung is the best; and the farmers, who have the conveniency of making it, spare no pains to make it good, being sure of a proportionable price for it. About Midsummer they plow a third time, and, between every sixteen feet and a half or pole in breadth, they leave a broad furrow or trench, which serves both as a boundary to the several parcels, when there are several proprietors to one inclosure, and to throw the weeds in at the proper season.

To this head likewise belongs the fencing of the grounds, because most commonly, though not always, that is done before

before they plant. The fences confift of what they call dead hedges, or hurdles, to keep out not only cattle of all forts, but efpecially hares, which would otherwife feed on the faffron leaves during the winter.

About the weather we need only obferve, that the hotteft fummers are certainly the beft: and therewith, if there be gentle fhowers from time to time, they can hardly mifs of a plentiful crop, if the extreme cold, fnow, or rain of the foregoing winter have not prejudiced the heads.

The next general part of the culture of faffron, is planting or fetting the roots: the only inftrument ufed for which is a narrow fpade, commonly termed a fpit-fhovel.

The time of planting is commonly in July, a little fooner or later, according as the weather anfwers. The method is this: one man with his fpit-fhovel arifes between three and four inches of earth, and throws it before him about fix or more inches; two perfons, generally women, following with heads, place them in the fartheft edge of the trench he makes, at three inches diftance from each other, or thereabouts: as foon as the digger or fpitter has gone once the breadth of the ridge, he begins again at the other fide, and digging, as before, covers the roots laft fet, and makes the fame room for the fetters to place a new row, at the fame diftance from the firft as they are from one another: thus they go on, till a whole ridge, containing commonly one rod, is planted; and the only nicety in digging is, to leave fome part of the firft ftratum of earth untouched, to lie under the roots; and, in fetting, to place the roots directly upon their bottom.

What fort of roots are to be preferred, fhall be fhewn under the fourth head; but it muft be obferved in this place, that formerly, when roots were very dear, they did not plant them fo thick as they do now; and that they have always fome regard to the fize of the roots, placing the largeft at a greater diftance than the fmaller ones.

The quantity of roots, planted in an acre, is generally about fixteen quarters, or one hundred and twenty-eight bufhels, which, according to the diftances left between them, as before affigned, and fuppofing all to be an inch in diameter one with another, ought to amount to three hundred and ninety two thoufand and forty in number.

From the time that the roots are planted, till about the beginning of September, or fometimes later, there is no more labour about them; but as they then begin to fpire, and are ready to fhew themfelves above ground, which is known by digging a few out of the earth, the ground muft be carefully pared with a fharp hoe, and the weeds, &c. raked into the furrows, otherwife they would hinder the growth of the plants.

In fome time after appear the faffron flowers; and this leads us to the third branch of our prefent method. The flowers are gathered as well before as after they are full blown; and the moft proper time for this is early in the morning. The owners of the faffron get together a fufficient number of hands, who place themfelves in different parts of the field, pull off the whole flowers, and throw handful by handful into a bafket, and fo continue till all the flowers are gathered, which happens commonly about ten or eleven o'clock. Having then carried home all they have got, they immediately fpread them upon a large table, and fall to picking out the filamenta ftyli, or chives, and together with them a pretty long proportion of the ftylus itfelf, or ftring to which they are joined; the reft of the flower they throw away as ufelefs. The next morning they return into the field again, whether it be wet or dry, weather; and fo on daily, even on Sundays, till the whole crop be gathered.

The chives being all picked out of the flowers, the next labour about them is to dry them on the kiln. The kiln is built upon a thick plank, that it may be removed from place to place, fupported by four fhort legs: the outfide of eight pieces of wood about three inches thick, in form of a quadrangular frame, about twelve inches fquare at the bottom on the infide, and twenty-two inches at top; which is likewife equal to the perpendicular height of it. On the forefide is left a hole about eight inches fquare, and four inches above the plank, through which the fire is put in. Over all the reft laths are laid pretty thick, clofe to one another, and nailed to the frame already mentioned; and then are plaiftered over on both fides, as are alfo the planks at bottom very thick, to ferve for an hearth. Over the mouth or wideft part goes an hair-cloth, fixed to the fides of the kiln; and likewife to two rollers, or moveable pieces of wood, which are turned by wedges or fcrews, in order to ftretch the cloth. Inftead of the hair-cloth, many people now ufe a net-work, or iron wire, with which it is obferved that the faffron dries fooner, and with a lefs quantity of fuel: but the difficulty in preferving the faffron from burning, makes the hair-cloth be preferred by the niceft judges in drying.

The kiln is placed in a light part of the houfe; and they begin by laying five or fix fheets of white paper on the hair-cloth, upon which they fpread the wet faffron, between two and three inches thick; this they cover with other fheets of paper, and over thefe lay a coarfe blanket five or fix times doubled; or, inftead thereof, a canvas pillow filled with ftraw; and, after the fire has been lighted for fome time, the whole is covered with a board, having a large weight upon it.

At firft they give it a pretty ftrong heat, to make the chives fweat, as their expreffion is; and in this, if they do not ufe a great deal of care, they are in danger of fcorching, and fo of fpoiling all that is on the kiln.

When it has been thus dried about an hour, they take off the board, blanket, and upper papers, and take the faffron off from that which lies next it; raifing, at the fame time, the edges of the cake with a knife; then, laying on the paper again, they flide in another board between the hair-cloth and under papers, and turn both papers and faffron upfide down; afterwards covering them, as above.

This fame heat is continued for an hour longer; then they look on the cake again, free it from the papers, and turn it: then they cover it, and lay on the weight, as before. If nothing happens amifs during thefe firft two hours, they reckon the danger to be over: for they have nothing more to do, but to keep a gentle fire, and to turn their cakes every half-hour, till thoroughly dry: for the doing of which as it ought, there are required full twenty-four hours.

In drying the layer plump chives they ufe nothing more, but towards the latter end of the crop, when thefe come to be fmaller, they fprinkle the cake with a little fmall beer, to make it fweat as it ought; and they begin now to think, that ufing two linen cloths next the cake, inftead of two innermoft papers, may be of fome advantage in drying: but this practice is followed as yet but by few.

Their fire may be made of any kind of fuel; but that which fmokes the leaft is beft; and charcoal, for that reafon, is preferred to any other.

What quantity of faffron a firft crop will produce, is very uncertain; fometimes five or fix pounds of wet chives are got from one root; fometimes not above one or two; and fometimes not enough to make it worth while to gather and dry it. But this is always to be obferved, that about five pounds of wet faffron go to make one pound of dry, for the firft three weeks of the crop; and fix pounds during the laft week; and, now the heads are planted very thick, two pounds of dried faffron may, at a medium, be allowed to an acre for the firft crop, and twenty-four pounds for the two remaining; the third being confiderably larger than the fecond.

In order to obtain thefe, there is only a repetition to be made every year of the labour of hoeing, gathering, picking, and drying, in the fame manner as before fet down, without the addition of any thing new; except that they let cattle into the field, after the leaves are decayed, to feed upon the weeds; or, perhaps, mow them for the fame ufe.

About the Midfummer after the third crop is gathered, the roots muft be all taken up and tranfplanted: the management requifite for which is the fourth thing to be treated of. To take up the faffron heads, or break up the ground, as the term is, they fometimes plow it, fometimes ufe a forked kind of hoe, called a pattock, and then the ground is harrowed once or twice over; during all which time of plowing or digging, and harrowing, fifteen or more people will find work enough to follow and gather the heads, as they are turned up.

They

They are next to be carried to the houfe in facks, and there cleaned and raifed: this labour confifts in cleaning the roots thoroughly from earth, and from the remains of old roots, old involucra, and excrefcences; and thus they become fit to be planted in new ground immediately, or to be kept for fome time, without danger of fpoiling.

The quantity of roots taken up, in proportion to thofe which were planted, is uncertain; but, at a medium, it may be faid, that, allowing for all the accidents which happen to them in the ground, and in breaking up from each acre, may be had twenty-four quarters of clean roots, all fit to be planted.

The owners are fure to chufe for their own ufe the largeft, plumpeft, and fatteft roots; but do leaft of all approve the longeft-pointed ones, which they call fpickets, or fpickards; for very fmall round or flat roots are fometimes obferved to flower. This is the whole culture of faffron in the county abovementioned; and we have only now to confider the charges and profits which may be fuppofed, one year with another, to attend that branch of agriculture; and of thefe I have drawn up the following computation for one acre of ground, according to the price of labour in this county.

	l.	s.	d.
Rent for three years	3	00	0
Plowing for three years	0	18	0
Dunging	3	12	0
Hedging	1	16	0
Spitting and fetting the heads	1	12	0
Weeding or pairing the ground	1	04	0
Gathering and picking the flowers	6	10	0
Drying the flowers	1	06	0
Inftruments of labour for three years, with the kiln, about	0	10	0
Plowing the ground once, and harrowing twice	0	12	0
Gathering the faffron heads	1	00	0
Raifing the heads	1	12	0
Total charge	23	12	0

This calculation is made upon fuppofition, than an acre of ground yields twenty-fix pounds of net faffron in three years; which I ftated only as a mean quantity between the greateft and the leaft; and therefore the price of faffron muft be judged accordingly; which I think cannot be done better than by fixing it at thirty fhillings per pound; fince, in plentiful years, it is fold at twenty, and is fometimes worth three or four pounds: at this rate, twenty-fix pounds of faffron are worth thirty-nine pounds; and the net profits of an acre of ground, producing faffron, will, in three years, amount to fifteen pounds thirteen fhillings, or about five pounds four fhillings yearly.

This, I fay, may be reckoned the net profit of an acre of faffron, fuppofing that all the labour were to be hired for ready money: but, as the planter and family do a confiderable part of the work themfelves, fome of this expence is faved: that is, by planting faffron, he may not only reafonably expect clear about five pounds yearly per acre, but alfo to maintain himfelf and family for fome part of each year: and it is upon this fuppofition only, that the refult of other computations can be faid to have any tolerable degree of exactnefs; but the calculations themfelves are undoubtedly very inaccurate.

I have faid nothing here concerning the charge in buying, or profits in felling the faffron heads; becaufe, in many large tracts of ground, thefe muft at length balance one another, while the quantity of ground planted yearly continues the fame; which has been pretty much the cafe for feveral years paft. *Philofophical Tranfactions, Numb.* 405.

SAGE, the name of a well known plant, much cultivated in kitchen-gardens.

Sage is moft commonly propagated by flips; not only becaufe its feeds cannot always be obtained perfect in this country; but alfo, becaufe that is by much the eafieft and moft expeditious way. Thefe flips fhould be planted about the beginning of April, in a fhady border, where they will foon take root, if they are watered now and then in cafe the feafon be dry. When they are grown ftrong enough to be removed, they fhould be taken up with a ball of earth about their roots, and tranfplanted into the places where they are to remain. This fhould be in a dry foil, where they may enjoy the benefit of the fun: for if they are left to remain in moift ground, or in a fhady fituation, they will not well bear the inclemency of the winter: neither will they be fo hardy, or fo highly flavoured, if they are fet in a rich foil, as when they grow on a barren, dry, and rocky fpot. Keeping them clear from weeds is the principal part of their culture. The roots of all the common garden forts of fage will laft feveral years: but their tops fhould not be cropped too often for ufe, left the plants fhould become ragged, and there fhould not be a due fucceffion of young fhoots. The fureft way to obtain this, is to fet a parcel of new flips every other year. The fide fhoots, and tops of the balfamic or tea fage, which is generally dried and kept for ufe, fhould be gathered in a very dry day, in the fummer; but thofe of the other forts are beft when taken green from the plants.

The fpecies of fage moft ufually cultivated in the kitchen-garden, are, the large broad leaved fort, of which the common green, the wormwood, the variegated green, the red, and the variegated red, are only accidental variations; the tea fage abovementioned, which alfo has broad leaves, but more jagged at their edges; and the fmall, or rather narrow, hoary leaved fage, commonly called fage of virtue. All the other forts of this plant are cultivated for variety, more than for ufe.

Sage in general flowers about the latter end of June, and beginning of July; and whenever its feeds ripen in this country, which is but feldom, it is in autumn.

SAINTFOIN, *or* SAINFOIN, the name given by the French, and continued by us to a fpecies of plant, frequently ufed for the food of cattle, either frefh or dried; it is called holy-hay, or wholefome hay, from its excellent nutritive quality. The ftalks of the plant are commonly about two feet long, but they grow fometimes to five or fix feet, and it has tufts of red flowers of three, four, or five inches in length.

This plant will make a forty times greater increafe in poor ground than the common turf; and this is owing to its having a long perpendicular root, of that kind, called tap roots, which finks to a great depth to attract its nourifhment. The length of this root is fcarce to be credited by any but thofe who have feen it; it is frequently drawn out of the ground to the length of twelve or fourteen feet, but it is faid to be often thirty feet or more in length.

The farmers have a general opinion, that this plant never fucceeds well in any land, where there is not an under ftratum of ftone, or chalk, or fome other hard matter, to ftop its running; but that otherwife it fpends itfelf in root, and comes to nothing above ground. This is an error too grofs to need much refutation. It is certain, that the roots being to plants what the ftomach and guts are to animals, the more and larger roots any plant has, the more nourifhment it receives, and the better it thrives.

Saintfoin always fucceeds where its roots run deep, and the beft crops of all are produced upon lands where there is no hard under foil to obftruct their paffage. An under foil of clay may kill the plants, by retaining the water, and chilling and rotting their roots.

The long root of faintfoin has, near the furface, many horizontal roots iffuing from it, which extend themfelves every way; there are of the fame kind all the way down, as the roots go, but they grow fhorter and fhorter all the way. Any dry land may be made to produce this valuable and ufeful plant, though it be ever fo poor, but the richeft and beft land will produce the beft crops of it. The beft way of fowing it is by drilling, but the earth muft be very well prepared, and the feed well ordered, or elfe very little of it will grow. The heads of thefe feeds are fo large, and their necks fo weak, that, if they be much more than half an inch deep, they are not able to rife through the incumbent mould; and, if they are not covered, they will be malted, as the farmers exprefs it; that is, it will fend out its root while it lies above-ground, and be killed by the air; and whether the farmer plants bad feed that will not grow, or good feed that is buried or malted, the event will be the fame. The ground will be under-

underftocked with plants. A bufhel of feed to an acre of land is full twenty feeds to each fquare foot of land; but, as there is fome difference in the largenefs of the feeds, there is no abfolute certainty as to this calculation. The worft feafons for planting it are the beginning of winter, and the drought of fummer; the beft is the beginning of the fpring; and it is always ftrongeft when planted alone, and is not fown together with corn, as is the practice of fome farmers. If barley, oats, or any other corn, fown with the faintfoin, happen to be lodged afterwards, it kills the young faintfoin. If it be planted with any other corn, it is beft done by drilling in the horfe-hoeing way; in this cafe it is not much liable to be killed by the lodging of the corn, as the drilled corn feldom falls at all, and, when it does, never falls fo low as the fown corn.

The quantity of feed to be drilled upon an acre of land will depend wholly upon the goodnefs of it; for there is fome feed of which not one in ten will ftrike, whereas in good feed not one in twenty will fail. The method of knowing the goodnefs, is, by fowing a certain number of the feeds, and feeing how many plants are produced by them. The external figns of the feeds being good are, that the hufk is of a bright colour, and the kernel plump, of a light grey or blue colour, and fometimes of a fhining black. The feed may be good, though the hufk be black, as that is owing fometimes to the letting it receive the wet in the field, not to its being half rotted in the heap.

If the kernel be cut a-crofs, and appear greenifh and frefh, it is a certain fign that it is good. If it be of a yellowifh colour, and friable, and look thin and pitted, they are bad figns. The quantity of feeds allowed to the acre in the drill way is much lefs than that by fowing, and is to be computed according to the number of plants that are to be allowed in that fpace, allowing for the common cafualties. It is not neceffary to be exact in this calculation, or to fay whether two, three, or four hundred plants are to be allowed to a fquare perch; neither is it poffible to know beforehand the precife number of plants that may live out of thofe that come up; for fometimes the grub takes them when they have only the two firft leaves, and the crop is greatly diminifhed by this means. Four gallons of good feed to an acre of land will cover it with plants, when judicioufly managed.

Single plants of faintfoin make the greateft crops; but the farmers, in general, plant them fo clofe, that they ftarve one another. The fingle plants always run the deepeft, and thofe which do fo will always draw moft nourifhment. The plants which ftand crowded ftarve one another, and often die after a few years; but the fingle ones grow to a vaft bignefs, and are every year better and better.

The beft way to calculate how many plants are to be allowed to a perch, is to compute how much hay each fingle large plant will produce; for, if kept fingle, and well cultivated, they will all be large ones. Without culture, thefe plants never arrive at a fourth part of the fize that they do with it. The hay of a large fingle cultivated plant will weigh more than half a pound, a hundred and twelve plants upon a fquare perch, weighing but a quarter of a pound a piece, one with another, amount to two tons to an acre. If faintfoin be planted on fome forts of land early in the fpring and hoed, it will fometimes produce a crop the following fummer; in a garden the feeds fown in February will yield plants of two feet high that will flower in the month of June following; and, though March be frofty, the young plants feldom fuffer by it. This fhews, that this plant is naturally a quick grower; but the farmers ufually plant it on poor or cold land, and give it too little culture, which make it backward, and flow of growth with them. The poor land, ufually allotted to this plant, alfo makes it generally yield but one crop a year, but on a rich land it will yield two very good crops annually, with a moderate fhare of culture and management.

The farmer who expects to make a profit of this plant muft not expect a good crop the firft year. Nothing is fo injurious to faintfoin as its ftanding too thick; if it be fown fo thick as to cover the ground the firft fummer, the plants will ftarve one another for ever after; but, if the owner will be content to place them fo thinly as to have but a fmall crop the firft year, they will increafe prodigioufly, and every fucceeding crop will be better and better. When faintfoin is well hoed, it will grow as much in a fortnight as it would otherwife do in fix weeks; and this quick growing is of advantage to it every way, not only making the plants large, but of better nourifhment to the cattle, whether they are eaten green or made into hay.

The proper diftance to drill this plant for the horfe-hoeing hufbandry is at double rows with eight inch partitions between them, and thirty inch intervals between every two and two. Thefe intervals need only be hoed alternately, leaving every other interval for making the hay on. This method of hoeing is of vaft advantage, and poor land by means of it will always produce two crops a year. The land is always to be perfectly cleared of grafs before the fowing the faintfoin, and the lumps of earth carefully broken. But no harrowing is to be allowed after it is drilled, for that would bury it; and; and it is not proper to roll it at all, unlefs for the fake of barley, when they are fown together; and when that is done, it fhould be with a light roller, and in dry weather. This fhould be done lengthwife of the rows, and as foon as it is drilled; if it be not done at this time, it is beft to ftay three weeks before it is done, that the necks of the young faintfoin may not be broken.

No cattle are to be fuffered to come in the firft winter upon the faintfoin, after the corn is out, among which it was fown. Their feet would injure it by treading the ground hard, as much as their mouths by cropping it, and it would never come to good. Sheep fhould not be fuffered to come at it, even the following fummer and winter. One acre of drilled faintfoin, confidering the difference of the quantity and goodnefs of the crop, is worth two acres of fown faintfoin on the fame land, though the expence of drilling be twenty times lefs than that of fowing. The firft winter is the time to lay on manure after the corn is reaped off. Pot-afhes, or the like, are very proper, and a fmall quantity of them will do, as there are at this time no other plants to partake of the benefit, but the young crop has it all; and the young plants, being thus made ftrong at firft, will continue fo, and be long the better for it.

It is obferved, however, that in the drilling and horfe-hoeing-way there is no neceffity for any manure at all. Some farmers fow eight or ten bufhels of the feed of faintfoin to an acre along with their corn, with intent that it fhould kill all the other weeds; but the confequence is, that the plants ftand clofe, and ftarve one another, and are no bigger than where the plant grows wild on the hills in Calabria, where it is fo fmall and feemingly defpicable a plant, that it feems a wonder that any body fhould be tempted to think of cultivating it: yet, when rightly managed, it feems capable of being as ufeful a plant as any in the world. Where thefe plants ftand fo thick, they draw out all the nourifhment from the ground, in a few years, and fo die, though manured ever fo carefully. Six or feven years feems their greateft duration; whereas, when the feed is drilled in, and the plants are horfe-hoed, they will be as ftrong and vigorous as ever, at thirty years ftanding.

Some people who have turned their thoughts to hufbandry, have been of opinion, that the cytifus would fucceed better with us than the faintfoin; it is probable enough that it would grow well; but the labour of fheering it would, with us, where the pay of fervants is fo dear, run away with the greateft part of the profits of the crop.

Lucerne is another thing which many have thought of introducing among us in the place of faintfoin, but it requires fo much care to fuit it with a proper foil, that, whatever are the profits of it, it never can be fo general as faintfoin. *Tull's Horfe-hoeing Hufbandry.*

Saintfoin, fays Mr. Duhamel, deferves the farmer's utmoft attention, as one of the moft profitable plants he can cultivate. It will do on almoft any land; and though it fucceeds beft in good foils, yet it will grow even on dry barren fpots, where fcarce any other grafs can live; provided its roots be not chilled by a cold clay, or other fubftance which retains water: and it has this farther advantage, that it may be mowed at different degrees of ripenefs, with nearly the fame profit.

1. It may be mowed before it is in bloom, for it is then admirable food for horned cattle; and when cut thus early,

early, it yields a ſecond crop, which makes ample amends for what was loſt by not letting the firſt come to its full growth. This early cutting is likewiſe attended with another benefit, which is, that it purges cattle, in the beginning of the ſummer, and thereby frees them from diſorders occaſioned by the winter's cold, or dry food.

2. If the weather be rainy, the ſaintfoin may be left ſtanding till it is in bloom; when it ſtill is excellent fodder for cows. But care muſt be taken in making it into hay, that the flowers do not drop off, as they are very apt to do: for cattle are ſo fond of theſe flowers, that they often induce them to eat the reſt of the plant.

3. If the rain continues, the ſaintfoin may be left ſtanding till ſome of its ſeeds are formed, and the crop will then be the more plentiful; not only becauſe it will have attained its full growth, but likewiſe becauſe its leaves, being more ſubſtantial, diminiſh leſs in drying. It is not indeed, then, quite ſo ſweet as before; but horſes eat it readily, becauſe they love to feel between their teeth the ſeeds, which now begin to be formed.

Mr. Tull ſays this fodder is ſo excellent, that horſes need no oats when they are fed with it. He affirms that he kept a team of horſes with it a whole year in good plight, without giving them any oats, though they were worked hard all the time. He adds, that he fattened ſheep with it, in leſs time than others which were fed with corn. But the hay of this plant can never be ſo good as when it is cultivated with the horſe-hoe: for in the common huſbandry, it bloſſoms almoſt as ſoon as it is out of the ground.

4. If the ſeaſon continues rainy, it may be more adviſeable to let the ſaintfoin remain ſtanding, than to run the hazard of having it rot upon the ground: for then the ſeed will ripen, and nearly make up for the loſs of the fodder; not only becauſe it will fetch a good price, but alſo becauſe two buſhels of it will go as far in feeding of horſes, as three buſhels of oats; and cattle in general, as well as poultry, are extremely fond of it.

The firſt of theſe ſorts of ſaintfoin hay, cut before the bloom, is Mr. Tull's virgin hay, which, he ſays, is the beſt beyond compariſon, and has not its equal, in the world, except lucerne. He gives the next place to the ſecond ſort, cut whilſt in bloom, and ſays that an acre of land, well cultivated, may yield three tons of this bloſſomed hay: and he eſteems the third ſort, which he calls the full grown, many degrees inferior to either of the former; though it yields a greater crop, becauſe it has grown to its full bulk, and ſhrinks but little in drying.

Even the ſaintfoil that has yielded its ſeed, may be cut down and dried; and when other fodder is ſcarce, this will be better food for horſes and large cattle, than the coarſe hay of flowed meadows, or any kind of ſtraw.

The manner of making ſaintfoin hay is thus directed by Mr. Duhamel.

In a day or two after the ſaintfoin has been mowed, it will be dry on the upper ſide, if the weather be good. The ſwarths, or mowed rows, ſhould then be turned, not ſingly, but two and two together: for by thus turning them in pairs, double the ſpace of ground is left betwixt pair and pair, and this needs but once raking, whereas, if the ſwarths were turned ſingly, that is, all the ſame way, the ground would require as much raking again.

As ſoon as both ſides of the ſwarths are a little dry, they ſhould be made up into ſmall cocks, the ſame day they are turned, if poſſible: for when the ſaintfoin is in cock, a leſs part of it will be expoſed to the injuries of the night, than when it lies ſcattered upon the field. The ſun and dew would exhauſt almoſt all its juices, in this laſt caſe, in leſs than a week's time.

Theſe little cocks of ſaintfoin may be ſafely made into larger ones, without waiting for their being ſo thoroughly dry as thoſe of common hay ought to be before they are laid together: becauſe common hay, by ſinking down cloſer, excludes the air neceſſary for keeping it ſweet; ſo that if the weather prevents its being frequently ſtirred and opened, it will heat, turn yellow, and be ſpoiled; whereas ſaintfoin, by admitting the air more freely, becauſe its ſtalks are leſs flexible, will remain much longer without any danger of fermenting.

Saintfoin hay is never better than when it has been dried by the wind only, without the aſſiſtance of the ſun. A little rain, or a miſt, which will turn common hay, clover, and even lucerne, black; will do no hurt to ſaintfoin, which is not really ſpoiled, till it rots upon the field.

If the weather threatens rain, and the ſaintfoin is not yet dry, it may be laid in cocks, without fear of its heating, provided a large baſket, or buſhy faggot, be ſet up in the middle of each cock, where it will ſerve for a vent-hole, through which the ſuperfluous moiſture of the hay will tranſpire.

As ſoon as all danger of its heating is over, theſe cocks ſhould be made into ricks, and thatched. That which is laid up quite dry, will come out of the rick of a green colour: that which has heated much in the rick, will look brown.

It requires ſome experience to know at what degree of ripeneſs it is beſt to cut the ſeeded ſaintfoin; becauſe all its ſeeds do not ripen at the ſame time. Some ears bloſſom before others; every ear begins bloſſoming at its lower part, and continues to blow gradually upward, for many days; ſo that before the flower is gone off at the top, the ſeeds are almoſt filled at the bottom. By this means, if the cutting be deferred till the top ſeeds are quite ripe, the lower, which are the beſt, would ſhed, and be loſt. The beſt time, therefore, to cut it, is when the greateſt part of the ſeed is well filled, the firſt blown ripe, and the laſt blown beginning to be full. The unripe ſeeds will ripen after cutting, and be, in all reſpects, as good as thoſe that were ripe before. Some, for want of obſerving this, have ſuffered their ſaintfoin ſeed to ſtand till all of it has ſhed, and been loſt in cutting.

Saintfoin ſhould never be cut in the heat of the day, while the ſun ſhines out; for then much, even of the unripe ſeed, will ſhed in mowing. The right time for this work, is the morning or the evening, when the dew has rendered the plants ſupple.

If the weather is fine and clear, the ſaintfoin will ſoon dry ſufficiently in the ſwarths, without turning them: but if any rain has fallen, and there is a neceſſity for turning them, it ſhould be done very gently, while they are moiſt, and not two ſwarths together, as in the other hay made of ſaintfoin before it has ſeeded. If the ſwarths are turned with the handle of the rake, it is beſt to raiſe up the earſides firſt, and let the ſtub-ſide reſt on the ground in turning: but if it is done with the teeth of the rake, let the ſtub-ſide be lifted up, and the ears reſted on the earth.

If ſaintfoin be cocked at all, the ſooner it is done, the better; becauſe, if the ſwarths are dry, much of the ſeed will be loſt in ſeparating them; the ears being entangled together. When moiſt, the ſeed ſticks faſt in the ear; but when dry, it drops out with the leaſt touch or ſhaking.

There are two ways of threſhing it: the one in the field, the other in the barn. The firſt cannot be done but in very fine weather, and while the ſun ſhines in the middle of the day. The beſt manner of performing this, is to have a large ſheet pegged down to the ground, for two men to threſh on with their flails, while two others bring them freſh ſupplies in a ſmaller ſheet, and two more clear away the hay that has been threſhed. The ſeed is emptied out of the larger ſheet, and riddled through a large ſieve, to ſeparate it from the chaff and broken ſtalks; after which it is put into ſacks, and carried into the barn to be winnowed. Care ſhould be taken not to let the hay get wet, becauſe it would then be ſpoiled.

A very important, and at the ſame time very difficult article, is the keeping of the ſeed that has been threſhed in the field, without having ever been wetted. If it be winnowed immediately, and only a little of it laid amidſt a great heap, or put into a ſack, it will ferment to ſuch a degree, in a few days, that the greateſt part of it will loſe its vegetative quality. During that fermentation, it will be very hot, and ſmell ſour. Spreading it upon a barn floor, though but ſeven or eight inches thick, will anſwer no end, unleſs it be frequently and regularly turned both day and night, until the heating it over: but even this will not make its colour keep ſo bright as that which is well houſed, well dried, and threſhed in the winter. This laſt,

laſt, laid up unthreſhed, will keep without any danger of ſpoiling, becauſe it does not lie cloſe enough to heat. The beſt way to preſerve the ſeed threſhed in the field, is, to lay a layer of ſtraw upon a barn floor, and upon that a thin layer of ſeed, then another layer of ſtraw, and another layer of ſeed, and ſo on alternately. By this means the ſeed mixing with the ſtraw, will be kept cool, and come out in the ſpring with as green a colour as when it was put in.

The following method is followed in cultivating ſaintfoin in the Iſle of Thanet.

Though the lands in general here are very rich and fruitful, owing to the good tillage, and the quantity of manure they enjoy, yet at ſome diſtance from the ſea they have land which is very barren and thin by nature; nevertheleſs, even this indifferent land they farm to the greateſt advantage. In theſe ſoils the farmers ſow ſaintfoin or French graſs with great ſucceſs, having ſometimes two loads of hay on an acre.

This graſs thrives beſt in theſe parts, on a thin coat of earth with a chalky bottom; it puſhes its long tap-root deep into the chalk, and extracts thence a nouriſhment, which is out of the reach of almoſt any other plant.

The land muſt always be exceedingly well prepared, before they attempt to put the ſeed in the ground; it has frequent plowings, and every the leaſt appearance of a weed or root of graſs is diligently picked off: graſs in particular is a very great enemy to this plant; without the utmoſt care it ſoon choaks and deſtroys it. They ſow this ſeed in April, either at the beginning, middle, or latter end of the month, according to the ſeaſon: dry weather is beſt, provided it does not long continue: however, a little rain in theſe light ſoils does no great hurt. The quantity of ſeed they allow to an acre is five buſhels; of courſe it is ſown very thick. It does not lie any great length of time in the ground: when it is come up, they carefully hoe and weed it, to keep down the roguery and graſs: this puts the plants forward, and makes them ſo vigorous and ſtrong, that they will of themſelves keep down the graſs, eſpecially in theſe chalky bottoms, where graſs does not thrive well, and is not apt to coat land with turf.

Saintfoin uſed formerly to hold good in theſe parts for twenty years together, but it does not now of late years laſt ſo long: this is probably owing to their want of care in chuſing their ſeed, which ſurprizes me, conſidering what good farmers they in general are. They get, it is true, when they can, the beſt ſeed the iſland affords: but it would certainly be a much better way were they now and then to procure ſome of a finer growth from France: for it was from that country, as far as I can underſtand, it firſt came hither, about the latter end of Charles the Second's reign; and I do not hear from the inhabitants that they ever remember the importing any more ſince.

The climate of France is more natural to it; of courſe the ſeed comes to greater perfection there, whilſt, on the contrary, in England, that, as well as many other crops, is apt to degenerate after a certain number of years.

Where this crop takes, it is very advantageous to the farmer; it yields him for many years plenty of excellent fodder, and that upon land which would otherwiſe, perhaps, ſcarcely yield him any profit at all; and beſides all this, when the ſaintfoin begins to fail, if proper care is taken, the land when broke up will be found greatly refreſhed, and in a better condition to bear tillage and a ſucceſſion of other crops.

The farmers here, when they intend breaking up a ſaintfoin lay, feed it the laſt three or four years: mowing it at this time, they think, hurts and exhauſts the land too much; and beſides, the dung and urine of the cattle are of great ſervice.

They obſerve here, as well as in other places where ſaintfoin is cultivated, that after land has been once ſown with it, it will not for ſome years, to any advantage, bear ſaintfoin again. *Muſeum Ruſticum, vol.* I. *pag.* 109.

The reader is obliged to Mr. Holdway, an old experienced farmer at Marlborough in Wiltſhire, for the following account of cultivating ſaintfoin in that county.

"About one hundred years ago, ſays he, the culture of ſaintfoin was firſt introduced into Wiltſhire, and was ſoon preferred to clover graſs; and there was indeed ſome reaſon for this preference, for it thrives much better, and yields a much larger encreaſe, on poor hungry ſoils, than clover can do.

"Another very good reaſon may be aſſigned why ſaintfoin was ſo well received. The ſowing it at all was conſidered as a new huſbandry, and the timorous farmers were very unwilling to hazard the trial of any new method on lands which would any other way yield them any conſiderable advantage: it was chiefly in corners of fields, of very little uſe to the farmer, that this paſture was firſt tried, and that on poor land, as, ſhould it not have ſucceeded, the only loſs would have been the ſeed; yet many occupiers of land would not, at firſt, hazard even this trifling loſs.

"But the ſentiments of theſe farmers were ſoon altered in this matter: clover wears out in a few years, whereas many, who ſowed ſaintfoin on poor land not worth above ſix ſhillings an acre, found their land ſo much improved, as to be very ſpeedily worth thirty ſhillings the acre, and at the end of twenty years it continued yet in good proof.

"In fact, it will thrive, and be a very conſiderable improvement, on the pooreſt, and ſeemingly the barreneſt land; but it muſt be remembered, that ſheer and ſlight ſands, and all clays, and other cold and wet ſoils, are to be excepted: on rich land the weeds ſoon deſtroy it. Beſides, as it ſends its roots very deep in ſearch of nouriſhment, the longer it occupies the land, the more good it does it; whereas this is far from being the caſe with ſhallow-rooting plants.

"A ſaintfoin lay may at any time be broke up, when it will be ſure to yield ſeveral good crops of corn, and may afterwards again with good ſucceſs be ſown with ſaintfoin; and one principal reaſon why it thrives ſo well on poor lands muſt be the length of the roots, by which it is enabled to reſiſt the parching heat of the ſun better than moſt other graſſes are.

"One thing I muſt notify, which is, that I am by long experience convinced that the land cannot be made too fine for ſaintfoin; it thrives the better for it, and is the more certain to take.

"I have often, with very good ſucceſs, ſown it with oats and barley in the manner clover is ſown, the proportion much about equal to the grain it is ſown with; for as the ſeed of ſaintfoin is much larger and lighter than clover ſeed, of courſe a larger quantity ſhould be ſown: it is much beſt for the plants to come up thick; the ground is thereby ſooner ſtocked, and the weeds are eaſier kept under.

"Some in this county have ſown it in rows with intervals, to afford a better opportunity of deſtroying the weeds; and I have heard that on tolerable rich land, apt to produce weeds, it has done very well in this way; but as I never experienced it, I ſhall not enlarge on that head.

"It is beſt not to feed it the firſt year; but whether it is ſown by itſelf, or with any other crop, it may be mowed the firſt year.

"It is much beſt, if a good crop is deſired, and it is to continue any time to the land, to ſow it in autumn by itſelf, the earlier the better: the proper ſeaſon is from the beginning of Auguſt to the end of September; but if you mix it with other grain, let it be ſown from the beginning of February to the end of March; the earlier in either ſeaſon, the better.

"I have, I think, before obſerved that the land cannot be made too fine for this plant; and it ſhould be well harrowed before ſowing, and again harrowed afterwards to cover the ſeed.

"I muſt once more repeat, that it muſt not be fed the firſt year; for the ſweetneſs of the graſs will cauſe the cattle to bite it too near the ground, which will greatly injure your crop: in fact, it is our practice not to let great cattle feed it till the third year, particularly in grounds that are inclinable to moiſture; for the roots are tender, and much treading is very injurious to it.

"When the ground is well covered, ſuppoſe in the third year after ſowing, if you intend to mow your ſaintfoin, it is beſt to lay it up by the middle of April at fartheſt; but it is better done three or four weeks ſooner. The time for cutting it is when it begins to flower, as it is then fulleſt of ſap: this will ſometimes be about the middle of May, but often later, according as the ſpring is cold or warm.

"In feeding it ſome neceſſary rules are to be obſerved. In the ſpring turn in your great cattle, and you may be pretty certain the buds will not be cropped too near. Oxen thrive well on it, without the danger, at their firſt grazing, that is to be apprehended from clover, &c. yet even this danger chiefly ariſes from the negligence or ignorance of the hinds.

"In the autumn, and part of the winter, you may feed your ſheep on it, which, if in health, will thereby be very ſuddenly fattened.

"Saintfoin hay is excellent food for horſes, and they are uncommonly fond of it.

"If you turn your cows in ſpring in your ſaintfoin lay, you will find it will breed in them abundance of milk; and all my acquaintance know that the butter made of it is excellent.

"When it is intended to ſave the ſeed of ſaintfoin, it is beſt to roll it in the ſpring, that the ſtones may be preſſed down, and the ſcythe go cloſe to the ground; or elſe the beſt ſeeds, which grow on the lowermoſt joints, will be loſt.

"When land is inclined to moiſture, ſaintfoin may thrive very well on it till a wet winter comes; but it is then a great chance if it is not deſtroyed.

"In this county it has long been the opinion of the ableſt farmers, that it is beſt not to dung our ſaintfoin; for the dung ſerves only to encourage weeds, and ſeldom reaches deep enough to give any ſupply of nouriſhment to the roots of the ſaintfoin.

"I have, if I miſtake not, before obſerved that the treading of great cattle, particularly in winter, is hurtful to this graſs: I would therefore by no means adviſe the farmer to fodder his cattle on it, as the field will thereby be poached full of holes, in which the wet lodging, it is a chance but the roots of the ſaintfoin are rotted by it.

"I have often fed my ſheep in winter with ſaintfoin hay; but whenever I intended this, I always cut my ſaintfoin ſome little time before it flowered: it is very eaſy to obſerve when the flower cup is forming: the ſheep will eat it very clean, and thrive well on it, provided it is not old and ſticky.

"When I ſay that ſheep in autumn will fatten very ſuddenly on ſaintfoin graſs, it muſt be obſerved, that I did not mean the aftermath of ſuch as had been mowed that ſeaſon; but the ſecond growth, when the field had been for ſome time ſhut up after the great cattle had fed it in the ſpring. The aftermath is, it is true, good for ſheep; but, I think, not quite ſo good as the aftermath of natural graſs; at leaſt, this I am certain of, that turn ſome ſheep into a field where there is a mixture of natural graſs and ſaintfoin, both of which have been mowed, they will to chuſe eat up the firſt, before they touch the other with any degree of appetite.

"Saintfoin ſhoots very early in the ſpring, and to nip it in the bud is very injurious; I would therefore adviſe that the ſheep be taken out about Chriſtmas, ſoon after which time it often begins to grow.

"Some of our Wiltſhire farmers have had a cuſtom of ſowing their ſaintfoin ſeed under furrow; but I do not much approve of this practice, though they ſay in light land it cannot be buried." *Muſeum Ruſticum, vol.* I. *pag.* 463.

The following method of cultivating ſaintfoin in Switzerland, was written by an experienced huſbandman of that country.

"You have bought, you ſay, a little eſtate, at no great diſtance from the metropolis, and have thought of improving ſome of the lands by ſowing ſaintfoin: you requeſt me to let you know what are the methods in practice in this country relative to that graſs, as, when you left Switzerland to go to our uncle in London, you were too young to gain the neceſſary knowledge in farming. I ſhall oblige you with pleaſure, and the rather as I have had very good ſucceſs myſelf in this particular article.

"The roots of ſaintfoin, ſays he, penetrate very deep into the earth, by which means they do not exhauſt the ſurface ſo much as one would imagine, the vigour of the plant conſidered: the roots are perennial, and conſiſt of a white woody ſubſtance within, covered by a black outward coat or bark: from the crown of the root proceed ſeveral leaves, and ſome branches about two feet long, which incline on all ſides. Our fodder is furniſhed from theſe branches and leaves. Saintfoin is a very vigorous plant, and yields a moſt excellent fodder.

"It is not nice with reſpect to ſoil, but grows in almoſt any, if we except ſuch as are clayey, very damp, and low, or ſtoney: the crop is in proportion to the goodneſs of the land; but the ſaintfoin that grows on poor land, though leſs in quantity, is moſt nouriſhing and heartening for cattle: the virtues of it ſeem concentrated, and the cattle thrive much better on it than on ſuch as grows in greater quantities on rich mellow land.

"When we have it in our power to chuſe our ſituation and ſoil for ſaintfoin, we ought to prefer a light land, gently ſloping on the ſouth ſide of an eminence: here it proſpers to admiration.

"This plant does not thrive in the ſhade; for this reaſon we ſhould avoid having any trees in the fields that bear ſaintfoin: and it is ſubject to be ſometimes chilled, by having ſnow lie too long on it in winter; it ſhould not therefore be ſown on flat level land.

"To have a good crop, the land ſhould be properly prepared, by having two or three good plowings between harveſt and barley ſeed-time: the ſtones muſt be very carefully picked off the field; and it muſt be cleaned from all kinds of weeds, and other ſuch traſh.

"If it is likely that there will be a wet ſeaſon, the ſpring is the beſt time for ſowing ſaintfoin, as it will be much forwarder than that ſown in autumn: but if the ſpring is too dry, the ſowing will be beſt deferred till about Auguſt, as by that means the plants will have time to acquire ſtrength in their roots, and make vigorous ſhoots in the ſpring.

"The farmer may take it for granted, that if the ſoil will admit of it, he cannot well plow his land too deep, or make it too fine: he will reap all the benefit of it in his ſucceeding crops.

"In Switzerland we ſow it three times as thick as we do wheat; or, which amounts to the ſame thing, we uſe the ſame weight of ſeed, the ſaintfoin ſeed being ſo much ſmaller as to make that difference.

"Good ſeed ſhould be heavy, plump, bright, and of a yellowiſh red colour: if, on opening the pods, you find the ſeeds black and ſhrivelled, reject it as of no value; for it has been heated in the heap, and will not grow: if it appears white and ſhrivelled, the plant was cut before the ſeed was ripe; from this you are to expect only ſtarved, meagre, ſhort-lived plants: you muſt therefore by no means ſow it. The pods encloſing good ſeed ſhould be plump, large, and armed on one ſide with ſmall prickles: and they ſhould alſo be of a deep brown colour: but it is beſt not to depend on the appearance of the pods, but open them, and examine the ſeed.

"The weather ſhould be mild at the time of ſowing the ſeed of ſaintfoin; and it ſhould be harrowed in, and not covered with above two inches of earth at moſt: ſome ſow it in the ſpring with oats; but this I by no means approve of: it is much better ſown alone, eſpecially if you would have a ſtrong vigorous plant, that ſhall laſt for years.

"In our very poor lands in Switzerland we ſometimes purſue the following method.

"Immediately after harveſt we give the land intended for ſaintfoin a good deep plowing, laying it in high ridges; in this manner it is left to be mellowed by the froſt and ſnow: we take advantage of the firſt hard froſt to carry on our dung, and manure it well.

"When the froſt breaks in the ſpring, we ſpread the dung and turn it in with the plow: we afterwards beſtow at leaſt two more plowings on the land, not only to keep down the weeds, but to make the land as fine as poſſible: in autumn we ſow wheat, and have reaſon to expect a tolerable good crop.

"When the wheat is got in, the land is again plowed, and left to meliorate and pulverize by the winter froſts: early in the ſpring it is plowed and laid level, the ſtones are

are all picked off, and the weeds cleared away: if rain is expected, it is now sown pretty thick with the saintfoin, otherwise the sowing is deferred till autumn. When poor land is managed in this manner, it will yield tolerable good crops of saintfoin for several years: it should not, however, be fed the first year, as the treading of the cattle will destroy the crown of the plant, and prevent its shooting the succeeding year: and sheep should never be turned in to feed on it, as they will crop it so close as to prevent its budding.

"Saintfoin comes up about a fortnight after sowing it, and if the weather is moist, something sooner. When the plants are come up, they should be set out at a proper distance with a hoe, that they may have room to spread. The young plants are very apt to be choaked by weeds; they must on that account be kept very clear of weeds, till, by their branches, stalks, and leaves, they cover the land; after which there will be no danger of the weeds getting a-head.

"As saintfoin seed is often faulty, it will not be amiss to make a trial of it, by sowing some of it in a detached bed of a garden, counting the seeds before they are put into the ground: by this means it may easily be known how many of them fail, and the quantity of seed to be sown may be proportioned accordingly.

"Some have asserted, that saintfoin should not be mowed the first year: but this is an ideal precaution; for in Switzerland we think it rather does it good than harm to mow it in autumn; and experience every day convinces us we are right in our opinion. The first crop is not, it is true, very large; but the mowing causes the plants to branch, and gives strength to the roots.

"No cattle, as I said before, should be turned on saintfoin the first year: and indeed, it is best, if possible, always to mow it. We have three crops of green fodder, or two of hay, from it, in one season in this country.

"When we intend to save the saintfoin seed, we leave a part of it standing, and do not cut it till we observe, by the colour of the pods, which will then be of a deep brown, that the principal part of the seed is ripe: we then either gather the heads by hand, or reap them with a sickle, and lay them carefully on a cloth. The heads must be dried in layers three or four inches thick: if they were laid thicker, they would be apt to heat and spoil: when dry, we gently thresh them with sticks; flails would be too heavy; for if the seed is the least bruised, it does not come up. The stubble that remains after the heads are cut off may be mowed, and given either dry or green to the cattle; for though a little sticky, they will not refuse to eat it.

"I generally use my saintfoin green, foddering the cattle with it as soon as it is cut; and this I the rather do, because the making it into hay is such critical work: but when there is a likelihood of my being short of winter-fodder, I have no choice to make.

"The weather should be very fine when it is cut; for as it is full of sap, it requires great heat to dry it; and if it happens to rain, it takes more damage than common grass; and it is best not to cock it, as it is subject to heat in a very small space of time: if it is much wetted, it grows black, and loses all its sweetness.

"Even when saintfoin is seemingly quite dry, it is apt to heat in the stack; but this is easily prevented by spreading alternately a layer of good oat or barley straw, and another of saintfoin: when it comes to be used all together, it makes an excellent winter-fodder.

"Great care must be taken both in turning the swarths of saintfoin, and in loading it on the waggons, as a very little stirring will, when it is dry, shake off all the leaves; and this greatly lessens its value: for this reason I make my men turn the swarths with the handles of their forks, which is easily done; and I never cart it, but either early in a morning, or late in the evening, when it is somewhat moistened by the dews.

"Saintfoin is a very hardy plant, and bears, without being sensibly affected, the extremes of heat and cold; but the bottom of the land where it is sown must not be wet, and there must be room for the roots to spread.

"A field of saintfoin on a good soil will last from sixteen to twenty years in prime, and even longer, with care; for if, after seven or eight years, some well-rotted dung is laid on it, the future crops, as well as its duration, will be greatly encreased. When it is sown on light land, marling it is of very great service.

"But if after all a piece of saintfoin falls off, our method is to plow it up in autumn as deep as possible; give it another plowing in spring, sow it with oats, plow it again immediately after harvest, dung it, sow it with wheat; when the wheat is off, plow it again, and giving it another plowing sow saintfoin in it about the end of August; and this in general succeeds as well as that which was first sown on the land.

"Before I conclude, I must give you a few cautions relative to this excellent fodder, which has of late so much improved this neighbourhood.

"It is so very sweet, and cattle are so fond of it, that without great care they are apt to eat too much of it; whence often proceeds a surfeit, and sometimes a corruption of the mass of blood, and cutaneous eruptions: they should at first have but a little at a time given them, that they may be by degrees habituated to it: by this management the danger vanishes.

"It is much more proper for slow draught-horses than for such as are used for berlins, or for riding; for it is apt to make horses thick-winded, foggy, and somewhat sluggish: for farmers horses nothing can be better, or more nourishing; speed is not required in them.

"When saintfoin is intended to be made into hay for horses, it is best not to cut it till the seed is formed in the pod, as by that means the hay will be much more nourishing; and when the dried seed itself is plenty, nothing better can be given to the horses by way of corn; for I can assure you from experience, that one bushel of it will go as far as two of oats.

"When saintfoin is cut to be given green to cattle, it is best to mow it when it is in full bloom, as it is then most juicy, and fullest of sap, and will consequently afford most nourishment to the cattle. The best way of managing is to cut no more than will serve for the day; and by properly apportioning, or parcelling out the field, there will be, during the whole summer, some of it in order to cut for green fodder.

"If this green fodder is intended for sheep, it may with great propriety be cut just before it flowers: the stalks are then in a tender state, and very nourishing and good either for wethers or ewes. When it is to be made into hay for sheep, the same rule should be observed.

"I have very little more to say on the subject of saintfoin, except that, as when a saintfoin lay is brought into tillage, it prepares land very well for wheat or rye, and bears good crops, there is seldom occasion among the good farmers to try how long it will continue in heart, as they generally break up these lays in turn, and find it advantageous so to do." *Museum Rusticum, vol. I. pag. 37.*

Experiments on Saintfoin.

The following judicious series of experiments were communicated by a gentleman of distinguished rank and fortune, in Yorkshire.

"From an entire conviction, says this excellent husbandman, that it is the duty of every subject to contribute all in his power to the good of society; I have endeavoured, during several years that I have resided in the country, to promote and encourage the advancement of agriculture. To this end I have made variety of experiments, on different soils, to prove and ascertain the most beneficial methods of husbandry, or how to employ land to the most advantage.

"A great part of my estate, consisting of waste and uncultivated heath, which did not let for more than a shilling an acre, I judged it to be a matter of importance to try if it was not possible, by culture, or by applying this ground to a different purpose, to increase the value of it. Happy would it be, could pleasure be made to coincide with profit! and it is certain, that whoever succeeds in the improvement of his own estate, may enjoy the inward satisfaction of rendering some service to his country: for the example of a landlord may be thought to have some weight with his tenants; and if, amidst a great number of experiments made for the sake of truth, some have proved fuccefsful, one may expect that the farmer will at laft adopt a method which he has for many years feen repeated with advantage: for however the common farmer may have been accufed of an obftinate adherence to old cuftoms, many inftances might be produced of his quitting the paths of his anceftors in favour of modern improvements; but then he muft be thoroughly fatisfied, that the new way is indeed preferable to the old, not in theory only, but in practice, confirmed by actual experiments often repeated before his eyes. And can we juftly blame the illiterate peafant for refufing to forfake a method he is well acquainted with, and can depend on for the fupport of himfelf and family, upon other terms? It is the province of the landlord to adopt a theory, and to try it by experiment; for if it fails, as is often the cafe, his ruin is by no means the confequence, and the lofs is amply made up to him, by the fecret pleafure always accompanying a good intention. But whatever fervice a gentleman may be of in encouraging refearches of this nature, or by his influence in his own neighbourhood; yet ought his benevolence to extend farther, fo as to be of ufe, if poffible, to his country and mankind. It is the defire of communicating the little knowledge I may have gained from the experience of a few years, that has prompted me to addrefs this letter to you, who are engaged in an ufeful and public undertaking: and you are at full liberty to make ufe of it, together with the detail of the experiments. They were begun without the leaft defign of making them public, and may therefore be deficient in point of method and order: but they are ftrictly true.

" On the third of April, 1759, two acres of very fandy land (which had a hundred loads of red marle laid on it the year before, and had borne a good crop of oats in 1758) were drilled with faintfoin, on four feet ridges in double rows, eleven inch partitions, the intervals three feet one inch wide, and took four pecks and a half of feed. This was intended to be horfe-hoed, as Tull directs; but the land was in fuch bad tilth, and abounded fo with the natural grafs, that, after once or twice attempting to deftroy it, by plowing the intervals, the horfe-hoeing fcheme was given up, and the faintfoin left to take its chance. However, a few plants remained thinly fcattered in the rows (whether this thinnefs was owing to the badnefs of the feed, or to its being fown too deep, I know not, though I rather impute it to the latter caufe, as, in fandy land, the fhares of the drill are very apt to penetrate too far into the ground.) Thefe remaining plants flourifhed exceedingly from the time of their being fown; many were in flower the following June, and afforded a tolerable crop, viz. about a load. The after-eatage was very good. In 1760, thefe plants feemed to have arrived at their perfection, and the product was two waggon loads, or about two tons. In 1761, and 1762, this fmall clofe, having had fome manure laid on it yearly, yielded nearly the fame quantity of hay; and it is now let for forty fhillings a year: a much higher rent than any land is let for in this neighbourhood, and four times the rent paid for it before the improvement.

" N. B. This clofe of two acres was feparated from another of twenty-feven acres, of fo fandy and dry a nature, that, unlefs in a wet fummer, the hay upon it was fcarce ever worth mowing: and this experiment was made in order to determine what improvement the adjoining large clofe was capable of, and to experience whether or no the common opinion, that faintfoin is improper for all fandy and deep foils, be founded on truth, or only the refult of prejudice: for the reafon given for its difagreeing with this kind of foil, did not appear to me fatisfactory; and great part of my eftate confifting of fuch fandy land, it feemed a matter of importance, to know, whether the great advantage derived from faintfoin, on fome foils, might not alfo be applicable to fandy foils.

" Encouraged by the flourifhing condition of the faintfoin on this fmall clofe, I determined to extend the improvement to the larger one alfo, as foon as it could be brought into fufficiently fine order to be laid down with this grafs. Accordingly, in the winter of 1759, twenty-five acres were plowed with the five coultered plough, as recommended by M. Duhamel, in his Treatife on the Cultivation of Land, in order thereby to prepare the ground for turneps the enfuing fummer: for I look upon this as one of the beft methods of deftroying the natural grafs, and preparing the land for any of the artificial graffes; efpecially if the turneps are drilled in rows, and cultivated with the horfe-hoe. The land was plowed level in the fpring of 1760, and into ridges of about five feet broad in June, and a fingle row of turneps was drilled on the middle of each ridge in July. It is to be obferved, that the natural grafs was far from being deftroyed by thefe three plowings; nor could it be entirely fo by the fubfequent hoeings of the turneps; fo that it certainly was a great prejudice to the faintfoin. The fame ground is now fown again with the fame plant: but I would ftrongly recommend to thofe who are inclined to follow this method on fuch a foil as I have defcribed, to continue the culture of turneps, with the horfe-hoe, two years, inftead of one: for by this means, the natural grafs and weeds may probably be effectually deftroyed. But to return to the experiment: the turneps fucceeded as well as could be expected on fuch a foil, and without manure: they were eaten off by fheep, and Scotch cattle, folded on the land.

" About four acres, on which the turneps were the firft fpent, were plowed level, and afterwards, viz. in November, drilled with faintfoin in equally diftant rows, one foot afunder. They took about a bufhel to an acre. This was an uncommon, and may be thought an improper feafon for the fowing of faintfoin: but I chofe to fow part of the field before winter, and part in the fpring, part with faintfoin mixed with corn, and part with faintfoin alone; in order to fee which method would fucceed beft, that I might make it my guide in other places, more likely to yield good crops.

" Five or fix acres of land were drilled in the beginning of April 1761, with faintfoin feed, in rows, at the fame diftance, and with the fame proportion of feed, as the four acres fpoken of before: about three acres were fowed foon after with faintfoin and oats, both drilled: and about twelve acres were drilled with faintfoin and barley; each in rows, about a foot afunder. The whole of this field, which contained twenty-five acres, had been plowed but once fince the turneps; whereas two plowings might have been better: but, on account of eating them off with fheep and cattle, there was not time for it.

" The three acres fowed with oats in rows a foot afunder, took four bufhels and a half of feed, and produced a very good crop; by computation, five quarters to an acre: but the exact quantity, neither of the oats, nor of the barley, could be known, on account of its being mixed in the barn with corn that grew in other places. The twelve acres fowed with barley took feventeen bufhels of feed, and produced a much greater crop than any land in the neighbourhood; though this was a great year for barley. All the farmers who obferved this crop, allowed that they had never feen finer barley; and it may be faid, without the leaft exaggeration, to have yielded above five quarters to an acre. I am convinced that this computation of five quarters to an acre is a very moderate one; not only from the number of fheaves, and the judgment of all who faw it; but likewife becaufe I had no more than twenty-fix acres and an half of land drilled with barley this year; and the whole produce, when threfhed, amounted to one hundred and twenty-eight quarters and two bufhels; which is very near five quarters to an acre, taking one part with another: but thefe twelve acres bore by much the greateft crop in proportion, and feven acres of the twenty-fix were fown on beds five feet broad, and horfe-hoed, which never produces fo large a crop.

" The fummer of 1762 was remarkably dry, and bad for grafs: many fields hereabouts, of ten acres, did not produce above a load or two of hay; but this of twenty-five acres produced twelve tons of good hay: which, confidering that the faintfoin was not nearly arrived at its perfection, may be faid to be confiderable.

" It was now eafy to fee in what parts of the field the faintfoin had fucceeded beft.

" The four acres fowed before winter had the fmalleft number of plants of faintfoin of any; perhaps not more than one or two in ten yards: but this ground abounded fo with natural grafs, that this alone furnifhed a tolerable crop. The five acres fown in the fpring, without corn, did

did not abound much lefs with natural grafs, or more with faintfoin, than the preceding: but there being a great mixture of the feeds of rye-grafs with all the faintfoin fowed in this field, the rye-grafs appeared diftinctly in tufts all along the rows; and, together with the natural grafs, feemed compleatly to have covered the furface of the ground. The rows were much better ftocked with faintfoin plants in the twelve acres fown with it and barley: but the rye-grafs abounded here likewife.

"It is remarkable, that the faintfoin flourifhes beft in thofe parts of the field where the land is moft barren; the reafon of which undoubtedly is, that, as fcarce any natural grafs, or weeds, arife to choak it there, its young and tender fhoots have the benefit of the whole pafture, and its roots are not obftructed in their progrefs by the growth of other plants.

"Though the greateft part of this field is much underftocked with faintfoin plants, yet it is in a very promifing condition for a good crop of hay this year.

"I attribute the bad fuccefs of the faintfoin on the firft four acres, partly to its being fowed too late, whereby the plants could not acquire much ftrength before winter, which deftroyed many of them; partly to fome violent hurricanes of wind, which blew clouds of fand from one part of the field to another, and overwhelmed many plants; and partly to the fhares going too deep, by which the feed was covered at leaft two inches. The bad condition of the five acres fowed alone in the fpring, I believe to be owing, in fome meafure, to the caufes already affigned, and alfo to the want of protection and fhelter from drought, which corn would have afforded in that very dry foil. Barley does alfo help to ftifle the natural grafs, faintfoin's greateft enemy. The faintfoin which was drilled with barley, looked, as was before obferved, by much the beft: but, indeed, fome precautions were ufed to fow the feed fomewhat fhallower on thefe twelve acres; and this may, in fome degree, have contributed to its fuccefs.

"Upon the whole, from the experiments made in this field (and feveral others made fince have ftrengthened my opinion on that head) I conclude, firft, that faintfoin is very fuitable to any fandy or deep foils, provided they are dry, and that the natural grafs and weeds can by any means be completely deftroyed: fecondly, that it is better to fow faintfoin in the fpring, and with barley, than in the autumn, or fpring, alone: thirdly, that the feed fhould not be covered above an inch deep; but I believe half an inch the moft proper depth. One foot may be a very proper diftance for drilling the rows; and from a bufhel to a bufhel and an half, a proper allowance of feed for an acre of ground, provided that feed be good.

"I have tried the horfe-hoeing of faintfoin fown on beds three and four feet broad: but, though the plants do by that means certainly grow more vigorous, I do not think the crop fo great; and when the ftalks are ftrong and pipy, I have obferved that cattle will not eat them. The fowing in equally diftant rows feems preferable, efpecially where a large extent of ground is to be fowed. But my experience is very infufficient to decide this point abfolutely. I could wifh that gentlemen would make trials of the horfe-hoeing of faintfoin in different foils and fituations.

"Experiments carefully made, and often varied, by perfons void of prejudice, may, in time, decide that important queftion in agriculture, viz. whether the common, or the horfe-hoeing, hufbandry be, upon the whole, moft advantageous to the Englifh farmer.

"If faintfoin be drilled on a fandy foil, or on one that is in very fine order, the fhares of the drill ought to be two inches thick, or they will go too deep; and a fmall wooden roller fhould be fixed to, and follow, the drill, inftead of a harrow with teeth, which would bring too much earth upon the feed. Such a roller will lay the ground fmooth, and fitter for mowing. A fpring made of three pieces of afh, as defcribed by M. Chateauvieux, is of great ufe, and may eafily be added to Mr. Tull's drill plough. It may be faftened underneath the middle of the plank, by four fcrews, and made to prefs more or lefs on the roller, or harrow, which ever is made ufe of, by a wedge put in betwixt the fpring and the hinder edge of the plank. If a harrow is ufed, iron teeth are much preferable to wooden ones.

"In the year 1757, I had a mind to try how much a foil naturally extremely bad, could be improved by art. Accordingly, I made choice of a piece of ground one acre and an half in extent, a barren fand, which produced only a few miferable weeds, and which the farmer who rented it did not think worth his while to cultivate. There happened to be a great quantity of red ftony marle in an adjoining field, of which near three hundred loads were laid on this acre and an half. It was drilled with barley in 1758, and horfe-hoed: but the crop proved a very bad one. In 1759, a load of lime, and about ten loads of dung were laid thereon, and it was drilled with turneps and horfe-hoed: however, the crop ftill was but moderate; though a good deal better than could have been expected from fuch a foil. In 1760, it had turneps again, managed in the fame manner as the former, but they were a great deal better. In 1761, it was drilled with oats, faintfoin and rye-grafs, mixed, in equally diftant rows one foot afunder. It took two bufhels and a peck of oats, and two bufhels of grafs feeds. The oats were very good, and produced four quarters and four bufhels. By continued horfe-hoeing three years together, the land was got into perfectly fine order, the marle and fand were thoroughly incorporated, and the natural grafs and weeds intirely deftroyed: fo that the faintfoin and rye-grafs grew and flourifhed exceedingly. In 1762, the fummer being uncommonly dry, the produce was about half a load of hay; which was as much as one could expect the firft year after fowing. It is very well flocked with plants, which now, in May 1763, feem as vigorous as in any of my other fields, though I have fome which yield two tons of hay to an acre. This little piece of ground, which before was not worth a fhilling a year, is, by the labour and coft beftowed on it, now worth at leaft fifteen fhillings an acre; which is a proof that, let land be ever fo bad, it may be improved, and perhaps made equal to the beft in the neighbourhood: but at the fame time it muft be confeffed, that the expence is too great to be repeated at once on a large extent of ground. I calculate that three hundred loads of marle, dug and carried about three hundred yards, might coft about four pence a load, or five pounds for three hundred loads, which has been the whole expence attending this acre and half: for the manure, plowings, and horfe-hoeings, were repaid by the crops of barley, oats, and turneps."

Mr. Duhamel has mentioned the following experiments relative to the culture of faintfoin:

In 1754, M. Eyma, near Bourdeaux, planted faintfoin, lucerne, and clover, in rows eight feet afunder, with diftances of fixteen inches between the plants in the rows, which yielded him an immenfe increafe. The alleys were horfe-hoed after each cutting.

In 1755, he planted a field, a little more than three roods fquare, with faintfoin, which he cultivated according to the rules of the new hufbandry; and this fpot yielded him 10,000 pounds of dry hay. M. de Chateauvieux had 15,300 pounds of lucerne, as we fhall fee, off fomewhat more than an acre of ground, which he cut five times: but M. Eyma thinks that 14445 pounds, Geneva weight, of faintfoin, which he had at another time, at one cutting, is a greater crop than M. de Chateauvieux's lucerne; befides the after crop, which indeed was but inconfiderable, on account of the drynefs of the feafon. He fays he cuts his faintfoin three times in good years, and that the two laft cuttings produce nearly as much as the firft: but he allows, that fuch years are not to be expected often.

M. Eyma doubts whether the preference be due to faintfoin, or to lucerne: but he is confident that either of them, properly cultivated, will produce furprizing crops.

He thinks that one row of faintfoin, or lucerne, planted in the middle of a bed three feet wide, will profit more by the different hoeings, and confequently produce more grafs, than double or triple rows, though thefe laft be planted on broader beds; becaufe the fingle rows have the earth loofened on each fide of them.

M. Diancourt fowed faintfoin, each plant of which, in 1753, had a head of two feet diameter. They throve fo well, that, in 1755, one plant, and that not the largeft in the field, yielded twenty-three ounces of hay.

The following inftructions were given by an ingenious gentleman in Lincolnfhire.

"Mr. Tull ſays, that a deep ſoil is beſt for ſaintfoin. I believe every thing grows better, in a better ſoil: but by what I have ſeen of this plant, I ſhall always prefer for it a ſhallow ſoil, where there is a rock, or ſome hard ſubſtance, within ſix inches, or a foot, of the ſurface, to ſtop the roots of the plants, and make them ſpread horizontally. This has not only the good effects propoſed in M. de Chateavieux's manner of tranſplanting lucerne, but, it is ſaid, occaſions its filling the ground with more ſhoots by their ſtriking up from the knots of the roots. This fact I cannot verify: but certain it is, that, in ſuch ſoils as I here ſpeak of, a crop of ſaintfoin which at firſt appears very thin, will afterwards fill the ground perfectly well, and the plants of it will appear in much greater quantities than at firſt.

"I have ſeveral times broke off a root of ſaintfoin four or five inches within ground, and it always ſprang up again. This is a ſmall argument for the fact I mentioned.

"Saintfoin is much cultivated in Lincolnſhire. The common allowance of ſeed is five buſhels to an acre. A gentleman ſouth of Lincoln adviſed me always to ſow a ſmall quantity of trefoil with it (about four pounds on an acre). The reaſon is, that, in this expoſed country, the young plants ſuffered more by the ſun in ſummer, than by the froſts in winter. Now the trefoil, coming to perfection the firſt year, and living only three, will be a ſhelter for the young plants, during the firſt year or two, and die off when the ſaintfoin wants its room. This ſyſtem is well ſupported by practice: but rye graſs ſhould on no account be ſowed with it; that being, when left for fodder, a great impoveriſher of ground.

"Saintfoin is obſerved to get to perfection in three years, laſts good four or five, and then dwindles during four or five more. Its firſt crops are from one or two loads; its ſecond-ſtage, from three to four loads, and it dwindles down again to one.—Laſt ſummer, which was remarkably dry, did very well with this graſs.

"I have ſown ſaintfoin with barley, with wheat, without corn in the ſpring, and now" (this gentleman's letter is dated September 4th, 1763) "am ſowing ſome more at this preſent writing; but can form no judgment as yet.

"Three years ago I drilled ſome, according to Mr. Tull's directions, in beds, with treble rows, and ſome at equi-diſtant rows. The horſe-hoed beds were good, as far as they went: the others, drilled at a foot diſtance, gave ſo much room for weeds to come up, that the ſucceſs was very moderate; which, indeed, would have been the caſe with the former, had not the horſe-hoe cleared them. On the whole as far as my ſmall experience and obſervations reach, I would never chuſe any one to drill his ſeed, but to ſow it in the broad caſt-way, on land very fine, with a good quantity of ſeed."

SALLENDERS, a diſeaſe in horſes, conſiſting in cracks in the bending of the hough, and occaſion a lameneſs behind. This diſeaſe is cured in the ſame manner as the mallenders. *See* MALLENDERS.

SALT-MARSHES, paſture-lands lying near the ſea, and ſometimes overflowed by the ſea-water.

"It has been obſerved, ſays an ingenious writer in the Muſeum Ruſticum, that horſes and black cattle thrive better, and get fleſh and fat ſooner, in ſalt marſhes, than in freſh-water meadows or upland paſtures; yet I do not remember ever to have heard any good reaſon aſſigned for it.

"Some will tell you that the air of the ſea whets their appetites; that the paſture is rich and nouriſhing; and that the herbs produced by the lands near the ſea are more conducive to the health of herbaceous animals, than ſuch as grow on upland paſtures, whether natural or artificial.

"But may we not rather attribute the thriving of cattle on theſe marſhes, to the ſaline particles with which the earth as well as its produce, is, when near the ſea, ſtrongly impregnated? Perhaps even the dews have their portion of ſalt; but of this I have made no experiment, therefore mention it only as a probable conjecture; for as they fall ſoon after they are exhaled from the ſea, without paſſing through the ſecretions neceſſary to ſeparate their ſaline parts, why ſhould not this be the caſe?

"But to return to my firſt ſubject: I am fully of opinion, that the ſaline particles only, with which the graſs is impregnated in the above-mentioned marſhes, cauſe cattle to thrive in them in the manner they are known to do. Theſe ſalts purge away the foul humours which the beaſts have contracted, either by idleneſs, or by being overheated in labour; by which means they are better diſpoſed to be nouriſhed by the aliment they receive.

"It may, perhaps, be objected, that if the graſs of theſe marſhes is apt to purge cattle, this very purging, by being long continued, will be a means of preventing their growing fat. To this I anſwer, that the cattle take with their food every day nearly the ſame quantity of theſe purgative particles; but that the quantity of ſalt, which at their being firſt put into the marſh will have that effect, will ceaſe producing it when they are, by cuſtom, habituated to take a daily portion of it: this muſt be allowed, as we all know, that a few grains of rhubarb will operate as a cathartic to a perſon that is not accuſtomed to take it; yet it is as well known, that a man may take many grains daily, if he uſes himſelf to it, without its being ſenſibly purgative to him.

"It is not convenient to every one to ſend their cattle to a ſalt marſh: would it not, therefore, be happy, if we could ſubſtitute a method that would nearly anſwer the ſame purpoſe? I do not think this impoſſible: perhaps, if common ſalt-water was to be laid in the fields for the horſes to lick as often as they pleaſed, they would thrive much better: were I to ſay I know it would have that effect, it would be no preſumption.

"Cattle are naturally fond of ſalt, and if left at their liberty, will take no more of it than what does them good. With this help, our freſh-water meadows, and upland natural and artificial paſtures, would yield us a greater profit, and of courſe be worth more both to the land-owner and farmer.

"Some will not allow a thing to have merit; unleſs it is ſupported by what they call a proper authority; and they do not allow the experiments of a particular perſon to be ſufficient. To ſatisfy ſuch I can aſſure you, that in the inland parts of Switzerland, when their horſes and cattle have endured the hardſhips of a long and ſevere winter, they turn them in the ſpring looſe into the mountains, laying ſalt here and there upon the rocks, for them to reſort to when they pleaſe; and of this they are ſo fond, that when the farmers want to catch their horſes, they take ſome ſalt in their hats, as we do oats in a ſieve, to allure them.

"Experience has long convinced them, that the ſalt thus laid in their way anſwers every good purpoſe: their cattle are more healthy in general than ours are in England; and almoſt to this alone do they attribute it.

"In the province of Munſter and Connaught, in Ireland, they very frequently lay ſalt on ſlates, for the benefit of their horſes when at graſs: this, they find, does the cattle great ſervice; and in this ſhould we imitate them, and not be too proud to learn of them, becauſe in Ireland agriculture is not in ſo flouriſhing a ſtate as in England.

"Some few farmers have (to do them juſtice) practiſed this method in our own country; but contenting themſelves with the profit reſulting from it, they have not propagated the knowledge of the many advantages they are ſenſible may be derived from this practice of giving ſalt to cattle.

"The farriers and horſe-jockeys know well the uſe of ſalt; they mix it often in their medicines, and find, by experience, that nothing proves ſo powerful a ſtomachic to horſes, as a little ſalt thrown into their oats.

"I muſt farther obſerve, that the uſe of ſalt is very proper when cattle are turned into clover, lucerne, or coleſeed to feed: it is well known, that, on theſe occaſions, they are very apt, unleſs great care is taken, to be ſurfeited; the ſalt would prevent this accident, and thereby greatly accelerate the fattening of the cattle, and make it much ſafer to the farmer.

"Salt has alſo been found to be of great ſervice in fattening hogs, by cauſing them to drink more plentifully than otherwiſe they would."

For the uſes of ſalt in rendering hay more grateful to cattle, *ſee the article* BRINING *of* HAY-RICKS.

SAND, a genus of foſſils found in minute concretions, forming together a kind of powder, the genuine particles of which

which are all of a tendency to one determinate ſhape, and appear regular, though more or leſs complete concretions; not to be diſſolved or diſunited, by water, or formed into a coherent maſs by means of it, but retaining their figure in it; tranſparent, vitrifiable by extreme heat, and not diſſoluble in, nor effervеſcing with acids.

Theſe are ſubject to be variouſly blended and intermixed either with homogene, or heterogene particles, particularly with flakes of talc; and according to theſe, and their different colours, are to be ſubdivided into ſeveral kinds, as red, white, &c.

Dr. Liſter divides the Engliſh ſands into two claſſes; the firſt, ſharp or rag ſand, conſiſting of ſmall tranſparent pebbles, naturally found on the mountains, and not calcinable: theſe he farther divides into fine and coarſe, and ſubdivides each, according to the colours, into white, grey, reddiſh, brown, &c.

The ſecond, ſoft or ſmooth, which he ſubdivides into that with flat particles broken from lime-ſtones, that with ſilver-like particles, and that with gold-like particles.

As to ſand, its uſe is to make the clayey earth fertile, and fit to feed vegetables, &c. for earth alone, we find, is liable to coaleſce, and gather into an hard coherent maſs, as is apparent in clay: and earth thus embodied, and, as it were, glued together, is no-ways diſpoſed to nouriſh vegetables: but if with ſuch earth, ſand, &c. i. e. hard cryſtals, which are not diſſolvable in water, and ſtill retain their figure, be intermixed, they will keep the pores of the earth open, and the earth itſelf looſe and incompact, and by that means give room for the juices to aſcend, and for plants to be nouriſhed thereby.

Thus a vegetable, planted either in ſand alone, or in a fat glebe, or earth alone, receives no growth or increment at all, but is either ſtarved or ſuffocated; but mix the two, and the maſs becomes fertile. In effect, by means of ſand, the earth is rendered, in ſome manner, organical; pores and interſtices being hereby maintained, ſomething analogous to veſſels, by which the juices may be conveyed, prepared, digeſted, circulated, and at length excerned, and thrown off into the roots of plants.

Grounds that are ſandy and gravelly, eaſily admit both of heat and moiſture; but then they are liable to theſe inconveniencies, that they let them paſs too ſoon, and ſo contract no ligature, or elſe retain it too long, eſpecially where there is a clay bottom; and by that means it either parches or chills too much, and produces nothing but moſs, and cankerous infirmities; but if the ſand happens to have a ſurface of good mould, and a bottom of gravel, or looſe ſtone, though it do not hold the water, it may produce a forward ſweet graſs; and, though it may be ſubject to burn, yet it quickly recovers with the leaſt rain.

Sea ſand is accounted a very good compoſt for ſtiff ground; for it effects the two things following, viz. it makes way for the tree or feed to root in ſtiff ground, and makes a fume to feed it.

Sand indeed is apt to puſh the plants, that grow upon it, early in the ſpring, and make them germinate near a month ſooner than thoſe that grow upon clay, becauſe the ſalts in the ſand are at full liberty to be raiſed, and put into motion, upon the leaſt approach of the warmth of the ſun; but then, as they are haſty, they are ſoon exhaled and loſt.

It is remarkable that ſand, though it appear a very hard, denſe, and indiſſoluble body, yet is contained inviſibly in the brine, or ſalt water of our ſalt ſprings; and even on the ſhooting of the ſalt, after evaporation, there ſtill remain the particles of it in the clear pellucid ſalt; and this, though wholly ſoluble in water, yet when a brine, made by ſuch a ſolution, is boiled, depoſits as much of the ſand as the common brine of the pits, or ſea water.

Dr. Plot, who was very curious to know the true hiſtory of this ſingular effect, procured experiments to be made in the following manner: eight folds of fine holland, and as many of much finer cambric, were put together, and, a quantity of the brine of the Staffordſhire ſalt pits being ſtrained through this, there was nothing ſeparated from it but a ſmall quantity of black duſt, which ſeemed to have fallen in by accident, and which was not at all like ſand; yet, on evaporating this brine, it was found to contain no leſs than one fourth part as much ſand as ſalt; the quantity of brine, yielding a buſhel of ſalt, yielding alſo a peck of ſand.

Some have ſuppoſed from theſe, and the like obſervations, that the ſand was generated during the time of the boiling the liquor, but the more careful examiners think otherwiſe; it appearing to them, that the particles of this ſand may be ſeen in the brine, by the help of a microſcope, before the boiling, in form of rectangular oblong plates, ſome nearly ſquare; theſe were ſo ſmall, as readily to paſs the ſtrainer with the water; and appearing as numerous in it after, as before the ſtraining, ſhew that they are no more to be kept, by ſuch means, than the ſalt.

The pores of the fineſt ſtrainers, examined by the microſcope, appear twenty times bigger than theſe plates, or particles of the ſand, and therefore it is not to be wondered at, that they let them through. There requires, therefore, no more to the formation of the ſand, than the coaleſcing of ſeveral of theſe particles into one larger granule, and ſo on; and this is very likely to be done by means of the evaporation of a part of the fluid which kept them ſeparate, and of the motion given to them in boiling, which naturally and neceſſarily brought them into the ſpheres of their own mutual attractions, at a time when their attraction with the fluid they ſwam in, was alſo much diminiſhed with its quantity. This attraction ſeems even evidently to increaſe between the particles, as the water becomes evaporated, and, when finally the ſalt is drawn from it, and it is examined, as it drops from the baſkets, in which the ſalt is put to drain, it is ſeen to contain more numerous particles of this ſandy matter than before; and theſe are found to coaleſce into yet larger concretions, by degrees, as the remainder of the fluid evaporates from them on the glaſs.

The particles of this ſtony matter, when once thus united, are no more to be ſeparated by water, nor is the matter any longer ſoluble in that fluid. The common ſpar found in form of ſtalactites and incruſtations on the roofs, walls, and floors of old caverns, ſhews that it was once diſſolved in water, and by that means brought to thoſe places, and made into thoſe forms; and it ſhould ſeem, that this ſand, as it is called, was only this ſort of ſpar, which is contained more or leſs in all water; and which, on the evaporating of that water and ſeparation of the ſalt, which might help in making the water a menſtruum proper for the retaining it, ſhoots out into its own natural concretions; for the figure of theſe thin plates is the true and natural thin parallellopiped or rhomboidal figure of the ſmaller concretions of that matter, and even of thoſe pieces into which it falls on breaking. *Phil. Tranſ.* N°. 145.

Common ſand is a very good addition by way of manure to all ſorts of clay lands; it warms them, and makes them more open and looſe. The beſt ſand for the farmers uſe is that which is waſhed by rains from roads, or hills, or that which is taken from the beds of rivers; the common ſand that is dug in pits never anſwers nearly ſo well. Sand mixed with dung is much better than laid on alone: and a very fine manure is made by covering the bottom of ſheep-folds with ſeveral loads of ſand every week, which are to be taken away, and laid on cold ſtiff lands, impregnated as they are with the dung and the urine of the ſheep.

Beſides clay land there is another ſort of ground very improveable by ſand; this is that ſort of black foggy land on which buſhes and ſedge grow naturally, and which they cut into turf, in ſome places. Six hundred load of ſand being laid upon an acre of this land, according to the Cheſhire meaſure, which is near double the ſtatute acre, meliorate it ſo much, that without plowing, it will yield good crops of oats or tares, though before it would have produced ſcarce any thing. If after this crop is taken off, the land be well dunged, and laid down for graſs, it will yield a large crop of ſweet hay.

Once ſanding this land will improve it for a vaſt number of years, and it will yield two crops of hay in the year, if there be weather to make it in. Some land in Cheſhire has been, by this means, rendered of twelve times it former value to the owner. The bogs of Ireland, when drained, have been rendered very fruitful land, by mixing ſand in this manner among the earth, of which they conſiſt. Add to this, that in all theſe boggy lands, the burning them, or firing their own turf upon them, is alſo a great advantage. The common peat, or turf aſhes, mixed with the ſand for theſe purpoſes, add greatly to its virtue.

Sea

Sea ſand, which is thrown up in creeks and other places, is by much the richeſt of all ſand for manuring the earth; partly its ſaltneſs, and partly the fat and unctuous filth that is mixed among it, give it this great virtue. In the weſtern parts of England, that lie upon the ſea coaſts, they make very great advantages of it. The fragments of ſea ſhells alſo, which are always in great abundance in this ſand, add to its virtues; and it is always the more eſteemed by the farmers, the more of theſe fragments there are among it.

The ſea ſand uſed as manure in different parts of the kingdom is of three kinds: that about Plymouth, and on other of the ſouthern coaſts, is of a blue grey colour like aſhes, which is probably owing to the ſhells of muſcles, and other fiſh of that or the like colour, being broken and mixed among it in great quantity. Weſtward, near the land's end, the ſea ſand is very white, and about the iſles of Scilly it is very gliſtering, with ſmall particles of talc; on the coaſts of the north ſea the ſand is yellowiſh, brown, or reddiſh, and contains ſo great a quantity of fragments of cockle ſhells, that it ſeems to be chiefly compoſed of them. That ſea ſand is accounted beſt, which is of a reddiſh colour: the next in value to this is the bluiſh, and the white is the worſt of all.

Sea ſand is beſt when taken up from under the water, or from ſand banks, which are covered by every tide.

The ſmall-grained ſand is moſt ſudden in its operation, and is therefore beſt for the tenant who is only to take three or four crops; but the coarſe or large-grained ſand is much better for the landlord, as the good it does laſts many years.

Where the ſand is dredged out of the ſea, it is uſually twice as dear as where it is taken from the ſand banks.

When the land has been well manured with the large ſand, they take four crops of corn from it, and then lay it down for paſture for ſix or ſeven years before they plow it again. The graſs is ſo good, that they commonly mow it for hay the firſt year; it always abounds very much with the white-flowered clover. If the graſs grows but ſhort, it is the farmer's intereſt to feed his cattle upon it, and it will turn to as good account this way, being very ſweet and rich, and making the cattle fat, and the cows yield a very large quantity of milk. *Mortimer's Huſbandry.*

SAND-*Flood*, a terrible diſaſter incident to the lands of Suffolk, and ſome other parts of England, which are frequently covered with vaſt quantities of ſand, rolling upon them like a deluge of water, from ſandy hills in their neighbourhood.

Violent winds break through the turf that covers theſe hills, and then the ſand, lying looſe and naked, is ſoon carried down upon the plains, where it covers and buries the graſs, and in a very little time eats through the light turf, and mixing itſelf with the ſand underneath, becomes one bed of this dry matter never to be covered with turf again. A large body of ſand being thus got together, nothing ſtops its progreſs; but it, at every ſtorm, rolls over more and more ground, ſo that in a few years it extends itſelf a vaſt way, eſpecially where the ground, over which it paſſes, is of the ſame ſandy nature, and only covered with a thin turf.

In ſome parts of Suffolk the ground encourages this change ſo greatly, that a bed of ſand broke looſe from a neighbouring hill, and covering only a few acres, perhaps eight or ten, will, before it has travelled four miles forward, which it does in a ſmall courſe of years, deluge a thouſand acres. It travels down hill faſter than any way elſe, but will not be ſtopped by aſcent, but will move up the ſteepeſt hill, only that it requires more time. The making of fences, in the common way, to keep it out, is vain. It runs through the hedges, and flies over the tops of the banks; and when it reaches a village, in its courſe, will bury the cottages, unleſs preſerved at more charge than they are worth. It will in a very little time beat up to the eaves of a houſe, of the low kind, that are uſually built in a country village, and has often weight enough to break down walls in its paſſage.

The beſt way of ſtopping its progreſs is by hedges of furze, planted one over another, as they become levelled; theſe, if well kept up, will, by degrees, ſtop or divert the progreſs; and ſome who have tried this, with reſolution, after they have had the ſand raiſed twenty feet high, have found it ſtop its increaſe, and then, having manured this adventitious ſoil with dung, found it as good ground as that which made the ſurface before.

About Thetford, the villages were wholly deſtroyed by this about ninety years ago, and the branch of the river Ouſe, called then Thetford river, ſo blocked up by it, that very ſmall veſſels only could go up it, where very large ones uſed before. The river has been of great ſervice in ſtopping its progreſs into Norfolk, where otherwiſe its courſe would have carried it, and its vaſt ſpreading ſideways, in proportion to its going forward, would have made it bury vaſt quantities of land in a few years.

The moſt probable conjecture, as to the cauſe of this ſtrange ſort of deluge in theſe parts of England, is, that this portion of the county of Suffolk lies eaſt-north-eaſt of a part of the great level of the fens, and is by this expoſed to very impetuous winds, which acquire more than ordinary force, by their paſſing through ſo large a tract of country uninterrupted; the ſtorms ſeem to be one great cauſe of the miſchief, and the ſandy nature of the ſoil the other. There are old ſtories, in the country, of ſuits at law commenced among the farmers, for grounds blown out of the owners poſſeſſion; but the people who gain this ſort of wandering land are the greateſt ſufferers. A little ſand ſprinkled by the winds over a tract of land, where there is a bed of ſand under the turf, ſoon eats through that obſtacle; and what was at firſt only a thin coat of ſand, becomes then a deep plain of it, capable of being blown away to the depth of eight, ten, twenty, or more feet, and is carried over every thing in its progreſs before the winds, when once taken up by them. *Philoſophical Tranſactions*, N°. 37.

SAND-*lands, or Sandy-lands*, a term uſed by our farmers to expreſs ſuch grounds as conſiſt wholly of a pure ſheer ſand.

This is of different colours, as white, blackiſh, reddiſh, or yellowiſh, and is very different in its nature, and in the ſize of its particles, ſome being harſher and ſome milder, and ſome very light, ſeeming only to be mere duſt. The grey, black, and aſh-coloured ſand-land are the worſt of all, and generally are found on heaths and commons. Gravelly lands approach much to the nature of theſe, and thoſe which conſiſt of the largeſt ſtones, and are mixed with the harſheſt ſands, are of all the moſt barren.

The propereſt plants for arable land, of this kind, are white oats, rye, black wheat, and turneps. The natural produce, in weeds, is quick graſs, ſorrel, broom, furze, fern and heath.

The beſt manure for them is either marl, or ſuch clay as will break with the froſts. Cow dung is alſo a good manure for theſe lands, and many uſe with ſucceſs chalk, mud, and the half rotten ſtraw from dunghils.

When the farmer has a mind to raiſe corn on theſe lands, he muſt order them the ſame as they do the clays; but where they are over-run with broom, furzes, and ſuch ſort of weeds, marle is to be laid on in great quantities. This is the practice in Staffordſhire, and by it they rid themſelves of theſe troubleſome weeds, and procure good crops of corn, though at ſome expence.

The firſt ſowing of this land is with black wheat, and for this they make three fallowings in winter, and ſtir them in the May following; at this time they ſow them, allowing one buſhel of ſeed to an acre, which generally yields them ſixty again. Then once plowing theſe lands, after this crop is off, they are fit to ſow rye on.

In Oxfordſhire, they ſeldom give theſe lands more than two fallowings for wheat, except they are very much over-run with weeds; and they eſteem the white and Lammas wheat the moſt agreeable for this ſort of land, and then after a fallow rathripe barley. They afterwards generally fallow them every other year, and reckon them unfit for beans and peas, though they ſometimes ſow them with winter vetches. If they ſow peas on them, they eſteem the rathripe kinds the beſt.

In Herefordſhire, they are much ſubject to moſs growing upon their ſandy lands, and they make a great improvement by burning it on the ground, and mixing the aſhes with lime, which they plow in.

They generally ſow them with rye after this manure, and that yields a very great increaſe upon them, and brings on a very good kind of graſs, if they are laid down after a crop or two. *Mortimer's Huſbandry.*

SAP,

SAP, a juice furnifhed by the earth, and changed into the plant, confifting of foffil, faline, aerial, and other particles from putrified animals, vegetables, &c.

The notion of the fap's circulation was entertained by feveral authors much about the fame time, without any communication from one another; particularly M. Major, a phyfician of Hamburgh, M. Perrault, Mariotte, and Malpighi. It has met, however, with fome confiderable oppofers, particularly the excellent M. Dodart, who could never be reconciled to it.

One of the great arguments for it is, that the fame experiments of ligature and incifion, which evince a circulation of the blood in animals, fucceed in the like manner in plants, particularly in fuch as abound with a milky fap, as the great tithymale, milk-thiftle, &c. if the ligature be faftened tight round them, the part above is found to fwell very confiderably, and that below it, a little: whence it appears, that there is a juice afcending from the branches; and that the latter is thicker than the former, which quadrates exactly with the common fyftem; the juice being fuppofed to arife in capillary veffels, in form of a fubtile vapour, which, condenfed in the extremes of the plant, by the neighbourhood of the cold air, turns back in form of a liquor, through the more patent pipes of the inner bark.

M. Dodart, inftead of the fame juices going and returning, contends for two feveral juices; the one imbibed from the foil digefted in the root, and from thence tranfmitted to the extremes of the branches, for the nourifhing of the plant; the other received from the moifture of the air entering in at the extremities of the branches: fo that the afcending and defcending juices are not the fame.

One of his chief arguments is, that if two trees of the fame kind be tranfplanted in one day, after firft cutting off their roots and branches, and if, after they have taken root again, fome of the new fhoots put forth each year be cut off one of them, it will not thrive half fo well, notwithftanding its root and trunk being intire as the other.

This he conceives to be a proof of the plants deriving nourifhment by the branches, and concludes it to be of an aerial nature, becaufe formed of the moifture of the air, dew, &c. whereas that imbibed from foil is terreftrial, &c. *Hift. de l'Acad. Roy. Ann.* 1709.

The humour or fap of a plant, then, is a juice furnifhed by the earth, and changed into the plant, confifting of fome foffil parts, other parts derived from the air and rain, and others from putrified animals, plants, &c. Confequently, in vegetables, are contained all kinds of falts, oil, water, earth, &c. and, probably, all kinds of metals too, inafmuch as the afhes of vegetables always yield fomewhat which the loadftone attracts.

This juice enters the plant in form of a fine and fubtile water; which the nearer it is to the root, the more it retains of its proper nature; and, the farther from the root, the more action it has fuftained, and the nearer it approaches to the nature of the vegetable.

Confequently, when the juice enters the root, the bark whereof is furnifhed with excretory veffels, fitted to difcharge the excrementitious part, it is earthy, watery, poor, acid, and fcarce oleaginous at all.

In the trunk and branches it is further prepared, though it ftill continues acid; as we fee by tapping or perforating of a tree in the month of February, when it diftils a watery juice apparently acid.

The juice being here carried to the germs or buds is more concocted; and here, having unfolded the leaves, thefe come to ferve as lungs for the circulation and further preparation of the juice.

For thefe tender leaves, being expofed to the alternate action of heat and cold, moift nights, and hot fcorching days, are alternately expanded and contracted, and the more on account of their reticular texture.

By fuch means is the juice ftill further altered and digefted, as it is further in the petala or leaves of the flowers which tranfmit the juice, now brought to a further fubtility, to the ftamina: thefe communicate it to the farina or duft in the apices, which is, as it were, the male feed of the plant, where having undergone a further maturation, it is fhed into the piftil, which performs the office of an uterus or womb; and thus, having acquired its laft perfection, it gives rife to a new fruit or plant.

The root or part whereby vegetables are connected to their matrix, and by which they receive their nutritious juice, confifts of an infinite number of vafa abforbentia, which, being difperfed through the interftices of the earth, attract or imbibe the juices of the fame: confequently, every thing in the earth that is diffoluble in water, is liable to be imbibed; as air, falt, oil, fumes of minerals, metal, &c. and of thefe do plants really confift.

Thefe juices are drawn from the earth very crude; but by the ftructure and fabric of the plant, and the various veffels they are ftrained through, become changed, further elaborated, fecreted, and affimilated to the fubftance of the plant.

The motion of the nutritious juices of vegetables is produced, much like that of the blood in animals, by the action of the air; in effect, there is fomething equivalent to refpiration throughout the whole plant.

The difcovery of this is owing to the admirable Malpighi, who firft obferved, that vegetables confift of two feries or orders of veffels.

Firft, fuch as receive and convey the alimental juices, anfwering to the lacteals, veins, &c. of animals.

Secondly, tracheæ or air veffels, which are long hollow pipes, wherein air is continually received and expelled, i. e. infpired and expired; within which tracheæ he fhews all the former feries of veffels are contained.

Hence, it follows, that the heat of a year, nay, of a day, of a fingle hour, or minute, muft have an effect on the air included in thefe tracheæ, i. e. muft rarefy it, and confequently dilate the tracheæ; whence arifes a perpetual fpring or fource of action, to promote the circulation in plants.

For, by the expanfion of the tracheæ, the veffels containing the juices are preffed, and by that means the juice contained is continually propelled, and fo accelerated; by which propulfion, the juice is continually comminuted, and rendered more and more fubtile, and fo enabled to enter veffels ftill finer and finer, the thickeft part of it being at the fame time fecreted, and depofited into the lateral cells or loculi of the bark, to defend the plant from cold, and other external injuries.

The juice having thus gone its ftage, from the root to the remote branches, and even the flower; and having in every part of its progrefs depofited fomething both for aliment and defence; what is redundant paffes out into the bark, the veffels whereof are inofculated with thofe wherein the fap mounted; and through thefe it re-defcends to the root, and thence to the earth again: and thus a circulation is effected.

Thus is every vegetable acted on by heat and cold, during the day-time efpecially, while the fun's force is confiderable, the fap-veffels fqueezed and preffed, and the fap protruded and raifed, and at length evacuated, and the veffels exhaufted; and, in the night again, the fame tracheæ being contracted by the cold of the air, the other veffels are eafed and relaxed, and fo difpofed to receive frefh food for the next day's digeftion and excretion.

What courfe the juice takes, after it is imbibed by the roots, is not very clear; the veffels that take it up, to convey it to the plant, are too fine to be traced; and hence it has been controverted, whether it is by the bark, or the pith, or the woody part, that the plant is fed.

The more common opinion is for the bark: the juice, raifed by the capillaries of the wood, is here fuppofed to defcend by the larger fibres, placed in the inmoft part thereof, immediately over the wood; in which defcent, the fap, now fufficiently prepared, adds a part of its fubftance to the contiguous wood, and thus increafes by appofition: and hence it may be, that hollow, carious, or rotten trees, which have neither pith nor wood, except juft enough to fuftain the bark, do grow and bear. Some contend for the wood, which they obferve to confift of flender capillary tubes running parallel to each other from the root up to the trunk, being proper to receive in a fine vapour; in the afcent whereof the fibres become opened, and their fubftance increafed; and thus the trunks of trees are faid to increafe in their circumference.

As for the pith; as the woody ſubſtance of the trunk becomes more woody, the pith is compreſſed and ſtreightened to ſuch a degree that in ſome trees it quite diſappears: whence it ſeems, that its office in vegetation is not very important, ſince ts uſe is not perpetual. By its ſpongious ſubſtance, it ſhould ſeem fitted to receive any ſuperfluous moiſture tranſuding through the pores of the woody fibres: and, if by the exceſs of ſuch moiſture, or the like cauſe, it corrupt and rot, as it frequently happens in elms, the tree does not grow the worſe for it; which is a convincing proof it is of no great uſe.

The learned Dr. Boerhaave diſtributes the juices of plants into ſix claſſes.

Firſt, the firſt claſs comprehends the crude nutritious juice, or the juices of the root and ſtem of plants, which are little more than the mere matter of the element, as drawn by the root from the body it adheres to, whether it be earth, water, or the like.

This juice is found in every part of the plant, and therefore may be held an univerſal juice; yet he conſiders it as the juice of the root and ſtem, becauſe it is chiefly found in them.

This he takes to be a ſubacid watery lymph, without any ſpecific taſte or ſmell, as not being yet arrived to the maturity of oilineſs.

To this claſs belong thoſe juices which diſtil in great abundance from wounds or inciſions made in the woody parts of plants; ſuch, for inſtance, is that tart liquor ouſing from the root of the walnut-tree, when cut off in the month of May.

Such alſo is that limpid, ſubacid humour, flowing out very plentifully at an inciſion in the birch-tree in the month of March, to the quantity of ſeveral gallons in a few days.

Such alſo is the juice iſſuing out of the vine wounded in the ſpring-time, which always taſtes tartiſh, and ferments like the grapes themſelves.

This juice may be eſteemed as yet foſſil, being generated of and in the earth; for the juice of the earth, being received into the canals of this plant, retains its nature during two or three circulations; nor does immediately commence a vegetable juice.

This claſs of juices therefore he accounts as the chyle of the plant, being chiefly found in the firſt order of veſſels, viz. in the roots and the body of the plant, which anſwers to the ſtomach and inteſtines of animals.

Secondly, the ſecond claſs of the juices is that of the leaves, which are the real lungs of plants, and accordingly make a further change of the juice, which they receive from the roots and ſtem by force of the air. The juice of leaves is different therefore from the firſt juice, as being more ſulphureous, and farther elaborated; not that it derives any ſulphur from the ſun, but that, its watery part exhaling, it becomes more oily, and leſs volatile.

The juice of leaves he diſtinguiſhes into three kinds:

The firſt is the nutritious juice of the leaves; which is that already deſcribed, only further elaborated in the minute veſiculæ of the leaves, and conſequently leſs watery, and more oily and ſaccharine.

The ſecond is wax, which, exuding out of the leaves, adheres to the ſurface, and is ſcraped off by bees with their rough thighs, to build their combs withal. This is chiefly afforded by lavender and roſemary: upon the latter of which, the wax may be plainly perceived ſticking to the leaves of it.

The third is manna: not that with which the Iſraelites were fed in the deſart, but a drug ſold among us: it is an eſſential ſaccharine ſalt, exuding chiefly by night, and, in the ſummer-ſeaſon, from the leaves of a ſort of aſh growing in Calabria and Sicily, and adhering thereto in the form of a cruſt, to be gathered the next morning before the ſun is up.

The like ſubſtance is found to exude from the leaves of the linden-tree and poplar, in the heats of May and June; at which time they have an honey-taſte, and are even ſeen with a fatty juice on them, which, at the approach of the cold evening, gathers into grains.

Thirdly, the third claſs of juices are thoſe of flowers, or the genital parts of plants; in theſe are:

Firſt, a pure, elaborated, volatile oil or ſpirit, wherein the particular ſmell of the plant or flower reſides, and which, by reaſon of its extreme volatility, exhales ſpontaneouſly; inſomuch that, if the flower be laid for ſome time in a warm place, the odorous juice or ſpirit will be all fled.

The ſecond is the juice expreſſed from the flower, which in reality is the ſame with that of the root and leaves, only farther prepared; it is thicker than the former, and has ſcarce any ſmell at all: thus, if you bruiſe an hyacinth, or other fragrant flower, and expreſs the juice, it will be found altogether inodorous.

The third is the ſweet juice called honey, which exudes from all flowers; aloes, colocynthis, and other bitter flowers, not excepted.

In all male flowers, that have utricles at the bottom of the petala, which Dr. Linnæus ſtiles the nectarium, is found a viſcid, ruddy, ſweet juice in ſome plenty; and accordingly we ſee the children gather cowſlips, fox-gloves, honeyſuckles, &c. and ſuck the honey from them: the bees too viſit theſe flowers, and, putting in their proboſcides or trunks, ſuck out the honey, and load their ſtomachs therewith, to be afterwards diſcharged and laid up in their combs: ſo that honey is a vegetable juice.

Fourthly, the fourth claſs of juices are thoſe of the fruit and ſeed; the preparative whereof is nature's final work: which performed, the plants ſeem to die for a time, as all animals are ſeen to languiſh after the emiſſion of their ſemen.

The juice of the fruit is like that of the root, only farther elaborated.

The juice of the ſeed is an eſſential oil or balm, elaborated and exalted to its laſt perfection. This juice or oil is not found in the very point or embryo in the center of the placenta; all we meet with in that part, is a few fine watery particles ſecreted from the placenta: but it is in the placentula or cotyledons themſelves, which conſiſt of innumerable little folliculi or cells, wherein this only juice is contained, ſerving to defend the embryo, and preſerve it from being corrupted by water, which, it is well known, will hardly paſs through oil.

Thus, if you take, for inſtance, fennel-ſeed, cut it through the middle, and apply it to the microſcope, you will eaſily perceive a clear ſhining oil in the cells of each lobe, inveſting the tender embryo. Without this oil, it were impoſſible a ſeed ſhould live a month, and, much leſs, a year or two, intire and uncorrupted in the ground.

This oil is found in the ſeeds of all plants; in ſome, for inſtance, in almonds, cocoa-nuts, &c. in very great quantities; in others leſs, as pepper, arum, &c. where one would ſcarce imagine any oil at all: and theſe ſeeds loſe their vegetative quality very ſoon.

Fifthly, the fifth claſs of juices are thoſe of the bark; which is an artful congeries or bundle of perſpirative ducts, and abſorbent veſſels.

Of theſe juices there are divers ſpecies; for the ſeveral humours raiſed and diſtributed through the leaves, flowers, and other parts of the plants, have all circulated through the bark, and accordingly are frequently found to diſtil from wounds made therein. In ſome caſes, even the whole plant is no more than bark, the pulp having been eaten out; as in willows, poplars, &c. which will live a long time in that ſtate.

The bark ſerves divers purpoſes; for it not only tranſmits the nutritious juices of the plants, but alſo contains divers fat oily humours, to defend the fleſhy parts from the injuries of the weather.

Sixthly, as animals are furniſhed with a panniculus adipoſus, uſually replete with fat, which inveſts and covers all the fleſhy parts, and ſcreens them from external cold; ſo are plants incompaſſed with a bark replete with fat juices, by the means whereof the cold is kept out, and in winter-time the ſpiculæ of ice prevented from fixing and freezing the juices in their veſſels; whence it is that ſome ſorts of trees remain ever-green the year round, by reaſon their barks have more oil than can be ſpent and exhaled by the ſun; and their leaves are covered with a thick oily film over their ſurface, which prevents their perſpiring, ſo much as other plants, and alſo defends them from the cold, &c.

All the juices of barks are reducible to eight, viz.

Firſt, the crude, acid, watery juice, called the chyle of the plant.

Secondly, an oily juice, which, burfting the bark in the beginning of the fummer, exudes out of feveral plants; as cyprefs, pine, fir, favin, juniper, and other ever-greens; and fuch alone: this oil diffolves by the fmalleft degree of warmth, and is eafily inflamed, and is that which defends the plant; which is the reafon why moft of thefe plants will not thrive in very hot climates.

For balm, or fatty liquor, more glutinous than oil, is nothing but the laft-mentioned oily juice, which was more fluid during the fpring-time; but which, by the greater heat of the fun, has evaporated all its moft fubtile parts, and is converted into a denfer liquor. Thus the finer part of oil of olives being exhaled by the fummer's warmth, there remains a thick balfam behind: thus alfo oil of turpentine, having loft its more liquid parts by heat, becomes of the thick confiftence of a balm.

Thirdly, a pitchy juice, which is the body of the oil itfelf, infpiffates, and turns black, when put into a great warmth: this is the moft obferved in the pine and fir.

Fourthly, refin, which is an oil fo far infpiffated, as to become friable in the cold, and may be procured from any oil, by boiling it much and long. Thus, if turpentine be fet over a gentle fire, it firft diffolves, and becomes an oil, then a balfam, then pitch, and then a refin; in which ftate it is friable in the cold, fufible by fire, and withal inflammable and combuftible; diffoluble in fpirit of wine, but not in water, which makes the character of refin.

Hence the oil is moft abundant in the barks in the winter-time, the balfams in fummer, and the refin in autumn.

Fifthly, colophony, which is a refin ftill farther exhaufted of its volatile part, being pellucid, friable, and approaching to the nature of glafs.

Sixthly, gum, which is an humour exuding out of the bark, and, by the warmth of the fun, concocted, infpiffated, and rendered tenacious, but ftill diffoluble in water and at the fame time inflammable, and fcarce capable of being pulverifed. This oily mucilage ferves as a pigment to cover over, and defend the buds of trees, from the injuries of wet and froft in winter; but will melt with a moift warmth, and eafily run from them, when the gentle warmth of the fpring approaches: nor is ever fo far hardened into a cruft, as to do any injury to the inclofed fhoot. This oily fubftance always contains in it an acid fpirit; which is a prefervative againft putrefaction.

Seventhly, a gummous refin; which is an humour fecreted in the bark, and dried by the heat of the fun; and thus conftituting a body that is partly gummous, and, as fuch, tenacious, and foluble in water; and partly refinous, and therefore friable, and foluble in oil, or fpirit of wine, but not in water.

Botanifts are now generally agreed, that all plants are furnifhed with organs and parts neceffary both for chylification and fanguification; that they have veins, arteries, heart, lungs, adipofe, cellules, &c. If fo, it is obvious, that there muft be fome difference between the juices, which have not undergone the action of thofe parts, and fuch as have already circulated a number of times.

The feveral juices, hitherto recounted, are the firft or nutritious juice, called alfo the chyle of the plant, under fuch alterations, and new modifications, as it undergoes in being received, and kept fome time, in parts of a peculiar ftructure; as leaves, flowers, feed, &c. This laft juice, called the blood, is the fame nutritious juice farther altered, by being divers times paffed through each of thofe parts, and remixed, and at length converted into a new juice, with properties different from any of them all.

To prove the circulation of the fap, inftances are brought from experiments made by Mr. Fairchild; as, his budding or inoculating of a paffion-tree, whofe leaves are fpotted with yellow, into one of that fort of paffion-tree whofe leaves are plain: for though, the buds did not take, yet, after it had been budded a fortnight, the yellow fpots began to fhew themfelves about three feet above the inoculation; and, in a little time after that, the yellow fpots appeared on a fhoot, which came out of the ground from another part of the plant; which has been accounted a plain proof of the fap's circulation.

Another inftance is, a fecond experiment of the fame perfon, who grafted the ever-green oak, or ilex, upon the common oak. The leaves of the common oak, which was the ftock, decayed, and fell off, at the ufual feafon of the year; but the ever-green oak, which was the cyon grafted upon it, held its leaves, and continued fhooting in the winter. From whence it is concluded, that, when trees drop their leaves, the fap keeps full in motion, and is not gone into the root, as fome perfons think.

There are alfo other experiments of the fame perfon, which were fhewn before the Royal Society; as the New-England cedar, or rather juniper, grafted on the Virginian: and what is taken to prove the circulation in it, is, the branch which was grafted was left feveral inches below the grafting; which continued growing as well as the upper-part above the grafting.

And alfo another, which is the viburnum, with the top planted in the ground, which was become roots; and the roots turned up, which were become branches: which plant was in as good a ftate of growing, as it was in its natural ftate.

A third experiment of his was on a pear-tree, which he inarched upon two pear-ftocks, in March 1721-2, having the roots out of the ground; and was in a good flourifhing ftate, with a branch in bloffom, that receives no other nourifhment but by the juices that return down the other two branches; which, though it had been done above two years, yet it continued fhooting fuckers out of the root; which is efteemed as a proof, that the branches are as ufeful to fupport the roots, as the roots the branches: and thence he infers, that it is not ftrange, that fo many trees mifcarry in planting, when there are no branches left to the head to maintain the circulation to the roots.

A fourth experiment he made on the cedar of Lebanon, grafted on the larix, which dropped its leaves in the winter, yet maintained the cedar in a flourifhing condition, as if it had been on a tree which held its leaves all the winter; and the circulation of juices fupported the graft below the grafting, and kept it in as good health as above the grafting.

In oppofition to the notion of the circulation of the fap in trees like to that in animal bodies, the Rev. Dr. Hales, in his excellent treatife on Vegetable Statics, prefents us with various experiments, and fays:

When the fap has firft paffed through that thick and fine ftrainer, the bark of the root, we then find it in greateft quantities in the moft lax part, between the bark and wood, and that the fame through the whole tree.

And if, early in the fpring, the oak, and feveral other trees, were to be examined near the top and bottom, when the fap firft begins to move, fo as to make the bark run, and eafily peel off, he believes it would be found, that the low bark is firft moiftened; whereas the bark of the top branches ought firft to be moiftened, if the fap defcends by the bark. As to the vine, he fays, he is pretty well affured, that the lower bark is firft moiftened.

He adds, that it is to be feen in many of the examples of the experiments he has given in that book, what quantities of moifture trees daily imbibe and perfpire: now the celerity of the fap muft be very great, if that quantity of moifture muft moft of it afcend to the top of the tree, then defcend, and afcend again, before it is carried off by perfpiration.

The defect of a circulation in vegetables feems, in fome meafure, to be fupplied by the much greater quantity of liquor, which the vegetable takes in, than the animal, whereby its motion is accelerated: for, by the firft example he gives, we find the funflower, bulk for bulk, imbibes and perfpires feventeen times more frefh liquor than a man every twenty-four hours.

Befides, nature's great aim in vegetables being only, that the vegetable life be carried on and maintained, there was no occafion to give its fap the rapid motion which was neceffary for the blood of animals.

In animals, it is the heart which fets the blood in motion, and makes it continually circulate: but in vegetables we can difcover no other caufe of the fap's motion, but the ftrong attraction of the capillary fap-veffels, affifted by the brifk undulation and vibration caufed by the fun's warmth; whereby the fap is carried up to the top of the talleft trees, and is there perfpired off through the leaves: but, when the furface of the tree is greatly diminifhed by the

the loſs of its leaves, then alſo the perſpiration and motion of the ſap are proportionably diminiſhed; as is plain from many of his experiments.

So that the aſcending velocity of the ſap is principally accelerated by the plentiful perſpiration of the leaves, thereby making room for the fine capillary veſſels to exert their vaſtly attracting power; which perſpiration is effected by the briſk rarefying vibrations of warmth; a power that does not ſeem to be any-ways well adapted to make the ſap deſcend from the tops of vegetables, by different veſſels, to the root.

If the ſap circulated, it muſt needs have been ſeen deſcending from the upper part of large gaſhes, cut in branches ſet in water, and with columns of water preſſing on their bottoms in long glaſs tubes, in his forty-third and forty-fourth experiments. In both which caſes it is certain, that great quantities of water paſſed through the ſtem; ſo that it muſt needs have been ſeen deſcending, if the return of the ſap downwards were by truſion or pulſion, whereby the blood in animals is returned through the veins to the heart; and that pulſion, if there were any, muſt neceſſarily be exerted with prodigious force, to be able to drive the ſap through the finer capillaries.

So that, if there be a return of the ſap downwards, it muſt be by attraction, and that a very powerful one, as may be ſeen by many of theſe experiments, and particularly by experiment the eleventh. But it is hard to conceive what and where that power is, which can be equivalent to that proviſion nature has made for the aſcent of the ſap, in conſequence of the great perſpiration of the leaves.

The inſtances of the jaſmine-tree, and of the paſſion-tree, have been looked upon as proofs of the circulation of the ſap; becauſe their branches which were far below the inoculated bud, were gilded. But we have many viſible proofs in the vine, and other bleeding trees, of the ſap's receding back, and puſhing forwards alternately, at different times of the day and night; and there is great reaſon to think, that the ſap of all other trees has ſuch an alternate receding and progreſſive motion, occaſioned by the alternacies of day and night, warm and cold, moiſt and dry.

For the ſap in all vegetables does probably recede, in ſome meaſure, from the tops of branches, as the ſun leaves them; becauſe, its rarefying power then ceaſing, the greatly rarefied ſap and air mixed with it will condenſe, and take up leſs room than they did, and the dew and rain will then be ſtrongly imbibed by the leaves, as is probable from the forty-ſecond experiment, and ſeveral others; whereby the body and branches of the vegetable, which have been much exhauſted by the great evaporation of the day, may, at night, imbibe ſap and dew from the leaves.

For, by ſeveral experiments in the firſt chapter of the book of Vegetable Statics, plants were found to increaſe conſiderably in weight in dewy and moiſt nights.

And by other experiments on the vine, in the third chapter, it was found, that the trunk and branches of vines were always in an imbibing ſtate, cauſed by the great perſpiration of the leaves, except in the bleeding ſeaſon; but, when at night the perſpiring power ceaſes, then the contrary imbibing power will prevail, and draw the ſap and dew from the leaves, as well as moiſture from the roots.

And we have a further proof of this in the twelfth experiment, where, by fixing mercurial gauges to the ſtems of ſeveral trees which do not bleed, it is found that they are always in a ſtrongly imbibing ſtate, by drawing up the mercury ſeveral inches; whence it is eaſy to conceive, how ſome of the particles of the gilded bud in the inoculated jaſmine may be abſorbed by it, and thereby communicate their gilding miaſma to the ſap of the other branches; eſpecially when, ſome months after the inoculation, the ſtock of the inoculated jaſmine is cut off a little above the bud, whereby the ſtock, which was the counter-acting part to the ſtem, being taken away, the ſtem attracts more vigorouſly from the bud.

Another argument for the circulation of the ſap is, that ſome ſorts of grafts will infect and canker the ſtocks they are grafted on; but by the twelfth and thirty-ſeventh experiments, where mercurial gauges were fixed to freſh-cut ſtems of trees, it is evident, that thoſe ſtems were in a ſtrongly imbibing ſtate; and, conſequently, the cankered ſtock might very likely draw ſap from the graft, as well as the graft alternately from the ſtock; juſt in the ſame manner as leaves and branches do from each other in the viciſſitudes of day and night.

And this imbibing power of the ſtock is ſo great, where only ſome of the branches of the ſtock will, by their ſtrong attraction, ſtarve thoſe grafts; for which reaſon, it is uſual to cut off the greateſt part of the branches of the ſtock, leaving only a few ſmall ones to draw up the ſap.

The inſtance of the ilex grafted upon the Engliſh oak ſeems to afford a very conſiderable argument againſt a circulation, for, if there were a free uniform circulation of the ſap through the oak and ilex, why ſhould the leaves of the oak fall in winter, and not thoſe of the ilex?

Another argument againſt an uniform circulation of the ſap in trees, as in animals, may be drawn from Dr. Hales's thirty-ſeventh experiment; viz. where it was found, by three mercurial gauges, fixed to the ſame vine, that, while ſome of its branches changes their ſtate of protruding ſap into a ſtate of imbibing, others continued protruding ſap, one nine, and the other thirteen days longer.

That the ſap does not deſcend between the bark and the wood, as the favourers of a circulation ſuppoſe, ſeems evident from hence, viz. that, if the bark be taken off for three or four inches breadth quite round, the bleeding of the tree above that bared place will much abate; which ought to have the contrary effect, by intercepting the courſe of the refluent ſap, if the ſap deſcended by the bark.

But the reaſon of the abatement of the bleeding, in this caſe, may be well accounted for, from the manifeſt proof we have in theſe experiments, that the ſap is ſtrongly attracted upwards by the various operation of the perſpiring leaves and attracting capillaries; but, when the bark is cut off for ſome breadth below the bleeding place, then the ſap which is between the bark and the wood below that diſbarked place is deprived of the ſtrong attracting power of the leaves, &c. and conſequently the bleeding wound cannot be ſupplied ſo faſt with ſap, as it was before the bark was taken off.

But the moſt conſiderable objection againſt this progreſſive motion of the ſap, without a circulation, ariſes from hence, viz. that it is too precipitate a courſe for a due digeſtion of the ſap, in order to nutrition: whereas in animals nature has provided that many parts of the blood ſhall run a long courſe before they are either applied to nutrition, or diſcharged from the animal.

But when we conſider that the great work of nutrition in vegetables, as well as animals (we mean after the nutriment is got into the veins and arteries of animals) is chiefly carried on in the fine capillary veſſels, where nature ſelects and combines, as ſhall beſt ſuit her different purpoſes, the ſeveral mutually attracting nutritious particles, which were hitherto kept disjoined by the motion of their fluid vehicle; we ſhall find, that nature has made an abundant proviſion for this work in the ſtructure of vegetables: all whoſe compoſition is made up of nothing elſe but innumerable fine capillary veſſels, and glandulous portions or veſicles.

Upon the whole, he thinks we have, from theſe experiments and obſervations, ſufficient ground to believe, that there is no circulation of the ſap in vegetables; notwithſtanding many ingenious perſons have been induced to think there was, from ſeveral curious obſervations and experiments, which evidently prove, that the ſap does, in ſome meaſure, recede from the top, towards the lower part of plants; whence they were, with good probability of reaſon, induced to think, that the ſap circulated.

SAVORY, a plant much cultivated in the kitchen-garden, and is of two ſorts, viz. ſummer and winter ſavory, the uſes of both which are nearly the ſame.

The former is an annual plant, raiſed only from its ſeed, which ſhould be ſown in the beginning of April, in a bed of looſe and light earth. If the plants are not intended to be removed, their ſeeds ſhould be ſcattered thinly; but if they are to be tranſplanted, they may be ſown thicker. They muſt be kept clear from weeds, and are, in other respects, to be treated as before directed for marjoram.

Winter savory may be propagated from seeds sown at the same time as those of the summer sort; or by slips off its roots, for these are perennial, and will last several years: but as they do not put forth equally tender or well furnished shoots after they are grown old, the best way is to raise a supply of young plants every other year. The slips of the winter savory will soon take root and flourish; and they, as well as the plants of this species raised from seed, will endure the greatest cold of our winters, and have the most aromatic smell and taste, when they are planted in a poor and dry soil. Wet ground is very apt to render them mouldy, and consequently make them rot. Mr. Miller has noticed some of these plants growing upon the top of an old wall, where they were fully exposed to the cold, and they there survived such severe frost as killed most of those of the same kind that were planted in the ground.

The winter savory flowers in June, and the summer savory in July; but the seed of both ripen in the autumn, and at no great distance of time from each other.

SCAB, a disease incident to sheep, chiefly occasioned by a tedious length of wet weather

"I imagine, says Mr. Vesey, your readers will not be displeased if I should, with your assistance, communicate to them a remedy for this disorder, which I have several times tried, and almost always found to answer extremely well.

"Some men, whom I have known to breed and feed a great number of sheep, have been grossly mistaken in their comprehension of the nature of this distemper, which they rashly judged to be merely cutaneous; whereas, when a sheep has the scab, the blood is always more or less affected by it: therefore the outward applications, which are in general alone resorted to for a cure, do for the most part more hurt than good, by driving in the eruption, and making it fix on the internals, thereby often occasioning the death of the animal.

"Now the true way to treat this disorder is, first to give the animal something inwardly to drive out the eruption; then comes, with propriety, the outward application, which completes the cure by killing the scab.

"When a farmer has any of his flock afflicted with the scab, let him attend to the directions which follow.

"Take a gallon of soft well or pond water, which divide into two equal parts: in one of these parts dissolve eight ounces of old hard soap; to which, when it is dissolved, add two ounces of spirits of hartshorn, and seven ounces of common salt, with four ounces of roll brimstone, beat to a fine powder and sifted: then take the other part of the water, in which put two ounces of tobacco leaf, and one of white hellebore root: boil this second part till you have a strong infusion, after which strain it clear from the leaves and roots.

"When you have got thus far in the process, take that part of the water, first mentioned, and set it over the fire; let it boil for about half an hour, keeping it continually stirring with a wooden ladle during that time: in the mean time heat again the other part, in which the tobacco and hellebore were infused; and when it is hot, mix the two parts gradually together over the fire, keeping the mixture continually stirring till it is taken off the fire, which should be in about a quarter of an hour: when it is quite cold, let it be put into a stone bottle, in order to its being kept in a cool place for use.

"Then take four quarts of new ale or beer: put into it twelve ounces of common salt, two ounces of bay salt, and eight ounces of pounded nitre, together with twelve ounces of pounded roll brimstone: set them over a gentle fire, and when the ale boils, take off the scum; let it boil for about half an hour; after which set it by till it is cold, and put it into a stone bottle for use.

"When you are so far prepared, take one quart of ale, set it on the fire; mix into it by degrees, three ounces of flour of brimstone; when it is just ready to boil take it off the fire, and let it stand to cool; and when it is only blood-warm, give this quantity inwardly to three sheep, which is to be repeated every second day till they have had three doses. This will drive out the disorder, when the first mixture is to be rubbed on the distempered parts: and two days afterwards the second, and so alternately for about eight or ten days, till the cure is effected: sometimes two rubbings will be sufficient.

"I must observe, that all these mixtures will be best boiled in well-glazed earthen or iron pots." *Museum Rusticum, vol.* II. *pag.* 173.

"The two greatest enemies the sheep, says another ingenious gentleman, or at least their wool (which is the most valuable part of them) have, are the scab and fly. I believe they destroy more wool than all the other diseases incident to that animal.

"Mr. Vesey has given us an approved remedy for the scab, and at the same time enters somewhat into the nature of that distemper. For my own part, I have not presumption enough to look into first causes; secondary ones are all I aim at: I always took nature to be a wise instructor, and the surest guide; but if we will hobble out of the way ourselves, she is not to blame.

"I agree with Mr. Vesey, that in this, and every other distemper a sheep labours under, the blood is more or less affected and disturbed; which disturbance, if I am not mistaken, the faculty call a fever; therefore it must be always considered, that a fever is no more than a struggle of nature to get rid of some enemy in the blood, by throwing it out by some of the outlets of the body, namely, by sweat, urine, or stool; or upon the surface of the skin; and then she seems to say, I have thrown the distemper out to your view, and there destroy it by proper applications.

"It surely is not scab until it is thrown out upon the skin; and when it is thrown out, what avails it giving internal remedies, to do that which nature has done before? If it be out, there's your ailment; and I think, gentlemen, it is an axiom in physic, that when a distemper is once known, it is half cured: if it is only coming out, my advice would be, not to disturb nature, who is always acting for our good, in a wiser and better manner than we can do ourselves: she sometimes indeed is too weak for her office, and sometimes too strong; in the one case she is to be properly assisted, and in the other, prudently restrained; and when we do more or less, the effects are generally fatal. I hope this will satisfy Mr. Vesey, that he is not altogether in the right, any more than his neighbours.

"To cure an illness with a few medicines, is as commendable, as to say a great deal in a few words. One great obstacle to Mr. Vesey's treatment of sheep with scab, is its being too compound, troublesome, and laborious, setting aside the expence, and, where there are a great number of sheep, hardly to be practised. I would have all remedies for the ailments of sheep be as simple as possible; and to be obtained and prepared with as little trouble; for certain I am, gentlemen, when it is otherwise, many will let their flocks go neglected, or at best leave them to a slovenly shepherd, who knows very little of the matter; and when clip-day comes, when the poor creatures are out of their wool, (if they had any on before) what a sight presents itself to view! most parts of their skins being one continued scab, and other parts eat quite through, and deep into the flesh, by the maggot: this I have seen at clip-day, and may speak it; but what must I alledge it was owing to? Sorry am I to say, to the over credulity of the master, who thought he had a shepherd who knew every thing; but the event proved the contrary.

"You must not be surprised when I say, what will destroy the fly, will also cure the scab, with little or no alterations: mercury is a mortal foe to both; and the remedy for the fly is as follows.

"Take of good corrosive sublimate, half an ounce; dissolve it in two quarts of rain water; to which add a gill of spirits of turpentine: this is the whole of it, which must be used in the following manner.

"When the sheep is struck, the shepherd must make a circle round the maggots with some of the water, by dropping it out of a bottle: this prevents them getting away, for they will not come near the water: then he must shred or open the wool within the circle, and drop a few drops of the water amongst them, and rub them about with his finger, and there leave them, for they will all die presently.

"I ſpeak this from my own certain knowledge, and many others in this part of the country (Iſle of Ely) can do the ſame.

"To a quart of the above water I add a pint of the ſimple lime-water of the London diſpenſatory; and I declare it from experience, there is no more certain cure for the ſcab than it: I am ſure it is the cleaneſt, the ſooneſt prepared, and, when ſo, the cheapeſt; which are inducements, I think, ſufficient to have every countryman make uſe of it." *Muſeum Ruſticum, vol.* II. *pag.* 369.

SCABIOUS, the name of a flowering ſhrub cultivated in moſt pleaſure gardens.

All the ſhrubby ſorts of ſcabious may be propagated by cuttings, which may be taken off during any of the ſummer-months, and ſhould be planted in a ſhady border, and duly watered in dry weather, which will promote their taking root; and then they may be potted, and placed in a ſhady ſituation, till they have taken new root, after which time they may be placed amongſt other hardy exotic plants, in a ſheltered ſituation, where they may remain until the end of October, when they muſt be moved into ſhelter. In ſome favourable ſeaſons theſe plants will produce good ſeeds in England, ſo that the plants may be raiſed from theſe, by ſowing them in an open border of light earth about the middle of March; and, if the ſpring ſhould prove very dry, it will be neceſſary to water the ground now-and-then, which will forward the vegetation of the ſeed; ſo that the plants will appear in about three weeks after the ſeeds are ſown. When they come up, they muſt be kept clear from weeds, and in dry weather duly watered; and, when they are ſtrong enough to tranſplant, they ſhould be planted in pots, and managed in the ſame manner as thoſe plants which are propagated by cuttings.

All the ſorts of ſcabious continue a long time in flower, for which they are regarded; for there is no very great beauty in many of their flowers: but, as moſt of the hardy ſorts produce flowers near three months ſucceſſively, ſo they may be allowed a place in the borders of large gardens, becauſe they require very little care to cultivate them. And as the ſhrubby kinds continue in flower moſt part of the year, ſo they make an agreeable variety amongſt hardy exotic plants in the winter. *Miller's Gard. Dict.*

SCALLIONS. *See the article* ESCALLIONS.

SCRATCHES, a diſtemper incident to the heels of horſes.

It has ſo much affinity with the greaſe, and is ſo often a concomitant of that diſeaſe, that the method of curing the ſcratches may be ſelected from that article.

The parts affected ſhould be firſt covered with the linſeed and turnep poultice, having a little common turpentine added to relax the veſſels; the green ointment may then be applied to promote the diſcharge, when the ſcratches may be dried up with the ointments and waſhes recommended in that article. *See* GREASE.

It is beſt afterwards to keep the heels ſupple, and ſoftened with curriers dubbing, which is made of oil and tallow. This will keep the hide from cracking, and be as good a preſervative as it is to leather; and by uſing it often before exerciſe, will prevent the ſcratches, if care is taken to waſh the heels with warm water, when the horſe comes in. When they prove obſtinate, and the ſores are deep, uſe the following; but if any cavities or hollow places are formed, they ſhould firſt be laid open, for no foundation can be laid for healing, till you can dreſs to the bottom.

> Take Venice turpentine four ounces, quickſilver one ounce; incorporate well together by rubbing ſome time, and then add honey and ſheeps ſuet, of each two ounces.

Anoint with this once or twice a day; and if the horſe is full or fleſhy, you muſt bleed and purge; and if the blood is in a bad ſtate, the alteratives muſt be given to rectify it. *Bartlet's Farriery, page* 294.

SCYTHE, SITHE, *or* SYTHE, the inſtrument uſed in mowing, being a crooked blade joined at right-angles to a long pole. *See the article* MOWING.

SEAGRIM. *See* RAGWORT.

SEAM, tallow, greaſe, hogs-lard.

SEAM *of Corn*, a quarter, or eight buſhels.

SEAM *of Wood*, a horſe load of wood.

SEAR, dry; oppoſed to green: ſpoken of wood.

SEARCHER. *See the article* BORER.

SEAVES, ruſhes.

SEAVY *Ground*, ground over-run with ruſhes.

SEED, the product of a plant, whereby the ſpecies is propagated.

The choice of the ſeed intended to be ſowed is an object of greater importance than many farmers ſeem to imagine. It is not ſufficient that the fineſt grains be choſen for this purpoſe, unleſs they are likewiſe very clean. Such wheat is not difficult to be had from land cultivated according to the principles of the new huſbandry; but we ſeldom find corn intirely free from ſeeds of weeds when it has been raiſed in the common way.

It is natural to ſuppoſe, that the grains of ſtinted and ſickly corn neceſſarily partake of the weakly diſpoſition of the plant which produced them, and that their productions cannot be ſo fine as thoſe which grow from the ſeeds of ſtrong and healthy plants. For this reaſon Mr. Tull adviſes to take the ſeed corn from a richer ſoil than that in which it is to be ſowed, and rather from ground in perfect tilth, than from land which has been leſs carefully cultivated. This ſeems to be very right (though the contrary opinion is almoſt generally received), becauſe more may reaſonably be expected from the productions of a fine good ſeed, which are full of vigour and well conditioned, than from a poor weak plant.

M. de Chateauvieux, who often ſowed with no other intention than merely to try, for the benefit of mankind, at what time, in what manner, and in what condition it is beſt to ſow wheat, found that this corn ſprouted pretty well even when ſowed ſo green that it had not yet loſt its milky quality; but thinks it much more adviſeable to ſow none but what is thoroughly ripe: becauſe the ſeed has then attained its full perfection, from whence we may moſt certainly expect the beſt and ſtrongeſt plants.

"The wheat, ſays he, which has been reaped in a warm dry year, ſeems to me fitter for ſowing, than that which has been gathered in a cold wet ſeaſon: for in ſuch a time as this laſt, all the productions of the earth are leſs good; their taſte is leſs ſavoury; and as that corn in particular in which there is moſt moiſture, is moſt difficult to keep, I infer from thence that the formation of its grain muſt be leſs perfect. I ſhould therefore prefer wheat a year old, provided the year it was gathered in was warm and dry, to that which may have juſt been gathered in too rainy a ſeaſon: for the ſame reaſon, I always chooſe for ſowing, wheat of the growth of my high grounds, rather than that which has been produced in flats. The benefit accruing from all this care, may, perhaps, not be extremely great; but at the ſame time it does not coſt any thing. Let us do in agriculture what is done in all manufactures, where the very ſmalleſt profits, the very leaſt ſavings, are not neglected. Thoſe ſmall articles, often repeated, make large ſums in the long run, and are a real gain.

"Another thing, of greater conſequence, firſt made known to me by chance, but ſince confirmed by repeated experiments, always attended with the ſame ſucceſs, I ſtrongly recommend as extremely ſerviceable to the firſt ſprouting of the ſeed. In my experimental ſowings, I commonly uſed wheat taken from the heap in the granary; and likewiſe, frequently, corn picked out of the ears the moment before I ſowed it. I counted exactly the grains of both ſorts, and ſuppoſe that few will think there could be any difference in their productions. Yet I found a conſiderable one. What was picked out of the ears always roſe extremely well; ſcarce a grain of it ever miſſed; whereas numbers of thoſe which were taken from the heap, never ſprouted at all. I did not perceive this difference at firſt; but at laſt it ſtruck me. I relate the fact as it is, without pretending to account for the cauſe of this difference, which would lead me into too long a digreſſion. The experiment itſelf may be of real uſe, by ſhewing us, that inſtead of threſhing the wheat intended for ſeed at any time, without diſtinction, it ought not to be threſhed till a very few days, at moſt two or three, before it is ſowed. A few hands will be able to ſupply the ſeeds-men with as much as they will want: nor will this method, which may be a means of ſaving ſomewhat in the ſeed, be attended with any extraordinary expence.

"Perhaps,

"Perhaps too this practice may be attended with a very valuable advantage. I have not indeed yet made the trials neceffary to fatisfy myfelf of what I imagine; but my defire to be of fervice to the public induces me to mention it, that the lovers of agriculture may reflect upon it, and try fuch experiments as will clear up my conjectures.

"Threfhing the feed only juft before it is fowed may poffibly, in fome meafure, or perhaps intirely, prevent the caufe of fmut in wheat. By this I mean, that the feed which has not been mixed with fmutty corn, or any way infected by its black powder, will be exempt from that diftemper. Not that I take black powder to be abfolutely the original caufe of this diftemper in corn; but I believe it is very capable of communicating it to grains which are found.

"That nothing may be neglected which can be of any fervice to the feed, great care ought to be taken in threfhing the corn, efpecially in the manner that bufinefs is commonly performed, with flails, upon the barn floor: for a great number of grains are frequently fo much bruifed thereby, that it is impoffible they fhould ever grow. If the wheat thus threfhed for feed is not thoroughly dry and hard, the mifchief is ftill greater; much more of it being then abfolutely crufhed by the flail.

"As fowing in drills requires lefs feed than is ufed in the common method, it will be the eafier to execute there an operation which might be too long and troublefome for fo great a quantity as is ufed in the old way. The method which I advife, and which I have practifed, is this. Let one or two beams, two feet and a half, or three feet thick, be laid a-crofs the barn floor: let the threfhers ftand on each fide of the beam, and take out of loofe fheafs of wheat, one of which fhould be placed behind every man, a handful at a time, and give it two or three ftrokes againft the beam. This will bring out a great deal of grain, which is to be referved for feed. The ears thus fhaken may be bundled up again, and afterwards threfhed out with the flail, for other ufes. This method is not fo tedious as fome may imagine: we are fure that not a grain is bruifed; and thofe are the moft perfect which drop out thus. I think I may compare this operation with what is done in the making of wine, where the firft running is always the higheft flavoured and beft.

Another excellent way to feparate the fulleft, and confequently heavieft grains, which are undoubtedly the fitteft for feed, from thofe which are of lefs value for that purpofe, and at the fame time to clear them from many feeds of weeds, is, to make a ftout man, with a broad wooden fhovel, throw the corn with all his force towards an oppofite corner of the barn, or rather of a large boarded hall, which generally is the fitteft for this work. All the light, fmall, fhrivelled grain, unfit for fowing, and the feeds of cockle, darnel, &c. not being fo heavy as the found folid corn, will fall fhort, and lie neareft to the man who throws them; while fuch as are large, plump, and weighty, out-flying all the reft, are feparated widely, and may eafily be gathered up. Experience will fhew the vaft advantages of fowing feed thus chofen.

The ufe of fteeps was introduced very early into hufbandry, not only as a means of preferving corn from feveral diftempers to which it is fubject, but alfo with a view to render the feed more fruitful. That fome of them have fometimes anfwered the former of thefe intentions is undeniable: but with regard to the latter, much ftronger and oftener repeated evidences than any that have yet been produced, are ftill wanted to confirm their boafted efficacy. I fhall however, give a concife account of fome of the moft famous of both kinds; with this previous obfervation, that even fuch of them as have not fucceeded in fome cafes, through caufes perhaps unknown to us, may poffibly do well in others, when tried with proper judgment, and attention. Experiments of this kind fhould by all means be continued on a double account; firft, to take off a prejudice which feems to gain ground, though it be not founded on any rational principle; and next, to be well affured whether thefe preparations do, or do not, produce any fenfible effect. Experiments feldom prove ufelefs to careful accurate obfervers. If they do not always anfwer the end propofed, they at leaft fometimes lead the way to other important difcoveries.

The Romans had their lees of oil, decoction of cyprefs leaves, juice of houfe-leek, &c. on which they have beftowed full as much commendation as they merit. Lord Bacon feems to have been the firft who paid any attention to this fubject in England: but he has only pointed out the path to others: nor do I know any author who has yet given us a fet of experiments with this view, long enough continued abfolutely to determine what effects fome kind of fteeps may have towards rendering grain more fruitful.

Van Helmont, and, fince him, the authors of the Maifons Ruftiques, have given many receipts for fteeps, which they vaunt exceedingly, as increafing the fruitfulnefs of the feed fteeped in them. But at the fame time that they recommend thefe receipts, they advife fowing the corn thinner than ufual; generally one third lefs; a circumftance which, alone, will add greatly to the crop, as very many experiments, and particularly all the good trials of the new hufbandry, have evidently demonftrated. That the comparifon may be juft, all circumftances fhould be alike, as to the goodnefs of the foil, the quantity and quality of the feed, &c.

M. Duhamel, to fatisfy himfelf whether any benefit does arife from the ufe of fteeps, by way of giving the feed a greater degree of fruitfulnefs, tried the following experiment. He infufed fome good wheat in a lye of dung, mixed with lixivial falts, nitre, and fal ammoniac, and fowed with this grain two beds in his kitchen garden, dug with a fpade. One of the beds was fowed very thick, and the other very thin. At the fame time he fowed two other beds, exactly like the former, with fome of the fame feed, not fteeped, one thick, and the other thin. At harveft time, the beds fowed with the fteeped feed were fo exactly like the others, that it was impoffible for the eye to diftinguifh between them.

A gentleman in his neighbourhood followed exactly the directions given in the Maifons Ruftiques, in the ufe of one of their boafted receipts, which is there faid to be of fuch efficacy, that the land need be plowed but once for wheat prepared with it. He did fo; and his crop was fcarce worth reaping.

On the other hand, M. Duhamel mentions his being informed by M. Peyrol, many years fecretary to the intendent of Auvergne, that he had made feveral experiments in imitation of thofe mentioned in the abbé de Vallemont's famous book. In the month of May 1755, he planted in his garden (an indifferent foil, in a hot expofition,) four fmall cabbages, which then had only four leaves. In September following, the fame cabbages were fix feet and a half in circumference. Some plants of red wheat, tranfplanted into a bed dug very fine in his garden, bore one hundred and thirty ears a piece, each of which contained from forty to eighty grains. Some plants of white wheat, tranfplanted at the fame time, produced one hundred and twenty ears, each of which had from thirty to forty grains. Two grains of red wheat, fowed in the fame bed, and not tranfplanted, produced each of them one hundred and forty ears, which contained fix thoufand grains. Five plants of red wheat, diftant from one another fix inches, did not branch fo well, being too clofe together: but each of them produced from forty to fifty ears, which contained from forty to fixty grains. Rye, which branches lefs than wheat, produced from thirty to thirty-five ears, each containing from fixty to feventy grains: and the barley of that country, which branches but little, produced however from fixty to eighty ftalks, though the feed of this laft had not been fteeped in any liquor before it was fowed.

The author of thefe experiments judicioufly obferves, that they muft be repeated and varied, before it can be made to appear that the extraordinary increafe is owing to the fteep.

This celebrated liquor of the abbé de Vallemont is made as follows.

Put into a tub, expofed to the fouth, one bufhel of horfe-dung, the fame quantity of cow-dung, half a bufhel of pigeon's-dung, as much fheep's-dung, as much afhes, three gallons of fmall pricked wine, two pounds of faltpetre, and as much water as will fufficiently dilute the whole, fo as to make it thin enough for ufe. Every time that

that any of this liquor is taken out to ſprinkle the plants, it is filled up again with water; and as it may be too ſtrong at firſt, it may be weakened accordingly.

It is eſſential to obſerve, that M. Peyrol added to this infuſion frequent digging; for the ground was dug five times between the plants of wheat: and he obſerved that each digging ſenſibly gave freſh vigour to the plants, which grew to the height of ſix feet.

M. Donat, another of M. Duhamel's judicious correſpondents, made trials of theſe mixtures, from the uſe of which ſo much is promiſed: but ſays he thinks them of no other ſervice, than to amuſe the curious, who do not regret expence. As the authors of them boaſt that all kinds of ſoils, whether good, bad, or indiffrent, well or ill plowed, reſted or not reſted, will produce ten times more than in the common way; this gentleman ſowed a large extent of ground, ſome good, ſome bad, ſome well, and ſome ill plowed, &c. He made the ſteep himſelf, was preſent when the ſeed was ſowed, and took care that no circumſtance was neglected. But notwithſtanding all his care, his crop was far from anſwering their promiſes. The good, well cultivated ſoil, produced fine wheat; but not extraordinary in point of quantity. The only advantage was in the ſaving of the ſeed. The poor ill cultivated land, and that which had not been reſted, produced very little grain: and the very bad ſoil, none at all. Theſe experiments convinced M. Donat, that the ſureſt means of obtaining good crops, is, to have the ground in good condition. This is the principle on which the new huſbandry is founded: nor indeed does it offer any thing marvelous, or contrary to the moſt ancient precepts of good huſbandry.

If there be in any of theſe ſteeps, or preparations, a more than common virtue, by which the grain infuſed in them is rendered more prolific than it would otherwiſe be, poſſibly ſome ſuch benefit may accrue from the following practice, which is recommended by the author of the New Syſtem of Agriculture.

"Take, ſays he, the corn which is intended for ſowing, and throw it, by a buſhel at a time, into a large veſſel full of water: let a man ſtir it with a ſtaff, as violently as he can, for a conſiderable while together, and then, giving it a little time to ſettle, ſkim off all that ſwims upon the ſurface: repeat this till no more riſes; then take out the corn which has ſunk to the bottom, and lay it by for ſeed; proceeding in the ſame manner till you have your intended quantity. After this, make a brine of bay-ſalt and rain-water, ſtrong enough to bear an egg. Steep the ſeed corn in this liquor during thirty hours; for leſs time will not have any effect: then take it out, ſpread it upon a ſmooth floor, ſtrew over it a good quantity of fine-ground powder of flaked lime, and ſweep the whole up and down till each grain leaves clinging to another, and becomes, as it were, perfectly candied with the lime. It is then fit for ſowing; and will infallibly produce a very abundant crop." Some farmers vary this ſteep, by adding to it a mixture of pigeons, or other dung; and in moſt parts of France, where this receipt is known, they omit the ſalt; perhaps becauſe it is too dear in that country, and ſteep the wheat in lime-water. For this purpoſe they put it into baſkets, and carefully ſkim off all that ſwims on the top, moſt of which would not ſprout, and is only fit to feed fowls.

The ſociety of improvers in the knowledge of agriculture in Scotland, call the following a very promiſing receipt for multiplying corn: but as no experiment that we know of, duly attended to, has yet confirmed that ſurmiſe, we can only ſay, that it may not be wrong to give it ſuch farther trials as will not hurt the experimentor, whether they do or do not ſucceed: a rule which ſhould be conſtantly obſerved in all experiments.

"Take as much water as will fully cover the quantity of grain you intend to uſe; add thereto a reaſonable quantity of a mixture of horſe, cow, and ſuch other dung as you can conveniently get, ſo as not to make the water too thick: add likewiſe for every boll (four buſhels) you are to ſteep, about a peck or ſixteenth part of the ſame ſort of grain as you are to ſteep. Boil all theſe till the grain is reduced to a pulp; keeping the kettle or cauldron cloſe covered, to retain the ſteam. When the boiling is over, pour off the water, and diſſolve in it a pound of nitre, or ſalt petre, to every four buſhels of corn: then, while it is luke-warm infuſe your corn for three days, after which, drain off the water, ſpread the grain on the floor, mix it with a ſufficient quantity of ſea-ſand, (if ſuch can be conveniently had), and laſtly, with lime, to dry it, as is uſually done in other caſes."

"It ſeems reaſonable to think," ſay the abovementioned ſociety, "that nothing can be more natural for impregnating grain, than the ſtrength and eſſence of itſelf. But, ſince nitre is added, it is beſt to be cautious: for it has been found by experience, that ſalts, though they have the virtues mentioned, kill or deſtroy the vegetative powers, when the application is immoderate, either with reſpect to the quantity, or the time the grain is ſteeped; ſo that there has often been a neceſſity to ſow over again with the ſame, or ſome other grain. To make the better judgment concerning this critical affair, the nature and condition of different grains are carefully to be conſidered; but the moſt certain knowledge and direction are to be obtained by a courſe of obſervations and experience. Mean while, it is beſt to obſerve the maxim, avoid extremes."

In Mr. Houghton's collection of papers relative to huſbandry and trade, are ſeveral experiments on the ſteeping of wheat and barley in a liquor which is there ſaid to have occaſioned a very great increaſe, and is thus made. "Take a quantity of rain-water, and diſſolve in every gallon of it two pounds of ſtone-lime: let it ſtand two or three days, ſtirring it three times a day: then pour off the water into another veſſel, and add to every gallon of it about four ounces of ſalt-petre, and one pound of pigeons dung: mix them well together, by ſtirring them three or four times a day, and then ſtrain off the liquor to keep for uſe." Mr. Everard, who communicated this receipt to Mr. Houghton, ſteeped a handful of wheat in a quart of this liquor, where he let it infuſe eighteen hours: he then took it out, and laid it to dry in the air for the ſpace of one day; and then ſteeped it again in the ſame liquor for about twelve hours, dried it as before, and ſteeped it again a third time, about ſix hours, after which he planted it in his garden, which was but common earth, ſetting it by ſingle grains, about ten inches aſunder, and a finger's length in depth. He could not remember whether every grain ſprouted, but thought that very few failed. Thoſe which did grow, produced an extraordinary increaſe, ſeveral of them yielding from ſixty to ſeventy, ſome of them eighty ſtalks with very large ears full of fine plump corn: many of the ears were ſix inches long, and contained ſixty grains: none had leſs than forty.

He alſo ſteeped peas and beans in the ſame liquor; but could not ſay whether their having been ſteeped two long was the cauſe that none of them came up: but he took the thick ſediment which remained after the liquor was ſtrained off, mixed it with four times the quantity of earth, let it lie all winter in a gravel walk, ſouth of a codlin hedge, then made a row of holes, about four inches diſtant, put a handful of the mixed earth into each hole, with a pea upon it, and covered it with common mould. The peas ſprouted well, ran up the codlin hedge to the height of about nine feet, ſhot out branches in ſeveral places, like vines, and bore ſo many well filled pods, that he judged he had above a buſhel from about three or fourſcore ſeeds.

He tried alſo an experiment on wheat infuſed in lime-water alone, ſome in brandy alone, and ſome in brandy and lime-water mixed, and had a great increaſe from each grain. With ſome of the liquor made with ſalt-petre, lime, and pigeons dung, he watered ſeveral trees in his garden, and found them grow and flouriſh much faſter than any other of the ſame kind which were not watered in that manner. He alſo ſteeped barley in the ſame liquor, and found its increaſe equal to that of wheat.

Whether there be, or be not, any kind of prolific efficacy in theſe, or any other ſteeps, of which great numbers are pompouſly recommended, and which proper experiments can beſt determine; they are at leaſt ſo far ſerviceable to the ſeed corn, that they clear it from filth, from many ſeeds of weeds, and from ſuch poor light and diſtempered grains as are not fit for ſowing, and prepare it in ſuch a manner, that, being already well moiſtened, it will ſhift much better than abſolutely dry grain, in caſe a drought ſhould enſue after it is ſowed.

This thorough cleanſing of the ſeed may probably be, in a great meaſure, the reaſon why corn ſo prepared is leaſt apt to produce ſmutty ears. All the lyes generally made uſe of, certainly preſerve the plants from mouldineſs, and that in which lime is a principal ingredient ſeems to be one of the moſt effectual. But as this part naturally leads to the diſtempers of corn, another very intricate, but highly intereſting ſubject, we ſhall reſume it under that head, to which it properly belongs; and give in the mean time M. Duhamel's farther opinion concerning the pretended prolific virtues of infuſions, with ſome late experiments relative thereto, as delivered in the ſixth volume of his excellent Treatiſe on the Culture of Land, publiſhed laſt year.

We liſten readily to the marvellous, eſpecially when it promiſes any great and ſingular advantage. Such was the abbé de Vallemont's prolific liquor, by means of which the huſbandman was to reap vaſt crops, without manuring, or ſcarcely plowing his land. He was only to ſoak his ſeed in this admirable liquid, which was to open, ſtrengthen, and amazingly fertilize the germe. Improbable as this doctrine is, it was greedily received.---It is known, that a ſeed contains in that part of it which is called the germe or bud, the embryo of a plant, that is to ſay, a plant in miniature, and that the reſt of the ſeed ſerves to feed the young plant, or plantule, till it acquires roots which draw its farther nouriſhment from the earth. As ſoon as theſe roots ſpread, the ſeed is exhauſted, and there remains only its then uſeleſs huſk. What benefit then can be derived from prolific liquors? perhaps they may render the nutritive ſubſtance of the ſeed fitter to ſupport the young plant, which, in conſequence thereof, may appear ſomewhat more vigorous at firſt, and till it has ſtruck out roots: but from the time of its producing thoſe roots, it ceaſes to ſubſiſt upon the lobes of the ſeed. Can it be imagined that a ſingle atom of any prolific liquor exiſts at the diſtance of four or ſix inches from the plants in the earth, where its roots are ſpread, and from whence they draw their ſubſiſtance? Yet, ſuch is the fondneſs of men for projects of this kind, de Vallemont's mixture was extolled as a wonderful diſcovery, indued with a magnetic virtue capable of attracting from the boſom of the air certain principles, which probably do not exiſt in it, and numbers of receipts have been deviſed for making prolific liquors. Writers upon agriculture have ſtuffed their books with them, and vaunted their miraculous effects. A deſire to ſee theſe mighty promiſes fulfilled, paved the way for their reception, and ill made experiments have given a ſanction to the error.

A little corn, impregnated with theſe pratended prolific liquors, has been planted grain by grain in a garden, and its extraordinary increaſe has immediately been imputed to the ſteep. I myſelf was deceived by ſuch trials: but when I extended them to three or four acres of ground, this great fertility no longer took place, and I began to doubt the efficacy of theſe boaſted ſpecifics. About the ſame time, I ſaw a ſingle grain of barley produce 230 ſtalks, without any preparation, and was informed by the Rev. Dr. Hales, that another grain of barley had in like manner, produced one hundred and fifty-four ears. From hence I concluded, that the prodigies of vegetation ſo much vaunted by ſome writers, as the effect of their favourite infuſions, have in fact been owing to the nature of the ſoil, to good culture, and to the grains being at ſuch diſtances from each other, that their roots have had room to ſpread, and thereby collect a great quantity of food. I then had recourſe to new experiments, which confirmed me in this opinion.

We ſee in the political ſtate of England, that a grain of wheat which grew by chance in a bed of onions, and had not received any preparation, produced 5600 grains. Upon which the author of that work remarks (as indeed I had done before in regard to the former of the abovementioned productions), that we muſt not from thence infer that the country where ſuch a thing happens is naturally more fertile than another, or the method of agriculture commonly practiſed in it better than elſewhere; for that the cauſe of theſe prodigious growths is, that the grains ſtand ſingle and in a good ſoil; that the only conſequence which can be drawn from thence, is that the new huſbandry comes neareſt to that ſtate in which theſe ſurpriſing growths are produced; that it certainly muſt increaſe the product of the crops; and that it will probably require leſs ſeed than is uſed in the common way.

Though it was pretty well proved by our experiments, that good culture and proper manures contribute more effectually to the increaſe of crops, than all the boaſted prolific liquors; yet ſeveral perſons, out of zeal for the public good, have publiſhed, ſome the advantages which they think ariſe from the uſe of certain fertilizing ſteeps, and others, receipts for making them.

In this ſpirit, M. de la Jutais has given us a little tract entitled, The true Philoſopher's Stone, according to which, an admirable prolific liquor is to be thus made. Fuſe ſome nitre in an iron veſſel; and when it is hot enough to burn the ſubſtances which are to be added, throw in a ſmall quantity of the ſame kind of ſeed as you intend to ſow: for example, if you would have a prolific liquor for wheat, throw a little wheat upon the nitre; if turnips, put in turnip ſeed, and ſo on. Theſe ſeeds take fire, are conſumed, and incorporate with the melted nitre. Your prolific liquor is then made, and you have only to mix the nitre with water. What reſults from this operation? Nothing more, than that there is in this prolific liquor a great deal of nitre with a ſmall portion of fixed nitre, or alkaline ſalt: whether this nitre be fixed with wheat, barley, turnip ſeed, or powder of coal, all chymiſts allow that the reſult will be the ſame, and that the ſame liquor might be made by mixing a little alkaline ſalt with a ſtrong ſolution of ſalt-petre. The queſtion is, what effect it will have upon vegetables. To try this fairly, two exactly ſimilar fields ſhould be ſowed, the one with wheat prepared with the prolific elixir, and the other with wheat only limed in the uſual way; taking care to ſow an equal quantity in each field: for the ſingle circumſtance of diminiſhing the quantity of the ſeed, may increaſe the crops in years when the corn does not tiller much, and in good ſoils. Many have been deceived by not attending to this circumſtance. The following are well made experiments.

" M. Delu, after trying M. de la Jutais's eſſence three times, with the moſt ſcrupulous care and exactneſs, thinks it of no ſort of ſervice.

" M. Peirol, whom I mentioned before, communicated to me in 1755, ſeveral experiments which he had made with great care, in order to ſatisfy himſelf whether theſe prolific liquors have any virtue; and thoſe trials made him then hope for ſucceſs. I thanked him for his obliging letters, and exhorted him to repeat the ſame experiments with ſome new precautions which I thought important. He did ſo, with all poſſible care; and it is with real pleaſure that I ſhall give a juſt account of them, becauſe they ſeem to me extremely fit to diſſuade thoſe who wiſh well to agricultre, from putting their truſt in ſuch illuſions. Inſtead of running after an empty ſhadow, they may employ their time in uſeful perquiſitions, by which the public will be benefited.

" M. Peirol ſowed, both in his own garden, and in that of the intendant of Auvergne, 1. many-eared wheat; 2. rath-ripe barley; 3. the common red wheat of the country; and had from each of them an amazing increaſe.

" Each plant of the many-eared wheat, had from fifty to ninety-two ſtalks, and theſe laſt yielded 13800 grins.

" Some of the rath-ripe barley had two hundred and forty-four ſtalks to each plant, and yielded 14640 grains.

" Several plants of the red wheat had three hundred ſtalks; but the grains were eaten by birds.

" Theſe were fine productions: but the moſt important thing to be obſerved here, is that M. Peirol ſowed all theſe different kinds of grain, as well in his own garden, as in that of the intendant, on the ſame day, viz. the 8th of September 1756; part of this corn having been ſteeped in the abbé de Vallemont's fertilizing liquor, while the reſt had not been infuſed at all: yet their productions were quite alike, the ground had been prepared exactly in the ſame manner for the ſteeped and the un-ſteeped grain, and both were equally watered from time to time with that prolific wafh. This laft circumftance fpoils the whole experiment: for who can doubt but that this watering of the plants with impregnations of dung, muft give them great vigour; even more than a confiderable quantity of dung itfelf would have done? However, the following experiment is, luckily, without that fault.

" On the 4th of April 1755, M. Peirol divided a pretty large field into five equal parts. The ground was in good tilth, and he fowed it with barley.

" The firft part was fowed with unfteeped barley in rows a foot afunder.

" The fecond was fowed with the fame kind of barley fteeped in de Vallemont's liquor, and likewife in rows a foot a funder. Both had a plowing between the rows, towards the end of April.

" The third was fowed in broad-caft according to the cuftom of the country, excepting that a quarter part of the ufual quantity of feed was retrenched: but ftill it was the fame fort of barley, and this had been fteeped in de Vallemont's liquor.

" The fourth divifion was alfo fowed in broad-caft, like the former; with this only difference, that the feed was fteeped in a prolific liquor invented by M. Robineau.

" Laftly, the fifth part was fowed intirely in the common way, with the ufual quantity of the fame kind of fead, un-fteeped.

" The following was the ftate of thefe five divifions at harveft time.

" The firft and fecond, which had been fowed in rows, with only a quarter part of the quantity of feed generally ufed in the common way, but prepared for the one by being infufed in de Vallemont's liquor, and fowed in the other without any impregnation, were both very fine, and yielded a great deal of grain.

" The third and fourth, which had been fowed in broad-caft, with an abatement of only a quarter part of the ufual quantity of feed, and where the grain for one had been fteeped in de Vallemont's liquor, and that for the other in M. Robineau's, were middling, and not vifibly different in any refpect.

" The fifth fpot, which had been fowed intirely in the common way, and with the ufual quantity of feed, was the worft of all.

" Though M. Peirol was prejudiced in favour of prolific effences, he neverthelefs concludes from this experiment, 1. That the un-fteeped grain ufed for the firft mentioned portion of the field, having yielded as fine a crop as that of the fecond which was fteeped, infufing the feed does not contribute much to make the plant's tiller.

" 2. That the products of the third and fourth divifions being quite alike, M. Robineau's fteep is not better than de Vallemont's.

" 3. That the difference between the crop of the fifth, and thofe of the third and fourth pieces of ground, was probably owing to the different quantity of feed.

" 4. That the fuperior beauty of the firft and fecond, which furpaffed all the reft, was occafioned by the grains being fo far diftant from each other, that the roots of the plants had fufficient room to collect their food, and that the hufbandman was enabled to ftir the ground between the rows, in the fpring, by which the vigour of the plants was confiderably increafed. All this confirms the advantages of the new hufbandry; and M. Peirol is fo convinced of it, that he has fowed a very large tract of land, near Riom, in the fame manner as the two firft parts of the above-mentioned experiment.

" He has likewife made another trial of de Vallemont's fpecific, by planting vines in two different places. In one of thefe, where the foil was good, the common practice was followed, and the cuttings fprouted foon: in the other, where the ground was lefs good, each cutting was watered with two quarts of de Vallemont's liquor. Thefe laft fhot out later, but then grew with great ftrength, and retained their leaves a long while. It cannot be doubted but that an infufion of dung will invigorate plants, and make them grow fafter than they would otherwife. The owners of vineyards are here to confider, whether the expence of people to do this bufinefs may not be greater than the advantages accruing from it will repay: but it is certain that by thus watering their newly planted cuttings, efpecially with a ftrong infufion of dung, they will fecure their taking root.

" To fatisfy myfelf in regard to M. Robineau's pretended prolific liquor, I chofe a piece of ground laid out for wheat, and divided it into three equal parts. One of thefe was fowed in the common way, with feeds only limed, and produced one hundred and ninety-two fheaves to the acre, which yielded fixty bufhels of corn. Another was likewife fowed in the common way, with feed only limed, but two fifths lefs in quantity than is generally ufed, and produced one hundred and fixty-eight fheaves, which yielded fifty-four bufhels. The third part was fowed with the fame quantity of feed as the firft, but prepared according to M. Robineau's direction. This produced one hundred and fifty-fix fheaves, which yielded fifty-four bufhels of grain. From whence it follows, that his method was not of any fervice to the crop.

" His liquor, when diftilled over a very flow fire, yields a little brandy; what remains in the matrafs, yields a great quantity of falt-petre, and the refidue is a bitter water which contains a fmall portion of alkaline falt. This is nearly what would be obtained from de la Jutais's liquor.

" M. Vandusfel has alfo tried M. Robineau's prolific liquor, and found it attended with no other effect, than that the field where it was ufed had fomewhat fewer fmutty ears than other grounds for which the feed had not been fo prepared. But other feed which he fteeped in an infufion of dung, afhes, and lime, produced corn totally exempt from fmut."

An ingenious correfpondent of the editors of the Mufeum Rufticum, has given us the following improved method of breeding feed-wheat.

" I join, fays this Effex farmer, with many others in opinion, that it is beft every year to change one's feed-wheat, and this has been my conftant practice: I have had many a weary ride to get feed that would pleafe me, for I am, and always have been, very difficult in this matter.

" I have near two hundred acres of land in conftant tillage: thefe I divide into three portions, fo that I have every year about fixty acres in wheat, fixty more in barley and oats: and the remainder are either fallow, or in beans, peas, or turnips, &c.

" When I firft came into my farm, I expended annually, of feed-wheat, thirty quarters; for, after the example of my neighbours, I allowed four bufhels of feed for every acre I fowed.

" Thefe thirty quarters often coft me above feventy pounds; and God knows I could fometimes but little fpare fo much money, after the great annual expence of getting in my harveft.

" Some part of my land differs greatly in its nature from the other: near half my farm is a ftiff deep clay; what bottom it has I know not, as I never could find it in digging my ditches, &c. the other half is a bed of light fandy loam; with a gravelly hard bottom.

" This difference in the foil of my farm is, on many accounts, a great advantage: particularly, my wheat does not all ripen at the fame time; I have generally nearly got in that growing on my gravelly land, before that on my clay is fit to cut; and I can befides plow in all weathers, froft excepted.

" But, not to digrefs too much, I took it into my head that, with proper care, I could breed for myfelf, on my own land, as good feed-wheat as any I could buy, if not better; and I determined within myfelf to make the experiment.

" Before I made this experiment, I had reduced the quantity of feed I ufed on each acre, to three bufhels, which was a great faving to me. I had ftill occafion for above twenty quarters.

" My firft ftep was to felect ten acres of the beft land I had; five from the heavy, and as many from the light part of my farm: this land was by nature rich and good; it lay on the gentle fouthern declivity of a hill, and required very little manure: it lay in two little detatched fields, at fome diftance one from the other.

" When I had prepared this land by a winter and fummer fallowing, in which time the clayey part was plowed feven times, and the light land five times, I had both

fields

fields fown with fome of the beft wheat I could procure; that for the heavy land I got from Hertfordfhire, the other from a particular friend who holds a farm in Cambridgefhire.

" When the feafon for fowing approached, I was mightily pleafed with the appearance of my two little plots; for they refembled the beft-kept gardens, not a weed to be feen, and the earth as fine as garden-mould.

" On this occafion I did not brine my feed, but had it put into a large tub: fome water was then poured on it, and I made a ftout labourer, with a ftiff half-worn birchen-broom, ftir it very brifkly about for near half an hour; this I imagined would wafh off the fmut, if any there happened to be: the light feeds, which were very few, were fkimmed off.

" I let the wheat afterwards lie three hours foaking, when my man again ftirred it brifkly with the fame broom, and immediately poured the water off.

" Whilft yet wet, the feed was fprinkled in the ufual manner with flaked lime, in order to prepare it for fowing.

" My reafon for not brining it was, that I thought it would bring it too forward; and I rather chofe to fow it early, which is, I know, in general, a very good practice.

" In fowing this land, I, in fome meafure, followed Mr. Tull's directions; that is, I fowed my wheat in rows with large intervals in the following manner.

" I had a furrow opened about a rod from the hedge: in this furrow fome feed was by a careful hand very thinly fcattered, not fowed in the common way with a fling of the arm.

" It took up time; fo I had two fowers to each plow. When the plowman had drawn the firft furrow, he then opened another, at about ten feet diftance from the firft in the land; and feed was in the fame manner thinly fcattered in this alfo: after this, he returned to the firft furrow, and drawing another clofe to it, covered the feed; the fame thing he did by the fecond furrow: he afterwards went two bouts without any feed being fown in the furrows; but the third bout, feed was thinly fcattered, as before, to form the fecond row of corn in each bed: another bout was made to cover the feed when the two beds were finifhed, the middle of the interval being left unplowed.

" In this manner both my little fields were fown, in double rows with intervals about five or fix feet wide betwixt the beds, and the rows about two feet afunder.

" The corn came up very well, and preferved a good wholefome appearance all the winter.

" Early in the fpring, that is, in the month of February, I made a careful man fow the fpaces betwixt the rows of corn on the heavy land with wood-afhes, and on the light land with foot: thefe were both foon wafhed in by the rain, and the effects were fpeedily to be feen in the new-affumed vigour of the crops, and this vigour continued till the corn was ripe.

" As foon as any weeds appeared, the intervals which were left unplowed at feed-time were turned up, and the fpaces betwixt the rows diligently hand-hoed: this hand-hoeing was feveral times repeated, to keep the crop quite clear from weeds, the intervals had alfo feveral other ftirrings; but this work was chiefly done with a very light plow, without an earth-board in the heavy land, and without either earth-board or coulter in the other little field.

" Every thing came very well forward; and when the wheat began to fpindle, I had the outfides of the rows well earthed-up with a plow, and the infides with a hand-hoe: the infides were done firft.

" At harveft the fields made a noble appearance: a fine well broke earth ftriped with rows of healthy wheat.

" The cutting this wheat was very eafily performed, it ftood fo ready to the reapers hands; and when it was houfed and threfhed, it yielded me about four quarters on an acre, one with another, the firft year, though I have fince had fometimes more, fometimes a little lefs.

" My ten acres then yielded me about forty quarters; and I had occafion for only about twenty-two to fow my common wheat-lands: I therefore took only the firft and prime part of this crop, getting the fheaves very lightly threfhed; what remained made excellent bread-corn.

" I never faw finer feed-wheat than mine was this year: my heavy lands I fowed with the feed produced by the light field, and my light lands with that produced by the heavy field.

" As foon as I had got in this felect crop, I got the intervals in order for fowing with a fecond crop, in moft refpects continuing the practice of the year before: I had the like fuccefs, and might, perhaps, with equal advantage, have continued cropping the fields every year in the fame manner: but, not to depend too much on Mr. Tull, my next crop was a full crop of barley on them, which fucceeded well: and I felected two other plots of ground, of equal goodnefs, for my feed-corn hufbandry, as I call it.

" In this manner I have now for feveral years paft managed, growing my own feed; and, if any thing, my crops have fince increafed: but I have again reduced the quantity from three to two bufhels of feed, for each acre of my wheat-land in common: that is, fuch as I fow in the ordinary way: on fome of my rich, ftrong land, I do not ufe above fix pecks, and find it anfwer very well.

" I could like to extend this new hufbandry, or this imitation at leaft of the new hufbandry, over all my lands that are in tillage: but in my method of practifing, the expence would be too great: my fowers are well paid; I have enough to do to make my plowmen go out of their ordinary way; and it cofts me a great deal hoeing: yet all this I do not grudge to procure good feed.

" By introducing the drill-plow and the horfe-hoe I could fave a great deal of labour on my light lands; and I may probably fome time or other attempt it: but, at the fame time, I am very fenfible, I fhall find great difficulty in getting men that will even try to do the work with thefe inftruments. The common labourers in hufbandry hate novelty: they purfue, without murmuring, the old beaten track; but put them out of it, and thought will become neceffary: the fact is, they imagine it a very great hardfhip to be obliged to work and think too, and all for the fame money.

" Without great refolution, and fome kind of authority, a farmer will be obliged to let them even dig a ditch their own way: innovation they like not in any fhape, often making ufe of the expreffion, that they are too old to learn.

" This, to a man who is very much difpofed to lend a helping hand towards the improvement of agriculture, is a mortifying circumftance: there is fcarcely any thing fo difficult as to make an obftinate man ufeful: if, by dint of authority, you oblige him to go out of his way, he will rather contribute to the lofs of your crop, than not to endeavour to convince you that he is in the right. I have often, to my forrow, felt the truth of this obfervation.

" Several reafons, though I deal not much in them, may be affigned for the feed-wheat, I raife in the above defcribed manner, being fo good.

" In the firft place, I fow it on land that has not tafted any dung for fome years, but is, in its own nature, rich and good: to this practice I afcribe a great deal of its goodnefs. In the next place, as the corn does not ftand too thick, it enjoys all the benefit it can receive from the fun and air: by this means it attains a perfect maturity, and is certainly improved both in bulk and quality.

" The flight fpring-dreffing I give it, of foot or afhes, is of very great fervice: it warms the roots, and brings the corn forward; it loofens the earth, and either itfelf gives nourifhment to the plants, or, at leaft, puts the earth in a difpofition to afford it.

" Not a little is to be attributed to the frequent hoeing betwixt the rows and the ftirings of the intervals; and I find one very particular and great advantage refult from it, which is, that it is an excellent means of clearing my land of weeds; for they no fooner attain a part of their growth, but they are deftroyed long before they feed.

" Farmers in general think their fields cannot in the fpring be too full of wheat-plants: the ground feems covered with verdure, and the blades are, as it were, crouded for want of room: when the weeds begin to get up, they fend

fend in a parcel of men and women with weeding-hooks, not letting a hoe come near the land to cut them up: they are fadly afraid they fhould not have plants enough at harveft; whereas, if they were to meafure and mark off a rod fquare of land in February, and count the plants growing on it then, and afterwards count them in the beginning of Auguft, it would almoft always be found, that four parts in five of them had perifhed in the intermediate months, and that what remained were, by far too much crouded ftill, and had each but few ftalks.

"I never weed my corn of late years; for as I allow only two bufhels of feed, and often lefs, to an acre, the plants come up thin; and there is of courfe room for a moderate-fized hoe, which is the inftrument I clean my land with: and fo far from being fearful of having my crop injured by this means, I order the workmen, where the plants ftand too clofe, to cut them up without mercy, as they would do the moft pernicious weeds: if there happens by any accident to be a vacant fpot, they eafily remove fome plants to it, with earth about their roots, by the help of their hoe.

"By this management, I, in fome meafure, reap the benefit of the advantages promifed by the new hufbandry; though I have not fuch opportunities of fo often giving the plants a frefh fupply of nourifhment, nor of earthing them up when the grain is forming in the ear; for, after the corn has put forth its ftalks to any confiderable length, it would not be fo proper to fend in the hoers: but all the lofs is the want of earthing up the plants fo late as I could wifh; for the weeds will, before this time, be pretty well got under, and few of them will be able to ripen their feeds before harveft, when they will of courfe be deftroyed by turning in the ftubble, which I always do as foon as poffible; though many of my neighbours let their ftubbles lie rough all the winter, for the fake of feeding a few fcore of ewes.

"Every farmer has methods peculiar to himfelf; and they are, for the moft part, fuch as were practifed by their fathers, grandfathers, &c. whom they fucceeded in the culture of their farms.

"My methods, as you muft now be fenfible, differ from moft of thofe ufed by other occupiers of land; and if I cannot fo well defend them by arguments, an experience of feveral years has convinced me that I ought ftill to perfift in the practice of them: they have anfwered all the ends I could wifh from them; what could I defire more?

"I am enabled to raife all my own feed without the trouble of procuring it from a great diftance, at a large expence, and with a deal of trouble.

"My crops are to the full as good as ever they were, and I ufe lefs feed by above one half: my manure goes a great deal farther than it ufed to do, becaufe I beftow more plowing and other tillage on my land; and I am not fo much peftered as I formerly was with weeds, for they now very feldom are fuffered to feed on my land.

"Of this laft evil, I mean that of weeds, I have not, however, yet got quite rid; for fuch of my fields as border on my neighbours lands are ftill often infefted; fome of thefe fame neighbours, I have feveral times mentioned, are but flovenly farmers, and the weeds which have winged or downy feeds, are conftantly wafted by the wind from their land to mine; fo that I, in fome meafure, am punifhed for their neglects: thiftles are this way particularly troublefome, as the feeds of them will fometimes be carried a very confiderable way by the wind.

"I have very little more to fay at this time, except that I never threfh the fheaves that are to fupply me with feed-corn till juft when I want to make ufe of it. I have a notion, that the feed keeps better in the covering nature has given it, I mean the chaff, than it would do without it; and I am pretty certain it fprouts fooner in the ground, the hufk or bran of the grain being preferved in a tenderer and more yielding ftate, than it would be were it expofed to the open air."

With regard to the feeds of plants fown in the kitchen-garden, all of them fhould be gathered in dry weather, when there is not any moifture upon them; and the beft way to preferve them is, to hang them up in bags, in a dry room, where vermin cannot come at them. The temperature of this place fhould be moderate; left either too much warmth, or a too ftrong current of air, fhould make them dry, and confequently decay, fooner than they would otherwife do: and at the fame time care muft be taken not to exclude the air totally from them; it having been repeatedly experienced, that feeds kept long in bottles clofely ftopped have entirely loft the power of growing. They will keep longeft in their pods, when they can be fo laid up, becaufe thofe coverings not only defend them from the injuries of the outward air, but, fo long as they are not disjoined from them, continue to fupply them with a degree of nourifhment which helps to maintain them in a plump ftate, fit for vegetation. The feeds of all foft fruits, fuch as cucumbers, melons, &c. are of courfe excepted from this general rule; for they muft be well cleanfed from their furrounding pulp, the rotting of which would otherwife foon corrupt them. Thofe of melons in particular, are fo far benefited by being kept in a warmer ftate than would fuit any others, that the plants produced from them are thereby rendered the lefs luxuriant, and therefore more fruitful: for which reafon it is that many people carry them in an inner pocket of their breeches for fix weeks or two months before they fow them, in order to exhale part of their moifture; and in effect, this will weaken them as much as two years keeping them in the common way.

Thofe feeds which fwim upon the furface of water, when they are put to that trial of their goodnefs, fhould be rejected for fowing; becaufe, as hath already been frequently obferved, though many of them will grow, they never produce fo good plants, or fo fine fruit, as the fuller, plumper, and more perfect ones, which fink to the bottom.

The age at which it is beft to fow the feeds of the plants before treated of, and the time to which they will keep good, are thus afcertained by Mr. Miller, after many years experience and very accurate obfervation.

The feeds of afparagus, bafil, beans, beet, borage, capficum, carrots, celeri, chervil, creffes, endive, fennel, finocchia, hyffop, kidney-beans, lavender, leeks, lentils, marjoram, marigolds, onions, parfley, parfneps, peas, purflain, radifhes, favory, fkirrets, fpinnage, thyme, and turneps, are beft fown the firft fpring after they have been faved; and indeed many of them will not grow if they are kept longer.

Thofe of cabbages, colliflowers, endive, lavender, lettuce, muftard, and forrel, will not be the worfe for keeping two years, if they are well preferved; though all of thefe are equally good for ufe the firft year.

The feeds of cabbages, cucumbers, lettuces, melons, and favoys, will grow very well at the end of three years, if they have been properly faved and kept. Some of them, and particularly thofe of cucumbers and melons, are generally reckoned beft when they are three years old; becaufe, when they are new, the plants produced by them will grow too vigorous, and yield but a fmall quantity of fruit. However, none of thefe feeds fhould be kept longer than four or five years, though they well grow at the end of nine or ten: but then their plants will be weak, and their fruit fmall.

The feeds of fennel will frequently remain in the earth a whole year, efpecially if they are fown in the fpring; fo that whenever the plants do not come up the firft year, the ground fhould be left undifturbed till the following fpring, except only keeping it clear from weeds, and the plants will then appear.

SEEDLINGS, young plants which have not been removed from the beds where they have been fown. It is alfo ufed to diftinguifh plants raifed from feeds from thofe of the fame kind which have been propagated by layers or cuttings.

SEED-LIP, SEED-LEAP, *or* SEED-LOP, a feed-bafket, or the veffel in which the fower carries his feed, in order to fow it.

SEELING, a term ufed by horfe-dealers to imply the time when a horfe begins to have white eye-brows; that is, when there grows on that part about the breadth of a farthing, a parcel of white hair, mixed with thofe of his natural colour. This is a mark of old age, a horfe never feeling before he is fourteen, and always before he is fixteen years old.

SELANDERS. *See* SALENDERS.

SEMBRADOR, an inftrument ufed in Spain for fowing corn. *See the article* DRILL-PLOUGH.

SEMIFISTULAR-*Flowers*, are thofe whofe upper part refembles a pipe cut off obliquely.

SEMIFLOSCULOUS-*Flowers*, are thofe whofe petals are hollow in their lower part; but in their upper flat, and continued in the fhape of a tongue.

SEMINARY, a feed plat, or place allotted for raifing plants from feed, and keeping them till they are fit to be removed into the garden or nurfery. *See the article* NURSERY.

SERRATED, indented, or notched, in the manner of a faw.

SERVICE-*Tree*, the name of a tree that grows naturally in many parts of England; and if fuffered to ftand, will become very large. The ftems are covered with a fmooth gray bark; the branches, while young, have a purplifh brown bark. The leaves are winged, fharply fawed on their edges; and, during the fpring, are hoary on their under fides. The flowers are produced in large branches, almoft in the form of umbels, at the ends of the branches; they appear in May, and are fucceeded by roundifh berries, growing in large bunches, which have a depreffed navel on the top, and turn red in autumn, when they ripen.

Though the fruit of the fervice-tree is not much efteemed in England, it is often ferved up to the table, as a part of the defert, in the fouth of France, and in Italy, where there is no want of a variety of fine fruits. The fpecies there is indeed much larger than ours: but as Mr. Evelyn has left us no room to doubt that our wilder fort, which grows naturally in many parts of England, may, like all other plants, be greatly improved by due culture, it is well worth the hufbandman's while to give it a place in his orchard, or other ground. Mr. Miller too gives more than one inftance of his having feen the fervice-tree brought to great perfection in this country. He has obferved three forts (Mr. Evelyn noted four) of our native growth, the fruit of one of which is fhaped like a pear, and that of the other like an apple. The former, which refembles moft the foreign fpecies abovementioned, is the beft and the largeft grower; for it will fometimes attain to the height of near forty feet.

It is a common, but a very miftaken faying, that the fower of thefe trees never fees the fruit of his labour. This notion may have arifen from their bearing moft plentifully when they are very old: but, with proper care, they may be made to produce fruit in a few years, even from the time of raifing them from their feeds; and if they are propagated by layers, or cuttings, they will foon begin to repay the pains beftowed on them.

To propagate them from their feeds, of which there are three in each berry, or chequer, as fome call this fruit, the pulp fhould be rubbed off clean, with dry fand, foon after the fruit is ripe, and the feeds, which are of a hard ftrong nature, fhould then, according to Mr. Miller's directions, be fown in pots, for the convenience of plunging thefe into a moderate hot-bed in the fpring, in order to forward their growth: for it will be fufficient to fhelter them under a common frame during the intermediate winter. When the plants are come up, they fhould be kept clear from weeds, watered in dry weather, and expofed to the open air: for a clofe hot bed would then draw them up fo weak as to fpoil them; nor indeed is any thing more intended here by this method of raifing them, than to make the feeds fprout fooner than they would do in the common open ground, which, that circumftance excepted, will do equally well, as thefe plants are very far from being tender. About the middle of October, at which time their leaves will decay, they fhould be taken out of the pots in the hot bed, and planted in the nurfery, in rows two feet afunder, and a foot apart in the rows. A little mulch fhould be laid upon the furface of the ground, over their roots, in the winter, to protect them from being injured by froft before they have well taken root, and in the next fpring the ground between them fhould be dug, and the mulch buried therein, with care not to cut or injure their tender roots. With this management, and keeping them conftantly clear from weeds, they will be fit in three or four years, according to their growth, to be tranfplanted into the places where they are to remain: but previous to this it will certainly be right to graft them, as Mr. Evelyn advifes, for the greater improvement of their fruit. They take well either on their own fpecies, or on the white thorn, the quince, or the medlar. The beft feafon for removing them from the nurfery is in October, or in the fpring juft before they begin to fhoot, and the foil in which they thrive beft, fooneft produce fruit, and laft the longeft, is a moift ftrong ground, defended from cold wind. However, they will grow even in the moft expofed places, and thrive where few other trees will fucceed; for they are extremely hardy. This renders them well worthy of the hufbandman's attention, as well for their timber (which will be fpoken of hereafter) as for their fruit. This laft makes a pretty appearance when ripe; but the black birds and thrufhes are fo fond of it, that they devour all they can come at. A way, therefore, to draw thefe warbling fongfters about an habitation, is to plant a quantity of thefe trees for that purpofe. Like the medlar, this fruit muft be kept till it is almoft rotten, before it will be fit to eat.

SETTER, a kind of fetom or iffue, made by cutting a hole in the dewlap of an ox or cow, and putting into the wound a fort of tent formed out of the root of hellebofter; by which the ill humours vent themfelves.

To SEW, *or go* SEW, to go dry; fpoken of a cow.

SHAKING, a difeafe incident to fheep, confifting of a weaknefs in their hinder quarters, fo that they cannot rife up when they are down. No cure is yet known for it.

SHARD, a fragment of an earthen veffel.

SHARE *of a Plough*, that part which cuts the ground, the extremety forward being covered with a fharp-pointed iron, called the point of the fhare; and the end of the wood behind, the tail of the fhare. *See the article* PLOUGH.

The length of the whole fhare from point to tail, according to Tull, fhould be three feet nine inches; at the top of the iron it has an upright piece called the fin; and near the iron at the other end, there is an oblong fquared hollow, called the focket; the ufe of which is to receive the bottom of the fheat. Near the tail there is a thin plate of iron, well riveted to the wood; by means of this plate the tail of the fhare is held firmly to the hinder fheat of the plough by a fmall iron pin, with a fkrew at the end, and a nut fkrewed on it, on the inner or right fide of the fheat.

The point of the fhare is that part in which it does not run up into the fin: this point is generally made of three inches and a half in length, and fhould be flat underneath, and round at the top, and the lower part of it muft be of hard fteel. The edge of the fin fhould alfo be well fteeled, and fhould make an acute angle with the fhare.

The focket is a fort of mortife; it fhould be a foot long, and about two inches deep: the fore-end of it muft not be perpendicular, but oblique, conformable to the end of the fheat which enters into it. The upper edge of the fore-part muft be always made to bear againft the fheat; but, if this end of the focket fhould not be quite fo oblique as the fheat, it may be helped by paring off a fmall part of the wood at the point.

SHAW, a wood that encompaffes a clofe.

SHAWLE, a fhovel ufed in winnowing corn.

SHEARING *of Sheep*, the operation of cutting off the fleece or coat of wool with a pair of fhears. *See the article* SHEEP.

SHEAT *of a Plough*, that part of the plough which paffes through the beam, and is faftened to the fhare.

The fheat, or as it is fometimes called the fore-fheat, there being another piece of timber behind it called the hinder fheat, fhould be feven inches wide, and faftened to the beam by a retch (a piece of iron with two legs) and by a wedge driven by it into the hole of the beam. The angle contained between the fheat and the beam of the plough fhould be about forty-two degrees.

SHEAVES, bundles of corn bound up in the field. *See the article* HARVEST.

SHED, a flight temporary covering.

SHEEP, *ovis*, in zoology, a well known fpecies of cattle, and which are kept at the leaft expence of any to the

the farmer. They will thrive upon almoſt any ground, and for that reaſon are preferred by many before the larger cattle.

The beſt ſort of ſheep for fine wool are thoſe bred in Herefordſhire and Worceſterſhire, but they are ſmall and black-faced, and bear but a ſmall quantity.

Warwick, Leiceſter, Buckingham, and Northamptonſhire, breed a large boned ſheep, of the beſt ſhape, and deepeſt wool we have got. The marſhes of Lincolnſhire breed a very large kind of ſheep, but their wool is not good, unleſs the breed be mended by bringing in ſheep of other countries among them, which is a ſcheme of late very profitably followed there.

The northern counties in general breed ſheep with long, but hairy wool: and Wales breeds a ſmall hardy kind of ſheep which has the beſt-taſted fleſh, but the worſt wool of all.

The farmer ſhould always buy his ſheep from a worſe land than his own, and they ſhould be big-boned, and have a long greaſy wool, curling cloſe and well. Theſe ſheep always breed the fineſt wool, and alſo are the moſt approved of by the butcher for ſale in the market.

For the choice of ſheep to breed, the ram muſt be young, and his ſkin of the ſame colour with his wool, for the lambs will be of the ſame colour with his ſkin. He ſhould have a large long body, a broad forehead, round, and well riſing, large eyes, and ſtraight and ſhort noſtrils. The polled ſheep, that is, thoſe which have no horns, are found to be the beſt breaders. The ewe ſhould have a broad back, a large bending neck, ſmall, but ſhort; clean and nimble legs, and a thick deep wool covering her all over. To know whether they be ſound or not, the farmer ſhould examine the wool that none of it be wanting, and ſee that the gums be red, the teeth white and even, and the briſket ſkin red, the wool firm, the breath ſweet, and the feet not hot. Two years old is the beſt time for beginning to breed, and their firſt lambs ſhould not be kept too long, to weaken them by ſuckling, but be ſold as ſoon as conveniently may be. They will breed advantageouſly, till they are ſeven years old.

The farmers have a method of knowing the age of a ſheep, as a horſe's is known, by the mouth. When a ſheep is one ſhear, as they expreſs it, it has two broad teeth before; when it is two ſhear, it will have four; when three, ſix; when four, eight; after this their mouths begin to break. The difference of land makes a very great difference in the ſheep.

The fat paſtures breed ſtraight tall ſheep, and the barren hills and downs breed ſquare ſhort ones; woods and mountains breed tall and ſlender ſheep, but the beſt of all are thoſe bred upon new plowed land, and dry grounds. On the contrary, all wet and moiſt lands are bad for ſheep, eſpecially ſuch as are ſubject to be overflowed, and to have ſand and dirt left on them. The ſalt marſhes are, however, an exception to this general rule, for their ſaltneſs makes amends for their moiſture, any thing of ſalt, by reaſon of its drying quality, being of great advantage to ſheep.

As to the time of putting the rams to the ewes, the farmer muſt conſider at what time of the ſpring his graſs will be fit to maintain them and their lambs, and whether he has turneps to do it till the graſs comes; for very often both the ewes and lambs are deſtroyed by the want of food; or, if this does not happen, if the lambs are only ſtunted in their growth by it, it is an accident that they never recover. The ewe goes twenty weeks with lamb, and according to this it is eaſy to calculate the proper time. The beſt time for them to yean is in April, unleſs the owner has very forward graſs, or turneps, or the ſheep are field ſheep, where you have not incloſures to keep them in, then it may be proper they ſhould yearn in January, that the lambs may be ſtrong by May-day, and be able to follow the dam over the fallows, and water furrows; but then the lambs that come ſo early, muſt have a great deal of care taken of them, and ſo indeed ſhould all other lambs at their firſt falling, elſe, while they are weak, the crows and magpies will peck their eyes out.

When ſheep are turned into fields of wheat or rye to feed, it muſt not be too rank firſt, for, if it be, it generally throws them into ſcowerings. Ewes that are big ſhould be kept but bare, for it is very dangerous to them to be fat at the time of their bringing forth their young. They may be well fed indeed, like cows, a fortnight before-hand, to put them in heart. *Mortimer's Huſbandry.*

The feeding ſheep with turneps is one great advantage to the farmers, from the crops they raiſe of them: they ſoon fatten upon them, but there is ſome difficulty in getting them to feed on them; the old ones always refuſe them at firſt, and will ſometimes faſt three or four days, till almoſt famiſhed; but the young lambs fall to at once.

The common way, in ſome places, of turning a flock of ſheep at large into a field of turneps, is very diſadvantageous, for they will thus deſtroy as many in a fortnight, as would have kept them a whole winter. There are three other ways of feeding them on this food, all of which have their ſeveral advantages.

The firſt way is to divide the land by hurdles, and allow the ſheep to come upon ſuch a portion only at a time, as they can eat in one day, and ſo advance the hurdles farther into the ground daily, till all be eaten. This is infinitely better than the former random method, but they never eat them clean even this way, but leave the bottoms and outſides ſcooped in the ground; the people pull up theſe indeed with iron crooks, and lay them before the ſheep again, but they are commonly ſo fouled with the creature's dung and urine, and with the dirt from their feet, that they do not care for them; they eat but little of them, and what they do, does not nouriſh them like the freſh roots.

The ſecond way is by incloſing the ſheep in hurdles, as in the former, but in this they pull up all the turneps they ſuppoſe the ſheep can eat in one day, and daily remove the hurdles over the ground, whence they have pulled up the turneps: by this means there is no waſte, and leſs expence, for a perſon may in two hours pull up all thoſe turneps; the remaining ſhells of which would have employed three or four labourers a day to get up with their crooks out of the ground, trodden hard by the feet of the ſheep; and the worſt is, that as, in the method of pulling up firſt, the turnips are eat up clean; in this way, by the hook, they are waſted, the ſheep do not eat any great part of them, and when the ground comes to be tilled afterwards for a crop of corn, the fragments of the turnips are ſeen in ſuch quantities on the ſurface, that half the crop at leaſt ſeems to have been waſted.

The third manner is to pull up the turneps, and remove them in a cart or waggon to ſome other place, ſpreading them on a freſh place every day; by this means the ſheep will eat them up clean, both roots and leaves. The great advantage of this method is, when there is a land not far off which wants dung more than that where the turneps grow, which perhaps is alſo too wet for the ſheep in winter, and then the turneps will, by the too great moiſture and dirt of the ſoil, ſometimes ſpoil the ſheep, and give them the rot. Yet ſuch ground will often bring forth more and larger turneps than dry land; and when they are carried off, and eaten by the ſheep on ploughed land in dry weather, and on green ſward in wet weather, the ſheep will ſucceed much the better; and the moiſt ſoil, where the turneps grow, not being trodden by the ſheep, will be much fitter for a crop of corn, than if they had been fed with the turneps on it. The expence of hurdles, and the trouble of moving them is ſaved in this caſe, and this will counterbalance at leaſt the expence of pulling the turneps, and carrying them to the places where they are to be eaten. They muſt always be carried off for oxen. *Tull's Horſe-hoeing Huſbandry.*

"It can hardly be doubted, ſays M. de Buffon, but that thoſe animals which are at preſent tame and domeſtic, were formerly wild. Yet the weakneſs and ſtupidity of the ſheep being conſidered, and likewiſe that this defenceleſs animal cannot ſave itſelf by flight; that all carnivorous animals are his enemies, ſingling it out in preference to others, and devouring it for the fineneſs of its fleſh: at the ſame time we muſt remember that this ſpecies is not very prolific, and that each individual is but ſhort-lived: when theſe particulars are conſidered, we ſhould be inclined to think, that from the beginning of things, the ſheep has been committed to the care of man; that his protection is neceſſary to its ſubſiſtance, and his care to its

its multiplying; nor are any desarts known to afford wild sheep; but in all places where man does not govern, the lion, the tyger, and the wolf, reign by violence and cruelty; these voracious animals live longer, and multiply much faster than the sheep: and were we even now to forsake the numerous flocks fed in the pastures, and on the hills, they would soon be destroyed before our eyes, and the whole species extirpated by the number and voracious appetites of carnivorous animals.

"Thus it appears that this species is indebted to our assistance and care for its continuance; for it could not subsist of itself. The sheep is absolutely without defence or resource; the weapons of the ram are but weak; his courage nothing more than a petulance, troublesome to others, useless to himself, and destroyed by castration. The weathers are still more timorous than the ewes. It is from fear that they so often assemble in flocks; the least uncommon noise causes them to leap over each other, or gather close together; while this fear is attended with the grossest stupidity: they have not sense to avoid danger; they even appear not to feel their disagreeable situation; they stray wherever they happen to be, whether it rain or snow; and such is their obstinacy, that in order to make them change their place, or follow any road, they must have a leader, trained to walk before them, whose motions they readily follow step by step. This leader himself would stir no more than the rest of the flock, were he not driven by the shepherd, or hunted by the guardian dog, which is taught to protect and defend them; to guide, separate, gather them together, and direct them in their motions.

"Sheep, therefore, of all quadruped animals are the most stupid, and have the least instinct and contrivance. The goats, which in so many respects resemble them, have much more sagacity: they stand in need of no guide, they shun dangers; new objects soon become familiar to them; whereas the stupid sheep neither shuns nor approaches: though under the greatest want of assistance, they do not approach man so freely as the goat; and what in animals seems the lowest degree either of fear or insensibility, they see their lambs taken away without anger, without resistance, and without expressing their grief by any cry different from their common bleating.

"But this animal, in itself so despicable, so destitute of sentiment and internal qualities, is to man the most valuable; its utility the most immediate and extensive: it alone satisfies wants of the greatest necessity; it furnishes both food and apparel, besides the advantages arising from the suet, milk, skin, intrails, bones, and dung of this creature, to which nature seems to have given nothing as its property; all is to be delivered up to man.

"Love, the most general and active sentiment, is alone able to impart some vivacity to the ram: he becomes wanton, fights, rushes against the other rams, and sometimes even attacks his shepherd; but the ewe, when in heat, seems not at all the more affected, or the more animated; her instinct reaches no farther than not to refuse the ram's approaches; to chuse her food, and know her lamb. The instinct of this animal is the surer, as it is more mechanical; and, if I may be allowed the expression, the more innate. A young lamb will, amidst a numerous flock, find its dam and seize the dug, without ever being mistaken. Sheep are also said to be impressed by modulated sounds, to feed more assiduously, to be in better health, and to fatten sooner by the sound of a pipe; and that they are evidently sensible of the charms of music. But it is also said, and I believe with more truth, that music rather serves to amuse the shepherd's tedious hours, and that to this supine and solitary life the origin of that art is owing.

"These animals, whose instinct is so simple, are also of a very weak constitution; they cannot bear walking any length of time; travelling exhausts them; running soon puts them out of breath; the scorching rays of the sun hurt them equally with the rain and snow. Their diseases are many, and most of them contagious. The superabundance of their fat often proves fatal to them, and always hinders their fruitfulness; they yean with difficulty; they frequently cast their lambs, and require more care than any other domestic animal.

"When a ewe is near yeaning, she must be separated from the flock, and watched, in order to be assisted; the lamb often presents itself a-thwart, or with its feet first; and in this case, without assistance, the ewe's life would be in danger. After yeaning, the lamb is raised on his feet; at the same time all the milk in the ewe's udder is milked out, it being vitiated, and very noxious to the lamb, which is kept from sucking till the udder is filled with fresh milk: the lamb is kept warm, and for three or four days shut up with the ewe, that it may learn to know her, during which time the ewe is fed with good hay, barley-meal, or bran mixed with a little salt; and water, whose chill is taken off, and mixed with a little quantity of flour, bean-meal, or ground millet, given her to drink. At the end of four or five days she may be gradually fed like the rest, and sent with the flock, taking care that she be not driven too far, lest her milk be heated. Some time after, when the sucking lamb shall have gathered strength, and begins to play, no farther care is requisite; it may be left to follow its dam to the pastures.

"All the lambs of a weakly appearance are generally disposed of to the butcher; those intended to be kept being the largest, most vigorous, and having the thickest fleece. Lambs of the first yeaning are never so good as the following. To bring up lambs yeaned in the months of October, November, December, January, and February, they must be kept in the house during the winter, going out only in the morning and evening to suck; but in the beginning of April they may be turned into the open fields. Some time before this a little grass is daily given them, in order to habituate them by degrees to this new food. They may be weaned at the end of one month; but it is better to delay it for six weeks or two months. White lambs, without spots, are always preferred to the black or mottled; white wool being more valuable than the black or mixed.

"The proper age for castration is at the end of five or six months, or even a little later in spring or autumn, when the weather is mild. This operation is performed by two different methods; the most common is by incision, when the testicles, which are easily separated, are drawn out through the wound: the other is performed without incision, by tying a string very tight round the scrotum above the testicles: for this compression destroys the vessels which supplies them with blood and juices. The lamb, on castration, becomes sickish and dull, so that it would not be improper to give him, for two or three days, a little bran mixed with a small quantity of salt, to prevent a loss of appetite, which this operation often causes.

"At the end of a year, rams, sheep, and weathers lose the two fore-teeth of the lower jaw; and they are known to want the incisive teeth in the upper jaw. At eighteen months the two teeth joining to the former, also fall out; and at three years, being all re-placed, they are even and pretty white. But as the creature advances in age they become loose, blunt, and afterwards black. The age of the ram is also known by his horns, which shew themselves in the very first year, and often at the birth, and continue to grow a ring annually to the very period of life. Though sheep are often without horns, yet they have bony prominences in the same places of the head, where the horns of rams appear. Some sheep however have two, and others four horns, five or six inches in length, but less twisted than those of the ram; when there are four, the two outward are shorter than the others.

"The ram is capable of generating at eighteen months, and a ewe may yean at the end of a year; but it is better to delay it till the ewe be two, and the ram three years old. The produce of these animals, if too early, and even the first, is always weak, and of a bad constitution. One ram will be sufficient for twenty-five or thirty ewes; but he should be remarkable for strength and comeliness. He must also have horns; for some have none, and such, in these climates, are very indifferent. In a good and comely ram, the head must be large and thick, the forehead broad, the eyes large and black, the nose short, the neck thick, the body long and raised, the back and rump broad, the testicles large, and the tail long. The best are white, with a large quantity of wool on the belly, tail, head and ears, down to the eyes. The best sheep for propagation are those which have most wool, and that close, long, silky, and white; especially if at the same time they have a large body, a thick neck, and a light method of walking. And it has been already observed, that those which were rather lean than fat, bring forth more easily than others.

"The season of the ewe's heat is from the beginning of November to the end of April; but they may be brought to conceive in any season, by giving them provocative foods, as salt water, and bread of hemp-seed. Each ewe is covered three or four times, and then separated from the ram, which always prefers the older sheep, and neglects the younger. In the season of copulation they should not be exposed to the rain or bad weather, wet hindering their retention; and a clap of thunder often produces abortion. A day or two after being covered, they are put again to their common diet, without having any more salt water; the continual use of which, as well as that of hemp-seed bread, and other hot aliments, would infallibly cause abortion. They go five months, and yean at the beginning of the sixth; they seldom bring two lambs. In hot climates they yean twice a year: but in France, and the colder countries, only once. Some have the ram given to them about the end of July or the beginning of August, in order to have lambs in the month of January; but the ram is given to a much greater number in the months of September, October, and November; and lambs are in great plenty in February, March, and April. They are also to be had in the months of May, June, July, August, and September, there being no scarcity of them but in October, November and December. The ewe yields, during seven or eight months, plenty of milk, which is a good food for children and peasants. It also makes good cheese, especially if mixed with that of cows. The time for milking ewes is immediately on their going out to pasture, or on their return; twice a day in summer, and once in winter.

"Ewes fatten very fast during their pregnancy, as they then eat more than at other times. As they often hurt themselves, and frequently miscarry, so they sometimes become barren; and it is not very extraordinary for them to bring forth monstrous productions. However, when properly tended, they are capable of yeaning during their whole life; that is, to the age of ten or twelve years; but generally, when they are turned of seven or eight, they break, and become sickly. A ram lives to twelve or fourteen years; but after eight is no longer fit for propagation: he should then be knit and fattened with the old sheep. The flesh of the ram, though knit and fattened, is but of a bad taste; that of the old ewe flabby and insipid; whereas that of the weather is the most succulent, and the best of all common meats.

"To form a flock, from which a reasonable profit may be expected, sheep and weathers must be purchased, of about eighteen months, or two years old; and one shepherd, if careful, and assisted by a good dog, may take care of a hundred. In leading them out to pasture he should go before them, and accustom them to know his voice, to follow him without stopping, or straying among the corn, woods, aud fallow lands, where they would do damage. The places that best agree with them are downs, and small eminencies; low, wet, and marshy grounds should be avoided.

"During the winter, they are fed at home with bran, turneps, hay, straw, lucern, saintfoin, the leaves of elm, ash, &c. They are, however, led out every day, unless the weather be very bad; tho' this is rather to walk than feed them; and in this inclement season, it is always near ten in the morning before they are led out; and after staying four or five hours, they are watered, and brought back about three in the afternoon; whereas in spring and autumn, they are led to the field as soon as the sun has dispersed the frost or humidity on the grass, and continue there till sun-set. It is also sufficient for them in these seasons, to drink once a day, just before they are brought back to the sheep-house, where they must always find fodder, though in less quantity than in winter. It is only in summer that they are to live entirely on the pastures, whither they are led twice a day, and also made to drink twice. They are led out very early in the morning to feed as soon as the dew is down, where they continue four or five hours; after which, and being had to the water, they are brought back to the fold, sheep-house, or some other shady place: about three or four o'clock, when the extreme heat begins to abate, they are a second time led to the pasture, where they continue till the evening; and were it not for the fear of wolves, they should pass the night in the open air, as they do in England, which would render them more vigorous, clean, and healthy. As too great a heat is remarkably troublesome, and the violence of the sun-beams disorders their heads, and throws them into vertigo's, it is proper to make choice of places shaded from the sun, and in the morning to lead them on eminences exposed to the east, and in the afternoon on those that are exposed to the west, that when they are feeding, their heads may be in the shadow of their body. Lastly, in order to save their wool, they must not be led through any bushy places.

"In dry and high grounds, especially if the herbage abound in wild thyme, and other odoriferous plants, the mutton is of a much finer quality than that which is fed in moist vallies and low plains; unless these plains be sandy and near the sea, the herbage then being sprinkled with salt; and the sheep are no-where so good as on these salt plains. The ewes also fed in them, yield more milk, and of a better taste. These animals are remarkably fond of salt, and nothing is more healthful when given in moderation; and in some places it is customary to put into the sheep-house a bag of salt, or a saline stone, which they all greedily lick one after another.

"Every year the flock should be examined, in order to find out such as begin to grow old, and are intended for fattening; for as they require a different management from the others, so they should also be formed into a separate flock. They should be led abroad in summer before sun-rising, in order to feed on the grass while moistened with the dew. Nothing forwards the fattening of weathers more than a great quantity of moisture; and nothing more obstructs it than the heat of the sun; so that about eight or nine in the morning, before the great heat begins, they should be brought back, and salt given them to excite thirst. About four in the afternoon they should be led a second time into cool and moist places; and after two or three months of these little cares, they will have all the appearance of being full of flesh: indeed they are generally fattened as much as they can be; but this fat proceeding only from the great quantity of water they have drank, may be said to be no more than an œdema, or bloated humour, which would in a short time turn to the rot, and can be prevented only by killing them while in this state of fatness. Even their flesh, far from being firm and juicy, is extremely insipid and flabby: in order, therefore, to make good flesh, besides letting them feed on the dew, and giving them a great deal of water, they should have, at the same time, more succulent food than grass. They may be fattened in every season, by only keeping them a-part in a sheep-house, and feeding them with the meal of barley, oats, wheat, beans, &c. mixed with salt, for making them drink more copiously. But in whatever manner, and in whatever season they are fattened, they must be immediately disposed of; for they cannot be fattened twice, and they will die by diseases of the liver.

"Worms are often found in the livers of animals; and a description of those found in the liver of sheep and oxen, may be seen in the journal de Scavans, for the year 1668, and Ephemerides of Germany, tom. v. 1675, 1676. These worms were thought to be peculiar to ruminant animals; but M. Daubenton has found the very same in the liver of the ass; and it is probable the like may be found in the liver of other animals: but it is also affirmed, that moths have been found in the liver of sheep." M. Rouille, secretary of state for foreign affairs, was so kind as to communicate to me a letter to him, from a doctor of physic at Montiers, in the duchy of Taranteisie in Savoy, from whence I have made the following extract. "It has for a long time been observed, that the sheep of our Alps, which are the best in all Europe, sometimes fall away surprizingly. Their eyes become white, sunk, and blared; their blood serous, with scarce any redness to be seen in it; their tongue dry and shrivelled; their nose stuffed with a yellow,

yellow, viſcid and putrid mucus; an extreme debility, though they eat a great deal; and, in fine, the whole animal ſyſtem viſibly decaying. After ſeveral cloſe enquiries, theſe animals were found to have in their liver white papilios, with proper wings; their heads of a ſemi-oval form, bilous, and of the bigneſs of thoſe belonging to the ſilk-worm. I have been convinced of the reality of this fact, by ſqueezing above ſeventy out of the two lobes; and, at the ſame time, all the convex part of the liver became lacerated. They have been found in the veins only, without a ſingle inſtance of their being in the arteries. In the cyſtic duct ſmall ones have been found, together with ſmall maggots. The vena porta, and the capſula of Douglas, which are viſible there as in man, yielded to the ſofteſt touch. The lungs and other viſcera were ſound." It were to be wiſhed that the doctor had given us a more circumſtantial deſcription of theſe papilios; that theſe animals which he ſaw may not be ſuſpected to be no other than the common worms found in the liver of a ſheep, which are very flat and broad, and of ſo ſingular a figure, that they would rather be taken for leaves than worms.

" Every year the whole flock, weathers, ewes and lambs, are ſheared. In hot countries, where the creature may without danger be laid bare, the wool is not ſheared, but plucked off; and often they yield two fleeces in a year. In France, and the colder climates, it is cut only once a year with large ſhears, ſtill leaving the ſheep part of their fleece, as ſome defence againſt the ſeverity of the climate. The ſeaſon for this operation is in the month of May, after thoroughly waſhing them, that the wool may be as clean as poſſible. In the month of April it is too cold, and if delayed till June or July, the wool would not grow ſufficiently during the remainder of the ſummer, to ſecure them from the winter's cold. The weathers have generally more wool than the ewes, and it is alſo better. That of the neck, and the top of the back is the prime; that of the thighs, tail, belly, throat, &c. is not ſo good; and the worſt is that taken from dead beaſts, or ſuch as are ſick. White wool is alſo preferred to the grey, brown, and black, as it may be dyed of any colour. Strait wool is better than curled; and it is even ſaid that the weathers whoſe wool is too much curled, are not in ſo good a ſtate of health as the others. A conſiderable advantage may alſo be drawn from ſheep by folding them; that is, by leaving them for a proper time on lands intended for improvement. In order to this, the ground muſt be incloſed, and the flock ſhut up in it every night during the ſummer. By this means the dung, urine, and heat of the body of theſe creatures, will in a ſhort time bring the ground into heart, whether exhauſted, or naturally cold and barren. A hundred ſheep will in one ſummer meliorate eight acres of ground, which will continue its fertility ſix years.

" We are told by the ancients, that all ruminant animals have ſuet, though this is ſtrictly true only of the goat and ſheep; and that of the ſheep is in greater quantity, whiter, drier, finer, and of a better quality than any other. Fat differs from ſuet, as continuing always ſoft; whereas ſuet hardens as it grows cold. It is chiefly about the kidneys that the ſuet is found; and the left has always more of it than the right. There is alſo a great deal of it in the caul, and about the inteſtines; but this ſuet is far leſs firm and good than that of the kidneys, the tail, and other parts of the body. Weathers have no other fat than ſuet; and ſo predominant is this fat in their conſtitution, that all the extremities of their fleſh are covered with it. Their very blood is not without it; and the ſeminal lymph is ſo ſaturated with it, as to appear of a different conſiſtence from that of other animals. The lymph of the human ſpecies, that of the dog, the horſe, the aſs, and probably of all animals without ſuet, liquifies by cold, rarifies in the air, and becomes the more fluid from the time it was ejected from the animal's body. On the contrary, the ſeminal liquor of the ram, as well as that of the goat, and probably other animals that have ſuet, inſtead of rarifying in the air, hardens like ſuet, and, with its heat, loſes all its liquidity. This difference I have perceived by microſcopical obſervations on theſe ſeminal lymphs. That of the ram coagulates in a few ſeconds after its leaving the body, and to perceive the living organical moleculæ, of which it contains a prodigious quantity, the object plate muſt be heated, in order to preſerve it in a ſtate of fluidity.

" The taſte of the fleſh, the fineneſs of the wool, the quantity of the ſuet, and even the ſize of theſe animals, differs very greatly in different countries. In France they chiefly abound in the duchy of Berry; thoſe in the neighbourhood of Beauvais, and ſome other parts of Normandy, are the largeſt, and the fulleſt of ſuet. In Burgundy they are very good; but the beſt are thoſe that feed on the ſandy coaſts of our maritime provinces. The wools of Italy, Spain, and England, are finer than thoſe of France. In Poitou, Provence, the neighbourhood of Bayonne, and ſome other parts of France, there are ſheep which ſeem to be of a foreign breed; they are ſtronger, larger, and have a great deal more wool than thoſe of the common breed. Theſe ſheep are alſo more prolific than the other, it being nothing extraordinary with them to have two lambs at a time, and yean twice a year. The rams of this breed, engendering with the common ewes, produce an intermediate breed, partaking of the two from whom it proceeds. In Italy and Spain, the number and variety in the breeds of ſheep is ſtill greater; but all muſt be conſidered as forming one and the ſame ſpecies with our ſheep; tho' this ſo numerous and diverſified ſpecies hardly extends beyond Europe. Thoſe long and broad tailed creatures ſo common in Africa and Aſia, and by travellers called Barbary ſheep, ſeem to be of a ſpecies different from ours, as well as the American, Vigonia, and Llama.

" White wool being much more eſteemed than black, ſpotted or black lambs are almoſt every where ſold to the butcher; though in ſome places the far greater part of the ſheep are black; and for black lambs to be produced by a white ram and ewe, is a phænomenon common in every country. In France there are only white, brown, black, and ſpotted ſheep; Spain has dun ſheep; in Scotland there are yellow; but all theſe differences and varieties in the colour are no more fortuitous than the differences and varieties of the breeds, which are, however, wholly owing to the effects of the food, and the difference of the climate." *Buffon's Hiſtoire Naturelle, tom.* v.

The reader is indebted to the ingenious Mr. Irwin for the following obſervations relating to the management of ſheep in Ireland.

" Of all the quadrupeds, ſays he, the ſheep perhaps is the animal beſt adapted by Providence to pay the rent. It requires great attention to it; but, at the ſame time, little bodily trouble. The chief care ſhould conſiſt in their cantonment for food, in which our Iriſh farmers are extremely negligent (I mean thoſe of them that have abilities to be otherwiſe); for they ſtation them promiſcuouſly over the land, encloſing only the fattening grounds, which is done but badly, and other cattle ſuffered to mix with them; whereas ſheep, in their rearing and fattening ſtate, ſhould be by no means ſuffered to perambulate a variety of paſture. For this reaſon,

" Moſt cloſes, or encloſed fields, have ſome herbage, beſides the common graſs, predominant in them; and where ſheep are ſuffered to run over too many of theſe at once, the different mixtures in ſuch extenſive paſtures have, I am convinced, from repeated experimental obſervations, very unfavourable effects on this tender and delicate animal, both as to rearing and fattening, or as to bone and growth.

" It actually gives, or inclines them to a ſcower (and other diſorders well known to the ſhepherds) oftentimes not leſs prejudicial than that which they never fail getting in low ſwampy grounds, which always proves mortal to ſheep that are ſuffered to remain ever ſo ſhort a time in ſuch places; for though the noxious inſane effects of ſuch paſture may not immediately appear, or operate on them, it never fails bringing on the rot in the end, which manifeſts itſelf by the ſcower, and other unhealthful ſymptoms.

" A gentleman in my neighbourhood, who occupies ſeveral thouſand acres of deep, rich ſoil, ſuffered a conſiderable loſs of ſheep, particularly ewes, in the ſpring of 1759, (I think it was) and that ſeaſon was far from being inclement, eſpecially wet, which is the moſt unfavourable weather to that kind of ſtock.

" I made cloſe enquiry into the cauſes of this uncommon mortality, for ſuch it appeared to me at that time.

 SHE

"The common reasons for this destructive pestilence were indeed given; but from some observations I made from appearances, I did not judge them satisfactory.

"It seemed to me that a too extensive run of over fertile, luxuriant soil, little or no shelter, negligence in folding, and other care not difficult to be taken, but absolutely necessary to the well being of this delicate animal, had brought on a deadly and general rot.

"Many were with difficulty saved, only to languish away, in all probability, the succeeding winter; for though a sheep, the first time it is tainted with the rot, whether in winter or summer, may for that season, with great care and difficulty, be preserved, it nevertheless seldom happens that any amelioration of pasture will make it a long liver; for when it is once touched with this disorder, a cure may (as in many human chronical diseases) be patched up; but it will never get thoroughly clear of it. Hence the generality of our farmers, though they may think otherwise from their practice, appear to me to be in great error in this respect.

"But their stock is commonly too large, and they are continually buying in, or selling out; so that by not keeping them for any length of time they have not proper opportunities to explore rightly the effects of the causes we are now investigating.

"The largeness of their stock, I say, prevents them from looking minutely into these necessary matters, which is not in general the case in England. Besides, from the great numbers they oftentimes possess, they are so accustomed to losses in this way, and so little attendant to physical causes, that they are things of course with them; neglects I call them, that a little attention would easily remedy, were the flocks never so large: and in this respect indeed it must be admitted, custom erroneously commits too many to the care of one shepherd in a country not yet thoroughly improved.

"Through the laziness or inattention of the herd (for careless they almost all are) many casualties they pretend arise from the unimproved state of the farm, and easily impose them as such on their employers, whereas they solely proceed from their own neglect.

"To remove sheep often is an excellent temporary preventative against the rot, and most other disorders incident to them; but to fold them dry a-nights is still more infallible; that is, to keep them from rain; but the largeness of the flocks in Ireland, most people imagine, is an absolute bar against this salutary expedient.

"This is an ill-founded surmize. If they would divide their stock into smaller proportions, that is, to limit their sheep-walks to one or two hundred acres at most, under the care of one man; to allow to these proportions (the land being, we will suppose, of no more than a middling good sort) three sheep *per* acre in summer, and one and a half in winter, in the rearing or breeding way; and to erect on every such farm proportionable shelter-houses to a south, or south-by-east aspect, (but never to the north or west, the winds blowing, especially from the latter point, too long and cold) there would not be one third of the annual dearth of sheep there is; and in this computation I fancy the proportion is exceeded.

"Those who hold very extensive tracts, may say this simple expedient is not practicable; but it certainly is, both to the considerable and inconsiderable farmer, even in parts where timber is not easily had, which seems to be the chief difficulty. Suppose now (to give a very feasible hint) a house made of turf (if no stone or brick could be conveniently had) one hundred feet long, about fourteen wide, and the wall about five feet high, with four large doors or openings to the aspects before mentioned; slight and cheap timber girthing, easily carried from afar, would do for this business as well as the best; the thatch, whether straw out of the barn, or stubble, which last is far the best, we know, is of trifling value in those parts, and ought to be well sowed on with ropes, which makes it effectually resist stormy weather; and the erecting the wall of turf, or, which is much better, with clay-mortar, well mixed with straw-rubbish, we also know; cannot cost much, where labour is but from a groat to six-pence a day.

"In short, I could erect one of these houses in this manner on every hundred acres, which is the quantity of land that ought to be allowed to each, for fifteen pounds, Irish money, or, at most, twenty. The land, spoiled by digging off the sods, would be soon restored by the treading of the sheep. The hay-yard, of course, to be adjoining this house.

"All the objection I think can be made is, the not being able to move these houses, thereby to ameliorate different spots of the farm, as they do in Switzerland their wooden houses that run on wheels.

"Conveniencies in countries are different: in Switzerland there is plenty of wood; in many parts of Ireland the length and difficulty of carriage renders a sufficiency of it for this purpose impossible to be had: besides, moving houses, for aught I know, may do well in Switzerland, or in England; but such as I mention would answer extremely well in Ireland.

"In this way I am sensible the winter-mucking would be almost always on one spot; but it would make much dung, which might be removed to great advantage; and if it had not, is it not evident that it would be much more beneficial to lose the night-mucking, during the three or four most inclement months of the year, than treble the worth of it of one's stock? Moreover, I am not clear, but the dung being preserved from the frost would go farther than if scattered by the sheep about the land in hard weather: and, though it is much the custom to turn out dung in that season, I am certain, (and many physical causes will demonstrate it) the sooner afterwards it is mixed with the land, the more of its virtue it will retain.

"But before I quit the article of sheep: as I said before, countries and circumstances differ; for though I do not approve of extensive unenclosed pastures in Ireland, it seems in Spain they do well enough: the flocks there are small, as in France; but they have a right of commonage in that country, perhaps not in any other civilized one that we know of.

"There it is a constant practice with the shepherds, soon after shearing time, to set out with their flocks, generally consisting of about an hundred each, and to pass from one province to another, feeding them promiscuously both on ley and corn lands, the meadows, and some other particular enclosed lands, as parks belonging to the nobility, and clergy especially, only excepted.

"These itinerant shepherds often travel three or four hundred miles from their habitation with their small flock: they sometimes take part of their family, a good deal of provisions, a tent, and some well-trained dogs, and are never stopped if they keep their sheep on the open lands, and often do not return home till after lambing-time.

"They generally have one third, or half the profit of the flock for their hire." *Museum Rusticum, vol.* I. *pag.* 449.

"I think, says another writer in the Museum Rusticum, that early shearing should be preferred on many accounts: some defer this work till at or after Midsummer; but this should be avoided as very bad consequences often ensue. By this late shearing, the maggot has an opportunity of breeding in their skins; and this frets them in such a manner, that they often pine away, and lose all their flesh.

"This is easily prevented by early shearing; and, therefore if the weather be any thing tolerable, I generally do this work about the middle of May, and sometimes the beginning of that month: by this method the new growth of the wool has time to get a-head, so as to secure the sheep from the attack of the fly. It is true, that at this time of the year the weather is often cold, and chilling rains fall, which might endanger my new-shorn sheep, was no farther care taken of them: but this danger I always guard against, by washing my sheep, after shearing, with salt-water taken from the Medway: this is of great service in killing any vermin that may harbour close to their skins; and, besides this advantage, the penetrating quality of the salt so warms this animal's mass of blood, that it is a great means of preserving it from many disorders to which it is fatally subject; such as the gripes, scab, red-water, rot, &c. &c. &c. This, I say, has been my practice ever since I have lived in Kent; but before that time, when I was not within distance of the sea or Medway, to get salt-water from thence, I always made a brine of a proper strength with common salt and soft water, and applied it to the same use with equal benefit, though it cost

me,

me, to be ſure, ſomewhat more. When my ſheep have ſores, either by the bite of flies, or by ſcratching, &c. I find the beſt remedy to be that which is commonly in uſe, viz. a little tar applied to the wound: many, if you aſk their advice, will, by way of ſhewing their judgment, preſcribe to you complicated mixtures, which have no other merit but being more expenſive: but be aſſured, the more ſimple the remedy, the ſpeedier the cure.

"Many farmers ſuffer great loſſes by buying ſheep that are rotten; for which reaſon, every prudent man ſhould, when he buys a lot of ſheep, agree with the ſeller, that he ſhall warrant them ſound for a month at leaſt: this would prevent many heavy loſſes, and be a means of guarding honeſt men from being impoſed on. If ſheep are the leaſt inclinable to the rot, the beſt remedy is to drive them directly into a dry upland paſture.

"Though I ſhear my ſheep ſooner than moſt of my neighbours, I ſhould alſo have obſerved, that I always ſhear my fat weathers firſt, as they are beſt able to bear the cold; and I reſerve my poor ſheep till laſt, as the cold and chilling rains pinch them more than the others." *Muſeum Ruſticum, vol.* I. *page* 210.

I never uſed, ſays Mr. Liſle, "to ſhear till the Monday before Midſummer-day; but I now (anno 1714) find I was in an error in ſo doing; and that, as my keeping is very good, by which means the wool grows the larger, and heats the ſheep the more, and their fleſhineſs being ſuch as to bear the cold the earlier in parting with their fleeces, I ought to begin to ſhear the firſt week in June; and the ſheep would not only thrive much the better, when the load of their wool was gone, but their new wool would alſo have more time to grow againſt Wayhill fair, which would make the ſheep look more burly." *Liſle's Huſbandry, vol.* II. *pag.* 275.

We cannot but in general approve of the early ſhearing of ſheep, beginning with the fatteſt; but no certain day can, with reaſon, be fixed for doing this work; for our ſeaſons differ ſo much in various years, that next year, in the beginning of May, the weather may be ſo warm as to be very proper for the work; and in the following year, the middle of the ſame month may, on account of the cold, be too ſoon to begin. The beſt regulator for this work, as well as many others, would be the ſtate of vegetation, from repeated obſervation of ſome particular tree or plant, on a particular ſoil and expoſure; for to bring plants to a certain ſtate, requires always a certain degree of heat, and this is ſooner or later, according to the ſeaſon. Every work of huſbandry, in ſpring at leaſt, might be regulated in the ſame manner, and that to great advantage, for nature is an unerring guide.

The ſheep of the Ardennes, a foreſt in Lower Germany, are every where celebrated for the exquiſite delicacy of their fleſh; and, from a particular method of ſhearing them, their wool alſo is in no leſs eſteem.

"Amidſt all the accidents and diſtempers to which ſheep are liable, ſeldom any of them are known to die, certain innocent remedies ſoon reſtoring them. I have obſerved, every where elſe there is a fixed ſeaſon for ſhearing ſheep; and accordingly I have ſeen not a few, after being ſhorn, ſhivering with the ſharpneſs of the air; whereas, in the Ardennes, if the month of April or May be too hot or too cold, the ſhearing is delayed; and it is not often they ſet about it before the middle of ſummer. If, when bared, they are found to have received any wound in the ſhearing, it is rubbed over with a liquid pitch, and all the reſt of the body well waſhed with wine or oil.

"In ſome part of the Ardennes, the wine is mixed with oil-lees, or an ointment is made of wine, oil, and virgin-wax; and this precaution is ſaid not only to thicken their wool, but alſo preſerves them from ſores and the ſcab. They are never ſheared in the morning, it being a proverb in the country, that wool is to be ſheared, as fruits deſigned for keeping are to be gathered, when the dew and coolneſs have been exhaled by the heat of the ſun. If ſheep are ſheared when ſweating, the wool, by imbibing the ſweat, becomes the ſofter and better coloured.

"Sheep are ſubject to a kind of diſtemper, which, within two or three weeks, frequently ſweeps away a whole flock; but, to prevent ſuch a fatality, the Ardennes ſheep, at the beginning of the ſpring, have a certain potion given them.

"The flock is firſt carefully examined, and the ailing ſheep ſeparated from the ſound; an excellent method! yet is the Ardennes the only place where I ever ſaw it practiſed: after this, the juice of wild ſage and hore-hound, well cleanſed, is mixed in their drink, and this continued for a fortnight ſucceſſively. In autumn this medicament is repeated; and thoſe which are ſick likewiſe go through the ſame courſe during a fortnight, and generally with a very happy effect.

"Upon being ſeized with the ſcab, which the negligence of the ſhepherds does but too often occaſion, an ointment is prepared for them of the juice of any kind of ſage, mixed up to a conſiſtency with pulveriſed ceruſs and freſh butter: with this the ſheep are rubbed, and, three days after, waſhed with the urine of a ſhe-aſs, which cures them.

"If the exceſſive heats have ſo affected them, that they grow ſickly and faint, and even to a total loſs of appetite, the juice of wild beets is mixed in their drink, and endeavours are uſed that they ſhould eat them, which if they can be brought to, they are the ſooner upon their legs; but if any aſthmatic ſymptoms appear in the ſheep, the tip of their ears is cut off, after which the paunch of a ſheep being thoroughly boiled in wine, a ſpoonful of the liquor is given to every ſheep; and this never fails, in a very little time, to ſet them to rights.

"The cough is ſo common a diſorder among ſheep, that one ſeldom paſſes near a flock without hearing it in ſeveral: yet in the Ardennes it is otherwiſe; for upon their firſt coughing, a radical cure is wrought by ſyringing, during ſix or eight days, up the ſheep's noſtrils, blanched almonds pounded in wine.

"It ſometimes happens that ſheep feed in paſtures intermixed with noxious herbs, which not ſeldom occaſion their belly to ſwell; and this, without a ſpeedy remedy, proves fatal; but, upon the firſt appearance of it, they are bled in the lip, and a ſpoonful of man's urine adminiſtered to them, which makes a perfect cure.

"If along with the graſs they have eat any worms or leaches, olive-oil, mixed with warm vinegar, is poured down their throats: this not only cures them of the preſent evil, but preſerves them from ſeveral other accidents.

"An abſceſs, or impoſthume, in the ſheep, is cut, and ſalt, well pulverized and burnt with liquid pitch, ſtrewed over the inciſions.

"In order to make the ſheep good nurſes, ſo that they may be able plentifully to ſuckle two lambs, all they do is to bind dittany (in ſome places called pepper-wort) and trefoil to their bellies.

"Upon the lambs being ſick, a few ivy-leaves are given them to eat, which after a week ſo well reſtore them, that they ſuck very vigorouſly." *Muſeum Ruſticum, vol.* IV. *pag.* 420.

"There are, ſays Mr. Mills, in this kingdom, vaſt tracts of ground, known by the name of downs, on which are chiefly fed large flocks of ſheep. Experience has abundantly evinced, that though the graſs there is naturally ſhort, it is an excellent food for ſheep; and as the welfare of theſe creatures is of the utmoſt conſequence to one of the moſt eſſential branches of the commerce of England, very great caution ſhould be uſed in making any alteration in their diet, till it be well proved, by fair experiments, that a richer paſture does not injure their fleeces. I would therefore recommend, in the ſtrongeſt manner, to gentlemen who have eſtates bordering on ſuch downs, particularly on that extenſive tract called Saliſbury Plain, which reaches from the weſtward of Malborough to the ſea, to bring ſome of their ſheep into rich paſtures, of different graſſes, as well natural as artificial, and to keep them there for ſome generations, in order to aſcertain with certainty, what the effect will be.—The word generations, may, perhaps, here terrify at firſt, as implying a long ſpace of time for theſe experiments, thoſe who do not immediately conſider in how few years this ſucceſſion may take place.—A lamb reared from its birth on, for inſtance, burnet, will, in two years, bring a lamb, which, in two years more, brings young, and the ſixth year may ſee the third generation: ſo that by the end of ſeven or eight years the fact may be aſcertained.

"If sheep will be equally benefited by richer pasture, then the farther improvement of these downs must become a matter of great concern, both to individuals and to the public; because, granting that they may be improved with safety, the number of our sheep may be greatly increased: but if such improvement shall be found in the least detrimental to their wool, instead of being encouraged, it should be forbidden, even by law." *Mills's Husbandy, vol.* III. *pag.* 379.

SHEEP's-DUNG. *See the article* DUNG.

SHEEP's- *fescue-grass.* *See the article* GRASS.

SHEEP-LEASE, *Sheep-slate*, or *Sheep-walk*, pasture-land, appointed to the feeding of sheep.

SHEER, pure, clean, unmixed.

SHELLS, a hard, and as it were stony-covering, with which certain animals are defended, and thence called shell-fish.

The vast beds of fossile shells found at great depths in the earth, as well as those found lying on the sea-shore, make an excellent manure for cold clayey lands. *See the article* CLAY.

SHEPHERD's-*Needle*, the name of a plant, so called from the remarkable shape of the seeds, with their appendage, resembling the crane's bill.

SHIPPEN, a cow-house.

SHOEING *of horses*, the operation of fastening a piece of iron on the bottom part of a horse's hoof.

The affair of shoeing horses, is so important in its consequences, both for the preservation of the foot, the safety of the legs, and the ease of their motion, that we cannot be too attentive to any innovations, that may be recommended to us in this respect; we shall therefore give Mr. La Fosse's sentiments on this subject, with such animadversions as have occurred to us.

In order to understand this new method of shoeing, it is necessary first to premise the following observations, and attend to the anatomical plates before referred to.

It is most certain, that all horses, except such as have their feet overgrown, or such as may have a particular occasion of being shod, to preserve the sole, may, at any rate, go without shoes; and there are many examples, without mentioning the customs of Arabia, or Tartary, of horses who are at daily work, without the least need of ever being shod: but as we employ all our care, and address, to hollow the foot, by paring it even to the quick, and to form an exact fine frog, it becomes absolutely necessary to set shoes on them.

The original design of shoeing horses, was undoubtedly intended as a preservative of the hoof, and a defence of the sole; but no one sure could think it necessary to pare away, what he wanted to preserve by the use of the shoes; because that would be to act contrary to his first principles, and destroy his own work.

This precaution could never be recommended, but in cases where the horny sole is uneven, insomuch, that the shoe could not bear equally upon it, which would take off from its necessary firmness; in such a case, it may be reasonable, otherwise it would be very absurd.

Let us now observe the going, as well as the external, and internal structure of a horse's foot.

The horse then who draws, presses first on the toe, then successively on the sides, to ease the toe; then the horse's heel yields upon the heel of the shoe, from which it immediately rises again.

The saddle, or pack-horse, places the toe but lightly, so that the point of support, is fixed neither upon the heel, or toe, but between both; which it is easy to demonstrate anatomically.

Thus the cannon-bone presses on the pastern, this on the coronary, the coronary upon the coffin, or foot-bone, and upon the nut-bone.

By this description of the bones, we may observe two essential things, which lay open the faults in the present method of shoeing, and point out the means of being able to remedy them for the future; one is, that the effort of the weight of a horse, does not bear, either upon the toe, or heel, but on the middle, between both; the other shews, the greater the distance of the sole from the ground, or from whatsoever point of support, the more the pushing the coronary-bone upon the nut-bone, will fatigue the nerve, or tendon upon which it rests, by the inordinate distension it undergoes at every step the horse takes.

Thus we see, that by hollowing away the sole in paring, the horse is sustained only upon the walls of the hoof, which having no assistance of support from the horny sole, is immediately worn, and battered by the weight of the horse's body; and the sooner he treads upon any hard substance, the sooner he grows quite lame.

For by the connection, thickness, and flexibility, as well as contexture of the horny sole, it seems to be wholly destined by nature, to serve, as a cushion to the fleshy sole, and tendon, which rests upon it, in order to break the violent shocks of a pavement, stone, or any kind of stump, or external violence; but by paring it away in the customary manner, the horse loses his defence of nature, against stumps, nails, glass, &c. and thus the fleshy sole becomes easily bruised, or wounded.

It is observable, that a horse seldom goes easy, or escapes being soon jaded, if the frog does not bear upon the ground, as it is the only point of support to the tendon; so that if you keep it at any distance from the ground, by paring it away, an inordinate distension will happen to the tendon; which being repeated at every step he goes, fatigues it, and causes an inflammation; whence also relaxations, defluxions, and tendinous swellings, especially after long journeys, or hard riding, which are occasioned more by the paring of the sole, than the length of the journey; experience has shewn, that the frog neither suffers, or has shewn the least sign of fatigue, or sensibility, by being thus exposed; and indeed from the structure of it, it is scarce possible; for being of a soft spongy flexible substance, by its natural elasticity, it yields to the weight of the body, the instant the horse presses his feet to the ground, and immediately recovers it again; however, there is one case, whereby the frog may occasion lameness, which is when it grows hard or dry; but by taking off the little end of the frog, this disorder is soon remedied.

As the bad consequences of paring away the sole and frog, have been pointed out, and, I think, evidently proved, let us observe now, the ill effects of modern shoeing; for it is upon the form of the shoes, and manner of setting them on, that not only the preservation of the foot, but also the safety of their legs, and the ease of their motion depends.

In effect, the more easy our shoes set upon us, the more active we are; so a large, long, thick shoe ought to have the same effect upon horses, that wooden shoes have upon us; that is, make them heavy, unweildy, and hobling.

A long shoe is not only perfectly useless, but it is even prejudicial; for the horse's heels coming to sink upon those of the shoes, the longer the lever, the greater will be the drag upon the clinches of the nails of the toe; and thus horses will be more apt to strike them off on many occasions; especially when they are apt to over-reach.

The longer the shoe is, and the more it covers the sole, the more liable the horse will be to fall, trip, and hobble in his walk; particularly if he goes on a pavement; because the surface being formed of round parts, and the shoe having a large uniform hard face, he can scarce have above two or three points of support.

It is thought by some, that strong shoe-heels are an ease to the weak heels, and fetlocks of horses; as if the body of the shoe was flexible enough to yield to the horse's heel; and under this notion, they raise the shoe-heel, and leave a vacant space between that and the horse's heel; but the direct contrary happens, for it is the hoof, that by its flexibility yields to the shoe-heel, which is quite inflexible: the thicker the shoe-heel is, the more subject that of the horse is to meet it, and instead of being eased, the horse's heel becomes more compressed, as if in a constant vice, because it has always the same point of support.

By this means, they deprive them of the liberty of going with ease upon a pavement; because the shoe does not bear upon a level, and produces an effect, like that of a pivot, upon the middle of the shoe-heels, and the vault, or hollow.

To obviate these inconveniencies, M. La Fosse proposes the following method of shoeing; that neither the sole, or frog should be pared at all; for neither will ever become too large by its growth; but in proportion as it grows, it will

will dry, fcale, and fall off in flakes; that the edge of the hoof, if thought too long, fhould be taken down as ufual; and then a fhoe, in form of a half moon, fet on, reaching the middle of the hoof; the heels may be thinned, and the fhoes made a little longer for fuch horfes as have weak hoofs.

Eight fmall nails, made in the old way, that is, having very fmall heads, are incrufted in the holes, which are made, as the head is, in an oblong form; the figures both of the fhoe and nail, are to be feen in the plate. This is the whole myftery.

By this method, the fole is preferved, and confequently the foot defended againft hard, or fharp bodies, which the horfe may chance to tread on; thus inflammations, and dangerous compreffions are avoided, and the many inconveniencies already mentioned, from the lodgment of fand, gravel, or ftones.

Another advantage arifing from this method of fhoeing, and preferving the fole, that natural defence againft external injuries, is, that in not paring away the fole, nor fetting on any more fhoe than is neceffary to preferve the horny fole; the horfe will not be fubject to flip, either on the winter's icey pavement, or the dry fmooth one of the fummer.

For by making a horfe walk upon the frog, and partly upon the heel, the former being ftrongly rubbed, and pufhed againft the ground, or pavement, impreffes itfelf, as it were, by the weight of the horfe's body, into the inequalities, and interftices it happens to meet in its way; by this means, the foot refting on a great many more parts, which mutually eafe it, by multiplying the points of fupport, gives the animal a ftronger adherence, and more fecurity upon the place he goes.

By paring away the fole, the air when it is in this thin ftate, penetrates, and dries it to fuch a degree, that by its contraction, it compreffes the flefhy fole, fo as to lame the horfe.

By this means, alfo fand, and gravel get in, and are ground between the fole, and fhoe; and again between the horfe's heel, and thofe of the fhoe; which not readily coming out again, caufe compreffions, inflammations, &c. which laft accidents are very often the effects of a ftone's being wedged in between the fhoe-heels.

To recapitulate the whole.

The weight of the faddle horfe, does not prefs upon the toe, or heel, but on the middle between both; fo that the greater the diftance of the fole from the ground, or from whatever point of fupport, the more the great tendon will be fatigued, by the inordinate diftention it undergoes at every ftep.

The more the fole is covered by the fhoe, the more the horfe will flip, flide, or fall; becaufe the furface being formed of round parts, and the fhoe having a large uniform hard face, he can fcarce have above two or three points of fupport; fo that the greater contact the horfe's foot has with the ground, the more points are multiplied; and the fafer of confequence he goes.

By fhoeing, no other intention could be expected, but preferving the hoof, after paring away its luxuriancy.

That long fhoes, and raifing the fhoe-heel, is a very pernicious cuftom.

By paring away the horny fole, it hardens in proportion to its being thinned, and by compreffing the flefhy fole, makes a horfe lame; he lofes alfo the defence of nature againft external bodies, by which means, the flefhy fole becomes often wounded, bruifed, &c.

By paring the frog fo much away, that it is not in contact with the ground, the tendon will be inordinately diftended: by which means, it becomes fubject to inflammation, relaxation, defluxion, and rupture.

Laftly, It appears from the anatomy of the foot, that horfes are chiefly lame in thofe bones and its tendon; that the prefent method of fhoeing contributes greatly thereto, by paring away the horney fole, and hollowing the foot; by which means, the flefhy fole becomes more expofed to accidents, and the tendon fatigued, ftrained, and ruptured; its fupport being taken away by paring the frog.

We may learn alfo from hence, that no more of the toe fhould be pared away, than to keep the foot uniform with the fhoe; that the fhoe fhould be made flat, in order to adapt itfelf the better to the foot; not made too thick, or hollow, nor projecting beyond the horfe's heel.

This is the fubftance of M. La Foffe's new method of fhoeing; which from its fimplicity, and the great eafe of performing it, feems to demand our regard and attention: but though it appears well calculated for the flat pavements, and roads of France, yet we doubt its general fuccefs with us; efpecially in fome of our rough ftony countries, where the heel, and frog, being left fo intirely defencelefs, might be liable to frequent injuries from fuch irregular loofe bodies, as flints, loofe ftones, &c. We fhould fufpect alfo its fuccefs, on moift, greafy, and flippery foils, or chalks; where the fhoe heel, or cramps, feems of great ufe, to fupport a horfe, by the impreffion it makes in the furface; how inconvenient foever it may be in other refpects; tho' it muft be confeffed, from our method of fhoeing race horfes, where the whole foot comes into immediate contact with the ground, notwithftanding the courfe they run over is often very flippery, yet they feldom fall.

But though this method may not be fo generally adopted by us, in its utmoft extent, for the reafons above given; as well as from the different texture of horfes feet, which in fome will always demand a particular method of fhoeing; yet it undoubtedly may fuit many horfes, and many different parts of the kingdom; and this particular advantage every one may reap from it, viz. to pare away as little of the fole and frog as poffible, even in the old method of fhoeing: the many inconveniencies of which, we apprehend, have been fufficiently pointed out, and amply explained; and would by this means, be in a great meafure obviated.

EXPLANATION of Fig. 1, 2, 3, 4, Plate XXIV.

Fig. 1. reprefents the bottom of a horfe's foot.

a. a. a. is the horny fole.

b. the frog.

2. The hoof towards its lower edge, called by the author the wall of the foot.

Fig. 2. fhews the horny fole *a.* raifed from the flefhy fole *c. c. c.* round which is the enchannelled flefh, 6. placed in the fulcus of the inner furface of the hoof: 5. the horny part of which is foft and white.

Fig. 3. reprefents the under part of the flefhy fole *c.* raifed from the foot-bone, or what Gibfon calls the coffin-bone *d. d. d.* *g.* the covering or fheath of the Tendo Achillis. 2. The cartilage. 6. The edge of the flefhy fole confined in the furrow of the channelled horny fubftance. *Bartlet's Farriery, pag.* 352.

SHOODS, oat hulls.

SHOVEL, a well-known inftrument, confifting of a long handle, and a broad blade, with raifed edges.

SHOWEL, a blind for a cow's eyes.

SHROUD, a fhelter, or harbour.

SHUCK, a hufk or fhell.

SICKLE, a toothed hook, with which corn is reaped.

SIEVE, hair, lawn, or bafket-work, ftrained on a hoop, for feparating the flour from the bran, the duft from corn, &c.

SIG, urine, chamber-lie.

SIKE, a little rill, a water furrow, a gutter.

SILK, an extremely foft and gloffy thread, fpun by a fmall animal called a filk-worm.

It has long been a difpute whether filk can or can not be produced to advantage in England; we fhall therefore lay before our readers the following account, which we hope will not prove difagreeable.

"Could filk be produced in England fo as to furnifh the whole, or great part of what we now confume, it would, perhaps, be more advantageous to the community, than any other fubject whatever, of produce or manufacture. And there is great reafon to believe, as well from the authority of the beft judges, as from conclufions drawn from the circumftances of the thing itfelf, that it is far from being impracticable.

"As the production of filk at home does not, however, feem to be attended to at prefent, in the degree, I conceive, it merits, it is my intention here, to fet both the utility and practicability of it in a juft and full light: the firft ftep towards the eftablifhment of any undertaking, which requires numbers, being to incite numbers to attempt it.

"In examining into the importance of producing raw ſilk in Great Britain, we muſt conſider it, as a commodity we at preſent wholly purchaſe of foreigners: as one of which we ſo purchaſe to an extreme great amount, that lies almoſt entirely againſt us in the balance of trade with the countries of whom we take it:—as one, the price of which is now ſo high, as to bring the moſt perplexing diſtreſs on our manufacture of wrought ſilk, by the temptation it gives to the contraband importation of that of the French, an evil, which muſt continue unleſs ſome extraordinary remedy be found for it:—and as one, of which the future ſupply is precarious, and may ſo fail, as to occaſion hereafter the abſolute ruin of our manufactories of wrought ſilk. The prohibition of the exportation of this article from China, whence we before obtained part of what we uſe, which has had a great effect on the general price of ſilk here, evinces the ground there is for the laſt of theſe conſiderations, as the ſame, or other cauſes, may, from various events, deprive us of the reſources we yet have for the procuring what we want. The reſt of the conſiderations are founded on ſuch notorious facts, as render any proof of, or argument for their truth unneceſſary; and take away all occaſion to expatiate further on the matter in this view.

"There is, nevertheleſs, another principle of equally intereſting conſequence, from whence the importance of producing ſilk in England may be deduced. This is, the employment it may afford to idle hands, and the diſtreſſed poor. To judge properly of the extent of this benefit, it is requiſite to enquire into two points: how many and what ſort of perſons theſe hands would be? As to the firſt of theſe points, or how many people might be employed in the buſineſs relative to the production of ſilk: could the matter be at all carried on with profit to the undertakers, the number of hands that might be enlarged in the various offices of tending the worms, and winding the ſilk, would be extremely great; far beyond what thoſe of any other manufacture or culture could equal. As to the ſecond point, or what kind of perſons might be proper for this work: it would happily be, for the moſt part, women and children, whoſe preſent idle and unemployed ſtate is not leſs the ſource of vice, than it is of miſery. This is a conſideration of the moſt moment to our country in its preſent ſituation, of any other whatever. Since to eſtabliſh the habit of induſtry in females, and the youth of both ſexes, is the only means to check the growth of that licentiouſneſs and depravity of manners in the lower people, which ſeems to threaten the deſtruction of all civil order among us. Nothing can more conduce to reform, as well as to enrich Great Britain, than the finding out the means of ſettling to work all the idle youth, women, and poor of both ſexes.

"In every light, the introduction of this moſt valuable produce, appears of ſuch conſequence to us, as renders it highly worthy the diſquiſition, how far there is a probability the obtaining it could be effected. In order to this, it is proper to examine into four ſeveral circumſtances, the right concurrence of all which is, indiſpenſibly, requiſite. The firſt is, whether the climate of this country will agree ſufficiently well with the ſilk-worms, to admit of their being duly propagated, and preſerved while they are making the ſilk: the ſecond, whether the proper food can here be provided for them: the third, whether the preſent rate of labour and other attendant charges, would not raiſe the expence of producing the ſilk beyond the due bounds: and the fourth, whether the knowledge neceſſary to the performing this matter, as a practical art, is to be obtained here by thoſe who may be diſpoſed to attempt it. To ſome, or all of theſe circumſtances, the objections muſt relate, which are brought againſt the practicability of our producing raw ſilk with profit: and I ſhall, therefore, conſider them ſeparately, in order to weigh more juſtly the force of what is alledged with regard to each.

"As to the firſt circumſtance, that is, whether the climate of this country will agree ſufficiently well with the worms, to admit of their being duly propagated and preſerved, till they have made the ſilk: the negative of it has been generally ſuppoſed; and offered as a principal reaſon againſt the practicability of our producing ſilk with profit. But this notion does not appear to be well founded, when the facts, which juſter obſervations and experience in the right method of treating the worms, have brought to light, are well attended to. It is true, that if the ſame method, with relation to the time of hatching the eggs, &c. was purſued here as in the more ſouthern countries, deſtructive accidents would frequently occur: but it is now well underſtood how to retard the hatching, &c. and keep back the otherwiſe too forward vital progreſs of this animal through its ſeveral ſtages, to accommodate it to the peculiar circumſtances of this climate: by which the hazard may be avoided. And if it be ſaid, that, after all, moiſt hot weather will ſometimes kill the worms, the ſame may be affirmed in a greater degree of the ſtrong heats in Piedmont, Lombardy, and other parts of Italy; ſo that the argument deduced from this fact, would prove too much: ſince it would equally or more forcibly operate againſt the practicability of producing ſilk in thoſe countries, where it actually is produced in the greateſt quantities. Theſe tender animals ſuffer in every climate from unfavourable weather; and more generally in ſome ſeaſons in the ſouthern countries than with us, provided we uſe the due precautions; but this is a diſadvantage and not a total obſtacle to the production of ſilk with profit, as we ſee by the abſolute fact itſelf. The principal ground of this opinion, of the unfitneſs of our climate for producing ſilk, aroſe from the improper treatment of the worms here; owing to the ignorance of a better method; as trials made in a more judicious manner, have experimentally ſhewn.

"As to the ſecond circumſtance, or whether the proper food can be provided for ſilk-worms here: it has alſo been denied, but with leſs foundation than the foregoing. The mulberry-tree, particularly the black kind, the leaves of which are the food of ſilk-worms, flouriſhes as well, and is as hardy here as moſt other trees; and the white kind, though ſomewhat more tender, is yet eaſily cultivated even by ſets or cuttings. But the black affords, in general caſes, as proper food for the ſilk-worm, as the white; and is indeed, in ſome ſilk countries, the kind in common uſe. There is, however, an advantage in intermixing ſome of the white, which is, that the buds open earlier, and the leaves are tenderer, and conſequently furniſh food for the young worms ſooner, and more kindly to them, than the black. As theſe trees can, therefore, be eaſily propagated in any number, here as well as elſewhere, even from cuttings, there can be no want of means of producing food for the worms, and at the ſame expence, as in other places. It muſt be allowed indeed, theſe trees come into leaf later here, and conſequently do not afford the food ſo ſoon as in the ſouthern countries; but the progreſs of the worm to the ſtate, which renders it neceſſary, may, as I obſerved above, be correſpondently retarded, and then this objection ceaſes. There is, moreover, one circumſtance peculiarly favourable to us in this point: which is, that the leaves of the mulberry-tree never blight here after the buds are opened: an accident to which they are greatly ſubject in ſome of the parts of Europe, where moſt ſilk is produced, to the great embarraſſment of thoſe concerned in it. In this particular of the proviſion of food for ſilk-worms, we ſtand therefore on at leaſt as good a footing as any of our rivals in it: and conſequently no juſt objection can lie on this head.

"As to the third circumſtance, whether the preſent rate of labour, and other attendant charges, would not raiſe the expence of producing the ſilk beyond the due bounds; it muſt be admitted, that the whole ſtreſs of uncertainty muſt reſt here, and that it is not ſo eaſily to be cleared up, as in the other three points. It is by no means, however, evident, that the price of labour would be an invincible impediment to the produce of ſilk, if we conſider, that the far greateſt part of the work may be done by women and children, and ſome of it even by perſons aged and infirm. And as, in a great many towns and villages, numbers of hands of this kind, are at preſent wholly unemployed, they could afford to work at very low rates, and yet with great advantage to themſelves. For where perſons, whoſe ſtrength, either in conſequence of youth, old age, diſeaſe, or want of habit of working, are not fit for common labour, and lie a dead weight on their families or pariſhes, every conſtant aid becomes of great conſequence to their comfortable and better ſupport. The argument drawn from the high rate of labour does not, therefore, hold good, with respect to undertakings, where those are to be employed, who earn nothing at present: because the price of such labour cannot be taken into the comparison, in this view, betwixt country and country, as it has in fact no price any where, and this principle is most manifestly verified, by experience at Birmingham. In that town, great numbers of women, children, and infirm persons, even most of those in the parish work-house, having been engaged in the manufactures, the undertakers have reduced to a surprizing degree the price of every article they have taken in hand. The people of Geneva, one of the cheapest and most industrious places of Europe, were beat by them out of the manufacture of enameled toys, which they had for a long time monopolized: the founding, gilding, and laquering ornamental articles in metal, have been carried by them over all other places in a most extraordinary manner, and proves that where waste hands are employed, the common high rate of labour in the country becomes no obstacle to the establishment of any manufacture. That there is not any want of such hands in most places of Great-Britain, is too regretfully obvious; and that they may, by proper degrees, be brought to work, where opportunity, example, and encouragement are duly given, is evident from the instance of the town here mentioned. The argument, therefore, from the great price of labour in England, against the production of raw silk, however specious, on a slighter view, seems to vanish, when these particulars are brought into consideration: and perhaps, the dearness of all the necessaries of life, which tend to the injury of those manufactures, where strong and able hands only can be employed, may, in a short time, conduce to the promoting those, which may be carried on by the weak, and less able: as distress is the most fertile parent of industry, and even women and children, though habituated to sloth, may be brought to work, when they can no longer find the means of eating without it. Though there are, indeed, too many instances, in some counties, which show, that the habit of idleness is proof against nakedness. Mr. Pullen in his ingenious treatise, of which it will occur to take further notice below, says, that "he takes it for granted the culture of silk-worms cannot be performed by the lower class of people." But he explains, that he only means, they cannot be undertakers of it, because the worms require proper rooms, fires, mulberry-trees, &c. But this by no means makes against their being employed by those who have skill to direct them; and a very moderate fund to provide these conveniencies. As to the other attendant charges, they would, in a large concern, be very moderate. A plantation of three thousand mulberry-trees, which might occupy three acres of ground when in maturity, or in proportion while they are younger, would provide for as many worms, as would produce in silk of good quality, twelve hundred pounds sterling in value or upwards. The rest, beside the labour, would be slight buildings, fire, stands, basons set in brick-work, reels, and some other trifling implements. But I cannot give a juster view of the small compass, the whole might be reduced to, than by quoting Mr. Pullen's observation on this point: who says: "When it can be shewed, that two or three large mulberry-trees, or a proportional number of small ones, will feed a sufficient number of worms to make a pound of silk: that the stand, which holds these worms, will not take up a yard space in a room: that one person, skilled in reeling, can, with the help of a boy to turn the reel, wind off two or three pounds of silk in a day: that one pound of this silk will make near five yards of padusoy: that the whole time, from the hatching of the eggs to the reeling of the silk, amounts to no more than six weeks: that a small part of each day is sufficient for the proper attendance: and that, besides all this, it can be done with much less trouble than is generally undergone. These things, I say, being considered, and, as I hope, shewn in the progress of the instructions given in this book, then the managing of the silk-worm will appear in a more inviting light, and be looked upon as an entertainment, neither unpleasing nor unprofitable."

"This may serve to give a general view, how easy and moderate the expence of labour, &c. would be, if women and children were employed in a large manufacture of raw silk; and how small the other disbursements would be in proportion to the return: so that, perhaps, there is no undertaking of equal consequence and extent, which could be carried on with a more moderate capital than this.

"As to the fourth circumstance, or whether the knowledge necessary to the performing this matter, as a practical art, is to be obtained here by those, who may be disposed to make such an attempt, it may be now safely answered in the affirmative, though till lately great difficulties arose on this head; as neither the art of breeding and managing the worms, in a manner suitable to this climate, nor that of winding off or reeling the silk, were well understood. But at present the proper treatment of the worms is well known: and not only models of the reel used in Piedmont, the best hitherto brought into practice, are to be easily obtained: but Mr. Pullen has constructed a very good one, different from what are in use elsewhere, and very well adapted to the purpose. He has, also, published a treatise on this subject, where all the principles are well inculcated, and many just instructions given for performing the particular offices, both with regard to the treatment of the worms, and the cocoons or silk balls. It must, indeed, be allowed, that some of the methods he teaches, are rather accommodated to the pursuit of this matter as an amusement than as an article of commerce; such as hatching the eggs in the bosoms of living persons, the keeping them in bed-chambers, and the killing the worms by the heat of the sun, or the steam of water; all which, together with the preservation of a due heat and dryness in the room, where the worms are to inhabit, might be performed by stoves regulated by thermometers, in large manufactories: but this will be easily allowed for by those, who study his book with a view to applying it to practice in large. This treatise, therefore, if well understood, will furnish sufficient knowledge to any intelligent person, to begin this work, as to the management of the trees, worms and silk; and the society for the promoting arts, &c. have, in their possession, both one of Mr. Pullen's, and one of the Piedmont reels, by which any person may, on application, have either kind made. And I doubt not, gentlemen, but that your Museum will be an open channel of communication, to the displaying or removing any difficulties that shall offer to such as may engage in this work: as I know some gentlemen, who are extremely well versed in the matter, that will be very ready to lend their aid, by furnishing all the requisite information, to any who shall publickly call upon them for it.

"The practicability of producing silk in Great-Britain with profit to the undertakers, may therefore be very reasonably presumed, from what has been here advanced. But it must be acknowledged there are some difficulties which stand in the way of our expectation, that we shall not soon see the matter accomplished.

"In the first place, though it is the poorest people, who must be employed in this undertaking, as to the actual labour, yet it is by no means they, who must begin it. A capital is wanting; and also a liberal turn of mind and docility, not belonging to the lowest class of people, to learn a new art, and conduct the several parts of it, till it is so established, that imitation may afterwards be a sufficient guide. A plantation of mulberry-trees is first requisite, after that, proper buildings, with the utensils, and other apparatus for breeding, feeding, and preserving the worms, and for winding the silk. For though, after the establishment of several large manufactories of this kind, the production of the cocoons or silk balls, and the winding of the silk, may be separate undertakings; yet in the infancy of an attempt to produce raw silk, and indeed, till considerable quantities of cocoons are produced in the same neighbourhood, they must be carried on conjointly. It is necessary, likewise, that some sagacious, sensible person enterprize the superintendance and direction of such a work, till the inferior hands are rendered capable of acquitting themselves well in their respective offices; and that extraordinary attendance and care be observed, till both the skill of performing properly, and habit of attending diligently, are acquired, by all who are concerned in the management of the worms; but, if a number of persons were once duly initiated into the knowledge, and habituated to the practice, they would soon be capable of leading and teaching others.

"The

"The reafons here advanced, for the practicability of producing filk in Great-Britain, are founded on the fuppofitions, that the methods now practifed are to be purfued. But a much more favourable profpect of fuccefs prefents itfelf, when it is underftood, that very great improvements may be made, in every part of this art, which regards the treatment of the worms, on principles that are inconteftable. In large concerns, all the difadvantages, arifing from change of weather, may be totally removed, and the deftruction of the worms, from that caufe, much more effectually provided againft, than they can in hot countries. Since it is much more practicable to procure a due degree of conftant equal heat in colder climates, than to prevent too great a one in hotter. By means of tin pipes, diffufing the moft regular heat from ftoves, and of proper ventilators, the air may be always kept of an exact temperature, and yet continually changed at difcretion, fo that neither cold, moifture, nor ftagnation, may affect the worms: and this may be done with a fmall comparative expence, either with regard to the conftruction of the apparatus, or provifion of fuel. The hatching, and killing the worms, may, in like manner, be performed by ftoves, with much greater eafe and certainty, than by any of the methods ufually practifed. By the fame means, it is alfo practicable, to have a fecond product from the fame breed in one feafon; as well here, as in the fouthern countries: an advantage never hitherto brought into confideration by thofe, who have taken their notions only from a view of the prefent methods, and the accidents attendant on the natural ftate of the air in our climate. The certainty with which I fpeak of a fecond product the fame year, is not the refult of fpeculation only; but of pofitive information. For a gentleman of unqueftionable veracity, who refided fome time in China, and was at a confiderable expence in diving into all the myfteries of the Chinefe methods of the treatment of the filk-worms, even fo as to procure operators from a diftant part of the country, to perform the whole in his own houfe; affured me, that they had the art to breed, hatch, and fet to work the worms, as many times repeatedly in the year, as they chofe, allowing the due time for the progreffion from the new-laid eggs, to the time of breeding in each fucceffion. This gentleman is now abroad; but he told me, before he went, that he had communicated the whole of the Chinefe method, to a very great perfonage, in order to its being rendered of public utility. It is, therefore, to be hoped, the particulars will in due time be laid open, and fome lights thence gained, that may conduce to the further improvement of this art. The great perfection to which the conftruction of clofe ftoves, conductory warming pipes, and ventilators of every fize, is now brought, renders the application of proper heat to any of the purpofes, refpecting the management of filk-worms, much more eafily and accurately practicable than it would have been formerly: and the improvements of the reel, and the methods of winding off the filk, equally facilitate that part of the work to thofe who are to learn it.

"From a juft view of all thefe circumftances, it may be reafonably inferred, that there is no natural nor œconomical caufe of impediment to the production of raw filk in Great Britain, as an article of commerce, and that the importance of fuch an undertaking is, as above obferved, fo great, as to merit every public and private encouragement. It may, neverthelefs, be objected by fome, that this article fhould be left to North America, where the government has appointed aids for it, and where fome beginnings have been actually made. But to this, I anfwer, that the very flow progrefs, or rather the prefent retrograde ftate of the undertakings there, though pufhed forwards by very extraordinary encouragements, as well from the London fociety for promoting arts, as the government: who, befides the giving a large bounty, have erected a public filature, fhew the great difficulties they labour under; and the little profpect there is, that the confumption at home fhould be provided for from this quarter. Indeed, it feems very apparent that this concern is not fuited to colonies, where there is neceffarily a want of thofe unemployed hands, which are alone proper to be employed in it. The number of thofe poor families, where the women and children live on the earning of one man, paid only as a mere labourer, are very few in fuch places, compared to what they are with us: and yet the work muft be done by fuch women and children, to put the undertaking on a footing with thofe of other countries, whence we now take the raw filk, where this is entirely the cafe. If America, therefore, has fome advantage in the warmth of the climate, an advantage, perhaps, that does not avail over a proper ufe of ftoves and ventilators, as above intimated; yet in this other point, of being provided with proper hands, we have an infinitely greater advantage over them: and there can be no reafon we fhould neglect or facrifice it to the fpeculation of ferving them, in a matter where the event is fo precarious. It would be a great length of time before they could find hands, fhould they fucceed at all in this attempt, to produce the great quantity of raw filk we ufe in our manufactures, which is indeed fufficiently large to find work for very great undertakings both there and here. And there is no reafon of policy, why we, in a matter which may be fo properly confidered in the light of a manufacture, fhould give them the preference." *Mufeum Rufticum, vol.* VI. *pag.* 89.

SILVER-WEED, or *wild Tanfey*, a fpecies of cinquefoil which grows naturally upon cold ftiff land in moft parts of England, and is a fure mark of the fterility of the foil. Its ftalks fpread upon the ground, and fend out roots from their joints; by which means, and by the frequent fhedding of its feeds, for it flowers during the whole fummer, it foon over-runs, and fills the land to a great diftance. The leaves of this plant are compofed of feveral lobes or wings, which are generally placed along the midrib, and terminated by an odd one: they are jagged at their edges, and are of a filvery colour, efpecially on their under fide. The way to deftroy this kind of growth has been already pointed out. Mr. Ray fays, that the root of wild tanfey, which is fomewhat of the parfnip kind, is good to eat, and that hogs are very fond of it.

SIMPSON, groundfel.

SIT-FAST, a part of a horfe's hide turned horny, and which if it cannot be diffolved, and foftened by rubbing with mercurial ointment, muft be cut out, and afterwards healed as a frefh wound. It generally proceeds from a warble. *See the article* WARBLE.

SIZZING, yeaft, or barm.

SKID, the chain by which the wheel of a waggon is faftened, fo as to prevent its turning round, upon defcending a fteep hill.

SKILLING, an ifle, or bay of a barn.

SKIRRETS, a kind of pafnep, which thrive beft in a light and moift foil. They are propagated either by feeds, or by flips from the root, which is compofed of feveral flefhy fibres, about the thicknefs of a man's little finger, terminating in one head. This root, for which only the fkirret is cultivated, is reckoned wholfome and nourifhing: but it is flatulent, and too fweet tafted for many palates. The feeds of this plant, which generally produce larger roots than the flips, fhould be fown about the end of March or the beginning of April, and if they are good, the plants will appear in five or fix weeks. When they have put out their leaves fo as to be well diftinguifhed from weeds, the ground fhould be carefully hoed; and this fhould be repeated three feveral times, in the fame manner as is practifed for carrots. In thefe hoeings, which fhould be performed in as dry weather as poffible, the better to deftroy the weeds, the fkirrrets, whether fown in broaft caft, or in drills, fhould be thinned to the diftance of at leaft three inches from each other. In autumn, when the leaves begin to decay, the roots will be fit for ufe. Thefe may be preferved all the winter, and till they begin to fhoot in the fpring, when they will become hard and fticky. So will alfo thofe which run up to feed the firft fummer, and which fhould therefore be pulled up and thrown away.

The feafon for propagating fkirrets by offsets is in the fpring, before they begin to fhoot. The old roots fhould be dug up then, and the fide roots fhould be flipped off with an eye or bud to each. Thefe fhould be planted four inches afunder, in rows fufficiently diftant to leave room for digging between them.

SLAB, the out-fide plank of a piece of timber when fawn into boards.

SLECK, fmall pit-coal.

SMALLAGE, or water parſley, a plant growing naturally by the ſides of brooks and ditches in many parts of England, and is rarely cultivated in gardens. Thoſe however, who are fond of it in their pottage, may raiſe it in a moiſt ſoil, either by ſlips, or from ſeeds ſown in March. This ſeed is reddiſh, and pretty big, of a roundiſh oval ſhape, a little more full and riſing on one ſide than on the other, and ſtreaked lengthwiſe.

SMUT, a diſtemper incident to corn, and which, according to M. Duhamel, may be diſtinguiſhed by the following marks.

"1. This diſtemper deſtroys entirely the germe and ſubſtance of the grain.

"2. It affects not only the ear, but alſo, in ſome degree, the whole plant, when it has made a great progreſs.

"3. It very ſeldom happens but that when one ſtalk is ſmutty, all the ears of the other ſtalks from the ſame root are ſo too.

"4. So early as in March or April, upon opening carefully the hood or blades which cover the ear, and examining the young ear, then not above the ſixth part of an inch in length, and almoſt cloſe to the roots, I found this embryo already black, and attacked with this diſtemper. Perhaps it may not always ſeize the plants ſo early.

"5. When the diſtempered ear comes out of its coverings formed by the blades, it looks lank and meagre; the common and immediate coverings of the grains are in this caſe ſo very ſlight and thin, that the black powder is ſeen through them; and from this time nothing is found, in lieu of grain, but a black powder, which has a fetid ſmell, and no conſiſtency. As this powder, of which the conſtituent particles have but very little coheſion, and of which the coverings are deſtroyed, is eaſily blown off by wind, or waſhed away by rain; the huſbandman, in houſing theſe plants, houſes only ſkeletons of the ears. If any impreſſion of this powder remains, it is eaſily taken off by ſifting: but I have not experienced it to be contagious, like that of burnt-grain.

"M. Tillet, who gained the prize propoſed by the Academy at Bourdeaux for the beſt account of what renders black the mealy ſubſtance of grain, has obſerved that theſe corrupted ears are often found to be vitiated even in the hood, though this laſt looks as green and perfect as if nothing ailed the corn within. The upper part of the ſtalk of a ſmutty plant is not, commonly, quite ſtrait, from within about half an inch below the ear. If ſuch a ſtalk is ſqueezed there, it ſcarcely yields at all to the preſſure. If it be cut aſunder at about a ſixth part, or a quarter of an inch, below the ear, it will be found to be almoſt entirely filled with pith, in ſuch manner that only a very ſmall opening can be perceived in the heart of this ſtalk, inſtead of the large pipe that is in healthy ſtems. M. Tillet concludes from hence, that the circulation of the juices is obſtructed in the upper part of the ſtalk of ſmutty plants.

"Bearded wheat is apt to be ſmutty, as that which is not bearded; but neither M. Tillet nor I have ever met with a ſmutty ear of rye.

"Cauſes of ſmut.—The ſmuttineſs of corn cannot be owing to a want of fecundation, as many have hitherto miſtakenly imagined; ſince it affects and deſtroys the organs of both ſexes long before the time of that fecundation.

"It cannot be imputed to the ſettling of wet upon the ears, or to fogs, or to a violent impreſſion of the ſun; ſince we have ſeen the ears ſmutty long before they ceaſed to be covered with the blades, which continue green till the diſtemper has made a great progreſs.

"The ſame obſervations refute abſolutely the opinion of thoſe who ſuppoſe the cauſe of the ſmut to be in the grains, after they are formed, and before they are paſt their milky ſtate.

"The ſmut of corn has been alſo aſcribed to the moiſture of the earth: but we do not ſee more ſmutty plants in the loweſt, and conſequently wetteſt parts of a field, than in the higheſt and moſt dry. Beſides, why ſhould there be a ſingle ſmutty plant in the midſt of numbers of ſound ones? However, as it appears that corn is more frequently attacked with this diſtemper in wet years, than when the ſeaſons are dry; too much moiſture may perhaps, without being the immediate cauſe of the ſmut, favour its progreſs more than drought would do.

"Some naturaliſts have aſcribed this diſtemper to inſects. If I am not authoriſed abſolutely to deny this, I can at leaſt aſſert that, after having been of this opinion for ſome time, all my endeavours to eſtabliſh it by facts have proved ineffectual. Some obſervers have indeed ſhewn me different inſects in ſmutty grains; but as I found the very ſame kinds likewiſe in ſound ears, I believe, with M. Tillet, that they are not in any manner the cauſe of this diſtemper. We know that the corn-caterpillar devours the mealy ſubſtance of the grain: but it does not occaſion ſmut. Numbers of flies lay their eggs upon theſe ſeeds; and the worms and maggots which proceed from them, eat the ſeeds: but this does not occaſion any thing like ſmut. The Reverend Dr. Hales, to ſatisfy himſelf whether the ſmut of corn might not proceed from the ſeeds being bruiſed by the flail, took a number of grains of different ſizes, and bruiſed them with a hammer. They grew well, and bore ears which were not ſmutty. Thus his own experience convinced this ſkilful philoſopher, that he had conceived a wrong idea of the cauſe of this diſtemper.

"Several cultivators have thought that pigeons dung and that of ſheep render corn ſmutty: but this is a groundleſs notion. We have large pigeon-houſes, the dung of which is ſtrewed upon our wheat lands: the ſame is done with the dung of our ſheep, and we even fold our flocks upon thoſe lands: yet we do not find that theſe fields are more infected with ſmut than others. This allegation is therefore abſolutely deſtitute of proof.

"Wolfius was of opinion that the ſmut of corn proceeds from a monſtroſity of the embryo: but M. Aimen has refuted that ſuppoſition, by ſhewing that the male flowers of certain kinds of plants are attacked with this diſtemper: now the flowers have not any embryo.

"M. Aimen, M. D. has very judiciouſly obſerved, that the ſmut of corn cannot derive its origin from a defect in the ſap; as all the parts of the plant, except the ear, look healthy, and there are plants whoſe roots are perennial, which appear vigorous, though their ſeeds are ſmutty every year. He is of opinion, that whatever weakens the plant is apt to bring on the ſmut, and inſtances, as a proof of this, that it is a frequent cuſtom in his country to cut rye as ſoon as it ſpindles, for food for their cattle; and that this rye generally produces other ears, which ſeldom contain any but diſtempered grain: to which he adds, that ſeed-corn which has been pricked or run through with a needle; or which is not throughly ripe, and that which produces lateral or ſecond ears, is ſubject to the ſmut.

"The ſame obſerver, who has made ſeveral careful reſearches into what is properly called the ſmut of corn, holds that this diſtemper proceeds from an ulcer which attacks firſt the parts that ſuſtain the ſeeds, and afterwards ſpreads to the reſt of the flower. But, ſome will ſay, what is the primary cauſe of that ulcer? In order to diſcover it, M. Aimen examined ſeveral grains of barley with a microſcope: ſome of them were bigger than others: ſome were very hard; and others yielded to the preſſure of his nail: ſome were of a deeper, and others of a lighter colour; ſome longer, and others rounder, than they ought to have been: their rind was ſometimes wrinkled in ſeveral places, whereas in its natural ſtate it is ſmooth: and laſtly, he perceived upon ſome of them black ſpots, which, when examined with a magnifying glaſs, appeared to be covered with mould. Theſe grains were ſeparated carefully, according to their ſeveral conditions, and ſown apart, though in the ſame ground. All the mouldy grains produced ſmutty ears, the ſhrivelled, the parched, and thoſe that were attacked by inſects, either did not grow at all, or did not produce any ſmut.

"He then ſingled out a parcel of ſound grains, ſowed them, and ſome time after took them up in order to examine them again with a magnifying glaſs. He found ſome of them mouldy, replanted them all, and obſerved that the mouldy grains produced ſmutty ears.

"M. Aimen, without pretending that this is the only cauſe of the ſmut of corn, concludes from theſe experiments, that mouldineſs is a cauſe of this diſtemper.

"It is very hard to conceive how mouldineſs can produce this diſtemper; for as ſoon as the ſeed has ſprouted and produced its plant, the whole ſubſtance of the grain is conſumed. Whether the hulls or coverings grow mouldy or not, feems to be a circumftance quite immaterial to the plant, which ceafes from that time to fubfift on what the feed had fupplied it with till then. We readily conceive that if this mouldnefs attacked the plant, it might either kill it or render it poor and weak: but we cannot imagine how this mouldinefs fhould affect only the organs of fructification, and entirely deftroy them, without doing any vifible injury to the other parts of the fame plant, even though it be a perennial. However, M. Aimen relates facts; to account for which one might conjecture, fuppofing the increafe of plants to be only an extenfion of the embryo, that the organs of fructification which exift in imperceptible miniature in the feed, were already affected by the mouldinefs before the grains were depofited in the earth. But let us abide by well obferved facts: it being of more importance to collect them, than to be in a hurry to explain them by conjectures hitherto attended with little probability.

"Means of preventing this diftemper.—M. Aimen is of opinion, that, to prevent this diftemper, the fineft and ripeft corn fhould be chofen for feed, that it fhould be threfhed as foon as poffible, and that it fhould be limed immediately after, as well, fays he, to keep it from growing mouldy, as to deftroy the mould already formed, if any fuch there be; adding, that every method he has tried to make corn fo prepared grow mouldy, has been ineffectual, and that he has never known it produce fmutty ears."

According to this principle, the preparations which have been experienced to be ferviceable in the cafe of burnt-grain, and particularly M. Tillet's lye, may be equally beneficial to guard againft fmut. But we fhall not attempt, continues M. Duhamel, to make any addition to M. Aimen's advice, becaufe we have not ftudied the diftemper properly called fmut, fo much as we have that far more dangerous one which we diftinguifh by the name of burnt-grain. According to fome experiments made by M. Tillet, the black powder of fmutty corn does not appear to be contagious. However, we fhould fpeak more affirmatively on this point, if we had been able to collect a fufficient quantity of that powder: but, as was faid before, the wind and rain carry it away, and but very little of it is found in granaries. We exhort thofe who wifh to contribute to the progrefs of agriculture, to make farther trials, in order to afcertain whether the fmut of corn be really contagious or not: but at the fame time we caution them to be careful not to confound this diftemper with the uftilago, or burnt-ear; for want of which diftinction feveral philofophers have hitherto been mifled.

As weak plants are moft fubject to fmut, M. Aimen recommends good tillage, as a fure means of giving them ftrength and vigour. It is probably for this reafon that corn is very feldom fmutty when managed according to the new hufbandry.

He obferves, that all the lyes generally made ufe of, preferve the plants from mouldinefs; and of all of them, lime feems to him the moft effectual.

"M. de Lignerolle fays, that the fureft means of avoiding fmut, and that which he has practifed with fuccefs ever fince the year 1739, on upwards of three hundred acres of land, is, to change the feed every year, to be very careful that the feed-corn be well dried and thoroughly ripe, and that it be not fmutty, nor have any fmutty powder fticking to it. He then pours boiling water on quick-lime, in a large tub; and after the ebullition is over, as much cold water as there was hot, and ftirs it all ftrongly together, in order to diffolve and thoroughly mix the lime. The quantity of wheat intended to be fowed is fprinkled with this lye, and then well ftirred with a fhovel, and laid in as high a heap as poffible. It is beft to keep the grain for a week after this preparation, turning it every day; for otherwife it would heat fo as to deftroy the germe. By thefe means he has not had any fmut, when the fields around him have been infected with that diftemper.

"M. Donat, near Rochelle, thinking the ingredients commonly employed in fteeps too dear for the ufe of farmers, ftudied for fome years to find out fomething cheaper, eafy to be had every where, and therefore better calculated to be of general ufe. "I have had, fays he, in a letter to M. Duhamel, the good fortune to accomplifh what I wifhed; for I now ufe only pidgeons-dung, quick-lime, afhes, and fea-falt, where this laft can be conveniently had. I have fometimes made with thefe ingredients, fteeped in water, fo ftrong a liquor, that it has even deftroyed the germe of the grain. But there will be no danger of that, if care is taken to obferve the following directions, which are the refult of feven years fuccefsful experience, even at times when farmers who have neglected to follow my example, have had fuch wretched crops as have not paid the charge of reaping.

"Take quick-lime and pigeons-dung, of each twenty-five pounds, forty pounds of wood-afhes, and twenty-five pounds of fea-falt, or falt-petre. Put all thefe into a tub large enough to hold half a hogfhead of common water added to them. Stir them all well with a ftick, till the lime is quite diffolved. This lye will keep fome time without fpoiling. It muft be ftirred again juft before the corn is fteeped in it. The grain is then put into a bafket, and plunged in the lye, where it remains till it has thoroughly imbibed it; after which it is taken out, and laid in a heap, till it is quite drained of all its moifture: or, which is a ftill better way, take a mafhing-tub, fill it with grain to within four inches of the brim, and then pour in the lye well ftirred beforehand. When the tub is full, let the lye run out at the bottom, into fome other veffel, in order to ufe it again for more corn. Let the grain be then taken out and laid in a heap to drain; and continue in this manner to fteep all your feed-corn. The wheat thus prepared may be fowed the next day, and muft not be kept above five or fix days, for fear of its heating. This I fay from experience. The quantity of lye above prefcribed, will ferve to prepare twenty bufhels of wheat.

"Mr. Tull obferves, that brining, and changing the feed, are the general remedies for fmut. The former of thefe, he had heard, was difcovered about feventy years before he wrote, by the fowing of fome wheat which had been funk in the fea, and which produced clean corn, when it was a remarkable year for fmut all over England: but he afterwards doubts whether this might not happen by its being foreign feed, and therefore a proper change for our foil. He tells us that two farmers, whofe lands lay intermixed, ufed feed of the fame growth, from a good change of land, and that the one, who brined his feed, had not any fmut, whilft the other, who neglected that precaution, had a very fmutty crop—But again he doubts whether this feed might not have been changed the year before, and fo might not be greatly infected; or at leaft not more than the brine and lime might cure. He adds, that fmutty feed-wheat, though brined, will produce a fmutty crop, unlefs the year prove very favourable; for that favourable years will cure the fmut, as unkind ones will caufe it: but above all, he affures us, that the drill-hufbandry is the moft effectual cure."

"Count Ginanni, a patrician of Ravenna, who has favoured the world with a very accurate and ingenious treatife on the diftempers of corn in the blade, deems the ruft incurable, after it has once taken place. He has prevented it by fprinkling the plants, before their ears were formed in their hoods, with a folution of fal ammoniac or falt-petre in water mixed with falt of tartar, and with other alkaline fubftances; but obferves, that fuch preparations are too dear for the ufe of farmers. He thinks, that fowing thin and keeping the corn quite free from weeds, will generally be a good prefervative, as he himfelf has frequently experienced."

"The fmut in wheat, fays a writer in the Mufeum Rufticum, is an evil which has long been complained of, and many methods tried to prevent it, all of which have proved ineffectual, or, at beft, but a mitigation of the difeafe; which methods I need not here enumerate, as they are generally known, or are to be met with in various authors who have wrote on agriculture: fome of them being calculated to forward vegetation, and ftrengthen the plant, fuch it will be advifeable to continue in the practice of.

"But amongft all the authors who have wrote on this fubject, I do not remember to have feen one who has pointed out a probable conjecture with refpect to the caufe of this malady, fo as to be fupported by any tolerable degree of reafon. And inafmuch as natural hiftory has been, and is my favourite ſtudy, (of which I take agriculture and a knowledge of cattle to be no ſmall part) I have frequently employed ſome leiſure hours, to endeavour to aſſign cauſes for various diſeaſes, to which the productions of the earth are ſubject; among which, this of ſmut in wheat is one. And being deſirous to improve my knowledge, I am willing to communicate, that if any thing worth notice might come from me, I may have the pleaſure of doing ſomething for the public good, and thereby induce others to make their diſcoveries known, from which myſelf, as well as many more, may reap ſome advantage.

" I remember to have read a little treatiſe, wrote ſome years ſince, by James Logan, (chief juſtice, and preſident of the council, of the province of Penſylvania) on the generation of plants, containing obſervations made on the maize, by which he diſcovered that plant to be (what Linnæus calls monoecia, or) a plant bearing male and female flowers, and, as ſuch, capable of being impregnated with a fructifying duſt from another plant of the like kind.

" I own, the reading this pamphlet firſt gave me the hint of the generation of vegetables, from which I continued my obſervations reſpecting other plants, and among the reſt to wheat, and the like; though this is not of the ſame claſs with maize, but of the claſs triandria of Linnæus, and is hermaphrodite, yet, nevertheleſs, equally ſubject to be impregnated by duſt from another plant, as well as with duſt from itſelf.

" Having frequently obſerved amongſt wheat, while green, (though ſhot up into ſpindle) ſeveral black, blighted ears, I examined them, and found theſe were ears in which, by ſome accident, the intention of nature was prevented; I ſuppoſe, by being detained too long in the hoſe, and by the natural humidity of the plant, a fermentation promoted in its ear, deſtroying the ſmall veſſels through which the corns were to receive nouriſhment; by which means their contents became black, dry, and duſty: theſe ears, growing up with the others, imbibe moiſture ſufficient to cauſe the duſty particles in the grains in them to expand, and burſt the fine ſkin which contained them: being thus ſet at liberty, the air, if it happens to be a dry ſeaſon, dries them again; by which means they become light enough to float therein, when ſeparated from the ſkin which held them. If this happens when the wheat is in bloſſom, which it often does, part of this duſt enters the ſtygma of healthy corns, and thereby infects them: the pulp in thoſe becoming black, a fermentation is raiſed therein, which deſtroys the life of the grain thus impregnated: hence the diſagreeable ſmell is acquired peculiar to this diſeaſe (the ſmell in a grain of ſmut being the ſame as in a black blighted ear.)

" From hence it is eaſily accounted for, why, often, a few grains in an ear are ſmutty, and the others good.

" Some may perhaps object, if this be the caſe, why are not barley and oats ſubject to the like diſeaſe, ſince both theſe are ſubject to the black blight as well as wheat? Such objectors would do well to obſerve, that theſe have a more tough ſkin than wheat, which does not burſt till after the blowing of theſe ſorts of corn is over; therefore, when it does burſt, the duſt can do no harm.

" Having thus pointed out the cauſe, I now proceed to preſcribe the remedy, which is, when the corn is ſhot into ſpindle, and the ears begin to appear, let ſome perſons go along each furrow in the field, and carefully break off all ears of the black kind, (not pull them up, becauſe often from the ſame root grow ſeveral others, which are good and ſound ears) and when broke off put them into a bag, and carry them away; for ſhould they be thrown on the ground, there may ſtill be danger of infection from them; and as, 'tis poſſible, there may be ſome of theſe diſeaſed ears, which are not burſten, and therefore may eſcape being gathered, theſe may be known by the ſtalk at the neck being crooked, and bent in the length of three or four inches backward, and forward five or ſix bends, and the hoſe nearer to the head of ſuch than the ears which are good.

" The ſeaſons in which wheat is moſt liable to be ſmutty are, it is well known, ſuch in which it happens to be dry weather and windy at the time of blowing; but if it happens to be wet during that time, it is very rare to ſee a ſmutty ear in a field." *Muſeum Ruſticum, vol.* II. *page* 19.

" As the ſmut in wheat, ſays another writer in the ſame work, is an evil greatly complained of, and not without reaſon, among farmers, I have no doubt but your readers will be well pleaſed to be informed of a means of preventing the damage which is annually experienced in this reſpect.

" As I write from experience, what I communicate may be depended on; and I have great foundation for thinking it will be found of particular ſervice to ſuch of your readers as are practical farmers, and who yet are unacquainted with the method I intend to recommend.

" I have, for many years paſt, eſcaped having ſmutty crops, by a proper care of the ſeed-wheat before it is put into the ground; and the method I purſue, though efficacious, is in itſelf ſimple and cheap.

" I take four buſhels of pigeons dung, which I put into a large tub: on this I pour a ſufficient quantity of boiling water, and, mixing them well together, let them ſtand ſix hours, till a kind of ſtrong lye is made, which, at the end of that time, the groſſer matter being ſubſided, I cauſe to be carefully drained off, and put into a large keeve, or tub, for uſe.

" This quantity is ſufficient for eighty buſhels of ſeed-wheat.

" My next care is to ſhoot into this ſteep a manageable quantity of my ſeed, which is immediately to be violently agitated, with either birchen brooms, or the rudders that are made uſe of in ſtirring the malt in the maſh-tub in a brewing-office. As the light grains riſe, they muſt be diligently ſkimmed off; and after the ſeed has been agitated in this manner for the ſpace of perhaps half an hour, it may be taken out of the ſteep, and ſown out of hand, with great ſafety: and I can venture to ſay, that if the land is in good heart, and has been properly tilled, it will not, when ſown with theſe precautions, produce a ſmutty crop." *Muſeum Ruſticum, vol.* III. *page* 81.

Another gentleman, who ſigns a Norfolk farmer, declares he always obſerved, that if the ſeed was well waſhed it never failed: that he took the hint, and waſhed ſome ſeed which he knew to be ſmutty, in a large tub filled with plain ſimple water, ſtirring it violently with birchen brooms, taking care, from time to time, to ſkim off the light. This anſwered very well, and he has ever ſince continued the practice.

" I read, ſays another gentleman, the above account with ſome degree of ſatisfaction, but am ſorry that your correſpondent ſhould be ſo much a lover of brevity, as to ſay no more on a ſubject of ſuch infinite importance.

" The truth is, we Engliſh farmers have hitherto known very little of the nature of this diſeaſe in wheat, imagining that whenever the corn was black it was infected with the ſame diſorder; but this is far from being the caſe, as any of your readers may ſee, by referring to a piece written by Monſ. de Gonfreville of Normandy, publiſhed in the ſecond number of the Foreign Eſſays on Agriculture, &c. (which I cannot but eſteem a very uſeful work) and containing a detail of a number of experiments made by the above gentleman to aſcertain the cauſe of the ſmut.

" I was not a little pleaſed to find that the method preſcribed in this invaluable Eſſay, for guarding againſt this diſtemper, does not materially differ from that above recommended.

" Both theſe gentlemen depend on the clean waſhing of the ſeed, and the trials of both met with the wiſhed-for ſucceſs."

We ſhall conclude this article, with the following method of preventing this deſtructive diſtemper, ſent us by the ingenious Mr. Bromwell Powell, of Green's Forge, near Stourbridge in Worceſterſhire, dated September 1766.

" I have here, ſays he, ſent you an infallible remedy againſt the ſmut in wheat, a thing ſo prejudicial to the community in general, and which I myſelf have made uſe of for ſeveral yeers paſt, and have ſown ſmutted wheat, prepared as under directed, and have not had one ſmutted ear from the produce; and am well aſſured if the farmers will obſerve the under direction, they never will have any. Now as the coating of wheat with brine and lime, is ſo well known to the farmers in general, I need ſay no more on that ſubject, as you have directions from many authors concerning it: but when wheat is so prepared with brine and lime as is usual, then to every strike of wheat so prepared, add one pound and an half of red lead, by putting it into a cullinder and shaking it gently over the prepared corn, and sometime stirring the corn with a shovel, that every corn may have a spot or two of the lead adhere to it, which when so done is an effectual preservative against the above malady, nor will any fowls lie upon it after so prepared.

"By the above method several of the penurious farmers will look upon it to be a great expence, as the lead will cost, bought in small quantities, three-pence per pound; but admit every strike was to cost six-pence per strike, it would greatly answer the farmer's purpose: I therefore have ordered as small a quantity as can be complied with; but if more was added it would still be a greater preservative. As the time of sowing is now near at hand, I hope the gentlemen will apply to some farmer, whom they can depend upon, to try the experiment of one strike so prepared; and, if they can readily procure it, let half a strike of it be smutted corn when sown, and to that half strike would advise one pound of the lead to be applied, which will be a convincing proof of the utility of the above."

SNAIL-COD, or *Snag-greet*, a name given by Mr. Worlidge, to a species of manure, found at the bottom of deep rivers. It is a kind of mud or sludge, very soft, full of wrinkles, and intermixed with many little shells and snails, to which it is thought to owe a great part of its fatness.

SNATHE, the handle of a scythe.

SOAP-ASHES. *See* ASHES.

SOIL, a general name for all sorts of land. *See the articles* EARTH *and* GROUND.

Soils are divided by our farmers into nine sorts, viz. the sandy, the gravelly, the chalky, the stony, the rocky, the hazely, the loamy, the marshy, and the clayey. *See the articles* SAND, GRAVEL, CHALK, &c.

SOOT, a fuliginous substance formed in chimnies.

Soot, either of vegetables or of coal, is good both for corn and grass, especially on cold moist grounds, or lands apt to be over-run with moss. Many have found their account in strewing it early over their grean wheat and barley: but Mr. Ellis says neither of them ought to be sooted after the 25th of April, because the wheat, and generally the barley, have then done gathering and branching, and are upon the spindle. He likewise thinks it proper to be sown over young turneps, just after they have appeared. But care should always be taken not to strew it too thick, lest its hot nature should hurt the plants. Mr. Worlidge seems to think wood-soot the best: but Mr. Mortimer prefers that which is made from sea-coal, of which about forty bushels are commonly allowed to an acre; though some grounds will require more: to which he adds, that it produces a very fine sweet grass, and destroys worms and weeds; and that it ought not to be sown upon wheat till Candlemas, because the long cold rains and snows are apt to wash it in too soon: nor is it safe to lay it on later, lest a drought succeed and burn it up. *See the article* COAL-SOOT.

SORREL, a well known plant propagated in kitchen-gardens.

Sorrel is used for many purposes in the kitchen, and they who are fond of acid herbs in their sallets cannot well have one whose tartness is more agreeable. The two sorts chiefly cultivated in the kitchen-gardens here are, the common sorrel, which has longish and sharp pointed leaves, and the round-leafed garden, or Roman sorrel. Both of these are perennial; but the round-leaved sort is most esteemed.

This is propagated by its creeping roots, which may be transplanted either in spring or autumn; but the autumn is best for dry ground. The distance between them should be at least two feet every way; for this plant spreads pretty far, and increases greatly, especially on stony land; for its natural growth is upon rocks. It seldom produces good seeds; and hardly any at all when it is set in a light soil.

The common sorrel, which grows naturally in pasture lands in most parts of England, and which is considerably improved by culture in the garden, is multiplied either by its seeds, or by parting of its roots. The former of these methods produces the largest and most succulent plants, if they are allowed sufficient room: but in whichever way they are raised, they should stand at least six inches asunder, in rows so far distant from each other as to admit of digging the ground between them every spring, if not oftener, especially in the hot months, besides hoeing up the weeds whenever these are numerous, or begin to grow tall. Autumn is the best time for sowing of these seeds upon dry land, and also for parting or transplanting the roots, which, with the above management, may stand un-removed for two or three years.

The seeds of the annual sorts of sorrel should be sown about the latter end of March, on a bed of common earth, in rows a foot and an half asunder; and when the plants are come up, they should be thinned to the distance of four or five inches from each other. This, and keeping them clean from weeds, is all the culture that they will require: but both their size and their goodness will certainly be increased by a good stirring or two of the ground, which may easily be given at the time of weeding; for both should be done in dry weather. These plants will flower in July, and their seeds will ripen in autumn.

SOUR LAND, a cold clayey soil. *See the article* CLAY.

SOW, the female of the swine. *See* HOG.

SOWING, the action of scattering the seeds of plants in the ground.

Writers of different countries mention the usual seasons for sowing their several kinds of grain, but do not take notice of any sign by which the husbandman may be directed when to sow his corn with the greater chance of success. For a rule of this kind we are indebted to the justly celebrated Linnæus, a man truly great, not only for his unequalled knowledge in natural history, and his indefatigable industry in the pursuit of that science; but even still more so for his disinterested zeal to turn the result of his studies to the advantage of his country. Far superior to that mean jealousy which little minds are apt to entertain on their discoveries, he nobly calls forth every assistant, and invites each of them to become his rival in promoting the general welfare of mankind, as we are particularly informed by one of his disciples.

"It is now the fourth year, says the ingenious Mr. Harald Barck, a member of the Swedish academy, since our illustrious president exhorted his countrymen to observe with all care and diligence, at what time every tree expands its buds, and unfolds its leaves; imagining, and not without good reason, that our country would, some time or other, reap some new, and perhaps unexpected benefit, from observations of this kind made in different places."

As one of the apparent advantages, he advises "the prudent husbandman to watch with the greatest care the proper time for sowing; because this, with the divine assistance, produces plenty of provision, and lays the foundation of the public welfare of the state, and of the private happiness of the people. The ignorant farmer, tenacious of the ways and customs of his ancestors, fixes his sowing season generally to a month, and sometimes even to a particular day, without considering whether the earth be prepared to receive the seed: from whence it frequently happens, that the fields do not return what might be expected, and that what the sower sowed with sweat, the reaper reaps with sorrow. The wise oeconomist should therefore fix certain signs whereby to judge of the proper time for sowing. We look up to the stars, and without reason, suppose that the changes on earth will answer to the heavenly bodies; entirely neglecting the things which grow around us. We see trees open their buds and expand their leaves, from whence we conclude that spring approaches, and experience supports us in this conclusion: but no body has hitherto been able to shew what trees Providence intended should be our calendar, so that we might know on what day the countryman ought to sow his grain. No one can deny but that the same power which brings forth the leaves of trees, will also make the grain vegetate; nor can any one justly assert that a premature sowing will always, and every where, accelerate a ripe harvest. Perhaps therefore we cannot promise ourselves a happy success by any means so likely, as by taking our rule for sowing from the leafing of trees. We must, for this end, observe in what order every tree puts forth its leaves, according to its species, the heat of the atmosphere and the quality of the soil. Afterwards, by comparing together the obſervations of ſeveral years, it will nót be difficult to define, from the foliation of trees, if not certainly, at leaſt probably, the time when annual plants ought to be ſown. It will be neceſſary likewiſe to remark what ſowings made in different parts of the ſpring produce the beſt crops, that by comparing theſe with the leafing of trees, it may appear which is the moſt proper time for ſowing: nor will it be amiſs in like manner to note at what times certain plants, eſpecially the moſt remarkable in every province, blow; that it may appear whether the year makes a quicker or ſlower progreſs. In upland, the ſowing of barley nearly coincides with the foliation of the birch."

Mr. Stillingfleet, who has given us a judicious tranſlation of ſome ſelect pieces publiſhed by ſeveral ingenious members of that great, and hitherto unrivalled ſchool of natural hiſtory, the univerſity of Upſal in Sweden, under the preſidence of the excellent Linnæus, was told by a common huſbandman in Norfolk, that when the oak catkins begin to ſhed their ſeed, it is a proper time to ſow barley: " and why," adds he, very properly, " may not ſome other trees ſerve to direct the farmer as to other ſeeds. The prudent gardener never ventures to put his houſe plants out, till the mulberry leaf is of a certain growth." Heſiod, continues this gentleman in his ingenious note on M. Barck's foliation of trees, began to fix the proper ſeaſons for plowing, ſowing, &c. by the appearance of birds of paſſage, or of inſects, or by the flowering of plants; but I do not find that this method was ever after attended to till Linnæus wrote. Heſiod ſays, that when the voice of the crane is heard over-head, then is the time for plowing; that if it ſhould happen to rain three days together when the cuckow ſings, late ſowing will then be as good as early ſowing; that when ſnails begin to creep out of their holes, and climb up the plants, it is time to leave off digging about vines and take to pruning. There is a wonderful coincidence, which probably takes place in all countries, between vegetation and the arrival of certain birds of paſſage. Linnæus ſays, that the wood-anemone (in Sweden) blows from the arrival of the ſwallow: and Mr. Stillingfleet finds by a diary which he kept in Norfolk for the year 1755, that the ſwallow appeared there on the 6th of April, and the wood-anemone was in bloom on the 10th of the ſame month. Linnæus obſerves, that the marſh-marygold blows when the cuckow ſings; and Mr. Stillingfleet finds by his diary, that the marſh-marygold was in bloſſom on the 7th of April, and the cuckow ſung the ſame day.

A due temperature of the ſeaſon, with reſpect to heat or cold, drought or wet, for all theſe greatly influence the ſtate of the earth, is eſſentially neceſſary, and ſhould be carefully attended to by the huſbandman when he ſows: but the preciſe time moſt proper for this work, cannot, by any means, be invariably fixed, becauſe it will always depend on the concurrence of a variety of circumſtances. The ſeaſons are more or leſs forward, and the ground is more or leſs dry, in ſome years, than in others. A proper ſeries of well made obſervations would furniſh the beſt of rules in this reſpect, but certainly would not fix the time of ſowing to any particular day, or week, for years to come. Linnæus's method, of carefully obſerving the foliation of trees, &c. would determine the proper times for ſpring ſowing; and Pliny, after mentioning the ſeveral conſtellations by which farmers were guided in his time, inſtructs the huſbandman with regard to autumnal ſowing, upon a principle ſimilar to that of our great modern naturaliſt. " Why," ſays he, " does the huſbandman look up to the ſtars, of which he is ignorant, whilſt every hedge and tree point out the ſeaſon by the fall of their leaves? This circumſtance will indicate the temperature of the air in every climate, and ſhew whether the ſeaſon be early or late. This conſtitutes an univerſal rule for the whole world; becauſe trees ſhed their leaves in every country according to the difference of the ſeaſons. This gives a general ſignal for ſowing; nature declaring, that ſhe has then covered the earth againſt the inclemency of the winter, and enriched it with this manure."

I therefore can only ſay, in general, that it is better to ſow early in autumn, than too late, provided the ſeaſon will admit of it; becauſe the plants are better able to reſiſt the ſeverity of the winter, after they have acquired a certain degree of ſtrength; and their roots being then longer, and conſequently better fixed in the earth, they will be leſs liable to be thrown out by froſt. For this reaſon, in particular, perhaps the colder the climate is, the earlier the wheat ſhould be ſowed. Some lands are of ſuch a nature, that they ſwell greatly in hard froſts, and, ſubſiding again upon a thaw, leave the roots of plants quite bare upon their ſurface. There have, indeed, been years in which fields ſowed very late, for inſtance in December, have done extremely well: but that ought not, on any account, to be made a rule; experience ſhewing that ſuch late ſowings very ſeldom anſwer. On the other hand, the corn is likewiſe expoſed to many dangers when ſowed too early: for the ſtalks which ſhoot up before winter cannot well bear hard froſts, though wheat would not be hurt by them when only in the blade.

M. de Chateauvieux, than whom we cannot have a better guide, is clearly of opinion, that, though the proper time of the year for ſowing be come, the corn ſhould not be put into the ground if the temperature of the ſeaſon be not favourable, and that on the contrary the ſowing of it ought to be deferred, in hopes of a change. " If, ſays he, the weather is very hot, and the earth extremely dry, it will be abſolutely neceſſary to wait till ſome rain has fallen; for otherwiſe the ſeed will riſe but very imperfectly. This I am ſure of, by which I contradict the common ſaying of ſome farmers, that the earth is the beſt granary to keep the corn in. Full of this notion, whenever the ſtated time comes round, they ſow without diſtinction, in wet land or in dry: even heat does not hinder them: they think their ſeed will certainly ſprout well after the firſt rain: but I have always experienced that the plants have come up thin.

" To ſatisfy myſelf ſtill farther in this point, I tried an experiment, purpoſely to know whether corn can be ſowed, with any reaſonable expectation of ſucceſs, when the weather is very hot, and the earth very dry. Upon reading Mr. Duhamel du Monceau's excellent Treatiſe on the Preſervation of Corn, I obſerved, that he had found by his experiments, that wheat dried in a ſtove heated to ſixty degrees of M. de Réaumur's thermometer, had loſt its faculty of growing. From thence I conjectured, that wheat which ſhould undergo a heat, for example, of thirty degrees, during a longer time, would be equally parched up, and rendered incapable of vegetating. I conſidered the earth, when hot and dry, as a kind of ſtove, in which the ſeed, if it remain too long without receiving any moiſture, may become ſo dry, that the greateſt part of it will never be able to ſprout. This reaſoning is juſt, and I therefore determined to have recourſe to that truſty guide, experience.

" On the 18th of July, 1754, at four o'clock in the afternoon, I placed M. de Réaumur's thermometer two inches deep in the earth, and ſcreened it from the immediate impreſſion of the rays of the ſun. The liquor roſe to the thirty-firſt degree, which ſhewed me the heat of the earth.

" The thermometer being afterwards expoſed to the ſun, the liquor roſe to thirty-ſix degrees.

" The ſame day, I ſowed eighty grains of wheat in this ground. The heat continued nearly the ſame during the reſt of that month, and almoſt all Auguſt. On the 31ſt of July, only ten grains had ſhot up, and on the 16th of Auguſt there were in all ſixteen; after which, not one more roſe: conſequently ſixty-four grains out of the eighty never ſprouted at all.

" On the 28th of July I ſowed fifty grains. Only four of them roſe by the ſixteenth of Auguſt, and not one after. Here were again forty-ſix grains which did not grow at all.

" The ſame day, I ſowed ſixty grains in another place. On the 16th of Auguſt only ſix grains had ſprouted, and not one plant more ever appeared after: conſequently here too were fifty-four grains which never grew. All theſe grains were ſowed in my garden, in exceeding good mould.

" I was ſure that the wheat which I ſowed was perfectly ſound, and in every reſpect capable of growing. It was therefore quite clear, that ſo great a number of grains out of the whole, which did not ſprout at all, had loſt the faculty of growing, by their being parched up by the heat and dryneſs of the earth. To be ſtill more certain of this, three weeks after I had ſowed theſe grains, I watered half of them ſeveral times; but to no purpoſe: not one of them roſe, and I found ſeveral of them quite whole in the earth where I had ſowed them.

"After this experiment, on the 11th of Auguſt I ſuſpended the ſowings I had begun on the 8th, and did not reſume them till the 26th, after ſome rain which fell on the 22d and 23d. Theſe laſt ſowings roſe much better than the firſt."

Upon the whole, M. de Chateauvieux concludes from his own repeated practice, that the beſt time for ſowing in ſuch a climate as Geneva (which differs very little from ours,) is, from the 20th of Auguſt to the end of September; and thinks that even the firſt fortnight in October may be taken in, if the land cannot poſſibly be ſowed ſooner. But he allows of this only in a caſe of neceſſity, and judges that, rather than ſow later, it is beſt to ſtay till ſpring.

"Thus, ſays he, it is that experience and obſervation teach us to leave off bad cuſtoms, of ſuch as are not founded on principles with which a man of ſenſe can reſt ſatisfied."

It is of the greateſt conſequence to farmers that every ſeed be placed in the earth at a proper depth, and in the beſt manner: but experiments are yet wanting to determine with due exactneſs, what is the depth which beſt ſuits each kind of grain, in different ſoils,

The method which Mr. Tull propoſes, is a very good and eaſy way to aſcertain this point for each particular ſowing. Take, ſays he, twelve ſticks, or gauges; bore a hole in one at the diſtance of half an inch from the end, in the ſecond at an inch, and ſo on, increaſing half an inch to each of the twelve. Drive a peg into each of theſe holes: then, in the ſame ſort of ground as you intend to plant, make a row of twenty holes with the half inch gauge; put therein twenty good ſeeds; cover them up, and ſtick the gauge at the end of that row; then do the like with all the other eleven gauges. This will determine the depth at which moſt ſeeds will come up; and the drill, if that inſtrument be uſed for the ſowing, muſt be ſet accordingly.

Upon the ſame principle, M. Duhamel dug a trench twelve feet long, ſloping it gradually from the ſurface at one end, to the depth of two feet at the other. He then ſowed different ſeeds in this trench, and, having put the earth into its former place, obſerved, 1, That hardly any ſeeds riſe when buried deeper than nine inches: 2, That ſome ſeeds riſe extremely well at the depth of ſix inches; and 3, That other ſeeds do not riſe at all when they are above one or two inches deep. Experience ſhews, that the ſame ſeeds may be ſowed deeper in a light, than in a heavy ſoil; that grains which lie too deep in the earth to ſpring up in a dry year, may riſe in a warm and moiſt ſeaſon; and that others which are buried ſtill deeper in the ground, will ſometimes remain there ſound and unaltered for ten or twenty years, at the end of which they will grow extremely well, and produce their proper plants, if they chance to be brought to the ſurface, by moving the earth, as was mentioned before.

The uſual way of ſowing in broad caſt cannot anſwer all the intentions of placing the ſeed properly in the earth, and muſt be attended with ſeveral inconveniencies; ſuch as, the ſeed's becoming the prey of various birds and animals; its being laid ſo ſuperficially, that the ſun often parches it up, or a long continued rain, inſtead of promoting a kindly vegetation, ſoaks into the grains and burſts them; the ſeed is very unequally ſowed, becauſe of the inequality of the handfuls which different ſowers graſp: and great part of it neceſſarily falls together into hollows, where the ſurface of the ground is at all unequal, &c.

Senſible of theſe diſadvantages, farmers have, eſpecially for their winter grain, adopted the method of ſowing under furrow, that is, ſowing one half of the ſeed in broad caſt, and then plowing it in, and afterwards ſowing the other half, which is covered by harrowing. But this method is alſo liable to almoſt as many objections as the other: for the quantity ſown in each particular ſpot, and the equal diſtribution which ought to take place throughout the whole, cannot but be even more uncertain than in the broad caſt, where the whole is ſowed at once; nor dares the farmer, in this ſowing under furrow, to omit ſowing the ſecond quantity, leſt great part of what has been plowed down be buried ſo deep that it cannot riſe, eſpecially if the ſoil is at all ſtrong.

Another general fault in the common ways of ſowing, is, that too much ſeed is employed; partly, becauſe cuſtom has eſtabliſhed a kind of rule in that reſpect, and partly on account of the allowance which it is neceſſary to make for what the birds eat, and for what lies too deep ever to riſe; circumſtances by which a very great quantity of corn is abſolutely loſt.

Theſe inconveniencies are prevented by the drill, which, 1, drops the ſeed at whatever depth and diſtance experience has ſhewn to be fitteſt for the particular kind which is ſowed; 2, fills all the furrows with earth, ſo that none of the grain remains uncovered; and 3, lets fall into each furrow the exact quantity of ſeed which has been found to be moſt proper. By this means every ſeed is ſo rightly placed in the earth, that we may be confident they will all do well, if they are not hurt by inſects. But as this inſtrument ſows only the abſolutely neceſſary quantity of ſeed, the huſbandman ought to be certain of the growth of every grain: becauſe it often happens, that part of the ſeed is imperfect and does not ſprout at all. As the eye cannot diſtinguiſh its quality, he ſhould aſſure himſelf of it, by previouſly ſowing fifty or an hundred grains taken by chance, but exactly counted: when theſe ſpring up, the number of plants will ſhew what proportion is deficient, and the quantity of the ſeed ſhould be increaſed accordingly. To know what ſpace ſhould be left between each ſeed thus planted in the furrow, for that ſpace ought to be different according to the nature of the plant, it will be neceſſary to obſerve how much ground a ſtrong and vigorous plant of the ſame kind takes up when arrived at its greateſt perfection, which it will moſt probably attain when cultivated according to the new huſbandry; and the drill may then be ſet ſo as to drop each grain at a due diſtance.

Beſides leaving ſtated diſtances between each of the ſeeds which the drill depoſits in the furrow, a farther eſſential object in the new huſbandry, is to leave proper ſpaces between the rows of corn, which, in this method, are ſowed with the greateſt regularity, nearer together, or farther aſunder, according to the nature of the plants intended to be cultivated. Some do beſt in ſingle rows, others in double, others again in triple rows, and others in quadruple; as will hereafter be more fully ſhewn by ſeveral experiments. *See the article* DRILL-PLOUGH.

SOW-THISTLE, a ſpecies of thiſtle common in corn-fields and paſtures.

SPADE, a well known inſtrument uſed in digging.

SPANCEL, a rope to tye a cow's hinder legs.

SPATLING-POPPY. *See* CHICKWEED.

SPARSED-LEAVES, are thoſe which are placed irregularly about the ſeveral parts of a plant.

SPAVIN, a diſeaſe in horſes, being a ſwelling in or near ſome of the joints, and cauſes a lameneſs.

There are two kinds of ſpavins, called a blood-ſpavin, and a bog-ſpavin.

A blood-ſpavin is a ſwelling and dilatation of the vein that runs along the inſide of the hock, forming a little ſoft ſwelling in the hollow part, and is often attended with a weakneſs and lameneſs of the hock.

The cure ſhould be firſt attempted with reſtringents and bandage, which will contribute greatly to ſtrengthen all weakneſſes of the joints, and frequently will remove this diſorder, if early applied: but if, by theſe means the vein is not reduced to its uſual dimenſions, the ſkin ſhould be opened, and the vein tied with a crooked needle and wax thread paſſed underneath it, both above and below the ſwelling, and the turgid part ſuffered to digeſt away with the ligatures: for this purpoſe, the wound may be daily dreſſed with turpentine, honey, and ſpirit of wine, incorporated together.

A bog-ſpavin is an encyſted tumor on the inſide the hough, or, according to Dr. Bracken, a collection of browniſh gelatinous matter, contained in a bag, or cyſt, which he thinks to be the lubricating matter of the joint altered, the common membrane that incloſes it, forming the cyſt: this caſe he has taken the pains to illuſtrate in a

young

young colt of his own, where he ſays, When the ſpavin was preſſed hard on the inſide the hough, there was a ſmall tumor on the outſide, which convinced him the fluid was withinſide the joint: he accordingly cut into it, diſcharged a large quantity of this gelatinous matter, dreſſed the ſore with doſſils dipped in oil of turpentine, putting into it, once in three or four days, a powder made of calcined vitriol, allum, and bole: by this method of dreſſing, the bag ſloughed off, and came away, and the cure was ſucceſsfully compleated without any viſible ſcar.

This diſorder, according to the above deſcription, will ſcarcely ſubmit to any other method, except firing, when the cyſt ought to be penetrated to make it effectual; but in all obſtinate caſes that have reſiſted the above methods, both the cure of this, and the ſwellings called wind-galls ſhould, I think, be attempted in this manner. If, through the pain attending the operation or dreſſings, the joint ſhould ſwell and inflame, foment it twice a day, and apply a poultice over the dreſſings till it is reduced.

SPAYING, the operation of caſtrating the females of ſeveral kinds of animals, as ſows, bitches, &c. to prevent any farther conception, and promote their fattening.

It is performed by cutting them in the mid flank, on the left ſide, with a ſharp knife or lancet, taking out the uterus and cutting it off, and ſo ſtitching up the wound, anointing the part with tar, and keeping the animal warm for two or three days. The uſual way is to make the inciſion aſlope two inches and a half long, that the fore finger may be put in towards the back to feel for the ovaries, which are two kernels as big as acorns on both ſides of the uterus, one of which is drawn to the wound, the ſtring thereof cut, and thus both taken out.

SPELT, the name of a ſpecies of grain, which though commonly reckoned a ſummer corn, is ſowed either in autumn, or in the ſpring, at the ſame time as wheat and rye. This grain, of which there are two ſorts, one with a ſingle, and the other with a double chaff, though both have always two ſeeds in each huſk, was formerly much eſteemed in Italy and Egypt, and is now very common in Germany, where they make of it bread, which is very nouriſhing and well taſted, but hard to digeſt. They likewiſe brew beer from it in ſome places. It was of this grain that the ancients made their frumenty, of which they were very fond. Though commonly ranked as a ſpecies of wheat, which it is not unlike when growing, its grain is ſmaller and of a blackiſh hue, its ſtalk thinner and leſs firm, and its ear flat and bearded, with ſeeds only on each ſide. Some writers diſtinguiſh a third ſort, by the name white-rye, which they take to be the olyra of the Greeks and Latins; and ſeems to be what Mr. Mortimer calls taitico-ſpeltum, a ſort of naked barley, or wheat barley, cultivated in Staffordſhire, ſhaped like barley, but with a grain like wheat. It is much ſown at Rowley, Hamſtal, and Redmore, where they call it French barley. It makes good bread, and good malt, and yields a good increaſe; and therefore would do well to be tried in other places. It ripens early, does beſt in a dry ſoil, and is not apt to be much hurt by birds, from which its beard and double huſk preſerve it.

SPIKY-ROLLER, a very uſeful inſtrument in huſbandry, lately introduced by the ingenious Mr. Randall, of York, who has alſo obliged the world with the following account of it.

" I think, ſays Mr. Randall, it was in the ſpring of 1752, when I had fifty acres of ground, deſigned to be ſowed with barley, at one particular farm; but the weather had been ſo unfavourable, and the ſpring ſo extremely dry, that there was no ſuch thing as preparing the ground for the reception of the ſeed: and this was the caſe with the whole country, in theſe parts of England. On looking, one morning, at a barley roller, they laid juſt before me, I recollected, that Mr. Ellis, in one of his eight volumes in Huſbandry, made mention of a ſpiky roller, and referred the reader to another volume for its plate and deſcription, which were no-where to be found. I immediately ſent for ſome workmen, and produced this uſeful inſtrument againſt the next morning, as the ſeaſon was far ſpent, and much ground was to be ſowed, in ſeveral farms, with this grain.

" On this morning, a neighbouring, ſubſtantial farmer, paſſed by us, with half the country for clotters, as we were going to put the horſes to the roller, as he had no longer patience to wait for rains, to reduce the rough ſtate of his ground, deſigned for barley-ſeed: he gazed at the roller, ſmiled, and went his way, with his troop. They, after clotting two acres, all returned the ſame way at night; their maſter rolled his eyes all over a field of about twenty acres, ſaw it perfectly fine (as the roller came back upon the ſame ground it went down), and, after a pauſe, ſaid, that was a good hedgehog, for doing ten times more in one day than all his troop together, and ten times finer, than a thouſand clotters could do, in the ſame time. This was the firſt time this farmer ever could be brought to ſay a civil thing of any uſeful inſtrument, though common ſenſe would pronounce the utility of this on his firſt ſeeing it; but the truth is, nothing but ſuch glaring effects can ever convince theſe people, as they have the great art of deſpiſing what they do not underſtand, or have not had in practice for ten centuries.

" While the ſame man was going over the other ground that ſtood in equal need of the roller, the ploughs were ſet on to turn up the ground he had rolled; and, when all was thus ploughed, the roller went again over the whole, to cruſh the clots, thus turned up, and made all as fine as before, by going twice in a place: then they ploughed for a ſeed furrow, ſowed the ſeed in the uſual way, and harrowed it in; then the roller, with a thorn buſh faſtened behind, went over again, once in a place, and left all exceeding fine, which even would not have diſgraced a gardener in his manner of preparing the ground for the garden culture in general.

" The conſequence of this lucky hit was, that, before the country could get their ſeed into the ground, my barley was fairly up, went forwards, and did extremely well; while, in general, my neighbour's barley made but a ſorry appearance, ariſing from the rough ſtate of the ground, which they could not bring into that fine order this grain requires, notwithſtanding all their toil and expence. This atchievement of the ſpiky roller eſtabliſhed its reputation, among the neighbouring farmers; but ſtill they could not prevail on themſelves to be at the expence, which indeed was not ſmall, in having one made for their own uſe. The reſult of all was, that I had other rollers made for the ground in other parts belonging to me, only they were made heavier, and both longer and larger, the better to ſuit the ſoils that were much ſtiffer.

" From this time we never ſowed any ſeed in the common form, but the ſpiky roller, and thorn buſh at its tail, followed the harrows; as it effectually buried the ſeed, and left the ground in a fine ſtate. It may eaſily be conceived, that this operation is of conſequence to vegetation: for the fine mould, being thus ſwept into the holes made by the irons, and where the ſeed was buried, muſt needs greatly promote their growing ſoon, and nouriſh them well above-ground; as it is well known, the finer the mould is, where the ſeed is depoſited, there vegetables are puſhed on to their deſtined maturity, if all other requiſites concur. And upon this principle it is, that if the corn in the ſpring is rolled once in a place in like manner, the owner will be far from having any cauſe to complain of the practice, provided the weather, and ſtate of the ground, will or ought to bear the tread of the horſes, and weight of the ſpiky roller.

" I am very ſenſible this will appear ſtrange to many perſons, as it looks like ſending a herd of rapacious wolves to nouriſh a flock of tender lambs, or tearing, bruiſing, and throwing all the corn up from their very roots, and bringing on a general deſolation over all the ground. This is like Siſyphus in Homer: we crop the ground with much ſweating and tugging, and then ſuffer all to be deſtroyed again, by this ponderous, grinning creature. But it may not, perhaps, be ill expreſſed, when we ſay, that, in order to come at the truth of things in farming, we muſt, according to the Greek epigram, aſcend downwards, and deſcend upward: the moſt triumphant ſucceſs, in the true bias of nature, in eſtabliſhing agriculture, riſes ſafely and ſurely on the foundation laid by bold experiments, that ſeem to contradict ſuperficial reaſon.

" Let us now conſider the effect of this terrible deſolator, as it goes over the young corn. If we conſider the ſyſtem of irons on the roller, they muſt leave ſome of the corn untouched by them, and then this is only rolling the corn

corn in the common way, as it is only ſqueezed by the roller, and not bruiſed by the irons: ſo far there is no harm done. There muſt be corn, you will ſay, that is cruſhed and bruiſed, if not quite deſtroyed, by the violence of the irons: but ſuppoſing the corn loſt, whereever the irons pitch, which is very far from being the caſe; yet the untouched corn will be ſo improved, by this ſhattering and looſening of the ſoil about their roots, and ſcraping of the mould by the thorn buſh, and ſhaking and tearing the tender blade, that the owner will judge for himſelf, whether the Greek epigram ought to have a place among the paradoxes in agriculture. However, it can do no gentleman much harm to let the roller go down in one place, and up again in another, and give over; and this ſingle trial is all that the author pleads for, and that the weather and ſtate of the ground be ſuch, as will ſafely admit of the experiment.

" The uſe of the roller, in making the fallows, and preparing the ground to a requiſite degree of fineneſs, in the old, new, and what this Treatiſe calls the Semi-Virgilian Huſbandry, is, by this time, pretty evident to the reader, and needs no more inſtances, where ſuch perfection is deſired. We come now to ſpeak of its uſe on graſsland, where the ſwarth is worn out by age, ſpoiled by moſs, or a bad ſort of graſs; or defective in any ſhape, from ſome cauſe or other, and yet it is very dangerous to plough it up, and lay it down better, on account of its ſituation, or it is not convenient, perhaps, for other reaſons, to diſturb it with the plough: whatever the caſe is, the owner, undoubtedly, would be exceeding glad to have a better burden of graſs on the ground, for the maintenance of his live ſtock, or for the pleaſure of ſeeing his ground, about his houſe, put on a better appearance.

" Here, then, there muſt be ſome compoſt prepared; that is, a mixture of the dunghill, ſods, aſhes, lime, mould, ſoap-aſhes, and ſuch like ingredients, or as many of them as can be conveniently procured, laid up in a heap, in this manner: a ſtratum of mould, about half a foot deep, then dung, then ſods, then ſoap-aſhes, then common aſhes, then lime, then dung; and to cover all with mould, about half a foot deep. When theſe have laid ſome time, that the dung may communicate its juice to the ſtrata beneath, the heap may be thrown down with ſpades, ſo as, in the operation, theſe ingredients, being mixed together, the firſt ſtratum, of half a foot, of the new heap, may be compoſed of all the ingredients; and ſo, in like manner, all the reſt of the ſtrata, till the new heap is compleated; and after theſe have laid ſome time, they will be very mellow, and fit for uſe the Michaelmas after the winter when the firſt heap was formed.

" We muſt now ſuppoſe the cloſe, whoſe ſwarth is to be improved, to have been laid down even, and not in ridges; and that between Michaelmas and Martinmas, the ſooner after the former the better, the ground is to be ſo moiſt, as to admit the irons of the ſpiky roller, but not the horſes feet; that is, the irons will penetrate three inches, or thereabouts, and the horſes feet make little or no impreſſions. Here, then, the roller muſt go up and down, till the ſwarth and ground are pretty well broken up: this being done, the ſeeds of clover, trefoil, and ryegraſs, or any other mixed with them, muſt be ſown, in the uſual way, and quantity: then the compoſt muſt be ſpread over the ſeed, ſo as to cover them, and a common barley roller, with a thorn buſh faſtened to it, muſt follow, and the ground ſhut up, leſt cattle ſhould do harm, by treading the ground. A gentleman, making this experiment, will have great cauſe to be pleaſed with what he has done; and will, alſo, ſee the neceſſity of laying down his ground as even as poſſible for the future, that he may increaſe the burden of his graſs, whenever it falls ſhort of a proper quantity, or quality." *Randall's Semi-Virgilian Huſbandry, Append. page* 1.

We have added the figure given of this uſeful inſtrument by the above ingenious gentleman, on Plate XXIV. Fig. 5.

A correſpondent of the editors of the Muſeum Ruſticum, who calls himſelf a clay farmer, has made the following obſervations on the ſtructure and utility of the ſpiky roller.

" Give me leave, ſays he, to communicate, to my brother farmers, a moſt uſeful implement in huſbandry, which has but of late been introduced amongſt us. It is ſo very efficacious, and its powers ſo much ſuperior to all other inſtruments yet contrived for the reduction of ſtrong land, that, I think, there is not any poſſeſſor of ſuch ground (who has no objection to a fine ſeed furrow) that will be without this inſtrument. This laſt autumn it has been of the greateſt utility. For whilſt the neighbouring farmers were waiting for rain, ſo that they might with their own rolls and harrows bring their land to that degree of fineneſs they could wiſh to have their ſeed ſown in: thoſe who were poſſeſſed of the ſpiky roller, (for that is the name of the implement I am going to give ſome faint idea of, as it is impoſſible by letter to make any body more fully acquainted with it) had their fallows in ſuch a degree of fineneſs, as I never before ſaw that kind of land in; and had finiſhed the whole of their ſowing, before the others ever thought of taking their ploughs, &c. into the field.

" To begin then with the beſt deſcription I can give of the moſt complete I have yet ſeen. The roller is of oak, ſix feet three inches long, ſeventeen inches diameter, hooped with iron at each end; the circumference divided into eighteen equal parts, where rows of iron ſpikes are ſet (in the quincunx order) at ſix inches diſtance, one from the other, in the rows: ſo that there are thirteen ſpikes in one row, and twelve in every other throughout the circumference. The number of the ſpikes is two hundred and twenty-five. They are to project four inches and a half from the roller, and to be one inch by three quarters of an inch ſquare at that part of the ſpike next the roll, tapering off to three quarters of an inch by half an inch at the top part. The whole length of the ſpike, with what is driven into the wood, will be about nine inches long. And I would adviſe the falling ſide at the end of each ſpike to have a ſtroke or two with the hammer, that they may be a little more pointed to give them greater facility in penetrating the very hard clots they are deſigned to break. Every ſpike will weigh about one pound and a quarter, which will be of ſufficient ſtrength.

" The frame ſhould be made for horſes to draw a-breaſt, or with a pole for oxen. For by the horſes, &c. drawing double, the roll is more eaſily turned; and, beſides, it is likely to prevent the end of the roller from going over the driver, if by chance he ſhould fall. That it may with greater eaſe and conveniency be conveyed from field to field, or to any diſtance, an axis is fixed upon the frame immediately above the roll with wheels; ſo that by turning the frame, the wheels take up the roll, and away you may drive. And, when you have brought it to the field, in order to make uſe of it, by turning the frame back again, you let down the roll, and then the wheels are carried by the roller.

" Since making of the above deſcription, I have talked with the wheelwright, who tells me, he could greatly improve the manner of fixing the wheels, by making them run within the frame: for as they now run without, it ſets the wheels at ſuch a diſtance, as makes it difficult to paſs through gates made only the common width. And likewiſe ſays, that great care muſt be taken in fixing that part of the frame which the gudgeons of the rolls runs in: for by that means the roll will be let down with greater eaſe; which will not be the caſe, if regard is not paid to that particular. The roller, frame, wheels, &c. are, together, about eleven hundred weight.

" If your land, by once paſſing over it with the roller, is not ſo fine as you could wiſh to have it, let a large harrow be faſtened to the frame of the roller, which will pull up the remaining clots, and thereby give the roller a better chance for breaking of them the ſecond time going over. Four able horſes are equal to this work." *Muſeum Ruſticum, vol.* V. *page* 372.

Theſe obſervations induced the inventor, Mr. Randall, to ſend the following letter to the editors of the Muſeum Ruſticum.

" In your Muſeum for laſt December, ſays he, I obſerve my name mentioned concerning the ſpiky roller. Without making any comment on the clay farmer's dimenſions, for conſtructing this implement of huſbandry, I beg leave to tell him, and the reſt of your readers, that the length of mine, which was the firſt I ever ſaw or heard of, except what the late Mr. Ellis mentioned to ſo little purpoſe, was ſeven feet, the diameters of the ends eighteen

teen inches, and the whole cylinder made of the heart of oak: and when the irons were burnt in, and the man feated on the box defigned for that purpofe, the weight of the whole was about a ton. But you will think it ftrange, that the blunt end of the irons were oppofed to the clods, and run more taper, till they came to the furface of the cylinder, into which the irons were burnt, and inferted about three inches: which was their length above the furface of the roller, and which, I always found, very fufficient to crufh the hardeft clod that ever came in their way. Had I, indeed, attempted to go on the ground, when the foil was not perfectly dry, this pofition of the irons would have carried the clods round with the roller: for it is not its province to fqueeze but crufh. Nor indeed can a man do more harm to his ground, than going upon it, when it is not quite dry, with a roller, conftructed according to the clay farmer's form and fize of the irons; or by that which I have recommended. I am fenfible, thofe, who conftruct the roller, according to the clay farmer's directions, imagine, that by inverting the fhape, there is lefs danger of carrying the moift clods round with the roller: but, I muft fay again, there is no occafion for this precaution: for, if the other form be at all neceffary, it muft be in the moift ftate of the ground: which is the only reafon, we fhould keep the roller off the foil. I had the irons fixed in four inches afunder, in the firft row, from end to end. The fecond row began juft between the firft and fecond irons of the firft row. The third row was like the firft; and the fourth like the fecond. Then alternately for the whole furface of the cylinder, as near as could be, the irons were four inches afunder in each individual row, and four inches from row to row, as nearly as the fuperficies of the cylinder would permit. I do not know how to convey a jufter idea to your readers of the fhape of the irons, than to call them ox-harrow-teeth. For when I fent for the workman, I defired him to make fo many of this denomination, fix inches in length; and burn the fmall end three inches into the wood: he went from me, as perfectly underftanding what I meant; brought his number of irons; and inferted them a proper depth into the cylinder. If fome of your fouth-country readers fhould be at a lofs to know what is meant by ox-harrow-teeth, they will be pleafed to remember, that they are irons faftened into two harrows, which are drawn by either four oxen and two horfes, or fix oxen alone, in very ftiff foils. Now, it will appear to you, that the roller itfelf, and one harrow, will require at leaft four able horfes, according to the clay farmer's ftating the cafe: but my roller, without harrows, always ftood in need of three ftout horfes, which the man, from his box, always drove a-breaft, for the greater convenience of turning on the land's ends. But were I to have two ox-harrows, (which would only extend the length of the roller) following the roller, for the purpofe of tearing up clods, in order to be crufhed, on going a fecond time over the fame, feven feet in length, I fhould be obliged to have a much ftronger team than four ftout horfes; and, therefore, I muft beg leave to obferve, for this, an unanfwerable reafon, that harrows are better omitted; as they always were, by my people, who fet in with their ploughs, and turned up the foil from all requifite depths, in order to have it crufhed by the roller going twice in a place.

"If the clay farmer will not take it amifs, I would tell him, that wheels to the roller only create expence and trouble. For I do not remember we ever had any difadvantage from the weight of them in my four rollers, made for near a thoufand acres of land, of all denominations of foils, ftiff and light: for, when the fellows had occafion to convey the roller from one inclofure to another, and fometimes over the hard high road, I never heard, or obferved, there was the leaft difficulty of doing it: as the irons were fo ftout, as not to receive any injury in the paffage, otherwife than by friction; by which they would be indeed in time fomewhat impaired. As to the width of the gates, I think there was never any ftoppage; fince the men, when they found the paffage rather too ftrait, could, by turning the horfes heads, eafily inline the roller on one fide, and by that means wriggle it in, where it was too long for entrance. Let who will be the father, or grandfather of this valuable inftrument of hufbandry, I had reafon to be extremely well pleafed with my lucky hit, in conftructing it from Mr. Ellis's barely mentioning a fpiky roller: though, from his ufual giddinefs, he gave his readers no more than the name. As it is of confequence to the world, to keep the expence of this inftrument as low as poffible, I fhall be very forry to hear any more of wheels; for it may deter farmers from ufing it; and without their hearty concurrence, all will be only playing at farming. Gentlemen may pleafe themfelves in every variation of the implements, and modes of culture: but without the affiftance of thofe, who blefs the nation with their endlefs toil, a thoufand years hence will be as to-morrow.

"Befides the purpofes already mentioned, this roller muft undoubtedly be of ufe in laying, originally, down lawns, or large pieces of grafs required to be level. Mr. Randal only mentions the reftoring fuch when depraved: but certainly this inftrument muft be extremely effectual in the cafe of all ftiff lands, for the producing a good face in the firft forming of fine pieces of grafs. The manner of doing this, in fuch cafes, is too obvious to perfons qualified for executing fuch work, to require any explanation: as the inftrument may be ufed concurrently with any of the common methods of manuring and fowing grafs feeds, as well as with Mr. Randal's compoft, &c. they being no ways particularly neceffary to the effects of the roller, though it may greatly aid them.

"This roller may likewife be very ufeful in preparing clay for the making canals or pieces of water. For where, as fometimes happens, the clay grows dry, and will not admit of being duly tampered for ufe without great pains in breaking it, a very large quantity may very foon be reduced to the requifite finenefs, by fpreading it on hard ground in a due thicknefs, and paffing this roller a few times over it. In very great works, much trouble and labour may be fometimes faved, by this means, where fuch a roller is at hand; and the clay prepared in a manner that will anfwer the purpofe much more effectually.

"It is certainly an inftrument, which no farm, where the land is ftiff, or in the leaft liable to clot, fhould want. For befides the conftant advantage of faving labour, and bringing land to a better condition for any kind of fowing than the plough and harrow with any affiftance of the work of hands can make it, in unfavourable feafons and under fuch circumftances as Mr. Randal has mentioned in the above quotation, the lofs of the whole crop by an otherwife unavoidable delay beyond the feed time, may be with certainty prevented."

We fhall conclude this article with the following ingenious account of the ufes of this inftrument, which we have been favoured with from Mr. John Berington, of Winfley, near Hereford.

"As I live, fays he, in a clay country, and had been often put to a great deal of difficulty in a dry unkind feafon, in reducing the land to a proper tilth, I refolved to make trial of Mr. Randal's fpiky roller; but apprehending great ftrefs muft lie upon the horfe and frame, in turning fuch, as well as tearing up the ground, it occurred to me, that I had feen recommended a double roller, that is, one divided in two parts. It is very probable that you have it already in defign, if not, the following directions I imagine may fuffice.

"Let the ends of each part be bound with narrow but ftrong bands of iron, and let the fpikes at the ends be placed clofe to them; let each part have a feparate frame, but let the cheeks in which the inward gudgeons turn, be made of iron plates, about two inches wide above, and four where the gudgeons enter; the thicknefs, a common flat bar of iron; and thefe fixed, in any firm manner, to two cheeks of wood reaching down juft to the bands, and of fuch a thicknefs at bottom as not to interrupt the fpikes. Let the inward gudgeons be made with quite flat heads, to prevent their flipping out in working; and this brings the two ends of the roller near together, which is of fome little confequence, as the fewer clots will be miffed in working.

"Let the frames be joined together by four eyes, like thofe of a fmall gate, two at one end about five or fix inches apart; the two at the end of the other, to take place juft within them; an iron pin through all four, and keyed. Let the trills be placed juft on the middle of each frame, and a bar of wood juft behind the horfe to ftrengthen ſtrengthen them; the bar ſawed through in the middle, and joined by a ſtrong flat hinge; one ſide made to haſp upon a ſtaple, kept down with a wooden clet. This gives the whole proper play in working; and I may venture to affirm, it will be found, next to the plough, the moſt uſeful inſtrument in tillage, not only in reducing a ſtiff ſoil, but with a buſh at its tail, as Mr. Randal expreſſes it, will cover the ſeed when ſown much more effectually, and in a better manner, than a harrow, as it turns up the earth light and fine behind it; and though ſeemingly unweildy, will turn with eaſe, and may be worked with one, two, or three horſes at moſt, upon any land that is of a proper dryneſs to work upon, of which I cannot well forbear giving you an inſtance: the carter that was to drive it exclaimed, when he firſt ſaw it, that it would kill all his horſes: ſome time after, as he was uſing it upon a piece of fallow, a fellow-ſervant wanted a horſe for ſome uſe, and was going to catch one; the carter called to him, and told him, he might take one of his, having three, as he could do very well with two. Now I believe you will allow, that if it could ſo eaſily overcome the obſtinacy of a clown, there are very few clods that will be too hard for it.

" The ſpikes are about four inches without, and three within the wood; the thickneſs of the roller, and number of ſpikes, I think, may be determined, in ſome meaſure, by the nature of the ſoil it is to work upon."

SPINAGE, a well-known plant, cultivated in kitchen gardens.

It requires a rich, light, and well looſened ſoil. It is propagated by its ſeeds only, of which there are two ſorts, namely, the rough and prickly, which produces the prickly ſpinage with arrow-pointed leaves, and the ſmooth, from which ſprings the ſpinage with oblong oval leaves.

The ſeeds of the firſt of theſe kinds, which is by much the hardieſt, and therefore fitteſt to be cultivated for winter uſe, ſhould be ſown upon an open ſpot of ground, in Auguſt, juſt before a ſhower of rain, if it can luckily be ſo timed: for if the ſeaſon ſhould prove dry for a long while after the ſowing, many of them will not ſprout at all, and the plants of thoſe that do grow will come up ſo irregularly, that half the crop will frequently be loſt. It therefore is highly adviſable to water theſe ſeeds within two or three days after their being ſown, if rain does not fall in the mean time.

When the plants begin to be ſtrong, the ground on which they grow ſhould be well hoed, to deſtroy the weeds, and to thin the plants to the diſtance of three or four inches aſunder. This, like all other hoeings, ſhould always be performed in dry weather, the more effectually to kill the weeds: or, if it be rainy, they ſhould be carried off the ground as ſoon as they are cut up, to prevent their taking freſh root: for if many of them ſpring up, and the ſeaſon prove wet, they will ſtifle the plants of ſpinage, and make them rot. A ſecond careful hoeing is therefore neceſſary in about a month or five weeks after the firſt; and with the help of this the ſpinage will begin to be fit for uſe by the end of October. The beſt way of gathering it is, to crop off only the largeſt outer leaves, and to leave the middle ones to grow bigger: for by this means a regular ſupply may be had during the whole winter, and even till the ſubſequent ſpring ſowing ſhall have produced plants large enough for uſe, which generally is in April. The winter ſpinage will alſo then be ready to run up, and ſhould therefore be entirely cleared off, unleſs a parcel be left for ſeed, if wanted. But if early cabbages, which will want earthing up, have been planted among this ſpinage, as is the uſual practice of the gardeners about London, a ſeparate ſmall ſpot of ground ſhould be allotted purpoſely for ſowing ſome of this ſpinage for ſeed, without any other plants among it, and to cut up all the remains of the other winter crop, as ſoon as the ſpring ſpinage is fit for uſe.

The oblong oval leaved ſpinage, commonly called plantain ſpinage, which has thicker leaves and more ſucculent ſtalks than the former ſort, is ſown in the ſpring, likewiſe upon an open ſpot of fine rich earth. The London gardeners, who always endeavour to have as many crops in a ſeaſon as they poſſibly can, generally mix radiſh ſeeds with thoſe of the ſpinage which they ſow at this ſeaſon: but the beſt way for thoſe who have ground enough, is to ſow their ſpinage ſeeds alone. This crop muſt be hoed, cleared from weeds, and thinned, in the manner before directed for the winter ſpinage; and when the plants, which were at firſt left three or four inches aſunder, have grown ſo as to meet, it will be right to cut them out here and there for uſe, and to thin them in this manner, as they are wanted for the table, till thoſe that are left, ſtand eight or ten inches aſunder. The thinnings in the mean time will give the remaining plants room to ſpread; and if, after this laſt, the ground between them is well ſtirred to a good depth, and kept perfectly clear from weeds, this ſort of ſpinage will frequently produce leaves as large as thoſe of the broad leved dock, and extremely fine.

A ſucceſſion of ſpinage may be had throughout the whole ſeaſon, by ſowing it every three weeks, from about the middle of January to near the end of May; only obſerving, that the earlieſt ſowings muſt be upon the naturally drieſt ſoils, and that the lateſt ſhould be thinned moſt at their firſt hoeing, becauſe the remains of the former crops will furniſh a ſupply till theſe are full grown, and the plants will not be ſo apt to run up to ſeed when they ſtand at a diſtance from each other, as when they are cloſe together.

In order to have good ſeeds of ſpinage, each particular ſort ſhould be ſown by itſelf, in an open ſpot of rich and well dug ground. This ſowing ſhould be in February, as ſoon as the danger of froſt is over; and when the plants are come up, they ſhould be thinned with a hoe till they are ſix or eight inches aſunder every way. All weeds ſhould at the ſame time be carefully cut up and carried off: and in about three weeks or a month after this, the plants ſhould be hoed and thinned a ſecond time. Their diſtance from each other ſhould then be enlarged to at leaſt twelve or fourteen inches: for they will cover the ground very ſufficiently after they have ſhot out their ſide branches. Particular care is requiſite at this time to keep them very clear from weeds; becauſe theſe would make the plants of ſpinage run up weak, and thereby greatly injure them.

Mr. Miller is here extremely judicious in his directions for the farther management of ſpinage intended for ſeed. " When the plants, ſays he, have run up to flower, you will eaſily perceive two ſorts among them, viz. male and female. The male will produce ſpikes of ſtamineous flowers, which contain the farina, and are abſolutely neceſſary to impregnate the embryos of the female plants, in order to render the ſeeds prolific. Theſe male plants are, by the gardeners, commonly called ſhe ſpinage, and are often, by the ignorant, pulled up as ſoon as they can be diſtinguiſhed from the female, in order, as they pretend, to give room for the ſeed bearing to ſpread: but, from ſeveral experiments which I have made on theſe plants, I find that, where-ever the male plants are entirely removed before the farina is ſhed over the female plants, the ſeed which they produce will not grow, ſo that it is abſolutely neceſſary to leave a few of them in every part of the ſpot, though a great many may be drawn out where they are too thick; for a ſmall quantity of male plants (if rightly ſituated) will be ſufficient to impregnate a great number of female, becauſe they greatly abound with the farina, which, when ripe, will ſpread to a conſiderable diſtance, when the plants are ſhaken by the wind."

When the ſeeds begin to ripen, they muſt be guarded from birds; and when they are thoroughly ripe, which is known by their changing their colour, and beginning to ſhed, the plants ſhould be drawn up, and ſpread upon cloths, for a few days, to be completely dried by the heat of the ſun. That they may be perfectly ſo, they ſhould be turned every other day; and when they are quite dry, they ſhould be threſhed out, well cleaned, and laid up in a dry place, where mice, which are exceſſive fond of this food, cannot come at them.

SPINDLING, running to ſeed.

SPILTER, an inſtrument uſed by gardeners in digging the ground; a ſpade.

SPLENT, a hard excreſſence growing on the ſhank bone of a horſe.

Some horſes are more ſubject to ſplents than others; but young horſes are moſt liable to theſe infirmities, which often wear off, and diſappear of themſelves. Few horſes put

put out ſplents after they are ſeven or eight years old, unleſs they meet with blows or accidents.

A ſplent that ariſes in the middle of the ſhank bone is no ways dangerous; but thoſe that ariſe on the back part of this bone, when they grow large and preſs againſt the back ſinew, always cauſe lameneſs or ſtiffneſs, by rubbing againſt it; the others, except they are ſituated near the joints, ſeldom occaſion lameneſs.

As to the cure of ſplents, the beſt way is not to meddle with them, unleſs they are ſo large as to disfigure a horſe, or are ſo ſituated as to endanger his going lame.

Splents in their infancy, and on their firſt appearance, ſhould be well bathed with vinegar, or old verjuice; which, by ſtrengthening the fibres, often put a ſtop to their growth; for the membrane covering the bone, and not the bone itſelf, is here thickened; and in ſome conſtitutions purging, and afterwards diuretic drinks, will be a great means to remove the humidity and moiſture about the limbs, which is, what often gives riſe to ſuch excreſſences.

Various are the remedies preſcribed for this diſorder; the uſual way is to rub the ſplent with a round ſtick, or the handle of a hammer, till it is almoſt raw, and then touch it with oil of origanum. Others lay on a pitch plaiſter, with a little ſublimate, or arſenic, to deſtroy the ſubſtance: ſome uſe oil of vitriol; ſome tincture of cantharides; all which methods have at times ſucceeded; only they are apt to leave a ſcar with the loſs of hair. Thoſe applications that are of a more cauſtic nature often do more hurt than good, eſpecially when the ſplent is grown very hard, as they produce a rottenneſs, which keeps running ſeveral months before the ulcer can be healed, and then leaves an ugly ſcar.

Mild bliſters often repeated, as recommended in the article ſpavin, ſhould firſt be tried as the moſt eligible method, and will generally ſucceed, even beyond expectation: but if they fail, and the ſplent be near the knee or joints, you muſt fire and bliſter in the ſame manner as for the bone-ſpavin.

Splents on the back part of the ſhank-bone, are difficult to cure, by reaſon of the back ſinews covering them; the beſt way is to bore the ſplent in ſeveral places with an iron not very hot; and then to fire in the common way, not making the lines too deep, but very cloſe together.

To SPRAIN SEEDS, ſignifies, to throw them with a ſingle motion of the hand at a certain diſtance from one another.

SPRIG, a ſmall branch, a ſpray.

SPRING, the ſeaſon in which plants vegitate.

Spring alſo ſignifies a fountain, or iſſue of water from the earth. *See the articles* DRAINING, *and* WATER.

SPRING-WHEAT, a ſpecies of wheat ſown in the ſpring. *See the article* WHEAT.

The following experiment and obſervations on the comparative ripening of ſpring and common wheat made by the ingenious Mr. John Wynne, baker, and reported by that gentleman to the Dublin Society, muſt not be omitted here.

" Some little time after receiving the inſtructions I was honoured with from the ſociety, I was deſired by the committee, then ſitting to ſettle the premiums for the ſucceeding year, to make a comparative experiment between ſpring and common wheat.

" The purpoſe of this experiment was to diſcover, whether common wheat would not ripen when ſown late in the ſpring, as well as ſpring wheat.

" Accordingly, on the twenty-eighth day of March, I ſowed two perches of each ſort of wheat in my garden, in drills three feet aſunder, at the rate of five ſtone to an acre. I had but two pounds of ſpring wheat, otherwiſe I ſhould have extended the experiment.

" The common wheat came up well, but the ſpring wheat came up very thin in the drills, which, for ſome time, I apprehended was owing to ſome fault in the ſeed; but the caſe was otherwiſe, as appeared afterwards from a ſecond ſowing in another place: add to this, that in a few days I diſcovered mice had eaten great part of the ſeed; however, ſome little of it eſcaped, and planted greatly, as did the common wheat.

" As a ſubſtitute for the horſe-hoe, which could not be introduced in theſe ſmall experiments, I uſed the ſpade; and the plants grew to admiration.

" The fatality, which attends all ſmall experiments in the corn tribe, followed theſe: for I was obliged to cut the ſpring wheat before it was ripe, the birds, in defiance of all protection, having devoured moſt of it; however, it would have ripened completely, and, as a proof of this aſſertion, I have a few ears, which I ſelected from the reſt, which are very fine.

" It may be proper to obſerve, that the ſpring wheat was more expoſed to the ravages of birds than the other, as the common wheat I ſowed was bearded, which is always a great, though not a perfect, protection to it from birds.

" The common wheat met with a diſtemper which was quite as fatal to it, as the mice and birds were to the other: this was the ruſt, or mildew. Before this diſeaſe came upon it, it was as fine corn as ever I ſaw, but it never ripened; although in appearance the ears were very fine.

" This diſeaſe attacking this corn and ſparing the other, I am inclined to attribute to this circumſtance, viz. that this was very thick and ſtrong; whereas the other was very thin, from the accident before-mentioned: perhaps, had it been as thick, it might have ſhared the ſame fate. So that I think theſe experiments are not by any means concluſive, as to the ripening of either of theſe ſpecies of wheat, when ſown late in the ſpring.

" I ſowed another plot of ground, as was before-mentioned, on the fourth of May with ſpring wheat, which came up well, grew very ſtrong, and formed very fine ears in appearance, but never ripened.

" On the twenty-ninth of April, I ſowed an acre of very good ground with common wheat, which I ſteeped before-hand in putrid water; it came up in eight days, but made no figure till June; it formed ſmall ears, but produced no grain at all.

" So far we have two concluſive experiments that ſpring wheat will not ripen when ſown in the beginning of May; and that common wheat will not ripen when ſown the latter end of April.

" Notwithſtanding that our queſtion is not anſwered by the two firſt experiments; yet the diſeaſe attending the common wheat has furniſhed ſome obſervations with reſpect to the mildew, or ruſt, upon corn and other plants, which tend principally to confirm thoſe made by the ingenious Mr. Tillet, director of the mint at Troys, and ſeem to contradict moſt of our Engliſh writers on this diſeaſe; many of whom ſeem to have implicitly followed others, who, I am afraid, have undertaken to account for, and furniſh remedies againſt, a diſeaſe, which perhaps they had never ſeen.

" Various are the opinions, and many of them contradictory in themſelves: but, upon the whole, candour obliges me to own myſelf as much at a loſs to determine with certainty the cauſe of this diſeaſe, as, I find, the many writers are, who have thought themſelves perfect maſters of it. Even by reading ſix pompous pages, which I have gone over many times, I ſhould ſcarcely know the diſeaſe, ſo faint is the deſcription; but it will ever be known by the greateſt ſtrangers to country affairs under the French name, which indeed is as truly deſcriptive as it is laconic, by them it is called *rouille*, or ruſt. By the Romans it ſeems to have been called *rubigo*.

" I ſhall omit to give my obſervations upon this diſeaſe at preſent, as it would oblige me to quote many tedious paſſages from the books; and where there is a contrariety of opinions, although without evidence: yet, a little man, with a few facts only to ſupport a new theory, would ſtand a chance of making but a poor figure.

" At preſent I join in opinion with Mr. Tillet, and Mr. Reneaume; who ſeem to think that the extravaſated juices of the plants, operated upon, and condenſed, by the acrimony of the air, I ſhould rather ſay incruſted, are the occaſion of it. To this I ſhall only add, that I am at preſent of opinion, that the lacerated parts of the plants giving paſſage to, or rather changing the courſe of, the juices before-mentioned (which are the nutriment and life of the plants) to the diminution, and loſs, of the vegetable food to the nobler parts, is the true cauſe of the

plants

plants failing in their produce: but, I repeat it, I attempt not here to account how, and from what caufe, thofe lacerations, which I believe to be the bafis of the difeafe, happen.

"The comparative experiment between fpring and common wheat, I think, fhould be repeated, as the difcovery thereby fought for tends to a public benefit: but it fhould be in a larger way, and in an open expofure.

"A circumftance has recurred to my memory, which had efcaped my attention from the time it happened, till fince I entered upon this fubject.

"Laft fpring a poor neighbour of mine told me he had loft the feafon for fowing his wheat, for want of money to buy feed, but that, if he could get a barrel of Poland wheat, (as he called it) which was the white cone, he would then fow his ground: accordingly he obtained the feed, and did fow it; but I underftand, upon enquiry, that it produced not a good crop. He fowed it fome time about the beginning of February.

"And yet I am informed there is a gentleman in Scotland, who makes it his conftant practice to fow his wheat in the fpring by choice: and that he intends to publifh a recommendation of that practice.

"The lateft I ever fowed any with fuccefs was the 30th of December; but that was only a fmall experiment."

SPROUT-HILL. *See the article* ANT-HILL.

SPRIT, a fhoot or fprout.

SPUR, a diftemper which frequently attacks rye, and fometimes does damage likewife to wheat. The following remarks will give an idea of it.

"1. The grains which have the fpur are thicker and longer than the found ones, and generally project beyond their hufks, appearing fometimes ftrait and fometimes more or lefs crooked.

"2. Their outfides are brown or black; their furface is rough; and one may frequently perceive in them three furrows, which run from end to end. Their outward end is always thicker than that which fticks to the chaff, and that moft fwollen end is fometimes fplit into two or three parts. It is not unufual to find on their furface cavities which feem to have been made by infects.

"3. When a fpurred grain is broken, one perceives in the middle or centre of it a pretty white flour, covered with another flour which is redifh or brown. Though this vitiated flour has fome confiftency, it may neverthelefs be crumbled between one's fingers. M. Aimen has indeed fometimes found this powder almoft as black as that of fmutty wheat.

"4. Thefe grains, when put into water, fwim at firft, and afterwards fink to the bottom. If chewed, they leave a bitter relifh on the tongue.

"5. The chaff appears found, though what is outmoft is fomewhat browner than when the ears are found.

"6. All the grains of the fame ear are not ever attacked with the fpur.

"7. The grains which have this diftemper ftick lefs to the ftalks than found grains do.

"8. M. Aimen imputes this diftemper to the grains not being impregnated; and affures us that he has not ever found a germe in grains which had the fpur. The fame obferver has collected, in a memoir which he has fent me, feveral reflections and microfcopical obfervations; but I pafs over in filence fuch refearches as are more curious than ufeful.

"9. I fhall not ftop to refute the opinion of thofe who have pretended that fogs, dews, rain, the moifture of the earth, may give this diftemper to rye. But I cannot help faying that M. Tillet thinks, as does alfo M. Aimen, that other plants, befides rye, are fubject to the fpur. M. Tillet has feen, and M. Delu has fhewn me, grains of wheat which had the fpur. The fpur ought therefore not to be confounded with the uftilago or burnt grain: they are two different diftempers: and what feems ftill more to eftablifh this difference, is, that M. Tillet's experiments prove that the powder of the fpurred grains is not contagious like that of the carious or burnt.

"M. Tillet is ftrongly inclined to think that the fpur is occafioned by the fting or bite of an infect, which turns the rye into a kind of gall; and he fufpects a fmall caterpillar of being the caufe of this mifchief. But neither he nor I dare to fpeak affirmatively on this point.

"Dodard, Longius, Fagon, Delahire, Noel, and, lately, M. Salerne, give particular accounts of the difeafes with which numbers of people have been feized in fome years, owing to their having lived upon bread in which there was much rye affected with this diftemper.

"As moft of the diftempered grains are much bigger than the found ones, it is eafy to feparate the greateft part of them by fifting. It is what the peafants of Sologne do, when corn is not dear; but in times of great fcarcity or dearth, they are loth to lofe fo much grain: and then it is that they are attacked with a dry gangrene, which mortifies the extreme parts of the body, fo that they fall off, almoft without caufing any pain, and without any hemorrhagy. The Hotel-Dieu at Orleans had had many of thefe miferable objects, who had not any thing more remaining than the bare trunk of the body, and yet lived in that condition feveral days.

"As it is not in every year that the fpur in rye produces thefe dreadful accidents, Langius is of opinion that there may be two kinds of this diftemper; one which is not hurtful, and the other which occafions the gangrene we have been fpeaking of. It is however probable that there is but one kind of fpur, and that it does not hurt, firft, when fufficient care is taken in fifting the grain; and, fecondly, when only a fmall part of the corn is diftempered. It is alfo faid, that the fpur lofes its bad quality after the grain has been kept a certain time: in which cafe, the reafon why fome peafants are attacked with the gangrene in years of dearth may be, that they confume their crop as foon as the harveft is over." *Duhamel's Culture de Terres.*

SPURRE-WAY, a horfe-way through inclofed lands, and free to any one to ride in by right of cuftom.

SPURREY, the name of a weed common in many parts of England. It feldom rifes above fix inches in height, flowers in the beginning of July, ripens its feeds in Auguft, and is an annual plant.

The beft method of exterminating this weed is by fummer fallows, and cutting it down before it can fcatter its feeds, which are very fmall.

They cultivate two fpecies of this plant in Holland and Flanders for the winter food of cattle, when there is a fcarcity of grafs. It is faid to enrich the milk of cows fo as to make it afford excellent butter; and the mutton fed on it is preferable to that fed on turneps. Hens alfo eat this plant greedily, and it is commonly thought to make them lay an extraordinary number of eggs.

Though this plant cannot, from the lownefs of its growth, afford a very great quantity of fodder, yet as it will grow on the pooreft fand, where no other grafs will thrive fo well, it may be cultivated to confiderable advantage in many places; and by feeding it off the ground, the dung of the cattle will improve the land.

The farmers in the low-countries commonly fow it twice a year; the firft time in April or May, to be in flower in June or July; and the fecond time after their rye-harveft, to ferve their cattle in November and December. The ufual allowance with them is about twelve pounds of feed to an acre.

STABBING *of Cattle*. *See the article* HOVEN.

STABLE, a place or houfe for horfes, &c. furnifhed with ftalls and proper apartments to contain their food, &c.

Nothing conduces more to the health of a horfe than the having a good and wholefome ftable. The fituation of a ftable fhould always be in a good air, and on a firm, dry, and hard ground, that in winter the horfe may go out and come in clean. It fhould always be built fomewhat on an afcent, that the urine and other foulneffes may be eafily conveyed away by means of trenches or finks for that purpofe. As there is no animal that delights more in cleanlinefs than the horfe, or that more abominates bad fmells, care fhould be taken that there be no hen-rooft, hog-ftie, or neceffary-houfe, near the place where the ftable is to be built; for the fwallowing of feathers, which is very apt to happen, when hen roofts are near, often proves mortal to horfes; and the fteams of a hog-houfe, or hog's-dung, will breed many diftempers. The walls of a ftable, which ought to be of brick rather than ftone, fhould be made of a moderate thicknefs, two bricks, or a brick and a half at leaft, for the fake of warmth in the winter,

winter, and to keep out the heat in the fummer. The windows fhould be made on the eaft and north fide of the building, that the north wind may be let in to cool the ftables in the fummer, and the rifing fun all the year round, efpecially in winter. The windows fhould either be fafhed, or have large cafements, for the fake of letting in air enough; and there fhould always be clofe wooden fhutters, that the light may be fhut out at pleafure, by which means the horfe may be made to fleep in the day as well as in the night, when it is judged proper he fhould do fo. Many pave the whole ftable with ftone, but that part which the horfe is to lie on fhould be boarded with oak planks, which fhould be laid as even as poffible, and crofs-wife rather than length-wife; and there fhould be feveral holes bored through them to receive the urine, and carry it off underneath the floor into one common receptacle; the ground behind fhould be raifed to a level with the planks, and it fhould be paved with fmall pebbles. There are two rings to be placed on each fide of the ftall, for the horfe's halter to run through, and a logger is to be fixed to the end of this fufficient to poife it perpendicularly, but not fo heavy as to tire the horfe, or to hinder him from eating; the beft place for him to eat his corn in is a drawer or locker, made in the wainfcot partition, which need not be large, fo that it may be taken out at pleafure to clean it, by which means the common dirtinefs of a fixed manger may be avoided. Many people are againft having a rack in their ftables; they give the horfe his hay fprinkled upon his litter, and if they think he treads it too much, they only nail up three or four boards, by way of a trough, to give it to him in: the reafon of this is, that the continual lifting up of the head to feed out of the rack, is an unnatural pofture for a horfe, who was intended to take his food up from the ground, and makes him, as they exprefs it, withy-cragged. When there is ftable-room enough, partitions are to be made for feveral horfes to ftand in: thefe fhould always allow room fufficient for the horfe to turn about and lie down conveniently, and they fhould be boarded up fo high towards the head, that the horfes placed in feparate ftalls may not be able to fmell at one another, nor moleft each other any way. One of thefe ftalls ought to be covered in, and made convenient for the groom to lie in, in cafe of a match, or the ficknefs of a horfe. Behind the horfes there fhould be a row of pegs, to hang up faddles, briddles, and other utenfils; and fome fhelves for the brufhes, pots of ointment, &c. The other requifites for a ftable are a dung-yard, a pump, and a conduit.

STACK, a large quantity of corn, hay, ftraw, &c. regularly piled up, and generally thatched to defend the contents from the weather.

It is very common, in order to preferve corn in the ftraw, to make it up into ftacks, by which means they often meet with very great loffes by the dampnefs of the ground, which commonly rots and fpoils it, fometimes near a yard thick; and by rats and mice, and other vermin that breed in the ftack, which eat and devour a great part thereof. To prevent both thefe inconveniencies, where timber is plentiful, they fet four, or fix, or more pofts into the ground, according to the bignefs that they defign the ftack, granary, or barn that the corn is to be laid in: on thefe pofts they lay what is the ground-plats of other building, upon which they make a floor, or lay pieces crofs to fupport the ftack: and if they make a barn or granary of it, they erect fides and a roof upon it; but if only a ftack, they cover it with thatch, and the pofts that fupport it, is by fome perfons, covered round with tin near the top, for about a foot or fo in breadth, in order to prevent the mice and rats getting up. But as tin is apt to ruft, and fo to loofe its fmoothnefs, it will not anfwer the defign long; therefore the better to prevent their getting up, is to cover them with Dutch tile, which will always keep fmooth. But in Hampfhire and other countries where they have plenty of ftone, they make their fupporters of two ftones, which is the beft way.

The lower ftone is about three feet high, two feet wide at the bottom, and one at the top; over this they lay another ftone, of about a yard fquare: fome make it of a round form, which is the beft. This prevents not only the mice and rats from climbing up, but alfo the dampnefs of the ground: and this way you may keep corn as long as you will, without much inconvenience or lofs, except what it lofeth in the firft year's fhrinking, and lofs of weight, which is very inconfiderable. Only you muft obferve, that what corn you ftack muft be bound up in fheaves, that fo the ears of the corn may be turned inward, and the ftraw-ends out, which will fave the corn from pigeons, crows, and other fowls, and likewife from the rain that beats on the fides. If your ftack be of wheat, you may lay oats or other coarfe grain on the top of it, under the thatch, the greateft danger of wet being from the top, if any of the thatch fhould blow off. And if you fufpect any rats or mice have got into the ftack, greafe a ftick and thruft it into it; and if there be any, they will gnaw the ftick. The chief inconvenience that attends this way of keeping of corn, is its bulkinefs, and the farmer's wanting of his ftraw to make dung with, and the chaff to give his cattle, &c. *Mortimer's Hufbandry, vol.* II. *pag.* 141.

STACK *of Wood*, a pile of wood three feet long, as many broad, and twelve feet high.

STADLE, the bottom of a corn mow, or hay-ftack. It alfo fignifies a tree fuffered to grow for coarfe and common ufes, as pofts or rails.

STAG-EVIL. *See the article* STAGGERS.

STAGGERS, a difeafe incident to horfes: a kind of apoplexy.

Farriers generally include all diftempers of the head, under two general denominations, viz. ftaggers, and convulfions, wherein they always fuppofe the head primarily affected. But in treating thefe diforders, we fhall diftinguifh between thofe that are peculiar to the head, as having their fource originally thence, and thofe that are only concomitants of fome other difeafe, where the head is affected fecondarily by confent of nerves, the fource of this diforder being in the ftomach, bowels, &c. By this method we fhall avoid many blunders, which would otherwife arife in practice, for want of knowing the true feat of the diforder.

In an apoplexy a horfe drops down fuddenly, without other fenfe or motion than a working at his flanks.

The previous fymptoms are drowfinefs, watry eyes, fomewhat full and inflamed; a difpofition to reel, feeblenefs, a bad appetite; the head almoft conftantly hanging, or refting on the manger; fometimes with little or no fever, and fcarce any alteration in the dung or urine: the horfe is fometimes difpofed to rear up, and apt to fall back when handled about the head, which is often the cafe with young horfes, to which it does not prove fuddenly mortal, but with proper help they may fometimes recover. If the apoplexy proceeds from wounds, or blows on the head, or matter on the brain, befides the above fymptoms, the horfe will be frantick by fits, efpecially after his feeds, fo as to ftart and fly at every thing. Thefe cafes feldom admit of a perfect recovery; and when horfes fall down fuddenly, and work violently at their flanks, without any ability to rife after a plentiful bleeding, they feldom recover.

All that can be done is to empty the veffels as fpeedily as poffible, by ftriking the veins in feveral parts at once, bleeding to four or five quarts, and to raife up the horfe's head and fhoulders, fupporting them with plenty of ftraw. If he furvives the fit, cut feveral rowels; give him night and morning, glyfters prepared with a ftrong decoction of fenna and falt, or the purging glyfter; blow once a day up his noftrils a dram of powder of afarabacca, which will promote a great difcharge, afterwards two or three aloetic purges fhould be given; and to fecure him from a relapfe, by attenuating and thinning his blood, give him an ounce of equal parts of antimony and crocus metallorum for a month; or which is preferable, the fame quantity of cinnabar of antimony and gum guaiacum.

If the fit proceeds only from fullnefs of blood, high feeding, and want of fufficient exercife, or a fizy blood (which is often the cafe with young horfes, who though they reel, ftagger, and fometimes fuddenly fall down, yet are eafily cured by the above method) an opening diet with fcalded bran and barley will be neceffary for fome time; and the bleeding may be repeated in fmall quantities.

help thinking that the quantity of water which falls in rain, would not be more than is requisite to moisten the mixture, and bring on that putrid fermentation which is necessary for the due incorporating and perfecting of the compost. It will, however, be right to have a shade to put over it occasionally, in case the season should prove extremely wet.—Columella informs us, that the Romans covered their stercoraries with hurdles; but does not speak of covering them with mould, as here directed.

The pit being thus prepared, the farmer's next study should be to fill it with a compost suited to the nature of his land. Thus, if his soil is a strong clay, a layer of dung should be covered with a layer of sand, rubbish of old houses, or other substances already mentioned for the improvement of clay. Litter of all kinds becomes a good addition, because it is slow in decaying, and if mixed with the clay, keeps its parts asunder. The compost for meliorating clay may be carried out, and mixed with the earth, fresher than for any other soil; because, in this state, it will more effectually keep the particles of the clay separated; and if some degree of its putrefaction is carried on in the soil, it will much more powerfully open it.—If, on the contrary, the soil is sand, the dung should be mixed with clay, scouring of ponds, or other fat slimy substances, which may give consistence to the sand. And if the farmer is happy in a soil in which neither of the extremes prevail, he may then mix his manure with the richest mould he can find, and incorporate them well together, by frequent turning, before the compost is carried to the field.—Columella thinks they are slothful husbandmen, who, in thirty days, have not a load of dung, of twenty bushels, from each of the lesser cattle, and ten loads from each of the larger sort, by means of judicious mixtures with their dung. He thinks this mixture, or compost, most beneficial to corn, after it is a year old; because it still retains all its strength, and does not then breed weeds.

"Many good effects, says Dr. Home, particularly that of hindering the oils from being volatilized, and of fixing them, will arise from a mixture of lime with these composts, after they are thoroughly rotted. But as many experiments have proved that quick-lime powerfully resists putrefaction, it does not seem judicious to mix it with dung-hills which are not sufficiently putrefied, as it must stop that process."

"There is a very great attraction betwixt quick-lime and all oily bodies. It unites intimately with expressed oils. With this intention it is used in the manufacture of soap, to help the junction of the alkaline salts and oils. It must, therefore, attract the oils powerfully from the air and earth, dissolve them, and render them miscible with water: it must, from this reason, soon exhaust the soil of all its oleaginous particles, if the farmer does not take care to supply them by dung or animal substances. Farmers have, by experience, discovered it to be gare at impoverisher of lands; but they did not know how it acted. Its operation is, to exhaust the earth of its oils. The proper cure for this is, to mix dung with the lime, so that it may have something to act on."

"Lime is a great dissolver of all bodies, both vegetable and animal; but particularly the latter. We know how soon it reduces hair and woollen rags into a pulpy substance. This effect is so strong, that, in the common method of speaking, it is said to burn them. In this way it certainly operates in the earth, by dissolving all animal and dry vegetable substances, and converting them to the nourishment of vegetables, at least sooner than otherwise they would be. Like other calcarious bodies, it is not dissolvable but by acids. With these, a great effervescence happens, a solution of the calcarious body is made, and a neutral salt is formed from that conjunction. This neutral salt is always soluble in water, unless where the acid of vitriol is used." *Home's Principles of Vegetation, page* 69, 70.

The Society of Improvers in the Knowledge of Agriculture in Scotland, have paid great attention to the subject of composts, and are very particular in their instructions on this head, to several of their correspondents. I gladly take this opportunity of paying the tribute of praise justly due to their public spirit, and congratulate them on the great success which has attended their labours in many parts of their country. At the same time I cannot help regretting, that, though all our neighbours have set us so many examples of periodical instruction in this most useful art, there is not yet any institution of that kind in England. It is to be hoped, that the Society for the Encouragement of Arts, Manufactures and Commerce, will soon take off this reproach, and not suffer it to be longer said that agriculture lies neglected in this kingdom, where the people enjoy every advantage requisite to promote it, in a far higher degree than the inhabitants of any other country in the world. The wealth of our farmers is incomparably greater; their property, and the tenure of their land, are infinitely better secured; and the happiest of soils and climates combine to reward their labour.

The Society in Scotland give to a gentleman who had written to them, and who had clay and lime at command, the following judicious directions for collecting a compost, or making a stercorary, for the improvement of a sandy soil. "Take, say they, in the field intended to be manured, a head-ridge, the most conveniently situated for a stercorary. Plow it two or three times, as deep as can be, in the cleaving way, if the ridge be high gathered, and harrow it well: then lay thereon your slimy clay, about a foot thick, leaving a part of the ground un-covered: next lay a thin layer of dung, another of clay, and after that a layer of un-slaked lime, at least a foot thick: then throw up the earth left uncovered on each side. After this, repeat another layer of clay, and lime-stone, as before, and finish it with a layer of clay and sea-wreck, covered with earth. The more of the slimy clay the better: for though it may be cold, yet it will not be the worse for a sandy hot ground. If you examine the clay, we doubt not but you will find it a very fat substance; being, as we conjecture, mostly muscle and other shells mixed with earth, brought by the tide and river Southesque. On the coast of Lothian, we found that slimy substance to be nothing else; and if it be so with you, it is certainly one of the best manures."

"After this stercorary has stood six weeks or two months, incorporating and fermenting, turn and mix it; and that this work may be performed to the better purpose, and with as small an expence as possible, yoke your plow, enter upon your stercorary with a cleaving furrow, and continue repeating the plowings the same way, until the very bottom of the stercorary be ripped up; then harrow it: it is impossible to over-do it. If it be very cloddy, it should be harrowed between the plowings. Begin then in the middle, and plow again and again in the gathering way, until it be brought into as narrow bounds, and be raised as high as possible. Let all that the plow has left be gathered up, and thrown with shovels on the top. Every such turning and heaping occasions a new ferment, and improves the manure. If the seeds of barley, or of any other quick-growing vegetable, were sprinkled thin on the stercorary, and the plants buried in it, when fullest of sap, before they come to seed, by turning or more heaping, the manure would be improved." This might be repeated several times in the course of the season; for the practice has been found successful. *Maxwell's Collection, page* 26.

In another place, they observe that such a stercorary may be turned in the same manner as ground is trenched. The higher it is raised, the better. Each turning will make it heat like a garden hot-bed, and this fermentation will reduce it to a fine fat mould. If the first heat should go off (which may easily be known by thrusting a pole into it) before it has produced this effect, it may be turned over again, and will take a new heat, which is of great advantage to it, besides the better mixing of the several manures. About fifty or sixty cart-loads of this compost are used upon an acre of ground. I have been the more particular in extracting this account, because any farmer, by attending to the rules here given, may suit his compost to the nature of his soil. Where the soil varies, he will do well to have another stercorary, properly composed, in a convenient part of the field he intends to manure.

The same society, in their directions for the management of sheeps dung, where the sheep are housed, or fed under cover during the inclemency of the winter, advise laying under them substances suited to the nature of the soil

soil intended to be improved. A layer of sand, for instance, for stiff land, will be greatly benefited by being covered with a couch of litter in the sheep-house. When their dung becomes troublesome or offensive to them, or begins to make them dirty, the whole should be removed to the stercorary. But if the dung of the sheep is to be laid on a sandy soil, clay, or any such substance, though covered with litter it would soon become wet, and too cold for the sheep to lie on. It would therefore be better, in this case, to spread a thick couch of litter under the sheep, and mix this in the stercorary with the lime, &c. by which means the same advantage may be obtained, without injury to the cattle. If loam, or a rich mould, be laid under sheep, the judicious farmer will be careful to collect a sufficient quantity of it, when it may be got dry, in the summer. Whatever is used for this purpose, should be renewed as often as it is sufficiently impregnated by the urine and dung of the sheep.

The well preparing of mixed dung, is, as Mr. Worlidge rightly insists, a piece of husbandry by no means to be neglected; for the more and better the dung is, the greater will be the crop; and an increase of the crop will augment the quantity of dung. On the contrary, a decay in the dung makes a decay in the crop, &c. The rise, or fall, of the value of many farms in this kingdom must therefore necessarily depend upon the good or bad management of this essential part of husbandry. *See the article* Dung-Hill.

STERILE, barren, unfruitful.

STEW, a small kind of fish-pond, the peculiar intention of which is to maintain fish, and keep them for the daily uses of a family.

STOCK, the trunk or body of a fruit-tree, into which the graft, or bud is inserted.

All stocks for fruit-trees should be raised from the kernels or stones of the fruit; for suckers (though some people use them), besides being hardly ever well rooted, are very apt to produce quantities of other suckers, which weaken the trees exceedingly, and become very troublesome in the borders and walks of a garden. The best way therefore is to sow a few stones and kernels annually, or at least every other year, for a constant supply. Both these sorts of seeds are best when their fruit has been suffered to hang upon the tree till it drops through ripeness, and is afterwards permitted to begin to rot: but they must be carefully taken out before that rottenness can affect them. They should then be well cleared from the pulp, and the largest, plumpest, and heaviest should be selected, and carefully laid up in dry sand, in a place where neither vermin nor moisture can come to them; for the latter would spoil their growth by rendering them mouldy, and the former, particularly rats and mice, are so very fond of the kernels of apples and pears, that they will even scratch them up after they are sown, and then devour them. Traps should therefore be set in the seminary, to catch those mischievous animals.

Layers, slips, and cuttings, when they have taken good root, make far better stocks for grafting on, than any suckers; but still they are much inferior to those which are raised from seeds.

The best stocks for each sort of fruit are the following.

For apples, which must always be grafted upon a free stock, that is to say, upon a stock of their own kind, for they will not take upon that of any other fruit, the sorts most generally used are, 1. The crab stock, as it is commonly termed; 2. The Dutch creeper; 3. The Paradise stock; and, 4. The codlin stock.

The first of these, called likewise free stocks, are usually raised from the kernels of all sorts of apples taken indiscriminately from the cyder-press; and as all the trees of this species are, without distinction, termed crabs before they are grafted, these are called by the general name of crab stocks: but the best, particularly for such apple trees as are intended for standards, are raised from the kernels of real wildings, or crabs, which have been pressed for verjuice; for these are always cleaner, freer from canker, more durable, and less luxuriant in their growth, than any that are raised from the kernels of finer and sweeter apples. They also produce the firmest, most juicy, and best tasted fruit, as well as the fittest for keeping, and will preserve the sorts grafted upon them in their true size, colour and flavour, far better than any of the other sorts of free stocks. These last will, indeed, produce larger fruit; but it will not be so well tasted, or keep near so long. For winter apples in particular, the true crab stock is incomparably the best. In short, it is remarkably with this, as it is with all other fruits, that, the sourer the stock is, the better its produce will be.

The second sort of stocks for apples, called the Dutch paradise apple, Dutch stock, or Dutch creeper, is generally preferred for espaliers, or dwarfs, because it is easily kept within the compass usually allotted to those trees, without stinting the graft too much; nor does it decay, or canker, near so soon as the third sort, commonly called the dwarf paradise apple, which is now raised only for very small gardens, or for the curiosity of setting an apple-tree upon the table with its fruit upon it, which never is at all numerous.

Codlin stocks are used by some, in order to stint the growth of their grafts: but as they never produce firm or lasting fruit, they should be absolutely rejected, at least for all winter apples, and especially if they have been propagated by suckers, as is the common way. Even the codlin tree itself is so much improved by being grafted upon a crab stock, that it becomes much more durable than it would otherwise be, ceases to put out suckers, and produces firmer and tarter flavoured fruit, which is also much fitter to keep.

November and December are proper times for sowing the kernals of apples in dry ground; but where the soil is wet, it is best to wait till February. The most regular and most convenient way of sowing them, in order to facilitate the taking up of the plants, is to drop them, but not too close together, in little channels opened across the bed, (which, it is taken for granted, has been well dug, raked, and properly prepared as before directed), and then to cover them with about half an inch deep of the same mould. The plants will come up in the spring, when they must be carefully weeded; and if the season should prove dry, it will be right to water them twice or thrice a week. The weeding of them must be continued during the whole summer, lest they should be choaked, or stinted in their growth; and if they thrive well, they will be fit to transplant into the nursery the next October; at which time the ground that is to receive them should be dug again thoroughly, and carefully cleared from all weeds.

The best stocks for all sorts of firm winter pears are raised from the kernels of the fruit of which perry has been made, or from the seeds of some of the strongest and quickest growing summer pears, such as the lady's thigh, and the Windsor. These kernels, if saved as before directed for apples, and afterwards sown, in the same manner, early in the spring, will come up in about six weeks; and if the plants thus produced are kept clear from weeds, they will be strong enough to remove from the seed bed into the nursery in the ensuing month of October. But for all sorts of soft melting pears, which are in general the summer and autumn fruits, quince stocks are preferred, especially for a strong soil, or for such trees as are designed for dwarfs or walls; because the luxuriancy of their growth is checked by these stocks, and their shoots are more easily kept within due compass, than they can be when grafted upon free stocks. They must not, however, be used indifferently for all sorts of pears; first, because there are some which will not thrive upon them, but will decay in two or three years, or at most but just keep alive; and secondly, most of the sorts of hard, or winter pears, are rendered stony by being grafted on a quince stock: besides which it is to be observed, that no sort of pear will do upon quince stocks in very dry and gravelly ground. These stocks are often propagated from suckers, which may be obtained in great quantities, by cutting down an old quince tree; but, for the reasons before assigned, they are not near so good as those which are raised from well rooted layers or cuttings.

The white thorn was formerly used as a stock to graft pears on; but it is now almost totally laid aside for that purpose, because it never keeps pace in its growth with the fruit grafted or budded upon it; and also because the fruit which it produces is generally dryer, and more apt to be stony, than that which grows upon pear stocks.

Cherries do best when grafted upon stocks raised from the stones of the common black, or wild red cherry, both of of which are ſtrong growers, produce clean ſtocks, and are more laſting than any of the garden kinds. Theſe ſtones, collected from the ripeſt and almoſt rotten fruit, may be ſown in the autumn in a bed of light earth; or they may be kept in ſand till the ſpring, and be ſown then. The plants produced by them muſt be kept carefully clear from weeds, and watered from time to time in dry weather, as before directed. They ſhould remain in the ſeed bed till the ſecond autumn after ſowing, and will then be fit to tranſplant into the nurſery, in October. Stocks of the Corniſh, and of the Morello cherry, likewiſe raiſed from the ſtones, have alſo been uſed with ſucceſs, to render the trees more fruitful and leſs luxuriant in their growth; for in theſe laſt reſpects they have nearly the ſame effect upon cherries, as the paradiſe ſtock has upon apples.

Plums will not do upon any but plum ſtocks, the beſt of which are raiſed from ſtones of the freeſt growing ſorts, ſuch as the muſcle, the white pear-plum, &c. Theſe ſtones ſhould be ſet in autumn, about three inches deep and four inches aſunder, in a bed of light dry earth, which it will be right to cover in the winter with a little dry ſtraw, or haulm, to protect them from the froſt; for that would deſtroy them, if it were to penetrate deep into the ground. Their plants will come up the next ſpring, when the covering of litter ſhould be carefully removed; and if they are watered ſparingly now and then in the ſpring and ſummer, and kept conſtantly clear from weeds, they will be fit to remove from the ſeminary into the nurſery in the then enſuing ſpring, or, which is more eligible, in the following autumn.

All the late, or autumn peaches, which are the hard ſorts, and all nectarines and apricots, ſucceed beſt upon ſtocks of the muſcle, or of the white pear-plum, raiſed from the ſtone; though any of the large growing plums, whether white or red, will afford very good ſtocks for theſe fruits. Some recommend almond and apricot ſtocks for the early, or ſummer peaches (commonly diſtinguiſhed by the appellation of melting peaches), which will not grow upon plum ſtocks: but the almond ſtocks are ſo tender in their roots, ſo apt to ſhoot too early in the ſpring, and of ſo ſhort duration, that the preference is deſervedly given, for theſe kinds, to the apricot ſtock, upon which they will take perfectly well, without being near ſo ſubject to blight, as upon the almond. Theſe ſtocks are raiſed, and managed, in the ſame manner as thoſe of the plum. They are particularly proper for all ſorts of peaches which are planted in a dry ſoil; becauſe the peach ſeldom does well in ſuch ground, if it be grafted on any other ſtock; but the apricot will thrive there exceedingly. For this reaſon, the common practice of the nurſery gardeners is, to bud the plum ſtocks either with apricots, or ſome free growing peach, and after theſe have grown a year, they bud the tender ſorts of peaches upon their ſhoots; by which means many ſorts ſucceed well, which would ſcarcely keep alive in the common way. The gardeners term theſe double worked peaches.

The ſtones of peaches are not worth ſetting for ſtocks to inoculate, unleſs it ſhould be for almonds; becauſe the plants which they produce are of a ſpungy nature, and will neither laſt, nor bear tranſplanting. They may indeed, produce ſome new ſorts of peaches, if they are neither budded nor grafted (for all the varieties of fruits have been originally obtained from their ſeeds); and theſe may be better ſuited to our climate, than ſuch as are brought from warmer countries: but ſo few fruits raiſed in this manner prove better than thoſe from which the ſeeds were taken, that they ſeldom make amends for the trouble of rearing them.

STONE-BREAK, or Engliſh ſaxifrage, a perennial plant common in paſture grounds. The root has a ſharpiſh and aromatic taſte. The ſtalks are round, ſtreaked, and reddiſh towards the bottom. The leaves are ſmooth, of a dark green, and divided twice into long, narrow, ſharp ſegments. The foot-ſtalks are membranaceous at the baſe. The flowers grow in looſe umbels; and of a pale yellow colour. The ſeeds are oval, ſtreaked, and red at the top.

"Every farmer, ſays a correſpondent of the editors of the Muſeum Ruſticum, knows which ſort of graſs he would wiſh to have predominant in his meadows: it would ſurely be very eaſy for him to ſave ſome of the ſeeds of ſuch graſs, and propagate it a-part till he had ſaved ſufficient to ſow, ſuppoſe an acre of land with it, pure and unmixed: when arrived at this point, he might propagate it as extenſively as he thinks proper.

"I muſt not however forget the chief intended ſubject of my letter, which is, to recommend to your readers the ſaxifrage as a plant proper to be intermixed with the graſs of their meadows.

"I have now in my holding above thirty acres of meadow land, which fortunately for me bear a graſs that needs no improvement; though this I in part attribute to my having drained my land properly ſome years ago, ſince which the bite is much improved.

"Amongſt this graſs in my meadows there grows a conſiderable quantity of ſaxifrage; which, in the opinion of all the dairy-men in my neighbourhood, is the reaſon my cheeſe is ſo particularly good.

"Now I ſhould imagine that when a farmer has plowed up a foul meadow, and intends ſowing it with good graſs ſeed, it would be no difficult matter to procure a ſprinkling of ſaxifrage-ſeed to mix with it: this would certainly be of ſervice; and we ſhould not deſpiſe this excellent plant becauſe it is common, and not far-fetched: there is great plenty of it in the Netherlands, in their fineſt cow-paſtures; and that I have often heard aſſigned as a reaſon for their having ſuch quantities of cheeſe of a ſuperior quality; though I muſt at the ſame time own, I have in London taſted ſome Dutch cheeſe, ſtuffed full of cloves, which was not the beſt in the world; but this might have been an accident, for they ſay their cheeſe is in general excellent.

"But, to return to my immediate ſubject, I would by all means recommend the propagation of the ſaxifrage plant in meadows, not only on account of its great uſe in improving the quality of cheeſe, and butter alſo, which it does, but becauſe it is a native of our iſland, and there is no danger of its ſucceeding to the farmer's wiſh; which cannot be ſaid of every plant recommended for cultivation.

"But it muſt be remembered, that I do not recommend it to be cultivated alone; I never tried it in that manner: that it will thrive very well when mixed with good meadow graſs, daily experience convinces me; and this method it is I urge." *Muſeum Ruſticum, vol.* I. *pag.* 472.

The burnet, cultivated to ſo much advantage by Mr. Roque and others is a ſpecies of the ſaxifrage. *See the article* BURNET.

STONE, a hard ſolid body, neither molliable, fuſible by fire, nor ſoluble in water; formed by ſucceſſion of time in the bowels of the earth.

M. Tournefort ſuppoſes that ſtones vegetate; but M. Geoffray accounts for the origin and formation of ſtones in a different manner. He lays it down as a principle that all ſtones, without exception, have been fluid; or, at leaſt, a ſoft paſte, now dried and hardened: and on this principle he examines the formation of the different kinds of ſtones, and ſhews that the earth alone is ſufficient for the ſame, independant of all ſalts, ſulphurs, &c.

It has been argued, and is not yet determined, whether ſtones are hurtful, or beneficial, to arable lands. Examples are not wanting on both ſides of the queſtion; though, in general, it ſeems rather to be carried for them. However, nothing can excuſe leaving a ſtone in any ground ſo large as to interrupt the plough. If they are very large, they ſhould be blown to pieces with gun-powder, and then be carried off. Some ſpots, very fertile in ſeveral kinds of grain, ſeem to conſiſt of nothing but ſtones; and inſtances are given of fields being rendered barren by taking away the ſtones which covered them. Theophraſtus accounts for this in a hot country, where it happened to the Corinthians, by ſaying, that the ſtones ſhelter the earth from the ſcorching heat of the ſun, and thereby preſerve its moiſture. The ſame holds true even in our colder latitude, where the heat of the ſun is leſs apt to hurt us; and Mr. Evelyn is clearly of opinion that huſbandmen rather impoveriſh, than improve, thoſe grounds which are almoſt covered with ſtones, eſpecially where corn is ſown, if they pick them off too minutely; becauſe they thereby expoſe the land too much to the effects of heat and cold. Certain it is, that a moderate mixture of ſmall gravel preſerves the earth both warm and looſe, and prevents too ſudden exhalations. But it ſeems highly probable that there muſt be ſome farther reaſon, beyond what has yet been aſſigned, for the benefit ariſing from ſtones. The example already given of the ſtone uſed in Oxfordſhire; and a remakable incident which happened to M. Du Hamel, give great room to think that the ſtones which are thus beneficial, are of the lime-ſtone or calcarious kind.

" The ſtone which is uſed for building at Denainvilliers, ſays M. Du Hamel, is very hard. It bears poliſhing like marble; and is here and there intermixed with ſhells, ſome of which are filled with a kind of oaker, and others contain a cryſtaline ſubſtance. This ſtone is very fit to make lime of. Some workmen, who were building about our houſe, cut pieces of this ſtone upon a graſs-plat. When they had done their work, the rubbiſh was cleared away, and nothing was left upon the graſs but the duſt and very ſmall fragments, which had fallen from the ſtones in cutting them. The next year, the graſs grew ſurpriſingly thick in all the places where theſe ſtones had been cut, was much taller and greener than any where elſe, and preſerved its vigour for ſeveral years. One would ſcarcely have thought that ſo hard a ſtone, reduced to powder would have produced an effect like that of marle. The goodneſs of lime, as a manure, is, perhaps, chiefly owing to the fineneſs of the powder, to which the lime-ſtones are reduced by calcination.

" This fact may help to clear up another, which cannot have eſcaped the notice of thoſe who attend to the differences of ſoils. They muſt have obſerved ſome grounds ſo thickly covered with ſtones, that ſcarce any thing elſe is ſeen after a heavy ſhower of rain. Yet ſome of theſe lands are very fertile, and produce fine wheat. I know not whether I am miſtaken; but I think I have obſerved that this fertility is found only in fields where thoſe ſtones are calcarious. It is very probable that the duſt which is formed by the mutual rubbing of theſe ſtones contributes to that fertility." *Culture des Terres, tom.* V. *pag.* 220.

The farmer may eaſily inform himſelf whether this be the caſe; and if it is, he has a certain rule to go by in the management of ſtones; viz. by trying with aqua fortis, or ſpirit of ſea-ſalt, as mentioned before, whether they are calcarious or not: for every ſtone on which the ſpirit does not efferveſce, is of no uſe, and therefore ſhould be removed, as an impediment to the neceſſary labour. However, the prudent huſbandman will make the experiment of clearing his land, firſt on a ſmall ſpot; that he may be ſure of the ſucceſs, before he embarks in a greater expence. *See the article* LIME.

STONE, alſo denotes a certain quantity or weight of ſome commodities.

A ſtone of beef at London is the quantity of eight pounds; in Herefordſhire, twelve pounds; in the north ſixteen pounds.

A ſtone of wool, according to a ſtatute made in the eleventh year of the reign of Henry VII. is to weigh fourteen pounds, but in ſome places it is more, in others leſs; as in Glouceſterſhire fifteen pounds, in Herefordſhire twelve pounds.

A ſtone, among horſemen, is the weight of fourteen pounds.

STONY-LANDS, ſuch as are full of flints, pebbles, or ſmall fragments of free ſtone.

Theſe lands, in many places, yield good crops, and the general rule is, that in ſtiff and cold lands the ſtones ſhould be as carefully picked out as poſſible, but in light and dry grounds they ſhould be left. In Oxfordſhire they have great quantities of a lean earth, and a ſmall rubble ſtone, or a ſour ſort of land mixed with it; this is ſometimes very full of weeds, and ſometimes very clear of them. If they are weedy they fallow them late; but if they are ſcary, as they call it, that is, if they have a ſward upon them, they either fold them in winter, and add ſome hay-ſeed to the ſheep's dung, to bring up the graſs; or elſe they lay old thatch or ſtraw, and dung upon it: for they reckon that if thoſe lands have no ſward upon them before they are fallowed, they will by no means be brought to bear a good crop, but a great deal of May-weed, and other uſeleſs weeds. In September, November, and December, they fallow as the ſward directs them: if this be done in either of the two laſt months, they call it a winter fallowing; and never ſtir it again, till they plow it, and ſow it with barley; and thoſe lands are reckoned to do better than if finely tilled. They will bear wheat and meſlin in a kindly year, and large crops of barley, if they are well managed, and kept in good heart.

They always fallow theſe lands every other year, unleſs they ſow peas upon them; ſometimes they ſow them with lentils; and, when they are quite worn out, they lay them down for clover or rey-graſs.

STOOKING, SHOCKING, *or* STACKING, the ſetting the ſheaves into ſhocks, the better to guard it from the rain.

A correſpondent of the authors of the Muſeum Ruſticum, has given us the following method of ſtacking, or ſtooking corn to preſerve it from the wet, and in which ſituation it may remain in the field ſix weeks or two months, without any danger from the inclemency of the weather.

" They ſet one ſheaf upright with the ears uppermoſt; and round that they place a circle of many other ſheaves, with their ears uppermoſt, inclining on the firſt ſheaf; and when ſo placed they look like the figure of an extinguiſher.

" Then they lay an horizontal circle of ſheaves, with all the ears in the center, and cover thoſe ears with a looſe ſheaf or two.

" Thus placed they are protected from all wet, and may remain in the field ſix weeks, or two months, as ſafe as in a barn; and this method of ſtacking has been adopted in Suſſex, Surry, Kent, and many other ſouthern counties, to the great benefit of the farmers and the public." *Muſeum Ruſticum, vol.* II. *page* 35.

In a ſubſequent number of the ſame work, the rev. Mr. Comber, of Eaſt-Newton, in Yorkſhire, has made ſome remarks upon the above method of ſtooking, and alſo deſcribed the method followed in Yorkſhire.

" It is to be wiſhed, ſays he, that this gentleman had been more particular in his account. He does not tell us whether this ſtack, as he calls it, is made immediately after the wheat is gathered, or after it has had field-room in ſome other manner, though this circumſtance is very material towards a right judgment of its uſefulneſs, and even of the expedition. He does not tell us, whether by a circle of many other ſheaves he means a circle of one row of ſheaves, or of more, though this circumſtance too is very material.

" I will now give a ſhort, but, I hope, ſufficient deſcription of the method of ſtooking uſed in Yorkſhire, &c.

" Ten ſheaves are diſpoſed in two rows, each row leaning againſt the other: then two ſheaves are laid on the top, ſo as to meet at the centre with their tails, and to ſlope downwards.

Now to compare the methods, I muſt obſerve, firſt, that in your correſpondent's the ſheaves appear to be ſet ſo cloſe as to exclude a free courſe of air, moſt eſſential to give, preſerve, or reſtore, dryneſs to corn; whereas in ours, the air has a free courſe, whether it bear againſt one or other end of the ſtook, or even againſt either ſide of it.

" Secondly, in your correſpondent's method, only ſome looſe ears are laid as a cover to the whole ſtook; and thoſe cannot reaſonably be ſuppoſed long to reſiſt the beating of the rain, but to tranſmit it to all, or many of the ears below them, which they are ſuppoſed to cover: and if we conſider what violent winds often viſit us in, and ſoon after, the harveſt, we ſhall readily allow, that theſe looſe ears may reaſonably be expected to be blown off, and become no cover; nay, to be blown about and away, and often totally loſt; whereas, in our method, the cloſeneſs and weight of two of the beſt ſheaves in the twelve may reaſonably be ſuppoſed to be a good cover, and to continue ſo, and hardly to be blown off by any wind, if carefully laid on; at leaſt, not to be blown away, but ſo as ſoon to be replaced.

" Thirdly, the flat poſition of your correſpondent's cover, muſt make it liable extremely to receive all the rain that deſcends, and tranſmit it to what lies beneath; whereas the ſloping poſition of our cap ſheaves, neither expoſes them to receive directly, nor to retain, nor tranſmit the rain to the corn below, but to throw it off, eſpecially as the tails of the sheaves, in which the straw is thickest and strongest, receive the most of the rain, which can do them little or no harm, and especially if the tails of these sheaves be thrust closely together. In short, gentlemen, your correspondent's method seems to threaten that dreadful malady, mow-burn, whilst ours gives the corn all possible guard against it, viz. access of sun and wind.

"It is of great consequence to the public, as well as individuals, to guard against every species of destruction to so valuable a crop as wheat is, in every stage, but more especially in its last, in which almost all the expence is over: therefore, the above gentleman's assertion, that his method of stacking is adopted in Sussex, Surry, Kent, and many other southern counties, made me more solicitous to examine it; and since, on a fair comparison with our Yorkshire method, it appears to have every disadvantage, I persuade myself I am doing my duty to my country by shewing to many counties a much better method than that which they have adopted. *Museum Rusticum, vol. II. page* 250.

STOOMING *of wine*, is the putting bags of herbs, or other ingredients into it. *See the article* WINE.

STOOP, a post fixed in the earth.

STOT, a young bullock; a steer.

STOVES, in gardening, are buildings erected for the preservation of tender exotic plants, which will not live in these northern countries, without artificial warmth in winter. These are built in different methods, according to the ingenuity of the artist, or the different purposes for which they are intended; but in England they are at present reducible to two.

The first is called a dry stove, being so contrived, that the flues through which the smoke passes are either carried under the pavement of the floor, or else are erected in the back-part of the house, over each other, and are returned six or eight times the whole length of the stove. In these stoves the plants are placed on shelves of boards laid on a scaffold above each other, for the greater advantage of their standing in sight, and enjoying an equal share of light and air. In these stoves are commonly placed the tender sorts of aloes, cereus's, euphorbiums, tithymals, and other succulent plants, which are impatient of moisture in winter; and therefore require, for the most part, to be kept in a separate stove, and not placed among trees, or herbaceous plants, which prespire freely, and thereby often cause a damp air in the house, which is imbibed by the succulent plants, to their no small prejudice.

These stoves may be regulated by a thermometer, so as not to over-heat them, nor to let the plants, suffer by cold; in order to which all such plants, as require nearly the same degree of heat, should be placed by themselves in a separate house; for, if in the same stove there are plants placed of many different countries, which require as many different heats, by making the house warm enough for some plants; others, by having too much heat, are drawn and spoiled.

The other sorts of stoves are commonly called bark stoves, to distinguish them from the dry stoves already mentioned. These have a large pit, nearly the length of the house, three feet deep, and six or seven feet wide, according to the breadth of the house; which pit is filled with fresh tanners bark, to make an hot-bed; and in this bed the pots of the most tender exotic trees, and herbaceous plants, are plunged: the heat of this bed being moderate, the roots of the plants are always kept in action; and the moisture, detained by the bark, keeps the fibres of their roots in a ductile state, which, in the dry stove, where they are placed on shelves, are subject to dry too fast, to the great injury of the plants. In these stoves, if they are rightly contrived, may be preserved the most tender exotic trees and plants, which, before the use of the bark was introduced, were thought impossible to be kept in England; but, as there is some skill required in the structure of both these stoves, we shall describe them as intelligibly as possible, particularly the bark stove; by which it is hoped every curious person will be capable of directing his workmen in their structure.

The dimension of this stove should be proportioned to the number of plants intended to be preserved, or the particular fancy of the owner; but their length should not exceed forty feet, unless there are two fire-places; and, in that case, it will be proper to make a partition of glass in the middle, and to have two tan-pits, that there may be two different heats for plants from different countries, for the reasons before given in the account of dry stoves; and were I to erect a range of stoves, they should be all built in one, and only divided with glass partitions, at least the half way towards the front; which will be of great advantage to the plants, because they may have the air in each division shifted by sliding the glasses of the partitions, or by opening the glass-door, which should be made between each division, for the more easy passage from one to the other.

This stove should be raised above the level of the ground, in proportion to the dryness of the place; for, if it be built on a moist situation, the whole should be placed upon the top of the ground; so that the brick-work in the front must be raised three feet above the surface, which is the depth of the bark-bed, whereby none of the bark will be in danger of lying in water; but, if the soil be dry, the brick-work in front need not be more than one foot above-ground, and the pit may be sunk two feet below the surface. Upon the top of this brick work, in front, must be laid the plate of timber, into which the wood-work of the frame is to be mortised; and the upper timber in front must be placed four feet asunder, or somewhat more, which is the proportion of the width of the glass-doors or sashes: these should be about six feet and an half, or seven feet long, and placed upright; but from the top of these should be sloping glasses, which should reach within three feet of the back of the stove, where there should be a strong crown-piece of timber placed, in which there should be a groove made for the glasses to slide into. The wall in the back-part of the stove should be at least thirteen inches thick; but eighteen inches is still better; because, the thicker the out-side wall is built, the more the heat of the flues will be kept in the house; and carried up, about nine feet above the surface of the bark-bed; and, from the top of this wall, there should be a sloping roof to the crown-piece where the glasses slide in. This crown-piece should be about sixteen feet high from the surface of the bark-bed or floor, which will give a sufficient declivity to the sloping glasses to carry off the wet, and be of a reasonable height for containing many tall plants. The back-roof may be slated, covered with lead, or tiled, according to the fancy of the owner: for the manner of this outside building is often very various, and differently built.

In the front of the house there should be a walk, about eighteen or twenty inches wide, for the conveniency of walking; next to which the bark pit must be placed, which should be in width proportionable to the breadth of the house: if the house is twelve feet wide, which is a due proportion, the pit may be seven feet wide; and behind the pit should be a walk eighteen inches wide, to pass in order to water the plants, &c. then there will be twenty-two inches left next the back-wall, to erect the flues, which must be all raised above the top of the bark-bed; these flues ought to be one foot wide in the clear, that they may not be too soon stopped with the soot; and the lower flue, into which the smoke first enters from the fire, should be two feet deep in the clear; and this may be covered either with cast iron plates, or broad tiles; over this the second flue must be returned back again, which may be eighteen inches deep, and covered on the top as before; and so, in like manner, the flues may be returned over each other three or four times, that the heat may be spent before the smoke passes off. The thickness of the wall in front of these flues need not be more than four inches; but it must be well jointed with mortar, and plaistered withinside to prevent the smoke from getting into the house; and the out-side should be faced with mortar, and covered with a coarse cloth, to keep the mortar from cracking, as is practised in setting up coppers. If this be carefully done, there will be no danger of the smoke entering the house, which cannot be too carefully avoided; for there is nothing more injurious to plants than smoke, which will cause them to drop their leaves; and, if it continue long in the house, will entirely destroy them.

The fire-place may be made either at one end, or in the middle, according as there is most conveniency; for, wherever it is placed, it should have a shed over it, and not be exposed to the open air; for it will be impossible to make the fire burn equally, where the wind has full ingrefs to it; and it will be troublefome to attend the fire in wet weather, where it is expofed to the rain.

The contrivance of the furnace muft be according to the fuel which is defigned to burn; but, as turf is the beft firing for ftoves, where it can be had, becaufe it burns more moderately, and lafts longer, than any other fort of fuel, and fo requires lefs attendance, I fhall defcribe a proper fort of furnace for that purpofe.

The whole of this furnace fhould be erected within the houfe, which will be a great addition to the heat; and the front wall on the outfide of the fire place, next the fhed, fhould be three bricks thick, the better to prevent the heat from coming out that way. The door of the furnace, at which the fuel is put in, muft be as fmall as conveniently may be to admit of the fuel; and this door fhould be placed near the upper part of the furnace, and made to fhut as clofe as poffible; fo that there may but little of the heat pafs off through it. This furnace fhould be about twenty inches deep, and fixteen inches fquare at bottom; but may be floped off on every fide, fo as to be two feet fquare at the top; and under this furnace fhould be a place for the afhes to fall into, which fhould be about a foot deep, and as wide as the bottom of the furnace: this fhould alfo have an iron door to fhut as clofe as poffible; but juft over the afh-hole, above the bars which fupport the fuel, fhould be a fquare hole about four inches wide, to let in air to make the fire burn: this muft alfo have an iron frame, and a door to fhut clofe when the fire is perfectly lighted, which will make the fuel laft the longer, and the heat will be more moderate.

The top of this furnace fhould be nearly equal to the top of the bark-bed, that the loweft flue may be above the fire; fo that there may be a greater draught for the fmoke; and the furnace fhould be covered with a large iron plate, clofely cemented to the brick-work, to prevent the fmoke from getting out; or it may be arched over with bricks; but you fhould be very careful, wherever the fire is placed, that it be not too near the bark-bed; for the heat of the fire will, by its long continuance, dry the bark, fo that it will lofe its virtue, and be in danger of taking fire; to prevent which, it will be the beft method to continue an hollow between the brick-work of the fire and that of the pit, about eight inches wide; which will effectually prevent any damage arifing from the heat of the fire; and there fhould be no wood-work placed any where near the flues, or the fire-place, becaufe the continual heat of the ftove may in time dry it fo much, as to caufe it to take fire; which ought to be very carefully guarded againft.

The entrance into this ftove fhould be either from a green-houfe, the dry ftove, or elfe through the fhed where the fire is made, becaufe, in cold weather, the front-glaffes muft not be opened.

The other fort of ftove, which is commonly called the dry ftove, as was before faid, may be either built with upright and floping glaffes at the top, in the fame manner, and after the fame model of the bark-ftove; or elfe the front glaffes, which fhould run from the floor to the cieling, may be laid floping, to an angle of forty-five degrees, the better to admit the rays of the fun in fpring and autumn: the latter method has been chiefly followed by moft perfons who have built this fort of ftoves: but, were I to have the contrivance of a ftove of this kind, I would have it built after the model of the bark-ftove, with upright glaffes in front, and floping glaffes over them, becaufe this will more eafily admit the fun at all the different feafons; for, in fummer, when the fun is high, the top glaffes will admit the rays to fhine almoft all over the houfe; and, in winter, when the fun is low, the front glaffes will admit its rays; whereas, when the glaffes are laid to any declivity in one direction, the rays of the fun will not fall directly thereon above a fortnight in autumn, and about the fame time in fpring; and, during the other parts of the year, they will fall obliquely thereon; and, in fummer, when the fun is high, the rays will not reach above five or fix feet from the glaffes.

Befides, the plants placed towards the back-part of the houfe will not thrive in the fummer-feafon for want of air; whereas, when there are floping glaffes at the top, which run within four feet of the back of the houfe; thefe, by being drawn down in hot weather, will let in perpendicular air to all the plants; and, of how much fervice this is to all fort of plants, every one who has had opportunity of obferving the growth of plants in a ftove, will eafily judge: for, when plants are placed under cover of a cieling, they always turn themfelves towards the air and light, and thereby grow crooked; and if, in order to preferve them ftraight, they are turned every week, they will neverthelefs grow weak, and look pale and fickly, like a perfon fhut up in a dungeon; for which reafons, I am fure, whoever has made trial of both forts of ftoves, will readily join with me to recommend the model of the bark-ftove for every purpofe. *Miller's Gard. Dict.*

STOVER, fodder for cattle.

STOUND, a wooden veffel to put fmall beer in.

STOWK, the handle of a pail; alfo a fhock of twelve fheaves.

STOWRE, a round of a ladder; a hedge-ftake; alfo the ftaves in the fides of a waggon, in which the eve-rings are faftened.

STRAIN, or SPRAIN, a violent extenfion of the finews or tendons of fome mufcle, where by the tendinous fibres are overftretched, and fometimes ruptured, or broken.

To form therefore a true idea of thefe diforders, let us firft confider every mufcle, and tendon, as compofed of fpringy elaftic fibres, which have a proper power of their own, to contract and extend themfelves: or, to make their action more familiar, let us compare them to a piece of catgut, that we may the better judge with what propriety oily medicines are directed for their cure. Thus then, if by a violent extenfion of this catgut, you had fo overftretched it, as to deftroy its fpringinefs or elafticity, and was inclined to recover its loft tone; would you for that purpofe think of foaking it in oil? And is not the method of treating ftrains, or overftretched mufcles and tendons, full as prepofterous, when you bathe or foak them in oily medicines, at a time that they want reftringents to brace them up? Yet cuftom has fo eftablifhed this practice, and fallacious experience feemingly fo confirmed it, that it would be a difficult tafk to convince the illiterate, and prejudiced, of the abfurdity; who, by attributing effects to wrong caufes, are led into this error, and the oils ufurp the reputation that is due only to reft and quiet: they feem however to be aware of the ill confequences, by their adding the hot oils, as fpike, turpentine, and origanum; which, though they in fome meafure guard againft the too fuppleing quality of the other oils; yet the treatment is ftill too relaxing to be of real fervice.

And indeed in all violent ftrains of either tendon or mufcles, whatever opinion we may entertain of bathing and anointing with favourite noftrums, which often fucceed in flight cafes, where perhaps bandage alone would have done; yet it is the latter, with proper refting the relaxed fibres, till they have thoroughly recovered their tone, that are the chief things to be depended on; and frequently fome months are neceffary for effecting the cure.

All violent ftrains of the ligaments, which connect the bones together, efpecially thofe of the thigh, require time, and turning out to grafs, to perfect a recovery. External applications can avail but little here, the parts affected laying too deep, and fo furrounded with mufcles, that medicine cannot penetrate to them. The fooner in thefe cafes, a horfe is turned out to grafs, the better, as the gentle motion in the field will prevent the ligaments and joint oil, from thickening, and of courfe the joint itfelf from growing ftiff; nor do I believe that firing, fo commonly practifed in this cafe, is of half the confequence as reft, and turning out for a confiderable time; which by the bye, is always advifed at the fame time the horfe is fired. I could not avoid faying thus much, in order to fhew the great advantages of reft in all ftrains, and that no horfe fhould be worked till he is thoroughly recovered.

When a horfe's fhoulder is overftrained, he does not put out that leg as the other, but to prevent pain, fets the found foot hardly on the ground, to fave the other; even though he be turned fhort on the lame fide, which motion tries him the moft of any. When trotted in hand, inftead of putting his leg forward in a right line, he forms a circle with the lame leg; and when he ftands in the ftable, that leg is advanced before the other.

In order to cure this lamenefs, firft bleed him, and let the whole fhoulder be well bathed three times a day with hot

hot verjuice or vinegar, in which may be diffolved a piece of foap; but if the lamenefs continues without fwelling, or inflammation, after refting two or three days, let the mufcles be well rubbed for a confiderable time, to make them penetrate, with good opodeldoch, or either of the following mixtures:

> Take camphorated fpirits of wine two ounces; oil of turpentine one ounce; this proportion will prevent the hair coming off.
>
> Or,
>
> Take the beft vinegar half a pint; fpirit of vitriol, and camphorated fpirit of wine, of each two ounces.

When the fhoulder is very much fwelled, it fhould be fomented with woollen cloths (large enough to cover the whole) wrung out of hot verjuice and fpirit of wine; or a fomentation prepared with a ftrong decoction of wormwood, bay-leaves, and rofemary, to a quart of which may be added half a pint of fpirit of wine.

A rowel in the point of the fhoulder in this cafe often does great fervice; efpecialty if the ftrain has been very violent, and the fwelling very large; but as to boring up the fhoulder with a hot iron, and afterwards inflating it, is both a cruel and abfurd treatment; and the pegging up the found foot, or fetting on a patten fhoe, to bring the lame fhoulder on a ftretch, is a moft prepofterous practice, and directly calculated to render a horfe incurably lame; for it can only be neceffary in cafes the very oppofite to this, where the mufcles have been long contracted, and we want to ftretch them out.

Where poultices can be applied they are at firft undoubtedly very effectual, after bathing with hot vinegar or verjuice, and are to be preferred greatly to cold charges, which by drying fo foon on the part, keep it ftiff and uneafy; let them be prepared with oatmeal, rye-flower, or bran boiled up in vinegar, ftrong beer, or red wine lees, with lard enough to prevent their growing ftiff; and when by thefe means the inflammation and fwelling is brought down, bathe the part twice a day with either of the above mixtures, opodeldoch, or camphorated fpirits of wine; and rowl the part three or four inches, both above and below, with a ftrong linnen rowler, of about two fingers width; which will contribute not a little to the recovery, by bracing up the relaxed tendon; and perhaps is more to be depended on than the applications themfelves.

As opodeldoch is varioufly made, and thofe ufually fold in the fhops, do not feem fo well calculated for horfes, we fhall infert the following, as better adapted to this purpofe, and recommend it to be kept ready prepared for the ufe of the ftable; it being not only very proper for the above ufe, but for bruifes, cold fwellings, benumbed parts, and for difperfing many other fuch fort of tumors: it may occafionally alfo be given internally for the gripes from wind, or taking cold; for the ftrangury alfo, and as a cordial; one ounce, or more, may be taken for a dofe, in a pint of ale.

> Take Jamaica pepper four ounces, winters bark, carraway feeds, laurel, and juniper berries bruifed, of each two ounces; rofemary, marjoram, and lavender flowers, of each one ounce; rectified fpirit of wine, three pints; let them digeft in a warm place ten days, then ftrain off the tincture, and diffolve in it Venice foap a pound and a half; camphor three ounces; Barbadoes tar four ounces; oil of turpentine fix ounces; oil of amber two ounces; mix and make a liniment.

In Strains of the coffin joint that have not been difcovered in time, there will grow fuch a ftiffnefs in the joint, that the horfe will only touch the ground with his toe; and the joint cannot be played with the hand; the only method here is repeated bliftering, and then firing fuperficially.

Strains of the back finews are very common, and are eafily difcovered by the fwelling, which extends fometimes from the back fide of the knee down to the heel, but for the moft part the horfe fets that leg before the other. The tendon fhould be well bathed three or four times a day with hot vinegar; and if much fwelled, apply the poultices above recommended; and when the fwelling is down, bathe with the mixtures above, or with camphorated fpirit of wine and oil of amber, in which is diffolved as much camphor as the fpirits will take up, and rowl up the tendon with a proper bandage, or laced ftocking; which laft properly fitted to the limb, might be wore to great advantage; not only in thefe fort of injuries, but in moft others, where there is a difpofition to the greafe, or other fwellings of the limbs, from weak and relaxed fibres. Curriers fhavings wetted with vinegar have been found ufeful for this purpofe; as has alfo tar and fpirit of wine: but where the tendon has fuffered by repeated injuries of this kind, the cafe will demand bliftering, firing, and proper reft.

Strains of the knees and pafterns arife frequently from kicks, or blows; if they are much fwelled, apply firft the poultices; and when the fwelling is abated, bathe with the above, or the following.

> Take vinegar one point; camphorated fpirits of wine, four ounces; white vitriol, diffolved in a little water two drams.
>
> Or,
>
> Take the whites of three or four eggs, beat them into a froth with a fpoon; to which add an ounce of roach allum finely powdered; fpirit of turpentine, and wine, of each half an ounce; mix them well together.

The following is alfo much recommended by the French writers, and has been found very fuccefsful in fome old ftrains, when other remedies have failed.

> Take one pound of tar, and two of rectified fpirit of wine, ftir them together over a fire till they incorporate (but take care the flame does not catch the fpirits) then add two ounces of bole finely powdered; and a fufficient quantity of oatmeal to bring it to the confiftence of a poultice; to which add lard enough to prevent its growing dry; apply it fpred on cloth twice a day.

As great weaknefs remains in the pafterns after violent ftrains, the beft method is to turn the horfe out to grafs till he is perfectly recovered; when this cannot be complied with, the general way is to blifter and fire.

When a horfe is lame in the ftifle, he generally treads on his toe, and cannot fet the heel to the ground. Treat him at firft with the vinegar and cooling reftringents; but if a large fwelling with puffynefs enfues, foment it well with the difcutient fomentation till it difperfes; and then bathe the part with any of the above medicines.

A lamenefs in the whirle bone and hip, is difcovered by the horfe's dragging his leg after him, and dropping backward on his heel when he trots. If the mufcles of the hip are only injured, this kind of lamenefs is cured eafily; but when the ligaments of the joint are affected, the cure if often very difficult, tedious, and uncertain. In either cafe, at firft bathe the parts well with the cooling medicines, four or five times a day; in the mufcular ftrain, this method alone may fucceed, but in the ligamentous, it is reft and time only can reftore the injured parts to their proper tone.

Strains in the hock are to be treated by foaking the parts with coolers and repellers; but when the ligaments are hurt, and they are attended with great weaknefs and pain, ufe the fomentation. If a hardnefs fhould remain on the outfide, it may be removed by repeated bliftering; if within, it may be out of the power of any external applications to remove; however the joint fhould be fired gently with fmall razes or lines pretty clofe together, and then covered with a mercurial plaifter. To the difcutient fomentation above mentioned may be added crude fal armoniac, with a handful of wood-afhes boiled in it.

The bliftering ointment for the above purpofes may be found under the article SPAVIN; but the fublimate fhould be omitted.

The firing ufed for the ftrengthening relaxed finews or tendons, fhould act only on the fkin, which by contracting and hardening it all round the finews, compreffes them more firmly like a bandage. *See the article* FIRING. *Bartlet's Farriery, pag.* 224.

STRANGLES,

STRANGLES, a diftemper to which colts and young horfes are very fubject; and begins with a fwelling between the jaw-bones, which fometimes extends to the mufcles of the tongue; and is attended with fo great heat, pain, and inflammation, that fometimes till matter is formed, the horfe fwallows with the utmoft difficulty.

The fymptoms are extraordinary heat and feverifhnefs, with a painful cough, and a great inclination to drink without being able; fome horfes lofing their appetite intirely, others eating but little, by reafon of the pain which chewing and fwallowing occafions: when the fwelling begins on the infide of the jaw-bones, it is much longer in coming to matter than when more to the middle; when it arifes among the glands, and divides into feveral tumours, the cure is generally tedious, as it breaks in different places; and when it forms upwards on the wind-pipe and gullet, there is fometimes danger of fuffocation, unlefs the fwelling foon breaks. But the moft dangerous kind is, when, befides the above fymptoms, the horfe runs at the nofe; this by fome is called the baftard ftrangles.

As this diforder feems to be critical, the moft approved method is to affift nature in bringing the fwellings to maturity, by keeping them conftantly moift with ointment of marfhmallows, and covering the head and neck with a warm hood. But as all fwellings in glandular parts fuppurate flowly, the following poultice may be applied hot twice a day: it is alfo a very proper one to ripen, or bring any other fwelling to matter.

> Take leaves of marfhmallows ten handfuls; white lilly-root half a pound; linfeed and fenugreek feed bruifed, of each four ounces: boil them in two quarts of water till the whole is pulpy, and add four ounces of ointment of marfhmallows, and a fufficient quantity of hogs-lard, to prevent its growing ftiff and dry.

In five or fix days, by thefe means, the matter is generally formed, and makes its way through the fkin; and if the difcharge is made freely and with eafe, the opening need not be inlarged; but fhould be dreffed with the following ointment fpread on tow, ftill continuing the poultice over it to promote the digeftion, and prevent any remaining hardnefs.

> Take rofin and Burgundy pitch, of each a pound and a half; honey and common turpentine, each eight ounces; yellow wax four ounces: hogs-lard one pound; verdigreafe finely powdered one ounce: melt the ingredients together, but do not put in the verdigreafe, till removed from the fire; and it fhould be ftirred in by degrees, till the whole is grown ftiff and cool.

If the fever and inflammation run high, and the fwelling be fo fituated as to endanger fuffocation, a moderate quantity of blood muft be taken away, and the remainder diluted with plenty of water gruel, or warm water, mafhes, &c.

The running at the nofe, which often attends the ftrangles, is dangerous; efpecially if it continues after they have ripened and broke, as the horfe will be greatly weakened thereby. To prevent this wafte and decay, give him every day for fome time an ounce of Jefuits bark; or a ftrong decoction of guaiacum fhavings, which hath been found extreamly beneficial in reftraining thefe glandular difcharges when too liberal, and in drying up ulcers of all kinds in horfes. *See the article* GLANDERS.

If a hardnefs remains after the fores are healed up, they may be anointed with the mercurial ointment; and when the horfe has recovered his ftrength, purging will be neceffary.

STRANGURY, a difeafe incident to cattle, confifting in a difficulty of making urine, attended with great pain. *See the article* KIDNEY.

STRAW, the ftalk on which corn grows, and from which it is thrafhed. *See the articles* DUNG *and* RICK.

STRAWBERRY, the name of a well-known plant, cultivated in gardens for its fruit.

Strawberries may be raifed from feeds; for by that means it is that we have obtained the fcarlet ftrawberry, which is a native of Virginia; the hautboy, originally an American plant; and the Chili ftrawberry, which was firft brought into Europe by M. Frezier, a French engineer: but the common, and moft expeditious way of propagating them is from their runners, which eafily take root at their joints, and there form plants, which, in two or three months, are fit to be cut off and tranfplanted. Thofe which root earlieft in the fpring, and neareft to the mother plant, are the fitteft for this purpofe: and the beft time for removing them is in October, that they may get new roots before the hard froft fets in. They fhould never be taken from old neglected beds, where the plants have been fuffered to run into a multitude of fuckers, nor from any but the moft fruitful plants.

The ground in which they are planted muft be well dug, and very carefully cleared of weeds; and when it is levelled, it fhould be marked out into beds three feet and an half, or at moft four feet wide, leaving a path way of two feet, or two feet and an half broad between them. Thefe paths are neceffary for the convenience of gathering the fruit, for weeding and dreffing of the beds, and, which is of effential confequence to plants that remain fo long in the ground as thefe do, to be frequently dug up, in order to lay fine frefh earth to the roots of the plants. Of the wood ftrawberry, which is a native of this ifland, but of the fmalleft growth of any, though greatly improved, both as to fize and flavour, by culture in the garden, four rows may be planted, in a quincunx order, at about eight inches from each other in the rows, and a foot diftance from row to row, in the beds that are four feet wide: but three rows in a bed three feet wide will do much better, becaufe thefe will be more benefited by the digging of the alleys. The fcarlet ftrawberry muft be planted at a foot diftance every way, and the hautboy at fixteen inches. The Chili ftrawberry, which is the largeft of all, muft be fet at about two feet diftant from plant to plant. This laft is found to fucceed beft under the fhade of trees, in a very ftrong brick earth, approaching nearly to clay: but it feldom perfects its fruit here, fo as to anfwer the trouble of cultivation. In Chili, where it grows wild, the fruit of the larger fort (for there are two kinds, but neither of them fit for the open air in this country) is as big as a wall-nut, but not fo well tafted as our own ftrawberries.

If the winter prove fevere, fome old tanner's bark, or if that cannot be eafily procured, faw-duft, fea coal afhes, or decayed leaves of trees, fhould be fpread over the furface of the bed, between the plants, to keep out the froft. This care is abfolutely neceffary to the Chili ftrawberry, which is frequently killed in hard winters.

In the fpring, after the danger of hard froft is over, the ground between the plants in the beds fhould be forked with a narrow three pronged fork, to loofen it and break the clods: and if the tan, or other covering, which was laid on in the autumn, is then mixed with and buried in the earth, it will be of fervice to the plants, efpecially in ftrong land. A covering of mofs fpread over the beds about the latter end of March, or the beginning of April, will not only keep the ground moift, by preventing the drying winds of the fpring from penetrating it, and thereby contribute greatly to fecure a good crop of fruit; but it will alfo preferve the fruit clean from that grit which is often thrown up by heavy rains after it is full grown, to the great detriment of its flavour, becaufe it muft then be wafhed before it can be eaten. When the plants begin to flower, they muft be watered very plentifully if the feafon is dry, and great care muft be taken to keep them clear from weeds. At Michaelmas, the beds fhould be forked again, the weeding fhould be repeated carefully, the alleys fhould be dug, and the weeds buried in them, all the ftrings or runners muft be taken from the roots, and the plants fhould be thinned, by pulling up the weakeft, wherever they ftand too clofe together. The throwing of a little fine earth over them, at that time, will alfo greatly ftrengthen their roots.

As thefe beds feldom continue good above three years, in the common way of managing them (though Mr. Miller, with greater care and judgment than is ufually exerted, has made them remain in perfection four or five years), and as they yield but little fruit the firft year; it is neceffary to new plant fome frefh ground every third year. When this is done, the old beds may be deftroyed, and the ground converted to fome other ufe, after the new ones

ones have had one year's growth. But that ſtrawberry beds may be made to yield good crops even for ſome years longer than the abovementioned uſual term of their duration, is perhaps more than probable, if they are cultivated according to the principles of what is called the new huſbandry.

The indefatigable M. de Chateauvieux, among his numerous and judicious trials of that huſbandry, upon different plants, applied it to ſtrawberries, of which he planted ſeveral beds of well and deeply looſened earth, ſix feet wide, with ſingle rows. The vigour of the plants, the largeneſs of their leaves, and the very great number of their roots, though cultivated only by ſtirring of the ground with the horſe-hoe, without the leaſt help of dung, manure of any kind, or watering even in the drieſt weather, gave him room to expect, before the firſt ſummer was over, that their fruit would be very large and plentiful the next year: nor was he diſappointed; for in 1754, which was their ſecond year, his ſtrawberries were admirable, extremely large, finely ſcented, and of a very high flavour. He continued the ſame method in 1755 and 1756, and with the ſame ſucceſs as before. In ſhort, though the year 1755 was ſo extremely hot and dry, that no watering could well ſuffice to keep alive the plants that were managed in the common way; theſe remained conſtantly green, and in great vigour, and their fruit was, in every reſpect, finer than that on which the utmoſt care was beſtowed in his kitchen garden.

An ingenious writer in the Muſeum Ruſticum has obliged the world with the following method of cultivating ſtrawberries.

" I have them, ſays he, of ſeveral kinds; and the fruit, in the ſeaſon, is in great perfection, being large, and poſſeſſing a fine flavour. Theſe I procure with no great trouble or difficulty in the cultivation.

" I plant them in regular rows on beds three feet wide. The ſoil I chuſe for them is a good, natural, freſh, rich loam: the leſs it requires of manure the better, the fruit being the ſweeter and finer.

" On each of theſe beds above mentioned, I plant three rows of plants, in quincunx order, at fifteen inches diſtance every way; and I rather chuſe to plant them each on a little hillock, as it were, ſomething in imitation of hops.

" Between the beds are intervals of the ſame width.

" My next care is, by frequent hoeing, to keep my plants as clear from weeds as poſſible, by which they are ſure to be ſupplied with plenty of nouriſhment; a matter of great conſequence, particularly when the fruit is ſet, as then they require moſt, and the weeds are alſo at that ſeaſon moſt luxuriant: I therefore then ſtir the earth with the hoe often, which anſwers, as I ſaid before, a double purpoſe.

" I obſerve to keep my plants as clear as poſſible from runners; by which means my fruit is larger, and ſooner ripe, than it would otherwiſe be.

" When my ſtrawberry plants have borne fruit two ſucceſſive years on the beds, I get the alleys, or intervals, dug up and prepared, into which I tranſplant them in the ſame manner they were planted in the firſt-mentioned beds, which then become in their turn the intervals.

" Here they remain two years more, when I again remove them into freſh land prepared for the purpoſe, in this manner never letting them bear fruit more than two years in one ſpot.

" I cannot eaſily deſcribe to you the great benefit this method of management is of to the plants, which are thereby greatly invigorated, and the fruit prodigiouſly improved, both in point of ſize and flavour, inſomuch that they appear to be quite of a different nature from thoſe of my neighbours, who firſt furniſhed me with the plants."

STRAWBERRY-TREFOIL. *See the article* TREFOIL.

STRICKLE, the whet-ſtone placed upon the extremity of the ſhaft of a ſcythe.

STRIKE, a buſhel, or four pecks of corn.

STRINGHALT, a diſeaſe in horſes, conſiſting in a twitching and ſnatching up of the hinder leg much higher than the other.

STUBBLE, the ſtalks of corn left in the field by the reaper.

It has been a diſpute among farmers, whether wheat-ſtubble ſhould or ſhould not be ploughed in. We ſhall therefore give the following remarks of a ſenſible vale-farmer on this ſubject.

" We are far from being advocates, ſays he, for plowing in ſtubble; yet our land is not light, but the contrary, and bears as good crops of wheat as any in the kingdom.

" As our ſoil is not light, it agrees very well with horſe-beans, which we frequently ſow after wheat; but if ever we let the ſtubble remain uncut till bean-ſeaſon, and plow it in, the conſequences are ſurely fatal; it cauſes the earth to lie hollow; the bean plants to fall down; the ſun and air get at the roots, and prevent the plant thriving; and the crop is always very greatly leſſened: beſides, the ſtubble, which with us is very ſtrong, clogs the plow-ſhare, and gathers up in clods, which are a ſure and a fatal ſhelter for many noxious inſects.

" Theſe facts, which every vale-farmer is well acquainted with, induce us always to mow our ſtubbles, which we apply to many and various uſes: if it is long, it ſerves very well for thatching: we litter our yards, ſtables, and cow-houſes with it for making dung; we uſe it for drying malt; and a great deal is burnt by the poor cottagers, for warming themſelves in winter, dreſſing their victuals, baking, brewing, *&c.*" *Muſeum Ruſticum, vol.* III. *p.* 295.

STUM, the unfermented juice of the grape, after it has been ſeveral times racked off, and ſeparated from its ſediment.

STUMP, the part of any ſolid body, particularly of trees, &c. remaining after the reſt are taken away.

A bare view of Fig. 6. Plate XXIV. is ſufficient to explain a very ſimple engine which Mr. Evelyn gives, for pulling up large roots.

The handle *A* turns the ſpindle of the pinion *B*, which has four or five teeth. Theſe teeth turn the larger wheel *C*, which moves the cylinder D, on which the rope *E* is rolled as the root is drawn up; one end of the rope being previouſly faſtened to the cylinder. The whole frame is let into a block of wood *F*, about four feet high and one in breadth; and the other end of the roller or cylinder is ſuſtained by a leſſer block of wood *G*. *H* is an iron plate which holds the wheel and pinion in the larger block. The cylinder, wheel, pinion, and handle of this machine ſhould be made of good tough iron. The cylinder may be about four inches in diameter, and fourteen or ſixteen inches in length. The reſt is obvious: though I apprehend an improvement might be made, by adding a catch, to ſecure either the handle or the cylinder, while the labourer (for one man will eaſily manage this engine) may be obliged to ſuſpend his work, in order to clear away any obſtacle that may have occurred. It would likewiſe certainty be right to place the wheels, and conſequently the handle, ſomewhat higher than is here directed, to ſave the very great fatigue of ſtooping down continually while this laſt is turned.

Where the roots are very large, and obſtinately tenacious, M. de Turbilly's advice, to blow them up with gunpowder, will be found very beneficial; eſpecially if neither of the abovementioned inſtruments can be had.

Where a place has been over-grown with wood, the earth is ſo thoroughly ſtirred by digging and pulling up the ſtumps and roots of the trees, that one plowing in autumn is generally ſufficient. The froſts in winter kill the weeds and break the clods; and after a ſecond plowing, in the ſpring, theſe lands may be ſown with expectation of an abundant crop: for the trees not having exhauſted the earth towards the ſurface, but having on the contrary manured it with their leaves, a conſiderable produce may be expected for many years.

M. Du Hamel mentions a ſmall field, which had formerly been underwood, and being converted into arable ground, produced plentiful crops of wheat and oats for upwards of twenty years running, without being reſted. It is true the ſoil was peculiarly proper for wheat, and would have been exhauſted much ſooner if it had been a poorer earth.

STUMPY, full of ſtumps; hard, ſtiff.

STURK, a young bullock; a heifer.

STY, a cabbin, or ſmall building to keep hogs in.

SUCCORY. *See the article* ENDIVE.

SUCCULENT, juicy, moiſt.

SUCKER,

SUCKER, a young twig, or shoot from the root.

SUFFOLK-GRASS, the same with meadow-grass, or poa. *See* POA.

SUILLAGE, a drain of filth.

SULL, a plough. *See the article* PLOUGH.

SULL-PADDLE, a plough paddle.

SUMMER, the season in which the sun arrives at the northern solstice, and the days are at the greatest length.

SUMMER, also implies the large piece of timber, or principal beam of a floor.

To SUMMER-LAND, or *To* SUMMER-STIR, to fallow land in the summer.

SUN-FLOWER, the name of a well-known flower, much cultivated in large gardens.

The sun-flower is an annual plant, and the seeds should be sown every spring in a bed of good light earth. When the shoots are about three inches high they should be transplanted into nursery beds, and set at eight inches distance every way; they should remain there till they are a foot high, and then be carefully taken up with a ball of earth at their roots, and planted in large borders, or intermixed with flowering shrubs, and other large plants; they must be frequently watered till they have taken root, after which they require no other care. The flowers appear in July, and stand a considerable time: the largest of them should be preserved for seed. The birds are very fond of the seed of the sun-flower, and must therefore be carefully guarded from them, and the head left on the plant till October, at which time it should be cut off, and hung up to dry in an airy place, and in a month more the seeds will be perfectly hardened. *Miller's Gard. Dict.*

SUN-SCORCHED, a term used in some parts of England to express a distemperature of fruit-trees, owing to the sun's affecting them too forcibly on a sudden; the consequence of which is the loss and withering of the fruit. Such trees only are subject to this, as are planted in places sheltered from the spring sun, and open to that of the summer; and may be always cured by proper waterings.

SURBATING, a term used by farriers to signify the sole of a horse's foot being worn, bruised, or spoiled by beating the hoof against the ground in travelling without shoes, or going in hot sandy lands, or with a shoe that hurts the sole, or the like. It also sometimes happens by over-riding a horse while young, before his feet are sufficiently hardened, or even by the hardness of the ground, and high lifting of his feet. The signs of this defect are his halting on both fore-legs, going stiffly, and creeping as if foundered.

There is nothing better for surbated feet than tar melted into the foot, or vinegar boiled with soot to a proper consistence and poured into the foot boiling hot, with hurds over it, and splints to keep it in.

SURFEIT, a disease incident to horses and other cattle.

Surfeits arise from various causes; but are commonly the effects of some diseases not attended to, or that have been ill cured.

A horse is said to be surfeited, when his coat stares, and looks rusty and dirty, though proper means has not been wanting to keep him clean. The skin is full of scales and dander, that lays thick and mealy among the hair, and is constantly supplied with a fresh succession of the same, for want of due transpiration. Some horses have hurdles of various sizes like peas or tares: some have dry fixed scabs all over their limbs and bodies; others a moisture attended with heat and inflammation; the humours being so sharp, and violently itching, that the horses rub so incessantly, as to make themselves raw. Some have no eruptions at all, but an unwholesome look, and are dull, sluggish, and lazy: some appear only lean and hide-bound: others have flying pains and lameness, resembling a rheumatism: so that in the surfeits of horses, we have almost all the different species of the scurvy, and other chronical distempers.

The following method is usually attended with success in the dry species. First take away about three or four pounds of blood; and then give the following mild purge, which will work as an alterative, and should be repeated once a week, or ten days for some time.

> Take Succotrine aloes six drams, or one ounce; gum guaiacum half an ounce; diaphoretic antimony, and powder of myrrh, of each two drams: make into a ball with syrup of buckthorn.

In the intermediate days, an ounce of the following powder, should be given morning and evening in his feeds.

> Take native cinnabar, or cinnabar of antimony, finely powdered, half a pound; crude antimony, in fine powder, four ounces; gum guaiacum, also in powder, four ounces: make into sixteen doses for eight days.

This medicine must be repeated till the horse coats well, and all the symptoms of surfeit disappear. If the horse is of small value, two or three common purges should be given, and half an ounce of antimony, with the same quantity of sulphur, twice a day, or the alterative balls with camphor and nitre, as directed in the preceding chapter.

If the little scabs on the skin do not peel off, anoint them with the mercurial ointment; during the time of using which, it will be proper to keep the horse dry, and to give him warm water. This ointment properly rubbed into the blood, with the assistance of purging physick, has frequently cured these kind of surfeits, without any other assistance.

The wet surfeit, which is no more than a moist running scurvy, appears on different parts of the body of a horse, attended sometimes with great heat and inflammation; the neck oftentimes swells so in one night's time, that great quantities of a hot briny humour issues forth, which, if not allayed, will be apt to collect on the poll or withers, and produce the poll-evil or fistula. This disease also frequently attacks the limbs, where it proves obstinate, and hard to cure: and in some horses shews itself spring and fall.

In this case bleed plentifully, avoid externally all repellers, and give cooling physic twice a week; as, four ounces of lenitive electuary, with the same quantity of cream of tartar; or the latter, with four ounces of Glauber salts, quickened, if thought proper, with two or three drams of powder of jallap, dissolved in water-gruel, and given in a morning fasting.

After three or four of these purges, two ounces of nitre made into a ball with honey, may be given every morning for a fortnight; and, if attended with success, repeated for a fortnight longer.

The powders above-mentioned may also be given with the horse's corn; or a strong decoction of guaiacum shavings, or logwood may be given alone to the quantity of two quarts a day. These, and indeed all alterative medicines, must be continued for a long time, where the disorder proves obstinate.

The diet should be cool and opening, as scalded bran or barley; and if the horse is hide-bound, an ounce of fenugreek seeds should be given in his feeds for a month or longer; and, as this disorder often proceeds from worms, give the mercurial physic too, and afterwards the cinnabar powders, as above directed; but as in general it is not an original disease, but a symptom only of many, in the cure, regard must be had to the first cause: thus as it is an attendant on surfeits, fevers, worms, &c. the removal of this complaint must be variously effected.

In a mangy horse the skin is generally tawny, thick, and full of wrinkles, especially about the mane; the loins and tail, and the little hair that remains in those parts stands almost always strait out or bristly: the ears are commonly naked and without hair, the eye and eyebrows the same; and when it affects the lymbs, it gives them the same aspect; yet the skin is not raw, nor peels off, as in the hot inflamed surfeit.

Where this distemper is caught by infection, if taken in time it is very easily cured: and I would recommend a sulphur ointment as most effectual for that purpose, rubbed in every day. To purify and cleanse the blood, give antimony and sulphur for some weeks after. There are a great variety of external remedies for this purpose, such as train oil and gun-powder, tobacco steeped in chamber-lye, &c. Solleysell recommends the following.

Take burnt alom and borax in fine powder, of each two ounces; white vitriol and verdigreafe powdered, of each four ounces; put them into a clean pot, with two pounds of honey, ftirring till they are incorporated; when cold, add two ounces of ftrong aqua fortis.

But when this diforder is contracted by low feeding, and poverty of blood, the diet muft be mended, and the horfe properly indulged with hay and corn. The following ointments are effectually ufed for this diforder, rubbed into the parts affected every day.

Take powdered brimftone, train oil, and tar, of each equal quantities; to which may be added ginger, or white hellebore.

Or,

Take fulphur vivum, half a pound, crude fal armoniac one ounce, hogs lard, or oil, a fufficient quantity to form into an ointment.

Or,

Take quickfilver, and oil of vitriol, of each one ounce; hogs lard, one pound, fulphur vivum four ounces, oil of turpentine one ounce and half.

Thefe are both very powerful remedies for this diforder, and can fcarce fail of fuccefs.

To the two firft, occafionally, may be added a third part of mercurial ointment; but as fulphur is in general allowed, to be the fpecific in the itch; and being found both more fafe, and efficacious than mercury; fo we apprehend it will fufficiently anfwer the purpofe here; for as this diforder feems beft accounted for by Leuwenhoek, from certain fmall infects he difcovered in the puftules, by the microfcope; fo it feems as if they were deftroyed, by the fteams of brimftone, though only raifed by the heat of the body; for in the human body, the itch may be cured by partial fulphurous unctions, on the legs only; but where the mange proves obftinate in horfes, let the parts be wafhed with fublimate water before the application of the ointment, and fubjoin the internal ufe of fulphur, in order to diffufe the fteams more certainly through the fkin; there being reafon to believe, as in the itch, that the animalcula may fometimes lie too deep, to be thoroughly deftroyed by external applications only.

SURVEYING, the art or act of meafuring lands; that is, of taking the dimenfions of any field, parcel, or tract of land, laying down the fame in a map or draught, and finding the content or area thereof.

As this art is of the utmoft importance to all owners and occupiers of land, we fhall endeavour to explain it in the eafieft and moft intelligent manner. And in order to this we fhall begin with the principles of the art, and proceed gradually to fhew how all the ordinary figures may be meafured, protracted, and caft up, with no other inftruments than chains, compaffes and fcales. We fhall afterwards endeavour to explain, in a very eafy and concife manner, the ufe of the plain table, and other inftruments ufed in furveying; fo that any perfon, of a common capacity, and that underftands the four firft rules of arithmetic, may be able to furvey and parcel out land, plat it, and give up its content with eafe and expedition.

Of geometrical definitions, divifions, and remarks.

I. A point is that which hath no parts, either of longitude or latitude, but is indivifible, ordinarily expreffed with a fmall prick, like a period at the end of a fentence.

II. A line hath length, but no breadth nor depth, whofe limits or extremities are points. This is either right or crooked.

III. A right line lies ftreight, and equal between its extream points, being the fhorteft extenfion between them; the crooked or circular not fo.

IV. A fuperficies hath length and breadth, but no depth; of this, lines are the limits.

V. A plain fuperficies in that which lieth equally (or evenly) between its lines.

VI. An angle is the meeting of two lines in one point, fo as not to make one ftreight line; and if drawn beyond that point, they will interfect or crofs one another. This in vulgar Englifh may be called a corner; of which there be two forts, one right, the other oblique.

VII. A right angle is that which is made by two right lines, croffing or touching one another perpendicularly, (or fquarely) like an ordinary crofs, or carpenter's fquare.

VIII. An oblique angle is that which is either greater or lefs than a right angle; and this is of two forts, obtufe and acute.

IX. An obtufe angle is greater than a right angle, like the left and right corners of a Roman X.

X. An acute angle is lefs than a right angle, like the higheft and loweft corners of the fame letter.

XI. A figure is that which is comprehended under one line or many; of this there are two kinds, a circle, and a right-lined figure.

XII. A circle is a perfect round figure, fuch as is drawn with a pair of compaffes, the one foot being turned round in a point, and the other wheeled about it. The point in the precife middle is called the center; the round line, the circumference or peripheri; a line going thro' the center, and divides the circle into two equal parts, is called the diameter; half of that line is a femi-diameter, or radius; half the circle is ftiled a femi-circle; the quarter, a quadrant; any portion of it, cut off by a right line not touching the center, is called a fegment.

XIII. Right-lined figures are fuch as are limited by three right lines, or more, and are either triangles or triangulate, that is, fuch as are compounded of, and refolvable into triangles.

XIV. Triangles are figures comprehended under three right lines, and (as Ramus thinks that for a reafon he gives, lib. 6. pr. 6.) might be better called trilaterals; but the name triangle from the number of the angles hath obtained.

Alfo from the nature and quantity of their angles, thefe triangles are diftinguifhed into three forts, 1. Rect-angled, having one right angle. 2. Obtufe-angled, having one obtufe angle. And 3. Acute-angled, having all acute angles; for no triangle can have more right or obtufe angles than one, becaufe by a well known old rule, no triangle upon a plain fuperficies can confift of three greater angles than fuch, as being jointly taken are equal to two right.

Thefe three forts of triangles may, according to the length and proportion of their fides, be fub-diftinguifhed into feven; for each of them may have either two equal fides or none; and the acute-angled may have all three fides or lines equal: but be triangles of what name or kind foever, they are all capable of being exactly meafured by one plain rule, as hereafter fhall fully appear.

XV. Triangulate figures are fuch as have more angles, and confequently more fides or lines, than three; and thefe are either quadrangular or multangular.

XVI. Quadrangular figures are fuch as have four angles, and as many fides, and thefe are either parallellograms or trapefias.

XVII. Parallellograms are figures that are bounded with parallel lines, that is, fuch lines as are every where of the fame diftance one from another, fo as if they were infinitely extended, they would never meet, like the upright lines of the Roman H. Thefe parallellograms are either rectangular or obliquangular.

XVIII. Rect-angular parallellograms are fuch as have four right angles, viz. the fquare or quadrat, and the long fquare, otherwife called the oblong.

XIX. The fquare is that figure that hath four right angles, and four equal fides, like any of the fix faces of a die.

XX. The long fquare hath alfo four right angles, and the oppofite fides are equal, but the adjoining fides meeting at each angle, differ in length. Of this figure is a well printed page in a book, and the fuperficies of a well cut fheet of paper, or an ordinary pane of glafs.

XXI. Obliquangled parallellograms are fuch as have oblique angles, viz. two acute, and two obtufe. Of thefe there are two kinds, the rhombus, and the rhomboides.

XXII. The rhombus is a figure that hath equal fides, but no right angles, like the form of a diamond on the cards, or the moft ordinary cut of glafs in windows, whofe oppofite angles are equal.

XXIII. The rhomboides is a defective rhombus; for if from any fide of a rhombus we cut off a part with a parallel line,

Fig. 38.

line, the remainder will be a rhomboides, which hath neither equal ſides nor angles, but yet the oppoſite ſides and angles are equal.

XXIV. The trapezium is a figure that is neither parallellogram, nor, conſequently, hath equal ſides or angles, but is irregularly quadrangular, as if drawn at adventure. Of this ſhape moſt fields prove, that ſeem to the eye to be ſquares or oblongs.

XXV. Multangular figures are ſuch as contain more ſides and angles than four, and they are either regular or irregular.

XXVI. Regular multangulars take their names from their number of angles, ſo a pentagon, hexagon, heptagon, octagon, eucagon, decagon, ſignify multangular figures of five, ſix, ſeven, eight, nine, ten angles, and conſequently ſides.

XXVII. An irregular polygon, or multangular figure, is that which hath more angles, and ſides than four, the ſides, and angles, being unequal to one another.

Of geometrical problems.

I. *To draw a line parallel to another, at any diſtance aſſigned.*

Plate XXV. Fig. 1. Open your compaſſes to the diſtance given, and chuſing two points conveniently diſtant in the line given, as here at A and B, deſcribe the arches C and D, to whoſe convexity, if you apply a rule, the parallel line is eaſily drawn.

II. *To raiſe a perpendicular upon a line given, or to croſs that line at right angles in a point aſſigned.*

Fig. 2. Suppoſe the point C in the line A B were aſſigned for the perpendicular, open the compaſſes to a convenient diſtance, and mark out the two points E and F in the line A B, then opening them ſomewhat wider, you may, by ſetting one foot in E and F ſeverally, deſcribe the two arches cutting one another at the point D, from which, if you draw a line to the point C, the work is done for the raiſing of a perpendicular; but if you be to croſs the lines at right angles, you may continue the line from D thro' C at pleaſure.

But if the ſaid line A B had been given to be divided in the preciſe middle, by another line croſſing it at right angles, the way is to ſet one point of the compaſſes in A and B ſeverally, and having deſcribed two arches above the line, interſecting one another as at D, do the like below the line A B from the ſame points, and with the ſame extent of your compaſſes, then through the ſeveral interſections, a rule being laid upon them, a line may be drawn, cutting the given line exactly in the middle at right angles.

Note, That when one point of your compaſſes ſtand in A, you may make both the arches belonging to that center above and below the line; and then removing the compaſſes to B, you may croſs them both.

III. *To raiſe a perpendicular at the end of a line.*

Fig. 3. Let O R be the line given, then to raiſe a perpendicular at R, make five little equal diviſions, and taking four of them with your compaſſes, ſet one foot of your compaſſes in R, and with the other deſcribe the arch P P; then take the diſtance from R to 5, and placing one foot in 3, with the other deſcribe the arch B B, interſecting the former in the point S; then ſhall the line S R (being drawn by a ſtrait rule) be a perpendicular to the line O R.

IV. *To let fall a perpendicular upon a given line from any point aſſigned.*

Open your compaſſes ſo as one foot being ſet in the aſſigned point, the other may go clear over the line given, and thereby deſcribe an arch cutting the line at two points; then ſhall the half diſtance between thoſe two points be the point to which the perpendicular may be drawn from the point aſſigned. But if you think it too much pains to find the point of half diſtance by trial, you may help yourſelf by the ſecond problem: for if you deſcribe two arches interſecting one another on the farther ſide of the line from the aſſigned point, placing (to that purpoſe) the foot of your compaſſes firſt in one of the interſections of the given line, and then in the other; you may by laying a rule upon the aſſigned point, and the interſection of the two arches, draw a perpendicular from the ſaid aſſigned point, cutting the given line at right angles.

N. B. All theſe problems with regard to perpendiculars, aim at no greater matter, than what may be performed in a mechanical way with exactneſs enough by the help of a ſmall ſquare exactly made, for if you apply one leg of ſuch a ſquare to any line, ſo as the angle of the ſquare may touch the end of the ſaid line, or any other point where the perpendicular is to be raiſed, you may by the other leg draw the perpendicular. In the like manner to let fall a perpendicular from a point aſſigned, you need only to apply one leg of the ſquare to the line, ſo as the other may touch, at the ſame time, the aſſigned point, whence you may draw the perpendicular by that leg that toucheth the point.

If the angle of your ſquare be a little blunt, either thro' ill making or long uſing, you muſt allow for it when you apply it to the point in a line. And when you are drawing a perpendicular, you muſt ſtop before you reach the given line, and then by applying the leg of your ſquare to that part of the perpendicular already drawn, ſo as part of that leg may paſs clearly over the given line, you may draw the reſt of your perpendicular as exactly as if the angle had been true. The ſame method is to be taken when a line is to be croſſed by another drawn quite through it at right angles.

V. *An angle being given, to make another equal to it.*

Fig. 4. The angle X A D being given, and a line drawn at pleaſure, as is the loweſt from the point E, open your compaſſes to any convenient diſtance, and ſetting one foot in A, deſcribe the arch B C. Then with the ſame extent ſetting one foot in E, with the other deſcribe the arch C H, long enough to equal or exceed the other. Then taking the diſtance B C between the points of your compaſſes, ſet one in C, and with the other mark the point H in the arch C H, through which point H a line being drawn from the point E, will make an angle with the line E C, equal to the angle given.

Note, When we ſpeak of the quantity of angles, their equality or unequality, we never regard the length of the lines; for if you extend or contract them at pleaſure, the angle is ſtill the ſame. But that is the greateſt angle whoſe lines are fartheſt diſtant from one another at the ſame diſtance from the angular point, or the place where its lines meet.

VI. *Any three lines being given, (equal or unequal) ſo as no one of them be longer than the other two joined together, to make a triangle of them.*

Fig. 5. The lines A B C being given, ſet the line A from D to E; then with your compaſſes take the length of the line B, and ſetting one foot in D, deſcribe the arch P O. This being done, take with your compaſſes the length of the line C, and ſetting one foot in E, with the other croſs the former arch at F, from which interſection drawing lines by a rule to D and E, the triangle is finiſhed.

Note, That if all the ſides, or two of them, be equal, the method is the ſame; but the labour leſs, becauſe we need not to take the ſame length twice over with the compaſſes.

VII. *To find the perpendicular of the triangle, in order to the meaſuring of it.*

Fig. 6. Let the line A B be accounted the baſe, and from the angle C, let fall a perpendicular as was taught Probl. 4. upon that line at D, which is ready for taking off with compaſſes, and meaſuring on a ſcale, of which hereafter in meaſuring the content of figures.

But if we have no occaſion to draw the perpendicular, but only to know the length of it, (as it moſt frequently falls out in meaſuring) no more is needful, but to ſet one foot of the compaſſes in the angular point C, and extend the other to the baſe A B, ſo as it may touch it, but not go beyond it; then have we the perpendicular between the points of the compaſſes.

VIII. *One ſide being given, to make a ſquare.*

Fig. 7. The line C D being given, raiſe a perpendicular at C of the length, at the leaſt, of the given line; then taking the line C D between the feet of your compaſſes, ſet it upon the perpendicular from the angular point C to A: with the ſame diſtance ſetting one foot in D, deſcribe the arch O P. Laſtly, with the ſame diſtance, or extent, ſet one foot in A, and with the other deſcribe the arch,

 croſſing

croffing the arch O P in N, from which interfection a line drawn by a rule to A, and another to D, finifh the geometrical fquare or quadrant A C D N.

IX. *To make a long fquare, the length and breadth being given.*

This is fo nearly like the former, that a particular figure is not neceffary to explain it. Suppofe each fide of the fquare in the laft problem to confift of 8 fmall equal parts, and you were to make a long fquare, whofe length muft be equal to a fide thereof, viz. 8, and the breadth half fo much: when you had drawn the line C D, for the length, and raifed the perpendicular at C, you muft take the fhorter line given for the breadth, and fet upon the perpendicular from C, upwards to a point, which for diftinction we fhall call the point E, imagining it fo marked: with the fame extent of the compaffes defcribe the arch, placing one foot in D. Laftly, extending your compaffes to the length of the line C D, fet one foot in E, and with the other crofs the arch aforefaid. Then a right line drawn from that interfection to E, and another from the fame to D, compleat the long fquare.

X. *To make a rhombus, the fides being given.*

Fig. 8. If the angles be not limited, draw any oblique angle at pleafure, either acute or obtufe, as here the angle B A C, which is acute. Then let the line O P be the length of a fide, which being taken with your compaffes, fet it from the angular point A, in both lines to D and E, in which two points, place a foot of your compaffes fucceffively without altering them, viz. in D, to defcribe the arch F G, and in E to defcribe the arch H I, croffing one another in the point K, from which, right lines drawn to D and E, finifh the rhombus D A E K.

Note, If any angle be given together with the fide, to limit the fhape and content, begin with that, and proceed as before; for you muft know, that to make a rhombus (or rhomboides) like to another for figure, or equal to it in content, it is not fufficient to have the fame fides; for the more oblique the angles are, the farther will the rhombus differ from a fquare, and the lefs will be the content. But you muft have an angle given, or elfe a diagonal line, which is a right line paffing through the rhombus from one oppofite angle to another, and dividing the figure into two equal triangles. If the former, viz. an angle, be given, we have fhewed what ufe is to be made of it. If the latter, *i. e.* a diagonal, together with the length of the fides, you may, by taking the length of the fides with your compaffes, and fetting a foot in the ends of the diagonal line, make a triangle on the one fide of the diagonal, by Probl. 6. and then another on the other fide by the fame problem, the diagonal being a common bafe to them both; and this will give the figure exactly.

XI. *To make a rhomboides, the fides being given.*

Fig. 9. If neither angle nor diagonal be given, make any angle at adventure, as here A B C. Then fuppofing the lines given to be O P and Q R, fet the length of the longer upon the line B C, from B to D, and the fhorter on the line B A to E. Then with the compaffes extended from B to E, fet one foot in D, and defcribe the arch F G. Likewife, with the compaffes extended to the length of the line O P, fetting one foot in E, with the other defcribe the arch H I, interfecting the former arch at K; from which interfection lines drawn to D and E, finifh the rhomboides.

XII. *To make a trapezium, the diagonal and lines in order being given.*

Fig. 10. Let the line HL be the diagonal of a trapezium, whofe fides are the lines A B C D; the fide A being counted the firft, as that which takes it, being from the point H, and the reft in the order as they are marked alphabetically.

Then with your compaffes fet to the length of the line A, place one foot in H, and with the other defcribe the arch E F. Next taking the length of the line B, with the one foot of your compaffes placed in L, with the other make the arch G I, interfecting the former at K; from which point of interfection, lines drawn to H and L, make the triangle H K L.

Then with the extent of the line C, fet one of the feet of your compaffes at L, and defcribe the arch O P. Laftly, fetting them to the length of the line D, and placing one foot of your compaffes in H, with the other make the arch S R, interfecting the former at Q; fo fhall lines drawn from Q, to L and H, make up the triangle L Q H, and finifh the trapezium H K L Q.

I could have been much briefer in this problem, by referring to the 6th; but this being of very great and frequent ufe, I defired to be very plain.

XIII. *To make a regular polygon, otherwife called a regular multangular, or multilateral figure, confifting of many equal fides and angles, viz. above four apiece.*

Being fatisfied what fhall be the diftance between the center and every angle, with that diftance defcribe a circle, which being equally divided into as many parts as the figure muft have angles (or fides, for they are equal in number) and lines drawn from the points of divifion within the circle from point to point, (ordinarily called chords) the polygon is finifhed, as in this diagram.

Fig. 11. Suppofe an heptagon, or multangular figure of feven fides, and as many angles, be to be defcribed, every angle being defigned to be diftant from the center A, feven eighths, or three quarters and a half of an inch; with that diftance defcribe the circle B C D E F G H, which being divided into feven equal parts, and lines drawn from point to point, the heptagon B C D E F G H will be therein included.

We fhall rather leave our reader to find out the points of divifion by many trials, than to puzzle him with the geometrical way for finding out chords to that purpofe.

XIV. *Having the fides of the triangles whereof it confifteth, orderly given, to make an irregular multangular, or multilateral figure.*

This will be more fully handled hereafter, when I come to fhew the method of drawing plats of ground. In the interim I will give you a fpecimen of an irregular pentagon.

Fig. 12. Having the lines of three triangles given, lay down the greateft of the firft, viz. 20, from A to B for a bafe, and by Probl. 6, make a triangle of it, and the other lines 16 and 10, viz. the triangle A B O.

Secondly, You find by the number 20 over the firft line of the fecond triangle, that it is the common bafe to them both; and therefore, by the fame Probl. 6, make the triangle A B P of the lines 20, 14, 18.

Laftly, Finding the bafe of the third triangle to be the fame with 18, one of the fides of the fecond make the triangle P B Q of the lines 18, 11, 12: fo is the quinquangular figure finifhed.

How every line is to be found in its due order in this, or any other fort of multangular figures, fo as to give a true and exact account, not only of the fuperficial content, but alfo of the figure and fituation, is to be taught hereafter in the doctrine and practice of Protraction.

How to find the fuperficial content of any right-lined figure, the lines being given.

As a foundation to what we fhall lay upon this fubject, there are fome few geometrical principles or theorems out of Euclid and Ramus, which I defire may be remembered; and becaufe underftanding is a great help to memory, we fhall make ufe of a kind of ocular demonftration; which, though not fo ftrict and artificial as that which is to be found in the commentators upon Euclid in the quoted places, will be more ferviceable becaufe more eafily underftood.

Theor. 1. *Every parallelogram being of the fame length with the bafe of a triangle, and of the fame height with the perpendicular of that triangle, is double to it.* Euclid 41. 1.

Fig. 13. Here are two equal oblongs, or long fquares, A B C D and B E F C, and within them two triangles infcribed, whofe bafes are of the fame length, and their perpendiculars, O P and Q R, of the fame height with the oblongs. Now each of thefe triangles being parted into two right-angled triangles by their perpendiculars, then it is plain to the eye, and from the nature of diagonals, which ever divide a parallelogram into equal parts, that the two new

new triangles O P D and OPC, which make up the first of the given triangles, are equal to the triangles D A O and O B C, which make up the remainder of the parallellogram A B C D. Therefore that parallellogram is double to that triangle, which was to be demonstrated.

In like manner it is evident, that the parallellogram B E F C is double to the triangle C O F, because C R Q is equal to B Q C, and Q R F is equal to Q E F.

Theor. 2. *All triangles having the same base, and lying between the same parallels, are equal.* Euclid 37. 1.

So in our last diagram, the two given triangles having bases of the same length, and lying between the same parallels, are evidently equal, because they are demonstrated to contain each of them the exact half of the parallellograms, wherein they are inscribed; and the parallellograms being equal, their halves must be equal also.

Theor. 3. *The sides of the triangulate (that is, one that hath four or more sides) are ever two more than the triangles of which it is made.* Ram. lib. 10. prop. 2.

Fig. 10, 12. This is plain by inspection, if you view again the figures of the trapezium and irregular pentagon, in the 12th and 14th problems.

These theorems being allowed to be true the doctrine concerning the superficial content of right-lined figures, might be reduced to a narrow compass; for he that knoweth how to husband these three theorems, may easily take up these corollaries, *ordine inverso*.

1. Any quadrangular figure, regular or irregular, may by a diagonal be parted into two triangles; any five-sided figure by two diagonals into three triangles; and six-sided figures into four by three diagonals, &c. by Theor. 3.

2. It is no matter of what shape the triangle is, as to the rule for measuring, for whether it be right-angled, acute-angled, or obtuse-angled, and whether it have three, two, or no lines equal, it is only the length of the base, and height of the perpendicular, and is considerable by Theor. 2.

3. The true measure or content of any triangle, whether alone, or as part of any triangulate figure of 4, 5, 6, or more sides, (and consequently of the whole figure, by summing up the content of all the several triangles) is found by multiplying the whole base of the triangle by half the perpendicular, or the whole perpendicular by half the base; which being a rule of such infinite use in surveying, we desire it may be remembered; and that it may be understood, we shall give a plain example.

Fig. 6. Suppose A B the base of the triangle belonging to the 7th problem, to be 44, and the perpendicular C D to be 20: whether you multiply 44, the whole base by 10, the half of the perpendicular, or 20, the whole perpendicular by 22, the half base, the product gives the content 440, as is here apparent.

44	20
10	22
440	40
	40
	440

Having thus given a general method how all right-lined figures may be reduced to triangles, and so their content found, we might pass to the next head concerning instruments, and their use; but because there are nearer ways in measuring particular kinds of triangulate figures proper to those kinds, we shall briefly mention them.

I. *To find the contents of a square, or long square.*

Multiply the length by the breadth, the product gives the area or content.

Example of a square.

17 inches length.
17 inches breadth.

119
17

289 square inches.

Example of an oblong.

25 feet long.
13 feet broad.

75
25

325 square feet.

II. *To find the area or content in measure of a rhombus.*

Let fall a perpendicular from one of the obtuse angles upon the opposite side; that side multiplied by the perpendicular, gives the area.

20 yards the side.
14 yards the perpendicular.

80
20

280 square yards.

III. *To find the area of a rhomboides.*

Divide it into two triangles by a diagonal drawn between either pair of the opposite angles, then from either of the other angles let fall a perpendicular upon that diagonal; then shall that diagonal, being multiplied by that perpendicular, give the area.

Example.

19 rods the diagonal.
5 rods the perpendicular.

95 square rods the content.

IV. *To find the content of a trapezium.*

Fig. 10. Divide it by a diagonal into two parts from angle to angle, as the trapezium, probl. 12. is divided by the diagonal H L, then from the other two angles, which in that figure are marked with K and Q, let fall perpendiculars upon the diagonal, half the sum of those perpendiculars being multiplied by the diagonal, or common base, gives the superficial content.

Example.

Suppose in the trapezium before mentioned the diagonal is 33, the perpendicular from K 13, and that from Q 15, the area or superficial content is thus computed.

13 chains the first perpendicular.
15 the second perpendicular.

28 the sum of both perpendiculars.

14 their half sum.
33 the diagonal.

42
42

462 square chains the area.

V. *To find the content of a regular polygonial, or multangular figure, otherwise called multilateral.*

Draw a line from the center to the middle of any side; half of the perimeter, or of all the sides, being multiplied by that line before-mentioned, gives the content.

VI. *To find the content of an irregular polygon, or many-sided figure.*

Divide it into trapezias and triangles by diagonal, then find their content severally, and sum up all together.

Fig. 12. Suppose the polygon belonging to the last problem were given without the diagonals A B and B P; then by drawing those diagonals, the figure is divided into three triangles, whereof two being upon the same base A B, make up a trapezium, whose content may be found just in the same manner as was taught even now in the fourth rule, having found the perpendiculars from O and P falling upon the line A B. Then there remains the triangle B Q P, whose content may be found by the general rule concerning triangles, having found the perpendicular falling from Q on the line B P; and then having added the content of that triangle to the content of trapezium, you have the area of the whole polygonial figure.

Concerning chains, compasses, and scales.

I. Amongst the many sorts of chains used for measuring land, three are most famous, bearing the names of their inventors, Mr. Rathborne, Mr. Gunter, and Mr. Wing, all of them ingeniously divided, and useful in their kind;

kind; but brevity will give us leave only to deſcribe one, and that ſhall be Mr. Gunter's, being moſt in uſe, and eaſy to be procured.

This chain contains in length, four ſtatute-poles or perches, each perch containing 16 feet and a half, or 5 yards and a half; ſo that the whole chain is 66 feet, or 22 yards long.

This whole chain is divided into 100 equal parts or links, whereof 25 are a juſt pole or perch; and for ready counting, there is uſually a remarkable diſtinction by ſome plate or large ring at the end of every 25 links, but eſpecially at the preciſe middle of the chain, which ſhould differ from the reſt in greatneſs and conſpicuouſneſs. Alſo at the end of every tenth link, it is uſual to hang a ſmall curtain-ring; and if there be at every five links end a piece of wire made like the bow of a link, with a little ſhank an inch or leſs long, or ſome ſuch diſtinction, it is ſtill better.

When you are to meaſure any line by this chain, you need to regard no other denomination but only chains and links, ſet down with a prick of your pen betwixt them. *e. g.* If you found the ſide of a cloſe to be 6 chains and 35 links long, it is thus to be put down, 6. 35.

But if the links be under 10, a cypher muſt be prefixed; ſo 7 chains 9 links muſt be thus ſet, 7.09.

In the uſing of this, or indeed of any, chain, care muſt be taken both to go ſtrait, and to keep a true account; for which purpoſe, it is good that he which goeth before, carry in his hand a bundle of rods, to ſtick down one at the end of the chain which leads, having firſt ſtretched it well, and that he which follows do not only gather up the rods to keep the account, but alſo at every remove, mark whether he ſee the leader directly between his eye and the angle, or other mark he aims to meaſure to; and if need be, call to the leader to move towards the right or left hand, till he ſee him in a direct line to it.

II. Compaſſes are ſo well known, that we need not deſcribe them; only they ſhould be of braſs, with ſteel points, ſmall and neatly wrought, nine or ten inches long from the joint to the points, turning ſo truly upon the rivet, that they may be eaſily opened, and yet ſtand ſo firmly, that an arch or circle may be, without their ſhrinking, deſcribed upon a large radius.

III. Scales are certain lines divided into equal parts, upon plates or broad rules of braſs or box, and they are of two ſorts, 1. Plain. 2. Diagonal.

1. Plain ſcales are made up of two ſmall lines parallel to one another at a little diſtance, and theſe are divided into great equal parts, which ſignify tens, and are noted 10, 20, 30, 40, 50, &c. according to the length of the lines.

They may be of any convenient length, but theſe great diviſions are ſeldom more than inches, or leſs than third parts apiece.

Again, one of the great diviſions is ſub-divided into ten equal parts by ſhort lines, whereof that in the middle ſtanding for 5, is longer than the reſt.

Fig. 13. According to the numbers of theſe little parts contained in an inch, the ſcale is named, A ſcale of 10, 11, 12, 16, 20, 24, 30, &c. in an inch. That ſhort one which we give you the figure of A, is of 10 in an inch, ſo noted at the top, according as is uſual upon the rules, and indices of plain tables. The line marked O Q, ſeparates units and tens; units being taken upward from that line, and tens downward; mixt numbers both ways.

As for example.

7 is the extent of the compaſſes upon the ſcale A, from the line O Q to K; 30 is their extent from the line ſo marked to O Q; and 27 is their extent from the line 20, to the ſhort line K aforeſaid.

Here note, that you muſt not expect to find the letters O Q or K upon the ſcales which you buy, being only marks uſed at pleaſure, to make my meaning plain; and likewiſe that this ſcale of 10 in an inch, and others that are ſmaller are uſually made, for more convenient uſe, ſo long as to contain nine or ten of the great diviſions, ſignifying tens; though the figure at A being deſigned for no other uſe than to help our conceptions, extends but a little beyond 30, that length being ſufficient for my purpoſe in this place.

Fig. 14. Theſe plain ſcales, eſpecially the ſmaller ſorts of them, ſuch as 24 or 30 in an inch, are very proper for drawing figures upon paper, where the numbers repreſented by the lines are not above 100, for then every diviſion may be counted as it is upon the ſcale, or above upon a long ſcale.

Alſo in the ſurveying of foreſts, chaſes, and great commons, where the lines are vaſtly long, and the miſtake of a few lines is not conſiderable, they may be conveniently uſed, accounting the tens and units to ſignify ſo many whole chains, and ſo eſtimating the parts of a chain with the compaſſes upon the ſmall diviſions, which a ſagacious man may do very near upon one of the larger ſcales. But it would be much better for ordinary meaſuring, if the grand diviſions of the ſcale were two inches apiece, for then the ſmaller diviſions being of five in an inch, would be ſo large as to be ſub-divided into five apiece, which repreſents 20 links; and then the half one of thoſe ſmaller diviſions ſignifying 10 links, and the quarter 5, a very ordinary judgment may come very near to the truth by eſtimation.

2. But the diagonal ſcale is ſo well known to every mathematical-inſtrument-maker, ſo eaſy to be procured, and every way ſo fitted to Gunter's chain, that we cannot but highly commend it.

It is made, as appears by the figure B, upon eleven parallel lines equidiſtant, ſo as to include ten equal ſpaces, which are all cut at right angles by tranſverſe lines dividing them all into four equal parts.

One of theſe tranſverſe lines, *viz.* P R, where it toucheth the firſt and laſt lines, ſeparates between the hundreds, or whole chains, and the tens, repreſenting 10 links apiece, the chains being numbered downwards on the left hand from P only to 3, but on the inſtrument itſelf they may go on to 9 or 10, but the tens upward from P to 10.

From the points of diviſion into tens upon the firſt line, beginning at P, to the like points beginning at R in the laſt line are nine diagonal lines drawn, the firſt beginning at P, and ending at the firſt diviſion above R. The ſecond begining at the firſt diviſion above P, and ending at the ſecond above R. In a word, they are all drawn from one diviſion leſs from P, to one more from R; by which it comes to paſs that every diagonal, by that time it hath paſſed from the firſt line to the eleventh, is a whole tenth part of an inch, which anſwers to ten links of the chain, farther diſtant from the line P R than at the points upon the firſt line whence it was drawn.

Every one of thoſe diagonals is divided into ten equal parts by the long parallel lines running through the whole ſcale, and numbered on the top from 1 to 9. Whereby it is evident that the interſection of any of the nine parallel lines that are numbered at the head with any diagonal, muſt be farther diſtant from the line P R, than the interſection of the line next before it with the ſame diagonal by $\frac{1}{10}$ of $\frac{1}{10}$, that is, by $\frac{1}{100}$, which anſwereth to a ſingle link of your chain.

From what hath been ſaid, and inſpection of the figure B, theſe things plainly follow; which, as ſo many clear inſtances, will help you to underſtand it fully.

The diſtance from P R, to the ſecond diviſion below it, anſwereth to two chains.

The diſtance from P R to the eighth diviſion upward, being taken (with compaſſes) upon the firſt line of the eleven from P to 8, anſwereth to 80 links.

Conſequently the extent of the compaſſes from the ſecond grand diviſion below P, to the eighth of the leſs diviſions upward, is proportionable to 2 chains 80 links.

The diſtance from P R to the firſt diagonal being taken upon the parallel line, noted with 9 above, anſwereth to 9 links: where note, that the firſt diagonal is not that which is noted with 1, but that which is drawn from the point P.

The diſtance upon the ſame line from P R to the diagonal that is marked with 7, is anſwerable to 79 links.

The extent of the compaſſes from the bottom of the figure upon the ſame line to the ſame diagonal, anſwereth to 3 chains 79 links.

In ſhort whole chains may be meaſured upon any line from P R, to the grand diviſion noted with the given number, decads alone, or chains and decads upon the firſt line of the eleven where the diagonals begin. Links alone, decads with links, and chains and decads with links, always upon that line upon which the number of the odd links ſtands at the head of the ſcale.

N. B. Theſe directions will as well fit, if half an inch be only allowed for a chain, and conſequently all the diagonals, genals drawn within that extent, as it is usual upon the other end of the same rule, the grand division for chains going the contrary way, and noted with numeral figures in order. It is therefore proper when you furnish yourself with scales, to have diagonal scales of both dimensions on the fore-side of your rule, and upon the back-side many plain scales of equal parts, with a line of chords.

How to cast up the content of a figure, the lines being given in chains and links.

Having described these plain instruments, and in some measure shewed the use of them in severals, it were very proper in the next place to teach their joint use in measuring and protracting; but because we would have our young surveyor, before we take him into the field, able to perform his whole work together, we intend to shew him, 1. How he ought to make his computations; 2. The grounds or principles that will justify him in so doing.

For the first, take these rules:

1. Put down your length and breadth of squares and oblongs, and your base and half perpendicular of triangles directly under one another, expressed by chains and links with a prick betwixt them, as was taught before, chap. 4.

2. If the odd links were under ten, put a cypher before the numeral figure expressing them, (as there also was shewed) and if there be no odd links, but all even chains, put two cyphers after the prick.

3. Multiply length by breadth, and base by the half perpendicular, according to the rules for finding the content of figures, chap. 3.

4. From their product cut off five figures, accounting cyphers also for such, reckoned from the right hand backward, with a dash of your pen, so shall those to the left hand signify acres.

5. If those five cut off were not all cyphers, multiply them by four, and cutting off five towards the right hand again, the rest will be roods or quarters.

6. If amongst these five figures towards the right hand that were cut off at the second multiplication, there be any figures besides cyphers, multiply all the five by forty, and cutting off five again by a dash of your pen, those on the left hand signify square perches, poles, or roods.

A few examples will make all plain.

Quest. 1. *What is the content of a square, whose sides are every one of them 7 chains, 25 links?*

```
Length  7. 25.
Breadth 7. 25.
        ------
          3625
         1450
        5075
        ------
       5|25625
             4
        ------
       1|02500
            40
        ------
       1|00000
```

Answ. 5 acres, 1 rood, and 1 perch, as here appears.

Quest. 2. *In a long square whose length is 14 chains, and the breadth 6 chains 5 links, what is contained?*

```
Length  14.00
Breadth  6.05
        ------
          7000
         84000
        ------
       8|47000
             4
        ------
       1|88000
            40
        ------
      35|20000
```

Answ. 8 acres, 1 rood, and 35 perches, as the work makes it evident.

Quest. 3. *In a triangle, whose base is 3 chains, and half the perpendicular 98 links, what is the content?*

```
The base        3.00
Half perpend.   0.98
               ------
                2400
                2700
               ------
               |29400
                    4
               ------
              1|17600
                   40
               ------
              7|04000
```

Answ. 0 acres, 1 rood, 7 perches.

There are other ways of computation by scales, tables, &c. But that this is demonstrative, will appear by the following steps.

1. It is evident, that in this way of multiplication, the product is square links; for every chain being 100 links, it is all one to multiply 7.25 by 7.25, or 725 by 725 without pricks; for the pricks signify something as to conceptions, but nothing at all in operation. The product therefore of the first example was really 525625 links.

2. Every chain being 4 perches long, it follows, that 5 chains, or 20 perches, in length, and 2 chains, or 8 perches, in breadth, make an acre, or 160 square perches; for 20 being multiplied by 8, gives 160.

3. From hence it plainly follows that there are exactly 100000 square links in an acre; for 5 chains multiplied by 2, is the same with 500 links by 200, which makes 100000. And he does not deserve the name of an arithmetician, that is ignorant of this old plain rule, when the divisor consists of 1 and cyphers, as 10, 100, 1000, 10000, 100000, &c. cut off from the right hand so many figures of the dividend as the divisor hath cyphers, accounting them the remainder; so shall the rest on the left side be the quotient. It is plain then that 525625 square links, make 5 acres, and 25625 square links over.

Thus we have made it clear to a very ordinary capacity, that as far as concern acres, the rules for computation are good. Now for roods and perches, though it might be sufficient to mention that known rule in decimal arithmetick, multiplying decimal fractions by known parts, gives those known parts in integers, due regard being had to the separation, we shall proceed thus: if 25625 square links, which remain above an acre, contain any quarter or quarters of an acre, then, if they be multiplied by 4, and divided by 100000, that is, five cut off from the product, they will contain so many acres as now they do quarters, or roods, for any number of quarters multiplied by 4, must needs produce the like number of unites or integers, and the division only reduce them into the right denomination. Now, 25625 being multiplied by 4, and five figures being cut off from the product, the result is, 1|02500, that is, an acre and above; which shews it was above a quarter before it was multiplied by 4.

And to find how much, that is, how many square perches are contained in this last remainder, you must consider this 2500, not as square links remaining above the rood or quarter, but as four parts or quarters of square links, or, which is all one, as the true number of square links multiplied by 4, and consequently being multiplied by 40, the fourth part of square perches in an acre, it must as often contain 100000 square links, or an acre, as the quarter of this number 2500, viz. 625, signifying square links, containing square perches; and so, for 100000 divided by 160, the number of perches in an acre, gives 625, answering to one perch; and 2500 multiplied by 40, gives 100000, or one acre, the five cyphers being cut off.

```
  2500        160      100 000625
    40                     960
 -------                  -----
 1|00000                   400
 -------                   320
                          -----
                           800
                           800
                          -----
```

How to meaſure a cloſe, or parcel of land, and to protract it, and give up the content.

Hitherto we have been like children learning to ſpell, now let us ſet our ſyllables together: that is, let us make uſe of the inſtructions before given to meaſure a piece of land, to plot it, and to caſt up the content.

All cloſes, or parcels of land, are either ſuch as need not be plotted for finding their true meaſure, but the chain alone doth the work; or ſuch as cannot be conveniently meaſured without plotting or protraction.

Of the firſt ſort are the ſquare and long ſquare, known before-hand to be ſuch, or found ſo to be by ſuch inſtruments as are not yet deſcribed, or by meaſuring all the ſides and diagonals. Theſe ſquares and long ſquares, need no protracting; for you need only to multiply the chains and links of the length, by the chains and links of the breadth, and ſo proceed as in the firſt and ſecond examples: but all others, whether triangles or triangulate, are to be protracted. We ſhall give examples therefore in the three ſorts of figures, triangular, quadrangular, and multangular.

But before we proceed to particular inſtances, let the young practitioner remember,

1. To begin at ſome notable angle of the field where there is ſome houſe, gate, ſtile, well, or the like; or if there be none, then to dig up a clod, drive down a ſtake, or at leaſt, to obſerve what quarter of the heavens it pointeth towards, whether eaſt, weſt, north, or ſouth, and on your paper mark it with the letter A, or any other.

2. To go parallel to the ſide of the field, if pits, buſhes, or the like, hinder not, and if they do, to allow for it, accuſtoming yourſelf to go either with your left hand towards the hedges, walls, or pales; or with your right hand towards them; and when you go contrary to your uſual cuſtom, note it on your paper by ſome mark known to yourſelf.

3. To ſet down the chains and links of every ſide as you meaſure them, and not truſt your memory. A black lead pen will be very proper for this purpoſe.

4. To take care, if you have more ſcales than one upon your rule, leſt you confound yourſelf by taking lines off of ſeveral ſcales, or meaſuring perpendiculars upon wrong ones; for every line of the ſame figure muſt be made by the ſame ſcale, and the perpendiculars meaſured by it.

5. To make uſe of a ſcale of larger diviſions when you meaſure ſmall cloſes, and of ſmaller when you meaſure great ones.

6. To make your lines and points where angles meet, ſmall, pure, and neat.

7. To ſet on your chains and links at twice, when any line is too long for your ſcale.

Theſe things being premiſed, proceed thus:

I. Suppoſe a triangular field is to be meaſured with the chain, beginning at eaſtern angle A, Fig. 15. and find the ſides in their order and meaſure to be ſeverally thus; 2.29, 3.45, 4.07.

Making uſe of the leſs diagonal ſcale, becauſe the other would make the figure too large, otherwiſe it were more proper for ſo ſmall a cloſe, with your compaſſes take off the ſcale 4 chains and 7 links, and ſetting them from A to C, draw that line for the baſe, becauſe the longeſt of the three; then take 2 chains 29 links off the ſame ſcale, and ſet them in the eaſtern point A, and turning the looſe foot of the compaſſes above the line A C, deſcribe, at that diſtance 2.29, the arch E E.

Next taking with your compaſſes upon the ſame ſcale the extent of 3 chains 45 links, place one foot in the point C, and with the other make the arch F F, interſecting the former in the point B; and drawing the lines A B and B C, the triangle A B C is the plot of the triangular field meaſured.

But before you can give the content, you muſt find the length of the perpendicular, which is done by ſetting one foot of the compaſſes in B, and extending the other to the baſe A C, ſo as it touch it, and paſs not over it, for then the length of the perpendicular is between the points of the compaſſes, and being applied to the ſame ſcale by which the triangle A B C was made, it appears to be 1 chain 42 links. With the half whereof multiply 4.07, the length of the baſe, the content appears to be 0 acres, 1 rood, 6 perches.

The baſe 4.07
Half perpend. 0.71

407
2849

28897
4

1|15588
40

6|23520

II. Suppoſe you were to meaſure a quadrangular or four-corned field, begin as before at ſome remarkable angle; and going round the cloſe, find the ſides to be 9.04, 6.72, 8.46, 7.28, and the diagonal from that remarkable angle to the oppoſite angle to be 10.02; we begin to protract it thus:

Fig. 16. Having by the help of your ſcale and compaſſes drawn the diagonal 10.02, from the remarkable angle A to C, the oppoſite angle, make a triangle of it, and the firſt and ſecond ſides 9.04 and 672, and another after the ſame method of that diagonal, and the third and fourth ſides 8.46 and 7.28, ſo you have the trapezium A B C D.

Then by the help of your ſcale and compaſſes, you find the perpendicular of the triangle A B C to be 6.02, and of the other, viz. C D A 6.01, which added, are 12.03, whereof the half ſum is 6.01; by which, multiplying the baſe 10.02, the content of the field will be 6 acres, 0 roods, 3 perches.

The baſe 10.02
Half perpend. 6.01

1002
60120

6|02202
4

|08808
40

3|52320

Before we paſs any farther, let it be remembered,

1. Any quadrangular cloſe, or parcel of ground whatſoever, having right lines, may be thus meaſured, protracted, and computed.

2. The odd meaſure above perches, is not valuable here, nor in the former computations, being always under a ſquare perch; but in multangulars, where there be many remainders, they muſt be ſummed up, and the perches contained in them added to the content before found.

3. This laſt, and the following figures, are made, that they might not be too large, by a ſcale of 400 in an inch, *i. e.* by the leſs diagonal ſcale, each chain and link being counted two.

III. Fig. 17. If this multangular figure be conceived to repreſent a cloſe of ſeven ſides, which is to be meaſured, begin at the remarkable angle A, and going round the cloſe, find the ſides will be 3.11, 2.49, 2.47, 1.77, 4.11, 2.29, 4.37.

Then meaſure the four diagonals, B D, D F, F B, and B G, in the order you will find them to be 3.45, 4.97, 4.13, and 4.36, which is as ſhort a way as can be taken, to prevent unneceſſary walks.

But when you come to protract by the help of your ſcale and compaſſes, firſt make the triangle B C D of the firſt diagonal, and the ſecond and third ſides. Then the triangle D E F upon the ſecond diagonal, and fourth and fifth ſides; and upon the ſame diagonal, as a common baſe, the triangle B D F of the firſt, ſecond, and third diagonals.

Next of the ſame third diagonal, together with the 4th and 6th ſides, make the triangle B F G, and upon the fourth diagonal, as upon a common baſe with the firſt and laſt ſides, the triangle A B G. So is the whole cloſe plotted.

And

And now it ſtands viſibly reduced into two trapezias A B F G and B D E F, together with the triangle B C D, which we ſhall not now caſt up, having ſo often ſhewn how ſuch work is to be done.

But it muſt be acknowledged that this method of plotting parcels of land that have many angles, requires not only more care and pains, but better ſkill and memory, than to draw diagonals upon paper, when the plot is already taken by the plain table, or other ſtanding inſtrument. We ſhall therefore, to help our young practitioner in this caſe, advertiſe him of two eaſy ways to help myſelf, ſo as to be out of danger of miſtakes.

One way is, to divide the multangular field into two or more parts, as the laſt might have been by the diagonal B F; then might each part have been meaſured ſeverally, as if they had been ſeparated by a pale, or were ſundry men's lands parted by a boundary.

Another way that much helps both the underſtanding and memory, is, to draw a rude draught of the figure of the land you intend to meaſure, not only as to the ſides, but alſo neceſſary diagonals. Then meaſuring the lines upon the ground correſpondent to thoſe on the paper, ſet the lines as you meaſure them upon the lines of the draught, as if it were the true ones, and when you have finiſhed your meaſuring, protract it truly. Such as you ſee here, but it is better larger, will do your buſineſs; for it is not a pin matter how rude or falſe the lines or angles be, reſemblance being all that is deſired.

Concerning the meaſuring of circles, and their parts.

We have hitherto purpoſely abſtained from meddling with the circle, and its parts, that we might lay thoſe things cloſe together without unneceſſary mixtures, that are of greateſt uſe.

It is very rare, if a land-meter ever have occaſion to meaſure any field or parcel of land, that will prove either circle, ſemi-circle, quadrant, or ſector. Sometimes indeed there will be a little crook in an old hedge bowing like an arch; but we have never ſeen any offer to meaſure it as a ſegment, but always take it as an angle or angles.

Yet becauſe it may be expected we ſhould ſay ſomewhat of thoſe things, we ſhall briefly do it.

I. To meaſure a circle in the more exact way, is, to ſquare the diameter, and to multiply that ſquare by 7854; ſo ſhall the content be in integers and decimals.

But the more uſual and quick way, (and near enough for any uſe we ſhall make of it) is, to multiply the half of the periphery or circumference by the ſemi-diameter.

In like manner to find the content of a ſemicircle, quadrant, or ſector, made up of ſemi-diameters, and arched lines, multiplying the half arch by the ſemi-diameter, gives the content.

Fig. 19. But that which falls out moſt frequently in menſuration, though ſeldom much regarded, except where a curious exactneſs is required, is that particular ſort of ſegment which we call a ſection, leſs than a ſemi-circle, ſuch as this figure A B C. And to find the content of it, the center of the circle, whereof this is a ſection, muſt be firſt found, as here at O, from which lines drawn to A and B, make up the ſector A O B C; which being meaſured according to the laſt rule, and from the content thereof, the content of the triangle A O B ſubſtracted, the difference or reſidue is the content of the ſection A B C.

But two queſtions may be here demanded:

1. How may the center be found? 2. How may ſuch a portion of land be truly protracted and computed?

To the firſt we anſwer, that the moſt exact and artificial way, is, by making a mark any where in the arch.

As for example.

At the point C, and then, by a problem known not only to every ſurveyor, but to ordinary carpenters and joiners, for finding the center of a circle, whoſe circumference will paſs through 3 given points that are not in a right line, as A C B, to find the center O. But if you know not how to do it ſo, croſs the line A B in the middle, as here it is done by the perpendicular O C; ſo you may by a few trials find both the due extent of your compaſſes, and the point in the perpendicular that will fit your purpoſe near enough; for if a little error be committed in making up the ſector, the moſt of it goes off again in the ſubſtraction of the triangle.

II. For the latter, you may take this ready courſe: meaſure the length of both your lines, the chord and the arch, and their diſtance at the middle of them both; then, when you come to protract, firſt take the length of your right line from the ſcale, and having laid it down, croſs it in the middle at right angles with a dry line, as in the laſt figure, ſo ſhall it interſect the line A B in the point E; then from the ſame ſcale take the meaſured diſtance between the two lines in the middle, and ſet it upon that dry line from the interſection at E, to the point C. Then, by trials, find a due place in the dry line O E C, and ſuch a diſtance with your compaſſes, that the one foot reſting in that line, the other may deſcribe the arch A C B, and the ſection is protracted.

Concerning cuſtomary-meaſure, and how it may be reduced to ſtatute-meaſure, & e contra, *either by the rule of three, or a more compendious way by multiplication only.*

Though the ſtatute-perch or pole is 16 feet and a half, and no more, yet there are poles of larger meaſure uſed in many places, as of 18, 20, 21, 24, and 28 feet, nay, in ſome 22 feet and a half. It were therefore very convenient that our young ſurveyor were furniſhed with a chain fitted to the cuſtomary meaſure of the country where he lives. But becauſe theſe are too large and cumberſome for ſmall cloſes, it is very convenient, inſtead of one chain of 100 links, to make two of 2 poles apiece, each pole divided into 25 links, as that of 100 is; which two half chains may, in meaſuring large fields, be tied together by the loops with pack-thread, or joined by a buttoning key-ring for more ſpeedy diſpatch; but in ſmaller we may uſe the half chain of 50 links, only taking care that we count not half chains for whole ones.

And in theſe caſes where the poles are large, and the cloſes ſmall, it were ſtill more convenient if you had a chain of 2 poles only, divided into 100 links. Only you muſt then take notice, that whereas working by whole chains and links, the firſt multiplication, after five cut off, gives the content in acres and parts. The like work by half chains and half links, will give the content in roods or quarters of acres, and parts of ſuch roods.

But though it is no hard matter, for one that can find out the length of a link by dividing the number of feet in a chain by 100, and provide himſelf of good iron-wire and curtain-rings to make it of, and a ſharp-edged file, and round-noſed plyers to make it with, to be furniſhed with ſuch a chain, yet becauſe every one cannot do this, we ſhall ſhew how you may eaſily, and yet very truly reduce ſtatute-meaſure into cuſtomary, that ſo the chain before deſcribed may do your buſineſs all England over.

Know therefore, for a ground to go upon, that acres bear proportion to one another as the ſquare of their poles; and therefore if you multiply 33, the number of half feet in the ſtatute-pole, by itſelf, which gives 1089, and alſo multiply the number of half feet contained in a pole of that meaſure you would reduce into; in the ſame manner you may, by the rule of three reverſe, obtain your deſire, making to that purpoſe 1089 the firſt number, the ſtatute-meaſure the ſecond, and the ſquared half feet of the pole given the third. As for example: ſuppoſe of a cloſe meaſured by the ſtatute-pole, the length and breadth, and their product be as here repreſented in the margin. And it is deſired that the content may be caſt up according to the large Cheſhire meaſure of eight yards, or 24 feet to the pole or rod. Then before you cut off any figures, conſider that in the ſtatute-pole are 33 half feet, and in the Cheſhire pole 48; multiply therefore 33 by 33, and 48 by 48, and you will have, 1089 and 2304, which, together with the ſaid product, may be thus placed: 1089, 672693 :: 2304, and ſo multiplying 672693 by 1089, and dividing their product, being 732562677, by 2304, the quotient is 317952; from which, if 5 figures towards the right hand be cut off, the content, by this cuſtomary-meaſure of 24 feet to the pole, will be 3 acres, 0 roods, 28 perches, as here appears:

```
  9.33 L.
  7.21 B.
 -------
   933
  1866
 6531
 -------
 672693 prod.
```

```
  3|17952
        4
  -------
   |71808
       40
  -------
 28|72320
```

But

But if the lines on the land had been meaſured according to that cuſtom of 24 feet to the pole, and the content muſt have been found according to ſtatute-meaſure, then we muſt have multiplied the product by 2304, and have divided that latter product by 1089. And in the ſame method you may proceed in all or any of the reſt. But the truth is, that though this way be very exact, plain, and comprehenſive, ſuiting all the cuſtomary-meaſures before-mentioned without fractions, it is ſomething tedious, except the practitioner knows how to relieve himſelf by a large table of logarithms, which we cannot ſtand here to treat of. Therefore to contract the work a little, take notice, that all the cuſtomary poles being mentioned, ſaving only thoſe of 20 and 28 feet, which we ſuppoſe are ſomewhat rarely uſed, having never heard nor read of them, but in Mr. Holwell; all the reſt are capable of being divided into half yards: and therefore, if inſtead of ſquaring the half feet, you ſquare the half yards of both poles, and work with them, you will attain the ſame end without any regardable difference, the ſmall diverſity that there is, being generally in the uſeleſs remainders, not at all affecting the deſired quotient that gives the anſwer near enough for uſe.

As for example.

```
 11
 11
----
 11
 11
----
121
----
 16
 16
----
 96
 16
----
256
```

If we had ſquared 11 the number of half yards in the ſtatute-pole, which would make 121, and alſo 16 the number of half yards in the Cheſhire-pole, which would make 256, and then multiplied the firſt product 672693 by 121, the ſecond product would have been 81319853, which being divided by 256, the quotient would have been, as before, 317952. And this way is in a manner co-incident with Mr. Holwell's firſt method.

Take notice alſo once for all, that whether you uſe either of theſe or the following methods, you need not reduce the particular ſquares, triangles, or trapezia's ſeverally; but ſum up all their products together and then reduce all at once.

But if you would reduce ſtatute-meaſure into cuſtomary by multiplication only, take notice of this preſent table following.

The content by the ſtatute-pole being multiplied by	.84027	Gives the content by the pole of	18	Feet.
	.68062		20	
	.61734		$21\frac{1}{2}$	
	.53777		22	
	.47265		24	
	.34725		28	

The uſe of this table.

When you have multiplied lengths by breadths, or baſes by half perpendiculars, multiply theſe products by the decimal fractions anſwering to the cuſtomary-meaſure, into which you would reduce ſtatute-meaſure, and from that latter product, firſt cut off five places towards the right hand, as not to be regarded, being only parts of a ſquare link, then cutting off five more, and proceeding to multiply by 4, and then by 40, as hath been often ſhewn, you will have the content by that cuſtomary-meaſure.

Example.

Suppoſe the length of a cloſe meaſured by Gunter's chain, and multiplied by the breadth meaſured alſo by the ſame, produced 672693 ſquare links; and it is deſired, that the content may be given in Cheſhire meaſure of 24 to the pole; you muſt multiply 672693 by 47265, the decimal fraction anſwering to 24 feet, and from that product, being 31794834645, cut off and caſt away 5 places, and the reſt being 317948, are in the uſual way eaſily reducible into 3 acres, 0 roods, and 28 perches, as here appears, agreeable to what it amounted to in the former method.

```
3|17948
      4
-------
|71792
     40
-------
28|71680
```

But if you meaſured by a chain of cuſtomary-poles, and deſire to know what the content is in ſtatute-meaſure, this following table is for your purpoſe.

	Feet.			
The content meaſured by the pole of	18	being multiplied by	1.19008	gives the content by the ſtatute-pole.
	20		1.46923	
	21		1.61983	
	$22\frac{1}{2}$		1.85950	
	24		2.11570	
	26		2.87970	

To underſtand which, take this example.

Suppoſe the length and breadth of a long ſquare being meaſured by a chain of 24 feet to the pole, and multiplied together, make their product 317952, let this be multiplied by 2.11570, which anſwereth to 24 feet, and the latter product will be 67269104640; from which, if you cut off and caſt away 5 places towards the right-hand, the remainder is 672691; which, in the uſual way, is eaſily reduced to 6 acres, 2 roods, and 36 perches.

```
6|72691
      4
-------
2|90764
     40
-------
36|30560
```

One thing more, and we have done with this buſineſs of reduction. If the content to be reduced, be caſt up into acres, roods, and perches, reduce all into perches, and then in other reſpects work as before, either by the Rule of Three, or by this laſt method of multiplication only. So ſhall you have the content in ſquare perches, according to the meaſure deſired, which you may reduce into acres by dividing them by 160; and if any thing remain, that remainder being divided by 40, will give you the roods in the quotient, and the latter remainder the number of ſquare perches.

For trial of which rules, remember the anſwer of theſe two following queſtions wrought all three ways.

Queſt. 1. *How many acres, roods, and perches according to the pole of 18 feet, are contained in 5 acres, 3 roods, and 11 perches, ſtatute-meaſure?*

Anſ. 4 acres, 3 roods, and 22 perches, as here appears.

How to meaſure a piece of land with any chain of what length ſoever and howſoever divided; even with a cord or cart-rope, being a good expedient when inſtruments are not at hand of a more artificial make.

If you can procure a chain, and find it is not divided as before hath been ſhewn, but into feet or quarters of yards, or any ſuch vulgar diviſions, make no reckoning of the diviſions at all, but meaſure it as exactly as you can find out the true length of the whole chain; and if it fit none of thoſe lengths mentioned before, nor any of their halfs, make it fit by taking off a link or two, or piecing it out with a ſtring; then dividing the length of that chain by 100, or the half of it by 50, find the true length of a link according to our artificial diviſions, and having got a long ſtick or rod, ſet as many of thoſe link-lengths upon it as it will hold; then may you meaſure all the whole chains by your regulated chain, and the odd links of every line by your divided ſtick or rod, as is manifeſt in this example following.

Being far from any inſtrument, and requeſted by a friend to meaſure him a cloſe, you muſt procure a pair of compaſſes, an ordinary carpenter's rule of two foot, divided into inches and quarters, and alſo with a piece of an old chain ſeemingly divided into feet, meaſure it by the rule, and finding it to be 45 feet long, and ſome odd meaſure, piece it out with a pretty ſtrong cord that will not ſtretch much, to 48 feet exactly; then it will ſerve for half a chain of 24 feet to the pole: this 48 multiply by 12, the number of inches in a foot, and that product being 576, divided by 50, the number of links in half a decimal chain, and the quotient is 11 $\frac{26}{100}$ inches, or 11 inches and an half, and a trifle over: dividing therefore a long ſtick throughout into ſuch parts, each containing 11 inches and a half, beſides the breadth of the nicks, you are provided of tools to meaſure lines to a link with exactneſs enough.

In like manner you proceed with a cord or rope, having fitted them to ſome known length or other; and then for protracting, it were eaſy with the compaſſes to make a plain ſcale of a large ſort, either upon paper, or an even piece of wood. This for once may ſerve a man's turn well enough.

Beſides, there is a way of meaſuring the perpendiculars of triangles and trapezias upon the ground itſelf, ſo as to prevent the neceſſity of a ſcale; for if you have a little ſquare with a hole in it to turn upon the head of a little ſtick, which you may fix where you pleaſe, as you are meaſuring the baſe of a triangle, or the diagonal of a trapezium, you may by a very few trials find the place where the one leg will be juſt in the line you are meaſuring, and the other point at the angle from which the perpendicular falls on it, and then the ſpace between your ſtick and that angle truly meaſured, is the perpendicular.

If you have not ſuch a ſquare, a ſquare trencher, or any end of a board that hath one right angle, and two true ſides, will ſupply the want of it.

And

And we shall make bold to add, that this is a good way to measure a trapezium, though it be protracted afterwards; for by measuring the perpendiculars as aforesaid, and observing at how many chains and links end the said perpendiculars meet the common base, the whole trapezium may be truly protracted without going about it; this little square competently supplying the place of an instrument, which is usually called a cross or square, made up, as it were, of two small indices, like those for a plain table, but much less, with fore-sights and back-sights, and cutting one another at right angles put together, and having an hole at the center.

Concerning dividing of land artificially and mechanically.

1. To divide a triangle into any parts required; divide the base as the demand imports, then shall lines drawn from the points of division to the opposite angle, finish the division of the triangle.

Example.

Fig. 20. A C, the base of the triangle ABC, being divided into 12 equal parts, a line drawn from the angular point B to the point 6, divides the triangle into two equal parts; 2 lines drawn to 4 and 8, divide it into three equal parts; 2 lines drawn to the points noted with 3, 6, and 9, divide it into four equal parts; and so lines drawn to 2, 4, 6, 8, 10, divide it into six equal parts.

Also it is very obvious, that if the same triangle were so to be divided, that the one part should be double to the other, a line drawn from B to 4 or 8, doth the work, or if it be required to divide it into two parts, so as the one shall be triple to the other, a line drawn from B to 3 or 9, compleats the work. So also a line from B to 2 or 10, divides it into two parts, whereof the one is quintuple, or five-fold, to the other, and a line from B to 1 or 11, divides it into two parts, whereof the one is 11 times as large as the other.

Farther yet, if it were required this triangle should be so divided, that the two parts should in quantity bear proportion, as 5 and 7, a line from B to 5 or 7, will answer the intention.

The divisions will indeed be sometimes a little more intricate than this, yet not such, but that the seeming difficulty may be easily overcome by observing the following method.

Suppose a large triangle of common land to be divided amongst three tenants, A, B, and C, according to the quantity of their tenements, A, having 19 acres of land to his tenement, B 13, and C 7, the base of the triangle being found by measure to be 17 chains and 27 links; and the demand is, where the point of the division must be placed in the base, so as lines drawn from thence to the opposite angle, shall truly limit each man's part.

To answer this, let us add 13 and 07 to 19, and they give 39: so is the work plainly reduced to the rule of fellowship; and therefore to find every man's distinct portion, we need only to multiply the base by his particular number, and divide that product by 39, the sum of all their numbers.

——
38

From these operations it is plain, that if we set off from the angular point where the base begins, 8 chains, 41 links, and a little above the third part of a link upon the base for A, and where that ends, 5 chains and 75 links and $\frac{2}{3}$ of a link for B, and consequently leave between this second division and the other end of the base 3 chains and almost 10 links for C; lines drawn from those points of division to the opposite angle, will give each man his due.

What has been said touching the division of triangles upon their bases, will, with a little variation, serve for the dividing of all sorts of parallellograms, whether squares, long squares, rhombus's, or rhomboides; all the difference is, that instead of drawing lines from points in the base to the opposite angle, you must draw parallel lines from points in one opposite side to another, as will be sufficiently plain by this one instance.

Fig. 7. Suppose the square figure to represent a close of six acres, and you are to cut off an acre at the side A C; having set off the 6th part of the line C D, from C towards D, and also from A towards N, a parallel drawn between those points, takes off exactly a 6th part of an acre.

If it be not thought convenient, as in some cases it is not, to cut off a piece so long and narrow, you may by the Rule of Three find what other length of any greater breadth will limit an equal quantity to it. Or you may multiply the breadth by 2, 3, or any other, and divide the length by the same number that you multiplied the breadth by. Or lastly, if you set out a double proportion that is $\frac{2}{6}$ or $\frac{1}{3}$, from C towards D, and from the point where it falleth, draw a line to the angle A, you will have a triangle equal to $\frac{1}{6}$ of the square A C D N.

But to return to triangles, the most simple and primitive of all rectilinears, and therefore the most considerable in this case of partition, as giving laws often to the rest, it may fall out that a triangle must be divided, by a line from some point in a side, so as that line may either be parallel to some other side, or not parallel to any.

Fig. 21. Let A B C be a triangle given, and it is required to cut off $\frac{3}{5}$ by a line parallel to A B. First, on the line A C describe the semi-circle A E C, whose diameter C A divided into five equal parts according to the greater term, and upon three of those parts, the lesser term, erect the perpendicular D E, which cutteth the arch line in E; then set the line from C E from C to F, and from thence draw the line E G parallel to A B; so will the triangle CGF contain $\frac{3}{5}$ of the triangle A B C, as was required.

Fig. 22. Now, for the latter case, when the line of partition goes not parallel with any side, take this example:

Let A B C be a triangle given to be divided into two parts which shall bear proportion to one another, as 3 and 2, by a line drawn from the point D in the base, or line A C.

From the limited point D, draw a line to the angle B; then divide the base A C into five equal parts, and from the third point of the division draw the line to E parallel to B D. Lastly, from E draw the line E D. So shall the trapezium A B E D be in content as 3 to 2, to the new triangle D E C.

We shall have now done with the division of triangles, when we have added the three following advertisements.

1. You must be sure to take very exactly the distance of every point, where a dividing line cutteth any side, to one of the ends of the same side, as in this last figure, the distances BE and AD; which distances being applied to the scale by which the triangle was protracted, will shew at how many chains and links end you are to make your dividing line on the field itself.

2. The proportions by which you are to divide, are not always so formally given as in the former examples, but are

ſometimes to be found out by arithmetical working, as in this caſe.

Suppoſe a triangular field of 6 acres, 2 roods, and 31 perches, muſt be divided ſo as the one of the two parts ſhall be four acres, 3 roods, and 5 perches, and the other, conſequently, 1 acre, 3 roods, and 26 perches; reduce both meaſures into perches, and the one will be 765, and the other 306. Their ſum is 1701, which, by their common meaſure, being reduced into their loweſt terms of proportion in whole numbers, will be 5, 2, and 7, which ſhews that the triangle being divided in 7 equal parts, the one muſt have 5 of thoſe 7 parts, and the other 2. And obſerve, that it will be ſufficient to find the common meaſure between the ſum of your terms, and either of the terms; the method whereof is ſhewn in every arithmetic-book for reducing fractions into their loweſt terms.

But the reader may multiply either of the parts; as ſuppoſe 765, by the length of the baſe, which we will ſuppoſe to be 8 chains and 75 links, or 87 links; and that product divided by 1071, the content of the whole cloſe in perches, gives the rule of three direct, 625 links, or 6 chains and 1 pole, the true diſtance from either end of the baſe, that his mind or occaſions may direct him to begin with, to the point of diviſion; for the diviſion muſt be not only for proportion or quantity, but alſo as to poſition or ſituation of parts upon the paper, as it is required to be on the ground.

3. In theſe and all other diviſions of land, where a ſtrict proportion in quantity is to be obſerved, you muſt have reſpect to the rules given hereafter concerning meaſuring of uneven ground, eſpecially if one part prove much more uneven than another: and if there be any uſeful pond, or well to draw your line of diviſions through it; but if it be an uſeleſs pond, lake, or puddle; or if there be any boggy or barren ground, that muſt be caſt out in the diviſions, meaſure that firſt, and ſubſtract it from the content of the whole cloſe, and then lay the juſt proportion of the remainder on that ſide that is free from it, that the other may have its juſt part alſo, beſides that which is uſeleſs.

What hath been ſaid, with an ordinary meaſure of diſcretion, may ſufficiently inſtruct a young artiſt to divide triangles, parallellograms, and regular polygonials, in an artificial way; but becauſe many cloſes and open grounds are trapezias, and many irregular polygons, and even thoſe that are regular enough, may fall under an irregular diviſion, in regard of the quality of the land, woods upon it, or quaries in it, or the conveniences of ways, currents of water, ſituation in reſpect of adjacent lands, &c. we ſhall propoſe a method, which though it hath ſomewhat of the mechanick in it, will be ſingularly uſeful in ſuch caſes.

Let A B C D be a trapezium to be divided betwixt a young heir and his mother, ſo as his part may be double to her's. Having by the diagonal B C divided it into two triangles, you will find the content of the triangle A B C to be 138550 ſquare links, and the triangle B C D to contain 103468, in all 242018 ſquare links, which, if reduced, as hath been formerly taught, would amount to 2 acres, 1 rood, and 27 perches.

But for the preſent work, they are in a better order already. Dividing then 242018 into three parts, each of them is 80676 and $\frac{2}{3}$, two therefore of thoſe third parts muſt contain 161353 and $\frac{1}{3}$, which $\frac{1}{3}$ being inconſiderable, regard them not.

Then if you reſolve to lay out the double part towards the line B D, ſtrike at adventures the line E F, and meaſuring the trapezium bounded by that line, and the oppoſite ſide B D, together with the interjacent parts of the lines A B and C D, which you will find to contain 119140 ſquare links; but becauſe it ſhould have been 161353, ſubſtract 119140, out of 161353, and their difference is 42213, and perceiving that the lines A B and C D are very near parallel, and finding their diſtance where they are cut by the line E F, to be 326 links, or 3 chains and 26 links, divide 42213 by 326, and the quotient is 129 links, and almoſt half, at which diſtance draw the line G H parallel to E F; ſo ſhall the trapezium G B D H be the heir's part.

Another way whereby the ſame thing may be performed is this. Finding the triangle A B C to contain 138650 ſquare links, ſubſtract it out of the heir's part, viz. 161353, the difference 22803, ſhews how many ſquare links muſt be taken out of the triangle B C D, and added to the triangle A B C; which to perform with all neceſſary exactneſs, ſuppoſe the ſide or line B D to be the baſe, which by meaſure proves to be 344 links, or 3 chains and 44 links. Say by the Rule of Three direct, if the whole content of the leſſer triangle, viz. 103468, give 344; what ſhall 22803 give? So will the reſult be 75 links, and ſomewhat more than $\frac{4}{5}$, of a link, for 22803 multiplied by 344, gives 7844232, which being divided by 103468, the quotient is 75 $\frac{84132}{103468}$; or according to decimal diviſion, 75,8131, which is ſomewhat more than 75 links and $\frac{4}{5}$, wherefore extending your compaſſes upon the ſcale to almoſt 76 links, ſet that diſtance upon the line B D, from B to I, and draw the line C I: ſo ſhall the trapezium A B I C be double to the triangle I C D, within ſo ſmall a matter as is not worth regarding, though the land were a rich meadow.

We hope it will be unneceſſary to tell any man of ſenſe, that if he pleaſe he may begin with the leſs part, and take out that; or if there be many partners, he may divide betwixt any one and all the reſt, putting their parts together, and then by the ſame method ſub-divide amongſt them till each hath his due ſhare; nor to ſpend many words in telling him he muſt ſubſtract where he hath, by ſeparating a line at adventures, or by chooſing out a triangle, taken too much, as we added, when we took too little. Nor laſtly, that theſe methods are not only applicable to trapezias, but to any triangular figure whatſoever, whether regular or irregular.

Concerning the boundaries of land, where the lines to be meaſured muſt begin and end.

If there be no agreement between the parties concerned, for if there be, that muſt be obſerved, reaſon and cuſtom are the ſurveyor's guide.

The farmer ſpeaks loudly, that when a piece of arable or meadow-land, is let for a year to be ſown or mown, no more ſhould be meaſured, nor expected to be paid for, either to the letter or workmen, than the plow or ſcythe can go over. So alſo when a parcel of land is let for paſture by meaſure to a farmer, it ſeems very reaſonable, that all, and only ſo much ſhould be meaſured, as is uſeful to that purpoſe.

But commons to be incloſed are uſually meaſured, except it be otherwiſe agreed, to the uttermoſt bounds of every man's particular proportion, without any allowance for ditch or fence, every man being to make them upon his own of what breadth he pleaſes. Nor is this unreaſonable, for it is as good for one as another, and the rate paid to the lord is uſually very little, ſometimes nothing.

It is alſo very uſual in meaſuring betwixt lord and tenant, in caſe of leaſes for lives, and long terms of years, to extend the lines to the utmoſt bounds of the tenant's claim, taking in the very walls, hedges, and ditches: but this is accounted very hard, and oft proves very unequal among the tenants of a lordſhip, ſome being forced to make much more waſte of their ground this way, than others that hold as much or more. But where the cuſtom obtains, the ſurveyor muſt obſerve it; for it is others work to appoint what muſt be meaſured, and his only to meaſure truly what is ſo appointed. A good landlord may, and will be apt, to conſider it in his rates, and a bad one it is like will be tenacious of a cuſtom to his own advantage.

Laſtly, in caſe of a ſale by meaſure at a rate agreed upon per acre, no boundaries being ſpecified in the bargain, the rule is to extend the lines to the quick wood-row, that is, to the place where the quick wood actually groweth, or where, according to cuſtom, it ought to be ſet.

Containing a deſcription of the plain table, the protractor, and lines of chords.

Though what hath been already ſaid, may competently ſuffice to inſtruct the young artiſt in meaſuring a cloſe of land, yet, to advance him a degree higher in uſeful knowledge, we ſhall take occaſion to deſcribe unto him the plain table, which conſiſts of ſeveral parts.

1. The table itſelf, which is a parallellogram of wood fourteen inches and a half long, and eleven inches broad, or thereabouts, and for neceſſity may be made by an ordinary country workman of one board; but for neatneſs, convenience of carriage, and freedom from warping, it is uſually

usually made of three little boards joined together side ways, with a ledge at each end to hold them fast together, and upon the middle board a socket of brass fixed with three screws, and with a fourth to be fastened on the head of a three legged staff; of which anon.

2. A frame of wood fixed to it, so as a sheet of paper being laid on the table, the frame being forced down upon it, squeezeth in all the edges, and makes it lie firm and even, so as a plot may be very conveniently drawn upon it. This is usually made with joints for more easy carriage, but a plain one may suffice. Upon one side of this frame should be equal divisions, for drawing parallel lines both long-wise and cross-wise, as occasion may require, over your paper, and on the other side the 360 degrees of a circle projected from a center of brass conveniently placed in the table.

3. A box with a needle and card, to be fixed with two screws to the table, very useful for placing the instrument in the same position upon every remove.

4. A three-legged staff to support it, the head being made so as to fill the socket of the table, yet so as the table may be easily turned round upon it, when it is not fixed by the screw.

5. An index, which is a large ruler of wood, or rather brass, at the least sixteen inches long and two inches broad, and so thick as to make it strong and firm, having a sloped edge, by which we draw the lines, called usually the fiducial edge, and two sights of one height, whereof the one hath a slit above, and a thread below, and the other a thread above, and a slit below, so set in the ruler, as to be perfectly of the same distance from the fiducial edge. Upon this index it is usual to have many scales of equal parts, and there might be a diagonal scale if the instrument-maker please, and lines of chords of sundry lengths; but if you have such a scale as before described, you need not to have them here.

The protractor is an instrument so well known and so easy to be made and procured, that we shall be very brief in the description of it. As it is usually made, it consists of two parts, a scale and a semi-circle, but the scale is no necessary part of it, but serving, if you be not otherwise provided, for other uses before-mentioned in the case of plain scales.

But the semi-circle is more essential, and it may be made of brass, or other metal of any convenient size, as four inches, more or less, for the strait side, this semi-circle being bounded as all others are by two lines, the one right or strait, the other circular.

The right line is divided in the precise middle, by a point which is in the center, upon which the circular boundary is drawn, and two other arches concentrical with it.

The center, when the semi-circle goes alone without the scale, should be guarded with two little lips, on each side one, or a little loop, for more convenient turning of the instrument about upon a pin fixed in a paper.

The arched or circular edge is divided into 180 degrees, or equal parts, numbered by tens, upon the upper concentrick arch from 0 to 180, and in the lower from 180 to 360. So that by applying the strait edge of the protractor twice to any line, keeping the center right upon a pin fixed in the line, that is, with the semi-circle first above it, and then below it, or contrarily, you may draw a whole circle by the guidance of the arch, or set out any number of degrees, as will appear more plainly hereafter.

A line of chords is a line divided into 90 unequal parts, whereof 60, and the radius upon which the circle was drawn, are equal, and the divisions upon that line are equal to the next extent in a right line, of so many degrees from the beginning of the quadrant, as answer thereunto.

When lines of chords are cut upon wood, it is both usual and necessary that there be two studs of brass, the one at the beginning, and the other at 60 degrees, with little holes for the feet of the compasses, when you take the extent of the radius, to preserve the line from being wounded by the compasses; and being thus fenced, it will for need do the work of a protractor, but not altogether so commodiously.

How to take the true plot of a field by the plain table, upon the paper that covers it, at one or more stations.

There are three ways or methods for doing this work, two more usual and ordinary, the third more unusual and extraordinary, though now pretty well known to most surveyors, and in late books published. The first performs the work by measuring every line from the instrument to every angle, and is a very sure substantial way where it can be done, as it ordinarily may in most closes.

The second doth it by measuring only the station or the distances, and is very quick, but not so sure and exact as the other; yet, if managed by a skilful artist, that knows how to plant his instrument, so as to avoid making acute angles unnecessarily, it will come near enough the matter in many cases; as in measuring for workmen, that take the mowing or reaping of fields by the acre, or when tythes are let at a small value per acre, as in poor barren parishes they usually are.

The third is the way of circulation or perambulation, the instrument being oft to be planted, and the plot to be measured about; by which not only difficult closes, but even the thickest woods, yea, bogs, meres, and pools of water, may be plotted, which by neither of the other methods can be performed.

In all these methods, two things are to be performed.

1. At every angle where there is no perspicuous mark already, as a tree, bush, stile, &c. one must be placed, as a white paper, or such like; or else some one must go from angle to angle, and remain there as your mark to look at, till you bid him remove to another; only when angles are near you, this labour may be spared.

2. Whenever you have occasion to plant your instrument more than once, as it will often fall out in the first method, and ever in the two latter, you must be sure it stand just as it did the first time for situation; for which your needle, if well touched and hung, will be good direction, but is not thought sufficient without backsight and fore-sight. The first method is this.

I. When you go about to plot your parcels of land, find such a place in it, if possible, from whence you can see all the angles, and in that place plant your instrument covered with a sheet of paper, and turning it about till the needle playing at liberty, hang over the flower-de-luce, or any other notable place that you make choice of, screw it fast. Then choosing any convenient place in your paper for a center; and to represent your station, or place where you fix your instrument, make a prick with the small point of your compasses; to which prick applying the fiducial edge of the index, which is easily done if you keep the point of the compasses resting in it, direct the index, by the sight to all the angles; and when through the slit, or long sight, you see the opposite thread, cut the mark in the angle, draw a neat dry line along the fiducial edge, to or from the center; then measuring from the instrument to every angle, set the measure by a scale and compasses from the center towards the angle upon the line that points at it, making a prick in the line where the chains and links reckoned from the center truly end; then shall lines drawn by a strait line from prick to prick, give you the perfect plot upon your paper, which you may divide, as hath been before shewed, into trapezias and triangles, and so find the true content. To make which plain, mark this example.

Fig. 24. Suppose A B C D E F G H to be a field; having planted the plain table, as before directed, at a convenient advantage, so as to see all the angles, as at I, a prick to represent the station in the little circle ⊙ marked with I; upon which laying the fiducial edge of my index, and directing the sights to all the angles, draw dry lines toward A, and all the rest of the angles in order from the center; and then measuring upon the ground from the instrument to the angle A, find it to be 3.45, which set from the center to the point A, and so upon all the rest according to their due measures, and then black lines drawn from point to point, as from A to B, from B to C, &c. limit the true figure of the field according to the scale used, viz. of 400 in an inch.

And now, before we pass to farther varieties, let the reader take notice of these following things.

1. From henceforth we shall forbear to take any notice of the measures of lines measured from the instrument to the several angles, having so often shewed how to measure by a scale.

2. When we speak of measuring from or to the instrument, we always mean from or to that part of ground that

that is perpendicularly under the head of the inftrument, where you are to draw your plot, which will ever be enclofed with the three legs of your ftaff.

3. That it is ufually the quickeft way to meafure firft from the inftrument to the firft angle, and then back from the fecond angle to the inftrument, and fo the reft in order, ftill one from the inftrument, and the other to it.

4. It is no matter at all whether your plain table be placed towards the middle of a field, as was reprefented in this figure, or at an angle, as will appear hereafter.

5. In all workings by this inftrument, you muft have a care that the inftrument be not moved out of its due place, till you have finifhed the work of the prefent ftation; for which purpofe, caft your eye now and then upon your needle, obferving whether it continue to hang directly over the fame point you fet it at when you began your work, and to rectify your inftrument if you fee caufe. But becaufe all tables have not needles, and where needles are, they are not accounted very accurate, make ufe of the following help.

When you have planted your inftrument, and made a point or prick in your paper, reprefenting your ftation, fet the fiducial edge of your index to it, and turning it foftly about till you find one remarkable thing or other upon one fide of the clofe, and another on the oppofite fide, as you look through the fights of your index, which we call fore-fight and back-fight, draw a remarkable line with ink, or rather with a black-lead pen quite over your paper, which in this figure is prefented by the black line K L; and then, if you fufpect that by any accidendal jog, or other cafualty, the inftrument is any thing removed, you may eafily try, and rectify it by applying the fiducial edge to the fame line, and making ufe of fore-fights and back-fights again upon the fame marks which you before obferved upon the oppofite fides of the clofe.

But if there be no convenient place for the placing of your inftrument, whence you may fee all the angles of the field, more ftations muft be made ufe of thus.

Fig. 25. Let A B C D E F G H I K L M N be a field whofe angles cannot be all feen from any one angle, or other place in it. Plant your inftrument at the angle A, and if it have a needle, mark what degree of the chord it cuts, or turn about the table on the head of the ftaff, till the needle hang over fome remarkable place, as fuppofe the flower-de-luce, and fcrew it faft; then fetting up a ftick with a white paper or cloth on the head of it, where you intend your fecond ftation, as here at Q, make a prick or point in your paper, to fignify the point A upon the paper on the table: to which point you muft apply the fiducial edge of the index, and when you fee the white at Q, fo as looking through the flit you fee the thread cut it, draw the line O P quite through the paper with a black-lead pen, and then keeping the fiducial edge ftill upon the fame point, and turning it round by degrees, look at the angles B C D E F L M N, ftill drawing dry lines with the points of your compaffes, and fetting on the meafures from the ftation A, to every angle meafured to or from, as in the laft example.

Then remove the inftrument to the place of your fecond ftation, having fet up a mark at A, and laying the fiducial edge to the line O P, turn about the table upon the head of the ftaff, till through the flit of the back-fight, you fee the thread cutting the mark at A, and then fcrew it faft; fo will the needle, if a good one, hang directly over the fame point that it did at the firft ftation; but however that be, fore-fight and back-fight will do the bufinefs; for which purpofe it is good to take back-marks as well as fore-marks at every ftation, as was taught in the example of a fingle ftation, only taking notice that the back-mark, when the inftrument is planted in an angle, muft needs be out of the field; as fuppofe here at O.

Having meafured the diftance between the firft and fecond ftation, and finding it to be 7, 10, fet it upon the line O P, from A to Q; where make another point to reprefent the fecond ftation, and turning about the index with the fiducial edge upon that point, and fo looking through the fights at the angles G H I K, draw lines towards them on your paper, and having meafured between every one of thofe four angles, and the inftrument, fet thofe meafures, as you did the other, with your fcale and compaffes, from Q towards every angle upon his proper line; and then having the drawn black bounding-lines from A to B, from B to C, and fo round about the clofe, the protraction is finifhed.

But here to make this figure yet more advantageous, remember the following advertifements.

1. Sometimes a ftation is fo taken, that you may meafure towards two angles at once, as here from Q to G and H, in which cafe you are to fet down the chains and links where the firft angle falleth, but ftill be proceeding to the farther angle, caufing the remainder of the chains at the fore-end to advance beyond the former angles; fo going on with whole chains fo far as you can, to which the odd links at the end are to be added.

2. If at any of your ftations, as fuppofe A, you can fee an angle, for example E, to which you cannot meafure in a direct line without paffing the boundaries of your parcel of land given to be meafured; you may notwithftanding take in that angle by a ftrait meafured line, as we have done, provided it may be lawfully done without trefpafs, and conveniently without troublefome paffing of fences, otherwife it muft be taken from another ftation.

3. One of your ftations was here taken at an angle, and the other within the body of the field, to fhew the variety of working taught by other authors, and that it is no great matter where you make your ftations, fo you can fee the angles; elfe it had been full as convenient to have taken the firft ftation alfo within the body of the field, as fuppofe at R.

4. Though this figure reprefents to your eye only two ftations, A and Q, your fancy may multiply them at pleafure; for fuppofe the angle H could not have been feen from A to Q, how eafy had it been to have fet up a mark at S, and then to have removed the inftrument thither, obferving the fame directions that were given at the removal from A to Q?

II. In the fecond method the inftrument is to be planted twice, or oftener, as occafion requires, the rules for removal of the inftrument fore-fight and back-fight, and meafuring the diftance of ftations, being the fame as formerly taught; but inftead of meafuring to and from every angle, we only view each angle through the fights from two ftations, having applied the fiducial edge to the points reprefenting thofe ftations, and having drawn lines with the point of the compaffes, or a protracting-needle, the interfections reprefent the angles, from which the boundary-lines may be drawn; fo is the field protracted. Which that the reader may underftand, let him note thefe three figures.

Fig. 26, 27, 28. In thefe three figures the angles are marked alphabetically, A B C D E F, &c. and the ftations by a fmall point in a fmall circle numbered, 1, 2, or 1, 2, 3, according to their number and order.

Fig. 26. The firft of thefe figures reprefents the plotting of a field at two ftations within it, from both which all the angles may be feen.

Fig. 27. The fecond performs the fame work by two ftations taken without the field, by which art a clofe may be meafured, though the prefent poffeffor will not give us leave to come into it.

Fig. 28. The third fhews how the work may be performed at three ftations or more, when two fuch places cannot be found whence to view all the angles; which laft having more of difficulty than the two former, though indeed not very much, and the explanation of that will fufficiently help to the underftanding of them, we fhall a little explain the meaning of it in thefe particulars.

1. From the firft ftation taken according to the former directions, you fee the angles A B C D F G K, and accordingly draw lines upon your paper towards them from the point reprefenting that ftation, by the fiducial edge of your index with the point of your compaffes.

2. Having removed the inftrument to the fecond ftation, and in fo doing, obferved the rules before given, you will thence fee the angles A B C D E F G H I K, and draw lines upon your paper towards them from the point reprefenting the fecond ftation. And now viewing my work, you find upon your paper interfections for the angles A B, D F, G K, but only fingle lines toward the angles C E H I; therefore,

3. Removing the inſtrument regularly as before, to a third ſtation, you will thence ſee thoſe four angles C E H I, and drawing lines towards them, you will have interſections for them alſo; ſo that having drawn the lines A B B C, &c. from one interſection to another, you have the field perfectly protracted. For theſe bounding-lines from angle to angle, do not only ſignify the boundaries of a piece of land given to be meaſured, limiting the figure or ſhape thereof, and are to that purpoſe given in this and all other ſurvey-books, but alſo are the true diſtance by a ſcale from angle to angle for the plot upon the paper; we mean by the ſame ſcale by which the ſtationary diſtances were laid down upon their own lines. And this holds true in all kind of true plotting, whether in this method or any other.

III. The third method is that of circulation; and this hath ſeveral varieties, according to theſe three following caſes.

1. When the diſtance from angle to angle, without any exception, is meaſured quite round the plot, either within or without.

2. When the diſtance is taken only between ſome more notable angles, and the perpendiculars of the reſt meaſured as you paſs along their baſes, within the plot, proper for plain ſolid ground.

3. When the like is done without the plot, as in caſe of plotting thick woods, meres, pools, bogs, &c.

The firſt of theſe are very eaſy, conſiſting in nothing but planting the inſtrument at every angle, either within or without, as neceſſity and convenience determine it, obſerving the former directions for planting and removing the inſtrument, and alſo for meaſuring the ſtationary lines on the ground, and protracting them on the paper, as is manifeſt in this example.

Fig. 29. Let A B C D E F be a park-pond or cloſe to be protracted, firſt plant your inſtrument at A, and direct the ſights to a mark in the angle B, drawing a dry line from a convenient point on your paper towards B, on the ground, then having meaſured by your chain the diſtance A B, ſet it by a ſcale upon the correſpondent line from A to B, drawing a black line between them with ink or a lead pen, the extremities whereof are the points A and B on the paper, and the little pricked line that goes beyond B, repreſents the remainder of the dry line drawn at random, as to length, with the point of the compaſſes.

Then ſetting up a mark at A, if there was none before, remove your inſtrument to B, and laying the fiducial edge to the line A B, turn about the inſtrument upon the ſtaff, till through the ſight you perceive the thread cutting the mark at A, and the needle directly over the ſame point, that it was when it was planted at A; and ſo ſcrew it faſt.

Your next work is to lay the fiducial edge to the point B, and direct the ſights to C, drawing a dry line towards it, and ſetting the diſtance B C meaſured by the chain from B to C.

In this manner you are to proceed, ſurrounding the cloſe till you come at laſt to A, where you began, by planting the inſtrument at every angle, uſing the help of back-ſight and your needle, as at B, and then from the point repreſenting your preſent ſtation, directing the ſight to the next angle, as you did from B to C.

In the ſecond caſe, we do not plant the inſtrument at every angle, but at the more conſiderable, taking in the ſmaller by their perpendiculars from the baſe as we paſs along; of which the following figure may be an inſtance.

Fig. 30. Let A B C D E F G H I K L be a cloſe to be meaſured; by planting the inſtrument only at A C F and K, we have the main ſubſtance of the cloſe in the trapezium A C F K; and for the five ſmall triangles which muſt be added to the trapezium, they may be eaſily protracted by the help of ſuch a little ſquare as was formerly mentioned; for by finding at how many chains and links diſtance from A upon the ground, the perpendicular B *b* falleth upon the line A C; and having meaſured the length of that perpendicular, and taken in between the compaſs-points of the ſcale, we erect a perpendicular of that length at b, which is the point upon the paper, where ſo many chains and links determine, as were meaſured upon the ground, from the angles A, to the place where the perpendiculars fell on A *c*, viz. at *b*. Juſt in the ſame manner we raiſe the perpendiculars D *d*, and G *g*, I *i*; and then by the help of the perpendiculars, we draw the boundary lines A B, B C, C D, D E, F G, G H, H I, I L, K L, L A: which, together with the line E F between the angles E and F, give the true plot of the field in one large trapezium, and five ſmall triangles ready for caſting up.

The third caſe is like the ſecond, ſo that there needs no new direction concerning it, but to annex one plain diagram; all the difference conſiſting in this, that becauſe we cannot go within it, being ſuppoſed to be ſome pool, bog, or thicket, we muſt of neceſſity go on the out-ſide, and conſequently all the triangles made by inward angles, and their lines upon the meaſured baſes, muſt be excluded, by the boundary-lines, from being any parts of the plot.

Fig. 31. Suppoſing A B C D E F G H I K L M N O P to be a great pool, though here be fifteen angles, plant your table only five times, viz. at A E F H and M, and upon the dry lines A E, F H, H M, and M A, raiſe their perpendiculars in their proper places, and alſo of a right height; by which, and the five ſtationary angles, we may draw the bounding-lines of the plot, excluding all the triangles as foreign to it, they being no reſemblances of any part of the pool, but of land adjacent.

Concerning the plotting of many cloſes together, whether the ground be even or uneven.

Though we do not deſign to make the reader able to ſurvey lordſhips and foreſts, much leſs to draw maps of countries, but to meaſure a parcel of land with truth and judgment; yet we would have him ſo expert, as not to be puzzled, if any ſhould deſire him to draw a true map of a tenement or ſmall demeſne, conſiſting of ſeveral cloſes; for which purpoſe, let him obſerve the following method.

Fig. 32. Suppoſe A B C D E F G H I K L M to be a tenement or ſmall demeſne, divided into fourteen cloſes, to be meaſured and protracted according to their ſeveral ſhapes and ſituation, firſt draw the plot of the whole by the method of circulation, planting your inſtrument either at every angle, or only at the moſt conſiderable either within or without, as you find moſt convenient. This being done, a line from B to M, gives the triangle A B M from the firſt cloſe. In the next place go round the ſecond cloſe beginning at M, then to B, and ſo about to M again: and then for the third cloſe, plant your table at C, and go round to B, the line B C being protracted already, and ſo of all the reſt, ſtill obſerving which are common lines belonging to ſeveral cloſes, repreſenting the fences, that you may avoid the trouble of meaſuring thoſe lines oftener than once, and lay every part of every cloſe in its due place; and be ſure to keep the inſtrument throughout the whole work to its true poſition by needle, fore-ſight, and back-ſight.

There are divers other ways of doing this work, but none more ſure or plain, eſpecially if the ground be uneven; for in that caſe, if you protract according to the length of lines meaſured from your ſtation to the angles, you will put your cloſes into unproportionable ſhapes, except you reduce hypothenuſal lines to horizontal, by inſtruments, or otherwiſe, which is ſomewhat troubleſome; and the like may be ſaid when you plot with the chain only. Indeed the method of meaſuring only the ſtationary diſtances were very proper for ſetting out the figure of each particular cloſe, provided the diſtance of the ſtations be large, and taken, if poſſible, upon pretty even ground, which ſometimes may be done, though moſt of the cloſe be uneven; and the work ſo ordered, as not to make too accute angles; but becauſe this requires ſkill and care, we adviſe the young artiſt to uſe the circling way, as generally moſt commodious.

It is convenient when you plant your table, that the needle hang juſt over the north-point of the compaſs under it in the box; then may you by the lines overthwart the frame of the table, eaſily draw two lines quite thro' the plot, cutting one another at right angles, the one pointing at north and ſouth, and the other at eaſt and weſt. And if you mark the two and thirty points of the compaſs upon the place where they interſect, and draw the forms of the houſes, woods, and other remarkable things upon the demeſne, and the courſe of brooks and rivers running through it, it will add to your commendation.

And

And so it will also, if you take in such parcels of land bounding it, whether common or peculiar to other men, as will make your plot look handsomely, like a perfect square or oblong. But however that be, you must be sure to protract truly all lanes going into it, or through it, and all closes of other men's mixed with it; and also all considerable ponds, ways, and out-lets, with the names of the closes, and quality of the ground, whether meadow, pasture, arable, &c.

Concerning shifting of paper.

In work of this kind, it sometimes happen through the multitude and largeness of fields, that one sheet will not hold your whole plot; in which case you may help yourself by shifting paper, as we call it, thus.

Fig. 33. Let A B C D represent the sheet of paper that covers the table, upon which the plot of the large piece of land E F G H I K should be drawn; having finished your first station at E, and the second at F, and find your paper will not receive the line F G, draw it so far as it will go to the edge of the paper, and planting your table again at E, proceed in your circulation the contrary way to K and I, where you will find yourself again at a loss for your line I H, but draw it also to the edge of the paper; then with the point of your compasses striking the line P O parallel to the edge of the paper B C, and the line Q O parallel to D C, and cutting P O in O, throw it aside for a while, covering the instrument with a new one, which mark with the figure (2) for your second sheet.

Fig. 34. Upon which second sheet, the leading part whereof is represented by the three lines meeting in the angular points, A and B, draw P O parallel to A B, the leading edge of the paper, and crossing it at right angles in the point O, by a parallel to B C, viz. the line O R, being of the same distance from B C, that Q O in the former sheet was from D C; then with a rule and a sharp penknife cut off the end of the first sheet at the line P O, and applying the edge of it to the line P O of the second sheet, so as it may touch that line all along, and the line Q O of the former touch the line O R in the latter, so as to make one line with it, draw the lines P G, being the remainder of the line F G, and the line O H, being the remainder of the line I H, and from their extremities the line G H. And if the plot required it, you might proceed on in the second sheet, and annex a third and a fourth, &c. as there is occasion.

These sheets may be pieced together with mouth-glew or fine paste, applying the edge of the former, as you did upon the table, to the line P O of the latter.

And note here once for all, that when we speak of applying the edge of the paper to a line, we mean the precise edge cut by the line P O; but when we speak of drawing lines to the edge of the paper upon the table, we hope none will think us so absurd as to mean the edge that is concealed under the frame, but that the meaning is, that the lines must be continued on the paper till they touch the frame.

Concerning the plotting of a town-field, where the several lands, butts, or doles, are very crooked: with a note concerning hypothenusal, or sloping boundaries.

Fig. 35. Suppose A B C D E divided, in the manner of a common field, into seven parts or doles, belonging to seven several men: first, plot the whole, as before hath been taught, then measuring from A to B upon the land, note down, as you go along, at how many chains or links, or both, the division is between dole and dole, and accordingly mark them out by the help of scale and compasses in the line A B on the paper-plot. In the very same manner you must measure and mark out the lines O C and E D; which being done, take the paper from the instrument, and laying it before you on a table, with the side A E towards you; the compasses must be so opened and placed, as by a few trials they may, that one foot resting upon the table, the other may pass through the points of division upon all the three lines, viz. A B, O C, and E D, as in this figure they do.

If the content of any one or more of these parts, butts, or doles, be desired without plotting, it may easily be done, without your plain table, thus: take the breadth by your chain at the head, middle, and lower end, and adding these numbers together, the third part of their sum is the equated breadth; by which multiplying the length measured down the ridge, or middle, the product gives the content.

But both in this case, and that mentioned before, the figure of a plot may be somewhat disordered, not only by the unevenness of the ground within, but also by the great declivity of the ground where the boundary lines go, either of the whole plot, or particular parcels. For whereas in plotting, every line is presumed to be horizontal, or level, that it may pass from angle to angle the shortest way, and that every part may be duly situated, and none thrust another out o its right place, if it be not level, but falling down towards a valley, or rising up hill, or compounded of both, a line over such ground, will be false as to the plot, and therefore must be reduced to a level, and so taken off the scale, and protracted. For the doing of this, there are several instruments very proper, especially Mr. Rathburn's quadrant upon the head of his perać‌ter, and divers others. But suppose our country friend to have no other but such as we have already described, we shall shew him a plain easy way much used by practical surveyors.

Fig. 36. Suppose A B C to be a part of a hill falling within your plot, your boundary line going crookedly from A to B, following the surface of the ground. To find the horizontal line, equal to A C, cause one to stand at the point A, the foot of the hill, and to hold up the end of the chain to a convenient height, and gently ascending the hill, you must draw it level, and make a mark where it toucheth the hill, observing the number of links betwixt your assistant's hand, and that place where he must take his second standing, and hold it up as before, and so draw it out level again, till it touch the place where he must take his third standing, noting the links as before, and so proceed, till at last, from his fifth standing, you draw the chain level to the highest point within your plot, viz. the point B. And now as the pricked lines of this figure put together are evidently equal to the line A C, so are the links noted down at every station, when summed up, equal to the horizontal line of that part of the hill.

In the very same manner, only inverting the order, you may find the horizontal lines going down hill, where that is most convenient: and if there be both ascents and descents in one line betwixt two angles, the horizontal lines of both must be found and joined together in protraction.

All this concerning declivities of rising or falling ground, is to be understood when they are considerable, and a very exact plot required; for small ones, especially when much exactness is not expected, are not regardable.

Concerning plotting a piece of ground by the degrees upon the frame of the plain table several ways, and protracting the same.

Hitherto we have shewn the use of the plain table as such, and our directions have been near as plain as the instrument itself. We will now shew how the plot of a field may be taken by the degrees on the frame by two methods, whereof the one is proper for an ordinary close, where all the angles may be seen from one station within it, the other fitting any parcel of land, though much larger, whatever be the figure of it.

For the former, take this example.

Fig. 37. Let A B C D E represent the figure of a field to be plotted by the plain table in rainy weather, put on the frame without a paper, the graduated side upwards, and plant it in some convenient place, whence you can see all the angles, as at O; then placing the index upon the table, so as the fiducial edge may, at the same time, go through the center upon the table, and the lines upon the frame of the table cutting it perpendicularly at 360, where the degrees begin and end, and 180, the exact half, turn about the table upon the staff-head, till through the sights, the side marked with 180 being next your eye, see the angle

gle A, and then ſcrew it faſt, obſerving where the needle cutteth, and by back ſight cauſing a mark to be ſet up in the line C D at the point F, that the inſtrument may be kept firm from moving, or be rectified if it be moved, during the work. And now the line A O F paſſing upon the land from the angle A, directly under the ſights of the inſtrument to the mark at F, is, as it were, the prime diameter whence the degrees of the angles are to be numbered, and accordingly you muſt mark the angle A in the table hereafter to be exemplified with 360 degrees. Then turning the index with the fiducial edge upon the center, till you ſee the thread cutting the mark at B, the ſaid edge will cut upon the frame at 76 deg. 15 min. which note down for that angle. The like muſt be done, turning the ſights to C D and D, but not to F, for there is no angle, but only a mark in the boundary, and you will find the index to cut for every angle as we have marked them within the pricked circle of the laſt figure, viz. 157 deg. 35 min. for C, 225 deg. 20 min. for D, and 278 deg. and 50 min. for E.

Then meaſure, or cauſe to be ſtrictly meaſured by others, the diſtances betwixt the place where the inſtrument ſtands, and every angle, and you will find them to be as ſet down upon the pricked lines in the little circle, viz. A 4 chains 20 links, B 4 chains 3 links, C 3 chains 84 links, D 5 chains 35 links, E 5 chains 6 links. And now your table both for lines and angles is thus perfected, and the work is ready for protraction within doors.

	D	M	C	L
A	360	00	4	20
B	76	15	4	03
C	157	35	3	84
D	225	20	5	35
E	278	50	6	06

Your judgment will eaſily inform you, that in ſuch weather we ſhall hardly ſtand to make our table neat and formal, but any thing, how rude ſoever, that we can underſtand, doth the feat. A Welſh ſlate with a ſharp ſtile, or for want thereof, a black-lead pen, and a ſmooth end of an hard board like a trencher, is more convenient at ſuch a ſeaſon, than pen, ink, and paper. But of all, we would commend for expedition a red-lead pen, whereby you may mark out every angle neatly with one touch upon the table itſelf, juſt where it toucheth the frame by help of the fiducial edge, and cloſe by it the length of the line from the center to that angle: all which may be eaſily cleared off by a wet ſpunge or cloth ſo ſoon as you have protracted.

Fig. 37. Now to protract our obſervation; draw upon a paper the line A F at adventure, ſo it be long enough, and ſtick a pin in it at pleaſure for the center O, upon which place the center of the protractor, ſo as the ſtraight ſide may juſt lie upon the line A F, the limb or arch-ſide being upwards towards B; by help whereof make a prick or point on the paper 76 degrees 15 minutes for B, and at 157 degrees 35 minutes for C, according to the number neareſt to the limb.

Then turning the protractor about on the pin with the arch or limb down towards D and E, till the diameter lie again juſt upon the line A F, number downwards from the right hand towards the left, by that rank of figures that are nearer to the center, beginning 190, 200, &c. and over againſt the places where 225 degrees 20 minutes and 278 degrees 50 minutes fall, prick the paper at the ſide of the limb, and through thoſe four points draw ſo many ſeveral lines, upon which, and alſo upon the line A O, mark out by points the true meaſure of every line, by a ſcale, from the center, and from thoſe points drawing the lines A B, B C, C D, D E, and E A, you have the true plot of the field.

Having proceeded in the field as before, and made your table for lines and angles, or done that which is equivalent by a red-lead pen, draw the line A F, and having extended the compaſſes to the radius, or 60 degrees, on a line of chords, ſet one foot towards the middle of the line A F, and with the other deſcribe a circle like that in this figure of a five angled field, but much larger, according to the length of the radius: then extending the compaſſes from the beginning of the line, to 76 degrees 15 minutes, ſet one foot in the interſection of the circle by the line A, and with the other foot make a mark in the circumference of the circle upwards, towards the right hand, and through it draw the dry line B O.

In the next place ſubſtract the angle 76. 15 from 157. 35, where the index cut for the angle C, and there remains 81 degrees 20 minutes, which take off the line as before, and ſet it upon the circumference from the interſection by B O, toward the end of the diameter marked with F, and through the point where it falls, draw the dry line C O.

In like manner ſubſtract 157 degrees 35 minutes from 225 degrees 20 minutes, and the difference is 67 degrees 45 minutes, which ſet from the interſection by the line C O, downwards paſt the prime diameter A F, and through the point where it falleth, draw the line D O.

Laſtly, having ſubſtracted 225 degrees 20 minutes from 278 degrees 50 minutes, there remains 53 degrees 30 minutes, which muſt be ſet downward towards the left-hand from the interſection by D O; and through the point where that falleth, draw the line E O. And now having ſet the particular meaſures upon every line, and drawn the boundary lines, as you muſt have done if you had uſed a protractor, the plot is finiſhed.

But for better aſſurance that you have done your work well, take the meaſure of the remaining angle A O E upon its proper arch, viz. from the interſection of the circumference by A F, to the interſection by E O, and applying it to the line of chords, you will find it to be 81 degrees 10 minutes, as it ought to be, for it ſhould be the complement of 276 degrees 50 minutes to 360.

And for farther ſatisfaction, ſum up the degrees and minutes of all the five angles, which for plainneſs-ſake we have noted in every one of them on the out-ſide of the circle in the figure ſo often referred to, and their ſum is 360, as it ought to be.

76. 15
81. 20
67. 45
53. 30
81. 10
360.000

The reader may now expect that we ſhould teach him how to take a plot at two or more ſtations, when all the angles cannot be ſeen from one: but becauſe this is ſo eaſy from the principles already laid, to any that is ingenious, and in part rendered unneceſſary by the method preſently following, we ſhall only give this general hint.

When you have from one ſtation taken in all the angles you can ſee from thence, and then are to remove to your ſecond ſtation, do juſt as you would do if the table were covered with a paper; only it is at your choice, whether you would guide your ſelf for back-ſight by a line that may be rubbed off, drawn upon the table itſelf, from the center to the degrees, on the frame along the fiducial edge, or by noting only what degrees it cuts on either ſide of the center, the edge paſſing through it, that by the help thereof and the needle, the inſtrument may be placed in the ſame line and ſituation as before, for taking in the reſt of the angles, if it can be; if not, another ſtation muſt be taken after the ſame manner.

Fig. 38. Let A B C D E be the figure of a field to be plotted, the weather being bad; ſend your aſſiſtants to find the length of every ſide, beginning at A, who return you ſuch an account of every ſide, in chains and links, as are noted upon the figure, and in the table following, viz. A B 3 chains 73 links, B C 4 chains 91 links, &c. In the mean time you are to find the angles; in order to which plant the inſtrument at B, and laying the index on the center look at C, and find the index cutting 10 degrees 15 minutes, and looking at A, it cuts 126 degrees 45 minutes; out of which if you ſubſtract 10 degrees 15 minutes, there remains 116 degrees 30 minutes for the angle A; but becauſe it will not be ſo convenient to ſubſtract there, you may ſet them down thus:

$B\begin{matrix}A & 126.\ 45\\ C & 10.\ 15\end{matrix}$ the meaning whereof is, that B notes the angle, and C A the lines meeting there, cutting ſuch degrees on the frame; and the reaſon why A is ſet above, is for more ready ſubſtracting afterwards; then removing to the angle C, and thence looking at B and D, you will find the index to cut as is here expreſſed, $C\begin{matrix}B & 153.\ 10.\\ D & 15.\ 40.\end{matrix}$

In like manner at D thus, $D\begin{matrix}C & 96.\ 05\\ E & 28.\ 50\end{matrix}$

At E thus, $E\begin{matrix}D & 141.\ 20.\\ A & 11.\ 45.\end{matrix}$

And

And laſtly, at A thus, A $\begin{matrix} E & 98.\ 30 \\ B. & 9.\ 20 \end{matrix}$

An.	D	M	Side.	Ch.	L.
A	89	10	A B	3	73
B	116	30	B C	1	91
C	137	30	C D	4	88
D	67	15	D E	9	64
E	129	35	E F	2	29

This being done, you may retire under covert, and by ſubſtraction find 116 degrees 30 minutes for the angle B, 137 degrees 30 minutes for C, 67 degrees 15 minutes for D, 129 degrees 35 minutes for E, and 89 degrees 10 minutes for A, as you will find them on the figure, and in this table, together with the length of the lines.

Note, that there is a way to find the angles without ſubſtraction, if at every ſtation you lay the fiducial edge over the center, and the diviſions 180 and 360, turning about the head of the inſtrument upon the ſtaff, till through the ſights you ſee one of the neighbouring angles, for the index turned upon the center to the other angle, will give you the quantity of the angle you are at, but this exact planting at every angle is more tedious than the other, and therefore not ſo fit for wet weather. But now to protract this plot:

Firſt, by your ſcale, rule, and compaſſes, draw the line A B in length 3 chains 73 links, ending at the point B; then laying the center of my protractor upon the line A B, ſo as the center of it be upon the point A, and that end of the diameter from which the numbers are reckoned on the arch or limb towards B, make a point for the angle A at 89 degrees 10 minutes, by the direction whereof, and the point A, draw the line A E, which according to your ſcale, muſt be 2 chains 29 links.

In like manner placing the diameter upon A E, juſt as it was upon A B, and the center upon the point E, mark out by the limb, for the angle E, 129 degrees 20 minutes, by which draw the line E D, 6 chains 64 links.

In the next place, bring the center of the protractor to the point D, its diameter lying on the line E D, and its limb towards A, by which prick out 67 degrees 15 minutes for the angle at D, and draw the line 1 chain 88 links.

Laſtly, the center being at C, and the diameter upon the line D C, in ſuch manner as before at other angles, prick out by the limb or arch 137 degrees 30 minutes, and draw the line C B, for at B your plot ſhould cloſe; and if rightly done, the angle at B will be 116 degrees 30 minutes, and the ſide B C 4 chains 91 links, which you will find it to be by meaſure.

But if you plot by a line of chords, you are not bound to this order, but may go from A to B, and ſo round that way if you pleaſe, which you could not ſo well do with a protractor, without reckoning the numbers backward, yet it muſt be granted that a line of chords neither doth the work ſo quickly nor conveniently: this is the way.

When you have drawn the line A B of a proper length, ſet the compaſſes to the radius, and placing one foot of the compaſſes in the point B, and with the other deſcribe an arch of a competent length, beginning at that ſide of the line A B that is deſigned not to be the inward ſide, and upon this arch, 116 degrees 30 minutes muſt be ſet; but becauſe the line of chords gives only 90, ſet them firſt on from the line A B, and then take off the remainder 26 degrees 30 minutes, joining them to the 90 upon the arch, making a point, through which the line B muſt be drawn of a due length. In the like manner you muſt do at C E, but the angles at A and D need no ſuch piecing, being capable of being meaſured out by a line of chords at once.

Nor do your angles only give you trouble in this kind of work, but your lines alſo will be often found too ſhort to receive the touch of an arch upon the radius, eſpecially if the line of chords be large, and your ſcale little; and ſo it may often fall out when you uſe the protractor upon ſuch ſhort lines as A E and C D of this laſt figure: in which caſe a rule muſt be applied to them, and they muſt be extended to a due length, that the arches may meet them without the figure. And if thoſe extenſions of lines, and deſcribing of arches, ſpoil the beauty of your plot, the matter is not great, it is ſo eaſy to be retrieved; for if you lay on a clean paper, and prick through every angle, lines drawn between thoſe points, will give you the plot neat and perfect.

The artiſt ſometimes loſeth his labour of protraction through ſome error in the field, ſo that his plot will not cloſe; it is therefore proper to know, before you begin that work, whether it will or no; for which purpoſe if we take a number leſs by two than the number of angles in the plot, and thereby multiply 180, that product being found to be equal to all the angles, the plot will cloſe, this appears by our plot in the preſent work; the multiplier being 3, becauſe the angles are 5, and the multiplier muſt be two leſs than the number of angles.

	Deg. Min.
180	89 . 10
3	116 . 30
——	137 . 30
540	67 . 15
	129 . 35
	——
	540

This kind of trial is grounded upon two principles of Euclid and Ramus, mentioned in the beginning of this article, ſhewing that in all plain triangles, all the angles taken together are equal to two right angles, and that the ſides, conſequently the angle alſo, of every triangle figure, are more by two than the triangles of which it conſiſteth.

Concerning taking inacceſſible diſtances by the plain table, and acceſſible altitudes by the protractor.

Fig. 39. The ſubſtance of what is to be ſaid for the firſt of theſe, is gathered from the inſtructions given for plotting a field, by meaſuring only the ſtationary diſtance; but to make the caſe more plain to an ordinary capacity, ſuppoſe the line A C to be the unknown breadth of a river, over which a bridge of boats is to be laid, and the general, that he may inform himſelf what ſtore of boats and planks is neceſſary to be brought down, commands you to tell him the true diſtance from A, where he is at preſent, to C, a little boat-houſe on the other ſide the water.

To ſatiſfy his demand, plant your table covered with a paper at A, cauſing one to ſet up a mark at B, at a good diſtance from you, along the bank of the river, the farther the better, if diſtance do not hinder ſight: then having choſen a point to repreſent A, and laid the fiducial edge upon it, direct your ſights towards C and B, and ſtrike lines towards them. Which done, ſet up a mark at A, and from thence meaſure to B, 6 chains 32 links, and ſo plant your inſtrument at B, laying the fiducial edge to the line A B, and turning about the head of the inſtrument upon the ſtaff, till through the ſights you ſee the mark at A, and then ſcrew it faſt.

In the laſt place take 6 chains 32 links off your ſcale, and ſet it on the line A B, from A to B, and laying the fiducial edge to the point B, from thence direct the ſights to C, and draw the line B C, meeting or cutting the line A C in C: ſo ſhall the ſpace A C meaſured on the ſcales viz. 8 chains 29 links, be the diſtance deſired, and becauſe the chain is 22 yards long, if you multiply 8.29 by 22, the product is 182 yards and $\frac{38}{100}$ of a yard, which by reduction is ſome little more than 13 inches and $\frac{1}{2}$ of an inch.

Now, to take the height of a tree, tower, or ſteeple by a protractor, without any arithmetical operation, hang a plummet with a fine ſilk thread at the center of it, and hold it ſtedfaſtly with that end to your eye, where the numbers begin, then look ſtrait along the diameter, ſtill removing backward and forward as there is occaſion, till you ſee the top of the tree, tower, or ſteeple, and the thread at the ſame time fall upon 45 degrees, ſo ſhall the diſtance from your eye to the tree, tower, or ſteeple, meaſured in an horizontal or level line, together with the height of your eye above the bottom of it, be equal to the height of the object.

If either for convenience of ſight, or any other reaſon, you think proper to ſet the other end of the diameter to your eye, then the thread for the above trial muſt fall upon 135 deg. inſtead of 45.

Of casting up the content of land by a table.

4375	0	07
3750	0	06
3125	0	05
2500	0	04
1875	0	03
1250	0	02
625	0	01

This table consists of three columns, the first containing links, the second roods, or quarters of acres, the third perches; and the use of it is thus:

```
  7.25
  5.50
———————
 36250
 3625
 3625
———————
3.98750
```

Suppose a field to be 7 chains and 25 links long, and five chains 50 links broad, these by multiplication make 398750, whereof 5 figures being cut off towards the right hand, the figure 3 signifies acres, and the rest, viz. 98750 denote parts; and to reduce them into roods and perches, first substract from 98750 the greatest number of links in the table that can be substracted from it viz. 90000, and put down for it 3 roods 24 perches, which you find over against it in the annexed columns, and the remain being 8750, look in the table, and find over against it 14 perches, which by addition makes 3 roods 38 perches; so is the whole content of the field 3 acres, 3 roods, 38 perches.

```
A R P
—————
3 3 24
    14
—————
3 3 38
```

But note here, that if the remainder after the first substraction cannot be found in the table, you may take the nearest to it, so the error will be but part of a perch.

As for example.

7.35 being the half perpendicular, and 9.23 the base, give for their product 6.78405. The 6 signifies acres, and from the rest 70000 being subducted, to which 2 roods 32 perches answer, there resteth 8405; which, because you cannot find in the table, you must take the nearest, which is 8125, to which 13 perches answer; so the whole content of that triangular close, is 6 acres, 3 roods, and 5 square perches, and a little better.

```

```

SUSSINGLE, or *Surcingle*, the girt which comes over the saddle, and binds it firmly to the horse.

SWAMP, a hollow, watery place, in any part of a field; a bog. *See* BOG.

SWANG, a fresh piece of green sward lying in a bottom among arable or barren land.

SWARD, the surface of the ground.

SWARM, a large number of bees, seeking a proper settlement. *See the article* BEE.

SWATH, or *Swarth*, a line of grass, &c. cut down by the mower.

SWATH-BAUK, a swarth, or line of new mown grass or corn.

SWATH-RAKE, a rake about two yards long, with iron teeth, and a bearer in the middle, to which a man fixes himself with a belt, and when he has gathered as much as his rake will hold, he raises it and begins again. This instrument is in some counties called a dow-rake, and much used in Essex for gathering barley after mowing.

To SWEAL, to singe, or burn off the hair, &c.

SWILL, a vessel to wash in standing on three feet.

SWINE. *See the article* HOG.

SWINE-CRUE, a hog's-sty.

SWINE-HERD, a keeper of swine.

SWINHULL, a hog's-sty.

SYCAMORE, the name of a tree well known in many parts of England. It grows to a large size; the wood is soft and very white, and therefore valued by the turners; but is not esteemed very valuable for other purposes. However, as this tree will thrive better than most other sorts near the sea, it is frequently cultivated to screen plantations of other sorts of trees from the spray of the sea.

SYTHE. *See* SCYTHE.

T.

TABERN, a cellar.

TAGGE, a ſheep of the firſt year.

TAIL-SOAKED, a diſeaſe incident to cows, by which the joint of the tail near the rump, will, as it were, rot away. The cure is generally performed by cutting a deep gaſh into the part affected, then rubbing a handful of ſalt into the wound, and binding it up with a rag. Others mix ſoot and a clove of garlick with the ſalt.

TAN, the bark of oak, chopped and ground by a tanning mill into a coarſe powder, to be uſed in the tanning or dreſſing ſkins.

Tan is of great uſe in gardening: firſt, by its fermentation, when laid in a body, which is always moderate and of a long duration, which renders it of great ſervice to hot-beds: and, ſecondly, after it is well rotted, it becomes excellent manure for all ſorts of cold ſtiff land; upon which one load of tan is better than two of rotten dung, and will continue longer in the ground.

The uſe of tan for hot-beds has not been many years known in England; the firſt hot-beds of this ſort, which were made in England, were at Blackheath, in Kent, about fifty-five years ago: theſe were deſigned for raiſing of orange-trees; but, the uſe of theſe hot-beds being but little known at that time, they were made but by two or three perſons, who had learned the uſe of them in Holland and Flanders, where the gardeners ſeldom made any other hot-beds: but in England there were very few hot-beds made of tanner's bark, before the ananas were introduced into this country, which was in 1719, ſince which time the uſe of theſe hot-beds have been more general; and are now made in all thoſe gardens, where the ananas plants are cultivated, or where there are collections of tender exotic plants preſerved: and the gardeners here are now better ſkilled in making and managing of theſe hot-beds, than in moſt other countries; which might render it leſs neceſſary to give a full deſcription of them here: but, yet, as there may be ſome perſons in the remote parts of England, who have not had an opportunity of informing themſelves of the uſe of tanners bark for this purpoſe, I ſhall inſert the ſhorteſt and plaineſt method of making and managing theſe hot-beds, as they are practiſed by the moſt knowing perſons, who have long made uſe of theſe hot-beds: and, firſt, I ſhall begin with the choice of the tan.

The tanners in ſome parts of England do not grind the bark to reduce it into ſmall pieces, as is commonly practiſed by the tanners near London; where there is great difference in the ſize of the bark, ſome being ground much ſmaller than the other, according to the different purpoſes for which it is intended; but in many places the bark is only chopped into large pieces, which renders it very different for the uſe of hot-beds; for, if the tan is very coarſe, it will require a longer time to ferment, than the ſmall tan; but, when it begins to heat, it will require a much greater degree, and will retain the heat a much longer time than the ſmall; therefore, where there is choice, the middling-ſize tan ſhould be preferred; for it is very difficult to manage an hot-bed when made of the largeſt tan: the heat of which is often ſo great, as to ſcald the roots of plants, if the pots are fully plunged into the bed; and I have known this violent heat continue upwards of two months; ſo that it has been unſafe to plunge the pots more than half their depth into the tan, till near three months after the beds have been made: therefore, where the perſons, who have the care of theſe beds, do not diligently obſerve their working, they may in a ſhort time deſtroy the plants which are placed in the beds: on the other hand, if the tan is very ſmall, it will not retain the heat above a month, or five weeks; and will be rotten and unfit for an hot-bed in a ſhort time; ſo that, where the middle-ſized tan can be procured, it ſhould always be preferred to any other.

The tan ſhould be always ſuch as has been newly taken out of the pits; for if it lies long in the tanner's yard, before it is uſed, the beds ſeldom acquire a proper degree of heat; nor do they continue their heat long: ſo that when it has been more than a fortnight or three weeks out of the pit, it is not ſo good for uſe as that which is new. If the tan is very wet it will be proper to ſpread it abroad for two or three days to drain out the moiſture, eſpecially if it is in the autumn or winter ſeaſon; becauſe, then, as there will be little ſun to draw a warmth into the tan, the moiſture will prevent the fermentation, and the beds will remain cold: but, in the ſummer-ſeaſon, there is no great danger from the moiſture of the tan; the heat of the ſun through the glaſſes will be then ſo great, as ſoon to cauſe a fermentation in the tan.

Theſe tan-beds ſhould always be made in pits, having brick walls round them, and a brick pavement at the bottom, to prevent the earth from mixing with the tan; which will prevent the tan from heating; theſe pits muſt not be leſs than three feet deep, and ſix feet in width; the length muſt be in proportion to the number of plants they are to contain: but if they are not ten feet in length, they will not retain their heat long: for, where there is not a good body of tan, the out-ſide of the bed will ſoon loſe its heat; ſo that the plants which are there plunged will have no benefit of the heat; nor will the middle of theſe beds retain their heat long; ſo that they will not anſwer the purpoſe for which they are intended.

When the tan is put into the bed, it muſt not be beaten or trodden down too cloſe; for that will cauſe it to adhere, and form one ſolid lump; ſo that it will not acquire an heat; nor ſhould it be trodden down at the time when the pots are plunged into the beds; to avoid which there ſhould be a board laid croſs the bed, which ſhould be ſupported at each end to prevent its reſting on the tan; upon which the perſon ſhould ſtand, who plunges the pots; ſo that the tan will not be preſſed down too cloſe. When the tan is quite freſh, and has not been out of the pits long enough to acquire an heat, then the beds will require a fortnight or three weeks time, or ſometimes a month, before they will be of a proper temperature of warmth to receive the plants: but, in order to judge of this, there ſhould be three or four ſticks thruſt down into the tan, about eighteen inches deep, in different parts of the bed; ſo that by drawing out the ſticks, and feeling them at different depths, it will be eaſy to judge of the temper of the beds; and it will be proper to let a few of theſe ſticks remain in the bed, after the plants are plunged, in order to know the

the warmth of the tan; which may be better judged of by feeling these sticks, than by drawing out the pots, or plunging the hand in the tan.

When the tan is good, one of these beds will retain a proper degree of heat for near three months; and when the heat declines, if the tan is forked up, and turned over, and some new tan added to it, the heat will renew again, and will continue two months longer: so that by turning over the tan, and adding some new tan every two months, or thereabout, as the bed is found to decline of its heat, they may be continued one year: but every autumn it will be proper to take out a good quantity of the old tan, and to add as much new to the bed, that the heat of the bed may be kept up in winter; for, if the heat is suffered to decline too much during the cold season, the plants will suffer greatly: to prevent this, there should always be some new tan added to the bed in winter, when the heat is found to decline; but the tan should be laid in a dry place, a week or ten days, to dry, before it is put into the bed; otherwise the moisture will chill the old tan in the bed, and prevent the fermentation: so that unless the tan is turned over again, there will be little or no heat in the beds: which often proves fatal to the plants which are plunged into them: therefore, whoever has the management of these beds, should be very careful to observe constantly the warmth of the tan; since, upon keeping the beds in a due temperature of warmth, the whole success depends; and, where this caution is not taken, it frequently happens, that the ananas plants run into fruit very small, or the plants are infested by insects; both which are occasioned by the growth of the plants being stopped by the decline of the heat of the tan; therefore great regard must be had to that, especially in winter.

The great advantages which these tan-beds have of those which are made of horse-dung, are, the moderate heat which they acquire; for their heat is never so violent as those of horse dung; and they continue this heat much longer; and, when the heat declines, it may be renewed, by turning the beds over, and mixing some new tan with the old, which cannot be so well done with horse-dung; and likewise the beds will not produce so great steams, which are often injurious to tender plants; so that these tan-beds are much preferable to those of horse-dung for most purposes. *Miller's Gard. Dict.*

Tan, when it is well rotted, is also an excellet manure for all cold and stiff lands: and if it is laid upon grass-ground in autumn, that the rains in winter may wash it into the ground, it will greatly improve the grass; but when it is used new, or in the spring of the year, when dry weather comes, it is apt to cause the grass to burn; which has occasioned the disuse of tan in many places; but, if properly used, it will be found an excellent dressing for all stiff lands. *See the article* BARK.

TANSEY, the name of a plant often cultivated in kitchen gardens, and of which there are three varieties, that have all been produced accidentally from the seeds of the common tansey. All the varieties are easily propagated by the creeping roots, which, if allowed to remain undisturbed, will overspread the ground where they are permitted to grow; so that wherever tansey is planted in a garden, the slips should be placed two feet asunder, and in particular beds, where the paths round them may be often dug, to keep their roots within bounds. They may be transplanted either in spring or autumn, and will thrive in almost any soil or situation.

Wild TANSEY. *See the article* SILVER-WEED.

TARES. *See the article* VETCHES.

TEAM, a number of horses or oxen drawing at once the same carriage.

To TEAM, to pour or lade out of one vessel into another.

TEAZLE, or *Fuller's Thistle*, a species of the thistle cultivated for the use of clothiers, who dress their cloth with them.

The teazle is propagated by sowing the seeds in March, upon a dry soil. About one peck of the seed will sow an acre; for the plants should have room to grow; otherwise the heads will not be so large, nor in so great quantity. When the plants are come up, you must hoe them in the same manner as is practised for turneps, cutting down all the weeds, and singling out the plants to about six or eight inches distance; and as the plants advance, and the weeds grow again, you must hoe them a second time, cutting out the plants to a wider distance; for they should be, at last, left at least a foot asunder; and you should be particularly careful to clear them from weeds, especially the first summer; for when the plants have spread so as to cover the surface of the ground, the weeds will not so readily grow between them. The second year after sowing, the plants will shoot up heads, which will be fit to cut about the beginning of August; at which time they should be cut and tied up in bunches, setting them in the sun, if the weather be fair; but if not, they must be set in rooms, to dry. The common produce is about an hundred and sixty bundles, or staves, upon an acre, and they will sell for about one shilling a stave. *Miller's Gard. Dict.*

M. de Chateauvieux extended the new husbandry even to the culture of the teazle, or fuller's thistle, which grew to a surprizing height, and produced an extraordinary number of the finest and best heads that the fullers in his country had ever seen.

" I am well informed, says an ingenious correspondent of the editors of the Museum Rusticum, that the principal place in the kingdom for the cultivation of the teazle, is about Wrington in Somersetshire, many of the inhabitants of that, and the neighbouring parishes, being chiefly employed therein; and from these places the cloth manufactories in the counties of Gloucester, Somerset, and Wilts, are supplied, and even a great many packs carried annually into Yorkshire.

" The land most suitable for this plant is that of a thin, sweet surface, and marly bottom, though a clay or stone-trash bottom will do, and produce large crops: rich loam, or strong clay, is very improper, as on them the plant is apt to grow luxuriant, and thereby cause the heads to be large and coarse-hooked, and, in a moist summer, subject to mildew and rot before they blossom and are fit to cut.

" As to situation, a southern aspect, on the decline of a hill, is to be preferred, though any other will do; but upland ground is to be most esteemed, more especially in an enclosed country, that the wind may assist in carrying off the natural humidity of the plant in moist seasons, which sometimes, in low and small enclosures, is retained so long as to cause the heads to taint, and become rotten.

" Having made choice of a piece of ground, (an old lay is preferable) in February cause it to be ploughed in ridges of three bouts each, at a depth suitable for a crop of beans, taking care that the furrows be laid strait, and as even as may be; the middle of the ridge highest, and a flesh furrow ploughed in the furrow between each ridge; after which let a man go along each ridge, and with a mattock, hoe, or spade, raise earth in small clods, at suitable distances from each other, to produce earth, when meliorated, to heal or cover the seed.

" Having done thus much, let it remain as it is until the time for sowing the seed, which will be about a week or ten days in April, as then the earth is generally moistened with rain.

" At this time cause a middle-sized harrow to be drawn over the land once or twice in a place, to fill the crevices between each furrow, and level the surface; after which sow the seed broad-cast, in the proportion of two bushels on an acre; then harrow it in, the same as turnep seed, and let it remain until the plants are come up, and grown into six or eight leaves each; when some person or persons should go over the field with a hoe, and cut out the plants, where they are too thick, to the size of about two feet from each other every way, if the ground be in heart; if it be thin poor land, sixteen or eighteen inches distance is sufficient.

" After this they may remain until the latter end of August, when they must be gone over as before, with this difference, the person should have a spade made about four inches broad, and eighteen inches long in the bit, or pan, with a tree in it of three feet six inches long: with this tool the workman must go backward, and turn the whole surface over, about two inches deep, in long spits, turning the spade from the plant, to turn the spit so as no earth may fall into the heart of the plant: but it would be adviſeable, at the time of firſt ſizing the plants, to leave more than are neceſſary to ſtock the ground, to have ſome to fill up the vacancies where any may happen to die, which is often the caſe during the ſucceeding winter, and more eſpecially ſhould it prove froſty.

" Having done thus much, in this ſtate they are to remain during the winter; only care muſt be taken that no cattle get into the field, eſpecially ſheep, which will eat out the cabbage of the plant, and ſpoil it.

" About the latter end of the ſucceeding February, the plants ſhould be digged between as in Auguſt, being very careful that none of the earth falls into the middle of them; and in May, when the plants begin to ſhoot into ſpindle, the ground muſt be digged over again, with this difference, inſtead of being laid plain, it muſt be raiſed into ſmall hillocks about each plant, to ſtrengthen them in the ground, ſo that the wind may not blow them down when loaded with heads.

" This being done, they are left till the ſeaſon for cutting, which will be a work of ſome time, as the heads become fit, which is known by their blowing: it is to be obſerved that the bloſſom firſt appears near the bottom of the head in ſmall, pale, blue flowers; and when theſe appear to have blown ſomewhat more than half way up, ſuch head is fit for cutting, which is generally done in this manner; a man has a knife, the blade about two inches long, with a ſtring in the haft to put over the hand, and a pair of ſtrong gloves to defend him againſt the ſharp prickles on the ſtalks.

" Being thus equipped, he muſt go along each furrow, and cut with one hand, putting them into the other, till he has as many as he can eaſily gripe; when cutting one which is a little more ripe than the others, and the ſtem about eighteen inches long, he binds the handful together with it, (the others are generally cut about nine inches long) which done, the handful is toſſed to ſome open ſpot, in order to be carried to the place for drying, which is done in the following manner.

" Some ſmall poles of aſh, willow, or any ſtrait-growing wood, about the ſize of [illegible]ge-ſtake, and ten or twelve foot long, muſt be pro[illegible] at the great end of which, about eighteen inches [illegible] it, a hole muſt be made, and a peg put through, to extend three or four inches on each ſide. The poles thus prepared, the handfuls of teazels muſt be put on them, by running the ſmall end through the handful, until the pole be filled: in this condition they muſt be ſet on one end to dry; but it is to be obſerved, that they ſhould be carefully carried into a houſe or ſhed every night, and brought out at days; and in the houſe ſet ſo as for the poles not to touch each other, leſt they taint, which, for want of a free circulation of air, they are very ſubject to, and more ſo, if it be cloſe moiſt weather.

" When they are dry, ſo as to be free from moiſture, they may be carried into ſome upper room, and placed up cloſe together: over a cow-houſe, or place where cattle are fed in winter, is to be preferred, becauſe their breath is ſuppoſed to help to brighten them in colour; wherefore they are the better eſteemed, and ſuppoſed to be more tough in hook than otherways they would.

" When they have by this means acquired from the gradual moiſture of the air an additional elaſticity to the hooks, and are brightened in colour, which will be completed a little after Chriſtmas; the time that generally the heads are ſorted, and made out in the following manner. The handfuls are brought from the ſtorehouſe into ſome large room, uſually a barn-floor, where they are untied one at a time; and generally made four ſorts of. The largeſt heads which are found, and are ſuch as grow on the middle ſtem of each branch, are thrown for the firſt ſort, and called kings. The next ſmalleſt which are found, and are commonly ſuch as grow as ſide heads on each branch, are thrown for a ſecond ſort, and are called middlings. Another, or third ſort, are ſuch of the largeſt, or thoſe which grew on the middle ſtem, as are damaged by the mildew, wet, or other accident; and which would have been kings, had not ſuch defect rendered them unworthy that appellation. Theſe therefore are thrown to a third ſort, and denominated ſcrubs. The laſt, or fourth ſort, is the refuſe of all, and are ſuch as are too ſmall, or too much damaged for any uſe; and are therefore thrown away.

" When a quantity is thus ſeparated, they are made out in the following manner: the perſons who do it, put of the kings ten in each handful. Firſt, ſix of the larger, in the manner of a fan extended: and four leſſer of the ſame ſort, in the boſoms of the ſix; and then bind their ſtems together with a ſpleet of willow, or ſome tough wood, by wrapping it about them three or four times, and tucking the end under. When the kings are tied up in handfuls in this manner, a ſtraight ſtick of about three-fourths of an inch diameter, and two feet ſix inches long, is ſplit to within four inches of one end. Twenty-five of theſe handfuls are put on this ſtick, alternately head to ſtem; letting two of the middle ſtems of each handful be in the cleft, to hold them ſecure: then a ſmall wreath, made of ſpleet, is ſlipped on the upper end of the ſtaff, which holds it together, and keeps the whole from falling about. In like manner are the ſcrubs, or third ſort, alſo made out and put in ſtaves. But of the middlings, or ſecond ſort, double the number of heads are put in one handful, by making two fan-like rows of ſix each, and four in their boſoms on each ſide; and theſe are put into ſtaves of three feet long each, ſpilt as the former, and thirty handfuls in each ſtaff. When they are thus made out, they are fit for ſale, and are to be laid by for that purpoſe in ſome convenient place, where they may not be bruiſed. Thirty ſtaves of the firſt and third ſort are accounted a pack; and forty ſtaves of middlings make alſo a pack.

" An acre of land, if well grown, and what is deemed a full crop, often produces nine packs of kings, nineteen of middlings, and two of ſcrubs. The common price per pack of the firſt ſort, is twenty, the ſecond ſort fourteen, and the third ſort eight ſhillings. But in a French war, they are generally double theſe prices.

The expences attending a crop per acre are,

	l.	s.	d.
1ſt, Rent of the ground for the crop, which is one year and a half	5	0	0
2d, Ploughing and ſowing	0	15	0
3d, Firſt dreſſing or delving	1	0	0
4th, Second delving	0	10	0
5th, Hilling	0	15	0
6th, Cutting and carrying home	1	15	0
7th, Tythe	0	5	0
8th, Clearing off the ſtalks, and binding them in bundles	0	5	0
9th, Making out, at two ſhillings per pack, ſpleets, ſtaves, and wreaths included	3	0	0
All which make the total expence, attending one acre of teaſels	13	5	0

" This, excluſive of ſeed, which is not often bought, becauſe enough may be ſaved in making out the crop in winter: but if the ſeed be bought, it is generally valued equally with wheat. Therefore, if two buſhels be ſown on the acre, ten ſhillings may be added as the medium price; which makes the whole expence of one acre thirteen pounds fifteen ſhillings, if it ſhould produce thirty packs. But ſuch produce is not always the caſe, for twenty is to be eſteemed a middling crop.

" With reſpect to crops of corn, raiſed amongſt the plants, it is practiſed in many places; and indeed it has been mine to plant field beans, or garden beans, at about three feet diſtance ſingly from each other, in a promiſcuous manner over the teaſel land: which crop of beans, by the cultivation neceſſary for the teaſel, is greatly forwarded in growth, and often produces from four to five and ſix ſtalks from one bean, well loaded with cods. This crop is no injury to the teaſel crop the firſt year, and frequently pays the expence of labour attending the whole.

" The crop, which generally ſucceeds the teaſel, is wheat. The ground, by being frequently delved and kept clean, during the teaſel crop, becomes very fit for this grain, and generally produces very large crops. Forty buſhels per acre is not uncommon, though the land in itſelf is often ſuch as is not annually worth more than ten ſhillings per acre. Hence, I think, it is evident, that a crop which well ſhades the ground, (in ſummer) and that has been two or three times turned and cleaned from all weeds, before such shading, greatly fertilizes the land on which it grows. But I have frequently observed an error, to which the occupiers of such land are too liable after these fertilising crops. This error is the ploughing away (by over cropping) the profits that would ensue. If after its being thus fertilized by the crops of teasels, it were to be laid down with suitable artificial grass-seed, sown amongst wheat, and properly managed afterwards, it would, I am experimentally sensible, be a lasting improvement." *Museum Rusticum, vol.* III. *pag.* 237, *and vol.* VI. *pag.* 1.

To TED, to spread abroad new mown grass, which is the first thing done in order to its being dried, and made into hay.

TEDDER, *or* TETHER, a rope with which a horse is tied in the field, that he may not pasture too wide.

To TEEM, to be pregnant; to engender young.

TENDRIL, the clasper of a vine, or other climbing plant.

TENEMENT, any thing, as a house, &c. held by a tenant.

TENURE, the manner in which tenants hold their lands, &c. of their lord.

TERRAGON, the name of a spicy plant, often cultivated in kitchen-gardens.

It is propagated by seeds, slips, or cuttings. March or April is the proper time for setting them, and they may be transplanted again in the summer. The plants should stand at least a foot asunder every way, and they should be kept clean from weeds. They will endure great cold; and even extraordinary drought will not hurt them, if they are but a little watered, or if the earth about them is kept loose and well stirred. A very few of their leaves mixed with a sallet, particularly of lettuces, give it a high aromatic flavour. The tenderest and freshest are the best for this purpose.

THATCH, straw laid on the top of a building, rick, &c. to keep out the weather.

THEAVE, *or* THIEF, an ewe of the first year.

THETCHES. *See the article* VETCHES.

THICKET, a close knot, or tuft of trees; a close wood.

THILL-HORSE, *or* THILLER, the last horse in a team; the horse that goes between the thills or shafts.

THISTLE, a well known prickly weed growing in corn-fields.

Where-ever thistles grow naturally, it is a sure sign that the land is strong: but they are, at the same time, a great annoyance to every plant intended to be cultivated. The best way to destroy thistles is to cut them up by the roots before their seeding time, which is in the autumn; for cutting of them too young, will only make them branch the more: or, which Mr. Lisle prefers, to pluck the thistles up by hand, when the ground is reasonably moist, before they are grown to the size at which they are usually cut. They may then be easily drawn up with their roots, by the thumb and two fingers; and the weeder may guard against their prickles by putting on a glove, or false fingers, made of hard leather. Chalking of land is a good way to destroy this very noxious growth: but thorough tillage, summer fallows, and repeated good harrowings, are the most effectual of all.

By an excellent regulation in France, a farmer may sue his neighbour who neglects to thistle his land at the proper seasons, or may employ people to do it at the other's expence. And it were to be wished, that a similar law was enacted here, to prevent the wide-spreading mischiefs occasioned by the seeding of this pernicious weed; among which may be reckoned, besides its choaking the young corn, that if wheat, in particular, be not well thistled, the reapers take up the grips so tenderly, lest they should prick themselves, that, by their loose handling of them, they sometimes leave upon the ground corn enough to sow the whole field.

THISTLING, the action of cutting or pulling up thistles, in order to destroy them.

THRESHING, the action of beating out the corn.

Though the flail be the best instrument yet known for threshing of corn, because it separates the grain from the straw and husks very effectually and expeditiously; yet, as it always bruises a great many seeds, even so as to render them incapable of growing, it were much to be wished that some method could be found, by which this essential inconvenience might be avoided. Some engine or other, provided with a number of flails, or other pieces answering the same end, might surely be made to move by water, wind, or a horse, so as to perform the business of threshing still cheaper and more expeditiously, and with less damage to the health of the husbandman, which is frequently thought to be injured by the dust, &c. which arises in the common way of threshing, as well as by the very great laboriousness of the work. This well deserves the attention and endeavours of skilful mechanics. At all events, the thresher ought not to wear thick iron-clouted shoes whilst he is at work, especially if he is to thresh new corn, and particularly wheat; because they will be apt to bruise it. His shoes for this business should be soled with an old hat, or some other soft substance.

Mr. Mortimer esteems it a day's labour for a man to thresh four bushels of wheat or rye, six bushels of barley, five bushels of oats, or five bushels of beans and peas, if the corn thresh well. But Mr. Lisle says a good thresher assured him that twelve bushels of oats or barley are reckoned a good day's threshing; that this very man had threshed fourteen bushels of oats daily, and winnowed them, for several days together; but that those oats yielded indeed extraordinary well: that five or six bushels of wheat are a very good day's threshing; and if the corn be clung, and yields ill, sometimes three bushels are as much as can be threshed in a day. He rates the common price of threshing at eight-pence for a quarter of corn; and observes, which may account for the difference between his estimate and Mr. Mortimer's, that six bushels of wheat of the growth of a warm gravelly vale are as easily threshed in a day, as four bushels of the produce of cold hilly land; because the stroke of the flail must be forced down stronger to beat out the grain of this last, than it need to be for the former: and also, that as the straw of corn of the growth of a light soil is shorter than that of a strong clayey ground, more sheaves, and consequently more ears of this first sort may be laid together on a floor of equal extent, than can be of the last, whose longer straw requires proportionably more room.

The worse wheat is, though it be never so dry, the rougher it will feel when handled; because thin and coarse wheat is not so plump and globular as fine wheat, but is apt to be pitted and wrinkled, which of course renders it less slippery. It will handle cooler out of a stack two years old, than it will out of one that is only a year old: for in that time the mists and rimes, especially in a hilly country, will be driven into the stack.

Mr. Lisle, who makes this remark, adds, from his own experience, that wheat threshed in damp weather generally yields but little flour, with a great deal of bran, when it is ground; and that if it be put into sacks, it will grow musty in less than three weeks, let the weather be ever so dry afterwards: but if it be threshed when the air is perfectly clear and dry, it will keep well in sacks, for a long time; especially if these are laid upon trestles high enough to secure them from the dampness of the ground or floor.

For the keeping of meal, in general, there is no better way than first to bolt it, and clear it from the bran, which is very apt to corrode and putrify it, and make it musty; then to tread it down as hard as possible, and head it up closely, in clean, dry, tight, and well bound casks, which must be laid in a cool dry place.

The beards of barley come off best, in threshing, when the swarths of this corn have taken the dew before their being housed. It will keep well in the mow, unthreshed, for one year; and for making it into malt, which must be done before the heat of the summer comes on, it should not be kept above a year and a half, or at most two years: otherwise it will be filled with weevils; unless it has been previously cured in a stove or kiln.

Oats, being defended with a double husk, are the grain least subject to harbour vermin. The best way to keep them after they are threshed, is to dry them well on a kiln, and then to barrel them up in clean close casks: but they should not be threshed earlier than Christmas, because they are not fit for keeping before that time.

Beans and peas always thresh best after they have sweated in the mow, which they are very apt to do, because, as the whole crop of either of them never ripens all together, the green parts heat, and communicate their ferment to the whole heap. The danger to be guarded against here is, that the ripe so heated do not give fire to the green, by which both might be either rotted or consumed; to which the bigness of their leaves, and hardness of their stalks, which continue moist and sappy a long time, will also contribute very much. For this reason farmers generally choose to stack them without doors, rather than to house them; that they may be the more thoroughly dried by the sun and air. But the best way of all is to kiln-dry them, or dry them well in the sun; after which they will keep many years, without turning or any other care, though they be laid ever so thick in the granary. As beans are a very large seed, and consequently full of moisture, it is found best to let those that are intended for keeping sweat in the mow till March, when they may be threshed without danger: for beans never give again, after they have once been thoroughly dried.

Peas are, of all grain, the most subject to rottenness and imperfection, because they are the most apt to breed worms, weevils and mites, by reason of the lusciousness and sweetness of their grain. The better they are dried, either in the kiln or sun, the former of which will generally be found most effectual in this country, the longer they will keep sound, and the fitter they will be for the food of cattle, by helping to make them thirsty; it being a just observation, that if cattle drink well, they will feed well. What is intended for the food of men should not be dried too much; because that would make the peas require double the time in boiling: nor need they be threshed for this use, but as they are wanted; or else they may be put into close casks, and headed up. In granaries, they keep best in thick heaps, or in bins; spreading of them thin upon the floor being apt to dry them too soon, and to take from them much of their sweetness and goodness.

Vetches wanted for sowing immediately after they are cut, may be threshed very well on a hurdle, with a cloth; though they may then be too soft, notwithstanding their being ripe, to be threshed on a floor, where the flail, and the thresher's feet, would bruise and break them.

When a careful husbandman opens and spreads his sheaves, he will pick out of them at least all the largest and most apparent weeds, before he begins to thresh. As he proceeds in his work, he will, from time to time, remove all the long straw from the corn beaten out of it, which last always lies underneath, with a prong or fork; and then the pieces of straw, broken ears, &c. with a wooden rake. He will then shovel the remaining grain up on one side of the floor, and repeat this till he has threshed out enough to make what is commonly called a clearing.

This heap is then passed through a wide sieve, which retains only the bits of straw, and such fragments or ends of the ears as have escaped the flail. These frequently contain very good corn; though the farmer seldom grudges giving them to his poultry, or binding them up with straw intended for fodder. A few of them inclosed in a small truss bound at both ends, the better to keep them in, will entice horses to eat heartily of this straw, which affords them good nourishment: and M. Duhamel judges that they would also be excellent and profitable winter-food for sheep, when there is a scarcity of grass.

A great deal of labour may be saved in the using of this sieve, by fastening a loop to its rim, and resting it thereby on a hook suspended by a rope. This will sustain half the weight of the corn, and the winnower may easily give it the necessary circular motion. But a yet more convenient method, is to place a square sieve, of wire is best, with thin boards for its sides, upon two polished rods of iron, to throw the corn up into it with a shovel, and to push it backward and forward upon these rods, on which it moves easily, and will sift a great deal of corn in a short time.

For separating the chaff, which is the next business, the casting-shovel is much more expeditious than either the wicker fan, or the common winnow with sails. When this shovel is used, the wind must blow through the barn, either in at one door and out at the other, or in at a window, and out at the opposite door. The winnower then, placing himself under the wind, and close to the heap of corn that is to be cleansed, takes it up, one shovelful after another, and, with a circular motion, throws it scattered in the air, against the wind, towards the opposite side of the barn. The best grains, which are the heaviest, go farthest; the lesser fall short of them; and the very small, shrivelled, and much damaged, with the seeds of cockle, darnel, and several other weeds, fall still nearer to the man who throws them; while the lighter seeds of other weeds, with the bits of straw, chaff, dust, &c. are blown from all the rest, by the wind. From time to time, the winnower quits his shovel, and sweeps away the second sized corn, which would be too much intermixed with the smallest, if the heap was left alone and suffered to accumulate till the end of the winnowing; and when the whole is done, he shovels up the finest grain. The least of all, which borders on the chaff, &c. is also then collected, and the three sorts, after being sifted or screened, to cleanse them from any remaining dust, are laid up separately; the first for sale, the next for domestic uses, and the third, if the farmer can afford it, chiefly for the food of poultry. The short straws and chaff are sifted in a pretty fine sieve, to clear them likewise of dust, and are frequently given to oxen and cows.

Mr. Lisle observes that the seeds cannot be separated from any grain by the common fan, but that it may be done with the screen; of which he therefore advises the constant use for all sorts of corn designed for sowing.

Though wind is, in all cases, the chief agent in the cleansing of seeds, which being intrinsically heavier than their coats or husks, are, by the same force applied to both, carried to different distances, in proportion to their weight, and thereby consequently separated; yet the natural action of this assistant is liable to many inconveniences: it blows not constantly; but frequently disappoints the winnower in his time of greatest need: when it does blow, it is not always in the best direction to answer the situation of his barn; and without doors it is intirely useless to his purpose, if it be not attended with fair weather. Besides, when its force can be applied in the best way, it is even then not equal; but generally acts by sudden blasts, which, as is well known, disorders the whole work, and occasions a considerable waste of seed.

The Dutch avoid these inconveniencies by using a machine (Plate XXVI. Fig. 1.) which creates an artificial wind, uniform and steady in its action, and always ready at command.

The fan, (Fig. 2.) which is the acting part of this engine, produces a wind proportioned to the velocity with which it is turned on its axis, and therefore capable of several degrees of strength, as best suits the purpose of the winnower.

This fan is inclosed in a large case or box, K L, and occupies one half of it; which is represented separately, and in a different view, in Fig. 3. It is suspended freely on its axis, and turned by the handle A. The other half of the box is empty, and receives the seed as it falls down from the hopper B, to the sloping floor visible at C, along which it slides out at D, while the force of the wind which is confined within this winnow, and always acts in the same direction, viz. lengthways of the machine from A to E, carries the chaff, light and rotten grains, dirt, &c. out at E. In this passage, the wind meets the seed constantly falling from the hopper, and impels it more or less toward the end E, according to its weight. Good seed never goes quite so far, but comes down within the box.

The hopper here is ingeniously contrived to save labour. It hangs by strings upon four pegs, and moves with such ease, that the necessary motion may be communicated to it by the same hand that moves the fan, without any hinderance to the workman. To this purpose, a triangular board *f*, is fixed upon the handle of the fan, and turns with it. The angles of this board, in their rotation, press against the lower end of a little lath, incurvated as in the figure, which moves freely upon a peg at *g*. This end accordingly recedes from the pressure towards H, and consequently the upper end moves the contrary way, towards I, and by a string fastened from it to the hopper, draws this last after it, out of its natural situation. When this pressure ends, and the sides of the little triangle are next

next to the lath, the hopper hangs freely, returns to its former place, and takes the lath along with it, till the next angle of the little triangle begins to act; and so alternately as long as the fan moves. As the hopper is thus in continual motion, the seed sheds down, and is winnowed as it falls.

The next care is to cleanse the corn from all foreign bodies, which could not be carried off by the wind, such as stones, bits of earth, &c. These are separated by running the grain through a sieve wide enough to let it pass with ease, while bodies of a larger bulk are retained: and it is likewise often necessary afterwards to use a fine sieve, which lets through only the dust, seeds of weeds, and other bodies smaller than the corn.

As the farmers in many places feed their cattle, and particularly their sheep, in the winter, with half-threshed straw; and as new straw is good food for horses, which are induced to eat it very readily when it still contains some grain; there is, in this respect, an advantage in threshing the corn only by degrees; besides, that the grain itself is allowed to improve in its quality when preserved in the ear, so as to attain the most perfect maturity, to sweat out its moisture, and to acquire a degree of hardness which fits it for long keeping. About three months after it has been cut, is generally reckoned the best time for threshing wheat that is intended for keeping; and accordingly our prudent husbandmen make this the business of winter, when their presence is least wanted in the field. But, on the other hand, seed wheat cannot well be too soon cleared from the chaff, as M. de Chateauvieux's experiments have proved; and the best way of doing this, is by striking the ears against a beam. By this method the husbandman will obtain fine, long, unbruised straw, fit for binding up his next year's sheaves, for thatching, and for various other useful purposes. Of this he should always save, and stack, as much as he can spare, when it proves long and good; for wheat straw will keep perfectly well a year or two; and if there be no occasion for it in that time, it will make litter and dung at last. Barley-straw is likewise very serviceable for thatching, or to throw over stacks of barley, or peas, till they can be thatched: but oat-straw is of no great use, unless it be to cover an oat-rick, peas for fatting hogs, or corn for fowls. In general, an empty space should be left in the barn, if it can be done conveniently in harvest time, to receive the litter, and foddering straw, that is threshed out before cattle come to fodder; or it should be laid under some cover, for otherwise it will rot.

THRASHING-FLOOR, the floor on which the corn is thrashed. *See the article* BARN.

THRAVE, a shock of corn consisting of twenty-four sheaves.

THREAF, a handful, a bundle, a pottle.

THROATING, the action of mowing beans against their bending, which is never done but in a thin crop.

THROATWORT, the name of a perennial weed common in pasture grounds. The stalk is cornered and undivided. The flowers grow in bunches at the top of the stalk. They are erect, of a beautiful purple colour, and divided in the middle into five acute segments.

THYME, a well known aromatic plant propagated in kitchen gardens.

Botanists enumerate nine different species of thyme, besides several varieties; but they are all propagated either by seeds or parting the roots.

The most useful sort, either for culinary purposes, or for medicine, is the broad leaved thyme, most commonly cultivated in the kitchen-garden; for the narrow leaved kind never grow so large. Their culture is, however, exactly the same.

The seeds of thyme, if it be raised from thence, should be sown either in March or October, but the former of these months is best, in a well dug bed of light earth; taking care, as they are very small, not to drop them too close together, nor to bury them deep, for this last would make them rot. When the plants are come up, they should be carefully over looked and cleared from weeds, and if the season be dry, their growth will be greatly promoted by watering them twice a week, for some time. In June, if it be a spring sowing, the plants should be thinned to the distance of six inches asunder every way, that they may have room to spread: and those which are drawn out may be set in other beds, at the same distance from each other. They must be watered till they have taken root, and will then require no farther care, except weeding them, till the winter, when they may be pulled up, and laid by in a dry place, for use. The autumnal sowing should be thinned as before, early the next spring, if it be let stand till then; for there will be little danger of its resisting the severest winter of this country, especially if the plants grow on a dry, poor, and stony land. In rich ground, indeed, where they grow luxuriantly, they are sometimes destroyed by severe frosts. Thyme will even flourish upon a stone wall.

If the plants are propagated by parting their roots, this should also be done in March or October. The old plants should be taken up, their roots should be slipt into as many parts as can be, and these slips should be set six or eight inches asunder every way, in beds of fresh light earth. If the season is dry, they must be watered there till they have taken root; and with only weeding of them afterwards, they will soon be fit for use.

To save the seeds of thyme, some of the plants should be left unremoved till the next spring. They will then flower in June, and their seeds will ripen in July. These must be pulled up and beaten out as soon as they are ripe; for the first shower of rain would otherwise wash them all out of their husks.

Thyme is so great an impoverisher of the earth, that no crop will thrive well where that stood the year before, unless the ground be trenched deeper than the thyme rooted, and at the same time enriched with dung, or some other suitable manure.

TICHING, setting up turfs in such a manner as they may be dried by the sun, and fit for being burnt for their ashes upon the land.

TIKE, an insect found in dogs, sheep, cows, &c.

TILLABLE, arable, fit for the plough.

TILLAGE, the act or practice of tilling, or cultivating land. *See the article* PLOUGHING.

" I was much pleased, says a correspondent of the editors of the Museum Rusticum, with an account which I received about six weeks ago, of a peculiar management of tillage at Market-Weighton, in the east-riding of Yorkshire, given to me by a sensible man of veracity, who was born and bred a farmer in that neighbourhood.

" The inhabitants of Market-Weighton have it seems five fields, two of a sandy soil, and three of a strong clayey soil; the former, as will easily be conjectured, destined to rye, and the others to wheat. Their sandy lands are disposed in four swathes breadth; and finding by experience that considerable parts of each land, towards each furrow, are starved by the coldness of the water dripping from the higher parts of the lands, they have for many years altered their former method: and only ploughed the half of each land, viz. the two middle swathes: so that they have now excellent rye growing on the higher and dryer half of every land, and excellent meadow growing on the lower and wetter half, which being just two swathes, is mowed with great ease and exactness.

" It will, perhaps, be thought by some, that by making narrower lands, they might have more dry land, and consequently more corn. But I apprehend, these industrious husbandmen find by experience, that when they make their lands narrower, and consequently with less descent, the water stagnates in the higher parts, and consequently spoils their whole crop. Nor could they, I suppose, sow more corn on their lands, in their present disposition, with convenience, as their present method allows them just one swathe on each side.

" They have rye and meadow in one of their two sandy fields every other year, and a fallow the next year. The having half of the field in grass, affords good grass for their sheep, &c. in that year; and allows them to keep a good stock thereon; and this stock, in return, manures the ground considerably, both the fallow and the swarth. One of their wheat-fields affords them plenty of worse or spring corn; and thus they are supplied with wheat, rye, spring corn, meadow, and summer grass, from their five fields, which in any other management they could scarcely be.

" It is observable also, that by this management they only plough as much as four fields, and consequently can afford

afford one fifth more ploughing to every piece of ground in tillage, than they otherwise could, on supposition that their fields are all of the same extent.

" These provident people, gentlemen, have another piece of management well worthy the attention of others. They have two great fairs for sheep; one in spring, and the other in autumn. They hold the former of these fairs in one of their fallow fields, which is to be ploughed up in spring. The concourse of sheep, horses, &c. manures this field surprisingly, and then they turn in the dung before it be evaporated or baked. Their later fair is held on the other fallow field, which is soon to be sown with hard corn. And here they receive equal benefit.

" Whether they have their spring fair on the rye or wheat field, I know not; but I apprehend them to have it on the former: as rye is sown sooner than wheat; and the time of sowing might be too late for their autumnal fair.

" Whoever has seen the useless nastiness which is made by sheep at fairs, in the streets of great towns, will think this management of the Market-Weightoners highly deserving of imitation; especially in the latter end of the year, when the rains bring in much soil with the sheep.

" I would, however, venture to recommend one improvement to these sensible people, viz. after a certain number of years to plough up one of their sandy fields intirely, and to cross-plough it, and endeavour to mix the soil of the ridges and furrows thoroughly together, and then to make the furrows where the ridges were, &c. and to sow down the outward swathes of each land with seeds proper to the soil. The advantages hence resulting, are so obvious, that it would be an affront to their understandings to insist upon them." *Museum Rusticum, vol.* VI. *pag.* 83.

TILLER, a branch or stem of corn.

To TILLER, to spread or shoot out.

TILLS, tares, or vetches.

TILTH, *or* TILT, the condition of the earth after ploughing, &c.

TIMOTHY-GRASS, the name of a grass now cultivated in England, of which it is a native, though the seeds of it were carried from Virginia, by one Mr. Timothy Hanson, to North Carolina, where it is now cultivated by the inhabitants; and from this circumstance it received the name it now bears.

It thrives most in low, damp, marshy grounds; for in such soil and situation it will produce a fine turf in three weeks from the time of sowing the seed. It is very luxuriant, grows to a considerable height, and has in some sort the appearance of wheat or rye, having a broad blade or leaf.

All sorts of cattle are very fond of this herb whilst in a green growing state; and it will not be improper to add, that they are nearly, if not quite, as fond of it, when dried and made into hay: but when it is intended for this use, it should always be mown when it is in full sap, just before it flowers, for if it is left longer before it is cut, being so luxuriant and quick a grower, it becomes harsh, and is much dryer and more chirky food, than when it is cut in its prime.

" Timothy-grass, says an experienced farmer, in a letter to Dr. Templeman, is in appearance a coarse grass, very little promising to be a pasture agreeable to cattle. Indeed, its appearance so strongly prejudiced many against it, that it would have been at once condemned to neglect, had it not been rescued by the enterprizing disposition of Mr. Rocque, who had sown a considerable spot of ground with the seed first sent from America; yet the fact is, that, whilst in sap, it is more agreeable to horses and cattle than any other grass has been observed to be. Mr. Rocque's horse soon gave him a convincing proof of this; for having got loose, he left very fine lucerne, and the moment he reached the Timothy-grass, instead of ranging about, as usual with horses, he eat clean before him.

" Deer, which are very nice in their food, are so fond of it, that, as I am well assured by gentlemen from North-America, they sow Timothy-grass there on the skirts of their corn land near the woods; in order to keep the deer from eating their corn; the Timothy-grass being much more agreeable to them than even corn.

" The dry hay of the Timothy-grass is exceedingly agreeable to cattle, as appears from a remarkable instance mentioned in a conversation in the Society for the encouragements of arts, &c. A worthy husbandman, who had himself often experienced how fond his cows and horses were of it, carried a friend into the field, that he might have ocular demonstration of it. The husbandman took a tuft of dry Timothy-hay in his hand, and as soon as one of the cows saw it, she came instantly to feed on it, though there was plenty of good grass under foot. Another cow soon followed the first, and both eat greedily of it: but each of them refused to eat the hay of common grass, which happened to be mixed with it. So fond were the horses and cows of this hay, that they would follow a person having some of it in his hand, as readily as they would one who carried corn for them.

" A very great advantage attending the Timothy-grass is, that it thrives well in such wet marshy land as will scarcely yield any other good grass; and here, its numerous and matted roots make so strong a sward, that land which was before a loose mire, shall become so firm as to bear cattle and even carriages without their sinking into it.

" It is almost needless to add, that in order to sow Timothy-grass seed in such marshy land, it must be drained, and then all the inequalities common in such land, as well as the strong matted roots of coarse grass, should be taken up and burnt. The land being then ploughed and laid smooth, the ashes should be spread upon it, and the seed may be sown early in the autumn; or rather, the plants should be raised in a nursery, and set in it at six or eight inches distance, every way, from each other. This grass will also thrive well on a clay bottom, where water is apt to stagnate in rainy seasons.

" The Timothy-grass will grow to the height of three or four feet high. I have been assured by a gentleman, that he has seen it between five and six feet high in Virginia. If it is cut down before the seed ripens, it will soon shoot anew, and yield a good second crop. The fowl meadow grass grows to the height of about three feet, and will ripen its seed twice in a season: we may therefore infer, that it may be cut for hay thrice in a season. It is not an early grass; but as soon as it begins to shoot, it makes up for that loss by its speedy growth. During the drought of last summer, the second crop made a surprizingly quick progress. Its not being an early grass is perhaps no loss; for as it delights in rather moist meadows, the ground might be poached, were cattle tempted to go early to feed on it.

" If from some imperfection in the soil, the plants of either of these grasses do not fill the ground sufficiently, they may be let run to seed, which falling in the vacant spaces, soon supply the want. So far as we have yet observed in this country, these self-sown plants do not arrive at the size of the parent plants, which were set at due distances: and this affords good reason to think, that if the seed was sown in broad-cast, and the plants came up thick, they would in the same manner be stinted in their growth.

" The success of the Timothy-grass, when sown alone, demonstrates the utility of sowing the seeds of each grass separately, in order to form a just estimate of their comparative values: for though this grass is a native of England, being a species of the fox-tail, it has hitherto been rather neglected than cultivated, even though nature has pointed it out as an useful plant in wet meadows, by its early verdure and growth. I make no doubt but that the practice of raising grasses separately, will bring other no less valuable grasses to light."

TINE, a tooth or spike. And hence the common phrase, of giving two or three tinings, signifies to draw the harrows twice or thrice over the same spot of ground.

TIT, a small horse.

TORE, rowen, or winter-grass.

TOVET, or *Toset*, half a bushel.

TRAMEL, an instrument or device, made sometimes of leather, but more usually of ropes, fitted to a horse's legs to regulate his motion, and teach him to amble.

Tramel also signifies an iron instrument hanging in the chimney, whereon to hang pots or kettles over the fire.

TRANSPLANTING, the act of removing trees or plants from the places where they are sowed, or raised, and planting them in others. *See the articles* LUCERNE, PLANTING, &c.

TREE, the firſt and largeſt of the vegetable kind, conſiſting of a ſingle trunk, out of which ſpring forth branches and leaves.

Standard-trees are ſuch as naturally riſe to a great height, and are not topped. For the choice of trees of this kind to be tranſplanted out of a nurſery, Quintiney recommends us to ſuch as are ſtraight, ſix feet high at leaſt, and five or ſix inches thick at bottom, and three or four at top; the bark pretty ſmooth and ſhining, as a token of their youth, and of the good ſoil they grew in.

Dwarf-trees are ſuch as are kept low, and never ſuffered to have above half a foot or ſtem.

Heat is ſo eſſential to the growth of trees, that we ſee them grow larger and ſmaller in a ſort of gradation, as the climates in which they ſtand are more or leſs hot. The hotteſt countries yield in general the largeſt and talleſt trees, and thoſe alſo in much greater beauty and variety than the colder do; and even thoſe plants which are common to both arrive at a much greater bulk in the ſouthern, than in the northern climates; nay, there are ſome regions ſo bleak and chill, that they raiſe no vegetables at all to any conſiderable height. Greenland, Iceland, and the like places, afford no trees at all; and what ſhrubs grow in them are always little and low. In the warmer climates, where trees grow to a moderate ſize, any accidental diminution of the common heat is found very greatly to impede vegetation; and, even in England, the cold ſummers we ſometimes have, give us an evident proof of this; for though the corn and low plants have ſucceeded well enough, and gooſeberries, currants, raſberries and other low ſhrubs, have brought forth fruit in ſufficient plenty, yet the production of taller trees has been found very much hurt; and wallnuts, apples, and pears, have been very ſcarce among us.

Heat is heat, be it from what cauſe it will, and acts as well upon vegetation one way as another. Thus the heat of dung, and the artificial heat of coal fires in ſtoves, is found to ſupply the place of the ſun.

Great numbers of the Indian trees in their native ſoil flower twice in a year, and ſome flower and bear ripe fruit all the year round; and it is obſerved of theſe laſt, that they are at once the moſt frequent and moſt uſeful to the inhabitants; their fruit, which hang always on them in readineſs, containing cool juices, which are good in fevers, and other of the common diſeaſes of that hot country.

Plantations of uſeful trees might be made to very great advantage in many places in every country, and the country greatly enriched by it, while the public would be alſo benefited by it, ſince it would raiſe a continual ſupply of timber uſed in ſhip-building, and on other public as well as private occaſions.

We have, in many places, heaths, and other barren and uncultivated lands, of very great extent; and how great an advantage would it be to the public, to bring theſe to be truly valuable? Many, if not all of theſe heaths, would be found on trial capable of producing trees; and ſome of them are truly the remains of deſtroyed foreſts; and, though the profits to be reaped from the planting theſe would come late, yet the expence of doing it would be very trifling in compariſon of that profit, and the means eaſy.

The authors who have given rules for planting, having employed themſelves only about ſmall ſpots of ground, the eſtabliſhing orchards, or parks, are by no means to be ſuppoſed proper guides in attempts of this kind; and Monſieur de Buffon, who had a great opinion of the knowledge of our Evelyn and Miller, who ſeem to ſpeak of every thing from their own experience, found, when he ſet about large plantations, that their opinions and rules were erroneous; and was obliged to have recourſe to experiments only; which he varied a thouſand ways: and, though many of them proved unſucceſsful, yet they all gave hints towards others, by which the attempt might afterwards be brought to ſucceed.

This ſagacious enquirer into the operations of nature in the growth of vegetables, having ſet apart a conſiderable quantity of land for the trial, and procured a number of young trees, firſt divided the whole quantity into a number of ſmall ſquares, and, having made a plan of it, examined the nature, depth, and other circumſtances of the ſoil in each, and minuted the whole down on a proper part of the plan; that himſelf or whoever ſucceeded him might judge, from the different growths of a number of trees planted in the ſame ſtate in the different ſoils, the different advantages and diſadvantages of every circumſtance in the depth and nature of the ground, in regard to the growth of uſeful trees. Different numbers of labourers were employed about different ſpots of this ground, and the acorns for the young growth planted at different ſeaſons; but the reſult in general was, that what ſhould ſeem the beſt methods ſucceeded the worſt; and thoſe pieces where many labourers were employed, and the acorns planted before winter, were much thinner of young oaks, than thoſe where the leaſt labour had been beſtowed upon the ground, and where the acorns had been planted in the ſpring; but thoſe places which ſucceeded beſt from the ſowing, were thoſe which had the acorns planted in holes made by a pickax, without any preceding culture of the ground. And thoſe where the acorns had only been laid upon the earth, under the graſs, afforded a great number of vigorous young trees, though the greater part had been carried away by birds, and other devouring animals. Thoſe ſpots of ground where the acorns were ſet ſix inches deep, were much worſe furniſhed with young ſhoots, than thoſe where they had been buried but at an inch deep; and in ſome places where they were buried at a foot deep, not one ſhoot appeared, though in others where they had been buried at nine inches there were many.

Thoſe acorns which had been ſteeped for eight or nine days in wine lees, and in the water of the common ſewers, appeared out of the ground much earlier than thoſe which were put in without this previous management.

But the moſt ſucceſsful of all the trials was that of planting in the ſpring ſuch acorns as had been ſown together in another place, and had time to ſhoot there; of theſe ſcarce any failed, and the plantation was perfectly flouriſhing, though the growth of theſe young ſhoots was not ſo quick and vigorous as thoſe of the acorns which had remained, when firſt ſown; which was probably owing to the injury the tender radicles received in tranſplanting.

Thus ſucceeded the experiments by ſowing, while, of thoſe made by planting young trees, ſuch as had been brought out of woods, and places under covert, ſucceeded much worſe than thoſe which had grown in more expoſed places.

The young trees of the ſeveral parts of the plantation kept on their growth in the manner they had begun to ſhoot, thoſe of the more laboured parts continuing more weak, and lower than thoſe of the leſs laboured.

Thus were a number of neceſſary experiments carefully tried, and the reſult of the whole was, that to make a plantation of oaks, on a ſoil of the common clayey or loamy kind, the moſt ſucceſsful method is this: the acorns muſt be preſerved during the winter in the earth in this manner: let there be made a bed of earth ſix inches deep, on this place a layer of acorns two inches deep, over theſe lay a bed of another half foot of earth, over that another layer of acorns, and ſo on ſucceſſively, till as many are employed as there will be occaſion for; the whole is then to be covered with a foot depth of earth, to preſerve all from the froſt. In the beginning of March, theſe beds are to be opened, and the acorns which will by that time have ſhot out, and are then in reality ſo many young oaks, are to be planted out at a foot diſtance each, and the ſucceſs of a plantation of this kind need not be feared. This is a manner of planting that is done at a ſmall expence, and even that might be in a great meaſure ſpared, were it not for the birds and other devouring animals; ſince, could the acorns be defended from theſe, they might be only laid on the ſurface of the ground under the graſs in autumn, and they would infallibly ſhew themſelves in ſo many young oaks the ſucceeding ſpring.

It is eaſy to continue the carrying the acorns, when taken out of their winter's bed, to the place where they are to be planted, without doing them much injury; and the ſmall ſtop the tranſplanting puts to their growth, is in reality rather an advantage than an injury; ſince it only retards the young ſhoots for about three weeks, or leſs than that: and by that means ſecures them from the few cold mornings that may be expected about the time of their natural appearance.

For

For the planting, pruning, felling, grafting, &c. of trees, *see the articles* PLANTING, PRUNING.

TREFOIL, a genus of plants, the flower of which has a tubulous permanent empalement of one leaf: it is of the butterfly kind, drying in the empalement. The standard is reflexed, the wings are shorter than the standard, and the keel is shorter than the wings: it has ten stamina, nine are joined, and one is separate, terminated by single summits, and an almost oval germen supporting an awl-shaped style, crowned by a single stigma. The germen afterward becomes a short pod with one valve, containing a few roundish seeds.

Mr. Miller enumerates twelve different species of trefoil, the first of which is well known in England by the name of red clover; and the manner of cultivating this plant has been already described under the article CLOVER.

The second sort, namely, the white Dutch clover, grows naturally in most of the pastures in England, and is generally known among the country people by the name of white honey suckle.

This is an abiding plant, whose branches trail upon the ground, and send out roots from every joint, so that it thickens and makes the closest sward of any of the sown grasses; and it is the sweetest feed for all sorts of cattle yet known: therefore when land is designed to be laid down for pasture, with intent to continue so, it should be sown with the seeds of this plant. The usual allowance of this seed is eight pounds to one acre of land; but this should never be sown with corn, for if there is a crop of corn, the grass will be so weak under it, as to be scarce worth standing; but such is the covetousness of most farmers, that they will not be prevailed on to alter their old custom of laying down their grounds with a crop of corn, though they lose twice the value of their corn by the poorness of the grass, which will never come to a good sward, and one whole season is also lost; for if this seed is sown in the spring without corn, there will be a crop of hay to mow by the middle, or latter end of July, and a much better after-feed for cattle the following autumn and winter, than the grass which is sown with corn will produce the second year. The seed of this sort may also be sown in autumn, and this autumnal sowing, if the seeds grow kindly, will afford a good early crop of hay the following spring; and if, after the hay is taken off the land, the ground be well rolled, it will cause the clover to mat close upon the ground, and become a thick sward.

The seeds of this white Dutch clover is annually imported from Flanders, by way of Holland, whence it received the name of Dutch clover; not that it is more a native of that country than of this, for it is very common in moist pastures, in every county in England: but the seeds were never collected for sowing in this country till of late years; nor are there many persons here, even now, who save this seed, though it may be done if the same method, as is practised for the red clover, be taken with this sort; it should therefore be recommended to every farmer, who is desirous of improving his land, to sow carefully an acre or two of this white clover for seed, which will save him the expence of buying for some years, when the price is great; and there will be a sure market for any quantity he may have to spare.

The third sort, namely hop-clover, called by some yellow meadow trefoil, grows naturally among the grass in the upland pastures of this country; but the seeds are frequently sold in the shops, and are by many mixed with the other sorts of clover and grass-seeds, for laying down ground to pasture. This plant grows with upright branching stalks about a foot high, garnished with trifoliate leaves, whose lobes are oblong and heart-shaped, but reversed, the narrow point joining the foot stalks. The flowers, which are yellow, grow from the wings of the stalk, upon long foot-stalks, collected into oval imbricated heads, having naked empalements lying over each other like scales, somewhat like the flowers of hops, from whence the plant had the name of hop-clover. But there are two sorts of this clover, which grow naturally in England. The other is a much smaller plant than this, and generally known by the name of none-such, or yellow hop-trefoil.

The hop-clover is strongly recommended by the following circumstances. 1. It not only grows, but flourishes on the most barren sands, and therefore must be a very proper grass to cultivate on such unfertile soils, where any other grass that is worth notice will not grow at all. 2. It is not apt to swell cattle, as the red clover does. 3. In good ground it will continue long, and bear a very good seed or crop, as Mr. Tull, though prejudiced against clovers, confesses; and, by its flourishing both on sands and clay, which have not been ploughed for many years, it seems likely to continue long in any soil.

The fifth sort grows naturally on chalky lands in many parts of England; and in some countries the seed is sown after the same manner as the common red clover, especially on chalky ground, where it will thrive, and produce a better crop than clover. The stalks of this are hairy, and grow erect to the height of two feet or more, garnished with trifoliate leaves, standing upon long foot-stalks, whose lobes are longer than those of the red-clover, and have no marks of white; they are of a yellowish green colour, and are covered with soft hairs. The flowers grow in oval spikes at the end of the branches; they are of a pale copper colour; their petals are long and tubulous, but the brim is divided into two lips, as the other sorts.

This is known by the title of trefoil, in the places where it is cultivated; but the seedsmen sell the hop-clover by that name, so they make no distinction between this, the hop-clover, and none-such; therefore, by which of these three titles the seeds are bought, they prove the same.

This sort of trefoil is much cultivated in that part of Essex which borders on Cambridgeshire.

The sixth sort grows naturally in Spain and Italy; this has upright stalks near two feet high, which are hairy, garnished with trifoliate leaves, having roundish lobes, which are sawed at their points. The flowers are produced at the top of the stalk in long, obtuse, hairy spikes, of a bright red colour, so make a pretty appearance during their continuance. It is an annual plant, so is not proper for sowing as fodder.

The seventh sort is an annual plant, which grows naturally in the south of France and Italy; it rises with a strong smooth stalk near three feet high, garnished with trifoliate leaves, whose lobes are two inches and a half long, and near a quarter broad, standing upon long foot-stalks, which are embraced by stipulæ or sheaths their whole length. The flowers are produced at the top of the stalks in very long spikes; they are of a beautiful red colour, so make a fine appearance. It flowers in July, and the seeds ripen in autumn.

The eighth sort grows naturally in Spain and Italy; this rises with a slender stiff stalk near two feet high, garnished with trifoliate leaves, whose lobes are very narrow and hairy. The flowers are produced at the top of the stalks in oblong conical spikes; the indentures of their empalements end in long bristly hairs, which are almost equal in length; the spikes are hairy, and the flowers of a pale red colour.

The ninth sort is the common hare's foot trefoil, which grows naturally upon dry gravelly land in most parts of England, and is a sure indication of the sterility of the soil, for it is rarely seen upon good ground. This plant is seldom eat by cattle, so is unfit for pasture, and is only mentioned here because it is sometimes used in medicine; it is an annual plant, whose root decays soon after it has perfected seeds.

The tenth sort grows naturally on arable land in many parts of England; this has trailing stalks, which put out roots at their joints. The leaves stand upon long slender foot-stalks; the lobes are roundish, and sawed on their edges; the flowers are collected in roundish heads, standing upon slender foot-stalks, which rise from the wings of the stalks; these have bladdery empalements, which terminate in two teeth. When these lie on the ground, their globular heads, having a little blush of red on their upper side toward the sun, and the other part being white, have a great resemblance of strawberries, and from thence it was called strawberry trefoil.

These sorts are preserved in botanic gardens for variety; they are easily propagated by seeds, which may be fown on an open bed of ground, either in autumn or fpring.

The plants which come up in autumn, will grow much larger, and flower earlier in the fummer than thofe which are fown in the fpring, fo from thofe good feeds may be always obtained, whereas the others fometimes mifcarry. When the plants come up, they require no other care than to keep them clean from weeds, and thin them where they are too clofe.

The eleventh fort is the common melilot, which is ufed in medicine, and has been already defcribed under the article MELILOT, which fee.

The twelfth fort grows naturally in Bohemia and Auftria, but has been long cultivated in England as a medicinal plant, though at prefent it is rarely ufed; it is annual. The ftalks are large, hollow, and channelled; they rife about a foot high, garnifhed with trifoliate leaves, whofe lobes are oval, and flightly fawed on their edges, ftanding upon pretty long foot-ftalks. The flowers are collected in oblong fpikes, which ftand upon very long foot-ftalks, fpringing from the wings of the ftalk at every joint; they are of a pale blue colour fhaped like thofe of the common melilot; thefe appear in June and July, and are fucceeded by fmall yellow feeds, of a kidney fhape, two or three being included in each fhort pod. The whole plant has a very ftrong fcent like that of fenugreek, and perifhes foon after the feeds are ripe. *Miller's Gard. Dict.*

TRELLISES, a contrivance for fupporting the branches of fruit-trees, confifting of laths of wood croffing each other in the form of a lattice.

Some perfons who are very curious in their fruit, and who do not mind a little extraordinary expence, erect trellifes againft their walls, extending from the infide of one pier to the neareft infide of the next; where the walls are built with piers, as they muft be for this purpofe. This frame-work is conftructed in the fame manner as that for efpaliers, like which it need not be fet up till the trees are well fpread, and begin to bear fruit plentifully; for they may be trained till then againft any ordinary low efpalier of afh poles or other flender fticks, in order not needlefsly to expofe the trellifes to the injuries of the weather; becaufe thefe, being generally made of regularly cut yellow-deal, or oak, and run up higher, coft more. Every fourth upright rail or poft of the trellis fhould be much ftronger than the reft, and faftened to the wall with iron hooks, which it is beft to fix in the wall at the time of building it. Thefe ftrongeft upright pofts fhould be about three, but by no means more than four feet from each other. The crofs rails may be flight, as for common efpaliers; but they muft be laid much clofer together. For peach, nectarine, and apricot trees, for example, which, for the moft part, produce their fruit on the young wood, the fquares of the trellis frame fhould not exceed three or four inches; but for trees which continue to bear on the old wood, they may be five or fix inches wide, and for vines, eight or nine inches. The fhoots of the trees are faftened to this frame with ozier twigs, rope yarn, or any other foft bandage, in the fame manner as they are to efpaliers: for they muft not be nailed to either, becaufe that would injure the wood-work.

Thefe trellifes, which fhould project about two inches from the wall, are thought to contribute greatly to preferve the beauty of the fruit, by preventing its lying too clofe to the wall, whilft it has at the fame time all the advantages of the heat reflected therefrom: nor are the walls where thefe are ufed hurt by driving nails into their joints, and drawing them out again every year, at the hazard of pulling out fome of the mortar with them, and confequently of weakening the wall, and making holes in which fnails and other vermin take fhelter and breed.

TRENCH, a furrow cut in the earth for draining land. *See the articles* BOG and DRAINING.

TRENDLE, any thing that turns round.

To TREFALLOW, to plough land the third time before fowing.

TROUGH, a long veffel for holding water, &c.

TRUG, or TRUGG, a hod for mortar.

TRUNDLE, a fort of carriage with low wheels, for carrying heavy and cumberfome loads.

TRUNK, the ftem or body of a tree; or the part between the ground and the place where it divides into branches.

TRUSS, a bundle of hay, ftraw, &c.

A trufs of hay muft contain fifty-fix pounds, or half a hundred weight; thirty-fix truffes make a load. In June, July, and Auguft, a trufs of new hay muft weigh fixty pounds.

TRUSS *of flowers*, fignifies many flowers growing together on the head of a ftalk, as in the cowflip, auricula, &c.

TUBEROSE, or PALIANTHES, the name of a genus of flowers greatly cultivated, and much admired.

The varieties of this plant are the tuberofe with a double flower, the ftriped-leaved tuberofe, and the tuberofe with a fmaller flower; the laft is mentioned by feveral authors as a diftinct fpecies, but is certainly a variety.

This fort is frequent in the fouth of France, from whence the roots have been often brought to England early in the fpring, before thofe roots have arrived from Italy, which are annually imported; the ftalks of this are weaker, and do not rife fo high, and the flowers are fmaller than thofe of the common tuberofe; but in other refpects is the fame.

The tuberofe grows naturally in India, from whence it was firft brought to Europe, where it now thrives in the warmer parts, as well as in its native foil. The Genoefe are the people who cultivate this plant, to furnifh all the other countries where the roots cannot be propagated without great trouble and care, and from thence the roots are annually fent to England, Holland, and Germany. In moft parts of Italy, Sicily, and Spain, the roots thrive and propagate without care, where they are once planted.

This plant has been long cultivated in the Englifh gardens, for the exceeding beauty and fragrancy of its flowers; the roots of this are annually brought from Genoa, by the perfons who import orange trees; for as thefe roots are too tender to thrive in the full ground in England, fo there are few perfons who care to take the trouble of nurfing up their off-fets, till they become blowing roots, becaufe it will be two or three years before they arrive to a proper fize for producing flowers; and as they muft be protected from the froft in winter, the trouble and expence of covers is greater than the roots are worth; for they are generally fold pretty reafonable, by thofe who import them from Italy.

The double flowering is a variety of the firft, which was obtained from feed by Monf. Le Cour, of Leyden in Holland, who for many years was fo tenacious of parting with any of the roots, even after he had propagated them in fuch plenty, as to have more than he could plant, that he caufed them to be cut in pieces, that he might have the vanity to boaft of being the only perfon in Europe who was poffeffed of this flower; but of late years the roots have been fpread into many parts; and as there is no method to propagate this but by the off-fets, moft people who have had of this fort are careful to multiply and increafe it, which is done by planting the off-fets upon a moderate hot-bed early in March, and covering the bed in cold weather with mats or ftraw; in fummer they muft have plenty of water in dry weather. In this bed the roots may remain till the leaves decay in autumn; but if there fhould happen any froft before that time, the bed fhould be covered to guard the roots from the froft, becaufe if the froft enters fo low as to reach the roots, it will kill them; and if the leaves are injured by the froft, it will weaken the roots. Where there is a due care taken to fcreen them from froft, and too much wet, it will be the beft way to let the roots remain in the bed till the end of November, or the beginning of December, provided hard frofts do not fet in fooner; for the lefs time the roots are out of the ground, the ftronger they will be, and the fooner they will flower. When the roots are taken up, they fhould be cleaned from the earth, and laid up in dry fand, where they may be fecure from froft and wet; here they fhould remain until the feafon for planting them again: this fame method fhould be practifed by thofe who are defirous to cultivate the fingle fort in England, and alfo that with ftriped leaves muft be propagated the fame way.

We fhall next give directions for the management of thofe roots which are annually brought from Italy. And firft, in the choice of the roots, thofe which are the largeft

and

and plumpest, if they are perfectly firm and sound, are the best, and the fewer off-sets they have, the stronger they will flower; but the under part of the roots should be particularly examined, because it is there that they first decay. After the roots are chosen, before they are planted, the off-sets should be taken off; for if these are left upon the roots, they will draw away part of the nourishment from the old root, whereby the flower-stems will be greatly weakened.

As the roots commonly arrive in England in the month of February or March, those who are desirous to have these early in flower, should make a moderate hot-bed soon after the roots arrive, which should have good rich earth laid upon the dung, about seven or eight inches deep; this bed should be covered with a frame, and when the bed is in a proper temperature for warmth, the roots should be planted at about six inches distance from each other every way. The upper part of the root should not be buried more than one inch in the ground; when the roots are planted, there should be but little water given them, until they shoot above-ground, for too much wet will rot them, when they are in an inactive state, but afterwards they will require plenty of water, especially when the season is warm. When the flower stems begin to appear, the bed should have a large share of air given to it; otherwise the stalks will draw up weak, and produce but few flowers; for the more air these plants enjoy in good weather, the stronger they will grow, and produce a great number of flowers; therefore, towards the beginning of May, the frame may be quite taken off the bed, and hoops fastened over it, to support a covering of mats, which need not be laid over but in the night, or in very cold weather, so that by enjoying the free open air, their stems will be large; and if they are well watered in dry weather, their flowers will be large, and a great number on each stem.

The first planting will require more care than those which are designed to come after them; for in order to have a succession of these flowers, the roots should be planted at three different times, viz. the first the beginning of March, the second the beginning of April, and the third at the end of that month, or the beginning of May; but the latter beds will require a much less quantity of dung than the first, especially that bed which is the last made; for if there is but warmth enough to put the roots in motion, it is as much as will be required; and this last bed will need no covering, for many times those roots which are planted in the full ground at this season, will produce strong flowers in autumn; but in order to secure their flowering, it is always the best way to plant them on a gentle hot-bed. As to the second bed, that should be arched over with hoops, and covered with mats every night, and in bad weather, otherwise the late frosts which frequently happen in May, will pinch them.

These plants may remain in the beds until the flowers are near expanding, at which time they may be carefully taken up, preserving the earth to their roots, and planted in pots, and then placed in the shade for about a week to recover their removal; after which time the pots may be removed into halls, or other apartments, where they will continue in beauty a long time, and their fragrant odour will perfume the air of the rooms where they are placed, and by having a succession of them, they may be continued from Midsummer to the end of October, or middle of November; but as the stems of these plants advance, there should be some sticks put down by each root, to which the stem should be fastened, to prevent their being broken by the wind.

It is a common practice with many people, to plant these roots in pots, and plunge the pots into a hot-bed; but there is much more trouble in raising them in this method than in that before directed; for if the roots are not planted in very small pots, there will be a necessity of making the beds much larger, in order to contain a quantity of the roots; and if they are first planted in small pots, they should be shaken out of these into pots of a larger size, when they begin to shoot out their flower stems, otherwise the stalks will be weak, and produce but few flowers; therefore the other method is to be preferred, as there is no danger in removing the roots, if it is done with care.

When the roots are strong, and properly managed, the stems will rise three or four feet high, and each stem will produce twenty flowers or more; and in this the great beauty of these flowers consists, for when there are but a few flowers upon the stalks, they will soon fade away, and must be frequently renewed; for the flowers are produced in spikes coming out alternately upon the stalk, the lower flowers opening first; and as these decay, those above them open; so that in proportion to the number of flowers upon each stalk, they continue in beauty a longer or shorter time.

The sort with double flowers will require a little more care, in order to have the flowers fair; but this care is chiefly at the time of blowing, for the flowers of this sort will not open, if they are exposed to the open air; therefore when the flowers are fully formed and near opening, the pots should be placed in an airy glass-case, or a shelter of glasses should be prepared for them, that the dews and rains may not fall upon them, for that will cause the flowers to rot away before they open, and the heat of the sun drawn through the glasses, will cause their flowers to expand very fair. With this management, Mr. Miller says he has had this sort with very double flowers extremely fair, and upwards of twenty upon one stem, so that they have made a beautiful appearance; but where this has not been practised, it is very rare to see one of them in any degree of beauty. *Miller's Gard. Dict.*

TUBULATED FLOWER, a term used to express those smaller flowers, a great number of which go to compose one large compound flower. These are called tubulated in distinction from another kind of them, which are from their shape called ligulated. The tubulated flofcules generally compose the disk, and the ligulated ones the radius of the compound flowers. The tubulated ones are formed into a hollow cylinder, which expands into a mouth at the top, and is divided into five equal segments, which stand expanded, and in some measure bent backwards.

TULIP, the name of a flower so well known as to need no description; and it would be to little purpose to enumerate the several varieties of these flowers, which may be seen in one good garden, since there is no end of their numbers; and what some people may value at a considerable rate, others reject: besides, there are annually a great variety of new flowers obtained from breeders, so those which are old, if they have not very good properties to recommend them, are thrown out and despised. I shall therefore point out the properties of a good tulip, according to the characteristics of the best florists of the present age. 1. It should have a tall strong stem. 2. The flower should consist of six leaves, three within, and three without; the former ought to be larger than the latter. 3. Their bottom should be proportioned to their top, and their upper part should be rounded off, and not terminate in a point. 4. These leaves, when opened, should neither turn inward, nor bend outward, but rather stand erect, and the flower should be of a middling size, neither over large, nor too small. 5. The stripes should be small and regular, arising from the bottom of the flower; for if there are any remains of the former self-coloured bottom, the flower is in danger of losing its stripes again. The chives should not be yellow, but of a brown colour. When a flower has all these properties, it is esteemed a good one.

Tulips are generally divided into three classes, according to their seasons of flowering; as Præcoces, or early blowers, Medias, or middling blowers, and Serotines, or late blowers; but there is no occasion for making any more distinctions than two, viz. early and late blowers.

The early blowing tulips are not near so fair, nor rise half so high, as the late ones, but are chiefly valued for appearing so early in the spring; some of which will flower the end of February in mild seasons, if planted in a warm border near a wall, pale, hedge, or other shelter, and a month after the others will succeed them; so that they keep flowering until the general season for the late flowers to blow, which is towards the end of April.

The roots of the early-blowing tulips should be planted the beginning of September in a warm border, near a wall,

wall, pale, or hedge, becaufe if they are put into an open fpot of ground, their buds are in danger of fuffering by morning frofts in the fpring. The foil for thefe fhould be renewed every year, where people intend to have them fair. The beft foil for this purpofe is that which is taken from a light loamy pafture, with the turf rotted amongft it; and to this fhould be added a fourth part of fea-fand. This mixture may be laid about eighteen inches deep, which will be fufficient; for thefe need not be planted more than four or five inches deep at moft. The off-fets fhould not be planted amongft the blowing roots, but in a border by themfelves, where they may be planted pretty clofely together, efpecially if they are fmall; but thefe fhould be taken up when their leaves decay, in the fame manner as the blowing roots, otherwife they would rot; for thefe are not fo hardy as the late blowers, nor do they increafe half fo faft as thofe, fo that a greater care is required to preferve the off-fets of them.

When thefe tulips come up in the fpring, the earth upon the furface of the borders fhould be gently ftirred and cleared from weeds; and as the buds appear, if the feafon fhould prove fevere, it will be of great fervice to cover them with mats, for want of which many times they are blighted, and the flower-buds decay before they blow, which is often injurious to the roots, as alfo the cropping of the flowers fo foon as they are blown, becaufe their roots, which are formed new every year, are not at that time arrived at their full magnitude, and are hereby deprived of proper nourifhment.

If, when thefe flowers are blown, the feafon fhould prove very warm, it will be proper to fhade them with mats, &c. in the heat of the day; as alfo if the nights are frofty, they fhould be in like manner covered, whereby they may be preferved a long time in beauty; but, when their flowers are decayed, and their feed veffels begin to fwell, they fhould be broken off juft at the top of the ftalks, becaufe if they are permitted to feed, it will injure the roots.

When the leaves of thefe flowers are decayed, which will be before the late blowers are out of flower, their roots fhould be taken up, and fpread upon mats in a fhady place to dry; after which they fhould be cleared from their filth, and put up in a dry place, where vermin cannot come to them, until the feafon for planting them again, being very careful to preferve every fort feparate, that you may know how to difpofe of them at the time for planting them again, becaufe it is the better way to plant all the roots of each fort together, and not to intermix them, as is commonly practifed in moft other kinds of flowers; for as there are few of them which blow at the fame time, fo, when the feveral roots of one fort are fcattered through a whole border, they make but an indifferent appearance; whereas, when twenty or thirty roots of the fame fort are placed together, they will all flower at the fame time, and have a better effect.

There are many curious perfons, who, in order to preferve their feveral kinds of tulips, and other bulbous-rooted flowers feparate, have large flat boxes made, which are divided into feveral fmall partitions, each of which is numbered in the fame manner as the divifions of their beds; fo that when a catalogue of their roots is made, and the numbers fixed to each fort in the beds, there is nothing more to do when the roots are taken up, but to put every kind into the divifion marked with the fame number which was placed to each fort in the bed, which faves a great deal of trouble, and effectually anfwers the purpofe of preferving the kinds feparate.

The late-blowing tulips are fo numerous, that, as I before obferved, it would be to no purpofe to attempt to give a catalogue of them. Thefe are generally obtained from breeders, which is a term applied to all fuch flowers as are produced from feeds which are of one felf-colour, and have good bottoms and chives; thefe in time break into various beautiful ftripes, according to the ground of their former felf-colour; but this muft be entirely thrown off, otherwife they do not efteem a flower well broken.

Of thefe breeders there hath been a great variety brought into England from Flanders of late years, which is the grand nurfery for moft forts of bulbous-rooted flowers; but there are fome curious perfons, who have lately obtained many valuable breeders from feed in England; and doubtlefs, were we as induftrious to fow the feeds of thefe flowers as the people of Holland and Flanders, we might in a few years have as great variety as is to be found in any part of Europe; for, although it is fix or feven years from the fowing before thefe flowers blow, yet, if after the firft fowing there is every year a frefh parcel fown, when the feven years are expired, there will be conftantly a fucceffion of roots to flower every year, which will reward the expectation, and keep up the fpirit of raifing; but it is the length of time at firft, which deters moft people from this work.

The manner of propagating thefe flowers from feeds is as follows: you fhould be careful in the choice of the feeds, without which there can be little fuccefs expected. The beft feed is that which is faved from breeders which have all the good properties before related, for the feeds of ftriped flowers feldom produce any thing that is valuable.

The beft method to obtain good feeds is to make choice of a parcel of fuch breeding tulip roots as you would fave feeds from, and plant them in a feparate bed from the other breeders, in a part of the garden where they may be fully expofed to the fun, obferving to plant them at leaft eight or nine inches deep; for if they are planted too fhallow, their ftems are apt to decay before their feed is perfected.

Thefe flowers fhould always be expofed to the weather, for if they are fhaded with mats, or any other covering, it will prevent their perfecting the feed. About the middle of July, a little fooner, or later, as the fummer is hotter or colder, the feeds will be fit to gather, which may be known by the drynefs of their ftalks, and the opening of the feed veffels; at which time it may be cut off, and preferved in the pods till the feafon for fowing it, being careful to put it up in a dry place, otherwife it will be fubject to mould, which will render it good for little.

Having faved a parcel of good feed, about the beginning of September is the beft feafon for fowing it, when there fhould be provided a parcel of fhallow feed pans or boxes, fix or eight inches deep, which fhould have holes in their bottoms to let the moifture pafs off; thefe muft be filled with frefh light earth, laying the furface very even, upon which the feeds fhould be fown as regularly as poffible, that they may not lie upon each other; then there fhould be fome of the fame light earth fifted over them; about half an inch thick. Thefe boxes or pans fhould be placed where they may have the morning fun till eleven of the clock, in which fituation they may remain until the middle of October, at which time they fhould be removed into a more open fituation, where they may enjoy the benefit of the fun all the day, and be fheltered from the north winds, where they fhould remain until winter, when they muft be placed on a fouth border, to fcreen them from froft; but in the fpring, when the plants are up, they fhould be again removed to their firft fituation; and if the feafon fhould be dry, they muft be refrefhed with water, while the plants remain green, but as foon as their tops begin to decay, there muft be no more given them, left it rot their tender bulbs; therefore the boxes fhould be placed in a fhady fituation during the fummer feafon, but not under the drip of trees.

Thefe plants, at their firft appearance, have very narrow graffy leaves, very like thofe of onions, and come up with bending heads, in the fame manner as they do; fo that perfons who are unacquainted with them, may pull them up inftead of grafs, whilft they are very young, before their leaves are a little more expanded; which is not performed the firft year, for they feldom appear before the middle of March; and they commonly decay about the latter end of May, or the beginning of June, according as the feafon is hotter or colder.

The weeds and mofs fhould alfo be cleared off from the furface of the earth in the boxes, and a little frefh earth fifted over them foon after their leaves decay, which will be of great fervice to the roots. Thefe boxes fhould be conftantly kept clear from weeds, which, if permitted to grow therein, when they are pulled up, their roots will be apt to draw the bulbs out of the ground. At Michaelmas they fhould be frefh earthed again, and as the winter comes on, they muft be again removed into the fun as before,

and

and treated in the ſame manner, until the leaves decay, when the bulbs ſhould be carefully taken up, and put into a cool ſhady room till the end of Auguſt, when they ſhould be planted in beds of freſh ſandy earth, which ſhould have tiles laid under them, to prevent the roots from ſhooting downward, which they often do when there is nothing to ſtop them, and thereby they are deſtroyed. The earth of theſe beds ſhould be about five inches thick upon the tiles, which will be ſufficient for nouriſhing theſe roots while they are young.

The diſtance which theſe young bulbs ſhould be allowed, need not be more than two inches, nor ſhould they be planted above two inches deep; but towards the end of October it will be proper to cover the bed over with a little tanner's bark, about two inches deep, which will preſerve the roots from the froſt, and prevent moſs or weeds from growing over them; but, if the winter ſhould be very ſevere, it will be proper to cover the bed either with mats or peaſe-haulm, to prevent the froſt from entering the ground, becauſe theſe roots are much tenderer while young, than they are after they have acquired ſtrength.

In the ſpring the ſurface of the ground ſhould be gently ſtoned to make it clean, before the plants come up; and if the ſpring ſhould prove dry, they muſt be frequently refreſhed with water, during the time of their growth; but this muſt not be given to them in great quantities, leſt it rot their tender bulbs; and when the leaves are decayed, the roots ſhould be taken up, and treated in the ſame way as before.

When the bulbs are large enough to blow, they ſhould be planted in freſh beds at the diſtance, and in the ſame manner as old roots, where, when they flower, ſuch of them as are worthy to be preſerved ſhould be marked with ſticks; and at the ſeaſon for taking up the bulbs, they muſt be ſeparated from the others, in order to be planted as breeders in different beds; but you ſhould by no means throw out the reſt until they have flowered two or three years, becauſe it is impoſſible to judge exactly of their value in leſs time; for many, which at firſt flowering appear beautiful, will afterwards degenerate ſo as to be of little value; and others, which did not pleaſe at firſt, will many times improve, ſo that they ſhould be preſerved until their worth can be well judged of.

Having thus given an account of the method of raiſing theſe flowers from ſeeds, I ſhall now proceed to the management of the roots which are termed breeders, ſo as to have ſome of them every year break out into fine ſtripes.

There are ſome who pretend to have a ſecret how to make any ſort of breeders break into ſtripes whenever they pleaſe; but this, I dare ſay, is without foundation; for from many experiments which I and others have made of this kind, I could never find any certainty in this. All that can be done by art is, to ſhift the roots every year into freſh earth of different mixtures, and to different ſituations, by which method I have had very good ſucceſs.

The earth of theſe beds ſhould be every year different; for although it is generally agreed that lean, hungry, freſh earth doth haſten their breaking, and cauſe their ſtripes to be the finer and more beautiful, yet, if they are every year planted in the like ſoil, it will not have ſo much effect upon them, as if they were one year planted in one ſort of earth, and the next year in a very different one; as I have ſeveral times experienced; and if ſome fine ſtriped tulips are planted in the ſame beds with the breeders, intermixing them together, it will alſo cauſe the breeders to break the ſooner.

The beſt compoſt for theſe roots is a third part of freſh earth from a good paſture, which ſhould have the ſward rotted with it, a third part of ſea-ſand, and the other part ſifted lime rubbiſh; theſe ſhould be all mixed together ſix or eight months at leaſt before it is uſed, and ſhould be frequently turned to mix the parts well together. With this mixture the beds ſhould be made about two feet deep, after the following manner: after the old earth is taken from out of the bed to the depth intended, then ſome of the freſh earth ſhould be put in about eighteen inches thick; this ſhould be levelled exactly, and then lines drawn each way of the bed chequerwiſe, at ſix inches diſtance; upon the center of each croſs, ſhould be placed the tulip roots, in an upright poſition; and after having finiſhed the bed in this manner, the earth muſt be filled in, ſo as to raiſe the bed ſix or eight inches higher, obſerving, in doing this, not to diſplace any of the roots, and alſo to lay the top of the beds a little rounding, to throw off the wet.

There are many perſons who are ſo careleſs in planting their tulip roots, as only to dig and level the beds well, and then with a blunt dibble to make holes, into which they put the roots, and then fill up the holes with a rake; but this is by no means a good method; for the dibble, in making the holes, preſſes the earth cloſely on each ſide, and at the bottom, whereby the moiſture is often detained ſo long about the roots as to rot them, eſpecially if the ſoil is inclinable to bind; beſides, the earth being hard at the bottom of the bulbs, they cannot ſo eaſily emit their fibres, which muſt certainly prejudice the roots.

Theſe beds ſhould be ſunk, more or leſs, below the ſurface, according to the moiſture or dryneſs of the ground; for the roots ſhould be ſo elevated as never to have the water ſtand near the reach of their fibres in winter, for moiſture is very apt to rot them; ſo that where the ſoil is very wet, it will be proper to lay ſome lime rubbiſh under the earth, in order to drain off the wet, and the beds ſhould be entirely raiſed above the level of the ground; but to prevent their falling down into the walks, after froſt, or hard rains, it will be proper to raiſe the paths between them, either with ſea-coal aſhes or rubbiſh, eight or ten inches, which will ſupport the earth of the beds; and theſe paths may ſlope at each end from the middle, which will make paſſage for the water to run off as it falls. But where the ſoil is dry, the beds may be ſunk eighteen or twenty inches below the ſurface, for in ſuch places the beds need not be more than four or ſix inches above the ſurface, which will be allowance enough for their ſettling.

During the winter ſeaſon there will be no farther care required. The roots being planted thus deep, will be in no danger of ſuffering by ordinary froſts; but if the winter ſhould prove very ſevere, ſome rotten tan or peaſe-haulm may be laid over the beds to keep out the froſt during its continuance, but this muſt be removed when the froſt is over; and in the ſpring, when their leaves begin to appear above ground, the earth upon the ſurface of the beds ſhould be ſtirred to clear it from weeds, moſs, &c. and when the flower-buds begin to come up, they ſhould be guarded from froſt, otherwiſe they are very ſubject to blight and decay ſoon after they appear, if the froſt pinches their tops; but they need only be covered in ſuch nights when there is a proſpect of froſt, for at all other times they ſhould have as much open air as poſſible, without which they will draw up weak, and produce very ſmall flowers.

When theſe breeders are in flower, you ſhould carefully examine them to ſee if any of them have broken into beautiful ſtripes, which, if you obſerve, there ſhould be a ſtick put into the ground by every ſuch root to mark them, that they may be ſeparated from the breeders, to plant amongſt the ſtriped flowers the following year; but you ſhould carefully obſerve, whether they have thrown off their former colour entirely, as alſo when they decay, to ſee if they continue beautiful to the laſt, and not appear ſmeared over with the original colour; in both which caſes they are very ſubject to go back to their old colour the next year: but if their ſtripes are diſtinct and clear to the bottom, and continue ſo to the laſt, which is what the floriſts call dyeing well, there is no great danger of their returning back again, as hath been by ſome confidently reported; for if one of theſe flowers is quite broken, as it is termed, it will never loſe its ſtripes, though ſometimes they will blow much fairer than at other, and the flowers of the off-ſets will be often more beautiful than thoſe of the old roots.

This alteration in the colour of theſe flowers may be ſeen long before they are blown, for the green leaves will appear of a fainter colour, and ſeem to be ſtriped with white, or of a browniſh colour, which is a plain proof, that the juices of the whole plant are altered, or, at leaſt, the veſſels through which the juice is ſtrained; ſo that hereby particles of a different figure are capable of paſſing through them, which, when entered into the petals of the flower, reflect the rays of light in a different manner, which

which occaſions the variety we ſee in the colours of flowers. This breaking of the colours in flowers proceeds from weakneſs, or at leaſt is the cauſe of weakneſs in plants; for it is obſervable, that after tulips are broken into fine ſtripes, they never grow ſo tall as before, nor are the ſtems, leaves, or flowers ſo large; and it is the ſame in all variegated plants and flowers whatever, which are alſo much tenderer than they were before they were ſtriped; ſo that many ſorts of exotic plants, which by accident have become variegated in their leaves, are often rendered ſo tender, as not to be preſerved without much more care, though indeed ſtriping of tulips doth never occaſion ſo great weakneſs in them as to render them very tender. The greateſt effect it hath on them, is in leſſening their growth; the more beautifully their ſtripes appear, the ſhorter will be their ſtems, and the weaker their flowers.

There is nothing more to be obſerved in the culture of ſtriped flowers than what has been directed for breeders, excepting that theſe ſhould be arched over with tall hoops and rails, that they may be ſhaded from the ſun in the day-time, and protected from ſtrong winds, hard rains, and froſty mornings, otherwiſe the flowers will continue but a ſhort time in beauty; but where theſe inſtructions are duly followed, they may be preſerved in flower a full month, which is as long as moſt flowers continue.

There are ſome perſons who are ſo extremely fond of theſe flowers, as to be at a great expence in erecting large frames of iron work to cover their beds of tulips, in ſuch a manner, that they may walk between two beds under the frames, over which are ſpread tarpawlings, ſo as to keep off ſun, rain, and froſt, whereby they can view the flowers without being at the trouble of taking off or turning up the tarpawlings, or being incommoded by the ſun or rain, which cannot be avoided where the covering is low; beſides, by thus raiſing the covers, the flowers have a greater ſhare of air, ſo that they are not drawn ſo weak as they are when the covering is low and cloſe to them; but theſe frames being expenſive, can only be made by perſons of fortune; however, there may be ſome of wood contrived at a ſmaller expence, which, being arched over with hoops, may anſwer the purpoſe as well as the iron frames, though they are not ſo ſightly or laſting.

When the flowers are faded, the heads of all the fine ſorts ſhould be broken off, to prevent their ſeeding; for if this is not obſerved, they will not flower near ſo well the following year, nor will their ſtripes continue ſo perfect: this will alſo cauſe their ſtems to decay ſooner than otherwiſe they would do, ſo that their roots may be taken up in June; for they ſhould not remain in the ground after their leaves are decayed. In taking the roots out of the ground, you muſt be very careful not to bruiſe or cut them, which will endanger their rotting, and, if poſſible, it ſhould be done a day or two after rain. When theſe roots are taken out of the ground, they muſt be cleared from their old covers, and all ſorts of filth, and ſpread upon mats in a ſhady place to dry; after which they ſhould be put up in a dry place, where vermin cannot get to them, obſerving to keep every ſort ſeparated; but they ſhould not be kept too cloſe from the air, nor ſuffered to lie in heaps together, leſt they ſhould grow mouldy; for if any of the roots once take the mould, they commonly rot when they are planted again.

The offsets of theſe roots, which are not large enough to produce flowers the ſucceeding year, ſhould be alſo put by themſelves, keeping each ſort diſtinct: theſe ſhould be planted about a month earlier in autumn than the blowing roots, in particular beds by themſelves, in the flower nurſery, where they may not be expoſed to public view; but the earth of the beds ſhould be prepared for them in the ſame manner as for larger roots; theſe ſhould not be planted above five inches deep, becauſe they are not ſtrong enough to puſh through ſo great covering of the earth as the old roots; they may alſo be placed much nearer together than thoſe which are to flower, and in one year moſt of them will become ſtrong enough to flower, when they may be removed into the flower-garden, and placed in the beds amongſt thoſe of the ſame kinds. *Miller's Gard. Dict.*

Tulip-Tree, a very beautiful American tree, which produces flowers, ſuppoſed like thoſe of the tulip.

This tree, which is a native of North America, and where it grows to be a tree of the firſt magnitude, is generally known through all the Engliſh ſettlements by the title of poplar. Of late years there has been great numbers of theſe trees raiſed from ſeeds in the Engliſh gardens, ſo that now they are become common in the nurſeries about London, and there are many of the trees in ſeveral parts of England, which do annually produce flowers. The firſt tree of this kind which flowered here, was in the gardens of the late earl of Peterborough at Parſons-green near Fulham, which was planted in a wilderneſs among other trees. Before this was planted in the open air, the few plants which were then in the Engliſh gardens, were kept in pots or tubs, and houſed in winter, ſuppoſing they were too tender to live in the open air; but this tree ſoon after it was planted in the full ground, convinced the gardeners of their miſtake, by the great progreſs it made, while thoſe which were kept in pots and tubs, increaſed ſlowly in their growth; ſo that afterwards there were many others planted in the full ground, which are now arrived to a large ſize, eſpecially thoſe which were planted in a moiſt ſoil. One of the handſomeſt trees of this kind near London, is in the garden of Waltham-Abbey; and at Wilton, the ſeat of the earl of Pembroke, there are ſome trees of great bulk; but the old tree at Parſons-green is quite deſtroyed by the other trees which were ſuffered to overhang it, and rob it of its nouriſhment, from a fear of taking down the neighbouring trees, and admitting the cold air to the tulip-tree, it ſhould injure it.

The young ſhoots of this tree are covered with a ſmooth purpliſh bark, garniſhed with large leaves, whoſe footſtalks are long; they are ranged alternate; the leaves are of a ſingular form, being divided into three lobes; the middle lobe is blunt and hollowed at the point, appearing as if it had been cut with ſciſſars. The two ſide lobes are rounded, and end in blunt points. The upper ſurface is ſmooth, and of a lucid green; the under is of a pale green. The flowers are produced at the end of the branches; they are compoſed of ſix petals, three without and three within, which form a ſort of bell-ſhaped flower, from whence the inhabitants of North America gave it the name of Tulip. Theſe petals are marked with green, yellow and red ſpots, ſo make a fine appearance when the trees are well charged with flowers. The time of this tree's flowering is in July, and when the flowers drop, the germen ſwells and forms a kind of cone; but theſe do not ripen in England.

This tree is propagated by ſeeds, which are now annually imported in great plenty from America. Theſe ſhould be ſown as ſoon as they arrive, in pots or tubs, filled with light earth, from the kitchen garden, or in a bed in the full ground. Thoſe which are ſown in the firſt way, may be placed on a very gentle hot hed, which will forward their growth; ſo that if they come up the ſame ſeaſon, the plants will acquire more ſtrength before winter. When the plants appear, they muſt be ſhaded in the heat of the day from the ſun, but freſh air muſt be admitted daily to prevent their drawing up weak; and as the ſeaſon advances, they muſt be gradually hardened to bear the open air. While the plants are young they do not care for much ſun, ſo they ſhould be either ſhaded, or placed where the morning ſun only ſhines upon them; they muſt alſo be conſtantly ſupplied with water, but not have it in too great plenty. As the young plants commonly continue growing late in the ſummer, ſo when there happens early froſts in autumn, it often kills their tender tops, which occaſions their dying down a conſiderable length in winter; therefore they ſhould be carefully guarded againſt theſe firſt froſts, which are always more hurtful to them than harder froſts afterwards, when their roots are better hardened; however, the firſt winter after the plants come up, it will be the better way to ſhelter them in a common hot-bed frame, or to arch them over with hoops, and cover them with mats, expoſing them always to the open air in mild weather.

The following ſpring, juſt before the plants begin to ſhoot, they ſhould be tranſplanted into nurſery beds, in a ſheltered ſituation, where they are not too much expoſed to the ſun. The ſoil of theſe beds ſhould be a ſoft gentle loam, not too ſtiff, nor over light; this ſhould be well wrought, and the clods well broken and made fine. There muſt be great care taken not to break the roots of the plants in taking them up, for they are very tender; then they ſhould be planted again as ſoon as poſſible, for if their roots are long out of the ground, they will be much injured thereby. Theſe may be planted in rows at about a foot diſtance, and at ſix inches diſtance in the rows; for as they ſhould not remain long in theſe nurſery-beds, ſo this will be room enough for them to grow; and by having them ſo cloſe they may be ſhaded in the ſummer, or ſheltered in the winter, with more eaſe than when they are farther apart.

When the plants are thus planted, if the ſurface of the beds is covered with rotten tanners bark, or with moſs, it will prevent the earth from drying too faſt; ſo that the plants will not require to be ſo often watered, as they muſt be where they are expoſed to the ſun and air; after this, the farther care will be to keep them clean from weeds, and if the latter part of the ſummer ſhould prove moiſt, it will occaſion the plants growing late in autumn, ſo their tops will be tender and liable to be killed by the firſt froſts. In this caſe they ſhould be covered with mats to protect them.

If the plants make great progreſs the firſt ſummer, they may be tranſplanted again the following ſpring; part of them may be planted in the places where they are to remain, and the other ſhould be planted in a nurſery where they may grow two years, to acquire ſtrength before they are planted out for good; though the younger they are planted in the places where they are to ſtand, the larger they will grow, for the roots run out into length; and when they are cut it greatly retards their growth, ſo that theſe trees ſhould never be removed large; for they rarely ſucceed, if tranſplanted when they are grown to a large ſize. Some indeed that have been removed pretty large, have ſurvived their removal; but young plants of two years old, which were planted near them, were much larger in fifteen years than the old ones.

When the ſeeds are ſown upon a bed in the full ground, the bed ſhould be arched over with hoops, and ſhaded in the heat of the day from the ſun, and frequently refreſhed with water; as ſhould alſo the plants when they appear, for when they are expoſed much to the ſun while young, they make but ſmall progreſs. The care of theſe in ſummer muſt be to keep them clean from weeds, ſupplying them duly with water, and ſhading them from the ſun in hot weather; but as theſe ſeeds will not come up ſo ſoon as thoſe which were placed on a hot-bed, they generally continue growing later in autumn, therefore will require ſhelter from the early froſts in autumn; for as the ſhoots of theſe will be much ſofter than thoſe of plants which had longer time to grow, ſo if the autumnal froſts ſhould prove ſevere, they will be in danger of being killed down to the ſurface of the ground, by which the whole ſummer's growth will be loſt; and ſometimes the plants are entirely killed the firſt winter if they are not protected.

As theſe plants will not have advanced ſo much in their growth as the other, they ſhould remain in the ſeed-bed to have another year's growth before they are removed; therefore all that will be neceſſary to obſerve the ſecond year, is to keep them clean from weeds; and now they will not be in ſo much danger of ſuffering from the warmth of the ſun as before, therefore will not require ſuch conſtant care to ſhade them, nor ſhould the watering of them be continued longer than the ſpring; for if the autumn ſhould prove dry, it will prevent the plants from ſhooting late, and harden thoſe ſhoots which were made early in the year, whereby the plants will be in leſs danger from the early froſts.

After the plants have grown two years in the ſeed-bed, they will be ſtrong enough to remove; therefore, in the ſpring, juſt at the time when their buds begin to ſwell, they ſhould be carefully taken up, and tranſplanted into nurſery-beds, and treated in the ſame way as has been before directed for the plants which were raiſed in pots.

There are ſome people who propagate this tree by layers, but the layers are commonly two or three years before they take root; and the plants ſo raiſed, ſeldom make ſuch ſtraight trees as thoſe raiſed from ſeeds, though indeed they will produce flowers ſooner, as is always the caſe with ſtinted plants.

This tree ſhould be planted on a light loamy ſoil, not too dry, on which it will thrive much better than upon a ſtrong clay, or a dry gravelly ground; for in America they are chiefly found upon a moiſt light ſoil, where they will grow to a prodigious ſize, though it will not be proper to plant theſe trees in a ſoil which is too moiſt, in England, becauſe it might endanger the rotting of the fibres of the roots, by the moiſture continuing too long about them, eſpecially if the bottom be a clay, or a ſtrong loam, which will detain the wet. *Miller's Gar. Dict.*

TUMBLER, a name given to a particular ſpecies of pigeon, called by Moore the columba revolvens.

It has its name from its peculiar property of tumbling, when it is in the air, which they are very fond of doing; and effect exactly in the ſame manner as our poſture-maſters do it, by throwing themſelves over backwards. It is a very ſmall pigeon, and is always ſhort-bodied, full-breaſted, thin-necked, narrow-beaked, and has a ſmall ſhort head; the iris of the eye, in this ſpecies, is uſually of a bright pearl colour.

The Engliſh tumbler is uſually of one plain colour; black, blue, or white: the Dutch is much of the ſame make, but has different colours, and is feathered on the legs ſometimes: it has alſo a larger head, and thin ſkin round the eye. Some of the fineſt pigeons of this ſort are bred from a mixture of the Dutch and Engliſh kinds.

Theſe pigeons are remarkable for the height they fly to; they never ramble far from home, but will riſe almoſt perpendicularly, till they appear no larger than a ſparrow, or become quite out of ſight: they will often keep at this height five or ſix hours, and then come gradually down again: they will never tumble when they are at any great height, but only as they aſcend or come down again. There are particular times alſo, at which thoſe birds will take much higher flights than at others; but they ought to be kept by themſelves, and practiſed to it by the company of one of their own ſpecies; for if they mix, while young, with other pigeons, they will learn to fly as they do: a flight of a dozen of theſe birds ſent out together will keep ſo cloſe as to be all in a compaſs that might be covered with a handkerchief; but they ſhould never be turned out in foggy weather, or in high winds; in the firſt caſe they loſe ſight of their home, and perhaps never find it again, and, in the others, they are blown away; and, if they return, it is not till another day: in the mean time, lying out, they are in danger of cats, and other accidents.

Laſtly, the hen ſhould never be turned out with egg, for ſhe is then ſick, and not fit for flying; and, beſides, often drops her egg, and the breed is loſt by it. *Moore's Columbarium.*

TUMBREL, a dung-cart.

TUMOUR, a preternatural ſwelling or eminence riſing in any part of a horſe, and ariſes either from external injuries, or internal cauſes.

Swellings cauſed by external accidents, as blows and bruiſes, ſhould at firſt be treated with reſtringents; thus, let the part be bathed frequently with hot vinegar or verjuice, and, where it will admit of bandage, let a flannel wetted with the ſame be rowled on: if by this method the ſwelling does not ſubſide, apply, eſpecially on the legs, a poultice with red wine lees, ſtrong beer grounds, and oatmeal, or with vinegar, oil, and oatmeal; either of theſe may be continued twice a day, after bathing, till the ſwelling abates; when, in order to diſperſe it intirely, the vinegar ſhould be changed for camphorated ſpirit of wine, to four ounces of which, may be added one of ſpirit of ſal armoniac; or it may be bathed with a mixture of two ounces of crude ſal armoniac boiled in a quart of chamber-lye, twice a day, and rags dipped in the ſame may be rowled on.

Fomentation made by boiling wormwood, bay-leaves, and roſemary, and adding a proper quantity of ſpirits, are often of great ſervice to thin the juices, and fit them for tranſpiration; eſpecially if the injury has affected the joints.

But in bruiſes, where the extravaſated blood will not by theſe means be diſperſed, the ſhorteſt way is to open the ſkin, and let out the grumes.

Critical tumours, or ſwellings which terminate fevers, ſhould by no means be diſperſed; except when they fall on the paſtern or coffin joint, ſo as to endanger them: in this caſe the diſcutient fomentation ſhould be applied three or four times a day, and a cloth or flannel frequently wrung out of the fame fhould be bound on, in order to keep the joint continually breathing.

But if the fwelling fixes under the jaws, behind the ears, on the poll, withers, or in the groins and fheath, &c. it fhould be encouraged and forwarded by ripening poultices, wherever they can be applied; oatmeal boiled foft in milk, to which a proper quantity of oil and lard is added, may anfwer this purpofe; or the poultice recommended in treating of the ftrangles: thefe muft be applied twice a day, till the matter is perceived to fluctuate under the fingers, when it ought to be let out; for which purpofe, let the tumour be opened with a knife or ftrong launcet, the whole length of the fwelling, if it can be done fafely, for nothing contributes fo much to a kind healing, as the matter's having a free difcharge, and the openings being big enough to drefs to the bottom.

Pledgits of tow fpread with black or yellow bafilicon (or the wound ointment) and dipped in the fame, melted down with a fifth part of oil of turpentine, fhould be applied to the bottom of the fore, and filled up lightly with the fame, without cramming; it may be thus dreffed once or twice a day, if the difcharge is great, till a proper digeftion is procured, when it fhould be changed for pledgits fpread with the red precipitate ointment, applied in the fame manner.

Should the fore not digeft kindly, but run a thin water and look pale, foment as often as you drefs, with the above fomentation; and apply over your dreffing the ftrong beer poultice, and continue this method till the matter grows thick, and the fore florid.

The following ointments will generally anfwer your expectations in all common cafes, and may be prepared without, as well as with, the verdigreafe.

> Take Venice turpentine and bees wax, of each a pound; oil of olives one pound and a half; yellow rofin twelve ounces: when melted together, two or three ounces of verdigreafe finely powdered may be ftirred in, and kept fo till cold, to prevent its fubfiding.

> Take of yellow bafilicon, or the above ointment without verdigreafe, four ounces; and red precipitate finely powdered half an ounce: mix them together cold, with a knife or fpatula.

This laft applied early, will prevent a fungus, or proud flefh, from fhooting out; for if you drefs too long with the above digeftive, the fungus will rife faft, and give fome trouble to fupprefs it; when it will be neceffary to wafh the fore as often as you drefs, with a folution of blue vitriol in water, or to fprinkle it with burnt allum and precipitate. If thefe fhould not be powerful enough, touch with a cauftic, or wafh with the fublimate water, made by diffolving half an ounce of corrofive fublimate in a pint of lime-water.

But this trouble may in a great meafure be prevented, if the fore is on a part where bandage can be applied with compreffes of linen cloth: for even when thefe excrefcences regerminate, as it were, under the knife, and fpring up in fpite of the cauftics above-mentioned, they are to be fubdued by moderate compreffion made on the fprouting fibres, by thefe means.

Authors on farriery have in general given very proper receipts to anfwer every intention of this kind by medicines; but as they have not, I think, laid down fufficient rules for their application in thofe cafes where they are moft wanted, I hope the following general directions will not be unacceptable; as the difficulty in healing fome kinds of fores arifes frequently from the unfkilful manner of dreffing them.

It may be neceffary then to obferve here once for all, that the cures of moft fores are effected by the fimpleft methods, and that it is often of much more confequence to know how to drefs a fore, than what to drefs it with; and in this confifts indeed the chief art of this branch of furgery; for the moft eminent in that profeffion have long fince difcovered, that variety of ointments and falves are unneceffary in the cure of moft wounds and fores, and they have accordingly difcarded the greateft part, formerly in repute for that purpofe; repeated obfervations having taught them, that after the digeftion, nature is generally difpofed to heal up the wound faft enough herfelf, and that the furgeon's chief care is to prevent a luxuriancy, commonly called proud flefh; which all ointments wherein lard or oil enters, are but too prone to encourage, as they keep the fibres too lax and fupple; and which dry lint alone, early applied, as eafily prevents, by its abforbing quality, and light compreffion on the fprouting fibres.

Thus if a hollow wound or fore is crammed with tents, or the dreffings are applied too hard, the tender fhoots of flefh from the bottom are prevented pufhing up; and the fides of the fore in time from this diftenfion may grow horney, and turn fiftulous; nor has the matter by this method a free difcharge.

On the other hand, if fores of any depth are dreffed fuperficially, the external parts being more difpofed to heal and come together than the internal, they will fall into contact, or heal too foon; and the fore not filling up properly from the bottom, will break out afrefh.

Hence we may juftly conceive how little ftrefs is to be laid on famous ointments, or family falves, unfkilfully applied; for unlefs this due medium is obferved, or obtained in the dreffing, no hollow fore can heal up properly.

I thought it neceffary to be a little explicit on this head, as gentlemen fo frequently complain of being difappointed in their cures, notwithftanding the excellency of their ointment, or balfam; and to convince them that lefs confidence fhould be put in thefe favourite medicines than is generally imagined; for where the habit is found, and the blood and juices in good condition, there are few fimple dreffings that will not fucceed; and when otherwife, the moft pompous will not avail, till thefe are rectified by proper internal medicines.

As foon then as a good digeftion is procured (which is known by the thicknefs and whitenefs of the matter difcharged, and the florid red colour at the bottom of the fore) let the dreffings be changed for the precipitate medicine; or the fore may be filled up with dry lint alone, or dipped in lime-water with a little honey and tincture of myrrh, or brandy: about a fifth part of the latter to one of the former; a pledgit of lint dipped in this mixture fhould alfo be applied to the bottom of the fore, which fhould be filled up with others to the furface or edges, but not crammed in too hard, as before obferved, nor yet applied too loofely.

By this method, the fore would incarn, or heal up properly, and foft fpongy flefh would be prevented, or fuppreffed in time; whereas when ointments or falves are too long continued, a fungus or proud flefh, is thereby fo encouraged in its growth, that it requires fome time to deftroy and eat it down again: a proper comprefs of cloth, and a linnen rowler is abfolutely neceffary both for this purpofe, and to fecure on the dreffings, wherever they can conveniently be applied. *Bartlet's Farriery, pag.* 236.

TUPP, a ram.

TUPPING-TIME, ramming time.

TURF, a blackifh, fulphureous earth, ufed in feveral parts of England, Holland, and Flanders, as fewel.

In Flanders, their turf is dry or pared from off the furface of the earth, and cut in form of bricks. The fedge, or fpecies of grafs growing very thick on the turf earth, contributes greatly, when dry, to the maintenance of the fire.

The Dutch take their turf from the bottom of the dykes or canals which run acrofs moft of their lands; by which means they not only fupply the defect of wood, which is very great in moft of the United Provinces, but alfo keep their dykes clear and navigable: this turf earth is very black. As they take it up from the bottom of the dykes, they fpread it about the edges, of fuch a thicknefs, as that it may be reduced to three inches when moderately dried. In this condition they cut it into pieces of turfs feven or eight inches long, and three broad, and, to complete the drying, lay them up in heaps, and at laft in ftacks.

In the north of England, Scotland, &c. turf is dug out of foft, moift, rotten earth, called peatmofs. They dig horizontally from the furface, to the depth of about four feet, with a fpade, which at once fafhions and takes them out in parallelopipeds nine or ten inches long, and three fquare; which are fpread on the ground to drain as faft as dug; and then fet up an end three or four againft each other, for the wind to blow through them; and at

laft

laſt they are ſtacked or houſed. The pits or dykes in a few years fill up again, and afford a freſh crop.

TURF-ASHES. *See the article* ASHES.

TURF-BOGS. *See* BOG, MOOR, and MOSS.

TURFING-SPADE, an inſtrument uſed to under-cut the turf, after it is marked out with the plough.

TURKEY, the name of a well known fowl, reared in many parts of England.

" Moſt of our houſewives, ſays a Swediſh author on huſbandry, have long deſpaired of ſucceſs in rearing turkeys, and complained that the profit rarely indemnifies them for their trouble and loſs of time: whereas, continues he, little more is to be done than to plunge the chick into a veſſel of cold water, the very hour, or if that cannot be, the day it is hatched, forcing it to ſwallow one whole pepper-corn, and then reſtoring it to its mother. From that time it will become hardy, and fear the cold no more than a hen's chick. After which it muſt be remembered that theſe uſeful creatures are ſubject to one particular malady whilſt they are young, which carries them off in a few days. When they begin to droop, examine carefully the feathers on their rump, and you will find two or three, whoſe quill part is filled with blood. Upon drawing theſe the chick recovers, and after that requires no other care than what is commonly beſtowed on poultry that range the court-yard.

" Theſe articles are too true to be denied; and in proof of the ſucceſs, three pariſhes in Sweden have, for many years, gained ſeveral hundred pounds by rearing and ſelling turkeys." *Rural Oeconomy, pag.* 739.

TURNEP, or *Turnip*, an eſculent plant, of which there are three ſpecies enumerated by Miller. The firſt is the turnip which is commonly cultivated in the fields, of which there are the following varieties, viz. the round red or purple topped turnip, the green topped turnip, the yellow turnip, the black rooted turnip, and the early Dutch turnip. The laſt ſort is commonly ſown early in the ſpring, to ſupply the markets in May and June, but is never cultivated for a general crop. The red rooted turnip was formerly more cultivated in England than at preſent; for ſince the large green topped turnip has been introduced, all the ſkilful farmers prefer it to the other ſorts; the roots of the green will grow to a large ſize, and continue good much longer than the other ſorts. The next to this is the red or purple topped turnip, which will alſo grow large, and is extremely good for ſome time; but the roots of this will become ſtringy much ſooner than thoſe of the green topped. The long rooted turnip, the yellow turnip, and the blackiſh rooted turnip, are now rarely cultivated in England, neither of them being ſo good for the table or for feed, as the red and green topped turnip, though there are ſome few perſons who ſow them for the ſake of variety.

The French turnip is not much cultivated in England, but in France and Holland they are in great eſteem, eſpecially for ſoups; their roots being ſmall, are boiled whole in the ſoup, and ſo ſerved up to the table; theſe muſt be uſed while they are young, otherwiſe they will become rank and ſtringy.

Theſe are ſuppoſed to be only varieties, which have accidentally been obtained from ſeeds, therefore I have not enumerated them as diſtinct ſpecies; but yet I am certain they are conſtant, where care is taken in the ſaving of their ſeeds not to ſuffer any mixture to ſtand for ſeeds: I have ſown of three or four ſorts ſeveral years, and have always found them retain their differences; however, it is not eaſy to determine if ſome of theſe were not by culture firſt obtained from ſeeds of the common white turnip. The yellow turnip ſeems moſt unlikely to have been an accidental variety, for I have never known this alter, and the roots are yellow within, whereas all the other have white fleſh, notwithſtanding their outſides are of very different colours.

The long rooted turnip is, I think, a diſtinct ſpecies, the form of the root, and its manner of growth being totally different from the other ſorts. I have ſeen theſe roots as long as thoſe of the parſnip, and nearly of the ſame ſhape; theſe run deep into the ground, ſo are unfit for feeding of cattle; and unleſs they are uſed very young, become ſtrong, ſo not proper for the table, which has occaſioned their being rejected of late years.

The green topped turnip grows above ground more than any of the other, which renders it preferable for feeding of cattle; and being the ſofteſt and ſweeteſt root when grown large of any of the kinds, is moſt eſteemed for the table; but in very ſevere winters they are in greater danger of ſuffering by froſt, than thoſe whoſe roots lie more in the ground, eſpecially if they are not covered by ſnow; for when they are frequently hard frozen and thawed, it cauſes them to rot ſooner than thoſe whoſe fleſh is leſs tender and ſweet. I have ſeen the roots of this ſort, which were more than a foot diameter, boiled, and were as ſweet and tender, as any of the ſmalleſt roots.

Turnips delight in a light, ſandy, loamy ſoil, which muſt not be rich; for in a rich ſoil they grow rank and are ſticky, but if it be moiſt they will thrive the better in ſummer, eſpecially in freſh land, where they are always ſweeter than upon an old worn-out or a rich ſoil.

The common ſeaſon for ſowing of turnips, is any time from the beginning of June to the middle of Auguſt, or a little later; though it is not adviſeable to ſow them much after, becauſe, if the autumn ſhould not prove very mild, they will not have time to apple before winter, nor will the roots of thoſe which are ſown after the middle of July, grow very large, unleſs the froſt keeps off long in autumn. But, notwithſtanding this is the general ſeaſon in which the greateſt part of turnips are ſown in the country, yet, about London, they are ſown ſucceſſively from March to Auguſt, by thoſe who propagate them to ſupply the markets with their roots; but there is a great hazard of loſing thoſe which are ſown early in the year, if the ſeaſon ſhould prove dry, by the fly, which will devour whole fields of this plant while young; ſo that where a ſmall quantity for the ſupply of a family is wanted, it will be abſolutely neceſſary to water them in dry weather; and where a perſon ſows thoſe ſeeds in April and May, it ſhould always be upon a moiſt ſoil, otherwiſe they ſeldom come to good, the heat of the weather at that ſeaſon being too great for them upon a dry ſoil; but thoſe which are ſown towards the middle or latter end of June, commonly receive ſome refreſhing ſhowers to bring them forward; without which, it is very common to have them all deſtroyed.

Theſe ſeeds ſhould always be ſown upon an open ſpot of ground; for if they are near hedges, walls, buildings, or trees, they will draw up, and be very long topped, but their roots will not grow to any ſize.

They are ſown in great plenty in the fields near London, not only for the uſe of the kitchen, but for food for cattle in winter, when there is a ſcarcity of other food; and this way is become a great improvement to barren ſandy lands, particularly in Norfolk, where, by the culture of turnips, many perſons have doubled the yearly value of their ground.

The land upon which this ſeed is ſown, ſhould be ploughed in April, and twy-fallowed in May, that is once more ploughed and twice well harrowed, and made very fine; then the ſeed ſhould be ſown pretty thin; for it being ſmall, a little will ſow a large piece of ground; one pound is the common allowance for an acre of land. The ſeed muſt be harrowed in as ſoon as it is ſown, with a ſhort-tined harrow, and the ground rolled with a wooden roll, to break the clods, and make the ſurface even. In ten days or a fortnight after ſowing, the plants will come up; at which time, if the ſeaſon ſhould prove dry, they will be in great danger of being deſtroyed by the fly; but if it ſo happen, the ground muſt be ſowed again, for the ſeed being cheap, the chief expence is the labour; but the ground ſhould be firſt harrowed to looſen it, eſpecially if it is ſtiff land.

When the plants have got four or five leaves, they ſhould be hoed to deſtroy the weeds, and to cut up the plants where they are too thick, leaving the remaining ones about ſix or eight inches aſunder each way, which will be room enough for the plants to ſtand for the firſt hoeing; the ſooner this is performed, when the plants have four leaves, the better they will thrive; but in the ſecond hoeing, which muſt be performed about a month after the firſt, they ſhould be cut up, ſo as that the remaining plants may ſtand fourteen or ſixteen inches diſtance, or more, eſpecially if they are deſigned for feeding of cattle; for where the plants are allowed a good diſtance, the roots will be proportionably large; ſo that what is loſt in in number, will be over-gained by their bulk, which is what I have often obferved. But in fuch places where they are fown for the ufe of the kitchen, they need not be left at a greater diftance than ten inches or a foot, becaufe large roots are not fo generally efteemed for the table.

It is not many years fince the practice of fowing turnips for feeding of cattle, has been of general ufe; how it happened that this improvement fhould have been fo long neglected in every part of Europe, is not eafy to determine, fince it is very plain, that this piece of hufbandy was known to the ancients. For Columella, in treating of the feveral kinds of vegetables which are proper for the field, recommends the cultivating rapa in plenty; becaufe, fays he, thofe roots which are not wanted for the table, will be eaten by the cattle: yet this plant was not much cultivated in the fields till within the laft fixty or feventy years; nor is the true method of cultivating turnips yet known, or at leaft not practifed, in fome of the diftant counties of England, at this time. For in many places the feed is fown with barley in the fpring, and thofe plants which come up, and live till the barley is cut, produce a little green for the fheep to pick up, but never have any roots. In other places, where the turnip feed is fown by itfelf, the method of hoeing them is not underftood; fo that weeds and turnips are permitted to grow together; and where the turnips come up thick in patches, they are never thinned, fo that they draw up to have long leaves, but never can have good roots, which is the principal part of the plant, therefore fhould be chiefly attended to.

The general method now practifed in England, for cultivating this plant in the fields, is the fame as is practifed by the farming gardeners, who fupply the London markets with thefe roots, and is the fame as before directed. But it is only within the compafs of a few years, that the country people have been acquainted with the method of hoeing them; fo that the farmers formerly employed gardeners, who had been bred up in the kitchen gardens, to perform this work; but it is now performed by many country labourers, by which means that practice is loft to the kitchen gardeners; the labourers doing it much cheaper.

There has alfo been another method practifed very lately, by fome very curious farmers, in cultivating of turnips, which is by fowing the feed in rows, with the drill-plough. In fome places the rows are fown three feet afunder, in others four, in fome five, and fome fix. The latter has been recommended by fome, as the moft proper diftance; and although the intervals are fo large, yet the crop produced on an acre has been much greater than upon the fame quantity of land, where the rows have been but half this diftance; and upon all the fields which have been tilled, the crops have greatly exceeded thofe which have been hand-hoed. The late lord vifcount Townfhend was at the expence of making the trial of thefe two different methods of hufbandry, with the greateft care, by equally dividing the fame fields into different lands, which were alternately fown in drills, and the intermediate lands in broad-caft. The latter were hoed by hand, in the common method, and the other cultivated by the hoeing-plough; and when the roots were fully grown, his lordfhip had an equal quantity of land, which had been fowed in the different methods, meafured, and the roots drawn up and weighed; thofe roots which had been cultivated by the plough, were fo much larger than the other, that the crop of one acre weighed a ton and half more than that of an acre in the other hufbandry.

But when the turnips are fown in drills, they will require to be hoed by hand, to feparate and cut out the plants, where they are too near together in the rows; as alfo to cut up the weeds between the plants, where the plough cannot reach them. If this is carefully performed, the ploughing of the intervals will encourage the growth of the roots, by thus ftirring of the ground, and make it much better prepared for the crop of barley, or whatever elfe is fown the following fpring. This method of culture may be fuppofed to be more expenfive than that commonly practifed, by thofe unacquainted with it; but thofe who have made trial of both, find the horfe-hoeing to be much the cheapeft, and by far the beft. For the country people, who are employed in hand-hoeing of turnips, are very apt to hurry over their work, fo that half the weeds are left growing, and the plants are feldom fingled out fo well as they fhould be; nor are they curious enough to diftinguifh the charlock, which is one of the moft common weeds in arable land, from the turnips; fo that about the middle of September, it is very common to fee the fields of turnips full of the yellow flowers of the charlock. Now, in the horfe-hoeing, all the weeds in the intervals will be entirely deftroyed; fo that if a few plants in the rows of turnips fhould be overlooked, they may be eafily drawn when they appear vifible, and by this method the land will be fooner and better cleaned from weeds.

The greateft evil which attends a crop of turnips, is that of their being deftroyed by the fly, which ufually happens foon after the plants come above-ground, or while they are in the feed leaf; for, after they have put out their rough leaves pretty ftrong, they will be paft this danger. This always happens in dry weather; fo that, if there fhould be rain when the turnips come up, they will grow fo faft, as to be in a few days out of danger from the fly; and it hath been found, that thofe, which have been fown in drills, have efcaped the fly much better than thofe fown in broad-caft; but, if foot is fown along the furface of each drill, it will be of great fervice to keep off the fly, and a fmall quantity of it will be fufficient for a large field, where the drills only are to be covered.

Another danger of the crops being deftroyed is from the caterpillars, which very often attack them, when they are grown fo large as to have fix or eight leaves on a plant. The fureft method of deftroying thefe infects, is to turn a large parcel of poultry into the field, which fhould be kept hungry, and turned early in the morning into the field; thefe fowls will foon devour the infects, and clear the turnips. To this evil the turnips, which are fown in drills, are not fo much expofed; for as the ground between the rows will be kept ftirred, the plants will be kept growing, fo will not be in danger of fuffering from thefe infects, for the parent infects never depofit their eggs upon any plants which are in health; but as foon as they are ftinted, they are immediately covered with the eggs of thefe infects; and this holds in general with vegetables as with animals, who are feldom attacked by vermin when they are in perfect health; whereas, when they become unhealthy, they are foon overfpread with them; fo that it is the difeafe which occafions the vermin, and not the vermin the difeafe, as is commonly imagined.

When the turnips are fown in drills, it will be the beft way to plough between every other row at firft, and fome time after to plough the alternate intervals, by which method the plants will receive more benefit from the often ftirring the ground than they would do, if all the intervals were hoed at one time; and plants will be in lefs danger of fuffering from the earth being thrown up too high on fome rows, while others may be left too bare of earth; but, when the earth has been thrown up on one fide of the drill, it may be turned down again foon after the next interval is ploughed. This alternate moving of the earth will prepare the ground very well for the fucceeding crop, and greatly improve the turnips; but, as the plough cannot well be drawn nearer to the drills than two or three inches, the remaining ground fhould be forked to loofen the parts, and make way for the fibres of the roots to ftrike out into the intervals; otherwife, if the land is ftrong, it will become fo hard in thofe places which are not ftirred, as to ftint the growth of the turnips. This may be done at a fmall expence; a good hand will perform a great deal of this work in a day, and, whoever will make the trial, will find their account in practifing it, efpecially on all ftrong land, where the turnips are much more liable to fuffer from the binding of the ground, than they will be on a loofe foil; but yet, in all forts of ground, it will be of great fervice to practife this.

When the ground is thus ftirred in every part, one ploughing will be fufficient, after the turnips are eaten, for the fowing of barley, or any other crop; fo that there will be an advantage in this, when the turnips are kept late on the ground, as will often be the cafe, efpecially when they are cultivated for feeding of ewes, becaufe it is often the middle of April before the ground will be cleared; for late

late feed in the ſpring, before the natural graſs comes up, is the moſt wanted, where numbers of ſheep or ewes are maintained, and one acre of turnips will afford more feed than fifty acres of the beſt paſture at that ſeaſon.

In Norfolk and ſome other counties they cultivate great quantities of turnips for feeding of black cattle, which turn to great advantage to their farms, for hereby they procure a good dreſſing for their land; ſo that they have extraordinary good crops of barley upon thoſe lands, which would not have been worth the ploughing, if it had not been thus huſbanded.

When the turnips are fed off the ground, the cattle ſhould not be ſuffered to run over too much of the ground; for, if they are not confined by hurdles to as much as is ſufficient for them one day, the cattle will ſpoil three times the quantity of turnips as they can eat, ſo that it is very bad huſbandry to give them too much room; therefore the hurdles ſhould be every day removed forward, and if the turnips are drawn out of the ground before the cattle or ſheep are turned into the new incloſure, there will be leſs waſte made, for they will then eat up the whole roots; whereas, if they are turned upon the turnips growing, they will ſcoop the roots, and leave the rinds, which being hollow, the urine of the ſheep will lodge in them; ſo that, when they are forked out of the ground, the ſheep will not eat any of thoſe roots which are thus tainted.

I cannot omit taking notice of a common miſtake, which has generally prevailed with perſons who have not been well informed to the contrary, which is in relation to the mutton which is fatted with turnips, moſt people believing it to be rank and ill taſted; whereas it is a known fact, that the beſt mutton this country affords is all fatted on turnips, and that rank mutton, whoſe fat is yellow, is what the low marſhy lands of Lincolnſhire, and other rank paſtures, produce.

In order to ſave good turnip ſeeds, you ſhould tranſplant ſome of the faireſt roots in February, placing them at leaſt two feet aſunder each way, obſerving to keep the ground clear from weeds, until the turnips have ſpread ſo as to cover the ground, when they will prevent the weeds from growing. When the pods are formed, you ſhould carefully guard them againſt the birds, otherwiſe they will devour it, eſpecially when it is near ripe; at which time you ſhould either ſhoot the birds as they alight upon the ſeed, or lay ſome bird-limed twigs upon it, whereby ſome of them will be caught; and, if they are permitted to remain ſome time, and afterwards turned looſe, they will prevent the birds from coming thither again for ſome time, as I have experienced. When the ſeed is ripe it ſhould be cut up, and ſpread to dry in the ſun; after which it may be threſhed out, and preſerved for uſe.

There have been many receipts for preventing the fly taking turnips, but few of them deſerve notice; therefore I ſhall only mention two or three which I have ſeen tried with ſucceſs. The firſt was ſteeping the ſeeds in water with flour of brimſtone mixed, ſo as to make it ſtrong of the brimſtone: another was ſteeping it in water with a quantity of the juice of horſe-aloes mixed, both which have been found of uſe. The ſowing of ſoot or tobacco duſt over the young plants, as ſoon as they appear above ground, has alſo been found very ſerviceable: in ſhort, whatever will add vigour to the young plants, will prevent their being deſtroyed by the fly, for thoſe never attack them, till they are ſtinted in their growth. *Miller's Gard. Dict.*

Mr. Liſle is inclined to think, that the beſt way to manage turnips, the ſeed of which, ſays he, is impatient of growth, and apt to burſt in too much wet, as alſo to corrupt, if the ground be ſo dry as only to give it a damp, but not wet enough to ſet it on growing, is, firſt to harrow the ground fine, after it has been brought to a perfect tilth by ploughing, then to roll it with a roller big enough to break the little clods, if any ſuch remain, and ſo let it lie till the next rain; then, the ground being mellow, to ſow the ſeed, and harrow it in with ſhort-tined harrows, which may not open the ground too deep, nor bury the ſeed; then roll it again with a one-horſe roller, in order to keep the moiſture in the ground as deep as the ſeed may be: for the ſurface of the earth muſt not be dried before the ſeed can ſtrike root, which may be in twice twenty-four hours; and yet that ſurface muſt be ſo fine, and ſo lightly compreſſed, that the ſeed may ſpear through it. He takes the myſtery, as he calls it, of the ſucceſs or miſcarriage of a crop of turnips to conſiſt in theſe four things, viz. firſt, in the ſeeds not lying too deep; ſecondly, in its not lying too wet, which it cannot eaſily do if harrowed in ſhallow, for the ſurface of the earth is ſoon dry; thirdly, in its not lying too dry; and fourthly, in its lying in a fine bed. In another place, he tells us, that his gardener affirmed to him, that he had found turnip ſeeds, which had been dropped by accident and covered over with earth in digging, freſh and good a year after, when the earth was turned back again, and that it has then grown and produced good turnips. The reaſon is, that every ſeed which is buried ſo deep as not to be affected by the changes in the air, may remain in a ſound ſtate, and in a fit condition to vegetate, for many years, as hath been evinced by numbers of inſtances.

Mr. Duhamel adviſes after the two firſt hoeings a ſlight ploughing all over the field, with a plough that has no fins to the ſhare, as a ſpeedier and cheaper way to thin the plants: the turnips will not require any farther care. They will have attained their full ſize in October, before the froſts come, and ſhould then be taken up, ſtripped of their leaves, which may be given to cattle, and laid upon hurdles in a dry place, with a layer of dry ſand between each layer of turnips, which may be thus piled up, and which will keep very well in this condition, for the food of cattle during the winter. In Norfolk, they ſtow them in their barns, when intended for fattening of bullocks.

A dry ſeaſon is the beſt for hoeing turnips, becauſe neither the weeds nor the turnips hoed up then will be ſo apt to grow again: and Mr. Liſle ſuppoſes that care ſhould be taken to hoe up thoſe that are deepeſt rooted in the earth, and to leave thoſe that grow upon, and almoſt out of it, without much regarding their ſize; becauſe thoſe which lie on the ground, and have room to grow, will ſoon become the largeſt.

Some ſow turnips on their flax and hemp grounds, at the ſame time as they pluck up thoſe plants, and the ſeed is pretty well buried by the ſtirring thereby given to the earth. Others give their corn ſtubble only a ſlight plowing after harveſt, then ſow the turnips very thin, and harrow in the ſeed. Theſe methods do very well when the ground is in good tilth. Others again, ſow late turnips, merely for the ſake of their leaves, which they uſe as green feed, when they are about a foot high; and in this caſe they ſow the ſeed very thick.

An eaſy way to have two growths of turnips in the ſame field, is to ſow ſeed of the laſt gathering, and ſeed that is two years old; for this laſt is longer before it riſes, than the new: and an advantage attending this method, is, that the turnips, by riſing at different times, will have the better chance to eſcape the fly, or grub, which ſometimes deſtroy them entirely: for it has been obſerved, that theſe flies often come ſuddenly in great ſwarms, and eat up the turnips as faſt as they riſe; and that they ſometimes diſappear as ſuddenly; ſo that the turnips which riſe a few days after, in a neighbouring field, are not at all injured by them: conſequently, when the turnips of the ſame field riſe at different times, one or other may eſcape the ravage of theſe inſects; for they deſtroy them only while in their ſeed leaf.

The worm to which turnips are very liable may be guarded againſt, at leaſt in a great meaſure, as Mr. Liſle informs us, by liming the ground. This will alſo render them much ſweeter than they would otherwiſe be: and we are of opinion that freſh ſlaked lime ſtrewed over the ground when the turnip ſeed is ſown, will contribute greatly to preſerve the young plants from the fly. It is to the worm lodged in the root of the turnip, perhaps engendered from the egg of the fly, that Mr. Liſle imputes the diſtemper or diſeaſe in turnips, which the Norfolk farmers call the hanbery; ſo named from a like diſtemper in a horſe's heel. It is a warty excreſcence, formed probably by this inſect, in the ſame manner as galls are formed upon the leaves of the oak. In ſome years it takes off whole crops, and the turnips never thrive after it has begun to grow in them.

A

A gentleman, remarkable, among many other good qualities, for several excellent improvements which he has made in agriculture, tried with succefs the following experiment, to preferve turnips from the fly, and the better to fecure their growth. He fowed the feed in a nurfery, where there was leaft danger of flugs or the fly, and where they might eafily be watered in cafe of great drought, to make them grow the quicker. They remained in this nurfery, till they were large enough to be tranfplanted. By this means he gained fome weeks longer, to perfect his fallow, or give a thorough plowing to ground which had borne a crop that feafon. He tranfplanted his turnips into the field, and by planting them regularly at due diftances, greatly leffened the expence of hoeing; their regularity making it very eafy to deftroy the weeds from time to time, as they appeared.

In the fecond part of the memoirs of the Society of Berne for the year 1762, the reverend Mr. Bertrand, not fatisfied with even a fcrupulous difcharge of the duties of his clerical function, has inftructed his parifhioners, his country, and mankind, in the important fubject of agriculture. The improving of light foils by the culture of turnips, is one of his objects: upon which he very judicioufly obferves, that though it be right to plough ftiff lands before the winter, in order to their being mellowed by the froft; yet as the fineft and beft parts of the foil will be in danger of being wafhed off, or carried down into the loofe earth underneath, when this is done in a light ground, or in mould which has a fandy or gravelly bottom; it will be moft adviseable here, to turn the ftubble down immediately after the corn has been taken off, and then to fow turnips; becaufe their fpreading leaves will fhelter and fecure the fine mould upon the furface, and keep the land in good heart, whilft the earth will be loofened and divided by their roots, fo that it will be rather fitter for a fpring crop, than if it had lain uncultivated.

The chief ufe of turnips is, to feed cattle in the winter and fpring, when there is a want of grafs for their pafture. Cows, oxen, and hogs, are very fond of this food, which fattens them, and increafes the milk of the former. Sheep too eat it readily, and thrive upon it, when they have been ufed to it early; but they do not relifh it when it has not been offered them till they are grown old: however, if they are kept fafting two or three days, moft of them take to it, and when they have once tafted it, they become very fond of, and feed kindly upon it. In fome places, they feed their lambs with turnips till the middle of April, though they then begin to run up to feed. Farmers choofe rather to do this, than to let them hurt their clover, fainfoin, lucerne, &c. Some parboil them a little, at firft, till their cattle, and particularly their fheep, are accuftomed to them: but a lamb only three weeks old, will, after it has once eaten of this food, fcoop out a raw turnip with great glee.

Turnips, if not clean eaten, and well cleared off the ground, may take root again, run to feed, and do great damage to the enfuing crop. Mr. Lifle inftances it in a gentleman of Berkfhire, who plowed up a turnip field in the fpring, and fowed it with peas: but the little dwarf turnips that were left behind, uneaten, notwithftanding his plowing them up, took root again, run to feed in great quantities, and did much damage to his crop of peas.

The practice of turning a flock of fheep, at random, into a large field of turnips, is very bad: for they will then fpoil more in a fortnight, than would keep them a whole winter. The beft way, therefore, of feeding them with thefe roots, is, as Mr. Tull advifes, and after him M. Duhamel, one or other of the three following methods, which are equally applicable to the drill, and to the common hufbandry.

The firft is, to portion out the turnip ground, by inclofing with hurdles fo much only as the fheep can clear in one day; and fo to advance the folds farther into the field every morning, until all be fpent. But it is to be obferved, that the fheep never eat them clean this way, but take only the leaves and the heart of the turnip: fo that great part of them remains in the earth. It is true that thefe fragments, if left there, rot, and become a manure: but when they are wanted for the food of the flock, and are to that end pulled up with iron crooks or forks made for this purpofe, the fheep do not relifh, and confequently eat but little of, thefe then dirty withered remains, tainted with their urine, dung, &c. nor can they nourifh them fo well as roots which are frefh and cleanly.

The fecond method differs from the former only in pulling up the turnips fo far as they are hurdled off, before the fheep are turned in. They then eat them better, becaufe the food is frefh and in good condition. Befides, as the whole turnips are pulled up more eafily than their pieces can be, there is not fuch wafte as in the other way. The turnips which grow next to the hurdles fhould be thrown towards the middle of the fpace hurdled off; becaufe they will be lefs liable to be trampled upon and fpoiled there, than nearer to the hurdle, where the fheep run about moft, in fearch of means, of efcaping into the open field.

The third way is to pull up the turnips, and carry them into fome other ground, and there fpread them every day on a new place, where the fheep will eat them up clean. This is done when there is land not far off, which has more need of dung than that where the turnips grow. The expence of carrying the turnips is compenfated by faving the price, or at leaft the carriage and removing of the hurdles: only when the turnips are laid on a fpot of grafs, as is frequently done in wet weather, the benefit of the dung and urine of the fheep is loft.

This method is requifite when the field on which the turnips grow is wet; becaufe, 1. The fheep would trample upon, and bury, part of the turnips, which would be loft. 2. In treading that wet earth, they would poach it, and render it unfit for corn. 3. By this means, a field may be dunged, as we have juft obferved, which wants it more than that where the turnips grew. 4. This muft neceffarily be done, if wheat has been fown in the alleys between the rows of turnips, according to the principles of the new hufbandry.

Turnips are always carried off the field, when they are intended to fatten the larger forts of cattle: and they fhould be cut in pieces for them, left they choak themfelves with the whole ones. They are given morning and evening to ftall-fed cattle, which in the intervals, eat likewife common fodder; but the turnips increafe their appetite to fuch a degree, that a middle fized bullock, ftalled for fattening, will confume near two hundred pounds weight of thefe roots in twenty-four hours, befides hay: whereas, if nothing but hay were given him, he would hardly eat half the quantity that he will with the turnips. A healthy bullock, in only good plight at the time of his beginning to be fed with turnips, will be very well fattened in three months.

Mr. Tull fays he found by experience, that the beft way of fowing turnips is in fingle rows, fix feet afunder. He fowed them in double rows alfo at that diftance, but they did not do well: and he likewife fowed them in fingle rows, with intervals of only three feet. Thefe laft yielded a greater crop than a neighbouring field, which was fown and managed in the common way: but neither the fingle rows three feet afunder, nor the double rows with intermediate diftances of fix feet, yielded, fays he, half fo much, as the fingle rows fix feet afunder: from whence he concludes, that it is beft to leave a fpace of fix feet between the rows; for that, if the alleys are well plowed, thefe turnips will thrive wonderfully, even though no other moifture falls but the dew, which will fink into the earth, to their roots.

However, notwithftanding Mr. Tull's experiment, M. Duhamel is for fowing turnips in double rows, if the intervals are of fix feet; or if they are fown in fingle rows, he would have thefe rows be but four feet afunder, which is the fpace left between the rows of vines in Languedoc, and which is there plowed with oxen.

An ounce of feed will fow as much land when drilled, as a pound will in the common way: and if care be taken to diftribute only the neceffary quantity, a great deal of trouble will be faved in the hoeing of the plants, afterwards, to thin them. But it is effential to obferve, we muft again repeat it, that all roots, whether turnips, carrots, parfneps, parfley, or any other, always thrive beft where there is a great depth of fine, light, well loofened mould. M. Duhamel trenched the whole of his kitchen-garden three feet deep: all his pot-herbs grew very fine, and his roots in particular were of a furprizing fize.

Mr.

Mr. Tull, by drilling his turnip feeds alternately at different depths in the earth, was fure to fucceed in one part or other, whether the feafon was wet or dry. If wet, the feed flightly covered fprouted firft; and in dry feafons, that which lay deepeft was the firft that rofe. By this means, and by mixing the feed, half new and half old, for the new always comes up fooneft, he had four comings up, which, as he obferves, gave the plants fo many chances to efcape the fly.

If one was fure of having rain immediately after the turnips are fown, it would undoubtedly be right to fow them very fhallow: but if no rain happens, they are beft deeper in the earth, becaufe they there meet with moifture fufficient to make them grow.

When the feafon has been fo kindly that all the feeds have grown, and the plants have not fuffered by the fly or other infects, they muft be thinned early, that the ground may not be exhaufted by fuch as are not intended to remain; for thofe that are left fhould be about a foot afunder.

When the turnips fown in drills thrive well, only each alternate alley need be hoed at one time, and the others a few days after; it being better to feed the plants gradually, by dividing the hoeings in this manner, than to give them a great deal of food at once, by hoeing all the alleys together, and afterwards leave them double the time without any culture at all. Another advantage attending this method is, that the plants will be the lefs liable to be killed by hot dry weather, and the lefs apt to be damaged by heavy rains. But it will not, indeed, fo effectually deftroy weeds, which ought always to be a principal object of the hufbandman's care, and which ever is one of the chief intentions of the New Hufbandry. However, as all weeds are very apparent in the alleys, it is eafy to extirpate them there; and as to thofe which may chance to be in the rows, the perfon who thins the turnips may cut them up at the fame time. He will there moft eafily diftinguifh the charlock from the turnips, efpecially when the leaves of thefe laft are come to be about the breadth of a half crown.

All plants fown in fingle rows are greatly benefited by the alternate hoeing of the alleys between them: for, as M. Duhamel obferves, 1. Four of thefe hoeings, which coft no more than two entire ones, are almoft as beneficial to the plants as four complete hoeings. 2. A plant which finds a great deal of nourifhment on one fide, is the better able to thrive without receiving fo much on the other. 3. If, in hoeing very near the plant, fome of its roots are broke; thofe on the other fide, not hoed, fupply the wants of the plant, till the broken ones have made frefh fhoots. 4. The horfe-hoe may therefore be brought very near to the turnips, without fear of hurting them; provided it do not force them out of the earth. 5. When a farmer has a great quantity of turnips to hoe, they are fooner fupplied by this culture, than they poffibly could be if all the alleys were to be hoed.

A furrow fhould not be left open near the turnips, while they are young; becaufe the earth about them would in that cafe become too dry: but there is no danger of this in the autumn, when they are grown ftrong, and the earth is moift. Neither is it adviseable to leave a furrow open near them during the winter; becaufe they would be in danger of being hurt by the froft.

When thefe plants are grown large, and their roots are confequently pretty well extended, the hoe-plough need not come quite fo near them as at firft: nor is it neceffary to hoe them at all, till they are about the bignefs of one's finger's end.

One alternate hoeing, or which is the fame thing, two half hoeings, will be fufficient when the turnips are fown late. But when they are fown early, and many weeds grow, one hoeing will not be enough.

By following this culture, M. Duhamel has feen turnips which weighed from fixteen to nineteen pounds; and we may depend on their weighing one with another twelve pounds a-piece in a good foil, which is a vaft produce from an acre of land. Mr. Miller fays, that one acre of turnips, thus properly cultivated, will afford more feed for fheep or ewes in the winter, than fifty acres of the beft pafture at that feafon.

Another vaft advantage which attends the fowing of turnips in rows, is, that inftead of occupying the whole ground when it fhould be fowed with wheat, and fometimes even when it fhould be fowed with fpring-corn, as is frequently the cafe in the old way; they are no hindrance to either in the New Hufbandry: for as the alleys are in good tilth, three rows of corn may be fown, feven inches afunder, between the rows of turnips; and when thefe roots are pulled up, the ground where they grew is hoed, and becomes the alleys between the beds of corn.

The beft turnip feeds are obtained from the largeft roots, which may either be tranfplanted for that purpofe, or marked out in the field where they were fown. Thofe which are commonly fold in the fhops, feldom produce the fineft plants.

Experiments on turnips cultivated according to the New Hufbandry.

In 1754, M. de Chateauvieux fowed turnips on beds, in two rows. They fuffered greatly for want of rain, and none of them grew to the fize they would have done in a more favourable feafon. Some of them weighed eight pounds; but their general weight was from three to four.

In 1755, M. de Chateauvieux fowed fome beds with one row, fome with two, and others with three rows. They were afterwards thinned, fo that the plants ftood a foot afunder in the rows. Thofe fown in one row were the largeft, and, in general, the moft equal. Some of them weighed fourteen pounds, and moft of them from feven to eight. In the other rows, they did not weigh fo much; but they were more numerous.

In confequence of thefe experiments, M. Duhamel, to whom they were communicated, makes the following ftriking calculation relative to the quantity of food which turnips will afford for cattle.

"Let a fquare whofe fide is 216 feet be formed into beds four feet wide, which is fufficient for one row of turnips. Thefe will be 216 feet long, and confequently will contain that number of turnips, planted a foot afunder. Thefe 216 multiplied by 54, the number of beds, will give 11664 turnips for the product of the fquare; and thefe multiplied by fix, the fuppofed weight of each turnip, will give 69,984 pounds for the weight of all the turnips on this fpot."

This may be looked upon as a very confiderable crop; for it will be fufficient to ftall-feed four bullocks during the three winter months, at the daily allowance of 200 pounds each: and yet there is reafon to believe that the quantity will be doubled in a good year, as will be pretty evident to thofe who confider at how low a rate the medium weight of the turnips is here eftimated.

In 1755, M. Duhamel fowed turnips in a field, on beds cultivated with the horfe-hoe. They grew extremely fine; many of them being twenty-nine inches circumference.

The following account of the advantages of the drill hufbandry in the culture of turnips, was fent by Mr. Willy, of South-Petherton, to the fociety for the Encouragement of Arts, &c.

The generous method you have taken to promote ufeful knowledge muft give every lover of his country the greateft pleafure, and incline him to do all in his power to increafe it; 'tis with this view, and by the perfuafion of many friends, I prefume to lay before you the following lines, hoping they may give you fome fatisfaction in refpect to the difference betwixt the Old and New Hufbandry.

I began hufbandry in the year 1742, had always an inclination to drilling, and was at much trouble and expence in getting one inftrument after another made for the purpofe; but was often difappointed, and for fome years was forced to lay by the thoughts of it. About eight years fince a gentleman lent me Mr. Tull's treatife; I then got fome new inftruments made, which fowed very regularly, and fince that time have fowed all my corn in rows. Several clofes I ploughed in fix furrow ridges, and fowed with three rows of wheat, ploughing the intervals with a fmall full, drawn by one horfe, and made it fit for wheat the next year; it generally took one third of the common quantity of feed, and in two years it yielded more than half as much again as the beſt crops in the common way did in one year; which, conſidering the ſmall expence of feed and labour, was ſome advantage, though not very great; but then it left the ground in very good order for the next crop of ſpring corn. I kept one cloſe, about two acres, four years to wheat in the ſame method; but the two laſt years did not anſwer to the two firſt, which makes me think Mr. Tull wrong, when he ſays, that plants of different natures are nouriſhed by the ſame ſort of food. I could give an account of the exact quantity produced in each year, but it would be tedious: upon the whole, I believe this method of ſowing wheat will be of no advantage except in poor ſtrong clays, where I apprehend it muſt exceed all others. But there are a few inconveniencies attending it; frequent ploughing the intervals is apt to make the wheat ſhoot freſh ears, which do not ripen with the others; and if any of the full ears when near ripe do but touch the freſh ploughed earth, ever ſo little wet will make them ſprout, and theſe will injure the whole crop; and I find it impoſſible to keep all up, as the rows are at ſo great a diſtance. But my method of drilling in the open fields, and which I intend to follow, is to put five rows about eight inches apart, on a ridge about five feet in breadth. This takes but two-thirds of the feed ſowed in the common way, and has always produced a better crop than the lands on each ſide of mine; this my neighbours are now convinced of, and ſeveral of them have drilled their wheat this ſeaſon: our ſoil, for the moſt part, is a deep heavy ſand.

I apprehend the principal advantage in drilling wheat is placing it at a proper depth, which I think is within two inches or thereabouts. I have obſerved, that the firſt motion of the wheat is by ſome roots, which in a little time run very deep; then it ſhoots up its blade; next it begins to form a head, about an inch under ground, from which come (very ſoon in a mild ſeaſon) the ſecond and third blades; and after this it begins to ſhoot freſh roots and branches from this ſame head, till in time it grows very large, eſpecially in a fruitful ſoil and a good ſeaſon; and it keeps on ſhooting freſh roots all the growing ſeaſon: now if the corn is too deep, and a ſevere froſt happens while this head is forming, the plant is quite deſtroyed: but if it lies ſhallow it ſhoots a new blade from the corn, and goes on in its operations as before; this was the caſe in 1763, a ſevere froſt happened in the night of the thirteenth of February, which deſtroyed a good deal of wheat; ſo that ſome which lay deepeſt was ploughed up, and ſown with other feed in the ſpring. Laſt year multitudes of plants were killed in the ſame manner, and brought the crop very thin. In ſhort, I am very certain, that whoever will make their obſervations will find that what I have ſaid is the truth; that the ſhalloweſt corn will flouriſh ſooner and better, and from thence will be led to ſee the advantage of drilling wheat.

But although I intend leaving Mr. Tull's method of ſowing wheat, yet I hope always to follow it in beans and turnips.

My beans I have ſown theſe four years in double rows, about ten inches a part, and about two feet intervals. Theſe I plough from and to the beans, when about ſix inches high; this is done with a little ſull drawn by one horſe, and will plough three acres in a day. This method hath ſucceeded ſo well, that many are come into it; although the farmers have always an averſion to new methods of managing; we ſow but one-third of the feed, and have a much better crop, as is allowed by all.

As for turnips, all my neighbours will allow the drill to beat every thing. I ſow a double row about eight inches wide, on a ridge about five feet, and though I did not ſow this year till Auguſt, I have turnips two feet round, after wheat. I have given them but one ploughing as yet, beſides hoeing them out at proper diſtances. I believe all will acknowledge I have double the crop in weight with any ſown in the old way. I left four intervals unploughed in one cloſe, to ſee the difference, and it is very ſurpriſing. One of my neighbours was prevailed on to ſow a few rows in a piece he was ſowing, and let my man plough them. The difference is ſo great that he is become an advocate for the drill huſbandry; indeed I do believe that it will ſoon make its way through all the prejudices of the old farmers to the contrary; eſpecially as we have a drill invented by an ingenious carpenter, with which ſeveral farmers have ſown beans, peaſe, turnips and wheat, and it anſwers exceedingly.

For theſe ſeventeen or eighteen years paſt, I have been ſtriving to improve a crop of turnips. Before this, nothing was known or aimed at hereabouts, but ſowing in the common way, one pound of feed on an acre; and then come thick, come thin, weeds and all grew together, till the ſheep were turned in to eat the crop as it was, and generally it was very poor.

The firſt improvement I made was by Ellis's direction, to drag them well with heavy harrows till they were got pretty thin, by which method I ſoon got better crops than any about me. But then I ſowed double the quantity of feed, that I might have ſufficient ſtock of plants for my after huſbandry. My neighbours were ſoon convinced of the advantage of this, and followed my example, which is now the common practice. After this, finding the thinneſt was beſt, I got ſome hoed: this I found ſtill better, but very expenſive, our people not being uſed to it. I tried Mr. Ellis's receipt to prevent the fly from deſtroying the young plants, but my ploughmen refuſed to ſow the feed when mixed with ſulphur. I then invented a long box, made full of holes, for the feed to fall through, and faſtened it to two wheels ſo as to keep it above ground; this went ſo light that a boy could draw it, and ſowed the feed very regularly. I ſhewed this to a friend of mine, (Mr. Joſeph Pittfield, of Sidland in Dorſet) who had one made immediately; and ſoon made an improvement on it, by having the holes made in rows about a foot aſunder. Finding that the plants could be thinned and cleared at a much leſs expence, I followed this method of ſowing for myſelf, as did ſome of my neighbours, for ſome years, and with a deal of ſatisfaction. A few years ſince, I was willing to try what ſtirring the ground deeper would do; and being reſolved to try the drill huſbandry in corn likewiſe, I had a ſmall ſull made, with which one horſe will plough more than two acres in a day, firſt turning four or five inches deep from the plants, and then back to them again: we generally ſow turnips after wheat, peaſe, and flax, and my method is to plough the ground into ſix furrow ridges, which with the open furrow makes about five feet in breadth. On ſuch a ridge I ſow (out of a ſhort box) two rows of feed, though ſometimes but one, and harrow it in with a very light harrow. When they have four or five leaves I get them thinned, and give them a ploughing; and ſome time after, when they begin to kern, I have them thinned and cleaned again: and this is all the huſbandry I have hitherto beſtowed, and all I think is neceſſary, as we do not ſow till late; the coſt of which is about three ſhillings *per* acre.

I have ſown ſome betwixt rows of beans, and they anſwered very well: when the beans were pulled, I had the plants thinned and cleaned, and the earth ploughed betwixt the rows.

The firſt I ſowed laſt year was a ſmall piece about half an acre, where hemp failed: I had the ground ridged up, and ſowed with two rows of feed, and managed, as I ſaid before: indeed the ground was dunged for the hemp. This was ſown the latter end of July, but did not come up till the middle of Auguſt, for the want of rain. I pulled them before Chriſtmas, and had fifteen putt loads, which every one will acknowledge to be a good crop; I believe double a common one: and though the rows were four feet apart, the leaves touched each other. The next I ſowed was after wheat, about the middle of Auguſt: when the wheat was carried off, I had the ground ploughed into ridges where the old furrows were, and ſowed one row of feed on each ridge: theſe coſt but little in thinning and cleaning, and once ploughing, and were a very good crop: the largeſt of them was more than two feet round, and weighed above ſix pounds; indeed towards the hedges they were much ſmaller; I had fifteen putt loads per acre, though the ground had borne three crops ſince it was dunged. Another piece of two acres I ſowed after peaſe, in double rows; but not till the latter end of Auguſt: I had the ground ridged up, and when the plants were fit, I had them thinned and cleaned as uſual, but left four ridges for ploughing to ſee the difference; and truly it was ſurprizing: thoſe that were ploughed were more than three times as large,

large, though they had all the same husbandry, except ploughing. They are as good a crop as the wheat stubble, though sown later, which makes me think double rows are best: our soil is mostly heavy good sand.

We have reserved for this article the following account of several very important experiments made by Mr. John-Wynn Baker, under the direction of the Dublin Society, and published at their request, on the culture of cabbages, the turnip-cabbage, boorcole, and turnips, by various methods; with an accurate state of the produce; and of the absolute and comparative advantages of each in feeding sheep and horned cattle. *See the articles* BOORCOLE, CABBAGE, POTATOES, and TURNIP-CABBAGE.

In the month of March, 1763, two acres of ground, very highly manured with dung, were planted with potatoes, in the manner usually practised in this kingdom, with spade and shovel; in the beginning of November following the potatoes were dug. The land being low, and the winter very wet, it could not be plowed until the beginning of March, 1764; when, it should be observed, the under stratum, upon which the dung and potatoes lay, rose at the plowing as stubborn and strong, as if no part of the ground had been tilled before: which proves the potatoe tillage, in the manner in which it is usually practised, not to be so beneficial to land as is generally imagined: the fact being, that only about thirty inches in every nine feet of the ground is tilled at all.

In the night of the 10th, and on the 11th and 12th, of May following, there was very fine rain; this rain enabled me, on the 12th, to reduce this stubborn ground pretty fine by the harrow.

In the month of March, 1763, the other part of this field was broke for fallow (an improper time to break fallows; but, my entrance upon the farm in that month was the cause); in June following it was cross-ploughed, which brought it into very large lumps; from the position this ploughing threw them into, they were exposed, in a greater number of points, to the influence of the weather, than the ground would have been, had the second ploughing been in the same direction as the first.

In this situation I left this fallow till the March following; when, it was ploughed for the third time, with the potatoe ground, in the same direction as at first; by this third ploughing this land was brought into an exceeding fine tilth.

This benefit arose from the ground not having been harrowed at all. This is something contrary to the common mode of culture; but was adapted to the species of ground I had to work upon; which I shall describe hereafter.

What the harrow would have done in part towards reducing it after the second ploughing, was completely effected by the influence of the summer and winter; the first destroyed all the weeds and couch-grass (with the latter of which the ground abounded); and the lumps exfoliating by the operation of the winter, by degrees fell into fine mold; whereas, had it been harrowed before the winter, the rains would have run the smaller particles together, so as to have given a great adhesion to the ground before the spring; abstracted from the like mischief, which the cattle would have done by drawing the harrow. In the beginning of June, I ploughed this part of the field a fourth time, and the potatoe ground a second; by which ploughing I laid the whole field into ridges of five feet width, except about half an acre, which I reserved for other purposes, as will appear hereafter.

In this field I had two parcels of manure ready prepared for it. One consisted of earth raised from the head-land, mixed with lime, which lay about twelve months, having been in that time twice turned.

The other parcel consisted of the like earth, and lime, mixed in the same manner, after which I mixed dung with it, *stratum super stratum*, which lay about two months, when I turned it: after which it lay about two months longer: by this stirring the ingredients, of which this parcel was composed, were perfectly incorporated with each other; and a new putrefactive fermentation was excited in it; which perfectly prepared it for the land: and all the earth was so fully impregnated with the juices of the dung, that it was very little, if any thing, inferior to the dung: whereas, when dung lies by itself, great part of the volatile saline particles are lost, as soon as the fermentation begins; some fly off in vapours, and others run off with the juices of the dung and rain, which fall upon it.

When I have mixed dung and earth, in the manner already described, I always once, or twice when the season affords it, cover the compost with a large quantity of snow, or ice; which, upon dissolving in its passage through the whole, causeth the earth to be finely impregnated by the dung. Snow, by being gathered with shovels or rolled together in balls, is longer dissolving than ice, and therefore I prefer it, unless it be ice of water which happens to be the soakage of a dung-yard, such ice being always replete with food for vegetables.

The land being now, in June, in five feet ridges, in the manner already described, I began to draw out my compost; which I disposed in the following manner: I drove the cars up every alternate ridge, and upon each of them dropped the compost, till I had manured about three acres of the fallow ground; then, with shovels, I divided this manure, as equally as could be, in every furrow; which was readily done, from the convenient manner in which it was deposited.

In the same manner I put out the other parcel of manure (which, it may be remembered, I before said consisted of lime, and earth) upon an acre and a half of the potatoe ground; and on a part of the fallow ground, where no compost, or other manure, had been put; and spread it in the same manner as the former.

The whole field being thus manured, I ploughed it again, which was the fifth ploughing of the fallow, and third of the potatoe ground: by this ploughing I altered the position of every ridge, by laying the middle of each exactly over the manure; consequently the furrows were made, where the middle of the ridges was before.

The half acre before-mentioned I manured with at least double the proportion of compost, which was allowed to the other part of the fallow; as it was flat, and it was necessary to manure every part of it, being intended for turnips, to be sown in the promiscuous way.

To this piece of ground I gave a sixth ploughing; as it could not have the benefit of the horse-hoe, when cropped, and therefore I thought it necessary to reduce it as fine as possible, in order to give the broad-cast crop of turnips every advantage I could.

The field being prepared in the manner already described, I proceeded to crop the land in the following order.

July the sixth and seventh, I planted one row of cabbage plants, upon the middle of every ridge, of about an acre of the fallow ground, the plants in the rows two feet from each other. In like manner I planted about half an acre with turnip-cabbage plants.

Hence it may be observed, that the plants were in rows five feet asunder, and two feet asunder in the rows.

This business ought to have been done, at least, a month sooner; but I could not get the ground ready in due time; however, the success of these crops may encourage others not to give up their expectations, although they may happen to be as late as I was, which must frequently happen in a course of business; though this is always to be avoided as much as possible.

I never begin to put my plants out till about six o'clock in an evening, unless I can be ready for planting in a rainy day, which is always to be preferred; in the other case, I always keep the men at this work as long as they can see. If it can be done in, or immediately after, rain, that will save the expence of watering the plants; which is an object worthy of attention in a large work of this kind; besides the circumstance of the plants succeeding much better.

On Friday the sixth of July we had fine rain, and on the seventh I finished. On the eleventh we had some light showers, and on the twelfth fine rain, which secured life to my plants; but they began to look sickly before the twelfth; three of the intervening days having been hot and dry.

On the seventh I also planted three of the five-feet ridges, with one row of boorcole plants on each ridge, the plants in the rows two feet asunder.

Be it observed, that, for the obtaining large cabbages of the spring sowing, the seed ought to be sown early in March;

March; and, if once planted out before the final planting them, it will be an advantage to the crop: the case is the same with respect to turnip cabbage; but it is more essentially necessary in the common way of raising cabbages; for, otherwise, they will run into long shanks, and will not cabbage well; most gardeners allowing their plants too little room: that is not the case here; my cabbage and turnip-cabbage seeds were not sown till the twenty-sixth of March, and I was so much hurried, that I never had time to get them planted out before the final planting, save about three thousand plants; and yet they are all very short in their shanks. This may justly be attributed to the manner of disposing them, and the culture they receive in this husbandry.

Here I cannot omit to remark one circumstance, for the observation of gentlemen and farmers who may adopt this husbandry, viz. That I have not one cabbage this year of the sort I intended to have; what I have being chiefly sugar-loaf, the seedsman having deceived me; and, if I had not happened to have about an ounce of turnip-cabbage seed by me four years old, I should not have had one plant of that kind this year; the seed, which I bought in Dublin for it, turning out a poor, small, wretched cabbage.

I shall now proceed to make my report of the farther treatment, and success, of these crops, before I proceed to the turnips, &c.

Upon the 17th of August, I horse-hoed my cabbage, turnip-cabbage, and boorcole, for the first time, by taking off, at one furrow of the plough, only one side of each ridge, close to the plants: thus they remained till the 25th, when, I ran the plough in the same furrow; by which, with the first furrow, I plowed about twenty-one inches deep. This being finished, I immediately returned the earth back to the plants; this afforded them fresh nourishment; and in order to give their roots time to penetrate this fresh earth, which, by the horse-hoeing, was become very fine mould, I let them remain in this state till the twelfth of September; when, I horse-hoed them again, by taking off the other side of every ridge; and, on the twentieth, deepened the furrow in the same manner as the former, and immediately returned the mold back to the plants; and, on the eighteenth of October, threw up a small furrow to each side of every ridge, which finished the culture of these crops, and restored the ridges to the form in which they were when the plants were put out upon them.

The plants all grew very luxuriantly; and, in the hottest weather, were infinitely more brittle in their leaves, than any I could see in the gardens of my acquaintances: which is a certain indication of health in this kind of plants.

The horse-hoeing was so effectually destructive to weeds, that it cost me but four-pence to weed these crops, which occupied about an acre and three quarters of ground.

The repeated horse-hoeings cost me two shillings and four-pence an acre, for workmen's wages, exclusive of horses, of which I used two, and sometimes three.

December the 8th, I cut one row of the cabbages, they beginning to decay, which is indicated by their bursting. The number was two hundred and fifty-eight, and they weighed sixteen hundred-weight, three-quarters, and twenty-one pounds, *i. e.* one thousand eight hundred and ninety-seven pounds: which, at an average, is seven pounds and near six ounces for each cabbage.

The produce upon an acre, on weighing this row, which was five hundred and sixteen feet long, amounted to twenty-three tons, four hundred, two quarters and fourteen pounds, *i. e.* fifty-two thousand and thirty-eight pounds: which is, at least, from ten to seventeen tons less, as I compute, than the produce would have been upon an acre, had I obtained the sort I intended to have, which was the large, late, Dutch cabbage. However, such a produce as was here obtained, will be an ample reward for the labour any one may bestow in this husbandry, as will appear when I shall come presently to shew how many cattle twenty-three tons will maintain.

December the 17th, I took up one row of the turnip-cabbages, which were in number two hundred and forty-nine, they weighed eighteen hundred weight, and fifteen pounds, *i. e.* two thousand and thirty-one pounds, after chopping off the roots and stalks below the turnip, which ought not to be weighed, as being no part of the food for sheep, or cattle: the weight of these plants, one with another, was something more than eight pounds and two ounces; some few weighed fourteen and fifteen pounds. The produce upon an acre, on weighing this row, which was four hundred and ninety-eight feet long, amounted, at the same proportion, to twenty-five tons, fifteen hundred, three quarters and seven pounds, *i. e.* fifty-seven thousand seven hundred and sixty-one pounds.

This crop was much greater than ever I had before; and, from some observations I have made this year, I am inclined to believe, their culture may be improved to a produce of ten tons more upon an acre: but, abstracted from that, the produce already obtained is more valuable than any crop I know of, for they are invincible by the winter, either in or out of the ground. The great distress of even the careful farmer is in the months of March and April, for his ewes and lambs, when turnips are gone, or are but very indifferent food, and all other green winter-food is exhausted.

Feeding ewes upon dry hay affords but little milk to their lambs; add to that, hay is not made without great expence and anxiety, over and above the rent of the land; for really, where the farmer is so unfortunate as to have his hay upon hand in wet weather, it is a business which will exercise his patience, no less than it will consume his money.

One superior excellence in these plants is, that sheep will prefer them to turnips; another is, that they are a firmer and more substantial food: and, to ascertain their firmness in texture, and quality in keeping after being drawn, I have kept them near twelve months exposed to the open air, to the extremes of heat and cold, and, after that, they were found, save some few.

If any person who may cultivate this plant for sheep, should keep a large stock, he may let the plants remain in the ground till he wants them; in that case, he may turn the sheep into the field, where they will eat them quite down to the stems; and, as the plants stand naturally above the ground, and by my manner of cultivating them, they are still higher, by being placed on the tops of the ridges, the sheep cannot dirty them, as they do turnips when turned into the crops; add to this, that when the sheep have eaten all the leaves, and begin to eat the butts or turneps of this plant, they will not rot as turnips do, when wounded; but will certainly keep sound, even after that, for six weeks or two months: nay, yesterday, the fifteenth of February, upon dressing some of them for seed, I found some, which had been accidentally wounded by cows, upwards of three months ago, perfectly sound, notwithstanding the great quantity of rain which had fallen upon them.

When the leaves are wanted early in the winter for sheep, or black cattle, or, the land is wanting for any other crop; in either case the plants may be taken up, the leaves taken off, and the turnips thrown any where upon a piece of sound dry grass ground, where they will keep, and be ready for sheep in the spring: but this work is attended with some trouble and expence, the roots being very firm in the ground.

The latter end of December, and in January, the plants begin to throw out fresh shoots, which are to produce the seed; and, when they begin to do so, all the leaves of the preceding year fall off, being first greatly decayed; and as the leaves, in October and November, are really very numerous, and afford a large quantity of food for cattle, it is well worth the trouble to take them off before they begin to decay; and, when this is judiciously done, the trouble is very little.

The method which I would recommend is, that two men be sent into the field, each taking one row before him, and, as he pulls off the leaves, laying them upon the ridge between the turnips; when these two ridges are finished, or as many as may be thought necessary, let one horse, or more, be brought with a pair of cleeves upon his back; let him be placed in the furrow, between the two rows; and, as he passes along, the two men fill the cleeves, which may be most conveniently done, from such a disposition of the business, without any injury to the turnips in the rows.

Where extenſive crops of theſe plants are raiſed, it will be very uſeful to collect all the roots, whether left in the field by ſheep, or otherwiſe ſeparated, and mix them with heaps of earth, where a putrefactive fermentation will ſhortly commence, by which the earth will be ſtrongly impregnated with volatile and fixed ſalts, and will then be an excellent manure; and, indeed, all ſucculent vegetables will contribute to the ſame end, under the like treatment.

I muſt beg leave in this place juſt to mention, for the conſideration of the ſociety, and which I earneſtly recommend to be tried by mariners, another uſe, to which, I think, this plant, may be converted, which is ſtill of more importance, than any which I have yet named.

We loſe more men in the beginning of a war in the navy, as I have been informed by the navy-ſurgeons, by the ſcurvy, than by the enemy, which is attributed to their ſudden change of food. From freſh proviſions and vegetables on ſhore, the men are at once brought to ſalt proviſions.

The turnip of this plant, I am inclined to believe, would keep three or four months on ſhip-board, perhaps longer; but the navy-ſurgeons have told me, that if it would keep ſix weeks, it would ſave the lives of many men. Something has been ſaid on this ſubject before, in a pamphlet intitled, Hints on Huſbandry, in a letter to the Dublin ſociety, printed by Flinn, in Caſtle-ſtreet.

I cannot diſmiſs this ſubject, without earneſtly recommending the culture of this plant to the attention of the farmer, particularly to ſuch as keep any ſtock; and, although the plant is very little known, except in the gardens of the curious, yet, whoever will cultivate it in the way I have here ſet forth, will find himſelf amply repaid for his labour; for how comfortable is it, for a man's mind to be at eaſe about his flock, in the months of ſcarcity? Whereas I have every year obſerved, that the farmer's flock, particularly ewes and lambs, are turned into his meadows to live upon the ſpringing graſs, to the irrecoverable injury of the hay-harveſt; as frequently have I ſeen them upon young clover, to the manifeſt injury of that crop.

I could enlarge greatly upon theſe injudicious practices; but in brief I ſhall only ſay, that if I ſhall live to ſee the culture of this plant generally eſtabliſhed, I ſhall have the comfortable reward of knowing that I have been uſeful to mankind; a circumſtance which will be more grateful to me, than if I had conquered a nabob, or extirpated an Indian nation.

December the eighteenth, I cut two perches in length of one of the rows of boorcole, which contained twenty-one plants; they weighed one hundred and eighteen pounds, which is very near five pounds ten ounces for each plant: but I am inclined to believe, that theſe plants will ſucceed as well, if they are planted only eighteen inches aſunder in the rows. However, at the above proportion, there would be ſeventeen tons and fourteen hundred upon an acre. But, if the produce would be the ſame, were the plants only eighteen inches aſunder, in that caſe an acre would produce, by this culture, above twenty-three tons and twelve hundred.

This plant is well worthy the farmers or graziers attention, for, as faſt as it is cut, it will again, in about a month or ſix weeks, afford another crop: I have been cutting theſe plants for my family-uſe ever ſince the middle of Auguſt laſt; I believe ſome of them have been cut three times; and they are excellent for the table. For feeding cattle and ſheep they are highly valuable, as no froſt will injure them; and, although the firſt crop amounts not to as many pounds upon any given quantity of ground as the others, yet the ſucceeding crops will, I believe, make their produce nearly, or quite, of equal weight with any other of the cabbage kind. But I muſt not omit to obſerve, that, as theſe plants afford only open leaves, and many of them very ſmall, there will be a little more trouble in collecting and carrying them to the ſheep and cattle, than there will be with the other kinds.

It may not be improper to obſerve, likewiſe, that, upon the approach of the ſpring, when they begin to throw out their ſpring-ſhoots for ſeed, if the large leaves have not been taken off for winter uſe, they will decay and fall off in the ſame manner as the turnip-cabbage leaves have already been deſcribed to do.

I have not yet tried it, but I believe that the beſt way of uſing this plant, would be to allot one whole field to the culture of it, proportioned in ſize to the ſtock intended to conſume the produce; and in September or October, to turn the ewes into the field for a few hours, morning and evening, and then lodge them on any piece of graſs or fallow, which may want improvement, to which they will greatly contribute by emptying themſelves upon it; and thus continue turning them into the boorcole field, till they have eat all the luxuriant leaves; then let the plants reſt a month, and there will be another crop. By having two ſmall fields under this crop, a flock of ſtore-ſheep might be maintained a whole winter at a very ſmall expence; for whilſt the produce of one field would be conſuming, the other would be coming on.

This method occurred to me from an accident, which attended my boorcole this year. My cows got into the field, and preſently devoured ſome of the leaves of the plants; theſe plants have engaged my attention ever ſince, and I have the pleaſure to ſee them again in a very luxuriant ſtate.

If any perſon ſhould be able to put this ſcheme in practice before I can accompliſh it, I recommend it to them, not to let the ſheep paſture ſo long upon the crop, as to wound the ſtalks for want of leaves; as too great an injury to the ſtalks may check the ſucceeding growth; which injury, I am inclined to believe, will not happen to the plants, at leaſt not in ſo great a degree, whilſt they have a ſufficient quantity of leaves.

It doubtleſs will be obſerved, that I confine this ſcheme to ewes or ſtore-ſheep: my reaſon for that is, that fat ſheep ſhould always have as much food before them, as they may chooſe to eat; add to this, that ſheep, when they are fat, are more ſubject to be lame, than ſtore-ſheep, to which ploughed ground will greatly contribute.

We ſhall now return to the ſtate of the field, in which it was after being manured, and ploughed into ſmall ridges of five feet breadth, with the compoſt under them in the fallow part, and part of the fallow with the lime and earth, and the potatoe ground aided with the lime.

Upon the fourteenth of July, I ſowed with my drill plough what remained of the ridges of the fallow manured with the compoſt. That part of the fallow which was manured with the lime and earth, and that part of the potatoe ground which was before deſcribed to be in ridges, with turnips: and that part of the fallow before deſcribed to be flat, and manured with a double proportion of the compoſt, I ſowed in the promiſcuous way with turnips alſo.

The drilled turnips filled only one row along the middle of each ridge.

When the drilled turnips were about three inches high, I thinned them by hand, as being much preferable, and more expeditious than any inſtrument, intending to have them ſingled out to about one foot aſunder in the rows: but, it being ſo new a work, the women could not be brought to do it effectually at once, they apprehending, that the whole crop would be loſt, and urging, that they were ſure there was already too much ground allowed to one row: under theſe circumſtances, I could not get this work done quite to my mind this year, as I had, beſides this field, two others ſown in the ſame way, amounting in all to about twelve acres.

My turnips ſhould have been ſown at leaſt three weeks earlier; but the immoderate, and continual rains of the preceding winter, involved me ſo much with my ſpring-ſowing, that I could not accompliſh my turnip-ſowing earlier.

The turnips, after being thinned, received the horſe-hoeings much about the ſame time, and diſtances, as the cabbages; with this difference only, that I deepened the furrows of but a few ridges in another field by a ſecond ploughing in the ſame furrow, which I did not find to benefit the turnips much: for, if the ground be well prepared before the ſowing, the depth of one furrow will be enough for turnips, provided that be deep and bold.

Thinning the turnips in drills by hand coſt me eight-pence an acre; weeding of them coſt me four-pence; and the

the repeated horse-hoeings about fourteen-pence an acre for workmen's wages, exclusive of the horses, of which I generally used two, except in very hot days, and then I found three were necessary.

The broad-cast turnips were carefully thinned by hand, when they were about two inches high; which the women did with more courage than they did the drills; and sometime afterwards, I hand-hoed them once, and wed them twice.

Thinning them by hand cost me four shillings. Hoeing them afterwards cost eight shillings, and weeding them cost me two shillings and four-pence. They were scarcely half an acre; this expence being therefore doubled, they cost me at the rate of twenty-eight shillings and eight-pence an acre, over and above the extraordinary ploughing, and double proportion of manure.

In truth, this crop greatly exceeded my expectations, being by far the best I ever had in the broad-cast way; but I attribute their success wholly to the thinning them by hand; for two, three, four, and often more, turnips will be so united and interwoven, that it would be impossible for the most dextrous hoer to separate them; whereas the fingers and thumb will preserve the master plant, whilst the others are most conveniently drawn from it by the other hand of the person employed: add to this, that there is no labour in which we are more liable to be deceived, than turnip-hoeing.

In one of my other turnip fields I manured about an acre of ground with shell marle, which I sowed in drills with turnips in the same manner as the former, on the sixteenth of July.

In the same field, I manured about half an acre with the native earth, which had been exposed to the weather for upwards of two years, which I sowed likewise in drills with turnips on the sixteenth of July.

Both these crops were thinned by hand, and horse-hoed, in the same manner as the former.

Thus we have five experiments in the drill way upon turnips, with different manure. One with the compost already described, one with lime, one on potatoe ground, aided with lime, one with shell-marle, and one with native earth; and also one in the broad-cast way, with a double proportion of the compost, and an extraordinary ploughing.

The principal point to be determined by these experiments is, whether sowing turnips in drills, or the broad-cast way, will afford the heaviest crop: but the trials with the different manures will, I hope, be also useful.

The produce of drilled and broad-cast turnips compared.

December the seventeenth, I measured out three square perches of the best of the broad-cast turnips, and also three square perches of the drilled; and the produce was as follows:

The three perches of the broad-cast turnips weighed sixteen hundred weight and one quarter, i. e. one thousand eight hundred and twenty pounds; which, at the same proportion, amounts upon an acre to forty-three tons, five hundred weight, three quarters and six pounds, i. e. ninety-six thousand nine hundred and seventy pounds.

The three perches of drilled turnips weighed seventeen hundred weight, two quarters, and twenty-one pounds, i. e. one thousand nine hundred and eighty-one pounds; which, at the same proportion, amounts upon an acre to forty-seven tons, two hundred, three quarters, and two pounds, i. e. one hundred and five thousand five hundred and ninety pounds.

	T.	C.	Q.	lb.		Pounds
An acre of drilled turnips	47	2	3	2	or	105590
An acre of broad-cast ditto	43	5	3	6	or	96970
In favour of the drilled	3	16	3	14		8620

Thus we see, that, notwithstanding the extraordinary proportion of manure, and the extraordinary ploughing, which was afforded to the broad-cast turnips, the drilled crop, with intervals of five feet, produced the greatest quantity upon an acre, by three tons, sixteen hundred, three quarters, and fourteen pounds weight.

The drilled turnips in my other fields were very large, regular, and even crops, as many gentlemen saw during their growth.

Those sown on the acre manured with the shell-marle were very near as good as the rest—those sown on the potatoe ground were not near so large, but were regular—those sown on that part of the fallow-ground which was limed, were very poor crops—and those sown on the ground manured with the native earth were miserable.

The crops in my other fields were all treated in the same manner as that already described; except, that the fallows were broke in September, 1763, instead of March, 1763.

It now remains to describe the nature and quality of the land, and then to draw conclusions from the various experiments.

The land lies upon a lime-stone quarry, which is very near the surface; and is, naturally, a very strong and stubborn soil, with an infinite number of loose lime-stones in it. With dry winds, or a parching sun, the ground unites, and is as hard as bricks; moderately wet, it is reducible by instruments; but, when thorough wet, it runs together, and is like brick-clay when tempered. This, I repeat it, is the natural quality of the land, and is what the writers would call a barren, grey, stiff earth, but is not quite a clay.

I have found repeated tillage, when the land is in a proper state of moisture, will reduce it, and divest it of its natural adhesion. Tillage and manure together render it capable of producing any thing; as, I believe, such agents will do upon any land, provided it can be kept moderately dry. The fields, which I had under turnips and cabbages, have been in appearance all the summer a fine loam, and really bore the complexion of very fine land, abstracted from the rich appearance of the crops.

I recommend to the practice of all persons, who may have such land as this to work upon, never to harrow the fallows before winter, but as early as may be in the spring, and during the working the fallow in the summer, but not to leave more than one day's ploughing unharrowed, but rather harrow in the evening what has been ploughed in the morning, and then the harrow will reduce it; but if the ploughing is continued for two days, without any harrowing, the harrow will have no more effect upon the land, than it would have upon bricks, unless it be moistened with rain; in which case it will be reducible, as, it may be remembered, I described the potatoe ground to have been reduced, after rain which fell on the twelfth of May.

Conclusions to be drawn from the preceding experiments.

These experiments prove gardens to be no more than farms in miniature, under an extravagant expence of culture; since we can with the plow raise more tons of the larger kinds of garden vegetables for twenty shillings, than by the spade for as many pounds: and indeed, I do not see, why most of the small ones may not be raised in the same way.

They also prove, that it is profitable for the farmer to raise different species of cabbage for his cattle in winter; and I have it in contemplation to try them for summer use also. However, for the winter, it is an object of great importance, not only to the well-feeding of cattle, but to the saving an infinite consumption of hay, which by this husbandry may, at least, be pastured in summer.

The experiments on the turnips prove, first, that it is more profitable to raise them in drills, than in broast-cast: secondly, that the culture is a great deal cheaper: thirdly, that less manure will produce a larger crop, than in broad-cast, provided it be disposed in the same way as mine was: fourthly, practice shews the expence of drawing the drilled turnips for sheep or black cattle, to be at least two-thirds less, than drawing the broad-cast: fifthly, in the drill way not a turnip need be left upon the ground; whereas, in the broad-cast way, the leaving many is unavoidable, to the great annoyance of the succeeding crop, particularly if that shall be barley: and sixthly, that the land is left, after drilled turnips, in a much higher state of preparation for a succeeding crop, than it can possibly be in the broad-cast way. To these advantages another may be added, which I find very material, viz. that of slicing them for black cattle, which is highly neceſſary, even when they are ſmall, nay more ſo, for cattle are ſometimes choaked with a ſmall turnip. A man will be near as long ſlicing a ſmall turnip as a large one, and will make no diſpatch; whereas, my men and boys now ſlice for me every evening about nine hundred weight in an hour; which is a taſk upon them after night-fall, except on Saturday nights; then they ſlice double the quantity.

As it ſeems to be a paradox to ſay a man will ſlice a large turnip as ſoon as a ſmall one, it may be proper to explain it to the reader. The man is in danger of cutting his hands when he is ſlicing a ſmall turnip; but in no ſuch danger with a large one: and, beſides that, one ſlice of a large one contains more food, than two or three whole ſmall ones.

Theſe experiments prove, that the potatoe tillage, in the manner it is now generally practiſed, is not ſo beneficial an improvement of land, at leaſt not of ſtrong ground, as is generally imagined; although there is a greater conſumption of dung than in any other huſbandry.

The experiment with the lime, upon the fallow ground, proves lime to be an inſufficient manure, for the high improvement of lime-ſtone ground. There are ſo many advocates for lime as a manure, that it is adventurous to ſay any thing againſt it; but, I hope, the reader will obſerve, that I pronounce upon it, as being inſufficient, "for the high improvement of lime-ſtone ground." I have tried lime in another field of my farm, in which I ſowed wheat, and my ſucceſs was no better in that than in my turnips: and I earneſtly recommend it to every improver, who may have favourable opportunities of getting lime, that he try it upon a ſmall patch, before he launches into a large expence for it; ſuch caution may perhaps ſave him money. This advice ariſes from practice; for, I imprudently burnt a large quantity of lime, at an expence of near an hundred pounds, and, I can truly ſay, I have not received in benefit as many ſhillings.

The experiment with the ſhell marle, proves that to be a very high and excellent manure; for, as it will produce turnips upon poor ground, it may be ſafely relied upon for any other crop.

The native earth proves to be perfectly inſufficient for turnips; though it certainly mends the ground a little, beſides that it adds to a ſhallow ſoil.

Accidents and diſtempers.

Turnips are ſubject to be deſtroyed by the fly. In an orchard I ſowed two acres with turnip ſeed in drills in July laſt. They were invaded by the fly; I had a conteſt with them for a fortnight, and at laſt conquered them, with a loſs of only four or five perches of my turnips, which happened where there were moſt trees. Every morning before the dew was off, I had the rows daſhed with lime, which was ſlacked every day on purpoſe. This lime adhered ſo cloſely to the leaves, when they were wet with the dew, that it defended the upper ſides from injury: then I found the flies began upon the under ſide of the leaves, which I had never ſeen them do before; however, upon this, I was obliged to have the duſt thrown very low; and, whilſt the plants were wet, a great deal adhered to them, even on the under ſides:—thus I ſaved my turnips, which were as fine a crop as any I had, ſave the four or five perches before-mentioned.

The upper ſide of the turnip leaf, in its infant ſtate, is very ſmooth, and on that part the flies always lodge, unleſs they are interrupted; in that caſe they will deſtroy the plants by wounding the under ſide, which is not ſo inviting to the inſect as the upper, it being a little rough, though not enough to protect it from them.

The greateſt inconvenience I found in this work was, that every little ſhower of rain waſhed off all the lime, and then the work was to begin again; ſometimes I repeated it three times a day: however, it will be found to anſwer well, but it requires to be done with care.

I have, by the ſame method, ſaved lucerne, which is alſo ſubject to be deſtroyed by the fly, upon its firſt coming up.

I diſcovered laſt ſeaſon three diſtinct ſpecies of the turnip fly (if I may ſo call it) one of them is black; it ſeems to hop like a flea, and reſembles it exactly. The ſecond is a ſmall degree larger, and very diſtinguiſhably has wings, upon which are two ſmall white ſpecks; and the inſect is of an oval form. The third is like a domeſtic fly, but not by a fourth part ſo large.

The turnip-cabbage is ſubject to the ruſt, or mildew. In my orchard I had ſome plants put out, at different diſtances, for experiments; they grew very well for a time, but they were all infected with the ruſt, and thoſe neareſt the trees ſuffered moſt. In my field I could find but three, which were injured by this diſtemper. This ſeems to prove, that they require an open expoſure; and therefore they better ſuit the purpoſe, for which I have recommended them.

Turnips, cabbages, turnip-cabbages, and boorcole, are food for black cattle and ſheep.

A ſheep, I find, will conſume about twenty pounds of turnips in twenty-four hours, provided they are allowed as many as they can eat, which ſhould always be allowed to fat ſheep: but as ſheep vary in ſize, ſo I preſume will they conſume more or leſs food.

An acre of turnips, of forty-ſeven tons to an acre, will maintain one hundred ſheep fifty-two days, allowing each ſheep twenty pounds a day. My ſheep weigh about twenty pounds a quarter.

In the month of November laſt, I gave my ſheep acceſs to ſome pea-ricks, which I had erected on purpoſe for them, of which they eat with great eagerneſs; but I find they affect them in the ſame manner as they do horſes, when given to them new; for the ſheep, I apprehend, from violent cholicks, which, I conceive, the peas gave them, were ſeized with ſtrong convulſions; and in this way I loſt ſix of them, in a few days, before I conſidered what could be the cauſe: but having examined the inteſtines of every one of them, and finding no ſymptoms of any other diſeaſe, I was led to draw the above concluſion; and what ſeems to confirm my opinion is, that I have not loſt one ſince I took them from the peas. If other perſons have not met with the like accident, who have fed their ſheep with new peas, it ſhould ſeem that turnips and peas together do not agree with ſheep. However, that is a fact which I ſhall ſoon be able to determine, for I ſhall admit the ſheep to the peas again to-morrow, which will be the twentieth of February; a ſeaſon in which it is imagined we may ſafely give peas of the preceding year to horſes, and therefore, I conceive, there can be no danger in giving them to the ſheep: but, if they ſhould be affected as they were before, I think there cannot remain a doubt, that the peas and turnips diſagree in their ſtomachs. And here I ſhall leave a ſpace to add to my report hereafter.

Now, the fifteenth of March, the ſheep have been ever ſince at the peas, and I have not loſt one.

Of cabbage, and turnip-cabbage, a ſheep, of about twenty pounds a quarter, will conſume about fifteen pounds a day. An acre, at that rate, will maintain one hundred ſheep about thirty-four days. The cabbage, and turnip-cabbage, are a firmer and more ſubſtantial food than turnips.

I have fed a cow this winter upon turnips, and I have now two bullocks which are ſtall-feeding upon turnips alſo. It is computed that they weigh between four and five hundred weight each; and I find by experiment, that they each of them eat about two hundred and ſixteen pounds in twenty-four hours; which is, therefore, about half their own beef-weight; from hence we may, with reaſon, imagine a beaſt will eat every day of turnips, at ſtall-feeding, about fifty-ſix pounds for every hundred weight of beef he may contain.

One of the bullocks was put up miſerably poor from the plough, for an experiment, on the fourteenth of December: he took kindly to the turnips; and on the ſixteenth I began to give him, with his turnips, pea-flower, to the amount of eight pounds every day; and I find he is greatly improved, but he will not be beef; though I am very inclinable to think, that if he had been put up ſix weeks ſooner, in April, he would have been good beef. This experiment I ſhall repeat next year. What induced me to mention it here is, that ſome other perſons may perhaps try it next winter, and, if they ſhould, I ſhall be much obliged by their report of the effect. I am led to believe, that bullocks may be profitably fed with peas, becauſe horſes, and pigs, thrive very faſt upon them.

When

When the cattle are firſt put to turnips they dung but little, the turnips going off chiefly by urine, the quantity of which is really incredible; but, after ſome time, they dung more; and, from a whitiſh colour, the dung reſumes the natural colour, and is of the common firmneſs. I allow each of the cattle ſeven pounds of hay every day, and I do not find that they eat fewer turnips on that account; the reaſon, I believe, is, that the hay makes them more eager for the turnips. They refuſe water.

To each of my cows, and ſtore-cattle, I allow ſeventy-two pounds of turnips a day, and a little ſtraw, thirty-ſix pounds being what I find a moderate-ſized beaſt will eat at a meal. To my plough bullocks I allow the ſame quantity of turnips, with as much ſtraw as they can eat; but I forbid their having the turnips till they have been unyoked about an hour, and after they have eat ſome ſtraw; as I conceive the turnips are too cold for them immediately after their labour.

I have lately confined a milch cow four days, and fed her with turnips, and I could find no diſagreeable flavour in her milk from that food, though I have often heard turnips complained of as giving a bad taſte to the milk, when cows are fed with them. Query, whether it might not ariſe from the leaves of trees falling upon the turnips? Leaves of trees always ſpoil the milk when cows eat them.—Here follow,

Calculations upon the feeding black cattle with turnips and cabbages.

Suppoſe four cows or bullocks, of four hundred weight each to be ſtall-fed upon turnips, allowing each beaſt two hundred and ſixteen pounds a day, an acre of forty-ſeven tons would maintain them one hundred and twenty-one days. Indeed a larger ſtock ſhould be put up, or heavier cattle, as the turnips will not keep ſo long.

Suppoſe ten dairy cows to be maintained upon turnips, allowing each cow ſeventy-two pounds of turnips a day; at this rate, an acre of forty-ſeven tons will keep them one hundred and forty-ſeven days. All cattle, fed in this manner, ſhould have about ſeven pounds of hay a day allowed to each.

The fat cattle eat about one hundred and a half of cabbages a day; therefore an acre of twenty three tons will, at that rate, maintain four bullocks, of four hundred weight each, ſeventy-ſix days.

When fed with cabbages, they dung more, and make leſs urine, than when they are fed with turnips, and will drink a little water.

Hence I am induced to believe, that cabbages are a better food for cattle than turnips. I am fully perſuaded near as many tons may be raiſed upon an acre, with proper ſeed and good management; but they will coſt five or ſix ſhillings an acre more.

There remains one general obſervation to be made, and which I imagine contributed greatly to the ſucceſs of the abovementioned crops, viz. that we had for theſe ſpecies of crops, very ſeaſonable and fine rains. From the ſixth of July, on which day I began to put down my cabbage-plants, to the firſt of December, both incluſive, we had ſeventy days, in which there was, more or leſs, rain; and the latter end of Auguſt, and beginning of September, the heavieſt dews that I have ſeen. From the ſixth of July to December the firſt, both incluſive, were one hundred and ſeventy-ſeven days; ſo that we had but one hundred and ſeven dry days, many of which, I ſee by my kalendar, were cloudy and inclinable to rain.

" Land, ſays an Eſſex farmer, cannot be brought into too good tilth for ſowing turnips: they require a deep, looſe, well-wrought mould; and to effect this, diſcreet plowing and harrowing is the beſt way. I ſay diſcreet, becauſe one plowing, properly timed, is worth three that are out of time. It is a maxim in huſbandry, that ſome land cannot be plowed too much; but we ſhould add, at proper ſeaſons and intervals, or an ignorant farmer might ruin himſelf, and yet think he had followed the directions that were given him.

" A light land requires leſs plowing, as well as leſs nicety in the times of plowing, than a ſtiff heavy ſoil; and it is alſo ſooner brought into good tilth: two well-timed plowings will often do it; whereas a clayey ſoil will require three or four, before it is brought into order.

" An early plowing will greatly forward the getting a ſtiff ſoil into order: the month of April ſhould be the lateſt that ſuch, when intended for turnips, ſhould be turned up. It may then lie till the beginning of June, when it ſhould be harrowed down with loaded harrows to break the clods, and immediately croſs-plowed: about a fortnight after this it ſhould be plowed for the laſt time, and immediately croſs-harrowed and ſowed out of hand with the turnip-ſeed pretty thick, and ſcratched with a light harrow to cover the ſeed.

" Light lands, as I ſaid before, may do very well with two plowings, one in the ſpring, and the other juſt before ſowing at Midſummer.

" I look upon it that turnip-ſeed cannot well be ſown too thick, for it ſeldom all comes up, and of what does get above ground, much is often deſtroyed by the fly, and ſlug; ſo that the plants ſometimes, though the ſeed was ſowed thick, require but little thinning by the hoe. In fact, I think it better at firſt to beſtow an additional quantity of ſeed, than to have to ſow three or four times over, as I have been often obliged to do, till I practiſed this method of ſowing thick, which generally ſucceeds very well with me.

" The beginning of July is the time in which I, for the moſt part, ſow my turnip-ſeed: in this matter the grand affair is to hit it off, ſo that the turnips do not grow ſticky or ſpongy before the winter, and yet are forward enough in their growth to reſiſt the froſts, &c. and be fit food for the cattle in the winter, or in the ſpring.

" To have a good and profitable crop of turnips, it is abſolutely neceſſary they ſhould, at proper times, be hoed, not only to kill the weeds, but alſo to thin the plants, and ſet them out at a proper diſtance.

" The proper time for the firſt hoeing, is when they have put forth their fourth leaf, and the ſecond hoeing ſhould be in about three weeks afterwards: twice is, in general, enough, unleſs a very following rainy ſeaſon ſhould come on, when it will be proper to take the advantage of the firſt ſun-ſhine weather, to give them a third hoeing: this, indeed, is often neglected, but I always found it pay well, by the thriving condition it put my crop in.

" As to the diſtance at which the plants ſhould ſtand one from the other, that muſt be regulated by the ſize of the turnip; but it ſhould be never leſs than one foot, nor is there occaſion for its being more than two: about ſixteen or eighteen inches is a proper diſtance for the common turnip we generally ſow about me.

" If the ſoil, on which the turnips grow, is light and dry, the moſt profitable way is to feed your ſheep on them in the ſpot where they grew; but if the ſoil is heavy and ſtiff, it is beſt to have them pulled, and carried in tumbrils on to ſome dry paſture, or on any dry field you want to mend; for was you to feed them on the land, one half of them, at leaſt, would be rolled in the dirt, trodden under foot, and ſpoiled.

" Land cannot be too rich, or too well dunged, for bearing turnips; and this will bring them forward, and make them eſcape the fly better; for when once the leaves become rough, the fly does not chuſe to touch them: it is therefore certainly beſt to encourage them in their growth, and bring them as ſoon as poſſible out of danger.

" When my young crop of turnips have come up, and I have been fearful of the fly, I have frequently ſown over them wood aſhes, and ſometimes ſoot: theſe have been of great ſervice, eſpecially if gentle rains followed, as neither the flies nor ſlugs choſe afterwards to touch them. But I muſt obſerve, that this is no ſafe remedy, if the weather is dry and hot, for aſhes being of a hot nature, will then be apt to burn up the crop.

" As to the ſlugs, the beſt way of deſtroying them in dry weather is with a light roller: this cruſhes and kills them, and does the crop ſervice, eſpecially if it is light land; for it preſſes the particles cloſer, ſo that the moiſture in the earth is not ſo ſoon exhaled by the heat of the ſun; conſequently, the young turnips do not ſo ſoon ſuffer by a continued drought.

" It is ſcarcely neceſſary to obſerve, that dry weather is beſt for hoeing turnips in, as then neither the weeds nor the turnips that are cut up are apt to grow again.

" In

"In light gravelly or sandy soils, the seed of turnips may be deeper covered than in stiff clayey land: in the first it may be pretty well harrowed in; in the latter, it should only be slightly scratched with a very light short-tined harrow, or even only bush-harrowed; as by that means they will sooner appear above ground, be sooner out of danger, and thrive better afterwards, the apple of the root growing almost entirely out of the ground, the whole nourishment being collected by the tap-root, and by the horizontal roots, which issue from it on all sides.

"The quantity of seed to be sown on an acre, should be from two to three pounds, according to its goodness; and many use equal qnantities of old and new seed, thinking this method best; for the new seed comes up first, and if the fly takes it, the old seed in a day or two succeeds, and generally fares better.

"If a crop of turnips fails, either through any defect in the seed, or by the ravages of the fly or slug, it is usual for the farmer to sow the same land again; and this, if there is occasion, he repeats two or three times, till at last he secures himself a crop. For the reason above-mentioned, it is esteemed best to sow early, as by that means there will be time, if the first crop fails, to sow another.

"Turnip-seed is very apt to take damage from wet, if it is not covered as soon as sown: without this precaution it will sprout prematurely, malt, or mould: by too early a germination the seed is apt to burst.

"When peas are sown on a rich mellow earth, they are apt to grow rank: in this manner they cover the ground, keep the moisture in it, raise a kind of fermentation in the soil, and make it hollow and porous; insomuch that when the crop has been off, turnips have been harrowed in without plowing, and have thriven amain: but there is danger in pursuing this practice without great caution." *Museum Rusticum, vol.* I. *pag.* 205.

"I have, in my time, says a Norfolk farmer, sown a great deal of land in turnips, and have applied them with great advantage to various uses; but our chief reason for cultivating them in this county is for feeding and fattening sheep.

"It is almost needless to say, that they answer this purpose extremely well: their use is too well known to all the eastern farmers, to be in these days controverted.

"We have various methods of spending them: some fold their sheep on the land where the turnips grew; I have done this, but it is not a method I approve of: however, for the benefit of such farmers as chuse to practise it, I shall give one caution; which is, that they use wicker hurdles for folding their sheep, which will otherwise be apt to thrust their heads through the bars, and, tangling themselves, are by that means often killed in the night, to the great loss of the owner.

"If, however, it should not be convenient to the farmer to get these wicker hurdles, but he should be obliged to take up with those made of rest stuff in form of a gate, let him then be careful, when he has set his hurdles, and staked and bound them tight, to pull up all the turnips that grow within two or three feet of the outside of the fold, and throw them over the hurdles for the sheep to eat within-side.

"This will take away any temptation the sheep may have to put their heads through the bars, and they will, by that means, escape the danger of being strangled.

"Every animal is fond of liberty; and though the sheep will bear confinement, perhaps, better than any other creature, yet whoever has seen them when first driven into the fold, must have observed that they naturally go round the hurdles to try to find an opening to get out at: by this means the turnips which grow near the hurdles are trampled on, dirtied, and spoiled. For this there is a very easy remedy; let the shepherd only pull up all the turnips that grow near the inside of the hurdles, and all will be well.

"I observed before, that I am not fond of giving my sheep turnips as they grow: I think it much the better way to have them pulled; by this means they have an opportunity of eating the whole root, and my stock of winter-fodder goes much farther; whereas, when they feed on the turnips as they grow, they generally scoop them out, and leave a hollow shell in the ground, which, though it may afterwards be forked up, the sheep will scarcely even by hunger be induced to touch, as it cannot but be soked by the dung, urine, and dirt, from the feet of the sheep.

"*I find it then the best way, to have my turnips pulled before they are given to my sheep; they go much farther, and do them more good.*

"But in this method there is one seeming inconvenience, which is, that in frosty weather, when the ground is hard, I cannot have them pulled; yet this difficulty is very easily removed, by laying up, at the beginning of the winter, a sufficient store of turnips, secured from wet, and not much exposed to frost.

"I think it worth while to have a building particularly dedicated to this use, and find it answer well: it is built in form of a small barn, and boarded round.

"In the beginning of the winter, before the frost sets in, I have a large quantity of turnips pulled, and the dirt is carefully scraped off them; and, after cutting off the heads and tap-roots, I cause them to be regularly laid in my store, with this caution, however, that all round the sides next the boarding, my men lay straw, to keep out the frost. The heads, or tops, I give to all my cattle in general, as they are cut off; by which means I, in fact, suffer no loss.

"I find these stored turnips a happy resource when hard weather comes on; then I open my repository, and deal them out to my sheep in such a manner that there may be no waste; and as soon as the weather breaks, and the earth becomes less hard, I resort again to the fields, and have them pulled as usual.

"For some years I had another manner of storing my turnips, which was by digging a deep pit in a sandy, dry field, which being filled with turnips, they kept there very well; yet, as this method was subject to many inconveniencies, I left it off.

"I have discovered another use for the turnip, besides feeding my sheep, oxen, and cows with it, which I must mention before I conclude this letter. I find it agrees remarkably well with hogs, which will eat of it greedily, and thrive on it apace.

"I have several times tried this, and have often killed fine young porkers that had for many weeks eat nothing but turnips boiled in swill, or wash, till they were tender.

"I have at other times given turnips to large hogs, that have been put up to fatten, in order to their being killed and salted for family use; and here I was not disappointed in my hopes; they always came on well: but I made it a custom to give them, for a week or two before they were killed, a few bushels of boiled peas, in order to harden their fat, that it might not boil away in the pot.

"I gave them boiled peas rather than raw, because, having been long used to eating the soft turnip, I found they did not afterwards take kindly to the hard, raw pea.

"Hogs may easily be brought to eat raw, unboiled turnips; but it is much better to boil them when the hogs are to be fattened; for, though they will eat enough of them raw to keep them in tolerable good plight, yet they will not eat enough to fatten them apace." *Museum Rusticum, vol.* I. *pag.* 335.

"I had last winter, says an ingenious clergyman of Northampton, a piece of turnips intended for feeding sheep; but my method of consuming them at first astonished my neighbours.

"I fed them off by the fold; but I first turned in some ewes, which greedily devoured all the tops and leaves: when they had finished them, I immediately folded my ewes on a fresh spot.

"After the leaves were eat off the first spot enclosed by the hurdles, by the ewes, I turned in some wethers, which eat with a very good appetite the apples of the roots, leaving, however, the lower part scooped out in the ground: these I had forked up, and they were eat by my store-sheep.

"My neighbours were convinced my method was right, because I evidently kept and fattened more sheep on the same quantity of land, than they did; yet they begged I would give them my reasons for this my practice.

"I told them I would readily comply with their request, and the more so as it might be a means of tempting them to imitate what they saw practised with success.

"Continuing my discourse, I informed them that many years experience, and constant observation, had convinced me, that if you turn a parcel of sheep promiscuously into a field of turnips, the ewes and lambs would immediately attack

attack the leaves; the fattening wethers would, for the most part, prefer the apple of the root; and the store-sheep, not being nice, would indiscriminately devour both leaf and apple, and even eat the leavings of either of the others.

"I farther informed them, that I had frequently observed, that when a parcel of wethers have been turned into a piece of turnips, the farmer, thinking to have no waste, generally kept them in till they have eat the roots clean up. But this is very bad husbandry; for after the wethers have eat the most delicious and sweet part of the root, they loathe the rest, which is generally gritty, dirty, and sodden, insomuch that nothing, but absolute hunger, will tempt them to taste it. In this period they pine, and lose flesh; and by the time they are turned into a fresh bite of turnips, they are but little better than they were at first.

"The appetite of a beast that is fattening should be tempted, not palled; and undoubtedly, such of the sheep as are most forward will be most delicate; and this delicacy, if the farmer is wise, he will indulge, as it will eventually turn out to his advantage.

"Thus, in my manner of feeding turnips, the ewes come first, because they prefer the leaves; the wethers that are to be fattened follow, and make the most pure and sweet repast; and the store-sheep, which are the least nice of any, come last, and clear off the remains; at least, as much of them as they ought to be permitted to eat; for I do not hold it good to oblige them to eat what are in a half putrefied condition, and sodden with dung and stale.

"My neighbours were so well pleased with my reasons, and so well convinced by what they saw, that they are determined to adopt my practice; and if any of your readers should be of the same mind, it would give me great pleasure, as I cannot feel a truer joy than what results from my endeavours to be of service to my fellow creatures." *Museum Rusticum, vol.* II. *pag.* 231.

"I last year sowed some turnips, says a farmer near Chelmsford, on near ten acres of good light land. Some other business interfering, prevented my getting them hoed in due time, insomuch that, by the latter end of August, they seemed to be almost covered with weeds.

"Being willing to endeavour at recovering my crop, I caused the field to be harrowed and cross-harrowed, which set them out pretty well, and cleared away a great number of the weeds, insomuch that the turnips got ahead, and grew to be a tolerable crop.

"I send you this for the information of some farmers, who, when they have delayed hoeing their turnips for a few weeks, if the weeds get forward, think they have lost their crop; whereas, would they adopt this method, which has been more than once recommended, they would find it answer any reasonable expectation they could form. I have several times tried it, and it always succeeded with me more or less. The work costs but little, and the benefit resulting from it is considerable. I have known farmers plough up a crop of turnips which, by harrowing, would have yielded them a good return." *Museum Rusticum, vol.* V. *pag.* 239.

"I have known many, says farmer White of Suffolk, who intend feeding off their turnips with sheep, keep the turnips till they are too old to be applied with advantage to that use. Your readers may give me credit, for I speak from experience; and I can assure them, that one acre of young turnips is of more value for fattening sheep than two acres of old ones, as the wethers you turn in will get flesh and fat at least as fast again on the first as the last.

"Let this maxim be treasured up in the farmer's memory; and let him not at any rate be tempted, for the sake of spending a few weeds and grass on his fallows, to keep his turnips till they are of little worth.

"If any of your readers should be incredulous, let them try the experiment; it will be but little expence, and still less trouble. I did so myself before I adopted the practice, and was in a very short time convinced: this happened some years ago, and I have continued this method ever since." *Museum Rusticum, vol.* II. *page* 279.

We shall conclude this article with the following letter we were favoured with from Mr. Matthew Cox, of Wallhampton, near Limington, in Hampshire.

"I have, says he, inclosed you a draught of a hoe-plough, which I have found to answer very well for hoeing carrots and turnips, which may probably be improved by some of your society: the following is the particulars of its success this year, 1766. I took possession of the farm I live on in April, and going soon after to London, ordered my servant to sow two acres of carrots with four pounds of seed; on my return, I found he had sown all the seed I had left him, being twenty-eight pounds. In May the carrots came up as thick as sand on the shore. The people here being intirely unacquainted with the method of hoeing, made my work very tedious, as I was obliged constantly to attend them, it cost me sixteen and six-pence *per* acre, and the work not half done; I then harrowed them, &c. according to Mr. Billing's directions, and in June found ten times too many to come to any size; but could not get the second hoeing performed under one guinea *per* acre: I then gave directions for this hoe, which I fixed to the common horse-hoe plough, and hoed my two acres in five hours with ease; next day I harrowed them with common harrows. About ten days after I harrowed them again, and have kept nine horses on them ever since August, except a quarter of oats in feed time.

Whoever uses this plough will find it answer the first hoeing extremely well, as it will leave whatever it hoes in two inches and a half distant; consequently the second hoeing, which must be by hand, will be very trifling; and often there will be no occasion for it. I first hoe the long way of the land, and then cross it. The hoe I have is bare two inches; but I find it is too narrow.

a a, Plate XXVI. Fig. 5. are the two out-sides of the hoe, which are flat, and so go on the out-side of the block on the common horse-hoe at A A, Fig. 4.

b, Goes on a mortice at the bottom of the block, at *b*.

c, The pin goes through the holes on the flat sides of the hoe at *a a* and the block A A.

d, *d*, *d*, The cutting parts two inches and a half wide; and leaves a space of two inches and a half.

E, A chain that hooks to a staple on the beam, and keeps all steady. I have ploughed ten inches deep with this hoe.

F, F, Two bars of iron worked in to the three uprights.

I always use the harrow belonging to the common horse-hoe with the above. I sometimes fix M. De Villier's cultivator to the above carriage. I have a field of twenty-two acres of wheat, in which is sixteen different ways of sowing, preparing the seed, and manuring the land.

TURNIP-CABBAGE, the name of a species of cabbage, so called because the stalk, at some distance from the ground, after rising of the usual thickness, and in the manner of those of other cabbages, enlarges suddenly to such a degree, that it forms a knob of a very large turnip; of which likewise it has sometimes the figure, though it is, in general, more oblong.

By this peculiar formation of the stalk, or production of the turnip-like knob, together with its being perennial, this species of cabbage is distinguished from all others. From the top of this turnip rise a number of leaves, of a greenish-red, or sometimes greenish-purple colour; which answer to the radical leaves in other plants. They do not, though this plant is truly of the cabbage kind, ever close together, and form a compact globular or oblong mass, as in the common species; but keep their erect growth, or turn outwards.

From among these leaves spring a number of other stalks, of which, those that are nearer the extremity, branch, and send out flower stalks, spreading horizontally; and those that are more in the center, grow erect, and without branches. On these stalks are leaves, springing out alternately, and of the same colour with the others. The flowers are small and yellow, and succeeded by long cods, full of seed, of the size of that of mustard, and a light-brown colour. We have given a figure of this plant on Plate XXVI. Fig. 6.

It may be justly doubted, whether or no this plant be originally a native of our country; though it is at present found growing wild in some places near Dover. But, from its general character, which does not agree with the indigenous

genous plants of the same kind; from its being unknown to the earlier botanic writers, or, at most, known only in the view of an exotic; and from its being now to be met with wild, only in the one place mentioned, it is most probable, that what is there found was the produce of seed conveyed originally thither by some accident; and which has since propagated itself, and spread spontaneously, as it easily might, from its perennial nature and extreme hardiness. It is frequently cultivated in gardens, where there are collections of vegetables: but, for the most part, rather as a curious than an esculent plant. Though certainly, the turnip, or knob, is at least as wholesome as either any turnip or cabbage, and is much liked by some; and the leaves are also thought good by others; but, in general, both are said to be strong, and seldom admitted to the table with us. This plant, however, affords sprouts, which, after they have undergone the action of a strong frost, are exceeding good; and may consequently be had at the time when all others fail. The lying in very small room, proportionably to the quantity of solid substance, and the keeping good much longer than any other sort of vegetable of a similar nature, are qualities, moreover, which fit this plant in a most peculiar manner for the use of seamen, as is ingeniously remarked by Mr. Baker, in his report to the Dublin society. *See the article* TURNIP.

It appears from Gerard, that there were, in his time, two kinds of this plant; one of which he calls *caulorapum rotundum*, or round rape-cole; and the other, *caulorapum longum*, or long rape-cole. The difference of these two kinds consisted only in the form of the knob or turnip, as is expressed by the names themselves; and in the long kind's shooting forth smooth indented leaves from the turnip part, which leaves the round kind wanted. I have here sent you a sketch of these two kinds, according to the prints Gerard has exhibited of them; and they may serve also to give some idea of the general figure of the plant, to those who have never met with it.

I have not however seen in any garden, nor find any traces in the late writers, of more than one kind of this plant; so that if the round and long kinds, mentioned in this manner by Gerard, were really different species, the long is now lost. But it seems more probable, that this was only a degeneracy of the plant, by means of the farina of the common kinds of cabbage; as the deviation from the round knob towards the plain stalk, and the breaking out of the leaves from it seem to indicate.

If there really were two original kinds, or this difference arose from a permanent seminal variation, it would merit attention under the present circumstances to recover them; since it frequently happens in correspondent cases, that where there are two allied species, the one has qualities which fits it to a particular purpose in a very superior degree to the other. This plant was rare in Gerard's time in our country; as he mentions his having the seed from Spain: and indeed it was so little known, that he says it is to be sown and set as cucumbers and melons; and that it was then accounted a dainty meat. It did not however make its way to the table in common, or even as a curiosity in gardens, much more at that time than since. For Parkinson, who wrote after Gerard, and enumerates many more species of cabbage than his predecessor, does not take the least notice of it. Tournefort, and most of the later writers, mention this plant under various names; but they do little more with regard to it, than give the name and description. Miller, in his Gardener's Dictionary, says, this kind of cabbage "never varies, for I have cultivated it many years, and have not found it to alter. It grows naturally on the sea-side, near Dover. It hath a perennial branching stalk, in which it differs from all other species. I have cultivated it these three or four years, and have eaten the young shoots, after they have been much frozen, when they were very sweet and good; but at other times they are very strong and stringy. In very severe winters, where the other sorts are destroyed, this is a very necessary plant, for the most severe frosts do not injure it."

Till lately we see, therefore, this plant was only considered, either as a kind of curiosity in botanic, or other gardens, where there were collections of different kinds of plants, or as an esculent herb: but, in this latter view, it seems not to have acquired any great reputation, as it is so seldom, even notwithstanding Miller's recommendation, met with on the table here; though I am well informed, that in some of the factories in the East-Indies, it has been cultivated from European seed, and is much liked.

The first public notice I find taken of this plant, in the present view of cultivating it for feeding cattle, is in a pamphlet published by the late Mr. North, gardener, near Lambeth, who speaks of it, under the article of cabbage; of which he says, "There are four species that may be cultivated to great advantage for cattle; to wit, the white cabbage, the hardy curled Savoy cabbage, the turnip-cabbage, and the green curled cabbage." When he comes to treat particularly of the turnip-cabbage, he thus expresses himself: "The turnip-cabbage is one of the hardiest roots that grow; and I dare affirm, might be propagated to great advantage for feeding sheep, &c. For in the most severe winter that I can remember, when cabbages, savoys, turnips, &c. have all been demolished by the extremity of the weather, the turnip-cabbages have not been hurt. The turnip part grows all above ground, which is crowned with many large smooth leaves, like those of the red cabbage, but which grow open like the tops of turnips. They are a very solid juicy root, and do not grow spongy when they are old, as turnips do. The tops may be cut off, and given to sheep, &c. in the spring, and the roots laid by in an out-house to feed them in April and May, when no other roots can be had. Sheep are so fond of these roots, that they will leave the best turnips for them. When they are given to sheep, they should be cut to pieces; but they will eat them fast enough, tops and bottoms, as they are growing in the fields. After Michaelmas, when turnip-cabbages have their full growth, they will weigh from four to eight pounds a root."

It may be proper here to caution against a misconception, from the inaccuracy of an expression of Mr. North's, in calling the turnip-like part of this plant, a root: for it is no more than an enlargement of the stalk in that part; being, when the plants are large, several inches above the ground. It is proper to observe likewise, that Mr. North has under-rated the weight of these plants; it appearing, by Mr. Baker's account, that some weigh fourteen or fifteen pounds. This is the first notice I find in any published work, of this plant's being considered as proper for feeding cattle: but it appears in the minutes of the society's books, that some little time before the publication of this pamphlet, on the enquiry set on foot by the late Mr. Wych, concerning a proper food for cattle in hard winters, this plant, together with the Chinese or white vetch, and the Syberian medicago, were proposed to the Committee of Agriculture for their consideration, by a gentleman well known to that society; and this plant was particularly recommended for its hardiness in the ground, its quality of not rotting, though long kept, its nutritive property, and the fondness which cattle shew for it, when offered to them as food.

Mr. Baker, nevertheless, whose report on this subject to the Dublin society, the reader will find under the article TURNIP, must have the honour of being the first who really introduced this plant into use, as an article of husbandry. For it was on the authority of his judicious experiments, related in that report, the same gentleman, who formerly recommended the turnip-cabbage, as above-mentioned, to the London Society, induced them last year to offer a premium for its culture: and there is no one object of a similar nature, hitherto taken into consideration, either by this society, or that of Dublin, which bids fairer for being of great public utility: as this plant seems to answer all the ends of what was sought for, with so much pains and attention, in the research set on foot by Mr. Wych, after a proper winter pabulum (as it was called by him) for cattle in scarce winters.

The turnip-cabbage may be cultivated in the manner of other cabbages; of which the particulars may be seen under the article CABBAGE. But the success Mr. Baker had with his method, particularly in relation to the magnitude of the turnip, which seems to go far beyond Mr. North's notion, recommends strongly the trial of that manner; except that, as he properly remarks, where the plants are raised in the spring, the seed should be sown in the very beginning of March; the plantlings, transplanted to a proper close bed, as soon as they are sufficiently strong to bear it; and the final transplantation of them out into the field at the distances in which they are to grow, should not be deferred later than the beginning of June. This would both give more time for the plants to become large before winter, and a better chance to avoid a total want of rain, after transplanting; the only accident, except the destruction by caterpillars, or other insects, to which this kind of crop is subject; as the plants bid defiance, after they have firmly taken root, to all inclemencies of weather, either with respect to cold, wet, or drought.

It may be inferred from the above particulars, which, as we see, stand on unquestionable authority, that, considered as an article of husbandry, this plant must be a very valuable acquisition; as it is of easy culture, and as little subject to fail by accidents, as any crop whatever: as the produce, with respect to quantity, is likely to prove, under favourable circumstances, thirty-five or thirty-six tons per acre, as appears from Mr. Baker's account: as its produce is greatly preferable either to turnips or other cabbages; being much more nutritious, and less watery and cold; a fault in the common turnips: as it may be depended on in the most rigorous and severe season, when every thing else but dry fodder fails, and may be taken from the place of growth, in case of exigence, whenever the ground is not covered with a very deep snow: and as it is much liked by neat cattle, sheep, deer, and hogs; agrees perfectly well with all of them; and fattens them in the most profitable manner. This is certainly very sufficient ground of recommendation, as an object of premium, to the London Society; and it is hoped, will be so, as a subject of experiment and trial to those gentlemen, or more liberal kind of farmers, who attempt improvements in husbandry.

I have thus endeavoured to give all the light I can into the nature of this plant, considered as an article of husbandry: but before I conclude, I must beg leave to subjoin a few words respecting it in another view, of such importance to a particular set of men, whose health and safety manifold reasons recommend to the care of the public, as makes it merit a very serious consideration. What I allude to is, the intimation given by Mr. Baker, of the probability that this plant might be rendered extremely serviceable to seamen in long voyages. As there can be no doubt of the just foundation of this opinion, it ought to be kept in sight as much as possible, till the matter be realized in practice. The putrid scurvy, arising from the eating salt provisions, is the great bane of a sea-faring life. The numbers disabled or carried off by it, particularly in time of war, are almost incredible; and, if we consider the public value of lives so lost, both with respect to the national power and expence, policy, as well as humanity, bids us listen to every feasible proposal for mitigating this evil. The use of vegetables in the diet along with the salt-beef or pork, is well known to be one of the most effectual means of prevention of this disease: and indeed, it has been so well understood, that great quantities of cabbages, &c. have been sent off to the fleets cruising in the bay, or elsewhere within reach, to the great relief and refreshment of the men. But this species of cabbage, abounding more in the saccharine juice than the other kinds, would be a more efficacious preventative or palliative of the scurvy; and the solid compact texture of these turnips, which makes a considerable weight, lye in a small compass, together with their repugnance to that putrefaction, to which other turnips, cabbages, &c. are quickly disposed, renders it practicable to keep them on shipboard, in any climate, for many months; provided they be preserved from the access of any extraordinary degree of moisture.

If this plant should be, therefore, generally cultivated in the field-way, and consequently produced at a very cheap rate, as Mr. Baker has shewn, that betwixt thirty and forty tons may be obtained by an easy method of culture, in one year, from one acre of ground, they might be purchased at a much cheaper rate than any other article of provision at present in use for the victualling ships.

This seems to be an object very well worth the consideration of the India company; as it might be a means of preventing that delay and ill success of some voyages, which arise from the sickness of the men; and it is attended with no difficulty, but what regards the stowage. For the plant being already cultivated in some of the factories in the East-Indies, where it succeeds as well as here, and consequently might in all the others, as no climate or season appears injurious to its growth, it might be procured at a proportionably cheap rate, as well for the supply of the homeward as outward bound ships: and indeed, considering the nature and state of the provisions on board ships returning from India, it would undoubtedly be peculiarly beneficial in that case. *Museum Rusticum, vol.* VI. *pag.* 46.

TURPETH, a species of the convolvulus or bineweed. *See the article* BINEWEED.

TWIFALLOWING, or TWYFALLOWING, ploughing the ground a second time, which is generally done in June.

V.

VALE, low ground; a valley.

VAN, an instrument to winnow corn. *See the article* THRESHING.

VASCULIFEROUS PLANTS, fuch whofe feeds are contained in veffels divided into cells.

VAT, *or* FAT, a veffel for holding wine, ale, beer, cider, &c. in the time of their preparation.

UDDER, that part of a cow, mare, ewe, &c. where the milk is prepared, anfwering to the breafts in women.

VEGETABLE, a term applied to all plants, confidered as capable of growth, *i. e.* all natural bodies which have parts organically formed for generation and accretion, but not fenfation.

Vegetables, according to the analyfes made of them by chemiftry, are diftinguifhable into two grand tribes, the acid and the alkaline; the firft affording a volatile acid, and the fecond a volatile alkali, upon a dry diftillation: thus guaiacum, cedar, box, cinnamon, cloves, forrel, mint, balm, &c. afford an acid; but garlic, onions, horfe-radifh, fcurvy-grafs, muftard, &c. afford an alkali, which, rectified, is hardly diftinguifhable from that of animal fubftances, fo as nearly to refemble the fpirit and falt of hartfhorn.

VEGETATION, the act whereby plants receive their nourifhment and growths; of which, three principal functions are underftood, viz. nutrition, increafe, and generation.

From Scripture we learn, that the earth has been endued, from the beginning, with a certain feminal virtue to produce plants; which virtue, proceeding from God, was not confined to the firft production of things, but extends likewife to all future confequences of times; and this faculty which the earth has of producing plants, is from this commandment of the Almighty: "Let the earth bring forth grafs, the herb yielding feed, and the fruit-tree yielding fruit after his kind, whofe feed is in itfelf upon the earth; and it was fo." Gen. i. 11.

Philofophers afk, what can be that virtue the earth is faid to be endued with, if it be only an inherent quality whereby it produces, naturally, all forts of plants, without the concurrence of feed? or if a feminal virtue (or feed) muft be adminiftered to it? Some follow the firft opinion, for this reafon, that earth dug up from a great depth and put into pots, after a fet time or feafon, produces feveral forts of plants of itfelf without feed; but though this opinion be approved of by many, it has not, however, the leaft appearance of probability on its fide; for who (confidering with attention the progrefs of nature, fees the marvellous mechanifm of the organs of plants, the whole texture of their internal as well as external parts) could be perfuaded to attribute it to a heavy and indigefted mafs of clay or earth: therefore, it is more rational to fay, that plants have their origin from feeds, which being taken from the firft plants, have propagated their fpecies by the Creator's will, as far as our times, and will continue to do fo (particularly where they are natives) to the end of the world.

The fun, rain, the exhalations of the earth, and the reft of the exterior caufes, are capable to excite a certain motion or fermentation in the bofom of the earth; but unlefs there be a feed which contains already the conformation of the plant, whofe parts are unfolded by that fermentation, never fuch fermentation or motion can give origin to the plant; therefore, we have great reafon to think, that all plants have their origin from feeds, actually or potentially, fince the firft rudiments of a plant can be difcovered no where elfe, nor by the naked eye, nor even by the help of a microfcope; fo that the feed contains not only the coarfer matter of the plant, with its organical parts, which have the ratio of a body, but likewife a certain fpirit, that is, an active and vegetative fubftance, which may be called the foul of the plant. Although, in fome manner, it may be faid to fleep in the grain or feed, yet when excited to motion by the heat of the fun, the warmth of the earth, and with rain impregnated with particles of volatile falts, it then unfolds its parts and pufhes the embryo plant forward.

A fprig or cutting muft contain in it this feminal property, for being fet at a proper feafon, it produces a tree with all its generative parts; which it would not do were it not endued with fome feminal virtues.

This generative or feminal faculty, is a power of the vegetative foul of a plant, by which it lives and produces its likenefs for the prefervation of the fpecies: but this faculty is not difcernable from the feed itfelf, nor from the fpirit contained therein, for as the feed is faid to be a part of fome fubftance, defigned for the production of another fubftance of the fame fpecies, it is not abfolutely neceffary to diftinguifh that prolific virtue from the feed itfelf, nor from the fpirit contained in it; for after the feed is fown and foftened by the warmth and humidity of the earth, its germ (wherein the plant is contained, as in an epitome) is unfolded by a gentle fermentation, and arifes into a plant.

That the heat of the fun and the temperate warmth and humidity of the earth, are the firft principles of vegetation, appears from the fterility or fertility of the foil in thofe climates where thefe two principal agents act, or do not act, in concert; fince, in the moft northern countries, where the humidity of the foil is exceffive, and its natural warmth is too much concentered, the fermentation of the feed being made with too much precipitation, and without that gradation neceffary for the eafy and moft perfect expanfion of the different parts of the plant, thereby they are fruftrated of that ftrength they fhould have before they come out of the matrix it has been formed in to refift the injuries of the air and the inconftancies of the feafons, it perifhes almoft as foon as it appears on the furface of the earth; for although the earth has in fome meafure, though very imperfectly, acted its part (as it cannot alone, and without the affiftance of the fun, carry the plant to its laft perfection) that tender parent of nature, by the obliquity of its fituation, being reduced to the incapacity of darting its rays as favourably and abundantly in thofe climates as he does in others more happily fituated, cannot either help the mother earth in her pregnancy, nor rectify what fhe has left imperfect in her productions, which therefore die almoft as foon as nature itfelf is apprifed of their exiftence.

Likewife in thofe other climates fituated quite different from thefe where the fun, by being too profufe of its influences, penetrates the inmoft parts of the womb of the earth, and by its too violent and too often repeated acts, and exalting its falts, and evaporating its radical humidity, caufes an exceffive dilation of its pores, a difunion, and

and but too often an intire laceration of its generative parts, ſo as to render them quite ſteril or barren, and therefore incapable to contribute to that fermentation abſolutely neceſſary for the production of plants.

On the contrary, in thoſe happy climates where the parts of the earth are ſo ſituated in reſpect to the ſun as to be under his moſt favourable aſpect, and expoſed to none but his moſt benign influences, it almoſt always continues in its natural flouriſhing ſtate, being ſeldom viſited by the moſt powerful and penetrating beams of the ſun but at thoſe regular and periodical times appointed by nature for its pregnancy, when they are neceſſary to excite her fœcundity, or to nouriſh and cheriſh her productions when once brought forth.

Suppoſe our ſeed to have been ſown in this laſt ſoil, and ſituation, the firſt things which preſent themſelves to the imagination are the ſun and earth concerting together, the one by its heat, and the other by her moiſture, how to rid the embryo of that hard tough ſubſtance it is enwrapped in, and which is the greateſt obſtacle to the burſting forth of its parts; therefore the earth, which is the firſt agent in this caſe, and which is to do the office of incubation, makes uſe firſt of its natural moiſture to ſoften the outer rind or huſk, by having it percolated through the pores or pipes of the ſaid huſk, whereby they are ſo opened and dilated as to facilitate the introduction of the different ſalts appointed to operate on the whole ſubſtance of the ſeed, by unfolding the different parts it contains, and diſpoſing them ſeverally towards aſſuming their reſpective forms.

It cannot be imagined that the earth acts alone in this firſt operation, that it could direct itſelf to action without the concurrence of the ſun, which on this occaſion excites, by a gentle warmth, the different ſalts the moiſture of the earth is impregnated with, that they may be capable to conquer the ſtubbornneſs of the huſk, by forcing themſelves into its almoſt imperceptible pores, conquering all the obſtacles, and raiſing all the obſtructions which the ſeveral ſubſtances may meet with; by this means a free paſſage being opened for ſuch a quantity of the moiſture as is neceſſary to make a due ſeparation of the huſk from the more eſſential part of the ſeed, the ſalts employed in that operation being volatilized or already fixed on that eſſential part, leave the huſk filled with nothing elſe but the lympha, which groweth turgid, and being deprived of the nouriſhment it received when united to the ſubſtance of the ſeed, begins to tend towards its deſtruction.

The following procedure in the vegetation of plants is exemplified by Malpighi in a grain of wheat; the firſt day the grain is ſown it grows a little turgid, and the ſecundine, or huſk, gapes a little in ſeveral places, and the body of the plant being continued by the umbilical veſſel to a conglobated leaf (which is called the pulp or fleſh of the ſeed, and is what conſtitutes the flour) ſwells, by which means not only the gem or ſprout (which is to be the future ſtem) opens and increaſes, but the roots begin to bunch out, whence the placenta, or ſeed-leaf, becoming looſe, gapes. The ſecond day the ſecundine or huſk being broken thro', the ſtem or top of the future ſtraw appears on the outſide thereof, and grows upwards by degrees; in the mean time, the ſeed-leaf guarding the roots becomes turgid with its veſiculæ, and puts forth a white down, and the leaf being pulled away, you may ſee the roots of the plant bare, the future bud, leaves, and the reſt of the ſtalk lying ſtill hid. Between the roots and aſcending ſtem, the trunk of the plant is knit by the navel-knot to the flower-leaf, which is very moiſt, though it ſtill retains its white colour and its natural taſte. The third day the pulp of the conglobated or round leaf becomes turgid with the juice it has received from the earth fermenting with its own; thus the plant increaſes in bigneſs, and in its bud or ſtem becomes taller, and from whitiſh becomes greeniſh, the lateral roots alſo break forth greeniſh and pyramidal from the gaping ſheaf which adheres cloſely to the plant, and the lower roots grow longer and hairy, with many fibres growing out of the ſame; indeed there are hairy fibres hanging on all the roots, except on the tops, and theſe fibres are ſeen to wind about the ſaline particles of the ſoil, little lumps of earth, &c. like ivy, whence they grow curled about the latent roots, and then break out into two other little ones. The fourth day the ſtem mounting upwards, makes a right angle with the ſeminal leaf, the laſt roots put forth more, and the other three growing larger are cloathed with more hairs, which ſtraitly embrace the lumps of earth, and where they meet with any vacuity, unite into a kind of net-work; the conglobate or flower-leaf is now ſofter, and when bruiſed yields a white ſweetiſh juice, like barley cream; by ſtripping it off, the root and ſtem of the plant are plainly ſeen, with the intermediate navel-knot, whoſe outer part is ſolid like a bark, and in the inner more ſoft and medullary. The fifth day the ſtalk ſtill riſing puts forth a permanent or ſtable leaf, which is green and folded, the roots grow longer, and there appears a new tumour of a future root, the outer ſheath is looſened, and the ſeed-leaf begins to fade. The ſixth day the ſtable leaf being looſened, the plant mounts upwards, the ſheaf ſtill cleaving round it like a bark; the ſeed-leaf is now ſeen ſinuous or wrinkled and faded, and this being freed or cut from the ſecundine, the fleſh, or pericarpium is found of a different texture, the outer part, whereby the outſide of the ſeed or grain is heaped up, being more ſolid, but the inſide viſcular and full of humour, eſpecially that part next the navel-knot. All the leaves being pulled off, the roots torn, and the flower-leaf removed, the trunk appears, wherein, not far from the roots, the navel-knot bunches out, which is ſolid and hard to cut; above there is a mark of the ſheath-leaf, which was pulled, and underneath, as in an armpit, the gem is often hid; the hind part of the plant ſhews the breaking forth of the roots likewiſe, with the faded placenta, &c. After the eleventh day, the ſeed-leaf as yet ſticking to the plant, is crumpled and almoſt corrupted; within it is hollow, and about the ſecundine the mucus and white ſubſtance of the ſeed being continued to the navel-knot, forms a cavity, all the roots becoming longer, put forth new branches out of their ſides, the ſecond leaf withers, and its viſicles are emptied; the internodes, or ſpaces between the knots, grow longer; new gems appear, and the middle root grows ſeveral inches longer. After a month, the roots and ſtalk being grown much longer, new buds break out at the firſt knot, and little tumours bunch out, which at length break out into roots.

Thus, according to Malpighi, in this ſhort ſpace of time, the plant paſſes through all theſe various changes and mutations, which, though his obſervations may be real as here repreſented, yet it does not happen with ſuch celerity in all ſorts of plants, though in ſome kinds all theſe variations may come to paſs in a ſhorter time.

The plant carried thus far, it ſtill wants food for the future preſervation of its vegetative life, which being deprived of ſuch nutriment, it cannot exiſt; of which naturaliſts are ſo ſenſible, that their common opinion is, that water is the great vegetable food, which they endeavour to confirm by repeated experiments, eſpecially by that made on a ſprig of baum, mint, &c. which being ſet in a phial of pure water, without any mixture of earth, grow and put forth roots, leaves, and branches; without conſidering, that thoſe ſorts of plants being of a ſhort duration, the juices which they have received from their mother earth in their firſt formation circulating through their veſſels, being continually recruited by the ſalts the water they are ſet in is impregnated with, together with thoſe they receive continually from the ambient atmoſphere, are more than ſufficient for the ſupport of their ſhort life in the water, which ſubſiſts no longer than that the water continues to ſupply them with ſalts, of which when once exhauſted, it grows viſcous, obſtructs the pores of the veſſels, and hinders thereby the admiſſion of ſalts even from the atmoſphere, imbecillitate by degrees the functions of the vegetative ſoul, which being forced for ſome time to feed on its own ſubſtance, becomes at laſt enervated and impotent, whereby the plant withers and dies for want of food, unleſs the water is changed before it comes to the laſt period, which appears at its growing offenſive to the ſmell; even that precaution becomes uſeleſs, at leaſt for the greateſt part.

Thoſe ſalts the water is impregnated with, being heterogeneous to thoſe which enter into the compoſition of the juices, which circulate through the veſſels of the plant, have ſoon, by diſordering the whole frame of that mechaniſm, procured the extinction of the plant.

The great quantity of oleaginous particles thoſe ſorts of plants are compoſed of, which keep their pores extremely dilated for the admiſſion of ſalts and other nutritive particles,

cles, contribute much towards the production of this phænomenon; but in plants of a closer texture, whose pores are so exiguous as not to be forced, but by the impetuosity of salts exalted and volatilized, best by the warmth of the earth and the heat of the sun, this experiment is of no effect; therefore, water cannot be simply considered as the great vegetable food, although it has a very considerable share in the nutriment of plants: but were it water alone, to which vegetables owe their increase, there would be no need of manures nor changing the kinds. The rain falls in all places upon the most barren land, as well as on the most fertile; nor could there be any reason why the same field should yield a large crop of wheat one year, and not the next, since rain showers down nearly alike on the earth.

VELLING, ploughing, or cutting up the turf, or upper surface of the ground in order to its being burnt. *See the article* BURNBAKING.

VENTILATOR, a machine by which the noxious air of any close place (as an hospital, jail, ship, chamber, granary, &c.) may be changed for fresh air.

The noxious qualities of bad air have been long known, though not sufficiently attended to, in practice; but it is to be hoped, that the indefatigable pains taken by Dr. Hales, to set the mischiefs arising from foul air in a just light, and the remedy he has proposed by the use of his ventilators, will at length prevail over that unaccountable sloth or obstinacy, which, where particular interests are not concerned, seems to possess the generality of mankind, and which rarely allows them to give due attention to any new discovery.

The ventilators invented by that ingenious gentleman consist of a square box, ABCD (plate XXVI. fig. 7. about ten feet long, five wide, and two deep; in the middle of which is placed a broad partition, or midriff, made to move up and down, from A to C, on hinges at the end E, by means of an iron rod Z R, fixed to the midriff at Z.

Another box, of the same size with the former, having a like midriff, bar, &c. is placed near the former (fig. 8.) with its rod, R Z. Both these rods are fixed to a lever F G, moveable on the center O; so that by the alternate rising and depressing of the lever F G, the midriffs are also raised and depressed alternately, by which means these double bellows are at the same time both drawing and pouring out the air.

That the midriffs may be rendered lighter, they may be made of four bars, lengthwise, and as many placed across them, each about three inches broad, and an inch thick, the vacant spaces being filled up with thin pannels of fir board.

In order to make the midriffs move with greater ease, and without touching the sides of the boxes, there is an iron regulator N L (fig. 7.) fixed upright to the end A C of the box. As very little air will escape if the edges of the midriff be within one twentieth part of an inch from the sides of the box, there is no necessity for leathern sides, as in common bellows. The end A C of the box must be somewhat circular, that it may be the better adapted to the rising and falling of the midriff; and at the other end of the midriff a slip of leather may be nailed over the hinges.

To the ventilators above described, eight valves are adapted for the air to pass through; these valves are placed at the hinge-end I Q, fig. 8. numbered 1, 2, 3, 4, &c. The valve 1 opens inward, to admit the air to enter, when the midriff is depressed at the other end, by means of the lever F G; and at the same time the valve 3, in the lower ventilator, is shut by the compressed air, which passes out at the valve 4: but when that midriff is raised, the valve 1 shuts, and the air passes out at the valve 2. The same is to be observed of the valves 5, 6, 7, 8, of the other box; so that when, by the motion of the lever F G, the midriffs are alternately rising and falling, then two of the ventilators are constantly drawing in the air, and two of them at the same time are blowing it out at their proper valves, the air entering at the valves 1, 3, 6, 8, and passing out at the valves, 2, 4, 5, 7. To the ventilators, before the valves, is fixed a hook Q Q M M (fig. 9.) as a common receptacle for all the air that comes out of these valves, which air is conveyed away through the trunk P, passing through the wall of a building, &c.

It would be foreign to the intention of this work to point out the various uses of these machines in extracting foul air out of ships, hospitals, &c. but we must not omit the following:

Experiments on the preservation of corn by ventilation.

M. Duhamel caused a case, or little granary of preservation, to be made of oak plank two inches thick, forming a cube of five feet every way. At six inches from the bottom was a flooring, or second bottom, of lattice work, placed upon joists five inches thick, and covered with a strong canvas. This small granary was filled quite full of good wheat, of which it contained 94 cubic feet, weighing 5040 pounds. It was covered with good oak planks, so closely joined, that neither rats, mice, or even the smallest insects could get in; leaving only some vent-holes, with trap doors, or covers, fitted very exactly to them, as mentioned before.

This corn, laid up without having been dried at all by fire, was not ventilated more than six days in a year, which was sufficient to keep it so well that the best judges allowed it to be as good as could be. Even when the bellows had not been worked for several months, the corn was still allowed, by good judges, to look and smell perfectly well: but they objected, that it did not handle well, that is, that there was some little dampness in it. The bellows were worked for half a day, and this objection was entirely removed,

This wheat was old, and had been as well dried as any corn generally is in a common granary: therefore it being still damp, at the end of a considerable time, shews the necessity of taking away the superfluous moisture, and of reducing our corn to the same degree of dryness, as that of the hottest countries, in order to preserve it in great bodies.

Experiment on ninety-four cubic feet of wheat.

In May, 1743, ninety-four cubic feet of wheat were put into one of the little granaries before-mentioned. It was of the harvest of 1742, of an excellent quality, perfectly clean, and so dry, that a small parcel of it which was put, for a trial, into a stove heated to fifty degrees of M. de Réaumur's thermometer (123 of Farenheit's) lost but one sixteenth of its weight. This wheat was well cleansed from dust, and deposited in the granary without being dried by fire.

During the first three months, it was ventilated for eight hours once a fortnight: during the rest of the year 1743, and all 1744, it was ventilated once a month: all the year 1745, and part of 1746, it was ventilated half a day once a month; and after that, but once in two or three months.

In June 1750, the granary was emptied, and the wheat looked and smelt very well, but felt a little rough in the hand, because, not having been stirred for six years, the little hairs that are at the extremity of the grain, and the particles of the bran, were roughed up: but after passing twice through the wind screen, that objection was entirely removed. *See the article* THRASHING.

This corn was eight years old, during seven of which it was preserved in one of M. Duhamel's small granaries, without any sensible diminution, and without any damage from vermin or insects: we cannot say absolutely, without any expence, because a man was employed from time to time to ventilate it. But this was a very trifling charge, and may be reduced almost to nothing, by working the bellows with swifts like those of a mill.

Experiment on seventy-five cubic feet of new wheat, extremely moist, grown, and which had already contracted a bad smell.

The harvest of 1745 was very rainy: almost all the wheat of that year was grown in the ear; the sheaves were extremely wet when they were housed; the grains adhered so closely to their husks, that they were greatly bruised by the flail; and if they were left but a very little while upon the barn-floor, before they were cleansed, they heated, and contracted a smell like that of pigeon's dung: in short, they were so very moist, that they lost an eighth part of their weight when dried in a stove heated to fifty

fifty degrees of M. de Réaumur's (one hundred and twenty-three of Farenheit's) thermometer; and when laid up in the common granaries, in the usual way, they were always in a state of fermentation, though but a foot thick, and turned every fourth or fifth day.

Seventy-five cubic feet of this grown wheat, which smelt very ill, and was so moist as to wet the floor of the granary where it laid but a few days, were put, in this condition, and without being dried by fire, into one of M. Duhamel's little granaries, with small hopes of success.

As this corn was very hot when put into the granary, it was ventilated three or four times the first week, and once a week during December and January: and as it had then lost great part of its bad smell, it was ventilated but once a fortnight from that time till June. Then perceiving, by thrusting his hand into the top of the heap, that it heated, and concluding that it was going to be entirely corrupted, M. Duhamel ordered the granary to be emptied: but after the depth of about a foot had been taken from the top, he was greatly surprised to find the rest cool, with very little bad smell, and drier than that which was preserved in the common granaries.

The reason why the top of this corn was the worst, was, undoubtedly, that the moist vapours were always forced upwards in ventilation. It therefore might, perhaps, have been kept very well, if, instead of emptying the granary, it had been ventilated oftener: for this would, probably, have dried away the remaining moisture, even at the top, as the following experiment will shew. But however that might have been, this teaches us one important thing, which is, that the top of the heap is most subject to heat in this sort of granary: so that if the grain taken out of the vent-holes is in good condition, it may be concluded that the rest is still better.

Experiment on five hundred and fifty-five cubic feet of wheat, very damp, mixed with smut, and which had contracted a bad smell.

The wheat of the year 1750 grew in almost continual wet; the harvest was very rainy; and the same weather continuing all the year 1751, no pains that could be taken to turn the corn laid up in the common way, could dry it, or prevent its heating and contracting a bad smell. The wheat of this crop was likewise mixed with a considerable quantity of blighted and smutty grains, which always contain a great deal of moisture, doubly difficult to be exhaled from them, and which soon makes them contract a bad smell, which they speedily communicate to the sound corn.

Five hundred and fifty-five cubic feet of this wheat were deposited in one of M. Duhamel's granaries of preservation, after being cleansed with such perfect care, that scarce any mark remained either of blight or smut among it; though these faulty grains amounted to near a sixth part of the crop. But there still remained a fine dust, or powder, occasioned by the moisture, so closely adherent to the corn, that it could not be taken off by any means.

This wheat was laid four and a half or five feet thick in one of these granaries, the bellows of which were worked by a wind-mill; and as there was no want of wind during all the year 1751, and till the spring of 1752, the corn was often ventilated, without trouble or expence; by which means it was not only well dried, but also cleared of great part of its bad smell. It was indeed, when taken out of the granary, very full of dust, which had fallen off the grains as their moisture was exhaled: but this was then easily separated by proper screening, and the wheat proved so good, that the bakers bought it at the highest market price.

This experiment proves, that even very moist corn, which has a great disposition to ferment, may be preserved by ventilation only: and as to the smutty grains with which this was mixed, the reverend Dr. Hales, after rightly observing that kiln-drying is apt to make wheat grind unkindly, proposes the following method of drying smutty corn, after it has been washed; cold air not hurting it, as kiln-drying is found to do. "That I might be well assured, says that friend to all mankind, of the good effect of thus drying smutty corn; having procured a quantity of very smutty wheat, which weighed seven pounds and fifteen ounces, on the twenty-sixth of May, at five in the morning, it was washed clean in four several waters, which was done in a few minutes, and was then laid to drain in an oat-sieve, till half an hour after five, when it had increased in weight, by wetting, ten ounces, besides the moisture that was equal to the weight of the smut-balls and smut that was washed from the wheat. It wasted but two ounces and an half, by the first two hours ventilation; two ounces and five drachms in the second two hours, viz. from eight to ten; in the next six hours, viz. from ten to four in the afternoon, it wasted at the rate of four ounces every two hours; from four to six, two ounces and an half, and from six to eight, one ounce and an half: in all, about twenty ounces; some allowance being made for what corn was wasted by handling and biting some of it from time to time. It was ventilated in these fourteen hours with about forty thousand gallons of air, which passed upwards through it, and made it sufficiently hard and dry, so as to be fit for grinding: it was well coloured, and handled well; and, from stinking, as smutty wheat does, it became much sweeter. The visible dewy moisture was blown off in three hours; but it continued damp and cold to the feeling till two o'clock, when some little dust began to fly off it.

"And whereas it wasted off much less moisture during the first four hours ventilation, when it ought to have wasted the most, on account of its being then wettest, this was owing to the foggy haziness of the morning: which as it went off, and broke out into fine warm sunshine, towards ten o'clock, so the air being thereby become dry, it imbibed moisture more strongly from the corn: and that this was the true case of the difference, is farther confirmed by a like experiment which I had before made on a gallon of wheat, April the first, there being then a very dry north-east wind.

"It will be advisable to begin to ventilate corn as soon as possible after washing, that the moisture may have the less time to soak in: for the less moisture soaks in, so much the sooner the corn will dry.

"If the moisture is so easily carried off from wet wheat, by ventilation, this method will doubtless much improve what is called cold wheat, viz. such as is grown, and has been housed in a cold wet season; and will therefore soon carry off the moist vapours which arise from corn, and which cause it to heat and grow musty."

Other experiments on the preservation of corn by ventilation.

The prior of the royal abbey of St. Stephen in Caen, filled a granary of preservation twelve feet wide, thirteen feet long, and six feet deep, which forms a parallelipipede of nine hundred and thirty-six cubic feet, constructed according to M. Duhamel's directions, with wheat that had been kept all the winter in a common granary. It was cooled from time to time by two bellows, which two men worked by means of a leaver; and though the place where this granary of preservation stood, was neither so dry nor so airy as might have been wished, the corn kept perfectly well in it.

In the beginning of September 1754, M. Vandusfel filled one of M. Duhamel's granaries of preservation, seven feet square and six feet deep, with good wheat, undried. It heated a little at the end of eight days; but two men, with a small double ventilator, cooled it in two hours time. It began to heat again about a week after, when he repeated the same operation, which cooled it presently. By the twentieth of October it was quite cool, though it had not then been ventilated for fifteen days; and according to a letter of his writing to M. Duhamel, dated the fourteenth of October, 1756, it still continued in the same good condition. Corn of the years 1754 and 1755, not dried, but only ventilated, had likewise kept with him as well as could be wished.

VERJUICE, a liquor obtained from grapes or apples too acid for wine or cider. It is generally made in England from the juice of the crab, or wild apple.

VERMIN, a collective name including all kinds of small animals, that are troublesome to men, beasts, corn, fruits, &c.

VERNAL, something belonging to the spring season.

VERTICULATE *Plants*, such as produce their flowers round the joints of the stalks in whorles; as hyssop, mint, thyme, &c.

VETCH, the name of a well known plant, much cultivated in many parts of England, and of which there are feveral fpecies.

Some forts of this plant, the feeds of which ripen in autumn, grow naturally in moft parts of England, in fhady places among bufhes, and by the fides of woods. The roots of thefe are perennial; but their ftalks are annual, weak, and grow to fo great a length (for they will climb up to the height of fix or eight feet wherever the tendrils which proceed from the end of their leaves can lay hold of boughs, branches, or the fide of a hedge, to fupport them,) that they are hardly fit to be cultivated in the field, though fome writers have recommended them for this purpofe: for as they cannot be fupported there, they will trail fo much upon the ground, that they will be apt to rot: nor do their fhoots, which are lefs fucculent than thofe of the vetch commonly raifed, grow to a fufficient height to be cut for ufe till late in the fpring, when there is little want of green food for cattle.

Mr. Miller, after fowing for many years the common vetch or tare, which is much cultivated in the fields for fodder, feems to think that which has black feeds, a diftinct fpecies from the white: for he has never found either of them vary. Both thefe are annual, and perifh foon after they have perfected their feed. Their ftalks are angular, ftreaked, and hairy: they are weak, and want fupport, and generally trail upon the ground when they do not find any thing to faften themfelves to. Their leaves are compofed of feveral pair of blunt lobes, and are terminated by tendrils. The flowers, which are pretty large, proceed from the wings of the ftalk, and fit very clofe to the bafe of the foot ftalks of the leaves. Two of thefe flowers generally fpring from the fame joint: thofe of the black feeded fort are purple, and thofe, of the white feeded are white. They appear in June and July, and are fucceeded by erect pods containing three or four round feeds in each, which ripen in Auguft and September.

The white vetch is rather the more fucculent plant of the two, and therefore it is beft for fodder: but many are unwilling to cultivate this fort, becaufe their feeds, being white, are much fooner difcovered by rooks and other birds, than thofe of the black, which bear a nearer refemblance to the colour of the ground. This objection may, however, be eafily removed, by fowing them in drills, and then covering them carefully, inftead of the ufual method of fcattering them with a broad-caft, and plowing them in lightly.

The fmall black-feeded vetch, which fome call rathripe, and others pebble, goar, or fummer vetch, is much tenderer than either of the former, and therefore lefs cultivated. This muft always be fown in the fpring: whereas the others may be fown in fpring or autumn.

But another fpecies of vetch, viz. the Siberian, hardly known, to the generality of farmers in this country, bids fair to become, perhaps, the moft ufeful of all for fodder; for its ftalks grow to a great length, and are well furnifhed with leaves, which do not decay in autumn, like thofe of the other forts, but continue green all the winter, in defiance of the hardeft froft: fo that in February and March, when there often is a fcarcity of green fodder for ewes and lambs, this may be of fingular fervice, efpecially if thefe plants are fupported from trailing upon the ground. Their flowers, which appear in July, are of a light blue colour.

This, like our common vetch, may be fown in the fpring, or in autumn; and when the plants are come up, they will not require any other culture than keeping them clear from weeds; a work which, if the feeds are fown thin in rows four feet afunder, as Mr. Miller rightly advifes, may be eafily done with the Dutch hoe, while they are young, and afterwards with the hoeing plough. By this thin fowing, the ftalks of thefe vetches, which fend out many branches, and extend very far, will be kept from matting fo clofely together as to rot each other by excluding the air; and by earthing up their ftems in the fame manner as fhould be done for peas and beans, they will be greatly ftrengthened, their leaves will grow the larger and more fucculent, and they will confequently yield an increafed quantity of fodder. The repeating of this as often as it may be found neceffary to deftroy the weeds in fummer, which may be done at a very fmall expence, and is particularly proper when the growth is intended for the green food of cattle, will be attended with the farther important advantage of preparing the ground thoroughly for whatever other crop may afterward be put upon it.

As the plants of this kind of vetch will not be in danger of being hurt by froft, they fhould not be cut till the fpring, when the beft way will be to take them as they may be wanted, green, for the feeding of ewes: but fome of them fhould be left untouched, for feeds; for if thofe which are cut do fhoot out again, they will flower fo late in fummer, that their feeds will not ripen, unlefs the autumn proves very warm. A better way will therefore be to fow a proper quantity of feeds for this purpofe in a feparate fpot of ground: becaufe, when the other is cut, the ground may be plowed for other crops; and if the feafons fhould be fo mild as to produce a fufficiency of green food independent of this, the vetches may be plowed into the ground, to which they will be an excellent dreffing for other crops.

Mr. Miller, who has a high opinion of this fort of vetch, and whofe recommendation of it ought to have very great weight, is now beginning to try it in the field, where he has not yet had experience of its culture: but the experiments which he has made with it for fix years paft, on fmall patches of it fown in gardens, in different fituations, have fully anfwered his expectation: for he has found thefe plants continue in great verdure in all thofe places, when moft of the perennial plants in the fame fituation have fuffered greatly by the froft, and could have cut from only eight of them as much fodder as would have been equivalent to half a trufs of clover.

Vetches are generally fown either in autumn, or early in the fpring: but the beft time, in this country, is toward the beginning of Auguft; becaufe the rains which ufually fall about that feafon will bring them up in a fhort time, and the plants will get ftrength before winter, and be fit to cut for the food of cattle early in the fpring, when green fodder is moft wanted: and if they are defigned for feed only, thefe early fown vetches will come early into flower, and their feeds will ripen early, fo that they may be cut and ftacked in good weather, which is a great advantage; for thofe which ripen late, are often ftacked or houfed wet, and then their feeds frequently fprout in the mow, and are fpoiled.

Vetches will do well in almoft any ground; not excepting even fuch as can fcarcely produce any other plant. The common method of fowing them is in broad-caft, ploughing them lightly in, as was obferved before; and the ufual allowance is two bufhels of feed for an acre of land; though fome fow two bufhels and an half. Either of thefe practices may do well enough for thofe vetches which are intended to be cut for fodder in the fpring; but when they are fown with a defign to let them ftand for feed, it will certainly be much better to fow them in drills, in the fame manner as is practifed for peas; and in this cafe lefs than half of the abovementioned quantity of feed will be fufficient: for the rows fhould be at leaft three feet afunder, that the hoe-plough may have room to go between them, to deftroy the weeds, and earth up the plants, which, when thus managed, will produce a much greater crop, and ripen better and earlier, than in the common way. Thefe drills fhould be of about the fame depth as for peas, and the feeds fhould be fcattered at about the fame diftance in the drills, in which they fhould be carefully covered over as foon as they are fown; for otherwife the rooks will difcover them; and when thofe voracious creatures once find the rows, they will fpeedily deftroy them intirely, if they are not carefully watched. The preventing of this is another advantage which attends the fowing of vetches early in autumn, rather than in the fpring: becaufe there is more food for rooks and pigeons in the open field in the former of thefe feafons, and the plants will then appear much fooner above ground. Toward the end of October, by which time the plants will have acquired confiderable ftrength, the horfe-hoe fhould begin to work between the rows, provided the weather be dry: and in doing this, particular care fhould be taken to lay the earth up as high to the ftems of the plants as can poffibly be, without covering their tops. This will help to fecure them againft froft, and clear the ground of weeds at leaft till March, when the plants fhould be earthed up a fecond time, and the intermediate fpaces between their rows be cleaned again, in the fame manner as before. This will make them grow fo vigoroufly, that they will meet and cover thofe fpaces in a little time: whereas thofe fown in the fpring will not grow to half this fize, and will be very late in flowering.

When vetches are intended only for fodder, of which they generally afford two good crops in the year, in hot countries, or when the farmer defigns them for plowing in, by way of manure, they need not be fown in drills, or hufbanded in the manner directed: the common broad-caft way will then do well enough: but ftill it is moft advifable, in either cafe, to fow them early in autumn; becaufe, in the firft place, they will produce the defired green fodder much earlier in the fpring; and in the fecond, they will be fit to plow in much fooner the following year, and thereby have time properly to meliorate the land, and prepare it to receive the enfuing crop, which they are generally allowed to do even more effectually than peas. Stiff clays are peculiarly benefited by this dreffing: but it furely is bad hufbandry to fow vetches for green fodder, where lucerne will thrive; becaufe this laft will yield greater plenty of ftill more nourifhing food.

In fome countries, efpecially abroad, they mix oats with their tares or vetches, an equal quantity of each, and fow them in February. The vetch, fupported in fome meafure by the oat, grows the higher for it: and, about the middle of May, this mixture is mowed, and given to horfes and other cattle, which it fattens greatly. Mr. Mortimer likewife thinks it a good way to fow horfe-beans and tares together: their feeds are eafily parted with a riddle: and another obfervation in which he agrees with the Maifons Ruftiques, is, that more vetches fhould not be fown at any one time, than can be covered the fame day, becaufe the dew is apt to fpoil them: confequently they fhould not be fown till two or three hours after the rifing of the fun; by which time the moifture will be exhaled from off the furface of the earth. But though their feeds cannot bear dampnefs, which would foon rot them, their plants, efpecially in fandy land, often perifh in dry years, for want of water. To make them flourifh well, they require a fhower of rain every ten or twelve days. One plowing to turn in the ftubble of the preceding crop, and another at the time of fowing, are fufficient for this plant: but thofe who give only one plowing, which is when they fow, and afterwards harrow in the feed, neither have, nor can expect, an equally good return.

When vetches are cultivated for their feeds, they fhould be cut foon after the pods turn brown, and ftacked as foon as they are dry: for if they are fuffered to lie out in the field, till they receive wet, and there then comes a hot day, moft of the pods will burft, unlefs they happen to have been blighted; in which cafe they will not open fo eafily. Their haulm, when dry, and threfhed, is efteemed good food for cattle, and fome fay that their feeds are as good for horfes, as beans; which, if true, fhould render them the more valuable, becaufe thefe will grow on the lighteft fandy land, where beans will not thrive; and may therefore, as Mr. Miller obferves, be a good improvement to fome counties in England where they do not even attempt to cultivate the bean. About three loads from an acre are reckoned a good crop.

Vetches, when threfhed out, will be as good for fowing at the end of five or fix years, as at firft, if care be taken to turn them in the heap from time to time. Mr. Mortimer cautions the hufbandman to lay them by themfelves in fome convenient place, feparate from his other corn, becaufe they will otherwife be apt to foul it.

It is commonly faid, that the farmer cannot fow any thing more profitable than vetches; for that, befides inriching the land, a load of them will go farther than two loads of hay: but Mr. Lifle has a calculation tending to prove, that an acre of broad clover is worth twenty fhillings a year more than an acre of any vetches, and that the clover fhould therefore be preferred, wherever the ground will bear it well.

" It would certainly, fays Mr. J. Smith, an ingenious farmer of Effex, be of great national advantage, could our ftock of cattle and fheep be encreafed without diminifhing the quantity of our lands that are in tillage.

" This can no otherways be done, but by encouraging the growth of artificial paftures, which the farmers have of late years fallen into.

" The turnip hufbandry is not of very old ftanding in this ifland, yet has it made a very rapid progrefs. The immenfe utility of it, when properly practifed, cannot but be evident, even to an ignorant common farmer, on the flighteft infpection. This evident utility of it has occafioned its being almoft univerfally practifed in the counties of Norfolk, Suffolk, and Effex, whence it has fpread to other parts of England, and is of late even adopted in Ireland, where, I am informed, the gentry are very intent on improving their eftates.

" The colefeed plant has alfo its utility, and in many places is as univerfally fown as the turnip. I have, myfelf, very often raifed this crop, as well for feeding fheep, &c. as for the fake of its feed, and have had no little fuccefs in this hufbandry, being very fond of it, as colefeed is an excellent crop to overpower, choak, and deftroy weeds.

" I wifh the burnet grafs, fo ftrongly recommended, may anfwer every purpofe that is expected from it: it feems to promife very fair from the accounts given of it by Mr. Rocque; and if it has not too much prejudice to encounter withal, it may probably fucceed, and the culture of it become as univerfally adopted, as is that of the turnip, or colefeed plant, already mentioned.

" So much in general; but the particular reafon of my now writing to you, was to recommend to the induftrious farmer the cultivation of vetches as food for cattle.

" I have often fown this crop with great fuccefs, to prepare my land for wheat, and have always found that by growing to a large cover they deftroy and choak up a great number of weeds, which would otherwife do me immenfe damage: indeed, I think them, for this purpofe, next in rank to a hoeing crop.

" When I fow vetches before wheat, I always, in the fpending my crop, have regard to the condition of my land. If my land is not in good heart, but wants mending, I not unfrequently fold my fheep on it, and feed off my crop in the field; but if it is inclined to be rank, or the wheat which is fowed on it, is apt to run much to ftraw, I often cut my vetches green, and feed my horfes in the ftable with them. I find no food agree better with them; they thrive well, grow fat, and are always in good health and fpirits when thus fed.

" I fometimes alfo mow my vetches when they are in bloom, and make them into hay, in the fame manner I manage my clover and meadow grafs; all which I leave in grafs cocks in the field, whilft it is haying, very feldom fpreading it, for fear of rain; and after two or three turns it is generally fit to carry.

" The great art, in making hay of vetches, is to contrive in fuch fort, that the leaves do not drop off the plants, which, if left too long, or dried too fuddenly, they are apt to do; and the farmer is to underftand, that great part of the peculiarly nourifhing quality of the hay refides in the leaf.

" I fay peculiarly nourifhing, becaufe almoft every kind of cattle, as horfes, oxen, cows, and fheep, is fond of it, and they all thrive on this food amazingly: this I have often experienced, and moreover obferved, that they make no wafte even of the ftalks, which they eat with an appetite.

" In this manner I manage for my hay, when I am inclined to have it very fine and fit for my cows and fheep; and in this manner it is no difficult matter to get it in in good order, fweet, and wholefome: but when I intend it only for my horfes, I generally let my crop ftand fomething longer; that is, till the kid, or pod, is formed, and the feed about half grown within it.

" When the hay is made in this laft way, the bufinefs is much more ticklifh, and conftant obfervation muft be made to fee when the crop is in proper order to cut, becaufe if it is left too long, the ftalks grow hard and fticky, and the leaves are apt to drop off.

" This hay is more nourifhing, when cut in this laft method, than I can well defcribe: it anfwers both for hay and corn; and with this food my horfes will be in good flefh, health, and fpirit, and be able to do a great deal of work.

work. I have often proved this to be true, and can therefore the better venture to assert it.

"I have still another method of making these vetches into hay, which is to leave the crop, till the seed is grown to its full size in the pod, though not ripe: I then mow them, and, when dry, thresh them on a cloth in the field; by which means I procure a considerable quantity of pigeons meat, which fetches me a tolerable good price; and this pigeons meat sells better at market, than if the vetches had stood till the seed was thoroughly ripe; for by cutting the crop when the seeds are barely full grown before they begin to harden, they shrink in the drying, and thereby become of a smaller size than they are by nature, and consequently more proper food for pigeons than if they were larger.

"I own, the hay in this last method is not quite so good, as many of the leaves will, in spite of all the care that can be taken, drop off, and the stalks will be a little sticky: yet, after all, it serves very well for my ordinary cattle, and even for my plow and cart horses, with the assistance of a few oats.

"Vetches are a very good plant to sow thick on land, and when they have formed a perfect cover, to plow them in, in order to the land's being sown afterwards with wheat on one plowing. In this intention they answer to the full as well as buck-wheat, or clover.

"When a farmer intends to plow in his vetches, I would by all means advise him to do it some weeks before he sows his wheat, that they may have time to ferment and rot, or the consequences may be fatal to his crop: I once, myself, lost the chief part of a fine field of wheat by this oversight." *Museum Rusticum, vol.* II. *pag.* 169.

"Vetches, says a gentleman farmer of Surry, are a grain often overlooked by the farmer; yet are they, when properly cultivated and applied to proper uses, highly valuable and very beneficial.

"They are a very hardy grain, and resist the severity of a severe winter better than most other crops; besides which, they have the additional advantage of growing in almost any soil; but then the farmer is to expect a produce in proportion to the goodness of his land.

"I would by all means advise, where it is intended for early seed, or to stand for seed, that the small winter vetch be cultivated in preference to every other sort, because it is not only hardier, but also, being sown about Michaelmas, it is forwarder, to serve as fodder, or will be earlier ready to mow for seed, which is no inconsiderable advantage; for the vetch being a succulent plant, and forming a very thick cover on the land where it is a full crop, it will be in danger of rotting instead of drying, if it should be cut late, or the harvest weather should be very rainy; but if the winter vetch is sown early, it will, in general, be fit to mow in July, or the very beginning of August, when there is less danger.

"Few farmers allow more than one ploughing for vetches: I always allow two, notwithstanding what the neighbouring farmers tell me of turning the fresh soil again down to the bottom of the furrow: I find my advantage in this practice, and shall therefore continue it.

"I have generally experienced the first week in October, if the weather is fine, to be the very best time for sowing vetches; and I allow only two bushels of good seed to every acre, which I find full sufficient.

"I sow them broad-cast on the rough land, as the plough leaves it after the second ploughing, taking care to harrow the field length-ways and cross-ways, in order to cover the seed the better; after which I pass over it a roller, heavier or lighter, according to the nature of soil and the dryness of the weather, observing, that if the weather is dry, and the soil light, I use a heavy roller, in order to close the pores of the light earth; but if the soil is stiff, and the weather damp, I use a lighter roller, lest I should knead and crust the field over, so as to stop the young shoot of the vetch.

"This crop will, in general, choak all the weeds that come up with it; but this must, however, be understood of the smaller sorts, for if there are many large rampant weeds, it will be necessary to have them extirpated with the hook.

"Vetches afford excellent food for sheep in the spring, make cows give a great deal of good milk, and horses are fonder of them, cut green, than almost any other food.

"The best way is to cut them fresh and fresh every morning as they are wanted; and if the farmer has occasion for them for this use only, he may sow in the spring, to great advantage, the large vetch, at different times; by which means he will have a succession of crops, which, to give green to his cattle, he should always cut just before the plant flowers, for it is then in its tenderest and most succulent state, and will afford most nourishment; whereas, if he leaves it till the seeds are nearly ripe, the stalks harden, grow sticky, and are of far less value; besides that many of the lower leaves will, by this time, be withered, or dropped off, and entirely lost.

"I must not conclude without mentioning an important use to which vetches are often applied; I mean, a full crop of them is frequently ploughed into the land as manure, to prepare it for a succeeding crop of wheat.

"When vetches are sown with this intention, I would recommend the large sort, and that four bushels of good seed should be used, to be sown broad-cast twice in a place: but my way of sowing it is somewhat peculiar when I mean to plough it in; therefore I think it may not be amiss to relate it.

"Most farmers sow it by casting it twice in a place, immediately after the land is ploughed, and then harrow and roll the field; but I proceed as follows.

"As soon as the field is plowed, I sow two bushels, broad-cast, on every acre; after which I harrow it length-ways and cross-ways. When this is done, I sow the remaining two bushels, and then harrow it twice again with a pair of heavier harrows, and finally scratch it twice over with light harrows to raise a mould, concluding my work by passing a roller over the whole field. By this management I scarcely ever miss of a full crop, which covers the whole land, choaks the weeds, and serves as excellent manure for the wheat that is to follow.

"I have always found that this husbandry succeeded best in light, hungry, sandy, or gravelly loams; and a brother of mine, who lives in Bedfordshire, tells me it does very well on a chalky soil, provided there is any heart in it.

"The time I choose to plough in the vetches is just after the blossom fades, and the kid begins to form; and it is really surprising to see what a strong fermentation they raise in the soil.

"I have sometimes had my crops so heavy that I have been obliged to mow, or hook up, the vetches before I could plough the land: but this is not often the case; when it is, the farmer has reason to rejoice.

"There are, as I hinted in the beginning of this account, scarcely any soils but the vetch will thrive in, though ever so various in their nature. I am an old man, and in the course of many years experience have sown vetches often on a sandy and gravelly loam, a chalk, though not for ploughing-in, a gravel, a low damp clay, and a perfect brown loam. On all these varieties of soil have they succeeded with me; but I must note, that the farmer may expect a larger crop from a gravel (I do not mean a pure gravel) that has some heart and strength in it, than from the finest loam, which has been, by a long-continued course of bad culture, starved and impoverished.

"The large vetch may be sown in January, February, March, April, or even the beginning of May, when designed for green fodder; but I would, by all means, have the industrious farmer avoid sowing it before Christmas, for it is a tender plant, and if hard frost ensue, he may chance to lose his crop." *Museum Rusticum, vol.* III. *pag.* 185.

VINDIMATION, the gathering the grapes, or vintage.

VINE, the name of a well known shrub, which is, with good reason, preferred to all other, not only for the sweetness of its fruit, but also for the ease with which it answers the labour bestowed upon it, almost in every country and every latitude in the world, except in the frozen or the torrid zones.

It grows as happily in plains as upon hills, and thrives as well in a strong soil, as in that which is loose and open; also in land that is poor, as in that which is rich; and in a dry soil, as well as in that which is naturally moist. It

alone

alone beſt endures the intemperature of heat, cold, or ſtormy weather.

Nevertheleſs, it is of great importance that the quality of the vine be adapted to the condition of the country: for neither is the culture the ſame in every ſoil and climate, nor are all vines of the ſame kind. It is not eaſy to ſay which is the beſt; experience teaching us, that every country has its own, which is more or leſs proper for it. A judicious huſbandman will however eaſily find, that that vine is proper for the plain, which bears fogs and hoar-froſt without being hurt; and for a hill, that which can bear drought and wind. He will plant in a rich and fertile ſoil, a ſlender vine, which does not bear plenty of fruit; in a ſtiff ſoil, one that makes ſtrong ſhoots and is covered with plenty of leaves; and in a looſe ſoil, one that makes but few ſhoots. He will find, that it is not proper to commit to a moiſt place a vine which bears tender and large grapes; nor to a dry place, a vine of a contrary quality.

The good huſbandman will alſo know, that the nature of the climate is of great conſequence; whether it be hot or cold, wet or dry, ſubject to hail and wind, or calm, clear, or cloudy. Two ſorts of vines are fit for a cold and cloudy ſituation, viz. either one which is early, and ripens its fruit before the winter; or one of firm and hard grapes, which bloom in the midſt of fogs, and afterwards mellow with the cold and hoar-froſt, as other grapes do with warmth. Where wind and ſtorms are frequent, the vines muſt take deep root and have hard grapes: where the ſituation is warm, they may be of more tender and more fruitful kinds. Vines whoſe grapes rot with rain and conſtant dews ſhould be planted in dry places; and thoſe in moiſt, which are hurt by drought. If any vines are planted in places ſubject to hail, it ſhould be thoſe which have large and ſtrong leaves; becauſe they will ſhelter the fruit. Where the ſky is uſually ſerene and fair, all ſorts of vines will grow: and thoſe may be planted to advantage, whoſe grapes fall quickly off.

Could we have the quality of the ſoil, the ſituation of the place, and the ſtate of the weather to our wiſhes; that ſoil ſhould be preferred, which is neither too ſtrong nor too looſe, but rather inclining to looſe; neither poor, nor exceeding rich, but rather fertile. The ſituation ſhould neither be a plain, nor ſteep, but yet on a riſing ground; it ſhould neither be wet nor dry, yet moderately moiſtened with dews: it ſhould neither have ſprings on the ſurface, nor at ſome depth in the earth; and yet it ſhould communicate to the vines a moiſture which is neither bitter nor ſalt; for either of theſe will vitiate the taſte of the wine, and give a ſcurvy rough coat to every plant that grows on ſuch land. The ſtate of the moiſture may be known, by diſſolving ſome of the earth in water. The vine does not proſper either in a frozen, or in a ſcorching hot climate; but it thrives beſt in a country that is rather warm than cold. It is hurt more by rain, than by dry weather, and proſpers better in a dry climate, than where rains are frequent. It delights in gentle and moderate gales, but is greatly damaged by ſtorms.

It is an obſervation of long ſtanding, that ground which has never been plowed, or had trees growing on it, is the beſt for a vineyard. All authors agree, that an old vineyard is the worſt of any for making a new plantation; becauſe the earth is entangled with the old roots of the vines matted together, poiſoned by their decay, and quite exhauſted by their long ſtanding. Wood-lands may be uſed, becauſe the roots of common trees and ſhrubs are eaſily extirpated. Where there is no unplowed land, the next beſt is a corn field, free from trees, or where trees have not been planted thick.

The fitneſs of new ground for the vine may be judged of by the ſhoots of ſuch ſhrubs as grow naturally in it: for if they make thriving ſhoots, which have not a ragged or ſtinted appearance, the vine will flouriſh there. Of all ſoils, a black rich mould is the beſt for vines. Stones which crumble, or rot as it were, with the weather, being broken, and laid to the roots of the vines, retain a moiſture, cool them, and, by that means, are exceeding fit for nouriſhing them. For the ſame reaſon gravel, pebbles, and looſe ſtones are approved of, provided they be mixed with rich mould: but if they are mixed with poor earth, they are bad. Flints are likewiſe very friendly to vines, if covered with a moderate depth of earth; becauſe, being cold, they retain the moiſture, and prevent the roots being parched up in the dog-days. The foot of mountains, which receive the earth waſhed down from their tops; or vallies, to which additions are made by the ſettling of rivers, which overflow them, are very proper for vineyards. A chalky bottom is fit for the vine; but clay, not excepting even that which approaches to marle or potter's clay, is very unfit; as is alſo coarſe hungry ſand. On mountains and riſing grounds, and on the ſides of hills, vines do not eaſily take firm root; but they yield wine of a laſting and excellent flavour. In moiſt and level places, vineyards are exceeding ſtrong; but they produce wine of a weak flat taſte, which does not keep long.

It may be eſtabliſhed as a general rule, to plant vineyards in cold countries ſo as to face the ſouth, and in warm countries facing the eaſt, unleſs they are ſubject to ſtorms from that quarter, in which caſe it is better that they face the north. In exceeding hot countries, ſuch for example as Egypt, it will be beſt to expoſe them to the north.

Mr. Miller ſays, that the beſt ſoil for a vineyard, in England, is that whoſe ſurface is a rich ſandy loam, and not above a foot and an half. or two feet deep, lying upon gravel or chalk; either of which bottoms is equally good for vines. If the ſoil is deep, or the bottom either a clay or ſtrong loam, it is by no means proper for this purpoſe: for though the vines may ſhoot vigorouſly, and produce a great quantity of grapes; yet we have not ſun to ripen them ſufficiently. If the ſoil is too deep, the roots of the vine will run to too great a depth to receive the influences of the ſun and air; whence the juices of their fruit will be crude.

According to him, our vineyards ſhould be planted on the north ſide of a river, upon an elevation inclined to the ſouth, with a very gradual deſcent, that the ſuperfluous moiſture may be the better drained off. Yet if the ground ſlopes too much, it is by no means proper for this purpoſe. Hills to the north, as they ſhelter the vineyard from cold, and reflect the heat, will be of great advantage. The country round about ſhould be open and hilly, to preſerve the air dry. The vineyard ſhould be open to the eaſt, that it may enjoy the morning ſun, to dry up the ſuperfluous moiſture.

Dr. Beal, in N°. 116 of the Philoſophical Tranſactions, after having mentioned ſome inſtances of the warmth ariſing from ſtones under ground, eſpecially lime-ſtone, and ſome kinds of pebbles, is of opinion, that, as I obſerved before (quoting this very paſſage more at large), many of our hills and rocks might be greatly improved: for it would be no hard taſk, ſays he, to ſhovel down the ſhallow and moſſy turf from the ſteepeſt declivities, into places, where it may have ſome receptable or ſtay; and there to impregnate it, with the ſpade and compoſt, for garden or vineyard.

The ground muſt firſt of all be cleared of the roots of trees or ſhrubs, or whatever elſe can be a hindrance to the diggers, or might afterward preſs down the trenched earth, by its weight, or by the treading of thoſe employed in carrying it off. It is of great importance that the earth be kept extremely looſe, even, if poſſible, without a foot touching it, in order that the mould, being all equally ſtirred, may eaſily give way to the young tender roots, wherever they extend themſelves, and inſtead of obſtructing them by its hardneſs, receive them into its tender nouriſhing boſom, which, in that ſtate, readily admits the ſhowers and other influences from above, and diſpenſes them equally to all parts, for the nouriſhment of the young plants.

A plain or valley muſt be trenched two feet and an half deep, and a riſing ground three. A ſteeper hill muſt be trenched four feet deep: for when the mould is turned down from a higher place, it can hardly be thrown up again to a ſufficient depth, unleſs the trenches are made deeper. Beſides, I never approve, ſays Columella, of planting a vine leſs than two feet deep, even in a valley; for it is better not to plant it all, than to leave its roots too near the ſurface ſuſpended from the nouriſhing moiſture, which lies low, except where ſprings riſe near the ſurface: there indeed the ground muſt not be trenched above a foot and an half deep.

The trenches muſt be made equally deep all the way to the bottom, the ſides being perpendicular, and the ground marked out by a line, which muſt be carried forward as the work proceeds, always at equal diſtances, till the whole ground is equally trenched. Where the bottom is of a binding nature, it is of great advantage to lay in the bottom of the trenches, ſmall ſtones, or other rubbiſh, to carry off the water, which otherwiſe, ſtagnating there, would chill the tender roots. In order to do this the more effectually, the bottom of the trenches are made ſomewhat convex towards the middle, the better to convey the water to drains cut at the extremities of the vineyard.

If neceſſity forces to replant an old vineyard, all remains of the old vines muſt be extirpated. The ground ought then to be dunged with old dung, if it can be had, if not with new, and trenched moſt carefully, picking out every remaining root, which ſhould be collected and burnt. The trenched earth ſhould then be covered with old dung, which does not breed weeds, or with freſh earth brought from among thickets. Columella adviſes particularly, to have a careful overſeer to inſpect the workmen, and to be watchful that they do not make baulks.

Mr. Miller, inſtead of trenching the ground as the ancients did, propoſes giving it a ſummer fallow, plowing it as deep as the ſoil will admit of, and clearing it of roots, weeds, or whatever elſe can obſtruct the growth of the plants.

Columella adviſes great care to be taken in the choice of the vine from which the cuttings are taken, and is therefore againſt purchaſing ſtrange plants at a venture, which may come from a ſoil and climate different from that they are intended for, and may not be of the ſort of vine which is deſired. A vine cannot be ſaid to be fruitful, becauſe it bears many grapes; for this may ariſe from the largeneſs of the trunk, and the great number of bearing ſhoots, which may have but a ſingle bunch on each. If ſeveral bunches of grapes are ſeen to hang from each ſhoot: if from each bud left the former year, ſhoots with fruit ſpring forth; if the ſhoots which ſpring out of the trunk of the vine have ſome bunches; and if even the ſecondary ſhoots, or thoſe which grow out of the preſent year's ſhoots, bear grapes; that vine may undoubtedly be eſteemed fruitful, and fit to afford cuttings. Whoever has this much at heart, will mark the vines which have been the moſt fruitful, and have yielded the ripeſt and ſoundeſt grapes, with ochre and vinegar, that it may not be waſhed off by the rain. Nor is this to be done for one year only; but the vines ought to be examined for three or more vintages, to know whether they preſerve the ſame degree of fruitfulneſs: for then it will be certain, that the fruitfulneſs muſt be owing to the good quality of the vine, and not to a favourable ſeaſon. Whatever grapes come to their full maturity without being rotted or damaged, for ſeveral ſeaſons running, will yield more, and higher flavoured wine, than any others.

It is not enough that the ſtock from which the cuttings are taken be fruitful, but they muſt alſo be taken from thoſe parts of it which promiſe the greateſt fruitfulneſs. Thoſe which grow from the ſtem or old wood of the vine, ſeldom bear fruit, or produce fruitful vines. Thoſe which grow from the ſummit of the vine are reckoned too luxuriant to plant; and though the number of cluſters on them may promiſe fruitfulneſs, yet they ſhould not be relied on; but rather thoſe which grow out of the middle of the vine, of which the wood is firmer than that of the former. This Columella calls the genital part of the vine; and ſays, that, having followed reaſon as his guide, and alſo a long experience, he chooſes from that fruitful part of the vine, ſhoots which, bearing plenty of fruit already, promiſe fecundity for the time to come. He is not contented with ſingle cluſters, but chiefly approves of thoſe which have the moſt numerous offspring; and adds, that the neglect of theſe rules has rendered many vineyards leſs fruitful, indeed ſome quite barren, when the cuttings have been very improperly choſen.

Some are of opinion, that the whole ſhoot, as it is taken from the ſtem, is fit for planting; and for that end, they cut it into pieces of five or ſix eyes, each of which they plant. Others, with more reaſon, think that no part of the ſhoot is fit for being formed into a cutting, but only that part of it which is next to the wood of the former year: for every bearing ſhoot abounds in fruit below the fifth or ſixth eye. The reſt either bears no fruit, or produces only ſlender twigs. The ancients, ſays Columella, always preſerved ſome of the old wood to the cuttings: but experience has ſhewn that this is wrong; for whatever is left of the old wood ſoon roots, when it is moiſtened and covered with earth, and kills the tender roots next to it; and when this happens, the whole vine ſhrivels, or is burnt up. Whatever remains of the old wood ſhould therefore be cut off, where the ſhoot grows to it, that the ſhoot may be planted with its own ſmall head. Mr. Miller differs here in opinion from Columella; for he directs, that the ſhoots ſhould be cut from the old vine, juſt below the place where they were produced, taking a knot, or piece of the two years old wood to each, which, ſays he, ſhould be pruned ſmooth.

Were cuttings, thus choſen, taken from the vines every time they are pruned, for ſeveral vintages, and carefully planted, vineyards might be raiſed, which would yield plenty of the moſt generous wines: nor need we grudge this delay; for when once we are aſſured of the fruitfulneſs of a vine, it may be multiplied by engrafting. This, ſays Columella, you, Publius Silvinus, can witneſs: for, from one early vine on your eſtate, I engrafted the ſtocks of two jugera of vineyard in two years. How much therefore, may the vine be multiplied from theſe two jugera, ſeeing that theſe are the offspring of only one?

There are two ways of planting vineyards; viz. either with cuttings, or with vines which have already taken root. Theſe laſt are called quickſets. In the provinces, ſays Columella, they plant cuttings, for they will not be at the trouble of having nurſeries. The expert huſbandmen in Italy approve of this practice, becauſe the quickſets are attended with ſeveral advantages. They are leſs apt to die; and by reaſon of the greater firmneſs of their wood, they ſuſtain better the extremities of heat and cold, and other intemperatures of the weather: and the tranſplanting of them quickens their producing grapes. Cuttings may do in a looſe yielding mould; but a ſtrong heavy ſoil muſt have rooted vines, or quickſets.

Mr. Miller prefers good cuttings to rooted vines, for planting a vineyard; becauſe the roots of vines do not grow ſtrong and woody, as moſt ſorts of trees do, but are long, ſlender and pliable; and therefore, after they have been taken up, they ſeldom ſtrike out any fibres from the weak roots: but theſe generally ſhrivel and die, and thereby rather retard, than help, the plants in their growth, by preventing the new fibres from puſhing out.

This difference of opinion between Columella and Mr. Miller may be accounted for, from the different depths at which they direct the vines to be planted: for were cuttings to be planted two feet and an half deep, no roots would ſhoot out from their loweſt part; and if the rooted vines were planted ſo ſuperficially in Italy as Mr. Miller adviſes, they would be dried up by the ſun.

Columella directs that the nurſery be made, neither in a poor hungry ſoil, nor in an ouſy wet one; yet where there is moiſture enough; and in a middling rather than a rich ſoil; becauſe, though cuttings take root ſoon, and make ſtrong ſhoots in a rich ſoil; yet, when tranſplanted, they ſhrivel, and ſeldom recover. It is therefore the huſbandman's intereſt, rather to tranſplant from a middling ſoil to a rich one, than from a rich to a poorer. From a rich ſoil to a rich ſoil, they will thrive apace. It is not adviſable to make the nurſery in very poor land, becauſe many of the cuttings will then die, and the others will arrive but ſlowly at a ſtate to bear being tranſplanted.

The nurſery ſhould be trenched to the depth of two feet and an half, and being formed into beds three feet wide, the cuttings are planted in them at about a foot diſtance from one another, every way. This may be done either in the ſpring or in autumn. The ſpring is beſt if the climate be cold, or ſubject to much rain; and the autumn if the climate be warm, and the ſoil dry, or ſituated on the ſide of a hill.

The length of the cuttings ſhould be regulated by the diſtance between their eyes: for when theſe are near one another, the cutting may be ſhorter, and when they are more diſtant, it ſhould be longer. This length ſhould not exceed a foot, nor ſhould it be leſs than three fourths of a foot, leſt, being planted on the ſurface of the earth, the cutting ſhould periſh with drought in the ſummer; and, on the other hand, becauſe when a cutting planted too deep has

has taken root, it cannot be taken up without ſome difficulty. If the cuttings are planted on the ſide of a hill, their length may be about fifteen inches on ouſy ground, they need not have above three eyes, which may reduce them to nine inches, but certainly to more than ſix. In theſe three eyes are not included the numerous eyes which uſually are on the cutting, near the part where it is taken from the ſtem: beſides thoſe numerous eyes, there ſhould be three others, with joints. The cuttings ſhould be planted ſo deep, as that the uppermoſt eye may be level with the ſurface of the ground; becauſe all the ſap will then be employed in one ſingle ſhoot, which will conſequently be ſo much the ſtronger. They ſhould be planted as ſoon as poſſible after they are cut off the vine; and in doing this care ſhould be taken to avoid a ſtrong drying wind, or a ſcorching ſun. It is therefore beſt to chooſe a calm day, or at leaſt a day in which there is but little wind. The ſun may be kept off by ſhades, or any covering. The nurſery ſhould afterwards be kept clear of weeds, and be frequently dug. Only one ſhoot ſhould be reared, and that ſhould be faſtened to a ſtick or ſlender pole, to bear it off the earth. The reſt ſhould be carefully rubbed off; and this ſhoot ſhould be pruned down to two eyes in the autumn. The ſtrongeſt ſhoot from theſe eyes ſhould be reared the next ſummer; and with this management the cuttings will be fit to tranſplant at the end of thirty or thirty-ſix months.

Vines are likewiſe propagated by layers. For this purpoſe, a trench is dug four feet every way, that the layer may not be hurt by other roots. A ſhoot of the laſt year is then laid down in it, in ſuch manner as to make its end riſe at the farther part of the trench. Four eyes are left on that part of the layer which goes to the bottom of the trench, and they are to put out roots. All the eyes between them and the ſtem ſhould be rubbed off, to prevent the growth of uſeleſs ſhoots. Two, or at moſt three, eyes are left on the farther end, which riſes out of the earth, and all the reſt, between them and thoſe at the bottom of the trench, are rubbed off. The layer thus prepared ſoon takes deep root, and in the third year, it may be cut off from the mother vine. When the ſhoot is not long enough to riſe again out of the earth, Columella thought of the following method. The end of the ſhoot is brought to the bottom of the trench, and the four lower eyes, left for the roots to ſhoot from, are covered with earth, as before: but inſtead of the eyes at the extremity, as in the former way, the two eyes next the ſurface of the earth, of that part which come from the ſtem, are left to make ſhoots, which they readily do, and in the third year, the layer may be cut from the mother vine, as in the other caſe. In order to encourage the roots to ſtrike out, they need not be covered with the whole depth of earth the firſt year, unleſs it ſhould become neceſſary before the winter, to keep the roots from being chilled by water which might gather in the trench.

The ground being thoroughly prepared, by trenching, harrowing, and clearing it of every thing that can be hurtful to the vine, it is marked out, in order to be planted. The Romans planted their vines five feet aſunder in a poor ſoil, ſix feet aſunder in a middling ſoil, and at the diſtance of ſeven feet from each other in a rich ſoil. Sometimes too they left a ſpace of ten feet between them, that there might be ſufficient room for the ſtrong ſhoots to extend themſelves.

They generally planted their vineyards in a quincunx form, for which they marked out the ground by ſtretching acroſs it a line trimmed with bits of red cloth, or of ſome other conſpicuous colour, at ſuch diſtances from each other as it was intended to leave between the rows. A piece of reed was ſtuck into the earth at each ſpot indicated by the cloth, and this was repeated till the whole field was marked out in equal diſtances. The planter followed, and dug a hole at each alternate reed, two feet and an half deep in level ground, two feet and three quarters if it lay ſloping, and three feet deep where the declivity was conſiderable. He then removed the quick-ſets from the nurſery, taking them up with great care, and tranſplanted them the very ſame minute, if that was poſſible. All their ſhoots were previouſly pruned off, except one, which was the foundeſt and firmeſt, and of that only two eyes were left above ground. If any of the roots were hurt in taking them up, though all poſſible care was uſed not to injure them, they were cut off, very ſmooth. If two plants were ſet in the ſame hole, a few ſtones, of about five pounds weight, were laid between them in the bottom of the hole, to prevent their roots from interweaving together. They were likewiſe of opinion, that theſe ſtones ſaved the roots from being chilled in the winter, or ſcorched by the heat of the dog-days in the ſummer. Mago adviſed to lay the huſks and ſtones of grapes mixed with dung, in the holes, under the roots of the vines, as a means of ſtrengthening them, and of haſtening the production of young roots. During the chilling wet of the winter, they gave a warmth; and in the ſummer, they afforded a nouriſhing moiſture. Columella diſapproved greatly of putting two vines in the ſame hole, becauſe their roots conſtantly mingled together, and formed a kind of net-work, which retained too much moiſture in the winter, and, by robbing each other of nouriſhment, proved prejudicial to both. If the ſoil of the vineyard was poor, Mago directed that the holes ſhould be filled up with rich earth brought from elſewhere. The ground ſhould be a little moiſt when the vines are planted; but it had better be dry, than mirey wet.

Mr. Miller orders that the ground, which he before directed to be fallowed, be again well plowed in March; and that after having laid its ſurface even, the rows ſhould be marked out, from ſouth-eaſt to north-weſt, at the diſtance of ten feet from each other. He then croſſes theſe rows at the diſtance of five or ſix feet, and thereby marks the ſpot where each plant is to be ſet. The rows will conſequently be, in this caſe, ten feet aſunder, and the diſtance between the vines in each row will be five or ſix feet; nearer than which they ought never to be planted. If they are ſet in ſquares ſo near together as ſix feet, there cannot be room for a ſufficient current of air to paſs between them when their branches are extended on one ſide; and for want of that the damps in autumn will be detained among the vines, to the great prejudice of their fruit. In places abroad, continues he, where they regard the quality of their wine more than the quantity, they never plant their vines at leſs than ten feet, row from row, and ſome allow twelve: and he confirms the juſtneſs of this rule by what happens to other fruits, which are never ſo well coloured, ſo early ripe, or ſo well flavoured, when in cloſe plantations, as when they are produced on trees where the air can circulate freely about them, and the rays of the ſun have free acceſs to the branches, whereby the juices are better prepared.

Preferring cuttings to layers, as well as to rooted vines, he directs, that the cuttings be taken from the vine in the autumn, and that their ends, being made ſmooth, they be laid in the ground, about two inches deep, the reſt of the cutting being left at full length; only obſerving to cover them with dry litter, or peas haulm, in dry froſty weather. In moiſt weather, the covering ſhould be taken off, leſt it heat, and make the cuttings grow, which would greatly injure them. In April, which he reckons the beſt ſeaſon for planting vines in England, the cuttings ſhould be taken out of the ground, and their upper parts cut off, ſo as to reduce them to about fourteen inches in length, according to the diſtance of the buds or eyes. He thinks it of great ſervice to leave their tops on all the winter, becauſe the air would otherwiſe penetrate the wounded part, and greatly injure the remaining eyes. The lower ends of the cuttings ſhould be put in water, about three inches deep, ſetting them upright, for ſix or eight hours, before they are planted, in order to moiſten them and open their pores: then, at the centre of every croſs mark, before made, a hole ſhould be dug with a ſpade, about a foot deep, and one ſtrong cutting ſhould be ſet, a little ſloping, in each of theſe holes, which ſhould afterwards be filled up immediately with earth preſſed down gently to the cutting. This earth ſhould be raiſed about three inches round each cutting, ſo as juſt to cover its upper eye or bud, to prevent the wind and ſun from drying it; for only that upper bud will ſhoot when the plant is thus managed.

Mr. Miller juſtly blames his countrymen for planting their vineyards, in the few attempts that have been made of them in England, with ſuch grapes as are the ſweeteſt and beſt for eating; this being contrary to the general practice abroad, where the rough auſtere grapes, which are by no means palatable, but which are by experience

 found

found to afford a noble rich wine, are preferred. This is alſo agreeable to the conſtant practice of the makers of cyder, who obſerve, that the beſt eating apples yield but a poor juice, and that the rough ſorts afford a ſtrong vinous liquor. I believe, continues he, that it will be found true in all fruits, that where the natural heat of the ſun ripens and prepares their juices, ſo as to render them palatable; whatever degree of heat theſe juices have more, either by fermentation, or from any other cauſe, will render them weaker, and leſs ſpirituous. Of this we have many inſtances in fruits: for if we tranſplant any of our ſummer or autumn fruits, which ripen perfectly in England without the aſſiſtance of art, into a climate a few degrees warmer, theſe fruits will be mealy and inſipid. So likewiſe, if we bake or ſtew any of theſe fruits, they will be good for little, becauſe they will loſe all their ſpirit and flavour by the additional heat of the fire: and on the other hand, many fruits which are not even eatable whilſt raw, are thereby much improved. Some of theſe, which have been tranſplanted into a warmer climate, have been ſo altered by the greater heat of the ſun, as to excel the very fineſt of the fruits that are ripened in this country. The grape moſt likely to ſucceed in England, is the Auvernat, or true Burgundy grape, which thrives very well in ſeveral places north of Paris.

Columella adviſes every prudent huſbandman to ſtock his vineyards with different ſorts of vines, becauſe the weather is not ſo equal in any year, but that it may be more hurtful to ſome, than to others. If, therefore, he plants but one kind of vine, and the weather happens to be prejudicial to it, he will be deprived of his whole vintage: but if he has vineyards of various ſorts, ſome of them may eſcape, and yield him fruit. He recommends particularly, that each kind of vine be planted by itſelf; becauſe otherwiſe one of the following inconveniencies will enſue; viz. either he muſt gather his late grapes with thoſe that are early ripe, which will cauſe an acidity in the wine; or if he waits till the late fruit come to maturity, the early grapes will be rotten, or deſtroyed by birds or rain: for the diſtinguiſhing of each kind cannot be truſted to the gatherer's diſcretion. The flavour of the ripe grapes is hurt by the addition of the unripe; nor will the wine made of them both, mixed together, keep till it is old. When each ſort is ſeparate, the vine dreſſer will be able to prune and manage it in the moſt proper manner.

He cautions his readers ſtrongly againſt the too prevailing opinion of thoſe who imagine, that the chief care and trouble are at an end when the vineyard is planted. He obſerves, that the vine is a tender delicate ſhrub, which can very ill bear neglect, and which, when young, often deſtroys itſelf, by being permitted to run too much to wood, or to bear too great quantities of fruit. Moſt people are ſo intent on having much fruit, that they load the vine with too many bearing branches, without having any regard to future years, or to poſterity; and then complain, that their vineyards do not anſwer their expectation, when they themſelves have deſtroyed them, either through covetouſneſs, negligence, or ignorance. When the vine has arrived at its full ſtrength and maturity, it can better bear ſome neglect. Believe Silvinus, ſays this excellent huſbandman to his friend, what I know from my own experience, that a vineyard judiciouſly planted with good vines, and well cultivated, never fails to bring its owner a moſt abundant return. This he confirms from Græcinus, by the example of Pavidius Veterenſis, who had two daughters, and a farm planted with vines. He gave the eldeſt daughter one third of his farm, on her marriage, and yet had as much fruit from the remaining two thirds, as he had before from the whole. He afterwards gave half of the remainder to the younger daughter, on her marriage, and ſtill had as good an income as at firſt. This, ſays Columella, muſt ariſe from the remaining thirds being proportionally better cultivated, than the whole had been before.

When the vineyard was perfectly well cultivated, and in a good ſoil, the Romans planted cuttings in the ſpaces between the vines, where they grew as in a nurſery. The vines and cuttings ſoon throve and gathered ſtrength, when the ground was kept in ſo looſe a ſtate by frequent digging, as to be reduced to powder, and always perfectly free from weeds, which would conſume the nouriſhing moiſture that ſhould feed the plants, whoſe roots extended eaſily in ſuch looſe mould. It was a general rule, that the diggings ſhould be repeated once a month, from the firſt of March to the firſt of October; and all weeds were carefully pulled up by hand, and carried off the ground, leſt they ſhould take root again. Mr. Miller ſays, that as the ſpace between the rows of vines is great, the ground there may be ſown or planted with any kind of eſculent plants, provided they are kept at ſuch diſtance from the vines, that theſe be not injured by them. This huſbandry, which is alſo the method in France, may be continued three or four years, till the vines come to bearing: but after that, no ſort of crop ſhould be ſet between them in the ſummer; becauſe, the clearer the ground is kept, the more heat will be reflected to the grapes. After they are gathered, a crop of coleworts, for ſpring uſe, may indeed be planted between the rows, and the ſtirring of the ground for them will be of great ſervice to the vines.

From the time that the vine firſt begins to bud, all ſuperfluous ſhoots muſt be carefully rubbed off, that the nouriſhment may be conſumed by thoſe only which are to be reared. Two ſhoots are generally ſet apart for growth; the one as a reſerve, in caſe the other ſhould fail. As ſoon as they riſe, a prop ſhould be ſet in the ground, for each of them. This prop ſhould be ſlender, becauſe the weak tendrils of the vine will then lay hold of it more eaſily than if it was thick. As the ſhoots grow up, they are tied to the props with a ſoft ſlack binding, till their tendrils have encircled them; and at leſs than four feet from the ground, ſticks are faſtened acroſs the props, that the vines may extend laterally, and thereby be the leſs expoſed to the force of winds. In nurſeries, this croſs ſtick, or rail, ſhould not be above a foot high, leſt ſtrong winds ſhould tear the young plants out of the earth. When the ſhoots are grown nearly to their full height, their tops are broken off, to make them increaſe in thickneſs and ſtrength, rather than run up into a needleſs length. The moſt thriving ſhoot, which is to be the leading wood branch, muſt be trained up ſtrait, and kept clear of ſecondary ſhoots for three feet and a half from the ground: but ſuch as grow above that height may be permitted to remain till the autumnal pruning; for if they are all rubbed off, new ſhoots will immediately ſpring out from other eyes, ſo that, perhaps, none may be left for the next year's buds. The ſhoots which are rubbed off from time to time ſhould never be ſuffered to grow ſo ſtrong, as not to be eaſily diſplaced with the finger; for the heat in ſummer hurts the vine greatly wherever it has been wounded with a knife. For this reaſon, if it ſhould be abſolutely neceſſary to uſe the knife, a piece of the ſhoot which is cut off ſhould be left prominent from the ſtem, to ſtop the effect of the heat, which, in that caſe, will not proceed farther.

About the middle of October, or before the cold came on, the Romans *ablaqueated*, as they called it, the roots of their vines; that is, they laid them bare, ſo as to expoſe to view the upper ſmall roots which the vine had put forth in the ſummer, and which ſhould be cut off with a knife; for if theſe are ſuffered to grow large, the lower ones will decay, and the vine will then be nouriſhed only by roots, which, extending themſelves along the ſurface of the earth, or but little deeper, muſt be expoſed to the inclemency of the winter's froſt, and be liable to be parched by the drought and heat of the ſummer. Whatever roots appear within a foot and an half of the ſurface muſt therefore be cut off. The beſt way is to cut them about an inch from the ſtem, and to leave that ſtump prominent; for if they are cut cloſe, either others will ſhoot out, or the water which ſtands in the hollow made round the root, being frozen, will deſtroy the ſtem to the very pith, where the ſcar is: but both theſe accidents are prevented, by cutting them off at a little diſtance from the ſtem. And now will appear a reaſon why the vines ſhould ſtand upright in the ground: it is, that if they are inclined, they muſt be liable to be wounded when they are ablaqueated; for while the digger is intent on digging, and forming a hollow round the vine, he may inadvertently wound the vines which grow obliquely, or even cut them quite through. If the winter is mild, the roots may remain uncovered till March; but if the ſeverity of the weather forbids this, the hollows ſhould be filled up by the beginning of December. Where the winters are very ſevere, ſome dung,

or,

or, if it can be eafily come at, pigeon's dung, or urine which has been kept a long while, fhould be laid to the roots before they are covered. The vines fhould be thus ablaqueated every winter, for the firft five years; and after that, as the lower roots will then have got pretty fufficient ftrength, it need not be repeated above once in three years.

From thefe directions of Columella, we may affign a reafon why Mr. Miller does not fpeak of ablaqueating the vine. Columella wrote for Italy, where the heat of the fun is very powerful, and dries the furface of the earth to a confiderable depth. It was therefore neceffary, in order to fecure moifture for the roots, to plant and keep them deep in the earth: but as the degree of heat in England is much milder, as well as of fhorter duration, and as the earth here is refrefhed by much more frequent fhowers during the fummer, Mr. Miller directs the vines to be planted much fhallower, and finds that it is not neceffary to ablaqueate them. He rather guards againft their taking too deep root.

The Romans reared all their vines in one ftem to fome height above the ground; and therefore, as foon as they had finifhed ablaqueating them, they cut off the weakeft of the two fhoots, which they called the fhoot of referve, and pruned the remaining fhoot to two eyes. Mr. Miller directs that both the fhoots be cut down to two eyes, and that the earth be drawn up in a hill about each plant, which will be a great defence againft froft. The wound fhould be made obliquely, almoft in the middle between the joints, left water fhould lodge in the pith, if the fhoot were cut horizontally: but the flope muft not be toward the eye, left this fhould be hurt by the trickling down of the fap, or tears, which will ooze from the wound. Mago recommends the fpring, as the fitteft time for pruning the vine; becaufe, being then full of fap, it affords an eafy paffage to the knife: but Columella does not approve of this, unlefs it be in countries where the winters are very fevere: otherwife, he thinks the autumn the beft feafon. The early writers on hufbandry forbid touching the vine with the knife during the firft year; and Columella, who likewife difapproves of it, making experience his guide, neither fuffered his vines to become wild, by running too much to wood; nor did he, by cutting off the young fhoots entirely, force them to fhoot from the ftem, which feldom proves fo fruitful as fhoots from the young wood.

During the fecond year's growth, the ground fhould be kept conftantly ftirred, as in the preceding year, only with this difference, that it may be done once feldomer. The weeds muft be kept under, till the vines, by extending their branches, fhade the ground, and thereby prevent their growing under them. All fuperfluous twigs muft be conftantly rubbed off as before, and only one fhoot fhould be permitted to grow up. The props muft be continued as in the former year. If any of the plants died in the firft year, two fhoots may be reared up on the ftrongeft of the vines next the vacant fpace; one to form the ftandard fhoot, and the other to be made a layer, to fupply the place of the dead vine. After the vintage, this fhoot muft be laid down, or if it be not long enough to rife out of the earth on the other fide of the hole, only its extremity need be put into the ground, as already directed. Next year, the layer muft be cut half through, in the bend, that fo it may not rob its mother too much, but be brought to be nourifhed by its own roots. When it is two years old, it may be cut off from the mother plant, and its root muft be carefully ablaqueated, that it may ftrike the deeper into the earth. If the neighbouring vines cannot furnifh layers, a rooted vine muft be brought from the nurfery; for it is too late to recruit a vineyard, when we fhould be gathering its fruit.

For the third year's growth, the vine muft be fupported with ftronger and higher props than before. Thefe fhould be fixed, either a foot from the vine, that they may not hurt the roots, and that fo the vine-dreffer may dig all round the vine; or in the middle between two vines. The firft way is the beft, becaufe the vine and prop mutually fupport each other. If the prop is fixed near the vine, it fhould ftand fo as to fhelter the vine from the north. It is of great importance that the prop ftand very firm. On each upright prop muft be put a crofs pole, fufficiently ftrong to bear the weight of the fruit. This year the vine may be permitted to make two fhoots, to cover the crofs pole on each fide with bearing branches, unlefs the vine be yet too weak to nourifh them. All fuperfluous fhoots and twigs muft be carefully rubbed off. The ground muft be frequently ftirred, to keep it loofe, and deftroy weeds. The roots muft be laid bare in October. The places of dead plants muft be fupplied, as directed for the preceding year, and this muft be a conftant rule every year. When a vine dies after it has ftood for fome years, the hole or trench which is made for the layer or young plant, muft be dug deeper and wider than it need to be after a young vine, in order that all the roots of the old one may be taken away. The trench fhould then be partly filled with frefh earth, or a good deal of dung mixed with the former foil. If each fide of the vine has produced two fhoots, and both of them fhew plenty of fruit; yet one muft be taken away, that the other may thrive the better, and bring its fruit to greater perfection.

When this vintage is finifhed, the vine may be pruned fo as, in a fertile foil, where it thrives well, to leave three eyes, to produce bearing fhoots for the next year; but four eyes fhould feldom be left. The binder muft feparate thefe fhoots, and tie them to the frame, to which another crofs pole is now added, in the form of a ftar: or thefe crofs poles may be fupported by four props. The fhoots fpread in this manner become a counterpoife to each other. Thefe crofs frames are the more neceffary if the vines are expofed to ftormy winds, or if they ftand on fteep declivities, where every means of propping them is wanted. In warm and dry fituations, the frame may be extended on all fides, in the form of an arched roof, the better to fhade the thirfty earth: but in cold and frofty climates, the vines muft be fupported only on fingle frames or efpaliers; for then the earth is more eafily warmed by the fun, the fruit is more thoroughly ripened, and a freer paffage is afforded to the air. The frames fhould not be lower than four feet, nor higher than feven. Young vines fhould be brought to this height gradually. The moifter the foil and climate are, the higher fhould be the frame; for there, the thriving ftate of the vines admits of raifing their branches, and their fruit being thereby raifed higher from the earth, is the lefs liable to rot. In this fituation, the winds blow freely through them, and dry up the dews and noxious fogs; the vines bloffom more kindly, and yield a better wine. On the other hand, vines in a poor foil, on a fteep declivity, and fubject to fcorching heat, require lower frames. If the vineyard is well placed, the beft height is five feet; though there is no doubt but that the wine is the better flavoured, the higher the frames are.

If the vineyard is interfected by foot paths which divide it into a number of fmall partitions, the fun and wind have the freer accefs to the vines; as hath alfo the eye of the mafter, which is of great advantage. The labour too feems lefs to the vine dreffers, when it is thus portioned out in fmall divifions. The paths afford convenient paffage for the grape gatherers, for thofe who repair the frames, and for bringing in manures, or what elfe may be wanted. The owner can likewife diftinguifh the fruitfulnefs of each fpot, and thereby be enabled to apply proper remedies. Where the rows of vines ftand very far afunder, too much ground is generally left uncultivated between them; one half of which is commonly ufed for alleys, or foot-paths.

The trunk of the vine fhould be carried up ftrait to within a foot of the top of the frame; not only to conduce to its beauty, but alfo to its fruitfulnefs and duration: for the moifture which nourifhes plants never has fo free a motion through a crooked ftem, as it has through a ftrait one; the bendings proving fo many lets or hinderances to the equal circulation of the fap. The top of the vine fhould be faftened to the prop, fo as to prevent its being bent, or dragged down, when it is loaded with fruit; and for greater fecurity in this refpect, the arms, or branches, which proceed from thence, fhould be trained along the frame, and tied to it, fo that only thofe parts of the fhoots on which the fruit grows may hang floping down from the edge of the frame: nor fhould this be at right angles from the binding, becaufe that pofition would endanger their breaking. When thus fituated, they are lefs expofed to rain and hail, than when they are faftened to the frame. They fhould however be tied up before the grapes are ripe, to guard againſt their being rotted by the dew. When the vine is five years old, it will be ſufficient to leave one fruit bearing ſhoot on each of its arms, or branches: but, ſome years after, when it has attained its full ſtrength, a luxuriant vine, in a rich ſoil, may convey nouriſhment to eight fruit-bearing ſhoots; and, indeed, unleſs it be checked by a quantity of fruit, it will waſte itſelf in wood and leaves: whereas a weak vine, in a poor ſoil, will ſoon be exhauſted if it is burthened with fruit.

The branches of a vine ſhould never be ſuffered to grow bigger than the ſtock: but, to ſupply their place, ſhoots iſſuing from their ſides ſhould be trained, and as ſoon as theſe begin to bear fruit, the old hard wood ſhould be cut away. Fewer bearing ſhoots ſhould be left on the branch which extends northward, than on that which is directed toward the ſouth; becauſe this laſt requires the greateſt ſhelter from the ſcorching heat of the ſun, and therefore ſtands moſt in need of leaves. All ſuckers muſt be cut away from the root, and the place whence they ſprung ſmoothed with a knife; for then it will ſoon ſkin over. No ſhoots muſt be ſuffered to grow from the trunk, nor ſhould any knobs or warts be left on it. All dry, cracked, and ſhrivelled bark, muſt be taken off. Moſs likewiſe, which ſhackles the vine, as with a fetter, and ſoaks it with its pernicious moiſture, muſt be carefully ſcraped off; and if the trunk is any way damaged, or rendered hollow by rain or inſects, it muſt be cut away to the ſound wood. The wound ſhould then be covered with earth which has been moiſtened with lees of oil; for this will defend it from inſects, ſun, and rain, and therefore make it heal the ſooner. All broad, ill-ſhaped, withered ſprays, and ſuch as hang downward, commonly called danglers, muſt be cut off; and the ſtrait ſhoots muſt be preſerved. When the vine is freed from all theſe incumbrances, it will thrive the better, and yield the purer wine. The vine dreſſer ſhould be particularly attentive, that all wounds in the ſolid wood be made ſloping and round; becauſe they afford the leaſt lodgment to water, and are the ſooneſt cloſed.

Sometimes a ſtrong ſhoot ſtrikes out of the fork of two of the leading branches, and cripples one of them. In this caſe, the crippled branch muſt be cut off, and the young ſhoot reared in its ſtead: but if it be taken in time, the young ſhoot ſhould be cut off. Whatever grows out of the trunk of the vine muſt be cut away ſo ſmooth, that no water may lodge in the ſcar: but what grows on the young ſhoots of the ſame year, ſhould be cut off between the two firſt eyes; leſt by cutting it too near the main ſhoot, this alſo ſhould be hurt by the wound, and the neighbouring bud be killed.

As to the length of the fruit-bearing ſhoots, there is no general rule; for it may depend greatly on the quality of the ſoil, and the vigour of the vines, as well as on the diſtance between the eyes; for where the joints are ſhorter, a leſs length of ſhoot may be equally loaded with fruit. The laſt year's vintage ſhould alſo be conſidered: for thoſe parts of the vine which then bore great plenty of fruit, muſt be ſpared in the following year; and ſuch as produced but a ſmall quantity, may be loaded the more. Moſt particulare care ſhould be taken, that every cutting inſtrument which touches a vine, be ſharp and well tempered; for otherwiſe, the labour of the vine dreſſer is greater, and the vine is rather torn than cut; ſo that there then remains an uneven ſcar, in which the juices putrify, ſo as often to kill the vine.

Mr. Miller agrees with Columella in keeping the vine clear of uſeleſs ſhoots, and in the frequent ſtirring of the ground: only, as the vines in England are not planted ſo deep as in Italy, he cautions againſt digging too deep cloſe to the vines, leſt their roots be cut or bruiſed. He differs ſomewhat in the method of propping and pruning, which he directs to be done as follows.

At the beginning of May, in their ſecond year, when the vines are ſhooting, two ſtakes, ſomewhat taller and ſtronger than thoſe of the preceding year, ſhould be fixed down to the ſide of each plant, and the two ſhoots ſhould be faſtened to them.

In the autumn, the vines which have produced two ſtrong ſhoots of equal vigour, muſt be cut down to three eyes each. When they have a ſtrong ſhoot and a weak one, the ſtrong ſhoot muſt be ſhortened to three eyes, and the weak one to two: and ſuch as have but one ſtrong ſhoot, ſhould be ſhortened to two eyes.

In March of the third year, two ſtakes ſhould be placed down by the ſide of all ſuch vines as have two ſhoots, at ſuch diſtance on each ſide of the plant, that the ſhoots, faſtened thereto, may form an angle of forty-five degrees with the ſtem: but they ſhould not by any means be bent down horizontally, as ſome injudiciouſly adviſe and practice: for the branches, then lying too near the earth, are generally injured by the damps which ariſe from thence, eſpecially if they have fruit, which is never ſo well taſted, nor ſo ripe, as when they are a little elevated. In May, the ſtrong ſhoots ſhould be faſtened to the ſtakes.

If the two ſhoots of the former year have produced two ſtrong branches, the uppermoſt of theſe ſhoots upon each branch ſhould be ſhortened down to three good eyes, not including the lower eye, which ſeldom produces any thing more than a weak dangling ſhoot; and the lower ſhoot ſhould be ſhortened to two good eyes; theſe being deſigned to yield vigorous ſhoots for the next year, as the former are to bear fruit. Where the vines are weak, and have not produced more than two or three ſhoots in the ſummer, but one of theſe ſhould be left with three eyes, for bearing; the other muſt be ſhortened down to two, or if it be weak, to one good eye, in order to obtain ſtrong ſhoots the following ſummer: for nothing is more injurious to young vines, than leaving too much wood upon them, or over bearing them.

In March of the fourth year, all ſmall horizontal roots, which may have been produced near the ſurface of the ground, ſhould be cut off cloſe to the trunk. A ſtake ſhould be placed about ſixteen inches from the root, on each ſide of the vine, and the bearing branches ſhould be faſtened thereto. Then another, and taller, ſtake ſhould be thruſt down near the foot of the vine, and to this ſhould be tied the two ſhoots which were pruned down to two eyes. In May, the ſhoots which ſhew fruit muſt be faſtened to the ſtakes, with baſs, to prevent their being broken, until they are extended to three joints beyond the fruit; when they ſhould be ſtopped, by nipping off the end: but the ſhoots, which are deſigned for bearing the next year, ſhould be trained upright to the middle ſtake; by which method, neither of them ſhading the other, each will enjoy the benefit of the ſun and air. The ſhoots ſhould be conſtantly kept in their right poſition, to prevent the inverting of their leaves; for when that happens, it greatly retards the growth of the fruit.

Mr. Miller very juſtly cenſures the abſurd practice of thoſe who pull off from their vines the leaves which grow near the fruit, in order to let in the rays of the ſun, to ripen it; not conſidering how much they thereby expoſe their fruit to the cold dews which fall plentifully in autumn, and which, being imbibed by the fruit, greatly retard it: beſides, no fruit will ripen ſo well when it is entirely expoſed to the ſun, as when it is moderately ſcreened with leaves. By pulling off the leaves, which are abſolutely neceſſary to prepare the juices before they enter the fruit, and of which juices the groſs parts are perſpired by them; the fruit muſt either be deprived of nouriſhment, or elſe, ſome of the groſs particles will enter with the more refined parts of the juices, and thereby render the fruit worſe than it would be if the leaves were left upon the branches.

This naturally leads me to another opinion, which I have long been inclined to entertain: it is, that not only the ſtripping the vine of its leaves, but alſo the ſummer pruning, which is intended to haſten the ripening, and increaſe the goodneſs of the grapes, has the contrary effect. For in the ſpring, and while plants are in a growing ſtate, their juices are of a watery acid nature, abounding in what the chemiſts call their native ſalt. As the ſummer advances, or as, reſpectively in each, their ſeed, or fruit, begins to ripen, their juices loſe that watery acid ſtate, and become gradually milder: and when the ſeed, or fruit, is come to full maturity, the juices of perennial plants become of an oily mucilaginous quality. This change in the nature of the juices of plants is gradual, and perfect, in proportion to the flouriſhing ſtate of the plant. Now, if a conſiderable length is cut off from the young ſhoots of the vine, while it is yet in its luxuriant growing ſtate, and the motion of the ſap is ſtill briſk in it; a check muſt be given to nature in her juices. This is confirmed by the effects of numbers of facts and experiments. As young shoots spring out again after this summer pruning, the juices are probably again brought to a thin watery state, in order to carry on that newly excited vegetation; the change of the juices into their milder and thicker state is thereby retarded, and consequently the richness and mellow ripeness of the fruit is impeded. It would therefore seem more advisable to defer shortening the shoots, till they have nearly arrived at their full length, and the grapes are beginning to ripen. The perfecting of the fruit requires so strong an exertion of all the powers of nature, that few, if any, shoots will then spring out; by which means the buds for the next year will be preserved strong, and the grapes will arrive at a more perfect maturity.

Mr. Miller directs, that the vineyard, being now arrived at a bearing state, should be treated after the following manner. Too many branches should never be left upon a root, nor should those be too long: for although a management contrary to this may be productive of greater quantity of fruit, yet that fruit will not be so well nourished, nor will its juice be so good, as when it is but moderately plentiful: neither will the roots of the plants be so much weakened in this last case, as they must be in the former. The ground should be constantly kept clear of weeds; and no sort of plant should be suffered to grow on it, excepting that which it is intended to cultivate. It should be manured every third year, according to the nature of the soil. If the land is stiff, and inclinable to bind on the surface, sea-sand, or sea-coal ashes, are very good manure: but if it is loose and dry, a little lime mixed with dung will do it the most service. After each spring digging, the stakes are fixed as already mentioned, and the same care and management of the vines, as was before directed, must be continued. Mr. Arnoux says, that, in Burgundy, they bind the branches of the vine in an horizontal position, at the height of half a foot from the earth, to props three or four feet high, stuck into the ground, without any order, at the distance of about a foot asunder. They tie the shoots to these props as they extend in length, and find in this method the advantage that one branch is not shaded by another, but for as little a time as is possible.

Columella directs, that the props and frames be carefully examined after every pruning, and that whatever is amiss in them be repaired. Broad and flat props are preferable to round ones, and oak is the best wood they can be made of. Next to them, are round props of juniper, laurel, forest pine, and elder. Such as are rotten must be taken away, and new ones put in their stead. The bindings should be new every year. The ligature which fastens the stem to the prop should not be always in the same place, lest it should occasion a wound. The four branches should be tied gently to the cross poles, so as not to twist or bend them much. The shoots should be fastened so as that, when they grow beyond the frame, they may go shelving from it, and not hang by their binding, which would be apt to break them, especially when loaded with fruit. When two branches are so near together as to go to the same side of the frame, another pole should be placed between the cross ones, for one of those branches to be fastened to.

Those who are curious in gardening know what great things Dr. Agricola boasts of from the use of his mummies, in rearing the tenderest plants, as well as in raising forest trees from cuttings. The lees of oil, as Columella directs, mixed with fine earth, to give it a consistence, may probably answer the same purposes. Where lees of oil cannot be had, some other bitter vegetable substance might be contrived, which, being free from the acrid oil in all turpentines (as in Agricola's mummies) might prove very friendly to plants, and be particularly useful in preventing their wounds from bleeding, and in preserving them from being scorched by the sun, or hurt by insects. It is necessary that this substance be bitter, that it may hinder the insects from preying on the tender juicy fibres, for instance, of the vine, wherever a wound is made. Even loam, by itself, is found to be serviceable for these purposes; and so is either goat's, sheep, or cow's dung, well mixed with a due proportion of earth. The vine-dresser should therefore constantly have some such substance ready to apply to every wound he makes in the vine. Perhaps too, it may prove useful to the cuttings, when these are planted, by retaining the juices, till they are employed in their office of vegetation, and thereby help to save them from being parched up by drought, as well as to render them less liable to be soaked in a wet soil, or by a rainy season.

Columella gives very particular directions for raising groves, in which trees grow till they are strong enough to become props for vines; as also for making nurseries of trees proper for supporting vines, or being married to them, as the ancients termed it. The plenty of wood in this kingdom, and the still greater abundance of it in America, renders that task unnecessary in this work.

He recommends the poplar as the most friendly tree to the vine, next the elm, and then the ash. As the poplar has fewer leaves, and these are not relished by cattle (which is an object of great importance in Italy, where grass is scarce) many reject it. The ash, whose leaves are agreeable to sheep and goats, is chiefly planted in rugged and mountainous places, where the elm does not thrive well. The elm is the most frequently planted, because it agrees exceedingly with the vine, and cattle are very fond of its cuttings.

When the trees are to be planted out, pits should be dug for them some weeks before they are removed. These pits should be made in a direction which may not interfere with the vine: as east and west, where it is necessary to plant the vine on the south-side of the tree, because of the cold; or south and north, where the vine is to be set on the east or west-side of the tree. If the trees are planted in a field, where corn is to grow, and in a rich soil, the distance between them should be about forty feet: but in a poor soil, where nothing else is planted, twenty feet will be sufficient.

Whatever tree is planted for the purpose of supporting the vine, it should not be pruned for the first two years. If it be an elm, and grows but slowly, all its branches should be cut off excepting one, which should be the fairest and straitest that can be singled out. If it does not grow so upright as one would wish, some inches of the stump of another branch may be left near it, and by tying it thereto it may be trained up strait, in order to form the trunk of the tree. In the next year, the stump must be cut off and smoothed. If there is no branch fit for this purpose, the whole top must be cut off, at the height of nine feet, that cattle may not reach the young shoots. It should be cut with one stroke, if possible; otherwise it should be sawed off, afterwards smoothed, and then covered with loam mixed with straw, to preserve the wound from the sun and rain. In two or three years, when a new head is grown, the useless branches should be cut off, and the rest formed into the following order. In a strong soil, an elm should not have a branch within eight feet of the ground; nor within seven in a poor soil. At these heights, three branches should be left as equally distant as can be, in the circumference of the tree, to form what is called the first story. At three feet above them, three other branches are left, but not in the same line as the lower ones, if there be a possibility of avoiding it, because these would rub against the tender buds of the shoots of the vine hanging from the higher branches, and shake off the grapes. The tree is to be formed into stories, in this manner, up to the top. The branches are suffered to extend more or less wide, as the soil is rich or poor, in order that the shoots of the vine may be spread accordingly. Care should be taken in lopping the elm, that the body of the tree be as little hurt as possible, and that the bark be not torn off, for this would do it great prejudice. The earth should be kept loose around the trees; and all suckers, or whatever else might shade the vine, should be cut away. When the tree grows old, and, either by a wound or otherwise, water lodges in it, a hole should be bored, or a channel cut, to give an outlet to the wet.

The vines should be planted before the trees are very strong. A young elm may bear a young vine, but it would be killed by an old one; wherefore their ages and strength should be proportioned. A trench must be dug for the vine, two feet and a half wide, three feet deep, five or six feet in length, and at least a foot and an half distant from the tree; for if it be planted nearer, the roots of the tree will not permit those of the vine to strike deep enough, and as the tree grows, it will oppress the vine. For a vine that is

to

to be planted in the spring, the trench should be dug in the preceding autumn; that the earth may be mellowed by the winter's rain and frost: and if it is to be set in the autumn, the holes should be laid open some weeks before, that the soil may have the benefit of the sun and rain. Though Columella had before found fault with putting two plants in the same hole; he here advises to put two in each trench, a foot asunder, that they may the sooner clothe the tree. A northerly wind, and cold dews, should be avoided at the time of setting them. If the climate is temperate, instead of having two plants in the same trench, a trench may be made on the east and another on the west-side of the tree, and a vine may be planted in each; by which means their roots will have sufficient room to extend in. Though Mr. Miller, as I observed before, thinks it of little consequence whether a tree that is transplanted be set to the same aspect as it had in the nursery; Columella recommends, as a circumstance which is attended with great advantage, particularly to vines (but he extends it to all trees which are removed from the place of their first growth) to mark them before they are taken up, in order that the same side may still be turned to the sun. In dry and warm situations, where neither a severe winter, nor a very wet one, need be feared, the autumn is the best season for planting both vines and trees; laying under their roots the depth of half a foot of the richest and finest mould, and covering them with well dunged earth. The vine should be planted in the trench with its stem inclining to the tree, against which it is to rise up strait; and it must also be defended from cattle. In hot countries, the vine should be planted on the north-side of the tree; in cold ones, on the south; and in temperate climates, either on the east or the west, that it may not be all the day in either the sun or the shade.

In the next autumn, the vines are pruned, as already directed, for frames. When they have reached the first story, shoots should be distributed to each branch, leaving a leading shoot, which is to go up to the top of the tree: and thus each story is gradually covered. It is a rule with many, to load chiefly the lower part of the tree, because there the vine bears most grapes, and they are most easily gathered: but those who regard the quality more than the quantity of their wine, clothe the upper branches most, and garnish the rest with bearing shoots in proportion to their strength. The future pruning consists in cutting off the shoots which bore fruit for the last vintage, and in rearing others in their place. If the vine is very thriving, the bearing shoots may be permitted to hang down sloping from the branch, to which their extremities should then be brought back, and tied: or if the vine is very luxuriant, they may be carried to the next tree. Though these shoots yield a great deal of fruit, they must be cut off at the next pruning, because, otherwise, they would weaken the vine too much. No shoots should be suffered to grow out of the firm wood, unless they are wanted in order to marry them to a widowed branch.

The young vine is tied to the tree at about four feet from the ground, and with this binding its growth may be checked, if it be too luxuriant, or if the tree has been deprived of its branches. It should be tied again at about half way up, and a third time at the top. The vines should be loosened every year, because they are then most easily pruned and cleared of all imperfections; and they are refreshed by being bound in new places. They are also then in less danger of being galled by the binding. The bearing shoots should be so laid on each branch, as that, being tied above the third eye, they may hang slanting down: but they must not be tied tight, lest the binding should cut them. At the same time that some shoots are thus laid for bearing fruit, others should be trained up to the body of the tree, to produce wood for the next year.

If the vine does not clothe the tree sufficiently, a shoot may be turned down to the ground at the autumn pruning, and made a layer, from which as many young plants may be raised, as, being led up to the tree, will cover it enough. When the trees decay, young ones should be immediately planted in their stead; and when the vines begin to be worn out, they should be renewed by layers from neighbouring vines, rather than by quicksets.

To the foregoing directions for the cultivation of tall vines in Italy, and the same are equally applicable to all other warm countries, Columella adds the following account (which we shall likewise abridge from him) of the manner in which vineyards of lower growth were managed in the provinces of the Roman empire.

The husbandman there never trenched all the ground, but only opened a deep furrow, in which the vines were set. This might be sufficient where the soil was naturally loose. In some of these vineyards, the plants stood without any props; in others, they were fastened to rails; sometimes they were tied to dwarf trees; and sometimes they were suffered to run upon the ground. In the first of these cases, a single stem was reared up, free from side-shoots, till it had acquired strength enough to support the fruit bearing branches, which, when they were of a sufficient length, were bent down in a circular form, and tied to the lower part of the stem. In the second case, the fruit bearing shoots were trained to rails, or espaliers, as they grew. In both these ways, the planting, pruning, and other culture, differed so little from the general directions already given, that it would be needless to particularise them here; especially as I shall soon have occasion to speak pretty fully of the management of low and of middle sized vines, as now practised by the French, whose best vineyards consist of none else. As to letting them trail upon the ground, Columella justly thinks it so bad a method, that no excuse can possibly be offered for it, unless the country be indeed uncommonly subject to very high winds: — and then, perhaps, a doubt may arise, whether such a place be at all proper for the vine.

In Gaul, the trees for supporting the vines, besides being kept very low, were, of choice, such as had the fewest leaves. The poplar was therefore much esteemed for this purpose; for which the hornbeam, the mountain ash, and sometimes the willow, were also reared. The willow was planted only in moist places, where other trees could not thrive well; because it was thought to hurt the taste of the wine. The elm was likewise so managed, whilst young, as to be turned to a dwarf; as it may easily be. In dry and hilly situations, the stories of these trees were about eight feet high; and in vallies, or moist places, about twelve feet. These trees were generally divided into three branches, out of which several lesser boughs arose; and all the small twigs were usually cut off, at the time when the vine was pruned, to prevent their shading the fruit too much. If the dwarf trees were planted where corn grew, they were set twenty feet asunder in rows forty feet distant from each other: but when they were planted where there was no corn, their usual distance was twenty feet every way. Here the young shoots of the vines were more frequently carried from one tree to another, than when the trees grew high. If the trees were too far asunder to afford a support to the shoots, poles were extended between them, and these were up-held by props, as soon as the weight of the grapes began to be too heavy for them. In all other respects, the culture of the vine was the same as in Italy.

In clearing the vines of their superfluous shoots and leaves, Columella observes that, in the provinces, in places which were shaded, or where the sun had not much force, or which were moist and cold, the vine dressers used to strip the vines of many of their leaves, that the fruit might be the better ripened by the warmth of the sun, and not be rotted by too much moisture: but in places that were dry, warm, and exposed to the heat of the sun, the grapes were left covered with their leaves and twigs; and if the vine had but few shoots and leaves, the fruit was sheltered by some other covering: "Thus," says he (in the passage before quoted), "my uncle, Marcus Columella, a man skilled in all the liberal arts, and the most diligent farmer in Bœtica, covered his vines with mats in the beginning of the dog days; because, during that season, the country was subject to a scorching easterly wind, which, like a fiery vapour, burnt up the grapes, if they were uncovered."

The authors of the Maison Rustique draw their precepts with regard to the method of cultivating vineyards in France, from the actual and most approved practice of Burgundy, Champagne, and Orleans, the wines of which countries are deservedly held in the highest estimation.

Their

Their directions for the choice of the soil, its situation, aspect, the manner of planting it, and the future cultivation of the vine, are so like to those of Columella, that it would be needless to repeat them here.—They are, indeed, more explicit as to the grafting of the vine, which is performed in cleft, as for many sorts of fruit trees, but with this difference, that a smooth part of the vine, at the distance of about seven or eight inches from the stem, and between two joints, is the most eligible part for inserting the cion, which, as repeatedly said before in other similar cases, should always be taken from the best bearing branch of the most fruitful vine. All small roots are cut away from about the place where the graft is to be inserted, and after it has been exactly fitted in the cleft, so as to make the inner bark of the cion coincide precisely with that of the stock, the wound is carefully bound up tight with slips of the inner bark of a young lime tree, of a willow, or with bass, in such manner as effectually to preserve it from the entrance of air or wet. The graft and its stock are then bent gently downward into a hole made on purpose to receive them, and are covered with earth so as to leave only two eyes of the cion above ground. The cion should be used as soon as possible after it has been cut, and its length should be about twelve inches.

Neither the middle sized vines, nor the low ones, of which two sorts all the best and principal vineyards in France consist, should be shaded by any neighbouring buildings, or trees. The tall vines in the southern provinces of France, such as Provence and Languedoc, are, like those in Piemont, Italy, and other very warm countries, reared up to trees, or formed into alcoves or arched walks, the better to defend them from the too scorching heat of the sun. The sorts thus planted are chiefly the Cioutat, the Corinth, the Damascus grape, and the Bourdelais. The vines about Auxerre are trained up against espaliers and trellises; but those of the lowest growth, of which most of the vineyards about Paris, Beaune, Tonnere, Chablis, &c. consist, are fastened only to common props, and are generally found to produce the greatest quantity of fruit, and, in some years, the best wine.

The people of Champagne, (who think that there is in the soil of their province a quality so peculiarly fit for the production of fine wine, as can never be found or imitated elsewhere,) plant their tallest vines in their middling lands, and the low ones in their best grounds. The former of these are reared to the height of four or five feet, and the latter to about three. They observe, that their vineyards yield the highest flavoured wine when they are most exposed to the sun; and therefore they always prefer a sloping situation, fully open to the south, for their best growths. They also prefer ground which is somewhat stony, and not naturally subject to much moisture. They manure this soil from time to time, by laying on dung and fresh earth; but with caution not to use too much dung, because that would render the wine flat and insipid, and apt to become ropy. They think cows dung better than that of horses, for their finest soils, because it is not so hot: but for stiff lands they use thoroughly rotted horse-dung, and sheep's dung, which they mix with about double the quantity of cow dung, to prevent its burning the roots of the vines. Towards the end of autumn, they spread in trenches cut across the vineyard, layers of this dung and of fresh earth, and after this mixture has remained there all the winter, to moulder, and grow mellow, they lay about half a basket full of it, early in the spring, to the roots of each vine, and particularly to those of the latest planted; making for that purpose a hole around it, deepest at its back, where the sloping ground is highest. This is done over the whole vineyard either every eight or tenth year, or, which amounts to the same, to an eighth or a tenth part of it each year.

The grapes most generally cultivated in Champagne are a small black sort; and to render the wine of that country the more perfect, great care is taken to root out all white ones, and such as, though black, are large and coarse: or, if those vines are not pulled up, they are grafted with such fruit as is desired.

About the end of June, and sometimes even in May, according to the forwardness of the vine, the upper end of each shoot is nipped off, in order that the greater quantity of nourishment may be conveyed to the fruit; for it is best that no part of a low vine be more than two feet and an half, or three feet, high from the ground. These low vines are earthed, as it is called, every spring; that is to say, they are inclined down into a hole dug close to them, and their shoots, being previously pruned to such lengths as are most consistent with the vigour of the vine, are covered with earth so as to leave only three or four of their eyes above the ground.---In Upper Picardy, it is the custom to renew, as it is termed, the vineyards every year, by burying the vines in this manner, and converting each branch into a layer.

It is a general rule, that the stronger the soil is, the farther asunder the vines should be planted; and that no layers, grafts, or cuttings should be used, but such as have a smooth shining bark, and of which the wood is of a clear green when cut. Those that are of a brown green, when a little bit of their rind is raised up with a knife, are rejected, as good for nothing.

To guard against the bad effects of frosts and fogs, the French vine-dressers, whenever they apprehended any danger of that kind, lay along that side of the vineyard from whence the wind blows, a ridge of dry litter, or straw, which they then burn slowly: but if, notwithstanding this, the vines are frozen, they cut them down very low, to enable them to bear the better the next year.

They hold it to be necessary, after a thick fog, to water their vines with juice of the roots or leaves of wild cucumbers, or with powdered coloquintida, mixed with water; and they are also of opinion that late pruning is frequently a means of guarding against the mildew, because their vines do not then blossom till the sun is become very powerful.

Careful husbandmen never suffer any one to go into their vineyards very early in the morning when dews or damps fall in May, June, or September; because the dew of those months, being generally cold, would blister the leaves of the vines if it were to be touched, and thereby fixed upon them before the rising of the sun, which afterwards removes that danger by drying up and exhaling the moisture: neither do they allow them to be entered, on any account, immediately after a hasty spring-shower, while the leaves are yet wet therewith, or when they are covered with a rime or hoar-frost.

Sea-water, salt and water, or stale urine mixed with dung and earth, are of excellent service to vines which do not bear well, and to those whose leaves turn red for want of moisture: and it is said that, when their leaves become white and dry, when their wood swells, and when their fruit drops off, all which are symptoms of decay, they are recovered by rubbing the stem, and watering their roots, with ashes reduced to powder and mixed with strong vinegar.---It is most certain that stirring of the ground around them, and keeping it in a fine loose state, will have this desirable effect; or rather it will keep them constantly in so vigorous a condition, that there will never be occasion to recur to other means to promote their fertility: neither will there, if this essential principle of vegetation is duly applied to, be any danger of the grapes shrivelling or growing dry upon the vine; to remedy which, if it should happen through careless management, the authors before quoted direct to pull off all the fruit thus injured, and to water the roots of the vine with stale urine. They add, that if the grapes rot upon the vine before they are ripe, some old ashes, or barley-meal, should be laid around the stem.

If the vines, as was before observed of other trees, are sprinkled with water in which tanners have dressed their hides, no cattle will touch them.

The young leaves and fruit of the vine are often greatly injured by very small green flies, which conceal themselves in the young buds, and weave there a thin web, not unlike to that of a spider, in which they deposit their eggs. All these webs, and the leaves on which the eggs have been laid, as well those which still adhere to the vine, as those which have fallen off, must be carefully collected, and burnt out of the vineyard.

As snails and slugs, which do great damage to the vines, generally hide themselves during the middle of the day, they should be carefully picked up early in the morning, or just after dew or a shower of rain has fallen, especially in in the ſpring and autumn, which are the ſeaſons when they appear moſt; and they ſhould be cruſhed to death, or burnt.

The vine-fretters, which the French call gribouris, abound moſt in the lighteſt land. When a vine is attacked by theſe inſects, its ſhoots are ſhort and meagre, its leaves are full of holes, and it yields but very little fruit, and that extremely poor, though never ſo great pains be taken to cultivate it. Theſe inſects are much ſmaller than the ſmalleſt gnats, which they reſemble both in ſhape and colour. They prey upon the vine during the whole year; for, in September, they get into the ground, and there gnaw its roots, eſpecially thoſe of young plants; and in May when the buds of the vine ſwell, they leave their former holes, feed upon the ſurface of thoſe buds, and then upon the leaves, and afterwards they fix upon the grapes, pierce their ſkin, ſuck out their juice, and lay in them their eggs, from whence proceed an infinite number of little worms, which complete the deſtruction of the fruit by the time it ſhould be gathered. To prevent this miſchief, the authors of the Maiſon Ruſtique adviſe the ſowing of a few patches of beans in different parts of the vineyard; becauſe theſe pernicious inſects will then reſort to them, and may conſequently be deſtroyed by plucking up the beans and burning them.

To get rid of numbers of other inſects, all of which endeavour to find a place of ſhelter when the winter approaches, either by creeping into the ground, or into dung, or any litter that lies upon it; they recommend the method before-mentioned, of laying a little heap of haulm, ſtraw, or any kind of mulch, round the ſtem of each vine when the weather begins to be froſty, and burning it in the ſpring, in a place out of the vineyard. Innumerable multitudes of vermin will be deſtroyed by this means: but, to render the remedy effectual, the neighbours all around muſt have recourſe to the ſame expedient, or theſe pernicious creatures will ſoon ſpread a-new from one vineyard to another.

Mr. Miller's method of guarding againſt flies, and waſps, which are often ſo very numerous, and voracious, as entirely to eat up all the fineſt and higheſt flavoured berries of well ripened grapes, deſerves much attention even in vineyards, though it is more eaſily practiſed in gardens; but the preventing of this miſchief will make ample amends for yet greater trouble. It is, before the grapes are quite ripe, and conſequently before they will be in much danger of being attacked by theſe enemies, to hang upon the vines, from ſpace to ſpace (the nearer the better), phials half filled with ſugared water, and rubbed at the neck with a little honey. Theſe will attract the waſps and flies, which, in attempting to get at the liquor, will fall into the phials, and be drowned. They muſt be carefully looked over every third or fourth day, to take out and deſtroy the flies and waſps, and to repleniſh them with liquor.

If, when the fruit is ripe, the ſtalks of the bunches are cut half through, about a fortnight before they are gathered, the juice of the grapes will be much improved thereby; becauſe, as not near ſo great a quantity of nouriſhment can afterwards enter the fruit, the watery particles will have time to evaporate, and the juice will be the better digeſted. This is practiſed by ſome of the moſt curious huſbandmen in the ſouth of France. But if, after the bunches are cut off the vines, they are hung up in a dry room, upon ſtrings, ſo as not to touch each other, for a month before they are preſſed, both the ſtrength and the flavour of the wine will be yet more exalted. To this, in a great meaſure, is owing the delicious richneſs of the vines of that part of the Tiroleſe which borders on Italy, where it is the conſtant cuſtom to keep the grapes for ſome time before they are uſed.

As we have already enumerated the different ſpecies of grapes, it will be needleſs to repeat it here; but refer the reader to that account, which he will find under the article GRAPE.

When a vineyard is planted in a ſtrong ſoil, it ſhould conſiſt of morillons, otherwiſe called white and black pineaus; but there ſhould be more of the latter than of the former, and they ſhould be intermixed with treſſeaus, otherwiſe called Burgundy grapes.

The pineau does not attain to its full perfection in ſtrong lands, though the ſeaſon be never ſo hot: for, notwithſtanding all the help that can be given it in ſuch a ſoil, it ſtill wants that undefinable ſomewhat, without which no grape can yield a delicate wine: whether it be, that, in imbibing its nouriſhment from the earth, its juices retain a portion of the moiſture which is natural to that earth, and which blunts the ſpirits of the wine; or that, as experience has ſhewn in very many caſes, though the heat be as great as poſſible, a ſtrong ſoil does not yield to the grape that ſort of juice which acquires a fine high flavour, and a racy vinous quality, by fermentation. Thus, it is known from facts, that the Madeira grape planted in a rich valley, no longer yields the ſame wine it does on its native rock. Yet the pineau is the only grape that ſhould be planted in a ſtrong land; becauſe it ripens earlier than others, and always yields a ſure crop.

If ſome plants of the treſſeau, whoſe fruit never ripens eaſily, are mixed with the pineaus, it is, ſays the authors of the Maiſon Ruſtique, becauſe our forefathers, having found by experience that the pineaus cannot of themſelves yield in ſuch a ſoil, wine which has a ſufficient body to keep long, judged it neceſſary to add theſe treſſaus, which, though they ripen very ſlowly, never fail to yield that ſort of wine which, without being ſpirituous, is, on the contrary, thick and heavy, which is the ſtate it ſhould be in when produced by ſtrong land, in order to its becoming good.

In a ſandy ſoil, whether it be coarſe or light, pineaus, and eſpecially the white ſort, are the vines moſt proper for planting. The meunier, or miller grape, delights in light ſands; and coarſe ſands agree with the meliés, otherwiſe called melon grapes, whether theſe be white, black, or green. In the diſtrict of Auxerre, theſe ſands, though naturally warmer than the ſtrongeſt land, do not, for all that, yield equally good wine: (theſe ſtrong lands are here ſuppoſed to be ſuch as were before adviſed, and their expoſition good.) This is what experience teaches us daily with regard to ſands, which, furniſhing no rich nutriment to the vine, yields only grapes whoſe juice is flat and inſipid, and not ſo ſugary as thoſe of ſtrong lands.

To theſe pineaus are therefore joined the meliés, as before ſaid. The white melié is a good grape, and yields greatly: the black is leſs ſo. Theſe ſorts of grapes become excellent (ſo far as their nature permits) in theſe ſands, which, being much warmer than they are ſubſtantial, ſuit the nature of the meliés, which require a great heat to ripen them. Theſe grapes yield a wine which is not apt to turn yellow.

Upwards of two thirds of the vines planted in ſuch ſands, in France, are thoſe of white grapes; becauſe it is the cuſtom of thoſe places to make more white wine than red.

A reaſonable proportion of the treſſeau grape ſhould always be planted with the others in ſandy ſoils: not that it ever attains to perfection there; but that, by mixing it with thoſe other grapes, whoſe juice acquires only a moderate ſweetneſs in ſuch ground, they may be enabled to yield wine which has a good body.

As to ſtony lands, thoſe which abound in blackiſh and large ſtones, and of which the earth is reddiſh and ſomewhat moiſt, muſt be treated in the ſame manner as ſtrong ſoils.

Thoſe which have ſmaller and white ſtones, and of which the earth is leſs red, are better than the former. Beſides the white and the black pineaus, and a ſmall number of treſſeaus, theſe lands are planted with the beaunier; and all theſe grapes do well on them.

Stony land whoſe ſoil is yellowiſh, and where the ſtones are yet much leſs than the preceding, are ſtill better than them for the laſt mentioned ſorts of grapes: for theſe do ſo well in a ſoil of this kind, that they always yield there a wine which is at leaſt pleaſant. They may be intermixed here with a few plants of muſcats and of chaſſelas: for theſe will acquire maturity enough to be of ſervice to the others, and will help to make their wine keep the longer.

Stony lands, which have otherwiſe a mellow and good ſoil, yield the beſt and fineſt flavoured wine when they are planted with pineaus; and in this caſe the number of the white grapes of this ſpecies ſhould greatly exceed that of the black. Thoſe from which the grayiſh wine, commonly called

called partridge's eye, is desired, should be planted chiefly with ferviniens, and here and there a few muscats and chasselas; but no tresseaus.

When such lands as these are intended for red wines, they should be planted with more black pineaus than white, with some ferviniens, and with a few tresseaus. These will yield a strong and mellow wine.

EXPERIMENTS on the CULTURE of the VINE.

Extract of a letter from M. Reussel in Brie, to M. Du Hamel, written in the year 1755.

" I have begun to try the New Husbandry upon the vine. It is hard to pay at least one hundred and twenty livres (five guineas) a year, for dressing an arpent (about an acre and one fifth) of vineyard, to have only our poor Brie wine; especially when the vines are entirely frozen, as they were last year, or laid bare to the very wood, by hail, as was the case in August last. I am therefore trying to find out a way to manage vines, without being at the expence of dressing, or propping them, and by which they may be less exposed to the injuries of the weather, and less liable to be plundered by thieves. To this end, I pitched upon a spot of ground, about half an arpent in extent, which had formerly been a vineyard, but was grubbed up many years ago. I planted on it four hundred poplars, six feet asunder, in a quincunx form. As the roots of this tree are few and small, I thought that distance might be sufficient. At the foot of each of these trees, I planted two vine cuttings, one on each side. The alleys are plowed, in order to their being sown alternately, with corn, or pulse, such as lentils, beans, barley, oats, &c. the produce of which pays the expence of plowing. While the three feet on one side of the tree are sown, the three feet on the other side are plowed, at proper times and seasons; by which means, both sides of the tree, and consequently both the vines, receive in turns the benefit of the stirring of the ground. All my plants have taken well. I intend to let the vines run up the trees, without doing any thing to them; and shall wait with patience the event of their produce, which, be it more or less, will be so much clear gain, as it will not have cost me any thing. This method was immediately approved of by the country people hereabouts, several of whom are now following my example. What helped to give them this good opinion of it, so suddenly, was, the example of a vine, which chances to grow a league from hence, in the middle of a field, at the foot of a pear-tree, and which never is either pruned or cultivated. Last year, when all the vines of this country were so damaged by the frost, as not to produce any fruit at all; this vine escaped unhurt, and bore as many grapes as yielded a barrel of wine. If the future produce of my vineyard, which contains eight hundred vines, were to be estimated on this footing, it would amount to eight hundred barrels of wine every year. But as no one can be so absurd as to make such a calculation; so, on the other hand, I believe none will deny but that my vines, producing only the two hundreth part of that proportion, will yield me four barrels of wine, which will not have stood me in the least extraordinary charge. And even supposing them not to yield me any thing, still I shall lose nothing, because they will have cost me nothing. The four hundred poplars, which do not stand me in above a penny a-piece, (being planted only by slips, without making or digging either holes or trenches for them) cannot fail, in a soil that is quite fit for them, to be worth, twenty-five years hence, ten livres (eight shillings and nine-pence) apiece, or four thousand livres (one hundred seventy-five pounds four shillings) the whole; which will be an excellent payment for the ground they will have taken up. I do not, however, mean to extend this method to all my vineyards. In most of them, the soil, though fit for the vine, is too dry and stony for the poplar. In Italy, vines are frequently planted at the foot of mulberry and other trees. The only thing necessary in that case, is, to make the alleys of a breadth proportioned to the shade of the trees."

Experiment on the vine, cultivated according to the principles of the New Husbandry, with remarks thereupon, by M. de Chateauvieux.

" When I began to reflect attentively on the principles of the New Husbandry, I soon perceived that it might prove a means of perfecting the culture of our vineyards, as well as that of our other lands.

" I was the more readily induced to turn my thoughts towards that important branch of agriculture, as it seemed to me to have been too much neglected for a long time. I plainly saw, that our methods of cultivating the vine, were, in general, not only defective, but badly executed, and that, in the common way of planting vineyards, the produce could not be proportioned to the great expence.

" I shall not at present enter into a detail of the principles and motives of my new scheme for the culture of the vine: that task would be too long for this narrative: and I should likewise be glad first to see the advantages of my method confirmed by a series of experiments repeated for several years together. My different operations, and first success, are all that I shall mention now.

" Every country has in the culture of the vine, some practice or other peculiar to itself, and which is thought essential there, though it be rejected in other places. All agree in pruning the vine, and in stirring the earth round it: but neither of these operations is performed in the same manner every where.

" For the better understanding of my new culture, it is necessary that I should give an idea of the manner in which our vineyards are laid out and planted. Their exposition is generally to the east or south, on a good deep soil, which has a gentle declivity, or on the side of a hill. The whole surface of the ground is planted without order or symetry; so that the vines are, almost always, either too close together, or too far asunder: very few are at proper distances. As the old vines decay and perish, the chasms are filled up by layers from the next neighbouring vines. This is the general disposition of our vineyards, from which great inconveniences must necessarily arise: but I shall not enter into that detail.

" With regard to the culture of the vine, it is sufficient, for my present purpose, to observe, that the whole of that labour is now performed by hand, which renders it very expensive. I say nothing of the manner in which it is executed; that part having appeared to me so very defective, that I have been obliged to alter and correct it in every point.

" By this short preamble it may easily be seen, that, in order to improve the culture of the vine, and bring it to greater perfection, it was necessary that I should attend chiefly to the three following things. 1. To dispose the vines in a better manner, by planting them in strait lines, and at equal distances from each other. 2. To contrive that disposition so as to lessen the present expence of culture, by using a plough to stir the ground in one part of the vineyard, whilst the other should continue to be stirred with the spade. 3. To execute the several cultures of the vine, in such manner as to make them promote its vegetation more than they do in any of the common methods.

" I shall treat each of these articles separately.

" The disposition which seemed to me the most agreeable to the principles of the New Husbandry, by which I was guided, was to lay the vineyard out in beds, as we do fields for corn, observing to leave an alley between every two beds, and making each bed five feet wide, in order to plant it with three rows of vines, which, by that means, would be thirty inches asunder, and the vines at the same distance from each other in the rows.

" As to the alleys, I thought it would be right to make them also five feet wide: and what I shall say hereafter will shew, that about that breadth is necessary.

" However, as that disposition might not be the best, I tried others on small spots of ground, by planting the vines at other distances. Some were set in single rows three feet and an half asunder; others in double rows, and in beds, with alleys of three feet and an half between them. These plantations were made in the spring of 1753.

" But as I could not expect to see the event of these trials, till a considerable time after making them, eight or ten years, at least, being requisite to shew what the success would be, when the vines should be come to their full strength and bearing; I considered at the same time, by what means I might abridge an experiment which was to be of so long duration.

" To that end, I formed a bed of vines in a vineyard planted twenty-four years before. The vineyard was good,

good, and yielded plentiful crops. I made my bed five feet wide, and planted it by laying down stocks of the old vines, to make the two outward rows, leaving two feet and an half distance from one layer to another. The old vines, which happened to be pretty well situated, formed the middle row. The remainder of the bed, which is two hundred and forty feet long, was planted with layers.

"An alley, five feet wide, was made on one side of this bed, by pulling up the old vines within that distance. Some of these which were left, served to form a row of vines, ready against the making of a second bed parallel to the first. It is plain, that the making of a bed in this manner, requires a breadth of ten feet, viz. five feet for the vines, and five feet for the alley. This bed was thus made in November 1752.

"After I had seen the crop which it produced in 1754, I no longer hesitated to extend this experiment; and accordingly, in November of that year, I made three other beds, like the former, and close to it.

"I not only made no doubt but that the vines, being so disposed, and having an equal quantity of earth to draw their nourishment from, would thrive better than they do in our common method of cultivating them; but I likewise hoped that their being exposed on all sides to the influences of the sun and air, by means of the alleys, would facilitate their vegetation, and hasten the ripening of the grapes.

"The manner in which I propose distributing the vines, shews at once the possibility and facility of giving the alleys every necessary culture, with the same plough and the same cultivator as we use for the alleys of our corn fields. I have not found the least difficulty in the execution of this practice.

"The ground thus cultivated in the alleys, will be about a third part of the whole: the remaining two thirds will continue to be cultivated by hand, as usual; and the expence will be considerably diminished, by the dispatch with which the plough, or cultivator, will perform its part.

"The plough may be brought as near the vines as one pleases, provided care be taken not to damage them. An expert husbandman will easily know how to manage in that respect.

"Another diminution of the expence attending the common culture of vineyards is, that as, by the method which I propose, the number of vines will be fewer, they will of course require less labour, and therefore less cost; and the vine-dressers, meeting with no hindrances or obstructions between the vines planted regularly in rows, will do more work in a day, and that much better, than in the old way. There will also be less occasion for many things necessary to the vine, such as propping, tying up, dunging, &c. Consequently this new culture will prove a considerable saving.

"It is well known how much vines are hurt when too great a quantity of water is retained in the ground. It chills them too much, their juices become less exalted, numbers of weeds spring up, &c. These inconveniences will be remedied in a great measure, by means of the alleys, by cutting with the plough, as I have done, towards the beginning of winter, a furrow along each side of the bed. The water will drain off into that furrow, and the bed will retain only the degree of moisture necessary for the vines.

"I shall speak only of the two principal parts of the culture of the vine, viz. the pruning of it, and the stirring of the ground; and the time when each of these ought to be performed.

"Before I began to execute the alterations I had thoughts of making in this culture, I had endeavoured to make myself so far master of it, as to be the less in danger of miscarrying in my experiment.

"The custom of this country is, to prune the vine during and after winter; frequently beginning that work about the end of January. I always thought that a wrong season; and judged that it would be much better to prune the vine before winter, immediately after the vintage is ended. Experience has since shewed me that I was right.

"In November 1750, I pruned above fifty vines with my own hands: none of them suffered in the least by the winter's frost: they made strong and vigorous shoots, and produced a greater quantity of grapes than any of the neighbouring vines.

"The next year, and in the same month, I pruned the same vines again. This pruning had the same success as the year before. Encouraged by this repeated experience, I determined to make the bed before mentioned, in my old vineyard. The vines have continued to be pruned before winter, always with success, and without any sort of inconvenience.

"Satisfied with these first trials, I thought I might safely venture to extend the same practice to a larger extent of ground. I had about three acres of vines, which had produced very little wood for two years past. Their branches were so poor and slender, that they would scarce bear laying down: in short, the vineyard perished daily. I conceived hopes of recovering it by means of this pruning. Accordingly, I pruned it in November 1754; and in 1755, the vines produced stronger and longer shoots. As the branches would then bear laying down, I began to replenish part of the vacant places. By this means, my vineyard was replanted with young vines, and quite renewed, only by altering the time of pruning.

"This last pruning underwent a severe trial, from the excessive hard frosts of the winter of 1755: yet, intense as the cold was, my plants bore it, without being hurt at all. I then looked upon it as certain, that the vine might be pruned before winter, without any danger from the inclemency of that season.

"It was absolutely necessary that the vine should bear pruning at that time, in order to enable me to perform the other cultures in their proper and most favourable seasons.

"That the vine may be benefited as much as possible by every stirring of the earth about its roots, these stirrings ought certainly to be performed at the times when they may be most likely to excite the greatest vegetation. Let us see whether the common practice answers that end. The usual time of beginning to dress the vineyard is in the spring, immediately after pruning the vines. Three dressings are judged sufficient; and it is generally thought, that the last should be finished by midsummer. The plants are then left to shift for themselves, till the time of vintage, which is upwards of three months after. During this time, quantities of weeds generally shoot up, which shade the vines, and hinder the grapes from ripening as they ought. Careful husbandmen pull them up: but the greater part are unwilling to take that trouble.

"In the common way of cultivating the vine, the earth is first stirred when the buds are just ready to come out, and even after they are come out; a time always extremely critical, because the uncertainty of the season exposes the buds to several dangers, which are increased by that stirring of the earth, from whence many exhalations, oftentimes very pernicious, proceed at this season. Would it not be much better to let the vineyard rest while the vine is budding?

"The last stirring, which is given about mid-summer, is too long before the vintage, and therefore is almost always followed by great quantities of weeds. Might not this last culture be performed later?

"I have experienced that these inconveniences may be avoided, without falling into others. To this end, after the vine has been pruned, before winter, let the earth be first stirred in that season: the second stirring, which would otherwise be immediately after winter, may then be deferred till towards the end of May: and the third stirring may be given in the beginning of August, or about the end of July.

"This has been my method of cultivating my vines, ever since their being planted in beds. The beds are dug by hand, and the alleys are stirred with the plough or the cultivator.

"The first stirring before winter produces the same effect on the vineyards, as it does on our beds of corn. The water is drained off, and the winter's frosts penetrate the earth, divide it, and keep it loose and light.

"It remains in this state till towards the end of May, when it receives the first stirring after winter: and, to have a more certain rule to go by, the second stirring should not be given till after the props have been stuck, the vines have budded, and the shoots have been tied up to the props.

props. This ſtirring may be given, either a little ſooner, or a little later, than is mentioned above, according to the ſeaſon. Sometimes one may be obliged to haſten it, if the ground is greatly burdened with weeds: but at whatever time it be performed near the end of May, it is certain that the vine will then have made great ſhoots, and that without having been diſturbed by any ſtirring of the earth during the time of its tender vegetation. As I have tried this culture in hot and very dry years, I have ſeen that the earth has not grown hard, but has retained the neceſſary degree of moiſture, ſo as to be ſtirred with the greateſt eaſe.

"The third ſtirring, which is the ſecond after winter, being deferred till towards the end of Auguſt, or at leaſt till the end of July; weeds have not time to grow in any quantity between that and the ſeaſon of the vintage: and what will render it ſtill more beneficial, is, that this is the time when the grapes fill moſt, and are drawing towards a ſtate of maturity.

"I may perhaps be thought not to enlarge enough on ſo important a ſubject as this is. It will, I confeſs, require being treated more fully hereafter: but in the mean time I beg the reader to conſider, that I am now relating only the ſucceſs of my firſt trials.

Good effects of this culture proved by the produce of a bea of vines two hundred and forty feet long, planted in 1752.

"I obſerved, in the beginning of this account, that every culture of the vine is performed with much greater eaſe and expedition in vineyards laid out in beds, than in thoſe which are planted all over; but at random. The very ſituation of the vines planted regularly in beds, is ſufficient to ſhew with what eaſe every thing that they require may be done, and that they muſt, of courſe, be well cultivated in every reſpect.

"In the next place, the pruning of the vine, and the firſt ſtirring of the earth before winter, are done at a time when the buſineſs of the field is over, and huſbandmen are, in ſome meaſure, un-occupied. That time, which would otherwiſe be in a manner loſt, may now be employed to very great advantage; and in conſequence of their being advanced in their work before the coming on of winter, inſtead of being over-loaded in the ſpring, by a multitude of things to be done at that time, they will have ample leiſure to attend properly, and without being hurried, to every branch of culture that a farm requires.

"The effect of our culture has been extremely viſible. The new vines have grown ſo prodigiouſly, that they now greatly ſurpaſs thoſe of the old vineyards, which they were part of: the ſhoots too are thicker and longer, and the bunches of grapes bigger and more numerous.

"When I firſt began to apply the principles of the New Huſbandry to the culture of the vine, I hoped indeed that the great fruitfulneſs of a ſmaller number of plants, might compenſate for the loſs of thoſe I was obliged to retrench: but I was agreeably ſurpriſed to find all the vines of my bed loaded with an equal quantity of grapes.

"Though my conjecture was founded on principles which I knew to be true, I was ſtill farther confirmed in my opinion by an obſervation I had made, that, even in our beſt vineyards, there are always great numbers of vines which abſolutely bear no fruit at all, and many others which produce but very little; ſo that it is not on the great number of plants that the great produce of the vineyard depends, but on the goodneſs of thoſe plants.

"Accordingly I concluded that I ought not to look upon my having taken up ſome vines in order to form the ally, as a loſs, provided thoſe in the bed were enabled by good culture to yield their utmoſt productions. The event ſhewed that I was right.

"I likewiſe judged, that the grapes would ripen more perfectly in this new way, than in the old: and in that too I was not miſtaken; for they were much higher flavoured, and made far better wine.

"Beſides theſe advantages, this culture preſerved my vines from a very bad accident, which happens frequently, eſpecially when the autumn is rainy: I mean, the rotting of the grapes. In our common vineyards, the grapes ripen, ſmothered beneath that quantity of leaves with which the vines are loaded, and ſurrounded by numbers of weeds, which often grow higher than the vines themſelves. Add to this, that the air around them is filled with various exhalations from the earth, which, for want of a free circulation, remain ſuſpended about the plants. Theſe cauſes cannot but make the grapes rot, and the wine that is made of them, muſt be greatly inferior to what it would otherwiſe be.

"Our vines in beds, being much leſs, if at all, liable to any of theſe accidents, will have the advantage of preſerving their grapes ſound and without rottenneſs, till they are perfectly ripe. This I have already experienced, at a time when above half the grapes of my old vineyard were abſolutely rotten.

"Notwithſtanding all the advantages of this new method, which, I may ſay, I have only glanced at; they would probably not be regarded, if they were not attended with greater fruitfulneſs than is obtained in the common way. I ſhall therefore ſhew, that the produce of my young vines was very conſiderable, and greatly ſuperior to that of my old vineyard.

"My bed, as I obſerved before, was formed in November 1752; and the two outward rows conſiſted, in a great meaſure, of young layers, which not being old enough in 1753, to bear much fruit, I could not expect any great matter from them that year. However, they bore as much as could reaſonably be deſired. A violent ſtorm of hail which fell in June, left ſcarce any thing to be gathered in all our other vineyards.

"The year 1754 produced, in general, but little wine. The young plants of my bed, being then only in their ſecond year, were too weak to diſtinguiſh themſelves by any extraordinary quantity of fruit; though their vigour gave great hopes for future years. However, even in this, they were loaded with ſo many and ſo large bunches of grapes, that they yielded rather more wine than the old vines which were next them.

"The year 1755 was one of the beſt years for wine, that has been known for a long time. The quantity was plentiful, and the quality exceeding good. The youngeſt plants of my bed, which were only in their third year, ſeemed no way inferior to the old vines cultivated in the common way.

"This bed, two hundred and forty feet long, and ten feet wide, including the alley, yielded three hundred and thirty-ſix pints of wine, Paris meaſure (eighty four Engliſh gallons), which was after the rate of two-fifths more than I had from my old vineyard; or to explain myſelf ſtill better, if my whole vineyard had been laid out in beds, it would have yielded five barrels of wine, for every three that it did yield.

"Twenty beds of the ſize of that we are ſpeaking of, would make about an arpent; and ſuppoſing them all to produce alike, they would, after the rate of this, yield ſix thouſand ſeven hundred and twenty Paris pints (one thouſand ſix hundred and eighty Engliſh gallons), or twenty-eight hogſheads; which, in this country (the territory of Geneva,) is a prodigious quantity; ſuch as no vineyard here has ever yet produced.

"The vintage of 1756 was neither plentiful nor good. I therefore did not make any compariſon; but remained ſatisfied with obſerving in general, that my bed yielded at leaſt as much as the old vineyard."

VINEGAR, an acid penetrating liquor, prepared from wine, cyder, beer, &c. of conſiderable uſe both as a medicine and ſauce.

The proceſs of turning vegetable matters to vinegar, is thus delivered by Dr. Shaw: take the ſkins of raiſins, after they have been uſed in making wine; and pour three or four times their own quantity of boiling water upon them, ſo as to make a thin aqueous mixture. Then ſet the containing caſk, looſely covered, in a warmer place than is uſed for vinous fermentation; and the liquor in a few weeks time will become a clear and ſound vinegar; which being drawn off from its ſediment, and preſerved in another caſk, well ſtopped down, will continue perfect, and fit for uſe.

This experiment ſhews us a cheap and ready way of making vinegar from refuſe materials; ſuch as the huſks of grapes, decayed raiſins, the lees of wine, grounds of ale, beer, &c. which are frequently thrown away as uſeleſs. Thus, in many wine countries, the marc, rape, or dry preſſing of grapes, are thrown in heaps, and ſuffered to putrify unregarded, though capable of affording as good vinegar as the wine itſelf. In ſome places they bury copper-

copper-plates in these husks, in order to make verdigrease; but this practice seems chiefly confined to the southern parts of France. Our present experiment shews us how to convert them to another use; and the direction extends to all the matters that have once undergone, or are fit to undergo, a vinous fermentation, for that all such matters will afford vinegar. Thus all our summer-fruits in England, even black-berries; all the refuse washings of a sugar-house, cyder-pressings, or the like, will make vinegar, by means of water, the open air, and warmth.

The whole process, whereby this change is effected, deserves to be attentively considered; and, first, the liquor to be thus changed, being kept warmer than in vinous fermentation, it begins, in a few days, to grow thick or turbid; and without throwing up bubbles, or making any considerable tumult, as happens in vinous fermentation, deposits a copious sediment.

The effect of this separation begins to appear, first, on the surface of the liquor, which gathers a white skin, that daily increases in thickness, till at length it becomes like leather; and now, if continued longer in this state, the skin turns blue, or green, and would at last grow solid, and putrify: therefore, in keeping down this skin as it grows, and thrusting it gently down to the bottom of the vessel, consists much of the art of vinegar making, especially from malt. For the difference between vinous and acetous fermentation, *see the article* FERMENTATION.

*Method of making Cyder-*VINEGAR. The cyder (the meanest of which will serve the purpose) is first to be drawn off fine into another vessel, and a quantity of the must, or pouz of apples, to be added: the whole is set in the sun, if there be a conveniency for the purpose; and, at a week or nine days end, it may be drawn off. *See* CYDER.

*Method of making Beer-*VINEGAR. Take a middling sort of beer, indifferently well hopped; into which, when it was worked well, and is grown fine, put some rape, or husks of grapes, usually brought home for that purpose: mash them together in a tub; then, letting the rape settle, draw off the liquid part, put it into a cask, and set it in the sun as hot as may be (the bung being only covered with a tile, or slate-stone) and in about thirty or forty days, it will become a good vinegar, and may pass in use as well as that made of wine, if it be refined, and kept from turning musty.

Or thus: to every gallon of spring-water, add three pounds of Malaga-raisins; which put into an earthen jar, and place them where they may have the hottest sun from May till Michaelmas; then pressing all well, tun the liquor up in a very strong iron-hooped vessel, to prevent its bursting: it will appear very thick and muddy, when newly pressed; but will refine in the vessel, and be as clear as wine.

Thus let it remain untouched for three months, before it be drawn off, and it will prove excellent vinegar.

*Method of making Wine-*VINEGAR. Any sort of vinous liquor, being mixed with its own fæces, flowers, or ferment, and its tartar, first reduced to powder; or else with the acid and austere stalks of the vegetable from whence the wine was obtained, which hold a large proportion of tartar: and the whole being kept frequently stirring in a vessel which has formerly held vinegar, or set in a warm place full of the steams of the same, will begin to ferment a-new, conceive heat, grow sour by degrees, and soon turn into vinegar.

The remote subjects of acetous fermentation are the same with those of vinous; but the immediate subjects of it are all kinds of vegetable juices, after they have once undergone that fermentation which reduces them to wine: for it is absolutely impossible to make vinegar of must, the crude juice of grapes, or other ripe fruits, without the previous assistance of vinous fermentation.

The proper ferments for this operation, whereby vinegar is prepared, are, 1. The fæces of all acid wines. 2. The leys of vinegar. 3. Pulverised tartar; especially that of Rhenish wine, or the cream, or crystals thereof. 4. Vinegar itself. 5. A wooden vessel well drenched with vinegar, or one that has been long employed to contain it. 6. Wine that has often been mixed with its own fæces. 7. The twigs of vines, and the stalks of grapes, currants, cherries, and other vegetables of an acid austere taste. 8. Bakers leaven, after it is turned acid. 9. All manner of ferments, compounded of those already mentioned.

The French use a method of making vinegar different from that above described. They take two large oaken vessels, the larger the better, open at top; in each whereof they place a wooden grate, within a foot of the bottom: upon these grates they first lay twigs, or cuttings of vines, and afterwards the stalks of the bunches, without the grapes themselves, or their stones; till the whole pile reaches within a foot of the brim of the vessels: then they fill one of these vessels with wine to the very top, and half fill the other; and with liquor drawn out of the full vessel, fill up that which was only half full before; daily repeating the same operation, and pouring the liquor back from one vessel into another; so that each of them is full, and half full, by turns.

When this process has been continued for two or three days, a degree of heat will arise in the vessel, which is then but half full, and increase for several days successively, without any appearance of the like in the vessel which happens to be full, during those days; the liquor whereof will still remain cool: and as soon as the heat ceases in the vessel that is half full, the vinegar is prepared: which, in the summer, happens on the fourteenth or fifteenth day from the beginning; but in the winter, the fermentation proceeds much slower: so that they are obliged to forward it by artificial warmth, or the use of stoves.

When the weather is exceeding hot, the liquor ought to be poured off from the full vessel into the other twice a-day: otherwise, the liquor will be overheated, and the fermentation prove too strong; whence the spirituous parts will fly away, and leave a vapid wine, instead of a vinegar, behind.

The full vessel is always to be left open at the top, but the mouth of the other must be closed with a cover of wood, in order the better to keep down and fix the spirit in the body of the liquor; otherwise, it might easily fly off in the heat of fermentation. The vessel that is only half full seems to grow hot, rather than the other, because it contains a much greater quantity of the vine-twigs and stalks, than that, in proportion to the liquor; above which the pile, rising to a considerable height, conceives heat the more, and so conveys it to the wine below.

Vinegar is a medicine of excellent use in all kinds of inflammatory and putrid disorders, either internal or external: in ardent bilious fevers, pestilential and other malignant distempers, it is recommended by Boerhaave as one of the most certain sudorifics. Weakness, fainting, vomiting, hysterical and hypocondriacal complaints have also been frequently relieved by vinegar applied to the mouth or nose, or received into the stomach. Distilled vinegar has the same virtues, only in a stronger degree.

There are also medicated vinegars, as vinegar of antimony, of elder, litharge, roses, squills, treacle, &c. which derive their chief virtues from the vinegar.

VINEYARD, *Vinetum*, a plantation of vines without the assistance of walls, &c. *See* VINE.

VINOUS, something that relates to wine, or that hath the taste and smell of it.

VINTAGE, a crop of grapes, or the produce of a vineyard each season.

VIPER, the name of a well known serpent, common in many parts of England.

The bathing the part bit by a viper with olive oil, is said to effectually prevent the fatal consequences, that would otherwise attend it.

VIVES, a disease in horses, which differs from the strangles only in this, that the swellings of the kernels under the ears of the horse (which are the parts at first chiefly affected) seldom gather, or come to matter, but by degrees perspire off, and disperse, by warm cloathing, anointing with the marshmallow ointment, and a moderate bleeding or two. But should the inflammation continue, notwithstanding these means, a suppuration must be promoted by the methods recommended in the strangles. *See the article* STRANGLES.

When these swellings appear in an old or full-aged horse, they are signs of great malignity, and often of an inward decay, as well as forerunners of the glanders.

The mercurial ointment mentioned in the article STRANGLES may be prepared thus:

> Take of crude mercury, or quickfilver, one ounce; Venice-turpentine half an ounce; rub together in a mortar till the globules of the quickfilver are no longer vifible; then add two ounces of hogs-lard.

Some authors recommend this ointment to be ufed at firft, in order to difperfe the fwellings, and prevent their coming to matter; bleeding and purging at the fame time for that purpofe; but as in young horfes they feem to be critical, the practice by fuppuration is certainly more eligible and fafe; for want of properly effecting which, the humours frequently fettle, or are tranflated to the lungs, and other bowels; or falling on the flefhy parts of the hind quarters, form deep impoftumes between the mufcles, which difcharge fuch large quantities of matter, as fometimes kill the horfe, and very often endanger his life. *Bartlet's Farriery, pag.* 99.

ULCER, a folution of the foft part of an animal body, together with the fkin.

The firft intention in the cure of ulcers is bringing them to digeft, or difcharge a thick matter; which will in general be effected by the green ointment, or that with precipitate; but fhould the fore not digeft kindly by thefe means, but difcharge a gleety thin matter, and look pale, you muft then have recourfe to warmer dreffings, fuch as balfam, or oil of turpentine, melted down with your common digeftive, and the ftrong beer poultice over them; it is proper alfo in thefe kind of fores where the circulation is languid, and the natural heat abated, to warm the part, and quicken the motion of the blood, by fomenting it well at the time of dreffing; which method will thicken the matter, and roufe the native heat of the part, and then the former dreffings may be re-applied.

If the lips of the ulcer grow hard or callous, they muft be pared down with a knife, and afterwards rubbed with the cauftic.

Where foft fungous flefh begins to rife, it fhould carefully be fuppreffed in time, otherwife the cure will go on but flowly; if it has already fprouted above the furface, pare it down with a knife, and rub the remainder with a bit of cauftic; and to prevent its rifing again, fprinkle the fore with equal parts of burnt allum, and red precipitate; or wafh with the fublimate water, and drefs with dry lint even to the furface, and then rowl over a comprefs of linnen as tight as can be borne; for a proper degree of preffure, with mild applications, will always oblige thefe fpongy excreffences to fubfide, but without bandage the ftrongeft will not fo well fucceed.

All finuffes, or cavities, fhould be laid open as foon as difcovered, after bandages have been ineffectually tried; but where the cavity penetrates deep into the mufcles, and a counter opening is impracticable or hazardous; where by a continuance, the integuments of the mufcles are conftantly dripping and melting down; in thefe cafes injections may be ufed, and will frequently be attended with fuccefs. A decoction of colcothar boiled in forge-water; or folution of lapis medicamentofus in lime-water, with a fifth part of honey and tincture of myrrh, may be firft tried, injecting three or four ounces twice a day, or fome refin melted down with oil of turpentine may be ufed for this purpofe: if thefe fhould not fucceed, the following, which is of a fharp and cauftic nature, as recommended on Mr. Gibfon's experience.

> Take of Roman vitriol half an ounce, diffolve in a pint of water, then decant and pour off gently into a large quart bottle; add half a pint of camphorated fpirit of wine, the fame quantity of the beft vinegar, and two ounces of Ægyptiacum.

This mixture is alfo very fuccefsfully appplied to ulcerated greafy heals, which it will both cleanfe and dry up.

Thefe finuffes or cavities frequently degenerate into fiftulæ, that is, grow pipey, having the infide thickened, and lined as it were with a horny callous fubftance. In order to their cure, they muft be laid open, and the hard fubftance all cut away; where this is impracticable, fcarify them well, and truft to the precipitate medicine made ftrong, rubbing now and then with cauftic, butter of antimony, or equal parts of quickfilver and aqua fortis.

When a rotten or foul bone is an attendant on an ulcer, the flefh is generally loofe and flabby, the difcharge oily, thin, and ftinking, and the bone difcovered to be carious, by its feeling rough to the probe paffed through the flefh for that purpofe. In order to a cure, the bone muft be laid bare, that the rotten part of it be removed; for which purpofe, deftroy the loofe flefh, and drefs with dry lint; or the doffils may be preffed out of tincture of myrrh or euphorbium: the throwing off the fcale is generally a work of nature, which is effected in more or lefs time, and in proportion to the depth the bone is affected; though burning the foul bone is thought by fome to haften its feparation.

Where the cure does not properly fucceed, mercurial phyfick fhould be given, and repeated at proper intervals: and to correct and mend the blood and juices, the antimonial and alterative powders, with a decoction of guaiacum and lime-waters, are proper for that purpofe. *Bartlet's Farriery, pag.* 253.

ULIGINOUS, an appellation given to a moift, moorifh, and fenny foil.

UMBEL, the extremity of a ftalk or branch of a plant, divided into feveral peduncles, or rays, beginning from the fame point, and opening in fuch a manner, as to form an inverted cone.

UMBELLIFEROUS *Plants*, thofe whofe flowers are produced in an umbel, on the top of the ftalks, fomewhat refembling an umbrella. Of this kind are the fennel, parfley, parfnip, carrot, hemlock, &c.

UNDERWOOD, coppice, or any wood not accounted timber. *See the article* COPPICE.

VOOR, fallow land. *See the article* FALLOW.

URE, the udder of a cow, fheep, &c.

URITH, etherings, or windings of hedges.

URRY, a fort of blue or black clay, lying near a vein of coal.

URINE, a ferous and faline matter feparated from the blood of animals, and emitted by the canal of the urethra.

It is of excellent ufe as a manure, when deprived of its hot fiery particles by time, which will fo alter its nature as to render it an extraordinary fertilizer of every kind of foil. Columella certifies that old urine is excellent for the roots of trees. Mr. Hartlib commends the Dutch for preferving the urine of cows as carefully as they do the dung, to enrich their lands; and inftances a woman he knew near Canterbury, who faved in a pail all the urine fhe could, and when the pail was full, fprinkled it on her meadow, the grafs of which looked yellow at firft, but afterwards grew furprizingly. Similar to this is what Mr. Bradley relates, as of his own knowledge. Human urine was thrown into a little pit conftantly every day, for three or four years. Two years after, fome earth was taken out of this pit, and mixed with twice as much other earth, to fill up a hollow place in a grafs walk. The turf which was laid upon this fpot grew fo largely and vigoroufly, befides being much greener than the reft, that, by the beft computation he could make, its grafs, in a month's time, was above four times as much in quantity as that of any other fpot of the fame fize, though the whole walk was laid on very rich ground. The author of the Englifh Improver is therefore very right in faying, that human urine is of greater worth, and will fatten land more, than is generally imagined by our farmers, whom he advifes, to take all opportunities of preferving this, and every fort of urine, for their ground, as carefully as is done in Holland.

USTILAGO, the fame with burnt grain. *See the article* BURNT-GRAIN.

UTENSIL, a domeftic moveable of any kind.

W.

WAD, black lead.

WAGGON, a vehicle or carriage, of which there are various forms, accommodated to the different uſes they are intended for. *See the article* WHEEL.

WAIF, an eſtray, which, for want of the owner's appearance after it has been cried and publiſhed in the neighbouring markets, is forfeited to the lord of the manor.

WALK, an ornamental and uſeful part of a garden, differing from an alley by being wider. *See* ALLEY.

Walks are either ſtrait or ſerpentine; the materials of which they are formed are gravel, ſand, or graſs; but where gravel or ſand cannot be procured, they are ſometimes laid with powdered coal, ſea-coal aſhes, and ſometimes with powdered brick, but none equals thoſe made with gravel: and in order to the laying thoſe kind of walks, it is very proper to fill the bottom with lime, rubbiſh, flint ſtones, coarſe gravel, or other rocky materials, which will be of ſervice to prevent weeds from growing through the gravel, and to hinder worm-caſts; this bottom ſhould be ten inches or a foot thick, over which a coat of fine gravel, mixed with a due proportion of loam, ſhould be laid, to the thickneſs of ten inches. The common allowance for a gravel walk of five feet breadth is an inch in the crown, ſo that if a walk be twenty feet wide, it ſhould be four inches higher in the middle than on each ſide.

When a walk has been evenly laid, trodden down, and raked, it ſhould then be rolled well both in length and width; and in order to make them more firm, it will be neceſſary to give them three or four water-rollings, that is, they ſhould be rolled when it rains very faſt; this will cauſe the gravel to bind, ſo that when the walks come to be dry, they will be as hard as terrace.

Gravel walks are not only very neceſſary near the houſe, but there ſhould always be one carried quite round the garden, becauſe being ſoon dry after rain, they are proper for walking on in all the ſeaſons; but then theſe ſhould be but few, and thoſe adjoining to the houſe ought to be large in proportion to the ſize of the houſe and garden: the principal of theſe walks ſhould be elevated, and carried parallel with the houſe ſo as to form a terrace; this ſhould extend itſelf each way in proportion to the width of the garden, ſo that from this there may be a communication with the ſide walks, whereby there may be dry walking all round the garden.

Sand walks are alſo frequently made in gardens; theſe are leſs expenſive in the making, and alſo in keeping in order than thoſe of gravel; for as the greateſt part of the walks which are made in modern gardens twiſt about in an irregular ſerpentine manner, it would be very difficult to keep them handſome if they were laid with gravel, eſpecially where they are ſhaded by trees; for the dripping of the water from their branches in hard rains, is apt to waſh the gravel in holes, and render the walks very unſightly; therefore thoſe walks which go through woods and plantations are much better if laid with ſand, which will be dry and wholſome, and whenever they appear moſſy, or any weeds begin to grow on them, if they are ſcuffled over with a Dutch hoe in dry weather, and raked ſmooth, it will deſtroy the moſs and weeds, and make the walks appear as freſh and handſome as when firſt laid.

The breadth of theſe walks ſhould be proportioned to the ſize of the ground, which, in a large extent, may be twelve or fourteen feet wide, but in ſmall gardens five or ſix will be ſufficient.

The ground being traced out in the manner as the walks are deſigned, the earth ſhould be taken out of the walk, and laid in the quarters; the depth of this muſt be proportioned to the nature of the ſoil, for where the ground is dry, the walks need not be elevated above the quarters, ſo the earth may be taken out four or five inches deep in ſuch places; but where the ground is wet, the bottom of the walks need not be more than two inches below the ſurface, that the walks may be raiſed ſo high as to throw off the wet into the quarters, which will render them more dry and healthy to walk on: after the earth is taken out, the bottom of the walks ſhould be laid with rubbiſh, coarſe gravel, &c. to the thickneſs of five or ſix inches, and beaten down cloſe, to prevent the worms from working through it; then the ſand ſhould be laid upon this about three inches thick, and after treading it down, it ſhould be raked over to level and ſmooth the ſurface: the ſand that is fitting for this purpoſe ſhould be ſuch as will bind, otherwiſe it will be very troubleſome to walk on them in dry weather; for if the ſand be of a looſe nature, it will be moved by ſtrong gales of wind, and in dry weather will ſlide from under the feet; and if it is too much inclinable to loam, it will alſo be attended with as ill conſequence as that which is too looſe, for this will ſtick to the feet after every rain; ſo that where ſand can be obtained of a middle nature, it ſhould always be preferred.

Graſs walks in gardens were formerly held in great eſteem, and were looked upon as neceſſary ornaments to a garden; but of late years they have been much leſs regarded; for theſe long narrow ſlips of graſs are far from being pleaſing to the eye, and are for the greateſt part of the year uſeleſs, being generally too damp for perſons of tender conſtitutions to walk on; and whenever they were conſtantly uſed, they became bare in the places frequently trodden, ſo were rendered more unſightly; and as the intention of walks in gardens is to have at all ſeaſons a dry communication through them for exerciſe and recreation, graſs walks were very improper, becauſe every ſhower of rain made them ſo wet, as not to be fit for uſe for a conſiderable time, and the dews rendered them too damp to walk on either in the morning or evening, and if they are not kept conſtantly cloſe mowed, then they become not only unhealthful but troubleſome to the feet; beſides, whenever the ground is ſo dry, as that perſons may with ſafety walk upon graſs, the lawns and other parts of verdure in gardens are better adapted for uſe than any of theſe formal ſtiff walks, which were ſo much eſteemed in the laſt age.

WALK, among horſemen, is the ſloweſt, and leaſt raiſed of all a horſe's goings. It is performed by a horſe's lifting up his two legs on a ſide, the one after the other, beginning with the hind leg firſt. Thus, if he leads with the legs of the right ſide, then the firſt foot he lifts is the far hind-foot, and in the time he is ſetting it down, (which in a ſtep is always ſhort of the tread of his fore-foot on the ſame ſide) he lifts his far fore-foot, and ſets it down before his near fore-foot. Again, juſt as he is ſetting down his far fore-foot, he lifts up his near hind-foot, and ſets it down again juſt ſhort of his near fore-foot; and juſt as he is ſetting it down, he lifts his near fore-foot, and ſets it down beyond his far fore-foot.

WALL, the principal part of a building, as ferving both to inclofe it, and fupport the roof, floors, &c.

Walls are diftinguifhed into various kinds, from the matter whereof they confift, as plaftered or mud-walls, brick-walls, ftone-walls, flint, or boulder walls, and boarded walls. In all which thefe general rules are to be regarded. 1. That the right angle therein depending is the true caufe of all ftability, both in artificial and natural pofition. 2. That the maffieft and heavieft materials be the loweft, as fitter to bear than to be borne. 3. That the walls, as they rife, diminifh proportionably in thicknefs, for eafe both of weight and expence. 4. That certain courfes or ledges, of more ftrength than the reft, be interlaid, like bones, to ftrengthen the whole fabrick.

Brick-walls are the moft important and ufual amongft us. In thefe, particular care is to be taken about laying of the bricks; that in fummer they be laid as wet, and in winter as dry, as poffible, to make them bind the better with the mortar: that in fummer, as faft as they are laid, they be covered up, to prevent the mortar, &c. from drying too faft: that in winter they be covered well to protect them from rain, fnow, and froft, which are all enemies to mortar: that they be laid joint on joint in the middle of the walls as feldom as may be: but that good bond be made there as well as on the outfide. Care is to be taken that the angles be firmly bound, which are the nerves of the whole edifice. In order to which, in working up the walls of a building, it is not adviseable to raife any wall above eight feet high, before the next adjoining wall be brought up to it, that fo good bond may be made in the progrefs of the work; it may be worth notice, that a wall a brick and a half thick, with the joint, will be in thicknefs fourteen inches, or very near; whence one hundred and fifty or one hundred and fixty bricks will lay a yard fquare meafured upon the face of the building; and to the fquare of ten feet are ufually allowed feventeen hundred or eighteen hundred bricks. Flint, or boulder walls, are much ufed in fome parts of Suffex and Kent, for fence-walls, round courts, gardens, &c. A right and left-handed man fits well for this work, as they have a hod of mortar poured down upon the work, which they part between them, each fpreading it towards himfelf, and fo they lay in the flints. The mortar for this work muft be very ftiff.

Of all materials for building walls for fruit-trees, brick is the beft; it being not only the handfomeft, but the warmeft and kindeft for the ripening of fruit; and affording the beft conveniency for nailing, as fmaller nails will ferve in brick than will in ftone walls, where the joints are larger; and if the walls are coped with free-ftone, and ftone pilafters or columns at proper diftances, to feparate the trees, and break off the force of the winds, they are very beautiful, and the moft profitable walls of any others.

In fome parts of England there are walls built both of brick and ftone, which are found very commodious. The bricks of fome places are not of themfelves fubftantial enough for walls; and therefore fome perfons, that they might have walls both fubftantial and wholefome, have built thefe double, the outfide being of ftone, and the infide of brick: but there muft be great care taken to bind the bricks well in the ftone, otherwife they are very apt to feparate one from the other, efpecially when froft comes after much wet.

There have been feveral trials made of walls built in different forms; fome of them having been built femicircular; others in angles of various fizes; and projecting more towards the north, to fcreen off the cold winds: but there has not as yet been any method which has fucceeded near fo well as that of making the walls ftrait, and building them upright. Where perfons are willing to be at the expence, in the building of their walls fubftantial, they will find it anfwer much better than thofe which are flightly built, not only in duration, but in warmth: therefore a wall two bricks thick, will be found to anfwer better than one of a brick and a half: and if in building of garden-walls they are grouted with foft mortar, to fill and clofe all the joints, the walls will be much ftronger, and the air will not fo eafily penetrate, as it does through thofe which are commonly built.

If the walls are built on arches, and the trees planted at thofe arched places, the trees will be thereby enabled to extend their roots underneath the wall, and be greatly benefited, and forwarded in their growth.

It has been hitherto an almoft unvaried practice, to plant all the finer fruits againft walls, without fufficiently inquiring into the motives for fo doing. But it fhould be obferved in the firft place, that the borders under the walls are feldom made fo wide as they ought to be, confidering that the trees which are planted there can extend their roots but one way: and fecondly, that due care is not taken to adapt the quality of the foil there to the nature of the trees; a precaution which ought to be attended to by thofe who are curious in their fruit, and which would coft only the trifling expence of bringing in a fufficient depth of proper earth.

The chief reafon affigned for planting trees againft walls is, the additional heat procured by the reflected rays of the fun, and the warmth communicated to the wall itfelf by the fun. This, fay the advocates for this practice, haftens the ripening of the fruit, and exalts its flavour; befides, that the fhelter of the walls protects trees, natives of warmer climates, from our fevere north and north-eaft winds.

To this it may be anfwered, that it is a conftant obfervation, that all plants brought from a warmer climate to a colder, endeavour to bloom at their ufual feafon, unlefs they are prevented by cold. The confequence of this is, that if the early part of the fpring happens to be warm, the bloffoms of fuch trees fwell, and expand themfelves: but as we cannot be exempted from froft fo foon in the feafon, thefe bloffoms are nipped in the bud; that is, the firft frofty night ftops the circulation in them, and they then neceffarily die. Nothing fhews more inconteftibly the ftoppages of the circulation in trees, than tapping, for inftance, a birch tree, early in the fpring: for the warmth, or coldnefs, of the air at that time may be determined by the greater or lefs velocity with which the juice flows, or by the greater or lefs quantity of it, that is difcharged, almoft as certainly as by a thermometer. In froft, the difcharge ceafes entirely. It therefore is not at all wonderful, that the circulation is interrupted, by the fame caufe, in the finer veffels of flowers, and that the death of the flower is the neceffary confequence. A very fharp froft, even after the early fruits are fet, has the fame effect on their yet tender veffels; and the owner is furprifed to find his fruit fall off, in a few days after, without any feeming caufe; unlefs recourfe be had to I know not what peftilential quality in the eaft wind, when the fame effect would follow, did the froft come from any other quarter. Hence it is evident, that fruit trees would be benefited, rather than hurt, by preventing their too early bloffoming.

Some gentlemen endeavour to guard againft this accident, by fheltering their trees with fkreens, which have a double effect; that of preferving them from the warmth of the fun by day, and that of defending them from the froft by night. But if thefe trees were planted as ftandards, where the air might play freely round them, the motion of the fap would be lefs forward, and the bloffoms would confequently be lefs expofed to the injuries which happen from their coming out too early. They would likewife efcape another great inconvenience which attends their ftanding againft walls; namely, the two great inequality of the heat, as increafed by the wall, and the coldnefs of the night, againft which the wall affords no fhelter, otherwife than as it fkreens the trees from the wind.

A farther reafon which renders walls the lefs neceffary is, that the fruits planted againft them ripen before the fun has acquired its full force in this climate. This is what happens to all our apricots, to moft of our nectarines, and to the fineft of our peaches: for it is well known, that the month of July is our hotteft feafon, and that the heat of that month will therefore the moft perfectly exalt the juices and flavour of fruit.

Walls may indeed be neceffary for the later peaches: though even a Catherine peach will ripen on a ftandard, in a favourable fituation.

All the ftone fruits are accounted peculiarly proper for walls, and fo are many kinds of pears. Some of the finer forts of thefe laft may indeed do well enough when fo planted: but I cannot by any means think the cherry, for example, a proper tree for a wall, becaufe it will not bear the cutting neceffary to train it in that manner. The late pears and peaches are, in my opinion, the only fruits really fit for this ſort of culture. However, for the ſake of thoſe who chooſe to continue to extend it to other kinds, we ſhall obſerve, that peach trees, and thoſe of nectarines, placed againſt walls, ſhould be ſet about twelve feet aſunder: apricots ſhould be allowed a breadth of ſixteen or eighteen feet; cherries and plums, twenty-five feet; and moſt ſorts of vigorous ſhootings pears, from thirty to forty, according to the goodneſs of the ſoil, and the height of the wall.

The root of the tree taken from the nurſery ſhould be placed in a hole dug about five inches from the wall, and its head ſhould be inclined thereto, with the bud turned outwards, to conceal the wounded part of the ſtock. The hole ſhould then be filled up, ſo as neither to leave chaſms between the roots, nor to preſs the earth down too hard upon them. Some of the twigs of the young tree ſhould then be faſtened to the wall, to prevent the wind's diſplacing it ſo as to break the tender fibres of its roots; the ſurface of the ground ſhould be covered with mulch, to keep out the froſt; and in the following ſpring, about the beginning or middle of March, according as the ſeaſon is earlier or later, the head of the tree ſhould be cut down to four or five eyes above the bud, juſt before it begins to ſhoot. In this cutting off the head, the gardener, to avoid as much as poſſible giving any diſturbance to the roots, ſhould ſet his foot down cloſe to the ſtem of the tree, and take faſt hold of the ſtock, below the bud, with one hand, to keep it ſteady, whilſt, with the other, he ſlopes off the upper part gently, with a ſharp knife, at the intended place, which ſhould always be juſt above an eye. This ſhould be done in dry wather; for if much rain ſhould fall ſoon after, and wet get into the wounded part, the tree will be liable to ſuffer conſiderable damage: and for the ſame reaſon, together with its preventing the cloſing of the wound, froſty weather ſhould alſo be cautiouſly avoided. After the tree has been headed, the earth of the borders ſhould be looſened gently, to render it more fit to admit the fibres of the roots, and if the mulch which was laid on in the autumn be rotten, it may be dug into the border, at ſome diſtance from the roots, with all poſſible care not to diſturb or break them. When the dry weather comes on, a few ſods pared off from a paſture ground, and laid upon the ſurface of the border, about the roots of the trees, with the graſs downward, will preſerve a gentle moiſture in the earth, and be leſs apt to harbour inſects, than any ſort of dung or litter.

The above is the uſual method of tranſplanting trees from the nurſery to a wall. But Mr. Miller is convinced, from experience, that, inſtead of taking from the nurſery ſtocks (eſpecially of peaches and nectarines) which have then made one year's ſhoots from the bud, it is better to ſingle out ſuch as were budded the preceding ſummer, and have not made any ſhoot; provided the bud be ſound and plump, and the bark of the ſtock well cloſed at the place of budding; becauſe, when this ſhall have put forth a ſhoot five or ſix inches long, in the following ſpring after being tranſplanted, as it will ſeldom fail to do, that ſhoot may be ſtopped by pinching off its top, and thereby be made to produce lateral ſhoots, which may be trained to the wall, without having any head to cut off, as muſt be done to thoſe trees which have had one year's growth in the nurſery. The benefit of avoiding this operation is particularly great to ſuch trees as are apt to bleed much, and ſingularly ſo to the moſt tender ſorts. The ſtock of the tree tranſplanted in bud, before it has made any ſhoots, muſt indeed be cut down, likewiſe in the ſpring, to juſt above the bud, becauſe this will rarely ſhoot unleſs that be done; and the nearer it is cut to the bud, the ſooner will the head of the ſtock be covered by the bud: for there is no occaſion to leave on trees which are planted againſt a wall, a part of the ſtock, above the bud, to faſten the ſhoots to, as muſt be done with thoſe in the nurſery; becauſe the ſhoots may here be immediately and properly ſecured, by faſtening them to the wall: nor is this cutting off the ſuperfluous part of the ſtock attended with any danger to the bud, if the wound be but covered with a little grafting wax, or clay, to keep out the wet.

No time is loſt, but ſome may be gained, by this practice; as the trees which have ſhot before their being tranſplanted muſt be cut down, and there is a hazard of their ſhooting again.

In watering of theſe new planted trees, which ſhould not be done unleſs the ſpring prove very dry, nor then often, or in great quantity, the pot ſhould have its noſſel on, ſo as to let the water out very gently, almoſt in drops only, as it were; for when it is poured down haſtily, it hardens the ground: and if the head of the tree is watered at the ſame time as its roots, and likewiſe gently, that refreſhing will be of great ſervice to it.

About the middle of May, the ſhoots of theſe trees, of which there will then often be ſeveral ſix or eight inches long, ſhould be nailed horizontally to the wall. All fore-right ſhoots, and ſuch as are weak, ſhould alſo then be rubbed off, to ſtrengthen thoſe that are left. But if no more than two ſhoots have been produced, and thoſe very ſtrong, the tops of theſe ſhould be nipped off at that time; and this will make each of them put out two or more ſhoots, whereby the wall will be the better furniſhed with branches. It will alſo be right to continue to refreſh them gently with water, from time to time, during the whole ſummer, if that ſeaſon ſhould be very dry, leſt their roots, having but little hold of the ground the firſt year after tranſplanting, ſhould be injured by the drought, ſo as to retard the growth of the tree.

In the beginning of October when the trees have done ſhooting, it will be time to begin to prune them. In doing this, the branches muſt be ſhortened in proportion to the ſtrength of the tree; that is, if it be ſtrong, they may be left eight inches long; but if weak, they ſhould be ſhortened to four or five. The ſhoots thus cut ſhould then be trained horizontally to the wall, ſo as to leave the middle of the tree void of branches, for that part will be eaſily furniſhed with wood afterwards; whereas, if the ſhoots are trained perpendicularly to the wall, the ſtrongeſt will draw away the greateſt ſhare of the ſap from the roots, run upwards, and leave the ſide branches ſo deſtitute of nouriſhment, as frequently to occaſion their decaying and dying.

In the next ſummer, when the trees begin to ſhoot, they ſhould be carefully looked over again; all fore-right or ill placed buds or ſhoots ſhould be rubbed off, and ſuch as are to remain, for future branches, ſhould be trained up horizontally to the wall, in due order, as they are produced; for this is the principal ſeaſon in which all fruit trees are beſt and moſt effectually modelled to their intended form. Every gentleman who wiſhes his trees to proſper to the utmoſt, and to grow with as much beauty as they are ſuſceptible of, ſhould therefore perſonally look over them at this time, and, with his own hand, rub off their ſuperfluous buds and ſhoots: for if this elegant and eſſentially uſeful part of gardening is left to the hired gardener, it will often be neglected, or ſlovenly performed. Whoſoever omits it, deſerves not to have good fruit. This important buſineſs ſhould not be deferred till Midſummer, as is the common practice, becauſe numbers of uſeleſs ſhoots, which muſt afterwards be cut off, will by that time have robbed the other parts of their due nouriſhment: and beſides, it is by ſtopping ſome of the ſtronger ſhoots (by nipping off their tops) in May, that they are made to put out ſide ſhoots, which, being guided to the vacant parts of the wall, furniſh every part thereof regularly with proper wood. Care muſt, however, be taken not to multiply theſe branches too much, for fear of weakening the tree ſo as to diſable it for producing good fruit; and therefore no ſhoots ſhould be ſtopped in the ſummer, unleſs there be an abſolute neceſſity for new branches in any particular place. Neither ſhould the branches be laid in too cloſe together againſt the wall, becauſe the great numbers of their leaves then exclude the air from their ſhoots, ſo that theſe are never duly ripened, and the fruit which is afterwards produced on them cannot, conſequently, be ſo well taſted as that of trees whoſe ſhoots receive all the advantages of the ſun and air, to bring them to maturity.

In the third year, the branches till then trained horizontally will have acquired ſuch ſtrength, that there will not be much danger in permitting ſome of their ſhoots to go in a more perpendicular direction, in order gradually to give the whole tree the form of a fan, which is by much the moſt beautiful, as well as the beſt way here, because the wall is thereby most equally filled with wood.

It is in continuing strictly to observe the two foregoing rules, viz. to furnish every part of the tree as equally as possible with bearing wood, and not to lay the branches in too close together, that the art of pruning fruit trees in general, and particularly wall trees, chiefly consists. The former of these will always be completely effected by pinching off the tops of the young shoots, wherever an increase of wood is wanted, in May, as above directed. But as some have advised the doing of this in June, and others even later, we must remark here, that if we reflect that young shoots made so late in the year have not time to acquire a sufficient strength and solidity of fibres to resist the winter's frost, May will certainly be found to be a much more proper season: for whoever casts an attentive eye over fruit trees after a hard winter, will find many of their shoots killed by the preceding frost; and if he looks still more closely, he will see, that most, if not all, of these have been injudiciously forced out in a too late season. It is almost needless to say that April, which others again recommend for this work, is too early; because the wounded branch would then be in danger of being destroyed by a frosty night. If these directions are judiciously followed, it will not be necessary to touch any fruit tree with a knife in the summer: and that the avoiding of this will be of infinite service to every species of them, is manifest from the many accidents to which they are liable when cut too much at that season. All the soft, tender, and pithy wooded sorts, such especially as the peach tree, require a considerable time to heal their wounds, when these are great, and in the mean while wet and rain easily soak into the wounded parts, so as frequently to make the branches canker and die.

As to the distance at which the branches of fruit trees, or rather the shoots of those branches, should be trained against a wall; nature gives us a sure guide, if we but attend to the size of the fruit and of the leaves: for it should be such that neither of these upon an upper branch may touch the branch underneath.

The winter pruning, as it is called, of fruit trees is commonly performed in February or March: but the best season for it is in October, when their leaves begin to fall; for that will be early enough for their wounds to heal before the frost comes on, so that there will be no danger of their being hurt thereby. Thus all the ascending sap in the spring will be employed to nourish only those useful parts of the branches which are left; whereas, if they are not pruned till February, the greatest part of the sap then in motion in the branches, as may be observed by the swelling of the buds, will be drawn up to the extreme parts of the branches, to nourish blossoms which must afterwards be cut off: for the extreme buds of strong shoots always swell sooner than most of the lower ones, and constantly draw from those below.

It is the constant practice of gardeners, founded upon long experience, to prune weak trees early in the winter, that they may be the less endangered by the cutting, and luxuriant trees late in the spring, in order to check their luxuriancy.

WALL-FLOWER, a species of yellow flower, so called from its growing naturally on old walls.

All sorts of wall-flowers, except the double ones, are raised from seeds, either by sowing when the seeds are ripe, or in the spring; those which produce double flowers are raised from slips, which should be planted in a shady situation, either in April or May, which, when sufficiently rooted, may be transplanted where they are intended to blow; these flowers appear in the spring, and are much admired for their fragrancy.

WALLNUT-TREE, the name of a well known tree formerly held in great esteem in this country, for its wood, which is, in fact, often very finely veined; but, on account of its aptness to be worm-eaten, it has of late given place to the beautiful and much sounder mahogany, with which our cabinet-makers have been pretty plentifully supplied from the British settlements in the West Indies.

As an useful fruit tree, independent of its timber, which is, however, still of good value, it merits the husbandman's attention; nor can the gentleman easily find a more stately one to adorn his park with, or to form a noble avenue to his mansion.

These trees are raised from their nuts, which it is best to keep in dry sand, with their outer covers on, till February; that being the right time for planting them. If they are intended for timber trees, they should be sown in the places where they are to remain, in order that the breaking or otherwise shortening of their roots, and especially those of the tap kind, may not stint their growth, and make them run out in branches: but if they are designed for fruit, their fertility will be increased by transplanting them, because their downright roots, which are those that chiefly encourage the luxuriant growth of wood in all sorts of trees, will be thereby checked, and they will be made, in lieu of them, to strike out numbers of lateral roots, which, as experience has proved, always conduce greatly to the production of the largest and fairest fruit. The most proper season for transplanting them is when their leaves begin to decay; and the best age, when they have had three or four years growth in the nursery. Mr. Miller says he has frequently experienced that there is little danger of their succeeding although they be eight or ten years old when they are transplanted: but, however that may be, it is certain that they will root best, grow largest, and last longest, if they are removed young. The less their branches are cut at the time of transplanting, or indeed at any time after, the better they will prosper; for much lopping often causes them to decay: but if there be a necessity for taking off any of their boughs, it should be done early in September, that the wound may have time to heal before the cold and wet comes on. It is likewise essential to cut the branch off quite close to the trunk, lest the stump which is left should decay, and rot the body of the tree; to prevent which, especially if the wound be large, it will be right to smooth it well with a chissel, and then to cover it over carefully with a cement of clay or wax, as in the case of grafting, with a piece of tarpawling, or of sheet lead, over that.

These trees should not be planted nearer together than forty feet, and more may be yet better, if they are designed for fruit. They delight in a firm, rich, loamy soil, or such as is inclinable to chalk or marl; and they will thrive very well in stony ground, or on chalky hills, as is evident from those large plantations near Leatherhead, Godstone, and Carshalton in Surry, where great numbers of these trees planted upon the downs produce annually large quantities of fruit, to the no small advantage of their owners.

In order to preserve this fruit, it should be left upon the tree till it is thoroughly ripe, and then, as it would be exceedingly troublesome to gather it by hand, it may be beaten off, but not with such violence as is commonly used, from a mistaken notion that the tree is improved thereby: for most certainly it cannot be benefited by that rough way of forcing off the young wood upon which this fruit grows. The nuts thus obtained should be laid in heaps for two or three days, after which they should be spread out, and when they have parted from their husks, which they will then soon do, and have afterwards been well dried in the sun, to remove the moisture of their shells, which would otherwise make them mould, they should be laid up in a dry place, where neither mice nor other vermin can get at them. In this manner they will remain good for four or five months: or, which is a yet better way, and will keep them still longer, let them, when their outward moisture has been dried by the sun, be put up in jars, or other close vessels, with dry sand between their interstices. The laying of them for four or five hours in an oven gently heated, as is the practice of some, will indeed dry the germ, and prevent their sprouting: but if the oven is too hot, it will make the kernels shrink, and prevent their being peeled with any tolerable ease.

Were it only for the oil that these nuts afford, the trees which produce them would be worth some care. Mr. Evelyn says that one bushel of them will yield fifteen pounds of peeled kernels, and that these will yield half that weight of oil, which the sooner it is drawn, is the more in quantity, though the drier the nut, the better in quality. He adds, that the lee, or marc of the pressing, is excellent to fatten hogs with. Certainly it would be good manure for land; as are the cakes of lin-feed, rape, &c. after the oil has been squeezed out of them. The green husks boiled, without any mixture, make a good colour to dye a dark yellow. The kernel being rubbed upon any crack or chink of a leaking vessel, stops it better than either clay, pitch, or wax.

The French are very fond of the kernels of these nuts scooped out of the shells before they are hardened, with a short broad brass knife; because iron rusts and communicates a disagreeable taste to the kernels. When scooped out, they are steeped in salt and water for a few hours before they are set upon the table, as well to take off all taste of bitterness, as to make them peel with the utmost ease.

WANG-TOOTH, a jaw tooth.

WANT, a mole. *See the article* MOLE.

WANTY, a broad girth of leather, by which the load is bound upon a horse.

WAPENTAKE, the same with what is commonly called a hundred, and generally used in the northern counties beyond the Trent.

WARBLES, small hard tumours on the saddle part of a horse's back, occasioned by the heat of the saddle in travelling, or its uneasy situation.

A hot, greasy dish-clout at first frequently applied, will sometimes remove them. Camphorated spirits of wine are also very effectual for this purpose to disperse them, especially if a little spirit of sal ammoniac be added to the camphorated spirit. If there be a necessity for working the horse, care should be taken to have the saddle nicely chambered.

WARP, miscarry, slink her calf.

WARREN, a franchise, or place privileged, either by prescription or grant from the king, to keep beasts and fowl of warren in; as rabbits, hares, partridges, pheasants, &c.

By statute 21 Edw. III. a warren may lie open, and there is no need of closing it in, as there is a park.

In the setting up a warren, great caution is to be used for the fixing upon a proper place, and a right situation. It should always be upon a small ascent, and exposed to the east or the south. The soil that is most suitable, is that which is sandy; for when the soil is clayey or tough, the rabbits find greater difficulty in making their burrows, and never do it so well; and if the soil be boggy or moorish, there would be very little advantage from the warren, for wet is very destructive of these animals.

All due precautions must be taken, that the warren be so contrived, that the rabbits may habituate themselves to it with ease. Many would have it, that warrens should be enclosed with walls; but this is a very expensive method, and seems not necessary nor adviseable; for we find but very few that are so, and those do not succeed at all the better for it.

The dung of rabbits is a great fertilizer of useless lands, and Mr. Mortimer tells us that he has known vast crops of rye upon barren lands that have been old warrens well dunged by rabbits; and large oak and ash upon the same, though the soil was very shallow.

WASTE, a name given to such lands as are in no man's possession, but lie common.

WATER, a simple, fluid, and liquid body, reputed the third of the four vulgar elements. Sir Isaac Newton defines water to be a fluid salt, volatile and void of taste: but this definition Boerhaave sets aside, inasmuch as water is a menstruum or dissolvent of salts and saline bodies, which does not agree with the notion of its being a salt itself; for we do not know of any salt that dissolves another. This last-mentioned philosopher, therefore, defines water, a very fluid, scentless, tasteless, transparent, colourless liquor, which turns to ice with a certain degree of cold.

Though water be defined a fluid, it is a point controverted among philosophers, whether fluidity be its natural state, or the effect of violence. We sometimes find it appear in a fluid, and sometimes in a solid form; and as the former, in our warmer climate, is the more usual, we conclude it the proper one, and ascribe the other to the extraneous action of cold.

Boerhaave, however, asserts the contrary, and maintains water to be naturally of the crystalline kind; since, wherever a certain degree of fire is wanting to keep it in fusion, it readily grows into a hard glebe, under the denomination of ice. Mr. Boyle is of the same opinion. Ice, he observes, is usually said to be water brought into a preternatural state by cold; but with regard to the nature of things, and setting aside our arbitrary ideas, it might as justly be said, that water is ice preternaturally thawed by heat.

If it be urged, that ice, left to itself, will, upon the removal of the freezing agents, return to water; it may be answered, that (not to mention the snow and ice which lie all summer on the Alps, and other high mountains, even in the torrid zone) we have been assured, that in some parts of Siberia, the surface of the ground continues more months in the year frozen by the natural temperature of the climate, than thawed by the heat of the sun; and a little below the surface of the ground, the water which chances to be lodged in the cavities there, continues in a state of ice all the year round; so that when, in the heat of the summer, the fields are covered with corn, if you dig a foot or two deep, you shall find ice and a frozen soil.

Water is generally divided into salt and fresh, with regard to the ocean and rivers. But, according to Dr. Shaw, it seems divisible into as many different species, as the earth is into beds. Thus there are mineral waters of various kinds, according to the mineral substance they run over, and become impregnated with; though this impregnation sometimes happens in the way of vapour and exhalation. Water, therefore, in general, may be as mixed a body as earth, and perhaps neither of them naturally exists in any considerable purity.

In a general analysis of water, the doctor found, 1. That common warm water throws up numerous little bubbles, and explodes, in the exhausted receiver of the air-pump; for which reason, water contains what may, by way of distinction, be called æther or spirit.

2. It contains a merely aqueous part, distinct from æther and the sediment, as appears from distilled common water.

3. It contains a dry solid matter, which is either earthy or saline, as appears upon a full evaporation, and from the insides of tea-kettles, which, after long use, are lined with a stony matter, that beats off in flakes or crusty pieces.

Water is not only contained in the earth as in a reservoir, but likewise floats in the atmosphere. In both cases, it is actuated, rarified, and put in motion by heat, so as to prove instrumental in producing effects. Thus it produces clouds, rains, dews, springs, and rivers. It refreshes the earth, recruits vegetables, and is the support of fish and other animals by conveying nutriment to all their parts. It is also the first and immediate instrument of fermentation, putrefaction, corruption, and change in all vegetable and animal subjects.

But the nature and uses of water, will best appear from the following experiments:

1. That water is contained in many solid bodies, and to appearance in dry bodies, was proved thus: a piece of the hardest and driest bone being procured, and distilled in an earthen retort, with degrees of fire, a very large proportion of water, along with much oil and volatile salt, was obtained: whence it appears, that animal matters are resolvable into the four chemical principles, water, oil, salt, and earth. This experiment holds true even of the oldest hartshorn, the driest and hardest woods, earths, and pulverized stones.

Whence it also appears, that water may be concealed in solid bodies, and make a constituent part thereof: for it is not meant that water insinuates itself into the superficial pores of bodies, such as wood, skins, &c. so as to swell them in moist weather, and leave them shrunk in dry; but that it remains permanently intermixed as an essential ingredient, or as a part of solid bodies. *See* BODY.

2. That water may be collected from the driest air, or in the hottest climate, was proved by the following experiment:

Half a pint of common water was put into a cylindrical glass, wiped perfectly dry on the outside; then was added to the water, two ounces and three quarters of pulverized and feems rational: for the water then, not only fupplies the moifture wanted in the earth, but it diffolves every fubftance foluble in water, and thereby converts to an additional manure, what might otherwife have remained long in its original ftate. Care fhould, however, be taken, to drain off the water before the feafon of ftrong frofts is expected; becaufe froft is obferved to deftroy all kinds of vegetables much more when the plants are full of fap, than when they are in a dryer ftate. We may eafily comprehend that it muft have this effect, when we confider with what force it breaks every veffel containing water expofed fo as to be frozen: for froft dilates all fluids to fuch a degree, that the veffels in which they are muft be broken thereby. Hence it is that fucculent plants foon become a putrid mafs after a hard froft: and thus it is that the ftrongeft trees are fometimes burft with a loud report.

When the water is brought to the defired height, the main channel fhould be cut, with fuch a defcent as only juft to keep the water in a gentle motion. That channel fhould be made in the higheft part of the pafture, and proportioned to the quantity of water neceffary to be introduced. If a hollow intervenes between the place at which the water is brought into the field, and another rifing ground in that field; it will be worth the farmer's while to convey it a-crofs that hollow, by pipes made of wood, or any other fubftance, laid either horizontally over that hollow, or underneath it. The motion of the water in this horizontal channel fhould be different, according to the quality of the ground. If it is a ftrong earth, the channel may be cut nearly horizontally: but if it is a light loofe foil, a quicker current fhould be given to the water, in proportion to the degree of lightnefs of the earth; or great part of the water will otherwife be loft, by finking into it. In a light foil of this kind, it may be proper to line this main channel with brick or ftone, well cemented with lime, to hinder the water from efcaping through the crevices; or at leaft to cover it with clay well rammed. As to the degree of defcent moft proper for the main channel, in order to give a current to the water, M. Bertrand, to whom we owe one of the ingenious differtations on this fubject in the memoirs of the Berne Society, obferves, that Vitruvius required fix inches in an hundred feet, which is a great deal too much: but that the moderns, who have made the moft exact experiments in this refpect, are fatisfied with two inches in fix hundred feet, when they cannot have more, and recommend particularly the avoiding of all fharp angles in the winding of the channel, and the making of its bottom quite fmooth and even. He adds, that this is nearly the declivity of the aqueduct of Rocquancourt, by which the water is conveyed to Verfailles; the diftance there being three thoufand four hundred yards, and the flope, in all, only three feet.

The main channel fhould be of breadth, rather than depth, fufficient to receive all the water that is intended to be conveyed through it, and that breadth fhould leffen gradually as the water is carried off in leffer channels, in order that the water may prefs into thofe fmaller ducts, which are to iffue all along from the chief. The leffer channels fhould be as fhallow, and as numerous, as can be: for the more equally the water is diftributed over the grafs, the greater will be the improvement. They fhould be made particularly wherever the water collects itfelf into a ftream: for though cutting fo much turf may feem to wafte a great deal of land, yet it proves not fo in the end; becaufe the quicker the water runs over the grafs, the more it benefits the pafture.

To keep the channels in repair, they fhould be frequently cleaned, efpecially after every cutting of the hay. The flime then taken out of them fhould be fpread upon the pafture, and the next growth of the grafs will be greatly improved thereby. Care fhould alfo be taken to have drains to carry off the water, fo that none of it may ftagnate upon the land.

The beft way of watering a flat meadow, which is ufually furrounded with a ditch, is to ftop the out-let of the ditch, and, by bringing in a quantity of water, to overflow the whole meadow, for fuch time as fhall be judged neceffary to moiften the earth fufficiently: but the water fhould not be continued upon it fo long as to wither the grafs. If this can be done in a rainy feafon, it will be fo much the better; becaufe the water will then be loaded with the enriching mud and flime wafhed down from the higher grounds.

The firft heavy rains which fall in the latter end of the autumn, and which carry with them the rich particles of putrified animals and plants, are thought to be more fertilizing than at any other feafon of the year, and are therefore brought into the pafture, as often as the abfence of the cattle fed on them will permit.

The next beft to rain, is clear and fweet fpring water, flowing from a copious fource. Here it is generally objected, that fpring water is hard, and therefore not fit for the nourifhment of plants. But Dr. Home, who judges otherwife, expreffes himfelf thus on this very occafion. "Is not hard water more nourifhing for vegetables than foft water? I imagine that the falt of vegetables enters their veffels in fuch a form as hath the falt which is found in hard waters. The falt of hard waters feems likewife to be of the nitrous kind, of which the nourifhment of plants is alfo fuppofed to be. This query thwarts the general opinion; for no gardener will make ufe of hard water, if he can avoid it. I watered fome plants with it, and thought that they grew better than thofe which were watered with foft water."

This is confirmed by an ingenious correfpondent of the Berne Society, who made feveral experiments on the qualities of different waters, and found that their greater or lefs hardnefs made very little difference in their effects, when ufed for watering of paftures. The water of an excellent fpring, which, upon trial, was found to be hard, fertilized greatly the pafture upon which it was let in.

Spring water may be ufed later in the winter, than any other, becaufe, being warm, a mild froft will not freeze it, even when expanded on the pafture. It fhould however be turned off foon enough to let the earth become a little dry before fevere frofts fet in. It may likewife be ufed earlier in the fpring, than other waters, and to better advantage, by reafon of the warmth which it communicates to the ground where it flows: and it becomes extremely proper in the fummer, becaufe it cools during the night (the only time for watering at that feafon) the heated foil, and grafs fcorched by the power of the fun.

The equal warmth of fpring-water, is what renders it peculiarly ufeful for watering paftures. The laft quoted correfpondent of the Berne Society tried its heat, in Swifferland, on the twenty-fixth of May, when the earth had been very little warmed by the fun, after a long winter's cold. He then found M. de Réaumur's thermometer, placed in the fpring of water, ftand at eight degrees and a half (equal to forty-feven and a half of Farenheit's) above the freezing point. On the fifth of July, in the evening, when the heat of the air was very great, Réaumur's thermometer, again placed in the fpring, ftood at nine degrees and a quarter (equal to forty-nine of Farenheit). He afterwards tried whether the warmth of the fpring was confiderably increafed towards the end of the fummer, when the earth was extremely heated: but even then, Réaumur's thermometer fcarcely reached ten degrees (equal to about fifty of Farenheit's). By this we fee, that fprings which yield a full and conftant ftream vary very little in their degrees of warmth.

For the fame reafon it alfo is, that a perpetual verdure reigns around fuch fprings, even during the hardeft froft; and if their water could be preferved from freezing when fpread over a field during the winter, it would be right to let them in upon paftures in that feafon: but as they foon lofe their heat when difperfed over the grafs, this is by no means advifable.

Experience has taught the inhabitants of the Alps (and the fame will hold equally true in all mountainous countries), that it is not advifable to water paftures with the floods which arife from melted fnow, or with the water of rivers fed thereby. One reafon which feems to render the water that defcends from mountains perpetually covered with fnow the lefs ufeful for watering paftures, is, that as all vegetation is at a ftand in fuch places, no vegetable matter can be mixed with this water; and it therefore cannot communicate the fertility which arifes from waters fraught with thofe rich fubftances.

We are frequently told of correcting the crudity of water, by making it turn a wheel, or putting it otherwife in-

to violent motion: but I know not what good effect this can have.

What are commonly called barren springs, are sometimes corrected by mixing dung with their water in ponds made higher than the pasture intended to be watered. Yet this, though an old custom, is liable to some objections; one of which, in particular, is, that the water will deposit its richness on the first part of the pasture over which it flows, and therefore improve the grass very unequally. But if dung has this effect, it will answer equally well, if it be spread upon the land. Care should, indeed, be taken, that the current of the water be very slow over a pasture newly dunged; because the fertilizing particles of the dung may otherwise be carried off by the stream, before they can have had time to penetrate into the earth.

When dung, marle, or lime, is laid on a pasture which has a considerable descent, the best way is to lay a larger proportion on the higher parts; because the common rain water will wash some of their richer particles down to the lower.

As clayey soils retain water, and by that means chill the plants growing on them, they are the least fit for watering of any. If the water abides on them, they become poachy; and when dried again, they gape, and become so hard that no plant can pierce them. Some sensible farmers have likewise observed, that their clayey lands have always yielded less grass in wet years, than when the season has been dry; which is a manifest proof that a soil of this kind does not admit of watering, unless it be a little, in case its surface is become hard after the hay has been taken off, or when the grass is short. Such lands are fitter for arable, if their situation permits it.

Hazel earth, which is a loam mixed with gravel, and of a clayey nature, is the strongest soil that can be watered with propriety: and that this has been surprizingly benefited thereby, is evident from several instances given in the Memoirs of the Berne Society, even of large tracts of such ground that have been vastly improved by this means: but I shall mention here only the following.

" In the summer of 1758, part of the pasture ground belonging to a farmer in Swisserland was so entirely covered with stones and gravel, by the sudden overflowing of a stream, that it looked like a bank of sand. As the removing of this quantity of stones and gravel would have cost a great deal of labour and expence, the owner of the land carried off only the largest stones, and threw over the gravel a reddish earth taken from a neighbouring hill; but so thinly spread, as only to fill the interstices between the pebbles, without entirely covering them. He then sowed this spot with hay seeds, and let in upon it the waters of an adjacent spring and a neighbouring rivulet. These waters were let in sparingly at first, till the grass began to appear, and after that they were flowed more abundantly. The consequence of this prudent conduct was, that the grass thus raised bore cutting once the first year, and after having been moved twice in the second, promised an excellent after-math at the time when this account was written, which was in the beginning of the autumn of that second year. The very first year's crop grew so prodigiously, that the grass was lodged, even though the pebbles were then felt under foot, if one trod upon it." *See the article* MEADOW.

When the land is above the level of the adjacent water, recourse must be had to some engine to raise it to a proper height, in order to overflow it; though this will be attended with a very considerable expence, especially at first.

The oldest instrument used for this purpose is known by the name of Archimedes's water screw, and is thus described by Mr. Emerson.

C *p* D (Plate XXVII. Fig. 1.) is a cylinder which turns upon the axis C D. About this cylinder there is twisted a pipe, or rather several pipes, *m*, *pq*, running spiral wise from end to end. This cylinder is placed higher at one end, D, than at the other; and its use is to screw up the water from the lower end to the higher. A B is a river running in the direction A B. *a*, *b*, *c*, *d*, are several floats fixed to the cylinder. E F is the surface of the water. As the cylinder stands in an inclined position, the upper floats *a*, *b*, are set out of the water, and the under ones *c d* within it: so that the water acts only upon the under ones *c*, *d*, and turn about the cylinder in the order *a*, *b*, *c*, *d*. By this motion, the water taken into the spiral tubes at the low end is, by the revolution of the cylinder, conveyed through these pipes, and discharged at the top into the vessel G. If A B is a standing water, there is no occasion for the floats *a b c d*; and then the cylinder is to be turned by the handle at D. Instead of the pipe, a spiral channel may be cut round the cylinder, and covered close with plates of lead. The closer these spiral tubes are, the more water is raised: but it requires more force. Also the more the cylinder leans, the more water it carries; but to a less height.

Where a considerable quantity of water is to be raised, a greater force is requisite, than can be applied to such a handle. Her royal highness the princess dowager of Wales has caused an instrument of this kind to be erected at Kew, by the ingenious Mr. Smeaton, and by means thereof a sufficient quantity of water is supplied, for all the ponds, and other uses, in that elegant and extensive garden: but it is there worked by horses.

The most common engine for raising water is the Persian wheel, of which Mr. Worlidge gives the following description.

" This wheel is made much after the manner of that of an under-shot mill, viz. with a double ring, into which are let two pins, on which the floats are fastened. These floats are made hollow; the half that is the most remote from the wheel, holds the water which is taken in at the open place, above the middle of the back of the float, and as the wheel goes round, and the float laden with water rises, so the water, by degrees, tends towards that part of the float which is next the wheel, and as the float surmounts the cistern or receiver, the water empties itself into it, every float succeeding the one the other, emptying itself into the receiver: so that if one float contain a gallon of water, and there be thirty floats on the wheel, at one motion round it delivers thirty gallons of water into the cistern. Such a wheel will be about fifteen foot diameter, the floats at eighteen inches distance, and will deliver the water at eleven or twelve foot above the level of your stream, and will go four times round in one minute, and carry up about one hundred and twenty hogsheads of water in an hour, with twelve or eighteen inches penning or stopping of but an ordinary current of water which will water very well thirty or forty acres of land: for if your land be cold and clayey, too much water does it hurt; and if it be light, warm, or sandy, a little water does it much good. It is also to be observed, that this motion is constant, and will last many years without repair, so that it stand not still, for one side to dry and wax lighter than the other: also observe, that the slower it moves, the better it delivers the water.

" The view of this wheel we have in Plate XXVII. Fig. 2. *aaaa* signify the wheel; *b*, the cistern that receives the water; *cc*, the trough standing on tressels, that conveys the water from the cistern to the place you desire; *d*, the hatch, or pen-stock that bays up the water to a reasonable height, under which the water drives the wheel; *e* (Fig. 3) one of the floats presented open to your eye, apart from the wheel; *f*, the place that is to receive the water; *g*, the open place out of which the water issues; *hh*, the two pins or ledges riveted on to the foreside of the float, and wherewith you are to fix the float to the two rings of the wheel. These, or such like wheels, are much used in Spain, Italy, and France, and are esteemed the most easy and advantageous way of raising water in great quantity, to any height within the diameter of the wheel, where there is any current of water, to continue it in motion, which a small stream will do.

" How many acres of land lie on the declining sides of hills, by the sides of rivers, in many places where the water cannot be brought unto it by any ordinary way? yet by this wheel placed in the river, may the land be continually watered, so far as is under the level of the water when raised."

Instead of raising the water by means of the hollow floats placed around the outer circumference of the rim of the wheel, as here described; M. Belidor proposes, for wheels of kind, to raise it in buckets placed at equal distances upon the side of the rim of the wheel, and suspended by a pin, upon which they play, as at A Fig. 4. When, by by the rotation of the wheel, one of these buckets comes to B, which is the summit of the wheel, the upright piece D, which is fastened to the side of the trough C, turns that bucket upon its side, and thereby makes it empty itself into the trough C, from whence the water is discharged into a receiver at E. — As these buckets keep full of water till they are carried up to the top of the wheel, where they are turned over, a much greater quantity of water may, undoubtedly, be raised by them, than can be by the floats of the Persian wheel, from which much must be spilled as it is carrying up. The size of these buckets should be adapted to the force of the current of the water which they are to take up.

Another wheel for raising water, though not to so great a height, is represented in Fig. 4. This engine was first invented by M. de la Faye of the Royal Academy of Sciences at Paris, and is now used with great success by the honourable Mr. Hamilton, at his seat at Pain's-hill in Surry, where that gentleman has shewn how far a barren spot may not only be rendered useful but even an ornament to the adjacent country.

This machine consists of a wheel whose size is adapted to the height to which it is intended to rise the water. A perspective view of this machine is represented Fig. 5. and its internal parts Fig. 6. The wheel turns upon its axis at A, and has several curved pipes, B, C, D, E, fixed to it, as represented in the figures. The mouth of each pipe ascends as the wheel is turned round by the stream, in the direction indicated by an arrow, and the water descends from C towards F, till it reaches the hollow axis, A, A, from the opening at the end of which it is discharged into the trough G, and thence conducted by troughs, as H, or other channels, to whatever place it may be wanted.

But if there be a necessity to raise the water higher than the axis of the wheel, we would recommend an ingenious machine, used for above twenty years at Zurich, for supplying a large dye-house there with water from the Limmat, and of which a description in the German language appeared in the third volume of the Zurich Acts, from whence the following account is translated.

The wheel itself differs little in appearance from other water-wheels. Its diameter, exclusive of the ladle-boards is not quite three feet. It is coated all over with tin plates, and forms a short cylinder, or rather drum, of the above diameter, and one foot thick. On its periphery the ladle-boards are fixed, as in other under-shot water-wheels, and by means of which it is put in motion by the stream. It turns on a hollow axis (like the last machine) of proportional thickness and length, and has one of its flat sides applied against a projection, or ledge, made round the axis, to which it is pressed close, and held fast by a wedge driven through the axis at the other side. That part of the axis which passes through the wheel is square, that the wheel may not slip, or be able to turn, without turning the axis with it: the remaining part of it is round. The wheel is hung in the water to about one third of its height, and supported in a moveable frame, so that it can be lowered, raised, or even taken out of the water at pleasure. In the periphery of the wheel are holes, by which the water enters. The axis turns as usual, on two pivots, one of which is of brass, considerably larger than the other, and hollow from end to end, communicating with the canal in the axis. The hollow pivot, which may be considered as a brass pipe, has its end fitted close to a leaden pipe, in which it turns. The leaden pipe, by a double bending, is confined to the wall of the dye-house, where it is bent perpendicularly upwards, and rises along the wall to the height of ten feet above the axis; it is there bent again under the eaves, and continued into the dye-house itself.

The singular and remarkable operation of this little wheel depends solely on its internal structure. The water entering at the circumference of the wheel, runs in a square spiral canal, which passes round the wheel, and consists of a number of circumvolutions, within one another, like the spring of a watch, till at length it comes into the axis. A necessary condition here is, that each of the inner circumvolutions be of the same magnitude with regard to their content, as the outer one; or that the width of the spiral canal be gradually enlarged in each circumvolution, in proportion as the diameter diminishes; that is, the bore of each of the inner spirals must be to the bore of the outer one, as the diameter of the latter is to the diameter of the former.

The wheel thus furnished with its spiral canal, is to be hung so deep in the river, that half a spiral, at least, may, in each revolution, be filled with water. To keep it in this state it would be necessary to immerse it to the axis, or further: but as its motion, at such a depth, would be extremely slow, a kind of scoop is made at the outer opening of the spiral pipe, which takes up so much water at once, as is sufficient to fill the due proportion of the outermost spiral in one revolution. One half of the outer spiral being thus filled with water, the other half remains filled with air: as the wheel turns the water and air pass into the second spiral, then into the third, fourth, and so on, till a sufficient number of turns brings the water and air to the axis, from whence they pass into the upright pipe, as already mentioned: thus the entrance and discharge of water continue without intermission, so long as the wheel is kept in motion. When the wheel scoops up just the proper quantity of water, and turns with due velocity, the water may be forced up in the perpendicular pipe to a height equal to the sum of the diameters of all the circumvolutions of the spiral canal.

If we consider the operation of this machine, we shall easily see the necessity of the inner circumvolutions being made to widen in the proportion above mentioned; and that, without this condition, the water passing from the large outer spiral, would be crouded and retarded in the inner, and in great part forced back.

It is also obvious that just half of one of the spirals must be filled with water at each revolution, for if less be taken in, there will be a diminution in the quantity delivered, and if more, it will be pressed too much together, and its quantity also diminished.

The velocity with which the wheel moves, or the number of revolutions it makes in a given time, is another essential point in regard to the quantity of water, and may considerably influence the quantity of water necessary to be raised. When this is known, and the height determined, it will be easy to construct a wheel in such a manner, as to answer the purpose intended.

We shall conclude our account of this ingenious contrivance, with the following directions for constructing it. The two flat sides of the wheel should be made of two strong circular pieces of good oak, the inner sides of which must be planed as smooth as possible, and fitted to one another; and to keep them from bending or warping, secured by pieces on the outside. The plan of the spiral lines is represented in Fig. 7. Plate XXVII. These spiral lines being marked out on the wood, a groove must be cut about a quarter of an inch deep, in order to make a channel for the partition, which must be formed of a thin piece of copper. The channel being filled somewhat more than half with good cement that will bear water, the piece of copper must be set in regularly, care being taken to keep the cement warm, or previously to heat the metal. The scoop also, which at every revolution of the wheel takes up a proper quantity of water from the river, may be made of the same metalline plate. The piece of copper for forming the partition must be cut at first exactly strait, and of an equal breadth throughout. This work being finished, the wheel must be put on the axis as far as the ledge made for it to rest against, and cemented. The second piece of wood requires little preparation: some cement must be spread all over it, and the whole surface covered with a thick piece of woollen cloth, which must also be done over with cement on both sides: while the whole continues warm, it must be put on the axis, and pressed close to the other part of the wheel, so as to cover the as yet open side of the spirals. The two parts are held firm together, by means of a wedge or key passing through the axis, and a proper number of screws, placed round the circumference: these screws are strong iron pins, somewhat longer than the wheel is thick, and a nut, when they are placed through the wheel, is screwed on the other. Thus the inside of the wheel, or drum is finished. The disposition of the ladle-boards, the shape of the axis, and the structure of the frame by which the machine is supported, will be partly understood from what has been already said, and more fully from Fig. 8. Plate XXVII.

It has been already obferved, that the wheel in the limmat is covered with tin plates; but this is of little or no confequence. It is however advifeable not to have one large opening, for the entrance of the water, but either a perforated plate, or a wire-grating nailed before it, in order to prevent weeds, or any other filth from paffing into the fpiral tube, and preventing, if not wholly ftopping, the courfe of the water.

The frame or fcaffold in which the wheel hangs, and the means of raifing or lowering it in the river, without difturbing the courfe of the water in the machine, deferves particular notice. It is plain from Fig. 8. that the wheel refts on two arms, which, for the greater fecurity, are bound together by crofs-pieces. At the fore-end they are both fufpended by iron chains, which pafs over a roller fo as to be wound off or on: on the other end they move on two ftrong joints or hinges. The communication of the leaden pipe, with the brafs one, or hollow pivot, at the end of the axis, is drawn on a larger fcale, in Fig. 9. This pipe is bent clofe by the pin, to a right angle, and goes horizontally along one of the arms of the frame as far as the hinge, (fee Fig. 8.) where it is again bent to a right angle, oppofite to the dye-houfe, and communicates in the fame manner as the hollow pivot of the axis, with another horizontal pipe, in which it moves round freely, without any impediment to the paffage of the water, in raifing or lowering the wheel. This large pipe paffes under a ftage built along the wall of the dye-houfe, and thence up the wall, where it diftributes the water in the manner reprefented in the figure.

But though water is fo neceffary to the growth of plants, yet in lands that abound with it, there is a neceffity for conveying it away, the beft methods for doing which the reader will find under the articles Bog, Drawing, Moor, &c.

Water-Farcy, a difeafe incident to horfes, and is of two kinds; one the product of a feverifh difpofition terminating on the fkin, as often happens in epidemical colds; the other is dropfical, where the water is not confined to the belly and limbs, but fhews itfelf in feveral parts of the body, by foft fwellings yielding to the preffure of the finger. This laft kind ufually proceeds from foul feeding, or from the latter grafs and fog, that often comes up in great plenty with continued cold rains, and breeds a fluggifh vifcid blood. In the former cafe, I have feen the limbs and whole body enormoufly fwelled, and very hard, the belly and fheath greatly diftended; which were as furprizingly reduced in four and twenty hours, by flight fcarifications within fide the leg and thigh, with a fharp penknife, and three or four ftrokes on the fkin of the belly on each fide the fheath; from thefe fcarifications there was a conftant and furprizing large dripping of water, which foon relieved the horfe; when a few purges compleated his recovery.

In the other fpecies of dropfy the curative intentions are to difcharge the water, recover the crafis or ftrength of the blood, and brace up the relaxed fibres throughout the whole body. To this end, purge once a week or ten days; and give intermediately either of the following drinks, or balls.

> Take black hellebore frefh gathered, two pounds; wafh, bruife, and boil in fix quarts of water, to four; then ftrain out the liquor, and put two quarts of white wine on the remaining hellebore, and let it infufe warm forty-eight hours; then ftrain off, mix both together, and give the horfe a pint night and morning.

> Take nitre two ounces, fquills powdered, three drams, or half an ounce; camphor one dram, honey enough to form into a ball, to be given once a day alone, or wafhed down with a horn or two of the above drink.

> Take of the leaves and bark of elder, of each a large handful; chamomile flowers half a handful, juniper berries bruifed two ounces; boil in a quart of water to a pint and a half, to which add honey and nitre, of each one ounce.

Give this drink every night, or night and morning; and to compleat the cure, and ftrengthen the whole body, give a pint of the fubfequent infufion every night and morning, for a fortnight, fafting two hours after it.

> Take gentian root and zedoary, of each four ounces; chamomile flowers and the tops of centaury, of each two handfuls; Jefuits bark powdered two ounces; juniper berries four ounces; filings of iron, half a pound: infufe in two gallons of ale for a week, fhaking now and then the veffel.

Before we clofe this article, we think proper to lay down the fymptoms of an incurable farcy, that the owners of fuch horfes may fave themfelves unneceffary expence and trouble in their endeavours to obtain a cure.

When a farcy by improper applications, or by neglect has fpread and increafed; or after long continuance refifted the medicines above recommended; if frefh buds are continually fprouting forth, while the old ones remain foul and ill-conditioned; if they rife on the fpines of the back and loins; if the horfe grows hide-bound, and runs at the nofe; if abfceffes are formed in the flefhy parts between the interftices of the large mufcles; if his eyes look dead and lifelefs; if he forfakes his food and fcours often, and his excrements appear thin, and of a blackifh colour; if the plate, or thigh vein continue large after firing, and other proper applications: thefe fymptoms denote the diftemper to have penetrated internally, and that it will degenerate into an incurable confumption: it is alfo moft probable, that the whole mafs of fluids are tainted, and become incurable by art. *Bartlet's Farriery, pag.* 193.

WATTLE, a kind of hurdle formed with fplit wood, and ufed for making folds for fheep.

WAX, *or* Bees-Wax, a fubftance formed by bees from the farina of flowers. *See the article* Bee.

WAY-BREAD, plantain.

WEANEL, an animal newly weaned.

WEED, any plant growing in a field different from what the farmer intended.

There is not a field where we do not find fome of thefe; they grow in the greateft plenty on the richeft foils.

Weeds will appear impediments to vegetation, if we confider the following particulars.

They rob the plants we defire to cultivate of their food; they prevent thefe plants from branching out from the root, and they leffen the vegetable pafture in the land where they are fuffered to grow.

Weeds are nourifhed by the fame food that would nourifh ufeful plants; and therefore, when allowed to grow along with them, muft rob them of part of their food. Although it is allowed, that the food of all plants is not exactly of the fame kind; yet as plants fuck in whatever juices, or fmall particles of matter are touched by their roots, it may be juftly faid, that all kinds deprive the earth of that vegetable food which would nourifh others. Experience convinces the farmer of the truth of this: for he finds, that his crop is bad in proportion to the quantity and kinds of weeds with which his land is infefted.

Weeds cover the furface of the land on which they grow, and thereby, confining the plants we defire to cultivate, prevent them from branching out from the root. For all plants, when confined by others at their fides, inftead of branching out, as fome of them are inclined to do, make vigorous efforts to get above thofe by whom they are confined.

Some perfons have attempted to fhow, that corn never wants room to grow; and that it is the want of food alone which makes fome plants decay, when they are fet too thick. If this is true, weeds can do no harm to plants, by covering the furface, and confining them while they grow. But let a perfon caft his eyes upon a plantation of any kind, and he will immediately obferve, that where the plants are placed very near to each other, they ftretch out chiefly to the length; and where they are placed at a greater diftance, they grow not fo much to the length, but more to the thicknefs, and branch out on all fides. So that the proportion of nourifhment which the plants receive, makes them grow either to the length principally, or to the thicknefs, and branch out, according as they are placed near, or at a diftance from each other. The fame thing happens, when there are many weeds growing amongft corn. Some fields are fo much infefted with weeds, that, though no grain is fown, the plants come up very thick.

thick. This obliges the farmer to give plenty of feed: in confequence of which the furface is quite covered; and the plants of corn being confined by the weeds, inftead of branching out from the root, and producing two or more ftalks, as they are naturally difpofed to do, pufh up one ftalk only, that fo they may the more eafily get above their rivals. The proportion of nourifhment which they receive, makes them grow to the length, inftead of branching out from the roots; makes them produce one ftalk and ear only, inftead of many. Experience confirms the truth of this. When land is rich, and at the fame time much infefted with weeds, the plants of corn grow tall enough; but feldom have more than one ftalk.

Some kinds of weeds have great numbers of fmall roots, which they extend to a great diftance. Thefe roots bind the foil in fuch a manner, as to leffen the vegetable pafture; or rather, make it very difficult to enlarge it by tillage. It may be obferved, that when a field is much infefted with quickening grafs, the foil is fo firmly bound together by the roots, that it is not poffible to pulverize it. When ploughed, the earth of the furrow is turned over whole, and the harrows fcarcely make any impreffion upon it.

It is of great importance, therefore, to know how to deftroy thefe ufelefs and noxious plants, that fo all the vegetable food in the foil may be applied to the nourifhment of the ufeful plants we defire to cultivate; that thefe ufeful plants may have room to extend themfelves, and branch from the root on all fides; and that the vegetable pafture, which, by the rain that falls, and the natural weight of the foil, is always leffening, may be the more eafily enlarged.

Different kinds of weeds.

Plants are commonly divided into two forts; annuals, that is, fuch as in one year come to perfection, carry feed, and die; and perennials, that is, fuch as continue in life for more years than one. Annual plants are almoft all propagated by the feed. Perennials are propagated, fome by the feed, others by the root, and a third fort both by the feed and root.

Weeds may be divided in the fame manner, into annuals and perennials. But, in treating of the methods of deftroying them, we will be better underftood, if they are divided into thefe two forts; weeds that are propagated by the feed, and weeds that are propagated by the root. It is needlefs to confider the weeds that are propagated both by the feed and the root, as a third fort. For when their feeds infeft the land, they muft be treated as weeds that are propagated by the feed; and, when their roots infeft the land, they muft be treated as weeds that are propagated by the root. It is neceffary, however, to divide weeds into thefe two forts, into which we have divided them: for, in fome cafes, that kind of management proper for difcouraging the one fort, tends to encourage the growth of the other.

But, befides thefe two forts of weeds mentioned, it will not be improper that we likewife take notice of thofe fhrubs by which fome land is greatly infefted. Thefe, though they are not commonly reckoned in the clafs of weeds, and though fome of them may have their particular ufes; yet, as they are plants different from what the farmer defires to cultivate in his fields, they fall under the definition which we have given of weeds, and fhall be reckoned by us a third clafs.

Methods of deftroying weeds.

The deftroying of weeds is certainly one of the moft important parts of agriculture. By allowing them to grow, we allow the land, as was formerly obferved, to be robbed of its vegetable food, and its vegetable pafture to be greatly leffened.

It may be inquired, what becomes of this vegetable food of which they rob the land? it is either conveyed to the air, and fent to enrich other land, or it is turned into a form that renders it deftructive.

When weeds wither and putrefy above ground, the falts and oils which they contain, and of which they deprived the land on which they grew, become volatile, and fly off into the air, and leave little more than their earth remaining.

When weeds carry feed, and fhed it upon the land, and when the roots, by the nourifhment they receive, are enlarged and extended; the vegetable food, of which they have deprived the land, is turned into a form that renders it deftructive, into feeds and roots, by which the land is further exhaufted.

The feeds and roots of weeds, though deftructive to ufeful plants, by robbing them of their food, yet they contain vegetable food in themfelves; and, when the feeds are picked up by birds, and the roots eaten by animals, the vegetable food is carried off. But, if thefe weeds are deftroyed, and reduced to a ftate of corruption, the vegetable food, which they have taken from the land, and rendered deftructive, is reftored to it, and becomes beneficial: fo that land that is poor, and unfit for carrying crops of ufeful plants, by being full of weeds, may be made rich and fertile, by deftroying them.

From thefe things it appears, that the deftroying of weeds is one of the moft important parts of agriculture. As it is important, fo likewife it is difficult.

There is fcarcely a field, in which we will not obferve weeds of the two firft kinds mentioned; of the kind that is propagated by the feed, and the kind that is propagated by the root. Some of thefe, perhaps, it may be eafy to deftroy, as they are foreigners, and not adapted to the foil; but others of them being natural to the foil, in that kind of it that is moft proper for them, it may be expected, not only that it will be very difficult to deftroy them, but alfo, that, by the culture given to the land, they will thrive wonderfully, carry great crops of feed, and multiply and extend their roots. As the deftruction of weeds is then fo important and difficult, it is a work that muft be particularly attended to.

Weeds have been divided into three forts. To deftroy thefe different forts, different management is required. It is neceffary therefore to treat of them feparately.

Methods of deftroying weeds that are propagated by the feed.

Weeds are very different in their natures. The feeds of fome of them will putrefy in a few years, if they lie moift in the earth, and are prevented from vegetating. But the feeds of others will lie many years in this fituation, without having their vegetative power deftroyed. This we know from experience. Land infefted with different kinds of weeds, has been frequently thrown out into grafs, and allowed to remain in that fituation for fome years. Though allowed to lie only a few years, fome kinds of weeds are found to be deftroyed, when the land is broke up again; but, though it lie twenty years, fome other kinds are found in as great plenty as before.

The firft fort may be deftroyed by turning the land infefted with them, from tillage into grafs, and allowing it to remain in that fituation for five or fix years.

Both forts may be deftroyed by bringing the feeds to vegetate, and then tearing up the young plants. Seeds will not vegetate without air. Some require a greater proportion, and fome a fmaller. The fmall feeds will not vegetate without a very great proportion of it. It may be obferved, in fallowing land which is full of weeds, that great numbers of them appear after every ploughing. This fhows, that fome of the feeds had not a fufficient quantity of air, in their former fituation, to make them vegetate. Now, to give thefe fmall feeds the proportion of air neceffary for them, they muft be brought near the furface, and the earth about them rendered free and open. If the land is frequently ftirred and turned over, both thefe will be done. For every time the land is ftirred and turned over, fome feeds, that before lay deep, are brought near the furface, and the earth about them alfo rendered free and open: and, befides, the plants that have appeared are thereby torn up and deftroyed.

Every farmer that practifes fummer-fallowing, is now fully convinced of the truth of this. For he obferves, when the feafon is favourable, and his fallow is well and frequently ploughed and harrowed, and time allowed betwixt every ploughing and harrowing for the weeds to vegetate, that his land, for feveral years, is not fo much infefted with weeds as before.

It has been obferved, that feeds will not vegetate without air, and that to give the fmaller kinds the quantity which they require, they muft be brought near the furface, and the

the earth around them rendered free and open. It is neceſſary likewiſe to obſerve, that water is as requiſite to promote vegetation as air; and that the bringing ſeeds near the ſurface, and rendering the earth free and open around them, as it ſupplies them with air, tends to deprive them of water. In the performance, therefore, of thoſe operations by which the land is ſtirred and turned over, to promote the vegetation of the ſmall ſeeds, great care muſt be taken to preſerve the ſap, as much as is poſſible. This will be done, if, in ſtirring the land, the ſurface is made ſmooth and plain. It is obvious, that, when the ſurface is rough and uneven, the drought has eaſy acceſs; but, when it is ſmooth and plain, the winds have leſs influence, and the ſap is better preſerved. Every farmer will obſerve, that, in dry weather, when land is allowed to lie ſome time after it has been ploughed, without being harrowed, the drought has eaſy acceſs, the ſap is exhaled, and the ſeeds in it, though near the ſurface, and the earth around them free and open; yet, being deprived of water, are prevented from vegetating: whereas, when the land is harrowed immediately after it is ploughed, the ſap is preſerved, and the ſeeds ſpring up. Hence the cuſtom of ſowing barley immediately after the plough. Barley is commonly ſown in a dry ſeaſon; and therefore the land is not allowed to lie long after it is ploughed, leſt the ſap ſhould be exhaled; but is immediately ſown and harrowed, by which the ſap is preſerved.

The vegetation of ſeeds in land is promoted, not only by ſtirring and turning over the land, but alſo by the application of dung and ſome other manures. Dung raiſes a fermentation; this opens the pores of the ſoil, allows the air to reach the ſeeds, and gives them liberty to put forth their roots. If dung, therefore, is laid upon land infeſted with weeds, and the land carefully ſtirred and turned over ſeveral times, all the ſeeds in it, by degrees, will be brought to vegetate; and thus the weeds will be deſtroyed.

It muſt be owned, that this practice, though proper for deſtroying weeds, may, in ſome caſes, deſtroy ſome of the virtues of the dung, before it is applied to promote the vegetation of the uſeful plants we deſign to cultivate. Dung promotes vegetation, by producing a fermentation in the ſoil upon which it is laid; and, by this fermentation, ſeparating its particles. If this fermentation is, in a great meaſure, over before ſeed is ſown, the natural weight of the ſoil, making it ſubſide, will render the vegetable paſture, while the plants are growing, much leſs than it would have been, if the dung had not been ſo ſoon laid on; and more harm may be done by this, than advantage gained by deſtroying the weeds. But, though it may be improper to follow this method, when ſeed cannot be ſown for a conſiderable time after the dung is laid on, as is the caſe ſometimes when ſummer-barley is ſown on fallow; yet it may anſwer very well, when ſeed is to be ſown ſoon after, as is the caſe when wheat is ſown. The advantages ariſing from the deſtruction of the weeds, though not in the firſt caſe, yet in the laſt, may probably do more than overbalance the loſs ariſing from ſome part of the ſtrength of the dung being exhauſted before ſeed is ſown.

It may, perhaps, be thought a little ſurprizing, that dung ſhould be propoſed as a means of deſtroying weeds, when it is univerſally conſidered as a great encourager of them. It is certain, that the laying dung upon land makes more weeds appear, than otherwiſe would do. If the ſeeds of theſe weeds are in the dung, it muſt be owned, that it increaſes, and not diminiſhes their number. But, if the ſeeds are in the land, and the dung only makes them vegetate, it becomes a proper means of deſtroying them.

It ſeems to be the general opinion, that the great plenty of weeds that appear on land after it is dunged, are produced from ſeeds mixed with the dung. But there are ſome reaſons to believe that this is a miſtake.

It is obſerved, that dung produces weeds, when it is taken from a dung-hill, ſo much heated as to deſtroy the vegetative power of any ſeed.

It is obſerved likewiſe, that the ſame dung produces weeds, according to the nature of the land on which it is laid. It often happens, that dung carried from a town is laid upon different ſoils; and it is certain, that this dung does not produce the ſame kind of weeds on all ſoils, which it would do, if the weeds aroſe from ſeeds, mixed with it; but always produces the weeds, with which the ſoil upon which it is laid is naturally infeſted.

Theſe obſervations make it very probable, that the great quantity of weeds produced by dung, is entirely owing to the fermentation occaſioned by the dung; by which almoſt all the ſeeds near the ſurface, receiving a proper quantity of air, are thereby brought to vegetate.

To this it may be objected, That ſuch numbers of weeds do not appear upon land that is new marled, as upon land that is dunged. But, in anſwer to this, let it be obſerved, that a great quantity of marle is laid on, and in large pieces, and that it is ploughed in with a ſhallow furrow: and therefore, though a fermentation may be raiſed, yet the undiſſolved marle prevents a great part of the ſoil from being expoſed to the air, in ſuch a manner as to make the ſeeds in it vegetate; and alſo occaſions ſuch a hollowneſs, that, after the ſeeds begin to vegetate, ſuch of the plants as are tender (and ſeveral ſorts of them are not ſo hardy as corn) are eaſily deſtroyed by drought or froſt.

Before we leave this article, it is neceſſary to obſerve, that the ſeeds of ſome weeds, particularly the different ſpecies of the thiſtle, are carried to a conſiderable diſtance by the wind; and where any earth is thrown up in ſuch a manner as to intangle them, as at the root of a hedge, or ſide of a ditch, there they appear in great plenty. It is ſurpriſing, that many farmers allow them to grow there undiſturbed: the conſequence of which is, that their ſeeds are carried in great plenty into the adjacent fields, and thereby great damage is done; which might have been prevented by cutting them down, at a ſmall expence, before their ſeeds were ripened.

Methods of deſtroying weeds that are propagated by the root.

There are many different kinds of weeds propagated by the root, and theſe of very different natures. Some of them infeſt the land that is in tillage, and others the land that is in graſs. Any perſon may ſatisfy himſelf of this, by inſpecting our fields. The farmer is very ſenſible of it: he knows that ſome kinds of weeds flouriſh and increaſe in his land, while in tillage, if he does not take all pains to diſcourage them; and when he lays down his land in graſs, other kinds that did not appear before, ſoon diſcover themſelves; and, if undiſturbed, continue to increaſe, while the land remains in that ſituation.

The firſt ſort, it ſeems, have ſuch a tender blade, and ſuch tender roots, that they cannot pierce earth that is hard; but are of a kind that increaſe very faſt, when the ſoil is free and open.

The ſecond ſort have the blade and roots ſo ſtrong, that there is ſcarcely any ſoil that, of itſelf, will become ſo hard and ſtiff, as to prevent them from making their way through it; but are of ſuch a nature, as to be eaſily torn up, when the land is free and open; and do not eaſily ſtrike root again when torn up.

The natures of theſe weeds point out methods of deſtroying them.

The firſt ſort, as they chiefly infeſt land in tillage, may be deſtroyed by turning the land from tillage into graſs, and allowing it to remain for ſome years in that ſituation. This is confirmed by experience. Land over-run with quickening-graſs, and other root-weeds of the ſame kind, is frequently laid down in graſs, and allowed to continue for ſome years without being ploughed. This land, when broke up again, if allowed to lie in graſs for ſix or ſeven years, is found to be clean, and the roots of the weeds deſtroyed.

The number of years neceſſary for deſtroying the roots, depends upon the nature of the ſoil. If the ſoil is naturally hard and ſtiff, it is the ſooner brought to ſuch a ſituation, as to prevent the roots and blades of the weeds from piercing it. But, if it is naturally ſoft and ſpungy, it takes a longer time before it is brought to that ſituation. For while the blade, or roots of the weeds, can pierce the ſoil, their vegetation is not prevented. In ſome ſoils, it is ſix or ſeven years before the roots of the quickening-graſs are deſtroyed.

The number of years found neceſſary for deſtroying theſe root-weeds, has, no doubt, been partly the occaſion of eſtabliſhing the practice commonly obſerved. Three

crops

crops of corn are taken, and then the land is allowed to lie ſix years in graſs, or lea. At the end of theſe, the farmer ſuppoſes that the lea is come to maturity, and fit again for being ploughed. When it is only two or three years old, it is called, in ſome parts of the country, calf-lea; and, if ploughed at that age, is commonly very full of roots.

The ſowing land with graſs-feeds, inſtead of turning it out into lea, deſtroys the roots of theſe weeds ſome years ſooner. For thereby a ſward being brought immediately upon the ſurface, the land becomes firm, the blades of the weeds are unable to pierce it, and the roots are deprived of air. Ryegraſs-feed, or the common hay-feed, is the moſt proper for this. For the plants ariſing from theſe, ſoon cover the ſurface, and, by the number and ſmallneſs of their roots, bind the ſoil. Clover, particularly the broad clover, is improper. For the roots of it being large, they open the ſoil in growing and extending themſelves, and thereby prevent it from arriving at that degree of firmneſs, neceſſary for deſtroying the weeds ſo ſoon, as if no graſs-feeds are ſown, but the land immediately turned into lea.

The ſecond ſort may be deſtroyed by turning the land infeſted with them, from graſs into tillage; and it is not neceſſary to continue it long in this ſituation, for the weeds commonly diſappear after the firſt ploughing.

But as it may be inconvenient to turn a field infeſted with weeds, from graſs into tillage, or from tillage into graſs; it is neceſſary to conſider, if there are any methods of deſtroying theſe weeds, without altering the ſituation of the land.

When land in tillage is infeſted with weeds, they may be deſtroyed by frequently ſtirring and turning it over in dry weather. For the weeds being removed out of their place, the drought prevents them from ſtriking root again. The ſtirring the land in wet weather, is rather hurtful than beneficial. For though the roots of the weeds are removed from their place, yet the weeds themſelves are only tranſplanted. If the land is wet, they ſoon ſtrike root again; and the quickening-graſs, in particular, having its paſture enlarged, makes quicker progreſs than ever. But, if the land is dry, the weeds do not ſo eaſily ſtrike root again; or, if ſome of them ſhould ſtrike root, they continue for ſome time in a languiſhing condition, and if removed out of their place, while in this condition, are eaſily deſtroyed by the drought. If land then is frequently ſtirred and turned over, by degrees all the weeds will be deſtroyed: for, by every ſtirring or ploughing, ſuch of them as are in a languiſhing condition are deſtroyed, while thoſe that are ſtrong and vigorous are weakened.

When land is to be freed from ſeed-weeds, it cannot be made too fine, nor the ſurface too ſmooth; for the more perfectly theſe are done, the greater number of ſeeds are brought to vegetate. But, when land is to be freed from root-weeds, it cannot be turned up in too large pieces, nor the ſurface left too rough: for the larger the pieces, and the rougher the ſurface, the drought has the eaſier acceſs, and the roots are the more effectually deſtroyed.

When land in graſs is infeſted with weeds, and it is inconvenient to turn it into tillage, the weeds themſelves muſt be pulled up by the root, or frequently cut; which are the only ways of deſtroying them.

Some perſons aſſert, that ſheep are very fond of the yellow rag-weed, by which light land, when laid out in graſs, is very much infeſted. If this is true, the putting ſheep to paſture upon this graſs, for a ſeaſon or two, will effectually deſtroy this weed. This may be the more ſafely recommended, as the trial, though it does not ſucceed, cannot be attended with any danger or loſs.

Some land, after being a few years in graſs, is liable to be over-run with fog. This, it is ſuppoſed, is owing to the ſoil becoming ſoft and ſpungy near the ſurface. If this is the caſe, rolling, which makes the ſurface firm, will be of ſome uſe to deſtroy this pernicious weed. It may be obſerved, that, when there is a foot-path through a graſs-field over-run with fog, not ſo much frequented as to break the turf, the graſs upon the path is clean, without any mixture of fog.

There is a third ſort of weeds found to infeſt both the land that is in tillage, and the land that is in graſs. This ſort have not only the blade and roots very ſtrong, ſo as to be able to pierce the ſoil, though hard, but alſo are of ſuch a nature, as makes it difficult to tear them up; or have their roots of ſuch a kind, that they may be divided into a great number of plants.

Theſe weeds cannot be deſtroyed, either by turning the land infeſted with them, from tillage into graſs, or from graſs into tillage: but they may be deſtroyed by the methods mentioned, when the ſituation of the land is not changed. If the land is in graſs, they may be deſtroyed by digging them out, or by frequently cutting them. And, if the land is in tillage, they may be deſtroyed by frequently ſtirring and turning it over in dry weather. This work muſt be performed with ploughs properly made for cutting their roots. This kind of weeds puſh their roots very far down, and their roots are ſo tough and hard, that our common ploughs ſeldom break them. If there are any ſtones in the land, they puſh their roots among the ſtones; and, in ſuch places, the plough not having freedom to act, they continue undiſturbed. In this land too the plough, moſt proper for cutting theſe roots, cannot go with ſafety. But if the ſtones are dug out, and the land ploughed with a broad pointed ſhare, the roots, by degrees, will be cut, and the weeds deſtroyed.

Beſides theſe three ſorts of weeds mentioned, there is a fourth that chiefly infeſts land that is wet. Frequent cutting, and even digging out by the root, have been tried to deſtroy them, but to no purpoſe. They are not to be ſeen on dry land, and, when on land only inclining to be wet, appear very weak. This points out draining to be the proper method of deſtroying them, which indeed does it effectually.

We ſhall now conclude this article with obſerving, that all kinds of root-weeds, and many kinds of the ſeeds of weeds, may be deſtroyed by depriving them of air. For air is neceſſary not only to the vegetation, but alſo to the life of every plant.

When land is in tillage, the weeds may be deprived of air, either by burying them deep in the earth, or covering the ſurface. Trenching does the one, and a good crop of peaſe, potatoes, or any other plants that lie thick on the ſurface, does the other.

Fog, by which ſome lands in graſs are much infeſted, may be deſtroyed in the ſame manner. The method propoſed is this: the graſs muſt be kept from the month of March to the month of December, for winter-paſturing, and the next ſeaſon preſerved for a crop of hay. The fog being, by this management, covered for two ſeaſons by the graſs, is thereby deſtroyed.

As different methods are neceſſary in the extirpation of different weeds, and it is of ſome importance to know which of them are perennial, and which only annual, we have added a liſt of the moſt remarkable weeds which infeſt the arable and graſs lands in England, ranged according to their duration. A pomp of names is carefully avoided, and thoſe which Mr. Hudſon has given in his Flora Anglica are choſen: it is a misfortune that many farmers will not know what plants are meant by ſome of theſe names; but it is a misfortune ſcarcely to be avoided, ſince the Engliſh names of vulgar plants are ſo various; altering not only with the county, but with the place, and even ſometimes depending on the whim of a common labourer.

By far the greater number of annual weeds infeſt the arable lands: in graſs lands the perennials chiefly flouriſh. The reaſon is obvious; in the former the roots are continually deſtroyed by cutting; in the latter they are made to ſpread by cutting or eating down the ſtems: perennials uſually require more than a year to come to perfection; and the ſeeds by which annuals are propagated, are not ſo readily received into the more compacted turf, as into land whoſe parts are conſtantly undergoing a ſeparation.

The annual weeds which infeſt arable lands and gardens are chiefly theſe,

Ivy-leaved ſpeedwell, or ſmall henbit. April.
Annual darnel-graſs.
Bearded oat-graſs, bearded wild oats, or haver.
Little-field madder. May.
Cleavers, or gooſe-graſs. May.
Parſley-piert. May

Pearl-

Pearl-wort, or chickweed breakftone. This fmall weed is very apt to infeft gravel-walks; and if it be fuffered to feed, will increafe prodigioufly, and grow very troublefome. June.

Baftard alkanet. May.

Small wild buglofs. June.

Male pimpernel. May.

Venus's looking-glafs, or codded corn-violet. June.

Dodder, hell-weed, devil's-guts, or fcald. July.

This is found chiefly on beans; it ftrangles the crop, and draws its nourifhment from the plants about which it entwines itfelf. It infefts alfo hops and flax.

Small corn-parfley. Auguft.

Goofefoot of feveral kinds flourifhes on dunghills, and is often fuffered by the farmers to grow there unmolefted, by which the dung is much exhaufted. Auguft.

Fool's parfley. This is generally allowed to be a ftrong poifon, and is very common in gardens.

Shepherd's needle, or Venus's comb. June.

Common chickweed. The peft of gardens.

Knot-grafs. This plant is remarkably full of feed, and propagates itfelf furprifingly: it will grow any where, particularly in places that are much trodden. The fparrows, and other fmall birds, a very fond of its feeds. June.

Black bindweed. June.

German knot-grafs, or annual knawel. Auguft.

Purple-flowered chickweed, or fpurrey; on fandy lands. June.

Cockle. June.

Corn fpurrey. Auguft.

Petty-fpurge. July.

Sun-fpurge, or wart-wort. Thefe are both very common in gardens. July.

Red-poppy, or corn-poppy. June.

Wild larkfpur. This has increafed fo much of late years in Cambridgefhire, as to become one of the common weeds among the corn.

Adonis flower, pheafant's eye, red maithes, red Morocco. Frequent in the corn-fields of Kent.

Corn crowfoot. The feeds of this do not come forth till the fecond year after fowing. June.

Upright ground-ivy.

Red archangel, or dead-nettle. Common in gardens.

Great henbit.

Narrow-leaved all-heal.

Nettle-hemp, or hemp-leaved dead-nettle.

Red eye-bright.

Fluellin; fharp-pointed, and round-pointed.

Gold of pleafure; among the flax. June.

Shepherd's purfe.

White-flowered charlock, with a jointed cod. June.

Yellow-flowered ditto.

Wild muftard, or charlock. May.

Thefe three, particularly the laft, are the *opprobium* of the farmers: they who will not be at the pains to extirpate them by hand, might do well at leaft to run a fcythe over the crops, while the weed is in flower, and before their fpring-corn (for it is that which is chiefly troubled with it) is got up too high.

Fumitory. April.

Yellow vetchling; very common in the corn-fields about Cambridge.

Common fow-thiftle. June.

Common groundfel.

Corn-marigold; the peft of light lands: it is not fond of dung. In Denmark there are laws for the extirpation of this weed. June.

Common camomile, or corn-feverfew. June.

Stinking May-weed. June; fomewhat earlier than the laft.

Blue-bottles. July.

Panfies, or heart's-eafe.

Leffer nettle. Auguft.

Oracee, of feveral kinds; along with the goofefoot, on dunghills, and in gardens. Auguft.

Annual weeds in pafture-grounds are only the following.

Purging-flax. May.

Knot-grafs. This fpreads chiefly by the path fides, and where dung or rubbifh has lain.

Yellow rattle, or cock's-comb, vulgarly penny-grafs; in moift meadows. This keeps its ground, for the feeds are ripe at the time of cutting hay. June.

Eye-bright; in dry paftures.

Red eye-bright.

Heart-trefoil, or clover. This is always mixed with clover, and particularly with the hop-trefoil, or non-fuch. It is a harfher plant, full of hard, prickly feed-veffels, and therefore not a good food for cattle; it is eafily known from other clovers, by its feed-veffels, and the fpots upon its leaves.

Common creeping moufe-ear. May.

Smooth fuccory hawk-weed. June.

Star-thiftle; in dry barren paftures, and by way-fides. July.

Hairy fheep's fcabious; on high paftures.

Biennial weeds in corn.

Viper's buglofs, called in Cambridgefhire, &c. cat's tail. It infefts the corn very much every third year. July.

Mithridate-muftard, or baftard-crefs.

Common melilot. The feeds of this ground along with wheat, are known to give bread a very ftrong tafte. June.

Spear-thiftle. July. This, with many other kinds of thiftles and other weeds, with downy feeds, are fuffered to ftand on banks, way-fides, and fallow lands, in order to ferve for a conftant fupply of weeds. If the wafte places were run over with an old fcythe, this evil would foon be prevented.

Biennial weeds in paftures.

Wild-carrot, or bird's neft. June.

Cow-parfnep. July.

Common-mallow. May.

Rough-fuccory hawk-weed. July.

Stinking hawk-weed. June.

Mufk-thiftle. July.

Wild carline-thiftle. June.

Perennial weeds in corn.

Field fox-tail, or moufe-tail-grafs.

Common wheat-grafs, dog's-grafs, quick-grafs, or couch-grafs. As every piece of this moft deteftable creeping weed will grow, there is no way of deftroying it, but by ploughing up the ground thoroughly, picking it out, and burning it.

Common field-fcabious. Auguft.

Small bind-weed. This fpreads its roots deep and wide; and as every piece of them will grow, it is no eafy matter to eradicate this pernicious plant.

Bladder-campion, white corn-campion, fpattling-poppy. July.

White-campion. May.

Small-bramble, or dewberry-bufh. June.

Corn-mint. Auguft.

White-archangel, or dead-nettle; chiefly in gardens and under hedges.

Corn reft-harrow, or cammock. The roots of this mat together with great ftrength, and are therefore very troublefome, where land is to be ploughed for corn. This property, however, makes it an excellent plant to fet on fea and fen banks, to keep them firm and compact. July.

Tree fow-thiftle. Auguft.

Way-thiftle. The fallows are ufually well overfpread with this weed, whofe downy feeds are eafily fpread by the wind. July.

Great knap-weed, or matfellon. Its roots are very ftubborn and hard. July.

Corn horfe-tail.

Perennial weeds in paftures.

Devil's-bit. June.

Great-plantain, or waybread. June.

Ribwort, or ribwort-plantain. June.

Yellow ladies bed-ftraw, or cheefe-renning. It is a vulgar notion, but a falfe one, that this herb will turn milk. The good women are fond of putting fome favourite plant into their rennet, and thus attribute to it a quality which it has no right to claim. July.

W E E

Cowſlips, or pagils. April.
Round leaved bell-flower. Auguſt.
Leſſer throat-wort, or Canterbury-bells. July.
Meadow-ſaxifrage. Auguſt.
Burnet-ſaxifrage. Auguſt.

Crow-garlic. This gives milk and butter an inſufferable ſtrong taſte. June.

Broad-leaved dock. July.
Common-ſorrel. May.
Sheep's ſorrel.
White ſaxifrage, or ſengreen. May.
Agrimony. June.
Drop-wort. Hogs are fond of the roots. July.

Meadow-ſweet. June. Only in very moiſt meadows. Goats are very greedy of this plant, which neither horſes nor kine will touch.

Tormentil, or ſeptfoil. June.
Creeping-crowfoot, or butter-cups. May.
Bulboſe-crowfoot, or butter-cups. May.
Upright meadow-crowfoot. June.

The three laſt, which occupy ſo much room in almoſt all meadows, are not eaten by any ſort of cattle, being of a very hot and acrid nature; ſo that the notion of their giving butter a yellow tincture, is as falſe as it is vulgar.

Pilewort, or leſſer celandine. April.
Meadow-rue. June.
Bugle. May.
Self-heal. Auguſt.
Common yellow toad-flax. July.
Common ladies-ſmock, or cuckow-flower. April.
Crowfoot cranesbill. June.
Common broom: in dry paſtures. May.
Reſt-harrow, or cammock; in barren grounds.
Dandelion. April.
Rough dandelion. May.
Yellow devil's bit. Auguſt.
Long-rooted hawk-weed. May.
Dwarf carline-thiſtle. July.
Common coltsfoot; in watery days. March.
Common butter-bur; in moiſt meadows. March.

Ragwort, or ſeagrim. Nothing touches this plant; though a perennial, it comes up eaſily by hand, when young, or when the ground is moiſt. July.

Fleabane; in moiſt places. Auguſt.

Common daiſie. We do not find that any cattle willingly eat of this plant, which occupies ſo large a part of our paſtures.

Greater daiſie, or ox-eye. May.

Common yarrow, or milfoil. The roots of this creep abominably, eſpecially where rubbiſh, or dung has been laid. May.

Common knap-weed, or matfellon. July.

Orchiſes of various ſorts; as,

Butterfly orchis. May.	In moiſt meadows.
Male fool-ſtones. May.	
Female fool-ſtones. May.	
Male-handed orchis. May.	
Female-handed orchis. June.	
Red-handed orchis. June.	
Purple late-flowering orchis. June.	In dry paſtures, chiefly in chalk.
Little purple-flowered orchis. May.	
Man orchis. June.	
Frog ſatyrion. May.	
Triple ladies traces. Auguſt.	
Bee orchis. June.	

Carexes of various ſorts; in low meadows and fenny grounds. Theſe are all very harſh: they are, however, mowed to fodder cows with in winter.

Common nettle.

Adder's tongue; in moiſt meadows.

Female fern, or brakes; on dry barren land. It ſtrikes its roots far and wide, and is difficult to eradicate even with the plough.

Moſſes of various ſorts. Old paſtures are moſt infeſted with theſe. Ploughing is the only effectual way of deſtroying them.

We have added the time in which moſt of the foregoing plants begin to flower; becauſe about that time it is proper they ſhould be deſtroyed.

Though the reader will find an account of many of the weeds enumerated in the above catalogue, under their proper articles, yet we were perſuaded that a general deſcription of the perennial weeds would not be unacceptable here, as two much cannot be ſaid to enable the huſbandman to know theſe pernicious plants, and exterminate them as ſoon as poſſible.

Annual darnel-graſs is called white darnel by Gerard, and in the ſouthern countries crap; though, in Worceſterſhire, they call the buck-wheat by this name. It was a ridiculous old notion, that this weed, which has ever been ſtigmatized as one of the greateſt peſts of corn, is produced from bad ſeed of wheat. The French call it *yvraie*; becauſe, put into bread, or beer, it is ſuppoſed to cauſe drunkenneſs. It has always been reckoned bad for the eyes, and to occaſion vertigoes. This plant is very like the red darnel-graſs, which has been ſo much cultivated, under the name of ray-graſs, or vulgarly rie-graſs: but the ſpike is much larger and paler; and has beards, which the ray-graſs is entirely without. It is likewiſe annual: whereas the ray-graſs has an abiding root. Its ſeeds ripen with the corn.

Bearded oat-graſs, or wild oats, is very like the common oat in appearance, but generally over-tops it. The ſeeds are alſo of a duſky reddiſh colour, and hairy towards the bottom. The beards or awns are very long, ſtiff, and bent. As it ripens with the corn, or but little before it, the extirpation of it is not very eaſy.

Baſtard alkanet is called, alſo, baſtard gromill, or gromwell, and falſern. Nothing is more common among the corn, eſpecially among rye, than this weed. It may eaſily be known, by its red roots, which yield a red tincture, and are uſed by the country girls in Sweden, to ſmear their faces with. From the root uſually riſes a ſingle ſtem, about a foot high, rough, and branching out at the top. The flowers are ſmall and white, ſurrounded with five long, narrow, hairy leaves, and ſucceeded by four white rough ſeeds.

The dodder is ſo remarkable a plant, that it cannot be miſtaken by thoſe who know the name. It is entirely without leaves, and does not depend on the ground for nouriſhment; but when it is grown up, rots at the bottom, and lives upon the juices of other plants, about which it entwines itſelf, by means of ſmall threads of a red colour, which it throws out. The flowers are ſmall, and come out in roundiſh heads, or bunches, many of them together, here and there, from the ſtem.

Small corn parſley, though it is very common among corn, does not ſeem to be much known. It is a low branching plant. The branches grow thick together, and are knotted and crooked. The flowers grow thick together after the manner of parſley, &c. and are of a white colour inclining to yellow. The ſeeds are large in proportion to the plant, and are ſet about with little crooked briſtles, which make them adhere to the ſtockings in great plenty, when the ſeeds are ripe, which is about, or a little after harveſt.

The leſſer hemlock, called by Gerard, thin-leafed wild hemlock, is ſo well known under the name of fools parſley, as ſcarce to need a deſcription. However, as it is a matter of conſequence to diſtinguiſh poiſonous plants from thoſe which they reſemble, we may obſerve, that though the leaves reſemble parſley, yet they are much darker on their upper ſurface, but pale and ſhining underneath. The diviſions of the leaves are much ſharper, and they have no ſmell, nor ſcarcely any taſte. When the plant is in flower, it is eaſily known by the three long narrow green leaves, which hang down from the little ſtems that immediately ſupport the flowers.

Shepherd's needle, or Venus's comb, has its names from the remarkable ſhape of the ſeeds with their appendage, reſembling in this reſpect the cranes bills: theſe would be alone ſufficient to diſtinguiſh the plant. They ſucceed ſmall white flowers; and come out in a bunch, like needles, or the teeth of a comb, ſet cloſe together. The leaves are very finely cut.

Knot-graſs is ſo called from its knots or joints, of which its ſlender creeping branches are full. After harveſt, the lands, in many places, ſeem all coloured with the little red flowers of this plant. It is called, alſo, ſwine's-graſs; and, in the north, bird's tongue.

Black bindweed has a ſtem that lays hold on any neighbouring plants, and twines about them from right to left. Its leaves are ſmooth, and ſhaped pretty much like thoſe of the buck-wheat, which its ſeeds alſo reſemble, being triangular, but ſmaller. It frequently ramps up in hedges and gardens, and is alſo very common among corn.

Corn-crowfoot has an upright ſtalk. The leaves are of a pale green, and cut into long, narrow, acute ſegments. The flowers are much ſmaller, and paler than in the crowfoots of the paſtures; but the ſeed-veſſels are the moſt remarkable, for they are covered all over with prickles. This is extremely common among corn.

Charlock, called, alſo, chadlock, catlock, carlock, and wild rape, is, I ſuppoſe, too generally known to need a deſcription. The white and the yellow-flowered charlock, or wild radiſh, which are only varieties of each other, and not ſo common as the former, may eaſily be diſtinguiſhed from it, by the paleneſs of their flowers, and the form of their ſeed-veſſel, which is round, ſmooth, and jointed. Almoſt the whole plant is covered with bent pellucid hairs.

Yellow vetchling, or ſmall yellow fetch, has long, ſlender, divided ſtalks. The leaves are triangular, and grow by pairs cloſe to the ſtalk. Out of theſe leaves comes a tendril, by which the plant ſupports itſelf; and, on a long ſtalk, one ſmall pea flower, of a yellow colour, which is ſucceeded by a flat pod, about an inch in length, containing ſix or ſeven roundiſh ſeeds.

Corn-marigold, or golden corn-flower, is the buddle, or yellow buddle of Kent. Its leaves grow cloſe to the ſtem, in an alternate order. They are of a blue-green colour, and are cut about the edges. The flowers are like thoſe of the marigold; large, and of a beautiful yellow.

Yellow rattle is known by its leaves being finely indented about the edges; its flowers being yellow; and its ſeed-veſſel ſwelling into a dry, large, compreſſed bladder, divided into two cells, and containing ſeveral compreſſed ſeeds, ſurrounded with a membrane.

Red eye-bright, or eye-bright cow-wheat, has a ſtem riſing not more than a foot high; long narrow leaves, indented about the edges, and purple flowers growing in ſpikes. It flowers in July and Auguſt.

Viper's bugloſs. The ſtalks are rough, round, ſolid, erect, undivided, and marked with black ſpots; the leaves are very rough, long, narrowing to a point, and placed without any certain order. The large ſpecious flowers, of a beautiful blue colour, grow in long bending ſpikes. They conſiſt of one petal, divided into five roundiſh ſegments, of different ſizes, and reſemble a horn in their figure, expanding by degrees, from a narrow beginning. The flower-cup conſiſts of five narrow ſegments, and contains four rough ſeeds.

Melilot is well known by its trefoil leaves, which are indented, and, as it were, eaten about the edges; and by its long, thin ſpikes of ſmall, yellow flowers, which are ſucceeded by ſhort rough pods, containing two ſeeds.

Wild carrot, bird's-neſt, or bee's-neſt. Is very like the cultivated carrot, of which it is indeed ſuppoſed to be only a variety. The wild ſort, however, differs in his roots, being ſmall and ſticky. In both ſorts, after they have done flowering, the umbels contract themſelves into the ſhape of a bird's neſt.

Cow parſnep, wild parſnep, meadow parſnep, or madnep. This grows three feet high. The ſtalk is round, furrowed, and hollow. The leaves proceed from a large membrane, or ſheath. They grow on long hairy ſtalks, and are divided and downy. The flowers grow in large umbels, are white, and conſiſt of five irregular petals. Two oval, ſtreaked, compreſſed ſeeds, ſurrounded by a wing, ſucceed each flower.

Stinking hawkweed may be diſcovered by its very ſtrong ſmell like caſtor. As it is not a common weed, it is not neceſſary to be particular in the deſcription of it.

Muſk-thiſtle is known by its handſome purple nodding heads of flowers, which come out rather ſooner than moſt ſorts of thiſtle. The ſmell of them is agreeable.

Carline-thiſtle is very different from the other thiſtles. The hard, woody root, ſends up one round purpliſh ſtalk, beſet with prickly leaves in no order. This is terminated with ſeveral flowers, growing in a head. The ſmall ones, compoſing the whole, are of a duſky purple, and contained in a ſwelling ſcaly cup; the inner ſcales of which are very long, ſhining, coloured, ſpreading, and placed in a ring round the flowers. The ſtalks and heads remain all the year, with very little variation, upon the dry paſtures.

Perennial weeds in corn.

Field fox-tail, ſmall baſtard fox-tail, or mouſe-tail graſs, is known by its long, round, ſlender, ſmooth ſpike, of a duſky purple colour. The ſpikes are ſo very long and ſlender, that they uſually bend a little. This graſs is found in the moiſt furrows of arable land, and in any places where the water is ſuffered to ſtand.

Common wheat-graſs, or couch-graſs, is univerſally known, by its long white creeping roots. It grows very tall, eſpecially in hedges. The ſpike reſembles that of wheat, in the manner in which the ſeeds are diſpoſed.

Common field ſcabious is all over rough and hairy. The ſtalk is upright; a foot, or a foot and a half in height, ſpotted, and branching. The lower leaves are oval, and indented about the edge. Thoſe which grow on the ſtalk are divided, and of that ſort which botaniſts call pinnatifid. The flowers are blue, of the compound kind; conſiſting of a conſiderable number of ſmall flowers, each divided into four parts, and having one ſeed under them. The taſte of the plant is a diſagreeable bitter.

Small bindweed, called, alſo, with-wind and hedgebells, though theſe names ſhould ſeem rather to belong to the great bindweed, which ramps in the hedges; whereas this overſpeads the arable lands. The common people, in their wrath, have given this pernicious weed the ſame opprobrious names with the dodder, viz. hell-weed, and devil's guts.

The ſtalks of this plant are weak, and twine about any thing. They come near, from left to right; and, when they find no ſupport, they trail along the ground. The leaves come out ſingle. They are three cornered, ſhaped ſomewhat like an arrow head, ſmooth, and placed on long foot-ſtalks. From the boſoms of the leaves comes out one flower on a very long foot-ſtalk. It is bell-ſhaped, of a beautiful colour, purple, red, white, or variegated; and is ſucceeded by a ſmall, roundiſh ſeed veſſel, containing four large, angular ſeeds. The whole plant is full of a milky juice.

Bladder-campion, white-corn campion, ſpattling poppy, white bottle, white ben, or frothy poppy. The ſtalks grow a foot and a half, or two feet high, round, ſmooth, jointed, branched towards the top; and at every joint is a pair of leaves, perfectly ſmooth. The flowers are white, and conſiſt of five bifid petals. The empalement, or outward covering, is puffed out into a roundiſh form; and is ſmooth, often varied with red, green, and white, and beautifully veined all over, like a fine net.

White campion, admitted into gardens, when it has a double flower, under the name of white batchelor's-buttons. It has a long and large root, of a ſharp bitteriſh taſte, ſending forth ſeveral ſtalks about two feet high; round, hairy, jointed, branching, of a red colour near the ground; a pair of leaves comes out at every joint, hairy, and ſharp-pointed. The flowers are like thoſe of the laſt: but the empalement, which is not puffed out like that, is oblong, with purpliſh ſtreaks down along it from top to bottom. The flowers of this are imperfect: the male or barren, and the female or fruitful, growing on diſtinct plants.

Small bramble, or dewberry-buſh, is diſtinguiſhed from the common bramble of the hedges, by the place of its growth, the trailing of its round branches, the ſmallneſs of its prickles, which are fewer in number, and chiefly on the ſtalks; the leaves growing only three together, being green underneath, and the ſide ones divided into two parts; and the blueneſs of its berries, which conſiſt of a very few large diviſions.

Corn-mint. We are told, on undoubted authority, that this herb will hinder milk from curdling; and that, when hungry cows have been put after harveſt into a field where this plant abounded, it has been ſcarcely poſſible to turn their milk for cheeſe.

Corn reſt-harrow, reſt-plough, cammock, petty whin, or ground furze. The hard, ſtubborn, creeping roots ſend forth many woody, round, ſlender, hairy branches, red towards the bottom. The leaves grow three together. The flowers of the pea kind, of a beautiful red colour, and are ſucceeded by a ſwelling, villous pod, containing a few roundiſh ſeeds.

Tree ſowthiſtle. The root is very creeping, full of milk, and with difficulty eradicated. The ſtalk is about two feet high, ſmooth at the bottom, but hairy where it begins to branch out. The leaves are like thoſe of the dandelion, deeply cut, ending in ſharp points, and having the edges ſet round with tender prickles. The flowers grow ſeveral together; and reſemble thoſe of the ſow-thiſtle, but are much larger, of a deeper yellow, and ſurrounded by a very rough, hairy, dark-coloured empalement. They have the ſmell of bitter almonds, and are ſucceeded by downy ſeeds.

Great knapweed, matfellon, or bulweed. This plant is about two feet high. The ſtalks are round, ſtreaked, and hoary. The bottom leaves are oblong and undivided; but thoſe, which grow on the ſtalk, are cut and divided. The flowers reſemble thoſe of the blue-bottle in ſhape, but are of a red colour. The ſeed is ſmall, oblong, reddiſh, and hairy in the upper part.

Corn horſe-tail grows in moiſt places. In April, naked ſtalks come up, which bear the flower and ſeed. Theſe are but of ſhort duration. In May, other ſtalks ariſe, hollow, jointed, about a foot high, and ſending forth all round, hollow jointed leaves, ſix or eight inches in length, ſubdividing into others at the joints.

Perennial weeds in paſtures.

Devil's bit is a kind of ſcabious. It differs from the common field ſcabious, in having undivided leaves, ſet thicker on the ſtalk; in the flowers not ſpreading out into a flat ſurface, but growing in a round form; and the ſmall flowers, which compoſe the whole, being all of a ſize and regular: and, laſtly, in the root looking, as if it were bit off at the end.

Great plantain, or waybread, is eaſily known by its broad leaves, ſpreading on the ground, and marked on the under ſurface with ſeven ſtrong nerves. From the centre of theſe ariſe ſeveral naked, round, hairy ſtalks, ſuſtaining a long, cylindrical ſpike of ſmall flowers, ſet thick together.

Rib-wort plantain has much longer leaves, marked only with five nerves. The ſtalks are higher, and not round, but cornered, and the ſpikes of flowers are ſhorter.

Yellow ladies bedſtraw, cheeſerenning, maid's hair, petty mugwet. Its ſlender ſtalks riſe to about a foot. The leaves come out in whorls, eight or nine together. They are long and narrow, and of a deep green. Towards the top of the ſtalk, two little branches uſually come out, ſuſtaining a conſiderable number of ſmall yellow flowers, conſiſting of one petal, divided into four parts, and ſucceeded by two ſmooth roundiſh ſeeds.

Round-leaved bell-flower. The bottom leaves are roundiſh: thoſe upon the ſtalk long, and narrow. The flowers are blue, bell-ſhaped, with the edge divided into five parts, and hang down.

Leſſer throatwort, or Canterbury bells. The ſtalk is cornered and undivided, about a foot high, and hairy. The flowers grow at the top of the ſtalk cloſe to it, ſeveral together. They are erect, of a beautiful purple colour, and divided to the middle into five acute ſegments.

Meadow ſaxifrage, Engliſh ſaxifrage, or ſtone-break. The root has a ſharpiſh, aromatic taſte. The ſtalks are round, ſtreaked, and reddiſh towards the bottom. The leaves are ſmooth, of a dark green, and divided twice into long, narrow, ſharp ſegments. The foot-ſtalks membranaceous at the baſe. The flowers grow in looſe umbels, and are of a pale yellow. The ſeeds are oval, ſtreaked, and red at the top.

Burnet ſaxifrage is of two kinds. The large is found in woods; and the ſmaller, in dry paſtures. Of this laſt there is a variety, differing only in the leaves, which are cut even to the root. The ſtalks are ſtreaked, and branching. The flowers grow in umbels cloſe together. They are ſmall, white, and conſiſt of five entire petals. Theſe are ſucceeded by two ſeeds of an oblong oval form. The root has a very hot taſte.

Crow garlick, or wild garlick. The leaves are round and ſmooth, reſembling much thoſe of ruſhes. From the midſt of theſe riſes a ſtalk, a foot or more in heighth, naked, ſlender, round, ſmooth, and hard; ſuſtaining many purple ſeeds, or little bulbs, about the ſize of grains of wheat collected into a round head.

White ſaxifrage, ſengreen, or ſtone-break, has kidney-ſhaped leaves ſpread upon the ground, and divided about the edges, not much unlike thoſe of ground-ivy, but ſofter and ſmaller, and of a faint yellowiſh green. Among theſe riſes a round, hairy, branching ſtalk, about ſix inches high, bearing ſpacious white flowers, conſiſting of five entire petals. This pretty little plant grows in dry paſtures, and may readily be known by its roots, which are made up of little knobs.

From a want of ſufficient diſtinction in names, a ſtrange confuſion has ariſen between the meadow ſaxifrage, Burnet ſaxifrage, Burnet, and white ſaxifrage. It is hoped theſe deſcriptions will contribute ſomething towards avoiding this confuſion for the future.

Agrimony has generally a ſingle, round, rough ſtalk, with leaves placed alternately upon it, which are winged with ſmall leaves, placed between the larger pairs. The yellow flowers grow alternately along the ſtalk, in a long row, after the manner of a ſpike, and are ſucceeded by rough ſeeds.

Dropwort is known by its winged leaves, the diviſions of which are all regular, and ſharply indented about the edges; by its white flowers, growing in a bunch like an umble: but, principally, by its roots, which conſiſt of a bunch of knobs hanging upon threads, from whence it has the names of filipendula, and dropwort. The flowers ſmell agreeably.

Meadow-ſweet, or queen of the meadows. The ſtalk is angular, ſmooth, ſtrong, branching, and of a reddiſh colour. The leaves grow alternately, are winged, and conſiſt of three or four pair of lobes, and a very large one at the end, divided into three parts, like a raſberry-leaf. They are indented about the edges, white underneath, and wrinkled, like the leaf of the elm. The flowers are ſimilar to thoſe of the dropwort. The whole plant has an agreeable ſmell.

Tormentil, or ſeptfoil. The root is large, of a reddiſh colour, and an aſtringent taſte. The ſtalks are weak, and lie on the ground at firſt; but afterwards riſe up. The leaves are hairy, grow cloſe to the ſtalk, and are divided into ſeven parts. The flowers are yellow, and conſiſt of four petals. There is another ſpecies, not ſo common, differing from this only in having its ſtalks lying intirely on the ground, and the leaves growing on foot-ſtalks.

The crowfoots are too common every where to need a deſcription. They are known under the names of kingkob, king cup, gold-cups, gold knobs, butter-cups, and butter-flowers. The bulboſe crowfoot is diſtinguiſhed not only by its round root, but by the diviſions of the flower-cups being bent back, the ſtalk being erect, and that which ſuſtains the flowers being furrowed. The upright crowfoot has the diviſions of the empalement ſpreading out, as in the creeping ſort; but the flower-ſtalks are not furrowed, as in that and the bulboſe one. The leaves are divided, firſt, into three parts; and each of thoſe again into ſeveral. The upper leaves are long, narrow, and undivided. This plant grows much taller than the others. The flowers of all three are alike, and of a fine ſhining yellow.

Pilewort, figwort, or leſſer celandine. The root conſiſts of oblong knobs. The leaves are heart-ſhaped, cornered, and placed on foot-ſtalks. The flowers reſemble in general thoſe of the crowfoots, but differs ſomewhat from them in having the cup divided only into three parts, the petals being about eight in number, and narrower. This low plant runs very much at the root, and choaks all plants which are near it.

Bugle, middle confound, ſicklewort, or herb carpenter. It riſes about half a foot high, with a ſquare ſtalk. The leaves come out by pairs, of a purpliſh colour, and indented about the edges. The flowers grow in a ſpike, are blue, and have a very ſmall upper lip.

Self-heal, hook-heal, ficklewort, carpenter's herb, or prunell. This differs from bugle, in the leaves being longer and narrower: and in the flowers growing in a thicker fpike; their upper lip being larger, and their filaments being forked.

Common yellow toad-flax, or flax-weed. It creeps very much with its hard woody roots: which fend up feveral fmooth ftalks, a foot, or a foot and a half high, covered with long, narrow leaves, placed without order. The flowers grow in clofe fpikes, on fhort foot-ftalks, at the top of the ftalks. They are of a light yellow, fhaped like a calf's mouth; and end in a fpur behind.

Ladies-fmock, cuckow-flower; in Norfolk, Canterbury-bells. The ftalk is upright, round, and fmooth. The leaves are winged, with the lobes of the lower ones roundifh; and of thofe upon the ftalk oblong. The flowers are large, handfome, and white, or purplifh; confifting of four obtufe veined petals. The feeds are contained in erect, compreffed pods, an inch, or an inch and a half long; divided into two cells: which, when ripe, burft with a touch, and throw out their feeds to a confiderable diftance.

Crow-foot crane's-bill, or blue crane's-bill. The leaves are divided, almoft to the middle, ufually into feven parts. The ftalk commonly divides into two branches, and each of thefe into two more. From the corner of each divifion, comes a flower-ftalk; fupporting two large blue flowers; confifting of five roundifh, intire petals, fucceeded by a long feed-veffel, refembling a crane's-bill. This bill-like feed-veffel is thick and rough; but not fo long, as in fome of the other forts.

Reft harrow, or cammock, of the paftures, differs very little from the corn reft-harrow defcribed before. The branches of this are armed with long ftiff prickles. The flowers are of a higher purple, and come out fingle: whereas, in the other, they come out two together.

Dandelion, or pifs-a-bed, is well known in all paftures, by its milkinefs, and its naked, hollow ftalks, fupporting one large, yellow, compound flower; which is fucceeded by a round ball of downy feeds.

Rough dandelion, or dandelion hawkweed. The whole plant is rough, with forked hairs. The flower-cup does not bend back, as in the common dandelion: and this is a taller plant.

Yellow devil's-bit, fo called, becaufe the end of the root feems as if it were bit off, is alfo known by the name of fmall hare's hawkweed. The leaves are fmooth, long, narrow, and cut into long, fharp-pointed fegments. The ftalks are a foot and a half, or two feet high, and branching. On the tops of thefe, grow many flowers, fmaller and paler than in the dandelion; fupported on fcaly flower-ftalks.

Long-rooted hawkweed. This has a very long tap root. The ftalks are a foot and a half high, or more; cornered, naked, and divided. The bottom leaves fpread in a circle on the ground, and are jagged and rough. The flower-ftalks are fcaly. The flowers, and down of the feed, refemble thofe of the dandelion.

Dwarf, or fmall purple carline-thiftle. This lowly plant fpreads its prickly leaves a foot round, and fuffers nothing to grow beneath them. Its purple flower comes out in the midft of thefe, without any ftalk, clofe to the ground.

Colt's foot, fole-foot, horfe-hoof, or bull-foot. In February, the fcaly ftalks arife, bearing one yellow compound flower; which is fucceeded by a hairy white down. The leaves come out later. They are fhaped fomewhat like a horfe's hoof; and are downy underneath.

Butter-bur, or peftilent-wart, refembles colts-foot in many refpects: but the flowers are purple, and grow in a thyrfe. The leaves come out after the flowers decay; and are like thofe of the colt's foot in fhape; but are three or four times as big.

Ragwort, ragweed, ftaggerwort, ftanerwort, St. James's wort, feggrum, or feagrim. The ftalk is ufually fingle, round, ftreaked, folid, and of a purplifh colour, in fame parts. The leaves are very much jagged, fmooth, and of a dark green. The flowers are yellow, radiated, and grow many together. When we affirmed, that this plant comes up eafily by hand, when young, or the ground is moift; we fpoke from experience. The fact, in few words, was this. Some clofes were notorioufly over-run with this weed. The owner, juft before the time of flowering, and after fome rain, turned in a man and woman upon them; ordering the woman to pull up all fhe could by hand; and the man to root out the reft, with his docking-iron. The rag-wort was not, indeed, left in a lane, for the downy feeds to ripen; and to be carried on again to the clofes, by the wind: but the plant was thrown in heaps, and burnt, and the afhes were fpread upon the grafs. It was not, indeed, all deftroyed at this firft attempt; but the few plants, which came up, the following year, were foon pulled up by the woman; and fcarce a plant has now appeared in thefe clofes, for feveral years paft.

Fleabane, middle fleabane, or fleawort. The ftalk is round, bending, folid, and hoary. The leaves are oblong, fharp-pointed, wrinkled, downy, and embrace the ftalk, on which they grow, very thick, without regularity. The flowers are yellow, radiated, and inclofed in a flower-cup, made up of narrow fcales like briftles. Mr. Ray tells us, that, if the leaves or tops of fleabane be fqueezed, they fmell like foap. Gerard fays, the herb-women call it herb Chriftopher.

Greater daifie, ox-eye, or maudlin-wort. The ftalk is five-cornered, folid, and branching. The leaves are jagged; and embrace the ftalk. The flowers are large, and radiated. The ray is white; and the difk yellow: the feeds have no down.

Common yarrow, milfoil, or nofebleed. The ftalks are flender, round, ftreaked, ftiff, and hairy. They are divided towards the top into feveral branches; and thefe again into flower-ftalks; fupporting fmall white or purplifh flowers; growing thick together in a kind of umbel. The leaves are cut very fine; and divide twice.

Common, or black knapweed, matfellon, black matfellon, or bulweed. The root is hard, thick and woody; and has a difagreeable aftringency. The ftalks are round, rough, ftreaked, ftrong, and very tough. The leaves are irregularly placed, oblong, and of a dark green. From the wings of the leaves, arife ftalks, fupporting one, two, or three heads of flowers; which are purple, and inclofed in a fcaly cup. The fcales are black, and furrounded with fine hairs, like the eye-lafhes.

The orchifes may be known by their roots; which are either a double bulb, refembling a pair of tefticles; or a bunch of long flefhy roots, like the fingers of the hand. The flowers, by growing in a fpike, make a handfome appearance. The colour is red in moft forts.

Adder's-tongue is hid among the grafs in low meadows. From a very low ftalk, arifes a fingle, thick, fmooth, oblong leaf; from the bofom of which, iffues a kind of tongue, ending in a point, and indented on each fide like a file.

WEEVIL, an infect of the beetle kind, refembling a fmall May-bug, with a long fharp pointed head, to the hinder part of which are fixed two antennæ. It is black, and therefore eafily diftinguifhed in any corn: but its principal and favourite food is wheat, of which, either old or new, it devours great quantities; without, however, communicating any bad fmell to it, as the moth does. Some call it the corn-loufe, becaufe it bites animals more ftrongly than fleas do. This has made it to be looked upon as a carnivorous infect; and many have pretended that it devours both the worm and the chryfalis of the falfe moth: an opinion which M. Duhamel does not think improbable, becaufe, in effect, very few of thofe moths are ever found in corn where there are many weevils.

Upon thrufting one's hand into a heap of corn, one may eafily perceive, by its heat, whether it contains many of thefe infects, which generally lie pretty much collected; and the particular places where they are moft numerous, feel much warmer than the reft. This obfervation foon led M. Duhamel to think, that a confiderable heat is probably neceffary for the hatching of their eggs; and that, in this cafe, even if they fhould live, they will not be able to breed, in his ventilating granaries.

To afcertain this fact, he put fome weevils into wheat (not ftove-dried) in one of thofe granaries, in May 1751. It was well ventilated from time to time, and opened in Auguft 1752, when none of them were found. He did the fame ſame with wheat which had been ſtove-dried; and when the granary was emptied, a year and half or two years after, not a weevil could be ſeen.

He again put ſome weevils into a ventilating granary in which wheat of the year 1754 was laid up, without having been ſtove dried. This corn was taken out in May 1756, and ſifted over a fine ſcreen; which gave him an opportunity to obſerve whether the weevils had increaſed. Their number ſeemed to him nearly the ſame as that he had put in: and a farther reaſon which induced him to think they had not multiplied, was, that this grain, inſtead of being heated, as corn is well known to be whenever weevils breed in it, was ſo cool, that a country fellow employed for this work could hardly remain bare-footed among it.

In 1755, Dom Edward Provenchere, procurator of the Carthuſians of Liget, near Loches, in the province of Touraine, intending to make ſome experiments on the preſervation of corn, choſe for that purpoſe a large caſk, at one end of which a little above the common bottom, he put a floor of lattice work, and over that a canvas. This caſk was filled with wheat of the harveſt of 1754, of which it contained 1080 pounds. He then fixed to it a pair of middle ſized bellows, ſo ſituated that they might eaſily be worked; and nearly in the centre of this corn, he put as many weevils as weighed ſix drachms; which is pretty conſiderable for that quantity of grain.

The bellows were blown an hour every week. In the beginning of September 1756, when that operation had been neglected for ſome time, the corn began to heat: but it was ſoon cooled again by uſing the bellows. The 15th of October, on taking the corn out of this caſk, in which it had kept perfectly well, not above twenty weevils were found in it. Dom Edward ſays he ſaw that inſect come out of the vent-holes every time the bellows were blown. He perceived in many places ſeveral grains of corn linked together by threads, certainly formed by moths that were in his wheat (which had not been ſtove-dried), and, not dying immediately, had had time to ſpin their web.

Dom Edward filled another caſk with nine hundred pounds of barley, not ſtove-dried, and put into it ſix drachms of weevils. Though care was taken to ventilate this caſk as much as the former which was filled with wheat, that is to ſay, during an hour every week, yet this corn heated prodigiouſly: the bellows could not cool it, and the weevils multiplied in it exceedingly.

"This, ſays M. Duhamel, is the very thing that happened to me in my larger experiment on the ſame kind of grain. Barley probably contains a great deal of moiſture; and the queſtion is whether ſtove-drying can be able to preſerve it. The increaſe of the weevils here ſeems to prove, that this inſect cannot multiply in corn which retains a proper degree of coolneſs."

Though the above experiments ſeem to prove pretty clearly, at leaſt that the weevil cannot breed in corn which is kept properly cool, and that if any ſure way to deſtroy this inſect be ever diſcovered, it will be moſt likely to ſucceed by means of the ventilating granary; yet M. Duhamel, with his conſtant candour and unvaried zeal for the welfare of mankind, exhorts the naturaliſt, the philoſopher, the lover of the public good, not to rely too much on any thing that he has ſaid in this reſpect; to look upon the trials which he has related, as ſteps only which may help to lead to that deſired end; and to continue their endeavours to render to the world the important ſervice of ſhewing how this creature may be effectually exterminated, by any ſafe and practicable method.

"I have tried, continues he, in his lateſt writings upon agriculture, many of the receipts moſt vaunted in books of huſbandry, as remedies againſt the weevil, and have not found the leaſt benefit from any one of them. All that they have taught me, is that this animal will endure a great deal before it can be killed. It will live a long time without eating: cold will benumb it ſo as to make it appear to be dead; but I have put ſome of them, in that ſtate, into a warm place, and after keeping them there for ſome time, have found that they were perfectly alive: the great coolneſs of my granaries has ſeemed to prevent their increaſe; but it has not killed them. They bear eaſily a heat of from forty-five to fifty degrees of Réaumur's thermometer (from one hundred and fifteen to one hundred and twenty-four of Farenheit's). I kept corn in which there were many weevils, during half an hour, in a place heated to upwards of eighty degrees of Réaumur's thermometer (two hundred and ten of Farenheit's): ſome of them periſhed; but others remained alive. They, therefore, who would deſtroy them by ſuch a degree of heat, muſt let their corn be expoſed to it during ſeven or eight hours at leaſt.

"I grant that the ſmoke of ſulphur will kill any inſect; but that method is not practicable in granaries: for this vapour, which is very light, aſcends to the top of the granary, and ſcarcely acts at all upon the corn on the floor. It is true, that the corn may be ſo diſpoſed as to let this ſmoke paſs through it, and all the inſects in it will then be deſtroyed. But, at the ſame time, this ſmoke will give the corn a very diſagreeable and laſting ſmell, which depreciates it entirely. Conſequently this method will not do.

"It is confidently ſaid, that the weevils may be driven away by turning the corn with ſhovels rubbed with eſſence of turpentine. To try whether this eſſence really diſpleaſes them, I ordered two large caſes to be made: the inſide of one of them was rubbed with eſſence of turpentine; both of them were filled with corn in which there were many weevils; and the inſects remained as quiet in the one as in the other. It is true, that when corn infeſted with weevils is turned with a ſhovel, ſeveral of thoſe inſects quit the heap, and haſten towards the walls of the granary. This may have been imputed to the rubbing of the ſhovel with oil of ſpikenard or eſſence of turpentine: but the ſame thing happens when the ſhovel has not been rubbed with any drug whatever; and the fugitive weevils ſoon return to the heap of corn.

"When corn is ſifted in a ſieve (and the ſame is applicable to a ſcreen) fine enough to retain the grain; the weevils, then agitated, ſhrink up their legs, and are, in that poſture, generally ſo much ſmaller than the good corn, that very many of them drop through the ſieve. The greateſt part of them may therefore be deſtroyed by this method, which is a very good one: but, unfortunately, there will ſtill remain enough of them among the corn, to do conſiderable damage. This ſieve or ſcreen ſhould be of wire; and under it ſhould be placed an earthen or copper veſſel, pretty deep, to receive the inſects, and ſmooth on its inſide, to prevent their getting out eaſily.

"Of all the methods I have tried, that which has ſeemed to me to be the beſt, is to dry the corn in a ſtove, or oven, heated to eighty or ninety degrees of M. de Réaumur's thermometer (from two hundred and ten to two hundred and thirty of Farenheit's) and to let it remain there twelve hours. I exhort all thoſe who wiſh the welfare of the public, to ſtudy the means of deſtroying the weevil, and, in conſequence thereof, to make particular experiments: but I beſeech them not to publiſh their diſcoveries till they have made repeated trials of them, and that in different granaries: for I have ſometimes ſeen theſe inſects forſake a granary, when no cauſe could poſſibly be aſſigned for their ſo doing."

WELD, *or* DYER'S WEED, the name of a plant much uſed by the dyers to give a yellow colour to woollens, ſilks, cotton, and thread.

Its root, which is compoſed of a few ligneous fibres, does not pierce deep: from this root it puts forth leaves about four inches long and half an inch broad, of a lively green, ſoft to the touch, and ſpread circularly near the ground, with ſome gentle wavings at their edges, but obtuſe at their points. Its ſtem, which riſes from amidſt theſe leaves to the height of three feet, or even more if the ſoil and culture be very good, often branches out, and is garniſhed with leaves like thoſe below, though ſmaller in proportion as they approach the flowers, which grow in long looſe ſpikes at the end of the branches or ſtem. Theſe flowers, which appear at the latter end of June, are each of them compoſed of three ſmall irregular petals of a greeniſh yellow, to which ſucceeds a globular berry of the ſame colour, terminated by three points, and in which are incloſed ſmall brown ſpherical ſeeds. Theſe ſeeds ripen in September. The plant becomes entirely yellow when it is dry, and the whole of it, but eſpecially the berry, is uſed in dying. The ſlendereſt weld, and particularly if it inclines to a ruſſet colour, is accounted the beſt: that

that which is larger, and of a dull green, is much less esteemed.

This plant grows naturally along the sides of high-ways, upon dry banks, and on old walls, in many parts of England, France, Spain, and other countries where the winters are not very severe: but the cultivated sort is far preferable to the wild, both for the quantity and the goodness of the colour which it yields. It will thrive tolerably on almost any soil, provided it be dry and warm: but the richer the land is upon which it is sown, the greater will be the produce; and in proportion to the care with which it is cultivated, the more vigorous and fit for dying will it be.

The ground for this, as for every other plant, should be in fine tilth at the time of sowing it; though here, unless it be very poor indeed, it will not require dung. The seed should be that of the preceding year; for if it be older, great part of it will not grow. Both Mr. Worlidge and M. Du Hamel are of opinion that weld-seed should, on account of its smallness, for it is but little bigger than that of purslane, be mixed with ashes, buckwheat, oats, or some other similar ingredient, in order the better to avoid sowing it too thick; for the plants of weld thrive best when they are about six inches asunder. For this reason, as was before observed in regard to all plants which require being hoed, it is best to sow weld in rows. Some sow it on barley, or oats after they have been sown and harrowed, this requiring only a bush to be drawn over it; for it should not be covered deep. A gallon of weld-seed thus used in the broad-cast way will be sufficient to sow an acre of land. It will not grow much during the first summer, when it is thus sown; but it will thrive apace after the corn is taken off.

The beginning or middle of August is a proper season for sowing weld in this country. The only care that it requires whilst growing, is to keep it clear of weeds which might choak it, or at least weaken its growth.

The French, in general, sow their weld in March, and pull it up in July or August of the ensuing year, when part of its seeds are ripe, and the plant is still of a greenish yellow: they then dry it and thresh it upon cloths, to get the ripest of the seed, and after this they tie the stalks up in bundles, and sell them to the dyers. But Mr. Miller rightly judges, that the best time to pull the weld for use is when it begins to flower, that is to say, about the latter end of June, because, like all other vegetables, it is then in its greatest vigour, and consequently best fitted to yield the greatest quantity of dye. For a produce of new seeds, it is much better to sow a small piece of land on purpose, or to set apart for this end a suitable portion of the field of which the plants are intended for use, rather than let the whole stand too long, that is to say, till part of the seeds are ripe; because, by letting the plants stand till then, their quality is injured far beyond the value of the seeds that are got from them (the berries being, as was observed before, the part which yields the finest dye); and besides, the seeds thus obtained will of course be a mixture of ripe and half-ripe ones, on the growing of which there cannot be a due reliance. The common way of drying these plants is to set them upright in small handfuls in the field, and when they are dry, to tie them up in bundles. They must also be housed dry; and care must be taken to stack them so loosely that there may be room for the air to pass between them, to prevent their fermenting.

The plants which are intended for seed should be pulled as soon as their seeds are ripe, and then be dried and beaten out for use: for if this is deferred, or if they are let stand too long, the seeds will scatter.

The method of cultivating this plant at Oissel, in Normandy, where great quantities of it are raised for exportation to Holland, independent of the consumption in France, is thus related by M. Dambourney, in the Memoirs of the Royal Society of Agriculture at Rouen.

"In the month of July, just after the kidney beans then in bloom have been hoed for the second time, and earthed up, especially if there be an appearance of approaching rain, weld-seed is sown among them, very thin, as equally as possible. Careful husbandmen bury this seed by dragging over it a small bush of thorns. Whilst the weld rises, the beans ripen and are gathered; after which the ground remains, of course, planted with weld only. This is hoed about Michaelmas, then left in that condition during the winter, and in the ensuing month of March, when the danger of frosts is judged to be over, it is hoed again, to extirpate such weeds as may have come up in the mean time. Towards the end of June in this second year, when the weld has done blossoming, when its berries form, and when the plant begins to turn yellow, advantage is taken of the first fair day after a rainy one, to pull it up. Two men will then pull up as much of it in one day, as four men can when the ground is dry and hard. It is carried off in large bundles: but these are untied before the weld is laid up for keeping, and the plants are spread out and set upright against walls or hedges well exposed to the sun, the heat of which completes their drying in two days. They are then laid upon a cloth, to prevent the loss of the seed, which drops very easily out of the now open capsules; and finally, after being tied up again in bundles weighing about thirty pounds apiece, they are piled up loosely in a barn or other well covered place, where they complete their ripening, and generally shrink to less than half of their former weight.

"Weld raised on rich ground is apt to be greasy and too full of stalks: that which grows in sandy places is of a better quality, and has only one main stem: but, in return, the produce here is much less than in the former case.

"As soon as the weld has been pulled, sheep are turned in upon the land, to eat up the grass it may have produced: it is then plowed once; and after another plowing at the end of October, it is sowed with wheat, or great rye, without using any other compost or dung. If the land is light and destined for spring-corn, turnips may be sown upon the first plowing after the weld; for they will have time to grow big enough to be pulled before the plowing for oats or small rye, which last crops it will be proper to help with a little shavings or raspings of horn.

"If it be intended to raise weld after peas, the ground should be plowed, and the seed sown very thin: to do which the more effectually, this seed, like that of turnips, should be taken up only in pinches between the middle finger and the thumb, and the fore-finger should remain extended, the better to help its spreading when it is dropped. This seed should be sown in rows sufficiently distant for the plants to have full room to grow; and the best way is to leave an alley after every third row. When sown, it is harrowed in, and the only farther care that the weld requires it to keep the plants free from weeds, by hoeing the ground at Michaelmas and in March, as before directed.

"The weld which is sown after peas does not injure the land it grows on; and therefore in this case, as after the kidney-beans before spoken of, wheat may be sown in October, without any previous manure."

WHEAT, the name of a well known plant, greatly cultivated in many parts of the world, especially in England.

As a crop of wheat, is, in general, the principal riches of farmers whose farms consist of arable land, we shall be very full in describing every method yet practised with success, for cultivating this useful species of grain; and in order to this, shall begin with the method of preparing the soil by ploughing, harrowing, and rolling.

Ploughing increases the food of plants, by opening the soil to receive the vegetable food from the air; and by enlarging the surface, and thereby exposing a greater quantity of the soil to its influence.

Ploughing enlarges the pasture of plants, by opening the soil, if too solid, and making it firm, if too light.

Ploughing prepares the vegetable food for entering the roots of plants, by reducing vegetables to a state of corruption, and dissolving oils.

Ploughing destroys weeds, by making their seed vegetate, and then tearing up the young plants; and by exposing their roots to the drought.

Ploughing removes wetness, by laying up land in proper ridges.

It may be said, therefore, that ploughing is one of the most important operations in agriculture; and that the greatest care is to be taken in the performance of it.

Though ploughing in general serves all the purposes mention d, yet commonly one of them only is chiefly in

view;

view; and according to the deſign in view the work is to be performed.

When the deſign of ploughing is to increaſe the food of plants, the ſurface cannot be made too uneven; for the more uneven that the ſurface is made, the greater quantity of the ſoil is expoſed to the influence of the air, and the greater quantity of food procured.

When the deſign of ploughing is to enlarge the paſture of plants, that kind is beſt that goes deepeſt, (provided the ſoil allows,) and moſt effectually breaks the mold; for the deeper that the plough goes, the greater quantity of ſoil is employed in vegetation; and the more effectually that the mold is broken, the larger is the paſture in the ſame quantity.

When the deſign of ploughing is to deſtroy root-weeds, the ſurface cannot be left too rough, nor the earth of the furrow raiſed in too large pieces; for the rougher that the ſurface is, and the larger the pieces of earth raiſed, the drought has the eaſier acceſs, and more effectually operates in the deſtruction of the roots.

When the deſign of ploughing is to deſtroy ſeed-weeds, the ſurface cannot be made too ſmooth, nor the mold too much broken: for the ſmoother that the ſurface is made, and more effectually that the mold is broken, the ſeeds are the more expoſed to the influence of the air, the ſap better preſerved, and their vegetation the more encouraged.

When the deſign of ploughing is to remove wetneſs, the land muſt be laid up in high and narrow ridges; for the greater number that there are of furrows, there are the greater number of drains; and the higher that the ridges are, the more eaſily the water finds its way to the furrows.

Thus we ſee how this operation of ploughing is to be performed, according to the chief deſign in view. It often happens, however, that land is in ſuch a condition as to require more than one of theſe advantages which ploughing is intended to promote. Theſe are ſometimes conſiſtent with each other, and the land may be ploughed in ſuch a manner as beſt to promote all of them. Thus land is ſometimes, at the ſame time, poor, and wet, and full of root-weeds: now, it may be ploughed in ſuch a manner as is moſt proper for increaſing its food, removing its wetneſs, and deſtroying its weeds: for, by one ploughing, its ſurface may be made uneven, which fits it for receiving an increaſe of food; it may be formed into narrow and ſteep ridges, which beſt removes its wetneſs; and the earth may be raiſed in large pieces, which beſt expoſes the roots of the weeds to be deſtroyed by the drought.

At other times the land is in ſuch a ſituation, that the advantages which it requires from ploughing are inconſiſtent with each other, and it cannot be ploughed in ſuch a manner as is moſt proper for promoting all of them. Thus land, at the ſame time, may be full both of ſeed-weeds and of root-weeds: now, it cannot be ploughed in ſuch a manner as is moſt proper to deſtroy both; for by one ploughing it cannot be raiſed in pieces and left rough, which is neceſſary to deſtroy root-weeds, and have the mold broke and be made ſmooth, which is neceſſary to deſtroy ſeed-weeds. This makes it neceſſary to have one of theſe things chiefly in view at firſt, and to conſider which of the two it is proper to begin with, and how the work may be performed in ſuch a manner, as the other may moſt eaſily ſucceed. Thus, in the preſent caſe, the land ſhould be ploughed, ſo as to be raiſed in pieces, and to be left rough; and in that condition it ſhould be allowed to lie, till the drought may be ſuppoſed to have deſtroyed the roots; and then it may be reduced, the pieces broke, and the ſurface made ſmooth, in order to deſtroy the ſeeds.

In ploughing there are ſome general rules to be obſerved, whatever is the deſign of it. Thus land is never to be ploughed when it is wet. When land is ploughed wet, the deſign of ploughing, whatever it may be, is fruſtrated; and this holds true in every kind of ſoil.

When ſtiff ſoil is ploughed wet, by drying too ſuddenly it becomes ſo hard, that it can receive no benefit from the air, and the paſture in it is entirely ſhut up: root-weeds ſtrike root again before the drought reaches them; and if there are any ſeed-weeds, the ſurface cruſts ſo ſoon, that they are prevented from vegetating.

When light ſoil is ploughed wet, though it may receive ſome benefit by expoſing a larger ſurface to the influence of the air, yet its pores, being full of water, will prevent its paſture from being enlarged; and the root-weeds that are in it, will not be deſtroyed; they will rather flouriſh, by being tranſplanted into a new paſture. In both kinds of ſoil the labour is very ſevere upon the cattle, and the land is greatly damaged by their going upon it, and treading it down with their feet.

Thus it is alſo to be obſerved, that whatever is the deſign of ploughing, the quantity of firm land taken off from the ſurface of the plough in going, ought not to exceed the wideneſs of the furrow which the plough makes below. If it does, the land is not clean ploughed; it is only ſcratched, and a quantity of the ſoil is left below untouched betwixt every furrow that the plough makes.

The quantity of firm land to be taken off by the plough, depends upon the deſign of ploughing, and the nature of the ſoil.

When the deſign of ploughing is to increaſe the food of plants, and deſtroy root-weeds, whether the ſoil is ſtiff or light, as great a quantity may be taken off as the plough can take conveniently; becauſe the greater that the quantity is which the plough takes off, the rougher and more uneven the ſurface is made, the more food is procured, and the root-weeds more effectually deſtroyed.

When the deſign of ploughing is to enlarge the paſture of plants, and deſtroy ſeed-weeds, though a large quantity may be taken off in light ſoil, that naturally falls in pieces when turned over, yet a ſmall quantity ought to be taken off in ſtiff land that is not ſo eaſily reduced; becauſe the ſmaller that the quantity is which the plough takes off, the ſoil is the more effectually broken, and the ſurface made the ſmoother; and the more effectually that the mold is broken, and the ſmoother that the ſurface is made, the paſture is the more enlarged, and the weeds more effectually deſtroyed. This is agreeable to the ordinary practice, introduced no doubt from experience; for we find that a much leſs quantity is taken off when land gets the ſeed-furrow, the chief deſign of which is to enlarge the paſture, than at any other ploughing.

In the directions which we have given about ploughing, we have had chiefly in our view land employed in tillage; it is neceſſary to add ſomething with reſpect to the ploughing lea, or opening up graſs ground.

The Engliſh writers on agriculture, when giving directions about the opening of graſs ground, always ſuppoſe that the land is to be ſummer-fallowed; and they recommend to plough as deep at firſt as the nature of the ſoil will allow. They aſſign this reaſon, That it is not poſſible to plough deeper afterwards. They likewiſe direct to turn the earth upſide down, or on its back, as we have called it. The reaſon they aſſign for this, is, that the ſward or turf may be the ſooner rotten.

Some perſons tried this method of breaking up graſs-ground in Scotland, but they found great difficulty in reducing it: and we have reaſon to believe that many find it ſo likewiſe in England; for Mr. Tull, in his chapter upon ploughs, tells us, That if the turf lie long without being turned, the graſs from the edges will ſpread and form a new turf, and that the roots often ſet up new heads, and the former heads are converted to roots. As Mr. Tull's deſign is to ſhow the neceſſity of the four-coultered plough, we need not doubt but he has a little exaggerated the matter; for, upon a narrow inſpection, it will be found, that if turf is turned upon its back, the graſs will grow only from the ſides. However, we may conclude, from what he ſays, that the land in England is not ſo eaſily reduced in this manner, as ſome pretend.

On the rich lands in Scotland, they follow a method the very reverſe of this which has been mentioned. They commonly ſow after one ploughing of graſs-ground, and plough as ſhallow and narrow as poſſible; and alſo ſet the turf as exactly as poſſible upon its edge. It is not our buſineſs in this place to conſider the propriety of ſowing after one furrow. We may only obſerve, that if the land is good, a good crop may be expected; and if there is a good crop, the turf will be completely rotten before next ſeaſon. What we have to conſider, is, which is the moſt proper method to break and reduce the turf. It is certain, that the thinner and narrower the turf is taken off, the more eaſily it is torn aſunder, and the more that it ſtands

on

on its edge, the harrows in going acroſs take the firmer hold, and make the greater impreſſion.

If this kind of graſs-ground is ploughed before winter in the manner mentioned, ſhallow and narrow, and the turf ſet upon its edge, it may be expected, if we are favoured with a little froſt, that in the ſpring the turf will be in ſuch a condition, as to be eaſily torn aſunder by the harrows, and the land itſelf in a proper condition to be ſown with oats, or to be ſummer-fallowed, and ſown with wheat.

Their barren lands they break up in the ſame manner as in England. They plough deep, and turn the turf over on its back. It ſeems, that the plants which grow on theſe lands have tougher and ſtronger roots than thoſe that grow on rich lands. This makes it more difficult to break the turf. If the earths of the furrows are ſet on their edge, the harrows turn them back, inſtead of tearing them aſunder. This happens whether the land is ploughed deep or ſhallow. But when the earths are turned on their back, and the land ploughed deep, the harrows raiſe a kind of mold upon the back of the turf, by which the hollows betwixt the earths are filled up, and nouriſhment afforded for the ſeed, the greateſt part of which falls into theſe hollows.

There is another method propoſed for opening up graſs-ground, and that is by trench-ploughing. This manner of ploughing is performed by one plough following another in the ſame track. The plough that goes firſt, turns over the ſward or turf; and the one that follows, turns up ſome inches of ſoil upon it. By this method there is ſufficient nouriſhment provided for the crop, and the ſward is rotten before next ſeaſon.

This kind of ploughing needs not be confined to the opening up of graſs-ground; it may be uſed in any ſoil that is deep; for by it ſome new ſoil is turned up, and a greater quantity employed in vegetation.

It has already been obſerved, that ploughing in ridges is proper for removing wetneſs. Every furrow becomes a kind of drain: the rain that falls upon the ridge, makes its way to the furrows, and by means of them is conveyed away from the field.

Ploughing in ridges is alſo proper for enlarging the ſurface. It is certainly an advantage to have the ſurface enlarged. Thereby not only a greater quantity of ſoil is expoſed to the influence of the air, but alſo a great quantity of it actually employed in vegetation. There is no more ſoil added to the field by enlarging the ſurface; but ſome of the ſoil that lies buried, while a field is in its natural ſtate, is expoſed to the air, and brought within reach of the roots of plants, when it is laid up in ridges. Some of the plants which we cultivate in our fields, have what are called horizontal roots, that is, roots that creep along the ſurface, and go down but a ſhort way. Now, it is obviouſly an advantage to theſe plants, to have a quantity of the ſoil below, to which their roots cannot extend, brought within their reach, which is done by enlarging the ſurface.

The tap-rooted plants, that is, ſuch as puſh one principal root perpendicularly downwards, have alſo horizontal roots, by which they are nouriſhed; and therefore it muſt likewiſe be an advantage to them, to have the ſurface enlarged.

To illuſtrate this further, let us ſuppoſe, that the roots of plants upon a field extend themſelves through the whole ſoil within four inches of the ſurface. Now, it is obvious, that there is more ſoil within four inches of the ſurface, when the ſurface is enlarged by ridges, than when the land is lying quite flat.

From theſe things then it appears, that a field contains more food, and has a larger paſture when in ridges, than when laid down level.

It muſt be acknowledged, that ſome conſiderable perſons are of a different opinion; and as this is the caſe, it will not be improper to conſider what is advanced by them.

There are ſome who mention the perpendicular growth of plants, as an evidence, that a ſurface, however much extended, can ſupport no more plants than the horizontal baſe. Though the fact is allowed, that plants grow perpendicularly, and that it is impoſſible to place more of them upon the ſurface than upon the baſe; yet it does not follow, that a field, when its ſurface is enlarged, can nouriſh no more of them: and it is to be remembered it is not more room which we contend for, but more nouriſhment. We may further obſerve, with reſpect to the growing of vegetables, that the enlarging the ſurface has this other advantage; it gives the plants more air, and thereby prevents them from falling down and lodging.

Mr du Hamel, to ſhow that the enlarging the ſurface by ridges is a real diſadvantage, obſerves, that ſuppoſing the ſlope in ridges is one foot in ſix, yet the ſurface will be to the horizontal baſe only as ſeventy-ſix to ſeventy-five, which, he ſays, is but a ſmall advantage, when compared to the loſs by the furrows.

In anſwer to this, it needs only be ſaid that there is no loſs by the furrows, unleſs when they are a real advantage to the reſt of the field. When land is dry, the corn is as good in the furrows as in any part of the ridge; and when the land is wet, the furrows ſerve for drains, and the loſs by them is more than made up by the advantage which the reſt of the field receives by being drained.

We may therefore conclude in the general, that the way of ploughing in ridges is preferable to the way of ploughing without ridges.

Having ſhown, that ridges are advantageous, as they remove wetneſs, and enlarge the ſurface, it is neceſſary now to conſider what kind of ridges are moſt proper for anſwering the ends propoſed.

As ridges remove wetneſs, when the ſoil is wet, the ridges ought to be narrow; for the greater number there are of ridges, there are the greater number of drains. When the ſoil is wet, the ridges ought alſo to be ſteep. For the ſteeper that the ridges are, the water more eaſily finds its way to the furrows.

When the ſoil is very dry, it is ſubmitted, if narrow ridges are not proper likewiſe. For by altering the ridges, and turning the furrows into the crowns, and the crowns into the furrows, a quantity of freſh ſoil is always employed in vegetation. When the crown of a ridge is turned into a furrow, it is obvious that ſome freſh ſoil is turned up, which was not employed in vegetation in its former ſituation; and the greater number there are of ridges, there is the greater quantity of freſh ſoil employed.

When the ſoil is juſt ſo wet as to occaſion loſs in the furrows, then the ridges ſhould be ſomewhat broader. For, in this caſe, the fewer there are of furrows, there is the leſs loſs.

It is proper to obſerve here, that a difference ſhould be made betwixt the ſituation of land in the winter, and its ſituation in the ſummer. It may be convenient ſometimes, when winter-grain is to be ſown, or when the land is to get winter-fallowing, to make the ridges very narrow; and, when ſummer-grain is to be ſown, to make them broader.

As it is an advantage to have the ſurface enlarged, the ridges ought to be made high in the middle, or crown. For the higher that the ridge is made, the more is the ſurface enlarged.

When the ſoil is ſhallow, the ridges, if broad, cannot be raiſed, without depriving the furrows of ſoil: and therefore, to enlarge the ſurface on ſuch land, the ridges muſt be made narrow. For this both enlarges the ſurface, and prevents the furrows from going below the ſoil.

When the ſoil is deep, the ridges may be made broader: for though the ridges are raiſed in the crown, yet ſtill there is ſoil left in the furrows. But then the ridges muſt not be made too broad: for it is evident, that narrow ridges give more ſurface than broad ridges, of the ſame degree of ſteepneſs; and do not cover the lower parts of the ridges ſo much from the influence of the ſun and winds.

It is neceſſary to obſerve, that though, in the general, it is recommended to raiſe the ridges in the crown, to enlarge the ſurface, and to allow the water more eaſily to find its way to the furrows; yet, in ſome low flat-lying land, it is proper to make the ridges as flat as poſſible, in order to raiſe the furrows. For the higher that the furrows are raiſed, there is, in ſome caſes, the greater command of the water, and it is the more eaſy to find a fall for conveying it away.

It is neceſſary to obſerve likewiſe, that flat ridges have this advantage over ſteep ridges; they can be ſown with greater exactneſs. It is obvious from the method of ſowing, that, in ſowing ſteep ridges, it is not poſſible to prevent a great proportion of the ſeed from falling into the furrows. It is obvious likewiſe, that this proportion is increaſed by harrowing. Whereas, in ſowing flat ridges, the ſeed is equal qually ſcattered, and the harrows do not remove it from its place.

From theſe obſervations, it is obvious, that ſoils in different ſituations require to be laid out in different kinds of ridges. It is abſurd, therefore, to aſſert, that, in every caſe, one kind of ridges is preferable to another; that narrow ridges are better than broad ridges, and flat ridges better than ſteep ridges. In ſome ſituations, one kind of ridges is moſt proper; and, in other ſituations, another kind is moſt proper. Every perſon ought, therefore, to conſider the nature of the ſoil he has to deal with, conſider the advantages and diſadvantages of each kind of ridges, and then determine which are moſt proper.

When there is nothing in the nature of the ſoil to determine what kind of ridges are moſt proper, then narrow ridges are to be preferred; for this reaſon, that a quantity of land in narrow ridges is ſooner ploughed than when in broad. It is obvious, that the two firſt furrows which the plough takes off from the ridge, are wider than any taken off afterwards, eſpecially if the plough begins in the furrow, as is frequently the caſe; ſo that the greater number there are of ridges, the field is the ſooner ploughed. Beſides, when ridges are broad, it is obvious, that the plough has more work, and muſt take longer time in turning, than when they are narrow. But then it is ſuppoſed that the ridges are ſtraight and equal. If they are not, the greater number there are of them, the greater is the trouble, and the more time is ſpent in ploughing. This, however, it muſt be owned, is of no great importance; becauſe it ſeldom happens, that the kind of ſoil does not determine what kind of ridges are moſt proper.

Having conſidered the kinds of ridges proper for land, according to its different ſituations; it is proper to inquire, whether there are any qualities which ridges ought to have, whatever is the ſituation of the land.

It will eaſily appear, that all ridges ought to be made ſtraight. Crooked ridges, it is obvious, are attended with ſeveral inconveniencies. In ploughing them, the cattle are not always going exactly in the ſame direction with the plough; ſhort turnings are often neceſſary, as fields are generally bounded by ſtraight lines, or lines not crooked in the ſame manner with the ridges; and, when there is a ſmall deſcent, the water, as it runs in the furrows, meets with reſiſtance.

It is obvious, that when the plough goes in a curve, as it does in ploughing crooked ridges, the draught is not in the ſame direction with the beam, but is either to the right or left of it; and this gives the plough either too much or too little land.

It is obvious likewiſe, that, when ridges are crooked in a manner different from the lines by which a field is bounded, in ploughing the ridges upon the ſides, one part of them muſt be finiſhed before ſome other parts are near done; and thus ſhort turnings are neceſſary, which hurt the land much by the treading of the horſes.

It is obvious likewiſe, that, as a crooked furrow is continually altering the direction of the water, and has a leſs deſcent than a ſtraight furrow, the water, as it runs along it, muſt meet with greater reſiſtance, and thus penetrates the ſoil, and makes it more difficult to convey it away.

Theſe inconveniencies are removed by making the ridges ſtraight. For, in ploughing ſtraight ridges, the cattle are always going in the ſame direction with the plough; no ſhort turnings are neceſſary, as fields can be made of an equal breadth in all places; and the furrows having a greater deſcent, the water meets with leſs reſiſtance, and is more eaſily conveyed away.

Straight ridges not only remove the inconveniencies with which crooked ridges are attended, but it is found that they are to be attended with no inconveniencies themſelves: they require indeed a little attention in the ploughman, which is itſelf an advantage; and therefore, upon all occaſions, are to be preferred.

As, in all kinds of ſoil, ridges ought to be ſtraight, ſo likewiſe they ought to be equal, equal one to another, and the ſame ridge equally broad in all places. Unequal ridges are attended with inconveniencies, as well as crooked ridges. It is difficult to ſow them with exactneſs; it is difficult to alter them, when neceſſary; and the plough muſt often turn in the middle of the ridge, which does great harm, by the treading of the horſes, or it muſt be driven empty to the end.

Theſe inconveniencies may be removed by making the ridges equal. Equal ridges may be ſown with greater exactneſs, and conſequently with leſs ſeed; it is eaſy to change them, one into two, or two into three, as occaſion requires; and the ſame furrow that finiſhes the ploughing of the ridge in one place, finiſhes it in all places; ſo that there is no neceſſity to turn the plough in the middle of the ridge, or to drive it forward the ſhorteſt ſpace, without turning up a furrow.

In many places of England and Scotland the ridges are ſtill crooked and unequal; and, in many places, they are much broader, and much higher raiſed in the crown, than the nature of the ſoil allows. Were the ridges altered, and the fields laid down in a proper manner, as the ſoil requires, it would be a great advantage. At the ſame time, it may be obſerved, that much harm is done, by proceeding in this matter with too much precipitancy. It is neceſſary, therefore, that we conſider it as an affair of ſome importance.

It is neceſſary to obſerve, in the firſt place, that ridges muſt not be raſhly altered; on the contrary, great caution is to be uſed.

If the ſoil is very dry, ridges may be altered without great danger, though high; and they may be made ſtraight without being levelled. For, though the old furrows are ſtill lower than the reſt of the field, yet this is attended with no bad conſequences in dry land; and by degrees, they are filled up in ploughing. But then, it is to be obſerved, that there is not much land in Scotland, on which the ridges, at preſent, are high raiſed, in its nature ſo dry, as to allow this to be done.

If the ſoil is *wet*, the ridges cannot be made ſtraight till the ground is level, without great danger. For the water will lodge in the hollows of the old furrows, from whence it will not be poſſible to force it. Some perſons that make their ridges ſtraight before they are ſufficiently levelled, draw water-furrows along the hollows of the old furrows, to carry off the water that is apt to lodge there. This is of ſome uſe, but does not fully anſwer the purpoſe. A quantity of looſe earth, in ploughing, is thrown into the old furrows. The water, as it falls, penetrates this looſe earth, and is retained by it, notwithſtanding the water-furrows. Beſides, theſe water-furrows muſt be neatly cleaned out with a ſpade, and made deeper in the places where they are intercepted by the crowns of the new ridges, otherwiſe they are of very little uſe.

Before ridges can properly be made ſtraight, it is neceſſary therefore that the land be made as level as poſſible.

But it muſt be obſerved, that it is as dangerous to level ridges raſhly as to alter them before they are levelled: for if ridges are levelled too faſt, and thereby a great depth of looſe earth thrown ſuddenly into the furrows, it will not be poſſible to convey away the water that falls upon them. The water as it falls will ſink to the bottom, and there will lodge and chill the ſoil; and the earth thrown into the furrows being looſe, the cattle in ploughing muſt ſink to the bottom likewiſe, by which the land is very much patched.

It is recommended therefore to every perſon, ſeriouſly, to conſider the nature of the ſoil he has to deal with, before he proceeds to the altering old ridges; and, if the ſoil is wet, to level the ridges very gradually. When the ſoil is deep, and inclining to be wet, and a ſufficient ſlope for carrying off the water, it is probable, that the loſs ariſing from the levelling ſteep and broad ridges ſuddenly, may exceed the profit of many years ariſing from the ridges being properly laid down; and therefore, if a view to incloſing makes it neceſſary to ſtraight the ridges, the levelling them ſhould be the work of ſeveral years. Even ſuppoſing that the ſoil is ſhallow, and the ridges raiſed ſo high, that there is nothing but graſs left in the furrows, yet ſtill it is improper to level the ridges too faſt, though levelling in this caſe is neceſſary.

In levelling ridges a great hollow is made in the crowns. This is occaſioned by frequent ſucceſſive cleavings, which is the method commonly uſed for levelling ridges. It is obvious, that by the firſt cleaving a hollow is made in the crown of the ridge equal to the depth and breadth of the furrow which the plough makes; whereas the parts on each ſide of the ridge are but little levelled, and

and at each succeſſive cleaving this hollow is made greater. Such a quantity of new earth immediately turned up, is not fit for vegetation. Beſides, this hollow becomes ſo great, and the parts of the ridge on each ſide of it become ſo ſteep, that it is impoſſible to plough them in a proper manner.

In this caſe, when levelling is ſtill thought proper, ſome furrows from each ſide muſt be thrown back by the plough into this hollow, by which a new ſmall ridge is formed upon the crown of the old one, and then the remaining parts of the ridge may be levelled as before. Some perſons, inſtead of this, plough acroſs the ridges. This method ſerves the ſame purpoſes; it both throws ſome earth into the hollows, and levels the ridges; for the plough in going carries off ſome earth from every height, and leaves ſome in every hollow. But then land muſt not be left in this ſituation during the wet ſeaſon, unleſs water-furrows are drawn along the furrows, and alſo in ſome caſes along the crowns; for unleſs this is done, the water that falls upon the field cannot be conveyed away. At the next ploughing, the whole old ridges may be levelled in the ſame manner as at the firſt ploughing; or, if thought more proper, may be divided into two equal ridges, ploughed in ſuch a manner that the furrow betwixt them may be exactly in the crown of the old ridge, and the other furrows exactly in the furrows of the old ridge. By this operation the old ridge is raiſed from the furrows, and levelled from the crown.

When a perſon is upon a ſcheme of levelling, this method of dividing the ridges into two will be found very proper, either when winter-grain is to be ſown, or when the barley-land gets the winter-ploughing.

Though land may be in ſuch a ſituation as to allow the ridges to be levelled with ſafety, yet unleſs it is remarkably dry, and in no caſe in danger of being damaged by too much water, the ridges ſhould not be altered, excepting when the land is ſummer-fallowed; and in that caſe, beſides the ploughing that alters the ridges, there ought to be another before the wet ſeaſon comes on, that ſo the bottom may be ſufficiently firm to reſiſt the water.

We have obſerved, that ridges ſerve to remove wetneſs, and to expoſe the ſoil to the influence of the air, and we have ſhown what kind is moſt proper for theſe purpoſes. But this is not enough; it is neceſſary likewiſe to conſider in what manner ridges ought to be placed. This is a matter of ſome conſequence: for, according to the poſition of ridges, water may be either conveyed away or retained; and ſome aſſert likewiſe, that by this the ſoil may be better expoſed to the influence of the ſun and wind. Theſe things therefore muſt be kept in view in the placing of ridges.

When the land is wet, as is often the caſe, it is certain that ridges ought to be placed with a view to the conveying away the water: but when land is dry, as is ſometimes the caſe, then ridges ſhould be placed with a view to the retaining the water.

The moſt common way of placing ridges where there is a ſlope, is along the declivity in a ſtraight line from the top to the bottom; and land is commonly laid out with a view to this. Where the declivity is gentle, this is, no doubt, a very proper way of placing the ridges; but if the declivity is great, this way of placing the ridges allows the ſoil to be waſhed away by the rain. It is obvious, that water, in running off of land, carries a part of the ſoil along with it, and the quantity is great, in proportion to the violence with which it runs. In climates where there are heavy ſhowers of rain, the damage done by this is not inconſiderable. Therefore, in this caſe, placing ridges acroſs the declivity is the moſt proper way; for when ridges are placed acroſs, the water meets with many interruptions in its courſe, and does not run off with ſuch violence as when placed along from top to bottom, and therefore does not carry off ſuch a quantity of the ſoil along with it.

Inſtead of this ſome perſons make the ridges very narrow. This ſerves the ſame purpoſe; for in proportion to the number of furrows, there is the leſs water in each furrow, and conſequently it runs with leſs violence. However, placing the ridges in this manner is not ſo proper for this purpoſe as placing them acroſs the declivity, and, beſides, is not ſo proper for retaining the water in a dry ſeaſon.

When land is very dry, and in no danger of being damaged by the ſtagnation of water, the ridges ought to be placed acroſs the declivity, as near the level as poſſible; for this retains both the water and the ſoil. It is obvious, that when ridges are placed in this manner, the water cannot get off by running along the ſurface, by which the ſoil is in greateſt danger of being carried away. As the furrows ſtop it in its courſe down the hill, it can get off in no other way than by penetrating the ſoil. By this a part of it is retained; what of it gets off is clear, and carries no ſoil along with it.

When land is dry at the head of the ridges, and wet at the foot, and no proper fall for carrying off the water, as is frequently the caſe, the ridges ſhould be placed in the ſame manner, directly acroſs the declivity. For, in this caſe, every furrow in ſome meaſure retains the water that falls upon the ridge above, and thereby prevents it from ſinking towards the bottom of the field, and lodging there. By this way of placing the ridges, the dry part of the field is rendered wetter, and the wet part of the field is rendered drier than otherwiſe they would be.

This is likewiſe a very proper way of placing the ridges, even when the declivity is but ſmall, if the land is in the ſituation mentioned, dry at the head, and wet at the foot. It muſt be owned, however, that this will not entirely anſwer the end propoſed: for the water will penetrate the ſoil; and when it is reſiſted by till or clay, will find its way along theſe to the bottom of the field. But this will not be ſo ſudden, as in the other way of placing the ridges; and the ſoil at the head, which is naturally dry, will receive more benefit from the rain as it falls.

When land is wet, and the water may be conveyed away from the bottom of the field, the ridges ſhould be placed acroſs likewiſe; not directly, but with a ſmall ſlope to a drain or furrow on the ſide of the field from top to bottom, by which the whole water is conveyed away. In this caſe every furrow becomes a drain to the ridge below, and prevents the water from running over it.

When land is wet from the breaking out of ſmall ſprings, this way of placing the ridges is alſo very proper. The furrows convey away the water as it riſes, and prevent it from doing any damage.

It is neceſſary to obſerve, that ridges placed in this manner, to ſerve theſe purpoſes, ſhould not be altered; for when the furrow is kept in one place, it is a more proper drain than when altered. When the furrows are kept in one place, the bottom is always firm, and the water runs eaſily along it; whereas, if changed, it may fall upon places of the field, where the ſurface, being raiſed by former ploughings, will prevent them from reaching the firm bottom. Beſides, if the ſprings break out in the furrows, by changing their place, they may break out in other parts of the ridge.

It is neceſſary to obſerve likewiſe, that ridges placed in this manner ſhould not be raiſed in the crown, but kept quite flat; that ſo, by the natural deſcent of the ground, the whole water that fall upon the ridge may be conveyed into the furrow below.

It was before obſerved, that ſome perſons aſſert, that, by a proper poſition of ridges, the ſoil is better expoſed to the influence of the ſun and air. Theſe perſons recommend the paying a regard to this. But it cannot be done excepting when the land is quite flat, and when the placing of the ridges makes no difference as to its wetneſs. However, as this is repreſented by thoſe perſons as important, ſome attention ſhall be given to what they ſay.

Some adviſe the placing the ridges ſouth and north; and the reaſon which they aſſign for this, is, that thereby the ſun may have an equal influence upon all parts of the ridge.

Others, again, adviſe the placing the ridges eaſt and weſt; and the reaſon which they aſſign, is, that they may ſhelter each other from the cold north wind.

Which of theſe advantages is the greateſt, is uncertain. It is even uncertain whether they can be called advantages at all.

It may be diſputed, whether, in the winter-ſeaſon, cold or heat is moſt beneficial to land. That heat is beneficial and cold deſtructive to plants, is certain. But cold poſſibly may be as proper as heat for preparing land for the nouriſhment of plants. It is allowed, that the coldneſs of the north wind,

is

is in some measure owing to the quantity of salts that it carries along with it. These salts are beneficial to land; and therefore an exposure to the north seems to be rather a benefit than a disadvantage. This is confirmed from observation. The lands on the north side of rising grounds are, generally speaking, more fertile than those on the south-side. It is certain, that the richest lands in Scotland have this situation, and are exposed to the north.

It may be disputed likewise, whether the north or the south side of an east and west ridge has most benefit from the sun in summer. It is not to be denied, that the rays of the sun fall more directly on the south side of the ridge; but then let it be observed, that the north side has the benefit of the sun's rays in the mornings and evenings, when the sun is so low, that the south side is under the shade; which may possibly balance the loss sustained by the greater obliquity of the sun's rays about mid-day.

These things have been mentioned, to show, that it is uncertain, which way of placing ridges exposes the land best to the influence of the sun and air; and therefore, that, in placing them, it is needless to have any view in this. When the placing of ridges makes no difference as to the wetness of land, then we are chiefly to have in view the conveniency of ploughing and laying out the land in proper breaks.

There are three different ways of ploughing ridges: gathering, casting, and cleaving.

Gathering keeps the crown and furrows of the ridge in the same place in which they were before. The plough begins in the crown, and ploughs out the ridge, turning the earth towards the crown, where it entered. Every ridge is ploughed by itself; or, instead of this, the halves of two contiguous ridges may be ploughed together. By this method of ploughing, the ridge is higher raised than before. It is obvious, that, as the earth on each side is turned upon the crown, and thrown up out of the furrows, the ridge is raised, both by making the crown higher, and the furrows lower.

Casting keeps the crowns and furrows likewise in the same place, in which they were before. The ridges are ploughed in pairs. The plough may enter in the furrow betwixt the ridges, and plough out the ridges, turning the earth towards the furrow, where it entered. Or the plough may enter in the furrow on the right side of the two ridges, then turn to the one on the left, and plough out the ridges, turning the earth to these furrows, and from the furrow that is betwixt them. By this method of ploughing, the ridges are kept of the same height in the crown, and one of the furrows made a little higher, and the other a little lower than before. The earth is taken from one furrow, and thrown into the other, and this is done alternately through the field. If this is reversed at next ploughing, that is, the earth turned into the furrows from which it was taken at the former ploughing, thereby the ridges are preserved in the same situation.

Cleaving is the reverse of gathering. The plough enters in the furrow on the right side of the ridge, turns to the furrow on the left side, and ploughs out the ridge, turning the earth from the crown towards the furrows. Every ridge is ploughed by itself; or, instead of this, the halves of two contiguous ridges may be ploughed together. If the ridge is raised in the crown, by this method of ploughing it is made flatter. It is obvious, that, by this method of ploughing, earth is thrown into the furrows, by which they are made higher; and that earth is taken from the crowns, by which they are made lower. If the ridge is already flat, by this method it is changed, and the crown turned into the furrow.

When a field is laid out in the manner judged most proper, with respect to the breadth and height of the ridges, it should be ploughed in one or other of these ways mentioned, according to its situation. If the ridges are broad and high, casting will be found to be the most proper method of ploughing. For this is the only way by which they can be ploughed, and yet kept in the same situation: cleaving will make them flatter; and gathering will raise them higher. If they are flat and narrow, cleaving will be found to be the best method. Cleaving flat ridges, and thereby turning the crowns into furrows, and the furrows into crowns, has these peculiar advantages: a field is much sooner ploughed in this way, than in any other; and a quantity of fresh earth, at every ploughing, is exposed to the air, and employed in vegetation: and the ridges being kept level, are sown with exactness. In no case gathering is proper, unless when the proper situation of the ridge renders it rather too wet for winter grain.

It may not be improper, in this place, to consider a method of ploughing, used in some places, called ribbing. This method of ploughing is performed by making furrows about two feet distant from each other: one half of the surface is untouched by the plough, and the other half, which the plough turns up in making the furrows, is thrown on the top of what remains fast. The land may be ploughed in this manner, either without regard to ridges; or the plough may be made to enter and turn, as it does in gathering, casting, or cleaving; that is, a ridge may be ribbed in the way of gathering or cleaving; and two ridges may be ribbed in the way of casting. This kind of ploughing is seldom practised but in the beginning of winter, and upon land to be sown with barley, after two more clean ploughings. It does not prevail so much as formerly, and is very much condemned by our modern improvers. But, however much it may be condemned, it certainly has its uses. It keeps the land dry; the rain that falls is confined to the furrows, from whence the loose earth is taken, and easily finds its way off. It facilitates the rotting of the stubble, by covering it and keeping it dry; it makes the frost penetrate a greater quantity of the soil; and it also exposes a larger surface to the influence of the air. These things make this kind of ploughing, in some cases, preferable to a clean ploughing.

There is also another method of ploughing called bouting. It is performed by throwing the earths of two furrows towards each other upon some fast land. This is certainly an improvement upon ribbing, and better answers all the purposes of it.

By this method ribs are placed where furrows were before, and furrows where ribs were before; and the surface is entirely changed, what was above turned down, and what was below turned up. These two ploughings may be performed with the same strength, and in the same time with one clean ploughing; and, it is probable, that, upon trial, in some cases, will be found more beneficial.

As a further improvement of this method of ploughing, it is proposed to rib the land, and, at the same time, to plough it clean. This is done by throwing the earths of three or four furrows together in such a manner, as to leave no fast land below; and is the same thing with ploughing the land in ridges about three feet broad, from the middle of one furrow to the middle of the other. This serves all the purposes of the other kinds of ribbing, and, besides, has these further advantages; the land being clean ploughed, weeds are more effectually destroyed, and the soil is better opened for receiving benefit from the frost and air. This method may likewise be reversed by another ploughing. The surface may be entirely changed, and the ribs turned into furrows, and the furrows into ribs.

These different methods of ploughing, the last two excepted, are known to every common ploughman, and they should be attended to by every improver, as of importance; without a proper knowledge of them he cannot give directions to his servants, nor prevent them from falling into blunders in the execution, which they are but too apt to do. The ignorance of a master in things which his servants are acquainted with, is attended with bad consequences; it gives them an indifferent opinion of his knowledge of farming, and makes them despise every new thing which he proposes, as absurd and whimsical.

It was observed, that ploughmen are apt to commit blunders in ploughing. Thus in gathering ridges, if care is not taken in beginning the ploughing of the ridge, some firm land will be left in the crown, and the crown itself so much raised above the rest of the ridge, that no seed will lie upon it. It is sometimes observed, that just on the crown of a ridge, where the soil is deepest, there is less corn, and more root-weeds, than in any other part of the ridge. This is certainly occasioned by allowing firm land to remain there in ploughing, and by raising the crown like a peak above the rest of the ridge. The ploughman, instead

ſtead of turning back the earth of the firſt furrow, and the firm land below it, keeps at ſuch a diſtance, as to lay the earth of the ſecond furrow up to it, or on the top of it. This leaves firm land betwixt the furrows, and raiſes the crown of the ridge to a peak. But if he is directed to draw the furrows ſo near, as to turn back the earth of the firſt in making the ſecond, no firm land will be left, and the earth, that by the other method is thrown upon the crown, will be ſcattered.

This blunder is oftener committed when flat ridges are cleaved. In cleaving, if the ridges are ploughed out turning the plough always to the left, it is impoſſible to prevent the two furrows, laid together in the crown of the new ridge, from being at too great a diſtance, and raiſed higher than the reſt of the ridge. When ridges are cleaved in this manner, the earth of the firſt furrow that the plough makes, is turned over upon firm land, and backed by the earths of the other furrows in their courſe. This makes it impoſſible to get at this firm land in ploughing the next ridge, without turning up the firm land itſelf, and the earth of the furrow laid over it, upon the top of the earth of the ſecond furrow, by which the crown of the ridge would be raiſed to a high ſharp peak. Now, to prevent this, the ploughman, in ploughing the next ridge, keeps at a proper diſtance, and does not touch the firm land, over which the earth of the firſt furrow is laid. But it may be obſerved, that he muſt either keep at ſuch a diſtance as to leave firm land in the crown of the new ridge equal to the breadth of two furrows, or he muſt turn the earth of his furrow upon the top of the earth of that firſt furrow. By this the crown of the ridge is ſtill high raiſed, and ſome firm land ſtill left.

But ridges of this kind may be cleaved without leaving any unploughed land, or without raiſing the crown much above the reſt of the ridge. The method of doing it is this: after the plough has made the firſt furrow, inſtead of turning to the left, and making a furrow on the other ſide of the ridge, it turns to the right, and throws back the earth of its firſt furrow along with the firm land below it, and after going round again in the ſame courſe, turns to the other ſide of the ridge, and goes twice round in the ſame manner, after which the ridge betwixt the two fierings, as they are called, is ploughed out, as at firſt propoſed. When the ploughing of the ridge is finiſhed, a new fiering is made in the next furrow, by the plough going twice round, as before directed, and then the ridge betwixt the laſt-made fiering and the ploughed land is ploughed out in the ſame manner as before; and in the ſame way the fierings are made till the whole field is ploughed. By this method there is no firm land left below the earth of the furrow; and the earth that is turned towards the crown being ſcattered, and not laid all in one place, the crown itſelf is not much raiſed above the reſt of the ridge.

It may be obſerved likewiſe, that in caſting ridges, if care is not taken, the furrow towards which the earth is thrown will be ſo filled up as to be improper for a drain. The plough enters the ridge near the furrow, and throws the earth towards it, turns to the right, and throws the earth from the oppoſite ſide towards it likewiſe; and then goes in the tract of the old furrow, betwixt the earths of the furrows made on each ſide. This furrow, towards which the earth is thrown, is ſometimes ſo filled up as to render it improper for a drain. We have ſhown how the earth around it is ploughed. The furrow which the plough makes going in the track of the old furrow, betwixt the earths of the furrows on each ſide, is called a gore-furrow. On the left ſide, the plough having no mold-board, the looſe earth falls back into the furrow behind the plough, and fills it up, or at leaſt makes it unfit for a drain, which in wet land is a great diſadvantage.

But this may be prevented by proper care; the furrow may be made clean, and fit for a drain. The method of doing it is this: the plough enters about two feet from the furrow, and inſtead of turning to the other ſide, returns on the ſame ſide, turning back the earth, and then goes round again in the ſame courſe; after this turns to the other ſide of the furrow, and does the ſame, goes twice round. By this the gore-furrow is made quite clean, and, like the crowns of ridges, formed at about two feet diſtance on each ſide.

Some other things of a like nature might be mentioned. Theſe have been inſiſted upon, to ſhow, that it is neceſſary to attend to every circumſtance of ploughing, that ſo this important work may be performed in the moſt proper manner.

The chief deſign of harrowing land is, to ſmooth the ſurface. By this weeds are deſtroyed, and ſeed, if ſown, is covered.

Root-weeds, that are looſed by the plough, are ſometimes torn up by the harrow, and thus are deſtroyed. When this is the deſign of harrowing, the harrows ſhould go acroſs the ridges, or rather acroſs the way that the plough has gone. Becauſe, by going acroſs the earths of the furrows, the teeth of the harrow are apter to catch hold of the roots, than if it ſhould go in the ſame way with the plough.

Though the harrow may bring ſome part of the roots above ground, yet commonly ſome other parts continue below, which will grow if undiſturbed. This makes it neceſſary for perſons to follow the harrows, and gather all the roots which they obſerve brought up, and carry them off of the field, or burn them.

If harrowing does not actually tear up the roots, it encourages their vegetation, by filling up the hollows, and thereby defending them againſt their greateſt enemy, the drought. On this account harrowing is improper for deſtroying root-weeds, excepting after a ſpring-ploughing, when the land is ſoon to be ploughed again for ſeed. For at this ſeaſon the drought is ſeldom violent, and it has not time to operate in the deſtruction of the roots; and therefore whatever the harrows bring out is ſo much deſtroyed.

The ſame things that make harrowing improper for deſtroying root-weeds, make it very proper for deſtroying ſeed-weeds. The ſmoother that the ſurface is made, and the more effectually that the mold is broke, the ſeeds near the ſurface are the more expoſed to the air, and the ſap, which is in the land, the more effectually retained. Both theſe are neceſſary to promote the vegetation of the ſeeds; and they muſt vegetate before they can be deſtroyed. But harrowing not only promotes the vegetation of the ſeeds of weeds, but alſo deſtroys the young plants when ſprung up; ſo that one ploughing, if the ſeaſon is favourable, and ſoil allows, may be attended with ſeveral harrowings, and thereby ſeveral crops of weeds deſtroyed.

If land riſes in hard clods, the harrow makes but little impreſſion; at leaſt before the clods are broken, the land is made ſo firm by the treading of the horſes, and the weight of the harrows, as to render the work uſeleſs, and ſometimes deſtructive. Great care ſhould therefore be taken to prevent land from being brought to this ſituation. If land once riſe in hard clods, it is vain to expect to break them with the harrow, ſo as to cover the ſeed. Unleſs the ſeaſon is very wet, it will remain in this ſituation through the ſummer, and afford but little nouriſhment for the crop. Sometimes it will remain in this ſituation after men have attempted to break the clods with malls.

If the ſoil is light and ſpungy, it can ſcarcely get too much harrowing; for the more that it is harrowed, it becomes the firmer. But if the ſoil is ſtiff, the leſs harrowing it gets the better, if the purpoſes propoſed are anſwered. The effects of harrowing are in this caſe contrary to thoſe of ploughing. Ploughing renders ſtiff ſoil more free and open, but harrowing renders it ſtill more firm and ſolid.

The ordinary way of harrowing after ſeed is ſown, is firſt along the ridges, then acroſs, and then along again. If ridges are flat, they may be harrowed either along or acroſs; and the work may be begun or ended either way. But if the ridges are ſteep, it is improper to begin by harrowing acroſs, becauſe thereby too much of the ſeed will be drawn into the furrows. If the ridges are very ſteep, for the ſame reaſon, it is improper to harrow acroſs at all. For another reaſon it is thought improper to harrow acroſs ridges when the land has been ploughed immediately out of lea or graſs. In ploughing this kind of land, the ſward is for the moſt part turned over whole; ſo that when the harrow goes acroſs, inſtead of tearing the ſward, it is apt to turn it back into the furrow from whence it was taken. When ridges are gathered or caſt, this will probably happen. In caſting, the earths of the furrows on one ſide of the ridge are turned towards the crown; and, in gather-

 ing,

ing, the earths of the furrows on both sides are turned the same way; and therefore the harrows, when drawn from the crown to the furrow, are apt to take hold of the unbroken sward, and turn it back But this does not so readily happen when the ridge is cloven. Because in cleaving, the earths of the furrows on both sides of the ridge being turned from the crown, the harrows, in going up from the furrow, are not in such danger of turning them back. In ploughing lea, the earths of the furrows are sometimes placed as exactly as possible upon their edge, that so they may be the more easily torn by the harrows. When these are turned to the crown, they do not support each other; and are therefore easily turned back by the harrow, in going from the crowns to the furrows: but when the earths are turned to the furrows, so they support each other by their weight; and therefore are not so easily turned back by the harrows in going up from the furrows to the crowns.

Rolling of land is practised with success, both on land lying in grass and on land in tillage. It is of advantage to land in grass, by pressing down mole-hills and mole-runs. Some say, that it also destroys fog.

When land is laid down in grass for hay, rolling is of use in smoothing the surface; and, when laid down in grass for pasture, it makes the grass stool, or tiller, and grow thicker.

There is a kind of land, which, when clover is sown upon it, throws out the young plants after frost. Rolling, in the beginning of winter, and immediately after the frost is gone, it is said, will, in some measure, prevent this. The first rolling prevents the frost from penetrating so deep, as otherwise it would do; and the second makes the land firm, after having been loosed by the change from frost to open weather.

Rolling may also be used with advantage upon land in tillage. When the land is naturally stiff, and may be reduced by the harrow, rolling is very improper: for it makes this kind of land still firmer than the harrow does. But if the land rises in clods, which the harrow does not reduce, rolling is very proper; for it smooths the surface, and breaks the clods, more effectually than harrowing.

When the land is light and spungy, the roller should always be applied after seed is sown; for it is scarcely possible to make this land too firm.

It was observed, that, to destroy root-weeds, land should be made rough, and raised in as large pieces as possible; and that it should be allowed to lie for some time in that situation. Rolling, after this, is of great use; for, without it, if the weather continues dry, it will not be possible to make the land fit for receiving another ploughing.

If the land is soft below, and some hard clods upon the surface, which the harrow does not break, rolling may be used with some advantage: for, besides smoothing the surface, it will bruise some of the clods; and such of them as are pressed down, will be dissolved by the natural fermentation of the soil, if in good heart.

Sometimes in stiff land, ploughed dry, after a former wet ploughing, or when, by any accident, it has been much trod upon, the whole rises in hard clods, which the harrows cannot break, so as to cover the seed. In this case rolling is of great use. It bruises some of the clods; and, when followed by the break-harrow, these clods are raised up and broken. Though rolling should do no service but smooth the surface, yet, on that account, it should be practised. For when the surface is smooth, the corn may be cut down more expeditiously than when it is rough and uneven. When grass-seeds are sown for hay, it is absolutely necessary to smooth the surface: the roller is most proper for this. Some use it before, and some after sowing. When it is used before sowing, the seed is more equally scattered.

Grass-seeds must be sown in such a manner, as to lie near the surface; otherwise they will not vegetate. The making the land firm by rolling is therefore an advantage, as, by it, the sap is better preserved; and this does not so much damage to grass as to corn, for the several kinds of it are commonly better foragers.

But however all the operations of ploughing, harrowing, and rolling are performed, something will be still wanting to promote vegetation, and this want is effectually supplied by certain substances called manures. To apply these substances in such a manner, as most effectually to promote vegetation, it is of importance to know their natures, and the ways in which they operate. This is the more necessary, as, without it, we cannot know how to apply them in the most proper manner to the different soils.

Manures operate, by communicating to the soil with which they are mixed, the vegetable food which they contain; by communicating to it a power of attracting this food in greater plenty from the air; by enlarging the vegetable pasture which it contains; and by dissolving the vegetable food which it is already possessed of, and fitting it for entering the roots of plants.

Manures are very different in their natures. Some of them operate in all the ways mentioned; and there are none of them that do not operate in more ways than one.

Great mistakes have arisen from supposing that manures operate only in one way. None have been attended with greater loss, than supposing that they serve only to divide the soil, and that tillage may be substituted in their place. This is Mr. Tull's opinion, and is, indeed, the fundamental principle of his horse-hoeing husbandry.

Before one changes the ordinary practice of agriculture, in so important a point as banishing manures from his fields, the good effects of which are so obvious; he must be certain, that the principle which determines him to so important a change, is itself well-founded.

Mr. Tull has endeavoured to prove, that earth is the food of plants; and hence infers, that to divide the earth into minute particles, by which it is fitted for entering their roots, is all that is necessary in agriculture: and this, he asserts, may be done by tillage, without manures.

When treating of the food of plants, we have attempted to show, that other principles, besides earth, are in the composition of this food: and, if this is true, the want of manures, which provide these other principles, cannot be supplied by tillage.

But supposing we allow, with Mr. Tull, that earth is the food of plants, yet still it does not follow, that tillage may supply the place of manures. It is certain, that every particle of earth which we observe, is not of the kind that is the food of plants. Every soil is a composition of different earths; several of which, it is obvious, are not of this kind.

The great difference in soils equally pulverised, is a plain and convincing evidence of this. Now, let it be observed, that the earth contained in dung is of this kind; it has already been food to plants, and therefore though all that is contained in the greatest quantity of dung laid on at one time, is but small in proportion to the quantity of soil employed in vegetation, as Mr. Tull justly observes; yet it may be considerable in proportion to the quantity that is really the food or pabulum of plants. If the quantity of earth contained in the quantity of dung commonly laid on at one time, is compared with the quantity of earth contained in the richest crop, it will be found several times larger; and therefore, by the laying on of this dung, food is provided for several good crops.

Besides, let it be observed, that the mechanical action of the plough cannot increase the number of the particles by which plants are nourished; they are so small as not to be observed in water. Mr. Tull supposes, that they are as small as those upon which the colour of bodies depends. Now, though pounding earth in a mortar may perhaps do something to increase them, yet the action of the plough can never be supposed to do it. The plough can do no more than open the soil, or enlarge the pasture of plants, and allow them to extend their roots in search of their food, but does not increase the quantity of it; and therefore tillage cannot supply the place of dung, which not only opens the soil by its fermentation, but also increases the vegetable food by the earth which it contains.

It may be further observed, that the fermentation raised by dung continues for a considerable time; so that though, by ploughing, the soil may be as completely divided as by the fermentation of dung, yet it will not continue so: for after seed is sown, the artificial pasture raised by ploughing is continually decreasing while the crop is growing; whereas the artificial pasture, raised by the fermentation of dung,

is

is continued by the continuance of this fermentation; and therefore, though in the horfe-hoeing hufbandry the want of dung may be fupplied by hoeing, yet, as Mr. Tull indeed obferves, dung is ftill neceffary in the old hufbandry.

If perfons attentively confider the effects of manures, it will appear that they operate in all the ways mentioned.

Manures are found to enrich the beft pulverifed foil, and to do this again and again, after it is exhaufted by crops. It is almoft an univerfal practice in Scotland, to lay dung upon land that is kept conftantly in tillage once in three, four, or five years. It is obferved, that after the dung is laid on the land becomes rich, and that the crops turn gradually worfe and worfe, till the whole virtues of the dung are exhaufted; and it is alfo obferved, that immediately upon the dung being again applied, the land becomes rich as before. It is natural to conclude from this, that dung promotes vegetation by increafing the quantity of the vegetable food.

It is found, that fome manures lofe part of their virtues by being long expofed to the air. After dung is fufficiently rotten, the longer that it lies it becomes of lefs value, and does not enrich fo large a quantity of land as when ufed in proper time. The dung of cows dried upon their pafture, gathered, and laid upon other land, is fcarcely to be difcerned in its effects on the crops produced: the fame quantity applied, whether carried from the byre, or by folding the cattle, enriches the land. From this it is obvious, that this kind of manure contains the vegetable food in itfelf, and does not receive it from the air.

It is found, that fome manures operate the fooner, and with the greater violence, the longer that they are expofed to the air before they are ufed. Lime and marles are of this kind; the longer they lie expofed, they operate the fooner; and it is obferved, that they have a ftrong power of attracting the virtues of the atmofphere. From thefe things it is reafonable to infer, that thefe manures operate, by communicating to the foil with which they are mixed, a power of attracting the vegetable food from the air.

It is obferved, that fome manures exhauft land of its vegetable food, and do not reftore it again when immediately applied. This is found to be the cafe with lime. Land thoroughly limed has been found to carry many very good crops: by degrees however the virtues of it have been exhaufted, and the land reduced to a worfe fituation than before the lime was laid on. In this fituation lime has been applied a fecond time, but its effects found to be far inferior to what they were when firft applied. This is fufficient to convince us, that this manure operates by diffolving the vegetable food which it meets with in the foil, and fitting it for entering the roots of plants.

It is certain, that all kinds of manures open the foil. Any perfon will be convinced of the truth of this, who will take the trouble to compare a piece of land, on which dung, or any other manure has been laid, with a piece contiguous that has not been manured; he will find the one much fofter, much more free and open than the other. It muft be allowed, therefore, that all manures operate by enlarging the vegetable pafture.

Manures are commonly divided into claffes. Some divide them into natural and artificial; others divide them into the foffil, the vegetable, and the animal; and treat of them in order, as belonging to each of thefe claffes.

The manures belonging to fome of thefe claffes, differ both in their nature and operation from thofe in the other claffes. Some of them likewife differ from others in the fame clafs. The dividing them into claffes, therefore, ferves no purpofe. All that is neceffary is, to treat of the different particulars which the farmer can command, without confidering to what clafs they belong.

The manures generally procured are dung, marles, afhes, foot, fea-weed, fhells, fown vegetables, and water.

There are feveral other things that are very rich manures, fuch as rags, leather, &c. But as thefe are to be procured only in fmall quantities, it is needlefs to treat of them feparately.

Dung is commonly ufed to fignify not only the excrement of animals, but alfo all rotten vegetables, when ufed as manures.

Dung is the food by which animals are nourifhed, reduced to a corrupted ftate. The ftomach diffolves the food of the animal, and reduces it to a ftate of putrefaction much fooner than is done by the air. It is by being in this ftate of putrefaction that the juices fit for the nourifhment of the body are conveyed by the guts into the blood. While bodies are in a found ftate, their parts adhere firmly together, and they are incapable of being turned into the parts of other bodies. To render them capable of this, they muft be reduced to their firft principles. This is done by corruption. It is obferved, that by corruption all the parts of bodies are relaxed, and the falts, oils, and other juices which they contain, from being fixed, are made volatile. It is by being reduced to this ftate in the ftomach, that the things which the animal feeds upon become nourifhment to it, and are turned into parts of its body.

All the juices contained by the things which animals feed upon, are not exhaufted by the guts; many of them, along with the earthy part of the food, are thrown out. There is no doubt that fome of the earthy part of the food goes alfo to the nourifhment of the animal; but as the earth is rendered volatile by the falts and oils, there muft be but a fmall quantity of it in proportion to the quantity of thefe exhaufted by the animal; and therefore in the dung there muft be a great quantity of earth in proportion to the other principles. However, as the dung contains all the principles of the food, we may confider the dung of thofe animals that feed on vegetables as vegetables in a putrefied ftate.

Of the fame nature is the dung of animals that feed upon other animals. Vegetables are the original food. All animals either feed on pure vegetables, or on other animals that feed on vegetables. Animals that feed on vegetables are made up of the fame things with vegetables, only under a different form; and therefore the dung of animals that feed upon thefe, is ftill to be confidered as vegetables in a putrefied ftate.

Chemifts inform us, that dung is compounded of the fame principles of which vegetables are compounded, of water, air, oils, falts, and earth. The earth which it contains is of the abforbent kind, and attracts the other principles. They alfo inform us, that dung attracts and ferments with acids, and by this fermentation produces falts. A quality of falt, as was before obferved, is to attract and diffolve oils, and make them capable of being mixed with water.

If thefe qualities of dung are confidered, it will appear that it promotes vegetation in all the different methods before mentioned.

It promotes vegetation by increafing the vegetable food. It is compounded of the fame principles of which the vegetable food itfelf is compounded, as we endeavoured to fhew, when treating of the food of plants. This is alfo confirmed by the experience of all places and all ages; and it is what no perfon will doubt of, who confiders that it has the fame effects upon land of all kinds, and in all fituations.

It promotes vegetation by enlarging the pafture of plants, it attracts acids from the air and foil; and by raifing a fermentation with them, thereby feparates the particles of the foil with which it is mixed. Every farmer knows the truth of this from experience. The land upon which dung is laid, though naturally ftiff, becomes foft and mellow, and is more eafily ploughed than before.

Dung, we have faid, enlarges the pafture of plants, by attracting acids, and fermenting with them. Thefe acids are in the foil and air. They are in the foil; for the foil produces acid plants. Chemifts tell us, that the neutral falt found in foil is compounded of an alkaline falt, fuch as is found in vegetables, and an acid fpirit. All alkalis are ftrong attractors of acids, fo that, in the procefs of an experiment upon foil, perhaps it may be difficult to keep them feparate, though they may exift feparate in it. The acid plants prevent thefe from mixing; or, perhaps, have a ftronger power in their veffels to feparate them, than other plants have.

But though there may be no acids in foil, excepting in the compound of neutral falts; yet there is no doubt, but they are in the air. Chemifts find this by innumerable experiments. Afhes, when expofed to the air, produce neutral falts; the application of acids has the fame effects. Any perfon may obferve a falt adhering to the lime of old walls; this falt is not in the lime, it is produced by the air. The fame falt is produced by acids. Other experiments might be mentioned, but thefe are fufficient.

Dung promotes vegetation, by communicating to the foil a power of attracting the vegetable food from the air. The earth which it contains, is of the abforbent kind, and attracts all the other principles of the vegetable food; and the falts which it contains and produces, attract oils.

It likewife promotes vegetation, by preparing the vegetable food for the nourifhment of plants. By the falts which it contains and produces, it not only attracts oils, but alfo diffolves them, and makes them capable of being mixed with water. It is probable, that oil is a principal part of the food of every plant which we cultivate in our fields, at leaft is the ingredient of which it is eafieft to exhauft the foil, and which it is moft difficult to reftore to it again. In proportion to the quantity of oil contained in any plant, in proportion it robs the foil by which it is nourifhed of its vegetable food. But the nature of oil muft be changed before it can enter the roots of plants. This change is made by falts; they diffolve it, and make it to mix with water.

Though dung promotes vegetation in all thefe ways mentioned; yet, as there are other bodies, that are much ftronger attractors of acids, by which many of its effects are produced; it is probable, that it principally operates by increafing the food of plants. Its effects in diffolving the vegetable food in the foil, muft be very trifling. The falts which it contains and produces, having its own oils to work upon, and being along with them conveyed into the roots of plants, cannot operate with any violence upon the oils which the foil contains. This is confirmed by experience. When the virtues of dung are exhaufted, the foil is no poorer than before it was laid on.

Some new improvers are pleafed to ridicule the old farmers, becaufe they are fo fond of dung; but none will do this who attentively confider the virtues of it. Such other manures as can be obtained, are to be ufed; and tillage is carefully to be attended to: but none of thefe are to fuperfede the ufe of dung, which can be employed to fo great advantage.

Though dung in general has all the qualities mentioned, yet there are fome kinds of it poffeffed of fome of thefe qualities in a higher degree than others. There are as many kinds of dung as there are of animals, and in fome refpects they all differ one from another.

The difference betwixt one kind of dung and another, is commonly fuppofed to arife from the different food of the animals. Green herbage, ftraw, or hay, do not contain fo much vegetable food in the fame quantity as grain does. Hence it is fuppofed, that the dung of cows is not fo rich as that of horfes, nor the dung of horfes fo rich as that of fowls.

But this difference muft partly arife likewife from the nature of the animals, if it is true, that the dung of horfes, cows, fheep, hogs, and geefe, all differ one from another, though fed upon the fame pafture. Some animals digeft their food more quickly than others. This makes a difference in the dung produced by the fame food. Some things are digefted, and turned into a ftate of corruption by fome animals, that pafs through others found and undiffolved. The matter then in the ftomach that digefts the food, muft be different in the different animals. The dung muft partake fomething of the nature of this, which makes another difference in the dung produced by the fame food.

Some writers in agriculture treat of the dung of the different animals feparately. But it is needlefs to do this; for it requires more pains and expence to keep them feparate, and ufe each of them by itfelf, than all the advantages arifing from this way, above the ordinary way, can poffibly amount to.

The dung of fowls, particularly of pigeons, is an exception to this. It is commonly ufed without any mixture, and it can be kept feparate from other dung without any trouble or expence. It is obferved, with refpect to it, that the effects of it are more violent, and fooner over, than the effects of common dung. The effects of fome other kinds of dung would perhaps be the fame, if they were ufed without any mixture. The pigeons dung, being thoroughly corrupted, foon diffolves, and becomes vegetable food. But the ftraw, with which the other kinds of dung are commonly mixed, not being fo thoroughly corrupted, prevents the effects of them from being fo violent, and fo foon over.

The way in which pigeons dung operates, points out the manner in which it fhould be applied. As it is very rich, and its qualities foon exhaufted, a very fmall quantity fhould be applied, in proportion to the quantity of other dung. If care is not taken of this, the crop will be deftroyed by being too luxuriant. Perhaps, mixing it with fome other things may have good effects. The ftrawing fmall chaff of any kind, from time to time, on the bottom of the pigeon-houfe, is very proper. The chaff fucks up the moifture, and makes it eafy to reduce the dung to powder, which is an advantage: for thereby the dung is fcattered more equally, and manures a greater quantity of land.

It is a cuftom, in fome places, to fold fheep and cattle, for the fake of their dung; which, in this way, is ufed without any mixture. Some writers on hufbandry give particular directions how to do this in the moft advantageous manner. But it is needlefs to confider thefe. The farmer muft confult the advantage of his fheep and cattle, and not the advantage of the land by the dung; and, therefore, muft fold them in the moft convenient manner. A fcore of fheep, with the beft management in folding, will not produce much more than ten fhillings worth of dung, in the feafon, above the expence of folding; a fum foon loft by an injudicious management of them.

Dung is commonly mixed with vegetables, and allowed to lie for fome time before it is ufed.

Straw is thrown below the cattle, and this is carried out along with the dung, and thrown upon the dunghill. On the dunghill is alfo thrown all the ftraw that is left after ferving other purpofes, and all the refufe of vegetables and animals, ufed in the farmer's family.

In the management of dunghills, two things are always to be kept in view: the promoting putrefaction; and the preventing the vegetable food from flying off into the air, or being conveyed away by water. The ftraw and other parts of uncorrupted vegetables, of which the dunghill is compounded, make it neceffary to keep the firft in view; and the falts and oils, which by corruption are rendered volatile, and the water, which extracts the virtues of dung, make it neceffary to keep the laft in view.

To promote putrefaction, the fituation of the dunghill fhould be dry, and the dung laid together as thick as is convenient. Putrefaction, indeed, cannot be promoted without water: but the quantity that falls in rain, with the natural fap of the dung, is fufficient for this purpofe. Too much water prevents that fermentation, which carries on the procefs of putrefaction moft quickly. This is confirmed by experience. If there is any part of a dunghill foaked with water, it is obferved that the ftraw is quite found, while, in other parts that are dry, it is completely rotten.

To promote putrefaction, the dung fhould be laid thick together; thereby the heat is the fooner generated, that produces the putrefaction; and thereby the natural fap is the better preferved, which prevents the dung from being burned.

When the natural fap of the dung is exhaled, and the dung afterwards covered, the heat is in danger of rifing to fuch a height, as to burn the dung. This muft be carefully guarded againft: for, when the dung is burned, its ftrength is exhaufted, and it is rendered almoft ufelefs. Dung, in this fituation, is dry and white; the ploughmen call it fire-fanged. When thus burnt, it is found, from experience, that it has loft almoft all its virtues. To prevent the dung from being reduced to this fituation, when it is carried out of the ftable or byre, particularly if there is much ftraw in it, it muft not be laid in heaps, which makes it dry too faft, but carefully fpread thick upon the top of the dunghill. This prevents the fap from being carried off by the wind, and thereby prevents the heat from being raifed to fuch a height as to burn the dung.

It may be obferved, that, when grafs is cut green, and immediately thrown into a heap, it heats, and this heat foon reduces the grafs to a ftate of putrefaction. But, if the grafs is for fome time expofed to the air, and then put together without being fufficiently dry, it heats alfo; but, inftead of being reduced to a ftate of putrefaction, is burned.

burned. So it is with dung: if, when carried out, it is laid in small heaps, being thereby too much exposed to the air, it loses its sap; and, being afterwards covered, the heat is raised to such a height, as to burn it: but, if it is spread thick upon the top of the dunghill, it retains the sap, and putrefies.

A distinction is here made betwixt dung putrefied and burned; and this distinction is represented as important. We know not if the chemists make any such distinction. A late author says, that the greater part of what remains of dung, after the putrefaction is completed, seems to be earth, and a fixed alkali. These things, we apprehend, make up the greater part of what remains, when dung is what we have called burned; but when it is only putrefied, it contains also salts and oils. But though chemists should make no such distinction, it is absolutely necessary that the farmer do it: for, when the dunghill is allowed to heat to such a degree, as to burn the dung, the value of it is thereby greatly lessened.

To prevent the vegetable food from being conveyed away, no foreign water, excepting what falls in rain, must be allowed to run into the dunghill; and the situation of the dunghill, if possible, should be high at the sides, and hollow in the middle. When foreign water is allowed to run into the dunghill, the fermentation is not only stopped, but, as it is often necessary to allow the water a passage from it, thereby much of the vegetable food is conveyed away. When the bottom of the dunghill is quite level, the rain, which sometimes falls in heavy showers, easily finds its way off; but this is prevented by making it high at the sides, and hollow in the middle.

The only way to prevent the vegetable food from being exhaled by the sun, or carried off by the wind, is to cover the dunghill. The covering the dung would certainly be an advantage, if it could be easily executed. If it was not for the additions that are daily made to it, earth would be very proper for this purpose. Some persons assert, that, by covering the dunghill, it would lose the influence of the air; and it is the air alone, they say, that makes it fit nourishment for vegetables; and, therefore, recommend the exposing it, particularly to the north and north-east; because the wind from these points brings along with it more aëreal nourishment than from the others. If the dunghill contained no vegetable food, but what it received from the air, this direction would be very proper: but, as the dunghill contains in itself all the ingredients of the vegetable food, and as its juices, the more it is putrefied, become the more volatile, the vegetable food in it by being exposed to the air, instead of being increased, would be diminished. The covering the dunghill, therefore, would be an advantage. But the difficulty lies in executing this.

Some propose to dig a large pit, lay the bottom with flags, build up the sides with stones, and cover it with a roof. This, it must be owned, will retain the juices, and promote corruption, as well as prevent the vegetable food from being exhaled. But then it must be so expensive, that few will be engaged to make trial, unless the benefits are more obvious than the assertions of the contrivers make them: and, besides the expence, it must likewise be attended with inconveniencies. In some situations, it will be very difficult to prevent too much water from getting into it; and as difficult to get the dung itself carried out.

The method which we proposed for preventing the dung from over-heating, will also, in a great measure, serve this purpose. The dung, when it comes from the stable or byre, is mixed with straw, which absorbs the juices, and prevents them from flying off, till the straw itself begins to putrefy. When, in this situation, it is laid thick upon the top of the dunghill, a small surface only being exposed to the air, and being covered before the straw begins to putrefy, the juices, in a great measure, are preserved. A person, by the smell, is sensible that the juices of the dung are not so volatile, when first laid upon the dunghill, as after they have been covered for some time, and then exposed to the air.

Dung, exposed to the sun and wind, or washed by rain, loses its vegetable food; it ought, therefore, to be ploughed in as soon as is possible, after it is laid upon land. Some persons assert, that they have found from experience, that dung is nothing worse, though it lie a considerable time spread upon land, in dry weather, before it is ploughed in. This, if true, is contrary to what has been supposed, that the vegetable food is exhaled by the sun, and carried off by the wind. It is probable, that, after dung is spread upon land, its fermentation ceases, and the salts and oils remaining in it may become fixed, and may continue so till a new fermentation is raised by mixing the dung with the soil; and that, by attracting acids from the air, more salts may be formed. By this its effects will be more sudden and violent, but sooner over.

It may be proper also to observe, that as the juices contained in the dung are washed downwards by the rain, it should be ploughed in with a very shallow furrow; excepting when the dung is not sufficiently rotten. In this case it requires a deep furrow to cover it.

The better that dung is mixed with soil, the purposes of vegetation are the better answered; all parts of the soil receive equal benefit, the vegetable food is equally distributed, and in all parts the fermentation equally promoted. When dung then is laid on land, it ought to be spread as equally as possible. This likewise prevents the breeding of vermin, which happens in some soils, when the dung is left in too large pieces.

Some are of opinion that lime is only a stimulus, that is, that it promotes vegetation, only by making the soil with which it is mixed, exert itself. Others, that it promotes vegetation by enriching the land, and adding to the quantity of vegetable food.

They first support their opinion by observing, that the crops which lime enables land to produce, exhaust it in a remarkable manner. It is a certain fact, that land thoroughly limed, may be reduced to a much poorer condition by cropping than land can be reduced to, that is not limed. It is possible to reduce limed land almost to a *caput mortuum*; and the better and the oftener the land is ploughed, this is done the sooner.

The other opinion is supported by observing, that, in some places, lime is applied regularly once in four or five years; that the land seldom gets any other manure; that it is kept almost constantly in tillage; and, with the assistance of fallowing, carries very good crops.

From these observations, one is led to conclude, that lime acts both ways; not only makes land exert itself in the nourishment of vegetables, but also enriches it, and adds to the vegetable food.

An inquiry into the qualities of lime will probably illustrate this.

Chemists tell us, that lime has the following qualities.

It is a great dissolver of all animal and vegetable substances: it is a very heavy body: it is an attractor of acids; with these it raises a fermentation, and produces salt; and it communicates its virtues to water.

When these things are considered, it will appear, that lime promotes vegetation in these ways following.

It communicates to the soil a power of attracting the vegetable food from the air. It attracts the acids from the air and soil; these it converts into a neutral salt, by which oils are attracted from the air. This operation of lime is confirmed by the experience of those who use it as a manure once in four or five years.

Lime enlarges the vegetable pasture. By its weight it penetrates the soil; and, by its fermentation with acids, it separates its particles.

This operation of lime is obvious to every person that views with attention any land that is thoroughly limed. It appears soft and mellow, and obviously in a state of fermentation.

Lime dissolves the vegetable food, and fits it for entering the roots of plants. It dissolves all the animal and vegetable substances which it meets with in the soil, and converts them to vegetable food; and, by the salts which it produces, it dissolves all oily substances in the soil; and conveys them into the roots of plants. We find from experience, that lime clears land of root-weeds. This it does by its dissolving power. Root-weeds, when torn up by the plough, have their growth checked, and are for some time in a languishing condition: if lime is applied to their roots while in this situation, by its dissolving power, it is apt to destroy them.

That it is owing to the salt which lime produces by its attracting and fermenting with acids, that it chiefly owes its

its power of promoting vegetation, is confirmed by this obſervation. The lime of old walls which has been long expoſed to the air, and where this ſalt is already formed, is much more ſudden in its operations, when laid upon land, than quick-lime.

It has been obſerved, that lime promotes vegetation by communicating to the ſoil a power of attracting the vegetable food from the air, by enlarging the vegetable paſture, and by diſſolving the vegetable food, and fitting it for entering the roots of plants. It is probable, that the two laſt are the ways by which it chiefly operates.

By this it exhauſts the land of its vegetable food. For it cannot be ſuppoſed to attract from the air a ſufficient quantity of food for the nouriſhment of the crops which it enables the land on which it is laid to carry; and it contains none of this food in itſelf. This is confirmed by experience. If land upon which lime has been laid, is exhauſted by crops, the application of lime a ſecond time has not the ſame effect as before; unleſs the vegetable food is ſupplied by dung, or the land allowed to reſt for ſome years, and have the vegetable food ſupplied by the air.

Thus it appears, that lime from its nature muſt act both as a ſtimulus and a manure; while it makes the earth exert itſelf in the nouriſhment of vegetables, in ſome meaſure alſo enriches it, and adds to the vegetable food.

In ſome lands, the diſſolving the vegetable food, and fitting it for entering the roots of plants, may be moſt beneficial: in others, the communicating the power of attracting the vegetable food from the air, may be moſt beneficial. It will not be improper, therefore, to point out how lime is to be applied, that ſo it may chiefly anſwer the one or the other of theſe purpoſes.

In uncultivated land, in which there is a large quantity of vegetable ſubſtance, lime ought to be uſed chiefly as a ſtimulus: and when improved land needs a recruit of vegetable food, it ought chiefly to be uſed as a manure.

When lime is intended for a ſtimulus, a large quantity ſhould be applied at once. For it takes a conſiderable quantity to diſſolve roots, and the other vegetable ſubſtances in the land, and to produce a high degree of fermentation.

When lime is intended for a manure, a ſmall quantity applied at a time is ſufficient. It is probable, that it requires only a ſmall quantity of lime to impregnate a large quantity of earth, and to communicate to it an abſorbent quality, in as high a degree as it is capable of receiving: and it is certain, that it is in proportion to the abſorbent quality which it communicates, that the ſoil is enriched by it. This is not mere conjecture. It is certain, that a ſmall quantity of lime will impregnate a large quantity of water, and communicate to it all its virtues, and theſe in as high a degree too as it is capable of receiving: it is not improbable, that it may operate in the ſame manner upon earth. If a ſmall quantity of lime communicates an abſorbent quality to a large quantity of earth, but has not ſuch influence in diſſolving vegetable ſubſtances, or in producing fermentation, it follows, that the ſmaller the quantity is which is applied, it will operate the more as a manure; and the greater the quantity applied it will operate the more as a ſtimulus.

It is proper to obſerve likewiſe, that when lime is applied in ſmall quantities as a manure, it is neceſſary to repeat the application frequently; for it is probable, that the ſoil by action loſes the abſorbent quality, which the lime communicates.

Theſe things which we have obſerved concerning the operation of lime in ſmaller and larger quantities, are, in ſome meaſure, confirmed by experience. They are agreeable to the practice in thoſe parts where lime is moſt uſed. When barren land is to be improved, it is laid on in large quantities; and when it is applied to land already improved, it is laid on in ſmall quantities, and frequently once in three or four years.

As lime operates by attracting acids from the air, the longer that it lies expoſed to the air before it is ploughed in, it will exert itſelf the more quickly, and with the greater violence. Some alledge, that this ſhould not be done in ſummer. For they ſay, that the ſun acts contrary to the air: as the air ſupplies the ſalt, the ſun exhales it, and communicates it again to the air.

As lime, when laid on in large quantities, exhauſts land of its vegetable food, it is neceſſary to ſupply this food by dung, or ſuch other manures as have it in greateſt plenty; or the land ſhould be managed in ſuch a manner, as to prevent, as much as poſſible, the vegetable food from being exhauſted. Laying off land, after a very few crops of corn, into graſs for paſture, is the moſt proper way of doing this. Land, when paſtured, has not its vegetable food ſo much exhauſted, as when it carries corn. The quantity of vegetable food carried off in fleſh, by the cattle, or conveyed to the air by their perſpiration, bears but a ſmall proportion to the quantity carried off by a crop of corn and ſtraw.

It is neceſſary further to obſerve, that, as lime communicates its virtues to water, land inclining to be wet, and from which the water has free acceſs away, is not proper for it: for the water, in running off, carries along with it the virtues of the lime.

There are a variety of marles, which are commonly reduced to three ſorts: the clay, the ſtone, and the ſhell.

The firſt has its name from its ſimilitude, in appearance, to clay; the ſecond from its hardneſs, and ſimilitude to ſtone; and the third from the ſhells, with which it is mixed, or rather of which it is compounded.

The clay and ſtone marles are of the ſame nature; the ſhell marle is very different from both. This makes it neceſſary to treat of them ſeparately.

Marle of the ſtone and clay kinds promotes vegetation in a ſurpriſing manner. It is probable, however, that it contains in itſelf few of the principles of which the vegetable food is compounded. Plants are not able to find their food in it. When in a bed below the ſurface, it reſiſts the entrance of water, like till or clay. When near the ſurface, and turned up by the plough in great quantities, the ſoil is little better than till, almoſt quite barren. The method of its operation will be beſt known by inquiring into its qualities.

It is obſerved, that both the clay and ſtone marles have the following qualities.

When long expoſed to the air, or put into water, they fall down into a powder: they are very heavy bodies: the earth of which they are compounded, is of the abſorbent kind: they are attractors of acids; with them they raiſe a fermentation, and produce ſalts.

The only difference betwixt them is this: the clay marle is ſooner diſſolved than the ſtone marle; and commonly has a ſtronger power of deſtroying acids, and producing ſalts. Dr. Home ſays, that the clay marle, which he tried, deſtroyed a third more of acids than the ſtone marle.

Theſe marles ſeem to have much the ſame qualities with lime; and, therefore, muſt operate in the ſame manner.

They communicate to the ſoil a power of attracting the vegetable food from the air, they enlarge the vegetable paſture; and they diſſolve the vegetable food that is in the ſoil, and prepare it for entering the roots of plants.

Theſe marles communicate to the ſoil a power of attracting the vegetable food from the air. The abſorbent earth which they contain, and the ſalts which they produce, are ſtrong attractors of oils.

It is obſerved, that they attract oils ſo ſtrongly, that they are uſed by ſome to extract greaſy ſpots from cloaths. When laid upon land, they will therefore attract oil from the air, which is the ingredient of the vegetable food moſt wanted.

Theſe marles enlarge the paſture of plants. They ferment with acids, and fall down into powder, when expoſed to the air, or put into water. Theſe things make them operate in ſeparating the particles of the ſoil, with which they are mixed.

Theſe marles alſo prepare the vegetable food for being nouriſhment to plants. The ſalts which they produce, not only attract oils from the air, but alſo from the ſoil; diſſolve theſe oils, and render them capable of being mixed with water; and of being conveyed by it into the roots of plants.

According to ſome, theſe marles contain ſome oily matter. This, if true, would make them operate in a manner different from lime. But this is uncertain. The earth of which theſe marles are compounded, is of the abſorbent kind; it cannot be long expofed to the air, without attracting oils; and, therefore, though they contain none in their original compofition, yet fome marks of them may appear upon trial.

Thefe marles are long in diffolving. Large pieces of the ftone marle are feen fometimes undiffolved, fix or feven years after it has been laid upon land. This makes it neceffary to apply a very large quantity of them, otherwife their effects will not be known.

As the quantity of marles applied is very great in proportion to the quantity of lime, land, when manured with marle, muft have a ftronger power of attracting the vegetable food from the air; and therefore the marle fhould be preferred, when it can be as eafily obtained.

As the earth of thefe marles is of the abforbent kind; as a great quantity of it is applied at one time; and as it is long in diffolving, it muft be many years before its operation ceafes; and, if the land is barren, the nature of it will be changed, and ever after, by the fame kind of dreffings it received before, will continue to carry better crops. In this refpect alfo it is preferable to lime. This advantage, however, depends, in a great meafure, upon the nature of the foil. If the foil is foft and fpungy, and has not a firm bottom, the marle, by its weight, will, by degrees, penetrate, like lime, beyond the reach of the plough; and, therefore, muft leave the foil no better than it found it.

Although, in fome refpects, thefe marles feem preferable to lime, yet we are to confider, that their principal operation is the fame with that of lime; which is enlarging the pafture of plants, and fitting the vegetable food for entering their roots. When land, therefore, manured with them, is exhaufted by crops, it cannot receive much benefit from them a fecond time, if immediately applied. This is confirmed, it is faid, by experience. It is obferved, that marle, when applied a fecond time to land exhaufted by crops, has not the fame effect as when firft applied.

As marle operates in the fame manner as lime, it follows likewife, that limed land exhaufted by crops, can receive little benefit from the application of marle; and that marled land, exhaufted by crops, can receive little benefit from the application of lime. As it exhaufts the vegetable food, the proper manure after it is dung, which contains this food in the greateft plenty.

It was obferved, that marle operates chiefly by attracting oils and acids from the air; the longer, therefore, that it lies upon land, expofed to the influence of the air, the more quickly it will operate.

The difference betwixt the clay and ftone marles was faid to confift in this: that the clay marle diffolves fooner, and has a ftronger power to deftroy acids and produce falts. This kind is therefore preferable, as a lefs quantity will produce the fame effects. If Dr. Home's experiments are to be depended upon, or rather, if all clay and ftone marles have the fame powers with thofe which he made his experiments with, then four cart-load of the clay marle is equal to five of the ftone.

What was faid of lime, with refpect to the application of it in fmaller and larger quantities, may likewife be faid of marle. When barren land is to be improved, the marle fhould be laid on in large quantities: but when land is in good order, the applying a fifth or fixth part of the quantity commonly ufed, once in fix or feven years, may have very good effects.

Shell marle is very different in its nature from the other two. It is commonly claffed among the animal manures.

It does not diffolve with water, as the other marles do. It fucks it up, and fwells with it, like a fpunge. It is a much ftronger attractor of acids than they. Dr. Home fays, that it takes fix times more of acids to faturate it than any of the other marles which he had met with. But the greateft difference betwixt the fhell marle and the other marles confifts in this. The fhell marle contains oils. It is uncertain whether the other marles contain any oils; but this kind, it is faid, contains them in great plenty.

This marle, it would feem, from the qualities which it poffeffes, promotes vegetation in all the different ways. It increafes the food of plants; it communicates to the foil a power of attracting this food from the air; it enlarges the pafture of plants; and it prepares the vegetable food for entering their roots.

It increafes the food of plants by the oils which it contains, and the falts which it produces: by thefe falts, and by the abforbent quality which it poffeffes, it communicates to the foil a power of attracting this food from the air. It enlarges the pafture of plants, by its fwelling with water, and the fermentation which it occafions; and it prepares the vegetable food for entering the roots of plants, by the falts it produces in fermentation.

It will not be improper to attend to the effects of thefe different operations. The communicating vegetable food immediately to the foil, and communicating to it a power of attracting this food from the air, have the fame effects. By both thefe operations the vegetable food is increafed.

The enlarging the pafture of plants, and fitting the vegetable food for entering their roots, have alfo the fame effects. By both the vegetable food is diminifhed. It is obvious, that, by thefe operations, plants are affifted in extracting this food from the foil.

The oils which it contains, it is probable, are foon exhaufted: having a ftrong power of attracting acids, and forming falts, it is natural to fuppofe that thefe falts do more than work upon its own oils: they will alfo attract and diffolve the oils which they meet with in the foil; and would exhauft it of the vegetable food which it contains, was it not for the ftrong abforbent quality which it communicates. This quality, it is probable, remains after the operation of the falts is over; and thus, upon the whole, the foil is rather bettered by it.

We had occafion to fhow, that the difference betwixt poor and rich foil confifteth in the different powers of attraction. As this marle has fo ftrong an abforbent quality, if it is applied in large quantities, and frequently repeated, it is poffible that it may communicate fuch an attractive power to the foil, as to enrich it in a very high degree, fo as to need no further manuring, but by proper tillage may be made to attract from the air in the winter-feafon fuch a quantity of vegetable food as is fufficient to nourifh a crop in fummer.

As this kind of marle does not exhauft land of its vegetable food, as the other marles, or as lime do, it may be applied to land exhaufted by them, or it may be repeated. As it diffolves fooner than the other marles, its effects will be more fudden, and as it does not diffolve fo foon as dung, its effects will not be fo foon over.

A late author fuppofes, that the marle found below mofs is compounded of earth and the alkaline falts of rotten wood. He explains in what manner he imagines it is formed. If there is a marle compounded of thefe ingredients, it is different from any of the marles that have been mentioned. However, it will operate much in the fame manner. It will communicate a power to the foil of attracting the vegetable food from the air; it will enlarge the pafture of plants, and it will prepare the vegetable food for entering their roots.

As it contains a large proportion of falt, its effects will be fudden and violent. It is not proper therefore that a great quantity of it fhould be applied.

As its effects are fudden and violent, it cannot be expected that they will laft long. It is probable that they will be foon over after it is entirely diffolved.

The falts which it contains, will make it operate chiefly in diffolving the vegetable food in the foil, and fitting it for entering the roots of plants. By this it will exhauft the foil, if care is not taken to prevent it, by the application of dung, or turning the land from tillage into grafs for pafture.

There is another kind of marle that goes under the name of fhell marle, and in fome parts of the country is found in great plenty. It feems to be almoft wholly lime, and it operates in the fame manner.

Afhes contain a large proportion of falt; they attract acids more violently than any other thing as yet known, but they foon lofe their virtue.

The effects of afhes will then be of the fame kind with lime. But as afhes contain falt, their operation will be more fudden; as they attract acids with greater violence, and fooner lofe their virtue, their operation will be more violent, and fooner over. This is confirmed by experience. The firft crop after land is manured with afhes is commonly very luxuriant, and the fecond crop exhaufts almoft the whole of their virtues.

As the effects of afhes are fudden and violent, they fhould be applied in very fmall quantities; and as they operate

rate in the fame way with lime, they fhould not be applied to land exhaufted by lime or marle; fhould not be followed by thefe, nor repeated.

Turf is compofed chiefly of vegetables; that which remains then after burning, muft be of the fame nature with afhes. To thefe the fertility communicated to the foil is chiefly owing. It is found from experience, that in proportion to the number of roots contained in the turf the burning turns out to advantage; and therefore land, with a tough fward of grafs upon it, is recommended as the kind moft proper for being improved in this manner.

The heat which part of the foil receives from burning the heaps of turf is fuppofed to contribute to its fertility: but this can have little influence except to deftroy any feeds or roots of weeds that may be in the land.

In burning the turf, care muft be taken to cover the heaps in fuch a manner as to prevent the fire from breaking out into flame. Where this happens, it is obferved, that the afhes lofe part of their virtue, and that the parts of the field manured by them are not fo much enriched as the other parts are by the heaps of turf that are burned without flame. It is natural to think, that the earth of the turf, when properly piled up, will retain the oils of the vegetables, and prevent them from afcending into the air in fmoke and flame.

This makes fome difference betwixt the manuring by burning and the manuring by afhes. However, as the oils contained in burned turf are in very fmall quantities, we may well fuppofe that they will foon be exhaufted by the falts; and therefore, though the effects of burning may be more violent, yet will be equally fudden, and as foon over.

To prevent burnt land from being exhaufted, one crop only, or two at moft, fhould be taken, and then turned into grafs for pafture. If a little dung is added after the firft crop, its fertility will be the longer preferved.

Soot cannot be procured in fuch large quantities as to be ufed by itfelf, excepting in the neighbourhood of large cities; it is needlefs therefore to infift much upon it.

It contains oil, falt, and earth. Thefe, it feems, are compounded in fuch a manner as to be ready to be conveyed into the roots of plants by water. For the effects of foot, when fpread upon the furface, are difcovered immediately after the firft rain. It promotes vegetation in the fame manner as dung, or fhell marle. It increafes the food of plants by the ingredients of the vegetable food which it contains. It enlarges the pafture of plants, enables the foil to attract the vegetable food from the air, and prepares it for entering the roots of plants by the falt that it contains, which is of the alkaline kind, attracts and ferments with acids, and attracts and diffolves oils.

As it contains great plenty of vegetable food, and as its effects are fudden, it muft be laid on in very fmall quantities. Sowing it in the fpring on winter corn or grafs, feems to be the moft proper way of ufing it.

When the quantity laid on is but fmall, and its effects fudden, it cannot be fuppofed to laft long. Its virtues are commonly exhaufted by one crop.

When its effects are over, the foil is left in the fame fituation as before it was laid on, not exhaufted of its vegetable food, as by lime or afhes; and therefore it may be repeated; or it may be followed by thefe manures, as it is very proper to be applied to land that is exhaufted by them.

All the plants that grow upon the rocks within reach of the fea, are good manures. Thofe that grow upon the rocks that are almoft always covered by the water, are the richeft.

Some kinds of fea-weed are burnt for kelp. This, it is thought, turns out to greater advantage than ufing them as manures. The beft kinds for manures cannot be reached, as their roots are almoft always below water; but they are frequently driven on fhore by the fea. A confiderable quantity of them may always be expected on the fhore in the neighbourhood of the rocks, where they grow, when a fpring-tide, heavy rain, and a high fwelling fea all happen at the fame time. The fpring-tide expofes their roots to the air, the frefh water falling in rain loofes the roots, and the high fwelling fea tears them up. Sometime the tide carries them to a confiderable diftance.

They are of a foft pulpy nature, eafily diffolve, and foon putrefy; and they contain oil, falt, and earth. They muft promote vegetation therefore in the fame manner as dung or foot.

Their effects are fooner over than thofe of dung mixed with vegetables from a dunghill; for they fooner diffolve and fooner putrefy.

They may be applied to foil in any fituation, and are very proper for land that is exhaufted by lime or afhes.

When their effects are over, the land is in no worfe a fituation than before they were applied, and any kind of manure may be applied after them.

The oftener they are applied, the land becomes the richer; for the earth of which they are compounded, is of the abforbent kind. This is confirmed by experience. The land near the fhores, where thefe fea-weeds are in greateft plenty, and have been long ufed as manures, are amongft the richeft in Scotland, and have been kept almoft conftantly in tillage.

They are preferable to dung in this refpect, that they do not produce fuch a quantity of weeds. Every perfon that has ufed thefe manures, knows, that weeds do not appear in fuch plenty upon land manured with fea-weed, as upon land manured with dung. This feems to confirm the opinion of thofe, who affert, that the great quantity of weeds that appear upon dunged land, are produced by feeds mixed with the dung. But it is fubmitted, whether this difference is not owing to the great quantity of falts contained in the fea-weed and applied with it, which at firft deftroys fome of the feeds and roots of weeds. Salt, applied in too large a quantity, is undoubtedly a poifon to many plants. According to Mr. Tull's experiments, a fmall quantity of falt water deftroyed a plant of mint. It is obferved likewife, when any grafs upon the fhore is overflowed by a fpring-tide, it withers away in a few days, and does not recover till it gets a plentiful fhower. Then indeed, by the frefhnefs of its verdure, it is diftinguifhed from the grafs that was not overflowed by the falt water. That it is the falt in the water that deftroys the plants, is obvious: for the fame quantity of frefh water would have had no fuch effect. And it is probable, that the oils attracted by the falts, and carried down by the rain, is the caufe of their recovery.

In many places, particularly near the fea-fhore, broken fhells are found in beds. Thefe are ufed by fome as a manure.

They ferment with acids, and, like other animal fubftances, contain oil, falt, and earth. The oil and falt are not in great quantities in proportion to the earth, and they take a long time in diffolving.

Their operation muft be of the fame kind with that of fhell marle, but flower and weaker.

They make fome addition to the vegetable food by the ingredients of this food of which they are compounded. They communicate to the foil a power of attracting this food from the air; and they diffolve it by the falts which they contain and produce. And they increafe the pafture of plants by their fermentation.

They operate chiefly by enlarging the pafture of plants, and preparing the vegetable food for entering their roots. They are fo long in diffolving, that the quantity of oil communicated in a feafon muft be fmall in proportion to the falts which they produce. Though thefe are their principal operations, yet in them they are inferior to lime, marles, or afhes.

As they take a long time to diffolve, and do not operate quickly, it is neceffary to apply them in large quantities. For without this their operations will fcarcely be perceptible.

For the fame reafon it may be expected they will continue for a confiderable time. They will continue till the fhells are wholly diffolved, and all their oils exhaufted in vegetation.

As they operate chiefly by enlarging the pafture of plants, and fitting the vegetable food for entering their roots; they will in fome degree exhauft the land of its vegetable food, though not fo much as lime or afhes do, as they communicate fome oils to it in diffolving. It is not proper therefore to apply them after lime or afhes, to repeat them immediately, or apply lime and afhes after them.

If

If they are taken up from below the furface, as muft happen moft commonly, it is proper to allow them to lie fome time expofed to the air before they are ploughed down. This will not only affift their fermentation, but will alfo promote their putrefaction.

As lime, when mixed with them, takes a very ftrong band, it is probable, that the mixing them together in the application may in fome cafes produce very good effects.

It is a practice in fome places to fow turnip, buck-wheat, peafe, &c. on land; and when grown up, to plough them down for manures.

Thefe may be called vegetables in an entire ftate, to diftinguifh them from dung made of putrefied vegetables; though no vegetable can be a manure till it is putrefied.

As thefe vegetables receive their food from the foil on which they grow, it is natural to think, that when ploughed down, they do no more than reftore what they have taken; and therefore, that by this operation land cannot be rendered more fertile than before; at leaft, cannot communicate fuch a quantity of vegetable food to it as may be done by frequent ploughings. For the vegetables, though ploughed down, are not all preferved; a part of them being uncovered, is blown away by the winds. Befides, the plants while growing cover the furface, and prevent the vegetable food in the air from entering the foil. Whereas, when land is frequently ploughed, none of its vegetable food is exhaufted, and it is expofed to receive all the benefits from the influence of the air. But, notwithftanding this, fome affert from experience, that a crop of fuch vegetables as thofe mentioned, ploughed down, render land more fertile than frequent ploughings without the application of manure.

To account for this upon the principles eftablifhed, let the following things be confidered.

The foil, manured by ploughing down a crop of vegetables, receives all the vegetable food contained in the feed fown. This quantity in peafe and buck-wheat is not very inconfiderable. The quantity in one grain is probably as much as there is in a whole ftalk after the feed is fully ripened. It is obferved, that plants, when cut green, exhauft land of its vegetable food, but in a very fmall degree to what they do when allowed to carry feed.

Some of the plants mentioned pufh down their roots below the reach of the plough, and bring up the vegetable food lodged there to the furface. Peafe, turnip, clover, and other plants pufh down their roots very far; and whatever vegetable food they find, is fucked up; and when they are ploughed down, this vegetable food is lodged near the furface, and thereby the quantity within the pafture of fome other plants, fuch as wheat and barley, is increafed. A late author makes a calculation of the quantity of vegetable food which clover in this manner communicates to land, and reprefents it as very confiderable. In few places the foil is fo deep as to have the vegetable food in great plenty beyond the reach of the plough; and therefore it is probable, that this author, in his calculation, makes the quantity of this food brought near the furface by clover much greater than it really is. However, it is certain, that as plants pufh down their roots below the reach of the plough, they there find nourifhment, which is communicated to their ftems and leaves; and therefore, when thefe are ploughed down, the quantity of vegetable food near the furface is increafed.

The covering of the furface feems to be an advantage; for thereby the air in the foil, not having a free communication with the external air, becomes putrefied, by which a fermentation is raifed, and the vegetable pafture enlarged. Whatever is the caufe of this fermentation, the fact itfelf is obvious. Every farmer knows, that when the foil has been covered for a confiderable time by a ftrong crop of peafe, or any other kind of corn laid down, and what is commonly called flooming, though naturally hard and ftiff, becomes mellow, foft, and free, and obvioufly in a ftate of fermentation. It is probable, that this is occafioned by the corruption of the air, or of the water, which the covering of the furface prevents from being exhaled.

To thefe things it may be added, that it is not impoffible but the plants when growing may fuck in the vegetable food from the air in as great plenty as the foil would have done, though there had been no plants growing upon it. If plants have this faculty, confidering what an immenfe furface is expofed by them to the influence of the air, the quantity of vegetable food acquired cannot be inconfiderable.

Having thus confidered the effects of ploughing, harrowing, rolling, and manuring land, in order to produce a large crop of wheat, we fhall now proceed to the cultivation of the ufeful fpecies of grain.

It has been very juftly obferved by the ancients, as well as moderns, that wheat will grow in almoft any part of the world, and that, as it is the plant moft neceffary to mankind, fo it is the moft general, and the moft fruitful. It thrives not only in temperate climates, but alfo in very hot, and very cold regions; and, when fown in places where it never grew fpontaneoufly, fucceeds as well as where it has been always common. The fuccefs of our crops of wheat in America plainly prove this: and in Peru and Chili in particular, where this grain was not known till the Europeans introduced it there, it now produces as large crops as in moft parts of Europe.

Wheat fhould be fowed in autumn, and always when the ground is moift. In the downs of Hampfhire, Wiltfhire, and Dorfetfhire, farmers begin to fow their wheat in Auguft, if any rain has fallen, and even employ their people to fow one place, while they reap another, if wet weather interrupts them in their harveft: for if the corn is not forward in autumn, fo as to cover the ground before winter, it feldom does well on thofe high dry lands, efpecially if the enfuing fpring prove likewife dry. In low ftrong lands, fome hufbandmen think they are in good feafon, if they get their wheat into the ground by the middle of November; nay, it fometimes is Chriftmas, or even later, before all their wheat is fown. But this late fown wheat, befides being apt to run too much to ftraw, efpecially if the fpring be moift, is liable to be thrown out of the ground by frofts.

In general, all wheat fucceeds beft upon ftrong foils, efpecially if they have been well drained, fo that the corn lies dry: but as fome forts of this grain thrive better in fome foils than in others, it might redound to the public welfare if more particular obfervations were judicioufly made, in regard to each kind, than have hitherto been. The white egg-fhell wheat is reckoned beft for light lands, and to fow with rye for meflin; becaufe it ripens fooneft. It fhould alfo be the earlieft in the ground. This fpecies is much fown in Effex, upon their hazely brick-earths, or loams; as the red-wheat, and the Poland bearded wheat alfo is there, and in Hertfordfhire upon ftiff yellow clays. The white Poland, or pole-rivet wheat has not a hollow ftraw, and therefore is not fo fubject to lodge as other corn that has. This kind is particularly fit for lands where the crop is apt to run much to ftraw.

In Oxfordfhire, they have a fort of wheat which they call long coned-wheat, and reckon the beft for rank clays. Its ftraw not being hollow, it is the lefs liable to lodge, and farmers obferve that it is the leaft apt to be mildewed, or be eaten by birds, from which laft it is greatly guarded by its long rough awns; but the flour of it is fomewhat coarfe. Their white kind of red eared wheat has a white ear and a red grain, and is a very good fort for clayey land. It yields a good crop, and feldom fmuts.

In Staffordfhire, they reckon the red Lammas or bearded wheat the beft for cold lands or ftiff clays.

In Berkfhire is a wheat called pendulum-wheat, from the hanging of its ear, much like the cone-wheat.

In Northamptonfhire, they have a fort of wheat with a white ftraw and reddifh ear and grain; much commended for the plumpnefs and largenefs of the grain, and the ftrength of the ftraw, which prevents its being fubject to lodge; nor is it apt to be eaten by birds. They have alfo a red eared bearded wheat, and a fort of pollard or duck-bill wheat, as it is called, known in Suffex by the name of fuller's wheat, which has fo clofe and thick a hufk, that the birds never injure it. Mr. Miller obferves that this fort of wheat grows very tall, and, if it be fown too thick, is very apt to be lodged by rain and wind; for that its ears are large and heavy, and incline on one fide as the grain increafes in weight; but that, if its roots are at a proper diftance from each other, it will tiller greatly and have ftrong ftalks, and that the grain of this wheat yields more flour in proportion than that of any other sort. The awns of this wheat always drop off when the grain is full grown.

Smyrna wheat, commonly called many-eared wheat, because several lesser or collateral ears grow around the bottom of the main ear, which is very large in its state of perfection, requires more nourishment than the common husbandry in the large way can give it, and therefore is not cultivated by our farmers: but it would, probably, do extremely well in the horse-hoeing husbandry, where the quantity of food can be enlarged almost at pleasure. For the same reason maiz, commonly called Turky or Indian corn, is fittest for this last husbandry. *See* MAIZ.

Some gentlemen have been curious enough to procure their seed wheat from Sicily, and it has succeeded very well as to the growth: but the grain of this species has proved too hard for our English mills to grind.

The best time for sowing wheat is about the beginning of September, especially if any rain has fallen; a circumstance so essential, that, if the earth be very dry, the farmer had better stay till friendly showers have moistened his soil, than put his corn in ground where it will not grow before it has been wet, let the time be every so long. Mr. Mortimer says he has known wheat to be so mustied and spoiled by laying long in the ground, before rain came, that it has never grown at all: to which he adds, that he has likewise seen very good crops of wheat from seed sown in July. At all events, the husbandman should certainly have his wheat sowing finished by the middle of October. Whoever neglect this, shews in so doing, a want of proper œconomy in his affairs, and will have cause to repent the delay.

Early sowings require less seed than late ones, because the plants then rise better, and acquire strength to resist the winter's cold. More seed should always be allowed for poor lands than for rich, because a greater number of plants will perish on the former. Rich lands, sowed early, require the least seed of any.

Another circumstance which the husbandman should carefully attend to in sowing, is that his estimate of seed be formed, not from the capacity of any particular measure, but from the number of grains which that measure will contain; because the grains of some growths of wheat are much larger than those from off other lands, though of the same species, and perhaps equally good. By not considering this, the ground will of course frequently be sown too thick, or too thin: though I believe farmers are seldom apt to run into this last extreme. That they too often commit the former error, so manifestly contrary to their interest in every respect, is demonstrated by reason, and by daily experience:—but neither of these is sufficient to make them deviate from the beaten tract. Instead of the usual allowance of three bushels of seed wheat to an acre of land, repeated trials have shewn that half that quantity is generally more than sufficent: consequently a great deal of corn is actually thrown away; for the expence of purchasing seed, which most skilful husbandmen do, at least every other year, amounts to a considerable article in large farms, and in a whole country, merits the attention of the public, especially in scarce years: besides which, the future plants, crowded together by being thus sown too thick, and not having a sufficient space allowed them for their sustenance, cannot yield near so fine and plentiful a crop as they would otherwise produce. A fair trial, made with proper care, would soon convince farmers of their error in this respect; for if they but examine a field of corn sown in the common way, they will find few plants with more than two or three stalks, unless by chance, where some of them stand so as to have room to spread. These will have six, eight, or ten stalks, and frequently many more; but a field of wheat sown with only a bushel of good corn has been known to be well covered with healthy vigorous plants, each of which has had from six to fourteen, or more, stalks, crowned with long well nourished ears, full of fine plump grain, of which it has yielded a much greater quantity than any of the neighbouring grounds sown with the common allowance. If the land is good, and the plants stand at a proper distance from each other, few of them will produce less than the above number of stalks and ears. But farmers think they shall have no crop if the ground is not covered with the blades of corn by the spring: whereas, if they would have patience to wait till the plants put out all their stems, they would be amply convinced of the contrary. Every one must have observed in places where foot-paths are made through corn fields, that, by the side of those paths, where the corn is thin, and has been trodden down in the winter and spring, the plants have stood erect, when most of the corn in the same field has been laid flat upon the ground; an advantage which can proceed from no other cause, than that their stalks are stronger from their having more room: for those of the other plants are drawn up tall and slender by being too close together.

More seed is commonly sowed upon new broke up ground, than upon that which has been longer in tillage. From half an inch to three inches is the usual depth at which wheat is planted, according to the nature of the soil; the stiffest lands requiring the shallowest sowing, as was before observed. The general custom is, to sow it under furrow, which is certainly most adviseable if the soil be shallow, to prevent the plants being thrown out by the winter's frosts, or their roots being left bare by the drying winds in the spring. Some sow in broad cast, either with a single cast, or a double bout, harrowing once between; after which the ground is again harrowed several times, till the seed is well covered. However, a great deal of it will become the prey of birds, in this manner of sowing. On the other hand, in planting the corn deep, there is the greater dander of its being eaten off by worms between the grain and the blade.

Great care should be taken to guard against the rooks just at the time when the wheat is shooting up. These mischievous birds perceive its sprouting much sooner than the farmer can, and are led by the shoot to pick it up. They must therefore be carefully kept off the ground for a week or ten days at this season; for at the end of that time the blade will be grown up, and the grain so exhausted of its substance, that they will not give themselves any trouble about stealing it. They never molest the wheat which is sown about Michaelmas; because so much grain of the late harvest then lies scattered about the fields, that they find it easier to pick up that, than to search for corn under ground, in the new-sown lands.

No part of husbandry requires the farmer's attention more, than keeping his land free from weeds; yet few trouble themselves much about this essential article, are sensible of it's importance, or understand the proper method of doing it: nay, many do not even know which weeds are annual, and which perennial; a distinction highly necessary to be made by every person who would keep his ground clean and in good order, and without which the greatest industry will often be baffled. Annual weeds may be soon destroyed, if taken in time: but if they are neglected, their seeds will ripen, and sow themselves in such abundance, that much additional labour and expence will be required to do that which might have been performed with ease at the beginning, without subjecting the corn to be robbed of its nourishment by bad neighbours. The common method of weeding is very absurd: for in that practice the weeds are left to grow till the wheat begins to ear, and they are in flower; by which means, the ground being covered by the corn, all the low weeds are hid, left to ripen, and scatter their seeds: only the tall weeds are taken out; and if the people employed are not careful, many of these will escape them, by being so intermixed with the stalks of the wheat, as not instantly to be distinguished. At the same time great numbers of the plants of wheat are broken and trod under foot by the weeders.

To obviate these inconveniences, Mr. Miller recommends the method now practised by good kitchen gardeners, who clear their ground with a small kind of hoe, which, if used among the wheat early in the spring, before the ground is covered by the blades of corn, will effectually eradicate all the weeds, especially if this work be done in dry weather; because, being small, they then soon wither and die. If the ground happens to be very full of weeds, it may be necessary to go over it a second time, about a fortnight after the first, to cut up those which may have been too small to be noticed. By this means the corn will be kept clean, freed from robbers which

which would deprive it of due nourishment, and there will not be time for new weeds to grow so as afterwards to do it any great prejudice: for the ground will be so much shaded by the corn, that the weeds will thereby be kept down, in such manner as not to ripen their seeds before harvest.

If, at the time of this operation, some of the plants of corn are cut up where they grow too close, the rest will be greatly benefited thereby: "but in this, adds Mr. Miller, I fear that few of the old farmers will ever agree with me, though what I mention is not from theory, but from experiments, repeated with great care, and such success, that the produce of twenty rods of ground was much greater, both in weight and measure, than that of the same extent in the very best part of the field, where this was not practised; and the stalks of the corn thus thinned stood upright, when a great part of the crop in the same field was lodged."

Both the advantage of having the plants of corn at proper distances from each other, and that of keeping them quite free from weeds, too difficult, not to say almost impracticable, tasks to be completely effected in the common method of sowing, are fully obtained in the New Husbandry, as will soon be evidently shewn.

M. Duhamel and Mr. Miller justly blame the practice of those who either turn hogs in among their wheat, to destroy part of it when it grows too thick; or sheep to eat it down, when they think it too rank. The absurdity of the former is self evident: and in regard to the latter, it is well known, from long experience, that the leaves, or blades, of corn are necessary to draw in nourishment from the air and dews, for the increase of the stalk and ear. To be thoroughly satisfied in this, Mr. Miller cut off the leaves of some plants of wheat, alternately, early in the spring, and always found the stalks of these plants much smaller, the ears shorter, and the grain poorer, than those of the intermediate plants whose blades were not cut. Several experiments made by M. Duhamel have proved, not only that all plants are impeded in their growth, and rendered less perfect in their productions, but often even killed, by stripping them of their leaves: and this is confirmed by Mr. Miller, who adds, that he has frequently observed in gardens, that plants divested only of their lower leaves, plucked off by ignorant persons upon a supposition of their drawing the nourishment from the head, have been greatly weakened thereby. The same will undoubtedly hold good with respect to corn; besides which, cattle, and particularly sheep, will often bite so close as to destroy the crown of the plant, from whence its future growth should proceed.

Wheat is ripe when its straw is turned yellow, its ears hang, no greenness appears in the middle of them, and the grain is hard when bitten. From four to five quarters is reckoned a good crop: but some would hardly credit how much beyond this the produce of good ground, thoroughly well cultivated, may be increased. Those who are sensible of the vast advantages of a perfect culture, will not be surprised at Mr. Miller's assuring us that he has known eight and ten quarters, and sometimes more, reaped from an acre, over the whole field, where the corn has stood thin upon the ground; and that he has been informed by persons of great credit, that even twelve quarters have been reaped from an acre of land drilled and managed with the horse-hoe.

Both wheat and rye may be cut somewhat before they are throughly ripe, especially if they be lodged; for if the straw be broken, it will no longer convey any nourishment to the grain. M. Duhamel seems to think this even the most eligible way for wheat, because the grain will harden afterwards in the sheaf; whereas, if it be let stand till it is too ripe, it will shed greatly in cutting, binding, and carrying home. It is partly to prevent this inconvenience, that good husbandmen tie it in the evening, and carry it off early the next morning. The ancients reaped their corn before it was full ripe, as Pliny informs us. And indeed it must be allowed that very great disadvantages necessarily attend the letting of some sorts of corn stand till their grains have acquired their utmost maturity. Both the chaff and the fodder are the worse for it; and, if such ripe corn takes wet, the increase in malt is lost, if it be barley, it having already spent itself; and if it be wheat, the quality of the flour is greatly impaired, as well as the quantity considerably lessened. But if corn be cut greenish, it will bear a pretty deal of wet without damage; for it will not imbibe the water like full ripe corn, but only take in so much as to be kindly fed thereby. Again, if any sort of corn be blighted, the sooner it is cut down, though but half ripe, the better it will be; for nourishment can no longer be conveyed to it by the straw; but it will be fed by lying in the ear. The straw would become more and more brittle, by standing till the corn is ripe; and the grain comes the clearer from the husk, when threshed, if this blighted sort be cut early.

One man, with a binder, may reap an acre of wheat, and somewhat more of rye, in a day, if the corn stand well: he will also clear about an acre of peas, vetches, &c. in the same space of time.

The medium price of wheat, in this country, is about five shillings the bushel. If it be much under four shillings, the farmer cannot pay his rent and live; and if it exceeds six shillings, the poorer sort of people cannot afford to purchase wheaten bread. A bushel of wheat weighs from fifty-six to sixty pounds; a bushel of barley, from forty-four to forty-seven pounds; and a bushel of peas, from sixty-three to sixty-six pounds.

"The husbandman, says M. Duhamel, cannot have a more favourable season to get in his harvest, than that which is afforded him by hot and dry weather: for the quality of the corn is improved, and the grain is rendered much fitter to keep, by the sun's having acted powerfully upon it, either towards the latter part of its standing, or just after it has been cut: though it is true, on the other hand, that this very circumstance renders the ears more apt to shed their grain, and that the value of a sowing is often lost thereby. To prevent this, as much as possible, the corn is first laid in gripps, and then tied up in sheaves, in the cool of the evening, or early in the morning before the heat comes on; and the mowers of oats frequently work during part of the night, to avoid the excessively fatiguing sultriness of the noon. These poor people, whose task is infinitely laborious, are liable to many grievous disorders; especially the reapers, who, being obliged to stoop to their work, almost to the very point where the rays of the sun are most violently reflected by the earth, breathe a perfectly burning air. This forces them to drink copiously of liquors, which, being heated by the sun, allay their thirst only for a few moments, and, I strongly suspect, often occasion severe illnesses: the inventing of a machine, engine, or instrument, by which the hardness of this labour might be mitigated, would therefore be a truly useful discovery; and I most heartily exhort all ingenious persons who have a mechanic turn, seriously to think of it.

"The two usual ways of cutting corn, are either with the scythe, or with the sickle. The former is commonly used for oats and barley, or, sometimes, for very thin, short wheat; and the sickle is generally appropriated to the reaping of tall and thick wheat and rye. The scythe dispatches so much more work than the sickle, that the difference of expence between reaping an acre, or mowing it, is nearly in the proportion of five to two.

"Every part of the mower's body labours and fatigues, and his work requires greater dexterity than that of the reaper: but as the mower is always in a kind of standing posture, he has the advantage of being refreshed by every breeze of air; which the reaper, for the reasons beforementioned, has not.

"I do not despair but that some engine may, one time or other, be found out, to ease these very hard labourers, and expedite their work. In the mean while, I am persuaded that M. de Lille's following account of what he himself has practised on his own estate, will afford satisfaction to all my readers, who will be pleased to observe, that he does not relate matters of mere speculation, but real facts; things actually executed by him, and which I should certainly have tried, if I could possibly have been in the country when our harvests were got in.

M. De Lille's account of his method of mowing wheat.

"When I first put a scythe into my corn, I was of course laughed at by some of my neighbours, because they had never seen any such thing. I let them enjoy their jokes; but persevered in my undertaking, which I have now

now practiſed ſufficiently to be able to point out minutely its advantages, and its inconveniences; for I allow that, though the former are very great and numerous, it is alſo attended with ſome of the latter.

" The year 1751 was very rainy; our graſs rotted upon the ground, our corn was poor and infeſted with weeds; and the weather continued extremely bad during all the harveſt ſeaſon. One of my fields of wheat, containing about fifteen acres, was, in particular, in ſuch wretched plight, that I did not think the crop worth taking off. However, after walking over it, and viewing it on every ſide, I found that the quantity of graſs and other growths upon it, might, if mowed, afford a great deal of fodder, which would make me ſome amends for the total loſs of my lucerne. I therefore determined to let my horſes have it all, with the little wheat which appeared here and there. This firſt made me think of mowing a field of wheat; tho' I ſoon recollected that I had met with the hint before, in ſome of your writings. Accordingly, I ſet my mowers to work: my field yielded a great quantity of fodder; the graſs, mowed within two inches of the ground, ſhot up anew, and afforded excellent paſture; and laſtly, my bailiff, more ſaving than I had been, ordered the truſſes to be thraſhed, and got out of them as much wheat as was yielded by other grounds.

" Whilſt I was congratulating myſelf upon the ſucceſs of my operation, by which my horſes and cattle were provided with plenty of fodder for the next winter, I learnt that the huſbandmen in Hainault, Flanders, Artois, and other adjacent parts, never cut their corn down otherwiſe than with a ſcythe; but at the ſame time I was informed, that they do not mow wheat in the ſame manner as oats; that the ſcythes are not made alike for both theſe works, and that there are ſome other eſſential differences.

" Theſe obſervations were a ſort of proof that the practice had been found to anſwer, ſince it was ſtill continued; and I concluded, that if my operation, imperfect as it was, had ſucceeded ſo well, I might expect far greater advantages when it ſhould be performed regularly: but, not to be too ſtrongly prejudiced in its favour, I reſolved to make a trial upon about thirty acres only.

" By dint of inquiry, I found within a few miles of me a huſbandman who came from the province of Artois, and had been uſed to this very buſineſs. I talked with him; he told me how the work ought to be done, pointed out its advantages, and I retained him for my intended next year's mowing of wheat: but as the ſeaſon was pretty far advanced, and there was not time to procure from his country other people equally well acquainted with the practice, to follow the ſcythe, and do the whole completely in every reſpect, he inſtructed two young lads, as well as he could. In ſhort, nothing was wanting but a mere matter of form, by the neglecting of which ſome of the lifts of the cut corn were miſplaced, ſo that there were ears at both ends of the ſheaf.

" I ought not here to forget the clamour raiſed by this novelty. I made the experiment upon my fineſt wheat; becauſe my new workman had told me, that the ſtronger the corn was, the better and more regularly the mowing would be performed. My neighbouring huſbandmen, and all the reapers employed by them, thought me out of my ſenſes, and ſome of them even came to reaſon the matter with me. They meant well, and I took it kindly; but deſired them carefully to notice the event.

" My experiment was made upon three pieces of wheat, of ten acres each, ſituated in much more extenſive fields of the ſame corn; ſo that there was the faireſt room to make a juſt compariſon between the operation of the ſcythe and that of the ſickle.

" Some of the neighbouring huſbandmen had the curioſity to ſee the work performed, and were ſurpriſed to find that leſs corn was ſhed in this way, than in the common practice of reaping with the ſickle. They thought the method good; but made a few objections to ſome particular circumſtances, in which the experience of ſubſequent years ſhewed them that they were wrong. Their entire approbation then followed; and their mowers, finding that they ſhould be able by this means to cut down all their corn without the aſſiſtance of ſtrolling ſtrangers who often do their work very badly, gladly learnt the new method, and commended it to others.

" This trial ſucceeded ſo well, that I reſolved to cut all my crops in the ſame manner; and that nothing might be wanting to perfect my mowers in this practice, I procured a ſufficient number of expert workmen, maſters of the art, from the village of Trie, near Valenciennes, to aſſiſt and inſtruct them for the harveſt of 1753.

" This work required a precaution which has been duly attended to ever ſince: it is, to pick all the ſtones from off the land, every year, as carefully as poſſible. The expence of ſo ding is a very trifle, when compared to the advantages attending it. All the roads around my land, which were formerly impaſſable in winter, are now firm and good, fit for any carriage. We no longer hear of horſes lamed, or waggons overturned by them; and, which is equally true, I find that my ground now requires a leſs quantity of ſeed.

" I have now practiſed this method, in an extenſive manner, during five ſucceſſive years, in the courſe of which I have had opportunities of experiencing every circumſtance neceſſary to be conſidered in order to determine its real merit; I mean, mowing in rainy weather, and cutting of corn either bent, laid flat, totally lodged, or lodged only in particular places, and in various directions. I ſhall firſt deſcribe the mechaniſm of this mowing, and then point out its advantages, with the objections of my neighbours, which will ſhew the only inconveniencies I have met with.

" The Flemiſh mowers whom I employed in the year 1753, brought with them ſcythes exactly like ours. I ſaw no ſort of difference in their ſize, make, manner of being mounted, or even in the hooks they were trimmed with; ſo that I found I had been miſinformed by thoſe who told me in 1751, that this work required an inſtrument different from that which is uſed for mowing oats. It was not till the year 1755, that an ingenious workman pointed out ſome very proper alterations, which have ſince been made.

" This intelligent mower obſerved, that the common ſcythe cannot ſuit any ground but ſuch as has been plowed flat; that it therefore was leaſt of all proper for our lands, which are plowed in ridges of ten or twelve furrows, raiſed very high in the middle; and that its hooks broke the ſtraw, plucked off numbers of ears, and did not lay hold of many ſhort plants which grow in the bottom of the furrows, whereby a loſs was occaſioned, or take up the intermixed graſs and weeds ſo exactly as might be wiſhed. To remedy this, he took a ſcythe at leaſt ſix inches ſhorter than thoſe which are commonly uſed, and, inſtead of the hooks, ſubſtituted what he calls the bender, conſiſting of two ſhoots of willow, or other green wood, placed ſemicircularly upon the handle of the ſcythe, where the hooks are commonly ſet. To this end, there muſt be four holes in the handle, ſo that the end of one twig may be put into the lowermoſt hole, and its other end into the third, and the two ends of the other twig into the ſecond and fourth holes. The ſcythe thus trimmed is to be uſed in the manner I ſhall now explain.

" When a mower ſets about cutting down a crop of oats, he places himſelf ſo that the corn is at his right-hand, from whence the action of the ſcythe throws the waving towards his left. The mower of wheat, on the contrary, proceeds from outſide to inſide, ſo that the corn which he is next to cut is always at his left hand; and that which he has juſt cut, being collected by the bender, is reſted, inclining a little, againſt the adjoining uncut part.

" A helper, which may be a boy of twelve or fifteen years of age, or an elderly woman, follows the mower at the diſtance of four or five feet, with a reaping hook, or a ſtick about a foot and a half or two feet long, and, by putting that through the interval between the ſloping late cut wheat, and the ſtanding corn againſt which it reſts, takes up the former, gives the ſtraw ends a gentle ſtroke or two upon the ground, to form that parcel into a grip, and lays it down at his right hand. This ſhould be done very expeditiouſly, becauſe the picker-up, as this perſon is called, is followed by another mower; and it ſhould alſo be done dexterouſly, becauſe the greater or leſs quantity of gleanings depends thereon. There ſhould be as many pickers-up (we call them binders), as there are mowers.

" The

"The posture of the mower is a circumstance of such importance, that I think myself happy in having taken particular notice of it in 1754. In cutting grass and oats, the mower goes in such manner that his feet, which are moved alternately at each stroke of the scythe, describe two parallel lines. But in the mowing of wheat, the mower's track should be upon a single line, so that his right foot, which should be foremost, be driven forward by the left, at each cut of the scythe; not unlike the attitude of a fencer when he advances.

"An accident, which had like to have over-set my whole operation in the year 1754, demonstrated to me the necessity of this different posture. I employed for mowing my wheat, men who used to come yearly to cut down my oats: they were seven in number. On the third day of their labour, five of them fell ill; upon which I set three others to work: but the consequence was, that I had ten sick people to take care of at the end of the week. I visited them, inquired into their ailments, and found, that some of them had a fever, but that all complained of violent pains and soreness under their left ribs. At first, I inclined to think them pleuritic; but, upon a closer examination, and upon considering the nature of the work they had been at, I saw that their illness proceeded from badly managed hard labour, the stress of which had been made to lie chiefly upon the left side. I therefore ordered them to take their rest.

"The next day, upon visiting my infirmary, I found that two of the mowers were returned to their work. I went out to them, and saw, even at some distance, that their posture in this work was the same as if they had been mowing of oats. This immediately shewed me the cause of their pains. The scythes which they then used had the common sort of hooks, and were much heavier than those with only wicker benders. I took up one of them, put myself in the posture of a mower of oats, and shewed them, that as a much greater weight rested upon the hooks of the scythe when they mowed wheat, then when they cut oats; it was not possible for them, in the posture they had chosen, to move that increased load to the left, without an irksome twisting of the body. Then, putting myself in the posture of a fencer, as I had seen my Flemish mowers do the year before, I demonstrated to them, that the body was thereby placed in such an attitude as enabled it to exert the greatest strength, when, by the motion from right to left, it had the greatest load to support, and that, by the same means, this load was carried round without fatiguing the ribs of either side. My man took back his scythe, tried as I had directed, was convinced of the truth of my demonstration, taught his companions the same method, and they have done their business easily ever since. I thought it necessary to relate the circumstances of this accident, because I am satisfied that even the strongest men would sink under the labour of mowing wheat, if they were to stand in the same posture as the mowers of oats.

"Such is the manner in which this operation should be performed, when the corn stands upright, that is to say, in the most favourable years. I ought to add, that the mower should take care to place himself, for his work, in such manner that his left hand may be toward the wind. The corn is then naturally inclined over the scythe, and is the more easily cut closer to the ground. The resistance of the wind, be it ever so little, helps to keep the corn which is cut steady upon the benders of the scythe, and facilitates the motion which rests it against the uncut corn, where the binder takes it.

"The mower is not hindered from mowing close, by the wind's blowing at his back; but the corn which he cuts will not be so exactly collected by the bender: some of the ears will be a little scattered: but the greatest inconvenience is, that it does not rest so well against the standing corn, but is often blown down; which renders the binder's work slower, and more troublesome, and occasions greater gleanings.

"The wind is in a bad corner for the mower when it blows in his face. It then occasions a loss of stubble, and a great dispersion of the ears.

"But the worst of all winds for this work, is that which blows upon the right hand of the mower. The stubble then remains long, and so great a quantity of ears lies scattered about, that one would hardly think the ground had been harvested. My mowers did not place themselves in this manner of their own accord; but I made them do it for a quarter of an hour, to try the effect, of which I am fully convinced.

"When the corn is inclined, or bent, the mower takes it in the direction of its bending, from left to right; which has the same effect, in calm weather, as if the wind blew towards his left.

"Corn which is lodged cannot easily be mowed inward, because the binder would be incessantly impeded by the intangling of his grip with the un-cut corn. A good mower judges by his eye, which part it is most proper to begin at, and takes advantage of the wind when it can be of service to him. The method which I have seen most commonly practised, has been by taking the corn in the direction of its bending, and throwing it in waves. The work thus done is neatly performed: no remains of stubble are seen after the mowing; but the field looks like a meadow.

Corn laid absolutely flat, and intangled, is the most difficult to cut well. I have seen a mower take it in every various direction in which it was beaten down, as if the wind had been constantly at his back, and by this means he has cut as close as if it had been only lodged. My wheat was in this condition in the year 1757, and was mowed very regularly: only the work was somewhat longer about, than it generally is in other cases.

"I shall not speak of rainy seasons till I come to the objections against this method of cutting corn; because they have nothing to do with our mowing, and the only thing requisite in such cases is to keep the corn from sprouting in the ear: but I shall here relate the advantages which I find in this practice.

"The preservation of my fellow creatures is so dear to me, that I look upon the means of lessening their excessive hard labour at a time when the heat alone is enough to over-power them, as the first and greatest advantage resulting from this method. Now I see that a good reaper, with his sickle, can scarcely cut an acre of wheat in a day, let him toil ever so much; whilst the mower will dispatch from an acre and a half to upwards of two acres, according to his skill and dexterity. I have, indeed, met with but few able to exceed two acres, when they have done their business well: but we may reckon that a good mower, taking them one with another, and the corn as it runs, upright, lodged, intangled, &c. will clear an acre and a half, or perhaps an acre and three quarters, in a day, neatly, and without wasting any of it. This mower does then three fifths more work than a reaper can. It is true, he has not the grips to tie up, because the person who follows him does that part: but he is obliged to whet his scythe when he comes to the end of the field, and still oftener when the corn does not grow thick; besides which, notwithstanding all the care that can be taken to clear the ground of stones, not a day will pass without his meeting some, which will oblige him to have his scythe new hammered; and lastly, when he has finished a row, he must go back to the other end of the field before he can begin another. All this takes up at least as much time as the reaper's binding up what he has cut: and in regard to the hardness of the labour on each side, I believe that every one who rightly considers the nature of their respective works, and their postures in working, will allow, that the mower's toil and fatigue is three fifths less than that of the reaper.

"Another circumstance, well worth attending to, in this method, is, that the mower is not exposed to those injuries from thistles, thorns, and other noxious plants, which often prove fatal to the reaper.

"From the first of these advantages result several benefits: 1, a greater riddance of the necessary work. Not a year passes without the husbandman's experiencing that some part or other of his corn ripens too suddenly; and this unexpected maturity, being exceedingly heightened by the least delay, occasions a great waste, by the shedding of the grain, both when the crop is reaped with the sickle, and in loading and un-loading it when carried home: whereas the scythe, by clearing in two days a field which could not be reaped in less than five, in the common way, guards against that excessive ripeness.

" 2. This method of cutting down the corn requires fewer workmen.—I muſt here explain myſelf; becauſe the fact would contradict me, if it be objected that a mower and a binder are neceſſary in this way, for what the reaper alone does in the other. But I conſider, that to harveſt ninety acres, for example, of wheat, I muſt employ ten men at leaſt twenty days, with the ſickle; whilſt ſeven mowers, and their binders, (fourteen people), eaſily do my buſineſs in ten days. The difference then is equal to ſixty days work of one man: and if I do not intend to get my harveſt in quicker with the ſcythe than with the ſickle, I take but four mowers and four binders, eight perſons, of which the four laſt ſtand me in leſs expence than three reapers; becauſe I employ for this buſineſs young people, who would not be ſtrong enough to reap with the ſickle. Conſequently I have two workmen the leſs, and ſome advantage in the compariſon between the grown-up man, who has a higher price, and the lad, who anſwers my purpoſe.

" 3. The thus employing of children, old women, and men whoſe conſtitution is not robuſt, would be an advantage to the inhabitants of the place. It would afford the means of ſubſiſtance to a greater number of people, and prevent idleneſs and beggary; an important object upon many accounts. Almoſt every pariſh would find within itſelf hands enough to get in it's harveſt, without being obliged to have recourſe to accidental paſſengers, who often work badly, require exorbitant wages, and ſometimes leave their maſter in the middle of the harveſt, if they do not ſubmit to their unconſcionable demands.

" Let us leave ſpeculation, and notice ſome advantages which are evident beyond contradiction. 1, It is not a ſmall one to have a greater quantity of ſtraw, and that ſtraw intermixed with more graſs and other fodder, than when the corn is reaped in the uſual way. This does not need any proof; for every one knows, that the ſcythe cuts as cloſe to the ground as the mower pleaſes. Experience has ſhewn me, that the ſtubble has not been left two inches long upon our mowed fields, where the ſtones had been carefully picked off; whilſt the ſickle generally leaves it eight or nine inches long, and ſometimes much more when the ground is infeſted with thiſtles and other ſtubborn growths, which make the reaper lift up his hand to avoid them. The ſtraw is therefore plainly ſix inches longer when cut with the ſcythe, than with the ſickle; a difference which may be valued at a ſixth part more than that which is uſually reaped in the common way.

" 2. The green fodder in the mowed fields ſhoots up anew when cut, and affords excellent paſture after the corn is taken off. The ſame demonſtrative evidence as before, will again take place here with thoſe who but conſider, that the reaper, leaving the ſtubble either eight or nine inches long, takes off only the very tips of the graſs which chances to be within his grip; ſo that, being then near its time of maturity, it ripens its ſeeds, ſows them, and withers away: whereas, when the ſcythe cuts it within two inches of the ground, in its greeneſt and moſt un-ripe part, the yet remaining eyes, and the crowns of the roots, ſend forth new ſhoots, which form a good after-crop for cattle.

" 3. The paſture upon fields mowed with the ſcythe, is attended with an advantage, in regard to cows, which may perhaps be peculiar to my country. I know not whether it be the ſame elſewhere. We find every year, and I have always taken particular notice of it, that our cows ceaſe to yield milk during the firſt week of their feeding among the wheat ſtubble. I take the reaſon of this to be, that the ſtubble gets into their noſtrils, pricks them, hinders them from feeding, and makes them range the whole field over in queſt of graſs unattended with this irkſome inconvenience; ſo that they ſpend their time in running about, without grazing. I do not find that this accident happens to cows which are turned in among the ſhort ſtubble left by the ſcythe: the graſs there ſoon ſhoots up a-new, and yields me plenty of paſture, eſpecially if a little rain happens to fall after harveſt.

" It reſults from hence, that the huſbandman is enabled to feed more cattle than he could otherwiſe do, to ſave his ſainfoin or lucerne, and to have a greater quantity of dung; as I have experienced with almoſt incredible ſucceſs.

" I now proceed to the objections, which I ſhall ſtate in the ſame order as they were made; that is to ſay, as each year gave room for one or other of them.

" The firſt was, that the ſcythe muſt make the corn ſhed very much by ſhaking it conſiderably. To affirm the contrary may ſeem paradoxical; though the aſſertion will be proved from manifeſt principles, and by facts. To judge rightly of my propoſition, it will be neceſſary to compare the operation of the ſcythe with that of the ſickle; both of which I have examined very attentively.

" The reaper preſents his hand to the corn, and with wide extended fingers, graſps as much as he poſſibly can; after which, to bring the lower part of the ſtalks ſo cloſe together that the ſickle may encompaſs the whole of his grip, and at the ſame time to give it a tenſion which renders the action of the ſickle more certain, he gives it a violent ſhake, and at that inſtant cuts it. The grip thus cut is generally intangled with the ſtanding corn; or the reaper, when going to lay it down, finds that he has miſſed cutting a ſtalk, or perhaps more, which he then breaks with a jerk of his hand. Thus ſeveral ſhakes precede that which the corn receives afterward when it is tied up.

" The ſcythe has not theſe effects. I have already explained the mechaniſm of its operation, and ſhewn that the corn, cut without any violent ſhake, is carried gently by the bender (or cradle, as we more commonly call it) upon the ſcythe, to the ſtanding corn, againſt which it reſts inclined, till the binder takes it away to tie it up.

" To prove my propoſition by facts, I inſtance the following. After my wheat was mowed in the year 1752, in the manner before related, upon the three ſeveral ſpots of ten acres each, which were parts of much larger fields, I went, with four other perſons, purpoſely to examine with all the care we could, what quantity of grain might have been ſhed by the mowing. We found none at all in the two firſt mowed pieces; but a great deal in the other parts of the ſame fields which had been reaped with the ſickle. In the laſt piece, which was not cut till the corn was riper, we found a little grain in the mowed part, but incomparably more in the other. I did not repeat this ſearch every year with the ſame care, becauſe I had not always the ſame conveniencies of making a compariſon: but I have ſeen enough to be certain that no grain is ſhed unleſs the corn be exceeding ripe, and that much leſs is then loſt by the ſcythe, than by the ſickle.

" The following more important objection was afterward made by a ſenſible huſbandman, who obſerved to me, that, in a rainy year, the corn cut after this manner muſt be more liable to grow in the ear, than that which is reaped in the common way, becauſe the heads of the grips not being ſupported here by a pretty high ſtubble, the wet cannot well drain off; and that the grain will imbibe a great deal of moiſture from the graſs underneath, when the ear is beaten down upon it by rain, which will render it very apt to ſprout as ſoon as the ſun ſhines upon it. I had been told how to guard againſt this accident, but did not try the method till the year 1756, when it anſwered perfectly well.

" This method conſiſts in laying the grips in a triangular form, ſo that the head of one reſts upon the foot of another. This operation is neither long nor fatiguing; nor does it require, in order to do it quick, any thing more than a little dexterity in cloſing the triangle, by making the foot of the third grip ſupport the ears of the firſt. The rains which fell during the harveſt of 1756, rendering the getting in of that year's crops extremely troubleſome, my neighbours had a great deal of ſprouted corn; but mine eſcaped by this method; and what little I had, proceeded from that which remained un-mowed when the rain became inceſſant.

" With regard to the ſheaves, when bound, my Flemiſh mowers informed me, in 1753, of their practice when they are overtaken by laſting rains. It is, to heap upon one another, ends to ends, as many ſheaves as they can poſſibly cover with one, which is then opened and laid over them. My people did not practiſe this method, which I believe the beſt; but they ſecured my corn by other means, which anſwer extremely well, and are generally known.

" From

" From the above objection my husbandman derived another, relative to the difficulty of drying the grass and weeds intermixed with the corn, in rainy years, and the danger of housing the sheaves when full of that trash, which may ferment, and be the occasion of the rotting of a whole pile of wheat, I cannot answer this objection otherwise than by my experience. The harvests of 1756 and 1757 were certainly not favoured by the weather: yet all the wild growths which were cut down with, and bound up among my sheaves, were well withered when they were housed. No sort of smell which indicated the least fermentation was perceived in any of my barns; the threshers did not find any thing that looked like it; and the straw which is taken from those barns, to feed my horses, attests that there was not any.

" I now come to the last objection; by so much the more serious, as it is one of those inconveniencies which I cannot remedy, but to which I readily submit. The ears of the corn, say the objectors, do not lie so even in your grips, as in those which are reaped with the sickle; some of them are in the middle, and others at the very bottom of the sheaf; so that your corn is not threshed so well or so regularly, and you thereby lose perhaps a considerable part of it. 2, All the grass and weeds contained in your sheaves are threshed with the wheat, and their seeds are mingled with the corn when the thresher measures it out: consequently you pay him for threshing this trash, which again increases the labour and pay of the winnower.

" All this is true: but let us discuss the matter a little more thoroughly. There are ears in the middle and at the bottom of my sheaves: but they seldom are of any other kind than those which we call backward or late ears; the weak productions of sickly plants, or of seeds not perfectly sound. Repeated examinations have convinced me, that very few others are in this case; and these ears hardly part with their grain at any time, in whatever manner they are threshed; for though the grains be torn from off them by the action of the flail, the inmost husk still adheres to the corn. These diminutive imperfect grains are so great a detriment to the fine plump, well nourished corn, that they lessen its value if not carefully separated by winnowing; after which they serve to feed poultry. If these ears escape the flail, the straw is so much the better. Our horses and other cattle reap therefrom a benefit which we ought not to grudge, because, I think, it turns to our advantage.

" The threshed grass and other wild productions, do indeed yield a considerable quantity of what are commonly called bad or useless seeds, for the beating out of which I pay the thresher. But the grass which occasions this expence, saves me that of a great deal of sainfoin and lucerne which my cattle would consume: and it would be unjust in me to complain of the additional charge in the winnowing, since my manager has thought of applying those seeds to domestic purposes, such as feeding fowls, &c. which prove more profitable to me than an equal quantity of the finest corn.

" A real increase of expence, is what I pay the thresher beyond the common price of the country. This difference, which consists in two-pence or three-pence for a quarter of wheat, is but a just compensation for his extraordinary trouble in unbinding and binding up again perhaps an hundred and fifty sheaves, and sometimes more, for what an hundred sheaves generally yield, when reaped in the common way. But this expence is so amply repaid by the extraordinary quantity of straw obtained by my method, that I rate the difference at more than the value of five quarters of corn, which, to silence contradiction, I will suppose to be otherwise lost in my practice. Still my crop is cut down and housed with far less toil and expence, than if it was reaped."

" They begin plowing in the isle of Thanet, says a correspondent of the editors of the Museum Rusticum, about the first week in November, contriving so that the wheat season may be over by the end of the month.

" In the spring, if the wheat is rank and the weather dry, they feed it down with their sheep, which they think makes the wheat branch more, and settles the earth about the roots of the plants. Experience has convinced them, that this method of sowing wheat after trefoil, is better than sowing it on a fallow; for the land hereabout is naturally very light and hover, and the wheat on that account very much subject to be root-fallen. To prevent this, it is no uncommon thing for them, as soon as they have sown their wheat, to drive a flock of sheep over the land, to settle the earth close to the seed.

" Their crops of wheat here are generally three, four, and five quarters on an acre; which last is, indeed, a very large crop, when it is considered, that the land is in general, by nature, poor and barren, and that it is almost entirely owing to the industry and good husbandry of the farmers that it is at all brought to bear wheat: in fact, they are an assiduous people, and spare neither cost nor labour to improve their land.

" On the light land here they for the most part sow about fourteen pecks on an acre, but on the richer lands they allow four bushels.

" The farmers here never sow the seed produced by their own land; they find their wheat succeed much better by change; for which reason the seed which they sow on the light hover-land they chuse to procure from a gravel or deep cledge, or clay land, taking care that the soil on which the seed has grown should be as different as possible from that on which it is to be sown.

" Instead of making artificial steeps with great parade, they make use of that which Providence has put in their way, wetting their seed with salt water, which they fetch from the sea; and they afterwards sprinkle it with lime, to prevent the smut: they are also particularly careful to clear their seed from wild oats, cockle, &c.

" I know no part of England where there are better farmers; for though they keep their lands constantly cropped without fallow, which they call sowing a round tilth, yet do they so manage matters, as to keep them still in good heart.

" They reap their wheat very high here, leaving as much straw as possible in the field: this they say they do to save barn-room. Some farmers here have a practice of sowing rye to make bands for their sheaves, the straw being longer, and as they think tougher, than that of wheat. The reaper makes the bands, which he cuts as low as he well can, and binds the sheaves.

" The wheat stubble, which, as I said before, is left very long, is generally mown for the maltsters, as they burn it in their kiln to dry their pale malts for the London market. The greatest part of this island is a light chalky soil, so that wet summers in general agree best with it; and it is by this means the farmers here get so much money: for when the crops fail in other parts of the kingdom, they are almost sure here to be very large; and they have the great convenience, besides, of water carriage to the London markets. It is extremely pleasant, towards the latter end of the summer, before harvest, to ride over this little island: I do not imagine there is a more improved spot in the kingdom; the fields are all kept so clear from weeds, that they resemble a well kept garden; they grudge no expence in hoeing, weeding, plowing, or manuring; and experience has long ago convinced them, that they pursue a right method. Their practices are many of them good and worthy imitation; it would therefore be great pity if they were not made known, by some means or other, to the rest of the kingdom." *Museum Rusticum, vol. I. pag.* 3.

" It is now upwards of seven years that I have been tenant of a considerable farm in Essex; but as there are some particular circumstances attending this farm, I must beg leave to say a few words on the subject.

" The soil, which is, for the most part, a fine mellow loam, or what is in general called a good wheat soil, was in very good heart, and not impoverished; yet the last tenant broke on this farm, and the landlord lost by him near two years rent; for his crops of wheat were continually damaged by smut, let him take what care he would of the seed, and were besides often laid, and the land got very foul, though he was not sparing of his fallows.

" On the contrary, since I have occupied this land, it has borne large crops of good sound wheat, with very little smutty corn, and barley, oats, peas, beans, and other things in proportion. What will appear still more furprifing is, that I do not lay on half fo much dung as he did.

" It will now, perhaps, be neceffary to explain this feeming paradox. At no great diftance from the farm lives the landlord, who is a man of fortune, and drives a fet of horfes. This gentleman keeps no land in his own hands, fo that he was for many years obliged to buy all the ftraw ufed for the litter of his ftables, which amounted to a very confiderable quantity: however, when the laft tenant of this farm came into it, having been a fervant in the family, he offered to fupply the efquire with ftraw for his ftables, provided he might have all the dung, except what the gardener had occafion for. The 'fquire thought this a good propofal, and the farmer imagined he had the beft of the bargain; fo the matter was foon fettled.

" Now, you are to underftand, that the 'fquire kept, befides feven coach-horfes, a ftable of hunters, a number of road-horfes, and a pack of hounds; fo that there was made on his premifes, in a year, an incredible quantity of rich dung.

" The farmer imagined he was now in a fair way of making his fortune; for his father had taught him, that the man who can command dung is always fure of large crops: but this did not prove true in the prefent cafe.

" To proceed; my predeceffor went on ploughing his land, got his fallows in good order, dreffed them largely with dung, and always fowed them with wheat.

" His crops of this noble grain, however, by no means anfwered his expectations: his wheat conftantly looked well and promifing in the winter and the early part of the fpring of the year; but as it advanced, it grew rank, and at harveft was either run all to ftraw, and was befides very fmutty, or elfe, if a heavy fhower of rain happened to fall, it was lodged, matted, and grew. This was indeed a very mortifying circumftance, but our farmer could find no remedy for it. He feveral times, without fuccefs, tried folding fome fheep on his wheat; but this part of hufbandry, for want of fkill, he managed fo badly, that he loft two entire crops, for he had fcarcely the return of his feed at harveft. This could never hold long; fo that in the end he was, as I faid before, broke and ruined.

" This man never could be perfuaded that any part of his lofs was to be attributed to the dung he laid on his land, though he conftantly manured it with the horfe-dung before it was half rotten, and without any mixture to allay its great heat: this kept the foil in a conftant ftate of fermentation, and ftocked it with weeds, infomuch that, when I took poffeffion of the farm, fome of the foil was abfolutely mouldy, and ftunk again, it was fo rank.

" I will now inform you of my method of management, that you may be enabled to judge how far I was benefited by the errors of my predeceffor.

" I found fixty acres of fallow ready for fowing with wheat: thefe, as the land was rank, I fowed with the winter tare, which I knew, by experience, would choak the weeds, and abate the ranknefs of the foil. In fome parts, where the foil was not fo rank, I ploughed in the tares in order to fow wheat over them; in other parts I fuffered the tares to ftand for a crop, which, however, was not confiderable, they ran fo much to ftraw or haulm.

" When the tares were off, I got the land inftantly in order, and fowed the whole with wheat, of which I had a better and cleaner crop than had been known upon the land for upwards of feven years before: this all my neighbours acknowledged: however, it was neither clean enough, nor confiderable enough, to fatisfy me. Some of your readers may, perhaps, wonder what I did with my tares, as but few are fold at the country markets; but I muft inform them, that I live within ten miles of a fea-port town, whither I fent them at various times, in order to their being carried by fea to London.

" I am to obferve to you, that I continued the agreement of giving the 'fquire ftraw for his dung; but I made a ufe of it very different from my predeceffor.

" I make it a rule never to manure for wheat, or fow wheat on a fallow. I do not indeed allow many fallows on my land; and when I do, I generally fow my fallow with barley, to which I allow four or five ploughings. This commonly yields me a large return, and I have a good crop of wheat after it.

" This, however, is not my general method; for I am very fond of the hoeing hufbandry, to practife which, in fome degree, is the only infallible way of keeping land clean. To begin then with my method, I never lay dung alone on my land, let it be ever fo rotten; but as foon as I get any long dung from the 'fquire's, I carry it to my compoft-heap, where it is mixed in alternate layers or beds, with frefh virgin earth, (if I can get it) lime, or chalk, lime rubbifh, fcourings of ditches and ponds, turf, leaves of trees, and all the dung and offal of my family, of the hog-yard, the poultry-yard, and the dog-kennel. As to my pigeons-dung, I always preferve it to mix with foot, and ufe the mixture as a top-dreffing for my wheat, whenever it happens to be too backward in the fpring.

" But to return to my compoft: I have always feveral diftinct heaps of different ages, and I fometimes leave it three years before I ufe it, and never lay on any under two years old.

" When I have got a plot of ground in order, I give it a thorough good dreffing of this compoft, which I immediately plough in. I then fow it with fome crop that requires hoeing, fuch as horfe-beans, broad-beans, or white or grey peas. During the whole fummer, I take care to keep thefe crops very clean by hoeing, efpecially if the feafon is rainy; and I am particularly cautious in preventing any of the weeds from perfecting their feeds.

" When my hoeing-crop, which generally more than pays me all my expences, is off the land, I immediately get it into as fine tilth as I poffibly can, by repeated ploughings, and then fow it with either wheat or barley, whichever is likely to pay me beft; for little as fome of your readers may think of it, barley, when it is fown on good land well prepared, is very frequently as profitable a crop as wheat.

" By thus fowing my wheat after a hoeing-crop with dung, I have always a good return of clean corn, often five quarters on an acre; and my land will ftill be in heart enough to give me a reafonable crop of oats; after which, without any fallow, comes my hoeing-crop, &c.

" When I fow barley after the hoeing-crop, I fuffer wheat to follow it; and then it is that, if I find it neceffary, I give the wheat in the fpring a top-dreffing of foot mixed with pigeons-dung.

" I fometimes allow only fix pecks of wheat-feed to an acre: this is when I fow over it, in the fpring of the year, eighteen pounds of broad clover-feed, which I harrow in with a pair of very light harrows; and it does not in the leaft damage my wheat-plants. I leave the clover only two years on the land; for the fecond year, after I have mown the firft crop for hay, I fuffer the fecond to grow very rank, (having given my land a flight dreffing from my compoft dung-hill the preceding year) which I plough in, and over it fow wheat, to be harrowed in on once ploughing.

" Thefe crops of wheat are fmaller in quantity than any others I get, but the grain is finer, plumper, brighter, and heavier, generally felling for more at market, as being always very clean and clear from feeds of weeds.

" In my method of farming, fome particulars are to be noted. In the firft place, as my crops fucceed one the other very quick, I am under a neceffity of having all my ftubble extirpated before I give the land the firft ploughing after the crop is off. If it is a wheat or bean-ftubble, I generally have it all pulled up by hand by women and children; barley and oat ftubbles I have torn up by a pair of loaded drags, and afterwards gathered into heaps and carted to the compoft-heap. This I do to prevent the ftubble from being buried by the plough, and from growing mouldy in the land; from which mouldinefs I have great reafon to think fmut often proceeds.

" Another thing to be noted is, that I allow lefs feed to my land than moft of my neighbours, my quantity being from feven to nine pecks of wheat, from nine to twelve of barley, and about twelve of oats to an acre of land; but it is always to be prefumed that the feed I fow is good. If any farmer fhould imagine that thefe quantities are too fmall, let him fuppofe every wheat-plant to occupy a fpace of fix inches fquare, which is fmall enough: let him then calculate how many fuch fpaces there are in a fquare acre. When he has done this, let him proceed to count how many grains of wheat there are in a pint, which multiply by the number of pints in nine pecks, and he will find by the refult that I, in fact, allow too much feed." *Mufeum Rufticum, vol.* V. *p.* 104.

"I have, for fome years laft paft, held a confiderable farm in the county of Leicefter, and have, thank God, met with fome fuccefs in my practice.

"My methods of farming are thought by many to have fomething peculiar in them; yet, as I do not often mifcarry, no one has a right to find fault with me.

"Great part of my farm is very good wheat land, the foil being a fubftantial loam.

"I frequently, as well as the reft of my neighbours, make ufe of lime as a manure; but then I ufe it differently from what they do.

"The common practice is, to lay about forty bufhels of unflaked lime on an acre, which makes a peck on every fquare perch, (half a bufhel when it is flaked.) On wheat land they fpread the lime at the fame time they fow the feed; but this is a way I do not much approve, and for this reafon I vary my practice. The method I ufe is as follows: I fow my wheat without laying on any manure; but in the beginning of the month of February I get, for every acre of land I intend to lime, twenty bufhels of that manure, unflaked, and forty bufhels of fand, or the rubbifh of a brick-kiln.

"Towards the latter end of the month I caufe the lime to be flaked, which doubles its meafure, and very well mixed with the fand; immediately after which, in the laft week of the month, I have it fcattered by way of top-dreffing over the green wheat; and as rain generally fucceeds, it is foon wafhed down to the roots of the plants, and gives them a vigour and ftrength of growth, that is really aftonifhing to a perfon who had never feen this method practifed.

"This is my way, if I fee the weather is inclinable to be wet; but if it is dry, and not likely to rain, I double the quantity of fand, in order to take away all danger of the wheat-plants being burnt, or hurt, by the ftrongly-corrofive power of the lime.

"The above method I would willingly recommend to the attention of your readers; and though I have benefited greatly by it, yet need they not take my word, as it is fo very eafy to make a fmall trial, and form a judgment from the fuccefs they may have.

"I muft obferve, that I look upon it to be almoft a matter of indifference what kind of fand I ufe, except that I prefer lime-ftone fand to the cryftal fand, as being moft abforbent, and in truth prefer the rubbifh of broken bricks to either.

"It will perhaps be unneceffary to tell your readers my motive for this preference; yet that I may not be thought obfcure, I fhall do it.

"When lime is flaked, it crumbles and falls into very minute particles: the fmalleft of thefe particles are, together with the moifture that adheres to them, abforbed by the large open pores of the brick rubbifh, which afterwards difpenfes them by flow degrees to the foil on which it is laid, for the fupport of the crop: this occafions the operation of the lime to be more equal; the parts which were not abforbed, are firft attracted by the earth; thefe nourifh the young plants, which, in time growing ftronger, have power to draw from the abforbent the particles it had referved for their ufe." *Mufeum Rufticum, vol.* III. *p.* 366.

"Almoft every part of this kingdom has a method of farming peculiar to itfelf; and this I have often found to be true, in the many journeys I have made through various parts of the ifland.

"A fhort time fince, my occafions calling me down into the Weft, I ftopped for a few days in Wiltfhire, where I could not help obferving, that the wheat-corn was remarkably backward, though it, in general, promifed to be a good crop.

"I thought it worth my while to afk fome of the neighbouring farmers the reafon of this appearance, when I was informed that moft of the wheat was fown late, owing to a wet autumn, which prevented them from giving their land the neceffary ploughing for that crop fooner than November, December, and even January.

"The foil is a pretty good loam, on a chalky bottom: and I found they often fow late; but whenever they do it, they take care to allow an additional quantity of feed, generally one fourth, or a third, more than they ufe when they fow early.

"I was alfo told, that many benefits often refulted from fuch late fowing; particularly, the crop is generally clearer from weeds; for in early-fown wheat, poppies, and other noxious weeds, are very apt to get a-head, and greatly injure the corn. I even faw in my walks many early-fown fields, which rather feemed to be under poppies than wheat, as the poppies were in full bloom, and made a glaring appearance.

"The Wiltfhire farmers, the beft of them I mean, often give their land four ploughings for wheat; and they find their advantage, as it is by fuch means brought to a fine tilth, and yields a good crop.

"Another advantage they told me they had from fowing their wheat late was, that in the blooming feafon the weather was generally fine; whereas, in a wet fummer, the bloom is often wafhed off from the forward-fown wheat.

"But it muft not be imagined this method of fowing wheat late is indifcriminately purfued: in many circumftances it would be very imprudent to do it.

"This method of hufbandry muft, to meet with fuccefs, be chiefly practifed on fallows, where the land is good, and has been well dreffed.

"Every crop, and method, has dangers to encounter; and the chief danger of late fowing is, that a froft may come on juft as the feed begins to fprout; but then good land, well dreffed, is not fo fubject to this misfortune as poor, unmanured land, that has, perhaps, been not half ploughed.

"I find, from enquiry, alfo, that it is dangerous fowing wheat on clover lays on one ploughing only, unlefs it is done fooner than the middle of November; for the turf, or grafs lay, forms a cruft immediately under the feed corn; and this not only prevents its taking a firm rooting, but alfo expofes it to the ravages of field fowls, which are, at this feafon, particularly voracious, as having a fcarcity of food; and the infant plant is, befides, liable to be killed by the froft, juft as it is about fprouting and fhooting out its firft leaf. It ftands, therefore, to reafon, and is warranted by experience, that wheat fhould not be harrowed in on a clover lay, on one ploughing, fo late after the middle of November, as the danger is great, though the lofs may not always be certain." *Mufeum Rufticum, vol.* III. *pag.* 1.

"As I have been many years a farmer, it is not to be wondered at that I fhould know fomething of hufbandry.

"Experience, which is an excellent miftrefs, has, in fact, beftowed on me moft of the knowledge I have acquired: I imagine, therefore, that an account of the refult of this experience, will not be unacceptable to your readers.

"Moft farmers chufe to fow wheat on a fallow; we, in Effex, on the contrary, often, not without good reafon, avoid it. Every fallow defigned for wheat requires a good dreffing of rotten dung, or fome other manure; and this dreffing, we imagine, often is the caufe of a fmutty crop, if laid on uncompounded; therefore, whenever I fow my wheat on a fallow, inftead of laying on my muck-heap unmixed, I make it into a compoft in the preceding fpring: this compoft confifts, according to the nature of the foil it is to be laid on, either of chalk, light earth, and rotten dung, or of lime, clay, and dung, laid in a heap, in alternate layers, or beds.

"This compoft-heap I caufe to be frequently turned during the courfe of the fummer, till it is thoroughly mixed, and forms one united mafs of manure, rather crumbly than otherways.

"With this manure I drefs my fallows in the fame manner farmers lay on their rotten dung alone; and I find, by experience, it is lefs apt to heat and canker the wheat-feed, and it is alfo much lefs inclined to mould and burn the feed.

"This, I fay, is my method of management when I fow my fallows with wheat as a firft crop; but I more generally approve of making wheat the fecond crop after barley, oats, beans, or peas.

"I am fenfible many of your readers will be furprifed at this method, and exclaim that it is impoffible to get a good crop of wheat but after a good fallow; yet I know the

the contrary: it is from experience I know it; may I not therefore venture to aſſert it?

"When I intend to ſow wheat as a ſecond crop, I lay my due quantity of compoſt on the land ſome time before I ſow it with barley, oats, beans, or peas.

"When this crop is off, the following year I ſow wheat. You may ſuppoſe the land to be duly prepared by well-timed and careful ploughings; but I am to premiſe, that after beans and peas, being hoeing crops, the land is much ſooner brought into good tilth, than after oats or barley.

"The wheat ſowed the ſecond year of the fallow is, with me, generally a good crop, and almoſt always clear from ſmut and pepper-wheat.

"If, by any accident, the wheat ſhould be ſickly, or pining, after Chriſtmas, I beſtow on it a top-dreſſing of wood aſhes, ſoot, if I can get it, or coal aſhes, if the ſoil happens to be ſtrong: this ſeldom fails anſwering my expectations; checking the growth of the weeds, and forwarding that of the corn.

"It is very frequently that I ſow wheat in this manner for a ſecond crop; but when I have an opportunity of chuſing, which I cannot always do, as I muſt ſuit my crop to my wants, I prefer, for the firſt crop, beans or peas, either of which I take to do the land nearly as much good as a fallow.

"Neither peas, nor beans, are, in my opinion, great impoveriſhers; and the frequent hoeing which they both require, if they are properly cultivated during their growth, brings the land into finer order than the beſt regulated courſe of huſbandry with the common implements could effect.

"Wheat ſucceeds particularly well after either of theſe two laſt-mentioned crops; and I have found, by experience, that if peas, or beans, are made intermediate crops, and are well and properly hoed during their growth, land of a moderate quality may, without being impoveriſhed or hurt, be made to bear a continued ſucceſſion of crops for many years; but it muſt be underſtood that it ſhould, from time to time, be refreſhed with proper dreſſings of well-prepared compoſt.

"I know, many farmers think there is no ſuch thing as carrying on a courſe of huſbandry without allowing, once in three or four years, a year of fallow; but ſuch are little acquainted with the benefit reſulting from hoeing crops; and it is this benefit that has of late induced farmers to ſow ſuch immenſe quantities of turneps in the counties of Norfolk, Suffolk, Eſſex, and other counties adjacent.

"Many of the advocates for intermediate fallows think that the earth requires reſt; but this is a great miſtake; for I could eaſily make it appear that, in a proper method of huſbandry, land might be almoſt continually cropped, without being impoveriſhed or worn out.

"The real benefit accruing from frequent fallows is, that they allow the huſbandman time and opportunity to bring, by good tillage, his land into proper order for the reception of the ſeed; but in the method of huſbandry I would recommend, the land would always be kept, by frequent ſtirring, in ſuch good tilth, that the time betwixt gathering the crops, and ſowing the next ſucceeding ſeed, would be abundantly ſufficient for any preparation it might require; for it is a well-known fact among huſbandmen, that when land is well tilled and kept in good order, one ploughing will go much farther than three where the land has been neglected, is rough, and grown hard and cloddy, through inattention or lazineſs." *Muſeum Ruſticum, vol.* III. *p.* 3.

"A wet harveſt, ſays an old huſbandman, is what a farmer dreads more than almoſt any thing, as it hurts the quality of his corn, increaſes his expences, and greatly leſſens his profits.

"So much depends on the well getting-in of our bread-corn, that every man, who knows any thing that can forward ſo good a purpoſe, is, I think, in duty bound to communicate it for the benefit of the public.

"It is a well-known maxim that wheat ſhould be left for ſome days in the field, after it is cut, before it is inned: this, the farmers think, and not without reaſon, improves its quality; the dews plump the kernels, and the ſun brings it to a proper and perfect ſtate of maturity.

"Theſe then are the benefits that reſult from leaving the ſheaves for ſome time abroad; but it is neceſſary the weather ſhould be fine, or great loſſes are often the conſequence of this practice.

"Sometimes, when the farmer leaſt expects it, the weather ſets in foul, and it rains for ſeveral weeks ſucceſſively: it is then very difficult to preſerve the wheat from being greatly damaged, notwithſtanding the many contrivances that have been thought of for this purpoſe.

"Some ſhock their ſheaves, ſetting them up in traves of ſix ſheaves of a ſide, and two to cap them; but this is a very dangerous method, and never to be practiſed after much rain has fallen: if the ſheaves were dry when the traves were ſet up, from an expectation of its raining, it is of great ſervice; but if the ſheaves are firſt ſuffered to be wet, ten to one but the corn ſweats, ſprouts, and rots, by being ſo cloſe confined from the action of the air.

"After all, I am apt to think that it is full as well not to cap the ſhocks; for if the rain is not very heavy and conſtant indeed, the ears, provided they do not touch the ground, will dry nearly as faſt as they are wetted.

"In Middleſex, Kent, and ſome parts of Eſſex, they generally bind their wheat as they reap; but then it muſt be ſuppoſed that their crops are, for the moſt part, pretty clear from green weeds, which would otherwiſe cauſe the ſheaves to ſweat violently in the mow, and greatly damage the corn.

"When a farmer is ſo unfortunate as to have his wheat-ſheaves thoroughly wetted, if fine weather enſues, I would by all means adviſe him to unbind them, and afterwards ſpread them out to be dried by the ſun. This ſimple method will often prevent great loſſes, and the wheat may at laſt be got in in tolerable good order.

"If the rain, however, ſhould continue long, and there ſhould be danger of the kernels growing, which by obſervation he may eaſily judge of, I would adviſe the thinking farmer inſtantly to carry it home wet as it is, and afterwards manage it as I ſhall direct from my own frequent experience.

"When the waggon, or cart, comes home loaded with ſheaves, let them be thrown promiſcuouſly into the bay of the barn, and not regularly mowed; for it is neceſſary they ſhould lie hollow, that the air may get into the vacuities, and prevent the ſheaves from heating during the little time they are to continue in the ſituation above deſcribed.

"Let our farmer next prepare ſome cutting-boxes, ſuch as horſe-meat is cut in, in Kent, and ſome other counties. The number of theſe boxes ſhould be according to the quantity of wheat he has wet; but three or four conſtantly kept going will do a great deal of work.

"With theſe cutters let the ears be cut off from the wet ſheaves; and when a ſufficient quantity are collected from all the boxes, let them be put looſely up in ſacks, and carried to a malt-kiln, there to be regularly and gradually dried; and when the firſt parcel is done, another is to ſucceed, and ſo on till the whole work is completed.

"This method I can, from my own experience, recommend to your readers; and it is leſs expence than would at firſt thought be imagined. The heat of the kiln may be kept up higher than when malt is drying, as the chaff of the ear will prevent the kernel of the wheat from being damaged by the fire, unleſs the heat is very intenſe indeed; but it will, however, be proper to keep the ears gently ſtirring with a fork, or rake, during the time they are drying.

"In this management the farmer will find great advantages; and his wheat will, with a very inconſiderable additional expence, be nearly, and ſometimes quite, as good in a wet harveſt, as if it was houſed in ever ſo good order, in fine ſun-ſhining weather.

"If, by chance, after you have cut off the ears from the ſheaves, the weather ſhould change, and become fine, you may often dry them without the aſſiſtance of the kiln, by ſpreading them thin on a large threſhing-cloth, and turning them frequently with a wooden rake; and even, if by this method you ſhould not entirely dry them, it will ſtill bring them ſo forward that the kiln will eaſily complete the cure.

"I muſt, however, before I conclude, caution the farmer not to ſuffer the kiln to be much heated, unleſs the ears are kept conſtantly ſtirring during the time they are drying." *Muſeum Ruſticum, vol.* II. *p.* 106.

"Give me leave, ſays a practical farmer of Warwickſhire, to mention to you a practice which, however, I do

 not

not abſolutely recommend, though with me it ſucceeded, and, as I have been informed, has done ſo with ſeveral other farmers, who have ventured to make the experiment.

" A few years ago, after what I thought a good fallow, I ſowed a field, containing five acres, with wheat. The foil was a good loam, but rather light than ſtiff, and inclined to be ſtoney. The wheat plants looked healthy during the whole winter, and promiſed fair to yield me a plentiful crop; but in the ſpring, warm rains coming on brought ſuch ſtore of weeds, that my wheat was in danger of being choaked.

" I was for ſome time puzzled what to do; for it being now the latter end of May, and the wheat being on the ſpindle, and ſome even in the ear, to weed it with hooks would have been endleſs, not to mention the damage that would have been done to the plants by the weeders feet.

" I had at one time thoughts of mowing wheat and weeds all together, and drying them to make fodder for my cattle: intending, if I had done this, to have got the land as faſt as poſſible in order, and ſown it again with wheat the ſucceeding autumn.

" However, in looking over the field, I found no great deficiency of wheat plants; but they were in moſt places ſo over-topped by the weeds, as to be ſcarcely viſible, and in the furrows, in particular, not a blade of wheat was to be ſeen.

" My method of ploughing for wheat-feed in this land is, to make narrow ſtitches, but wider than a ridge, and more rounding, being not ſo ſharp on the back.

" Whilſt I was meditating what to do in this matter, a gap was by ſome accident made in the hedge, and a parcel of my ſheep got into the wheat field.

" As ſoon as I ſaw where they were, apprehending great damage, I ordered them to be immediately driven out, and the gap mended.

" On taking a ſurvey, I was not a little ſurpriſed to find that the ſheep, inſtead of doing any damage to the wheat, had done it a great deal of good, for they had eat up almoſt every weed which grew in that part of the field next to the paſture.

" Encouraged by this accidental diſcovery of a propenſity in ſheep to eat weeds rather than wheat, I turned a hundred of my flock, into the field, two or three hours in the morning and the evening, for ſeveral days together, till all the weeds were nearly conſumed.

" On inſpecting my field afterwards, I found the ſheep had done very inconſiderable damage to the wheat, but the weeds were eat down ſo cloſe that they could never again get a-head; the wheat going on proſperouſly, and yielding me at harveſt a plentiful crop of clean, good corn, which was more than any of my neighbours could that year boaſt of.

" Whilſt the ſheep were eating the weeds, I found they moſtly walked in the furrows, as being eaſier to their tread than the ſloping ſides of the narrow ſtitches; and this might be one reaſon of their doing the wheat ſo little damage by their treading.

" In this new method of huſbandry I took, however, one precaution, which, I am apt to think, greatly contributed to my ſucceſs.

" The precaution, I mean is, that I never let them lie in the fields at night, as the weight of their bodies when they lay down to ſleep could not have failed doing great damage to the plants." *Muſeum Ruſticum, vol.* III. *p.* 31.

" Permit me, ſays another experienced farmer, to communicate to your readers, for their benefit, I hope, a little of the experience I have in many years acquired.

" Being now grown old, and retired to ſpend the remainder of my days in this city, I trouble myſelf but little about the practical part of farming; yet did I ſome years ago occupy a conſiderable tract of ground in Norfolk.

" I ſhall, for this time, confine myſelf to the propriety and impropriety of feeding wheat down with ſheep in the ſpring; a practice which has by many been hitherto but little underſtood.

" This practice, when prudently adopted, is replete with many and great advantages; but if indiſcriminately adopted, nothing would ſooner ruin a farmer.

" The advantages to be derived from it are, that it affords feed for your weathers and ewes after the turneps are conſumed, and before the ſpring feed comes in; it cauſes the wheat to tiller and branch more than it would otherwiſe have done, and of courſe produce a larger and better crop; it brings, by the rich manure it affords the land, the crop forwarder, and makes it heavier in the ſcale, as well as plumper in the buſhel.

" The diſadvantages attending this practice are, that, in certain circumſtances, it checks the growth of the corn, and makes the ſecond ſhoot diminutive and ſmall; of courſe the ears are lean and poor, and the crop in proportion. It gives the weeds an opportunity of getting a-head, and ruining the crop, to the farmer's great loſs and diſappointment.

" I ſhall, to be better underſtood, relate ſome caſes which happened to myſelf, as I find them noted in my journal, for I always kept one.

" In the year 1742, I had ten acres of wheat, which, after Chriſtmas, ſeemed proud. The ſoil was a looſe loam, and I had, when I fallowed, laid on plenty of dung.

" I turned into this field a parcel of ſheep on the twenty-ſecond of January, in order to feed it down, which they did; but the weather coming in milder than I expected, the weeds, which had been brought in with the dung, got ſuch a head, that I was above twenty pounds loſer by feeding it.

" In 1744, I fed, very indiſcretely indeed, another piece of wheat of fifteen acres. The land was poor, and had not been well dreſſed, ſo that about the tenth of March the wheat-plants ſtood very thin. I turned in ſome ſheep, thinking it would afterwards branch more, and produce a better crop; but I was diſappointed, for the ſheep bit off the knot of the plant, and I had, I think, the worſt crop I ever reaped.

" The next year, 1745, I had another thin crop of wheat on much the ſame land as the laſt: I turned in ſome ſheep the ſixth of February, before the knot was above the ground within reach, and it ſucceeded; for, as I gave it a good top-dreſſing within a fortnight, it tillered and branched ſo well, as to produce a much better crop than I expected.

" I could relate to you many other circumſtances of this nature, but it would take up too much room; I ſhall therefore proceed to make ſome obſervations on my general experience in this manner.

" I find wheat ſhould never have any ſheep turned on it, unleſs it is forward in January, and likely to be lodged at harveſt, except now and then, with great precaution, when you want to thicken a crop.

" Such wheat only ſhould be fed down as was early ſown; and I hold it a bad practice if the land is rich with dung.

" Wheat ſhould not be fed down, unleſs the land is pretty clear of weeds, and has ſtrength and ſubſtance enough to afford the wheat nouriſhment in plenty, that it may get into ear at the proper ſeaſon, notwithſtanding the growth was ſo checked.

" There is in every plant of wheat a certain knot, or crown of the root as I call it, from which all the branches iſſue: now, if this crown is nipped off by the ſheep, a dwindled production is the certain conſequence; for this reaſon, ſheep ſhould never, (unleſs it is in a very backward ſeaſon, and then it will not be prudent to feed wheat down at all;) I ſay, ſheep ſhould never be turned on it after the middle of February: the beſt time, in general, is the latter end of January, or even the middle of that month.

" If ſeaſonable rains follow, provided the ground is clear of weeds, it will be greatly to the advantage of the farmer.

" If the farmer has the leaſt doubt of the ſtrength of his land towards giving the checked plant nouriſhment, I would by all means have him afford his wheat a top-dreſſing of ſoot, aſhes, malt-duſt, or whatever other proper manure he may have at hand, provided he is ſure it is quite clear of weeds.

" Let not the induſtrious farmer be at all uneaſy if, after feeding down his wheat, he perceives the plants ſtand at a diſtance one from the other; for if he has practiſed this piece of huſbandry, with the precautions above noted, he may depend upon it, that every plant will throw out a number of branches, and that he will have a field full of ſtalks at harveſt, and a crop that will ſurpriſe him.

" I am very fond of recommending wheat crops to the farmers attention, not only becaufe it is the moft noble of grains, but alfo becaufe, if well managed, it is the moft profitable.

" We muft not always judge of the farmer's profits by the produce of his land; which fome of your readers may think odd; but I will make it appear by an example from my own practice.

" In the year 1743, I had two fields, of twenty acres each, in wheat; one of which yielded me, at harveft, at the rate of four quarters an acre throughout; the other yielded me only twenty bufhels, one acre with another; yet I got more by the laft than the firft. The cafe was thus: falling fhort of dung, I was obliged to buy; but it was fo dear, that I only bought enough for the firft field, giving the other two ploughings extraordinary, inftead of manuring it; and thefe ploughings I reckon at a mere trifle, as my horfes would otherwife have ftood ftill." *Mufeum Rufticum, vol.* III. *pag.* 151.

" I have often thought that it would be of great fervice to the public, if, by any method, there could be determined a mean weight for any given quantity of corn, and likewife what number of grains, upon an average, ought to be contained in each ear, and the proportional weight between the ear, with the grains in it, and when taken out, and likewife the proportional difference between the weight of the whole ftalk, including the ear and the grain.

" But in order to fettle this medium, under our prefent confideration, it will be abfolutely neceffary, in the firft place, to make accurate and impartial experiments for a number of years, and then, by comparing the produce and the weight, &c. of the whole, both feparately and together, we may come pretty near the mark in view.

" In order therefore to purfue the plan I had laid down, in the beginning of the harveft of the year 1757, I got three ears of common red Lammas wheat out of —— field, Auguft 26. I then cut off the ftalk clofe to the ear, which I weighed with the corn in it: I then weighed the grains when rubbed out of the ear, and cleared from the chaff: in the next place I compared the difference, and then counted the number of grains in each ear refpectively; and at the end of every year fet down the weight of a cubical inch of the produce of that harveft.

" But in order to give a clearer idea of my method of proceeding, I will fet down the weight, &c. of the corn which was gathered from the firft field, in columns, in the manner I entered it in a book kept for that purpofe, which will be fufficient to explain the whole without a multiplicity of figures.

Number of ears, when and where got.		Weight of the ear with the corn in it.	Weight of the grain when free from the chaff.	Difference.	No. of grains in each ear.
1757.		ʒ ℈ gr.	ʒ ℈ gr.	ʒ ℈ gr.	
Three ears got	1	0 1 5	0 0 19 5	0 0 5 5	28
in —— field,	2	0 1 2	0 0 17 5	0 0 4 5	27
Auguft 26.	3	0 1 7	0 1 1	0 0 6	36
Total.		1 0 14	0 2 18	0 0 16	91

"I proceeded in the fame method with each of the three ears taken out of fourteen other different fields, during the time of the fame harveft: then cafting up the fum total of each column, and dividing their products by the number of ears gathered that feafon, the quotient would give me the mean weight, &c. of an ear of that harveft, and its number of grains, &c. &c.

" I then made a cubical veffel containing exactly a fquare inch; and having mixed all the corn together, I filled the above veffel, and weighed its contents with the greateft accuracy; which weight I fet down, repeating the operation feven or eight times, having well mixed the little heap of corn together, after each trial, and then fet down the weight of each as before: and as there would fometimes be the difference of a grain or two more or lefs in each cubical inch, I divided the product of the whole by the number of times the experiment was made, and fet down the quotient as the mean weight of a cubical inch of corn for that year, which in 1757 I found to be 3 dr. 12.3 gr. I have perfevered in this method every year fince: but to avoid troubling you with the particulars of each, I will give you at one view the mean weight, &c. the number of grains in an ear, and the weight of a cubical inch for each of thefe laft feven years paft, and after that the medium of all taken together.

" I made ufe of apothecaries weights upon account of the fmaller fubdivifions of the ounce into drachms, fcruples, and grains, which I have afterwards, in reckoning up the weight of the bufhel, reduced to troy, and averdupois. But we will now give the refult of the feven years experiments in the following columns.

A. D.	Mean weight of each ear with the corn in it.	Mean wt. of the grains alone.	Difference.	Mean No. of grains.	Mean weight of a cubical inch.
	ʒ ℈ gr.	ʒ ℈ gr.	ʒ ℈ gr.		ʒ ℈ gr.
1757	0 1 10 5	0 1 5	0 0 5 5	38	3 0 12 3
1758	0 1 5	0 1 0 5	0 0 4 5	30 4	3 0 13 3
1759	0 1 8 2	0 1 2 4	0 0 5 [illegible]	37 6	3 0 14 5
1760	0 1 14	0 1 4 4	0 0 9 6	36 8	3 1 4 3
1761	0 1 9 5	0 1 4 5	0 0 5	36 6	3 1 4 3
1762	0 1 17 4	0 1 8 3	0 0 9 1	36 5	3 0 16 5
1763	0 1 10 1	0 1 3 3	0 0 6 8	35 5	3 0 17
Total.	3 1 14 7	2 2 8 4	0 2 6 [illegible]	251 4	23 0 2 [illegible]
Mean wt.	0 1 10 67	0 1 4 05	0 0 6 62	35 9	3 0 17 457

The total divided by feven gives the mean weight, &c. &c. of the whole together, as in the preceding line.

" The firft of the above columns (the date of the year not being reckoned) fhews us, at one view, what we may expect a fingle ear of Lammas wheat, feparated from the ftalk, to weigh upon an average; and the fecond what its produce in grain fhould weigh when feparated from the chaff: the next divifion gives the difference, being the weight of the ear and chaff alone without the grain; the fourth, the number of grains in each ear; and the laft, the weight of a cubical inch; which latter we fhall further confider, and fee what will be the mean weight of a bufhel, omitting the odd grains and decimal parts, as immaterial in fo large a meafure.

" As the ftandard Winchefter bufhel contains 2150.4 cubical inches, if the above weight of one, viz. 3 ʒ 17.457 gr. be multiplied by that fum, the product will be 73 lb. 8 oz. 12 dwt. troy. But this ftandard bufhel is in fact too fmall, the real contents of a bufhel dry meafure being 2178 cubical inches, which, according to that calculation, will give 74 lb. 7 oz. 19 dwt. which fums reduced to averdupois weight will ftand as follows.

$$\text{Troy}\left\{\begin{matrix} \text{lb. oz. dwt.} \\ 73\ \ 8\ \ 12 \\ 74\ \ 7\ \ 19 \end{matrix}\right\} \text{equal to} \left\{\begin{matrix} \text{lb. oz. dr.} \\ 60\ \ 10\ \ 8\ 6 \\ 61\ \ 6\ \ 15\ 9 \end{matrix}\right\} \text{averdupois.}$$

" But it will be proper to take notice that none of this corn was weighed till thoroughly dry, and feldom till the harveft after it was got, and fometimes later; therefore there muft be fome allowance made for the lofs of weight by keeping; which I found upon trial to be about four grains yearly in a cubical inch, and confiderably more the firft year, efpecially if the corn happened to be got in a wet harveft: therefore I think we may fairly eftimate the mean weight of a bufhel of wheat, containing 2178 inches, to be about 62 lb. averdupoife weight.

" I know that a bufhel of good wheat is, by the generality of writers upon agriculture, calculated at about 64 lb.; but our prefent enquiry is not whether it is good or bad, light or heavy of its kind; but what is the medium betwixt the two extremes, in order the better to judge of its qualities, according as it falls fhort of, or exceeds, that determined weight.

" The fields out of which the corn was gathered for the above experiments, are moftly fituated within a circle of ten or twelve miles round the town of Warwick, and fome of them in Northamptonfhire; and in foils of different kinds, and fuch as have been productive of good, bad, and indifferent crops.

 " With

" With regard to the obfervations, which I now offer to the public, they may be affured that they have been made with the greateft accuracy, and, barring any errors in the calculations, without the leaft deviation from the truth.

" My method of gathering the ears of corn was, to crop them ftanding during the time of harveft, always endeavouring, as near as I could guefs, to take fuch as were of a middling growth, avoiding the fulleft ears, as well as thofe which were fhrivelled, or ftinted. I therefore generally got them from about the middle fpace between the ridge and the furrow; I then carefully wrapt up the produce of each field in feparate papers, to prevent the corn from fhedding, or intermixing.

" The column which fhews the difference between the weight of the ear with the corn in it, and that of the grains alone, is meant only as relative to the ear itfelf, without the ftalk added to it, which latter was always feparated from it. But I have fince made fome few experiments with regard to the proportional weight between the whole ftalk and ear, and its produce in grain; and I found the former to be to the latter as about fixty-feven to feventy-two. But I cannot depend fo much upon the juftnefs of this calculation, as of the others, it being only tried upon the produce of one harveft.

" It muft be obferved that the weight of corn will vary more or lefs by keeping, according to the nature of the grain itfelf, the feafons that it has had for its growth and maturity, and the drynefs or moifture of it when reaped: for notwithftanding, it was before obferved, that there may be an annual lofs of about four grains in every cubical inch upon an average, yet it may fo happen that the weight of it may even be encreafed by keeping, as was really the cafe with regard to the corn which was got in the harveft of the year 1762, after an exceffive dry fummer; for I found, upon weighing a cubical inch of the fame corn, a year after the firft trial, that it had actually encreafed in weight 2.6 grains, which I can by no means account for, but upon a fuppofition that the corn contained in the ear, having been fo thoroughly dried, whilft ftanding, by the preceding heats and great drought, there was no room for any further evaporation of aqueous particles; but that, on the contrary, being laid up in this extreme ftate of drynefs, it muft even imbibe moifture afterwards, from the coolnefs of the place where it was repofited; by which means the grain would become more plump than when frefh gathered, and would confequently encreafe in weight. From hence the reafon is very obvious, why corn that is thoroughly ripe, and well ended, will undergo a much lefs change by keeping, than that which has been plumpt up by preceding rains, though perhaps it may look better to the eye than the other. But I think it may be laid down as a rule, that the more the external coat of the grain is extended by redundant moifture from within, the more will it appear fhrivelled and wrinkled, whenever that moifture is evaporated, which it muft lofe upon being kept for any confiderable time in a dry place: therefore it will be moft to the advantage of the owner to have fuch corn fpent as foon as it is fufficiently dry for common ufe, and not to hoard it too long in the granary, as the heap from the above-mentioned caufe will be daily decreafing.

" If further experiments of this kind were to be tried in other parts of this kingdom, and even in different climates; and if the refult of each obfervation was to be compared with the others, we might probably come ftill nearer to the medium which we have been aiming at; and the fame trials might be made with any other fort of grain." *Mufeum Rufticum, vol.* II. *p.* 175.

" The experiments made by the above ingenious gentleman are very accurate, though, in my opinion, much too fmall to determine matters of fuch importance: but he has, I think, fallen into a miftake that I alfo did in trying fome experiments upon wheat, viz. in fuppofing that a middling ear is a ftandard for computing the crop. This, indeed, would be the right rule, provided there was a regular gradation in the ears above and below the middle fize: but, in fact, it is otherwife; there are generally more fmall ears than large ones, and yet the corn in the large ears may weigh moft.

" To explain this, let us fuppofe a perfon going to choofe fome middling ears as they ftand in the field: he muft do this either gueffing by his eye, or by meafuring fome of the different fizes, and taking thofe of the middle fize as near as he can. The fizes can only be determined by their length and fullnefs: and if, for example, the longeft are five inches, and the fhorteft one, the medium is three inches. Now, though thofe of three inches are undoubtedly the middle fize, yet, unlefs the weight and meafure of the corn in the ears below three inches are equal to that of the ears above that fize, the calculation of the crop from the three-inch ears will be wrong. This will be feen in the following tables.

" I once took an account of great part of a fheaf of red Lammas-wheat; but having miflaid my notes of it, I fhall at prefent take notice chiefly of an experiment made upon white Lammas wheat, of the crop of 1762. The ears and ftraw of this crop were in general very fhort; but the corn was remarkably fine, full, and heavy. The wheat of this experiment was raifed upon clover lay, and the crop about twenty bufhels upon an acre. A nine-gallon bufhel of this wheat weighed above feventy pounds averdupoife, which is ufually reckoned the full weight of good wheat, though fome will weigh more, as the beft generally did that year.

" In February, 1763, I took fome of this corn out of a middling fheaf, and, as near as I could, of the middle-fized corn: but it was taken out all together, and, without feparating of it. I forted what was thus taken out, into four parcels, nearly according to the length of the ftraw, in order to difcover the proportion between the ears and ftraw of different lengths; but there feems to be little certainty in this.

" Thefe four parcels were weighed feparately, ears and ftraw together; then the ears by themfelves; and, laft of all, the corn when feparated from the chaff.

" I weighed twenty of the firft parcel by themfelves, that had the longeft ftraw, and longeft fulleft ears; and afterwards weighed them fingly, taking the weight and meafure of each, as in the table.

" Being defirous to know the weight and produce of the ears of different lengths, I forted each parcel according to the length of the ears, differing one from another about half an inch; and I weighed thefe fubdivifions feparately, noting the length of the ears, and the number of chefts and grains in each. The length of the ears was meafured from the bottom of the loweft cheft that had any corn in it, to the top of the ear. The longeft ear was three inches and a half, but there being only one of that length, it is included among thofe of three inches and a quarter. The twenty ears firft weighed are included in the fixty-three large ears in this laft weighing.

" Several ears have fome very fmall grains in them: thefe are fet down in the table, but not reckoned in the weight, becaufe I fuppofed them not marketable, and that they would go to the tailing, or off-fall corn. Of thefe fmall grains two thoufand one hundred and eighty-feven weighed an ounce averdupoife. The reft were weighed by troy weight, as below.

The weight of the four parcels.

" In the first of the following tables are inserted the assortments of the four parcels, by the length of the ears, with the number of chests and grains in each, and the separate weight of the ears, grain, and chaff. I must observe, that by accident I missed taking the distinct weight of the two hundred and fifty smallest ears: they are set down in the table as I computed tham, in proportion to the third, or preceding parcel, which may differ a little from the real weight; but this cannot be much, for the weight of the whole parcel is right.

" In the second table, the length, weight, &c. of the twenty largest ears, are set down in the first line: in the second line are the sixty-three large ears, including these twenty: and the third line contains the two hundred and eighty-eight smallest ears. They are set thus together to give the more easy comparative view of them. The next three lines of this table shew the weight, &c. of all the middle-sized ears, and of all those above and below the middle size, brought thus together also by way of comparison. To these I have added, in the following columns, a calculation of the number of chests in each assortment of ears, and the mean number of grains in each chest; also, the number of grains, and weight of a mean ear, of each assortment.

" The last table shews the total weight of the corn, chaff, and straw, upon an acre, agreeable to this experiment, reckoning the crop at twenty bushels of nine gallons, or seventy pounds, averdupoise, per bushel.

" The very small grains are not reckoned here, for the above reasons; and that the waste in reaping, carrying, threshing, and some left in the straw, is more than they amount to. But by adding them, and allowing for about seven or eight inches long of stubble, the total weight of the crop may be nearly estimated.

A table of the length, weight, &c. of one thousand two hundred and fifty ears, sorted according to their length.

" Small experiments are not so satisfactory as large ones; and I could wish this had been more extensive, but I had no thoughts of offering it to the public view till I read your correspondent's letter, who has, I apprehend, gone upon a wrong rule in computing a crop, and has also chosen the mean ears too large: for, though the ears of red Lammas wheat are usually longer than the white, it cannot be supposed that, upon an average, they are above double, both in weight and number of grains, as we find those were to the mean ears of this experiment. Neither is it at all probable, that the mean ears of the common crops in any part of England, and in the same year, should be heavier, and contain more grains in them, than the very largest ears of this experiment.

" The ears of this wheat being from three and a quarter to three quarters of an inch in length, the medium is two inches. I have ranged all these together in the second table. They are a fair medium in regard to length; and they are so also as to fullness, because they are all included: but, as appears in the table, they are not so in

respect

respect to the weight of the grain, which is the rule for the medium of the crop; for the small ears are more than double the number of the large ones, and yet the large ears are the heaviest. If, in order to make the number of ears equal, we choose the mean ears shorter than two inches, the inequality of weight will be greater than before; and if we take our medium higher than two inches, the weight may be made equal, but this will encrease the disproportion in the number; and hence I think it is evident, that we cannot fix upon any size of ears that will give us a just medium of the crop. The same will happen in other crops, for they all vary one from another in the size and number of ears: and, as we cannot be certain of their real proportion as they stand in the field, it is impracticable to calculate a crop from those of any size.

"The calculation of a crop from a mean ear is made by multiplying the weight of grain in that ear by the number of ears upon an acre. A mean ear of this experiment weighed, as in the table, 10.232 grains troy, and the crop was about twenty bushels upon an acre. Your correspondent reckons the weight of a mean ear at 24.05 grains troy, upon an average of seven years; so that, reckoning the same number of ears upon an acre as in this experiment, his crops will amount annually to forty-seven bushels per acre, of seventy pounds, averdupoise, per bushel. These are such crops as, I suppose, no considerable extent of contiguous lands in England produce annually; and are, doubtless, more than double the common crops upon an average.

"The disproportion in the number of small and large ears is very remarkable, and also their disproportion in size: for, if we calculate from the twenty largest, we shall find that forty-three of them weighed as much as all the two hundred and eighty-eight small ones, viz. one large ear produced as much corn as seven small ones, and the grain in them also larger, and consequently more flour in them: for one hundred of the large corns weighed seventy-eight grains troy, and one hundred of the small but sixty grains; so that four grains of the large ears were heavier than five of the small. This great difference is not from any defect in the rudiments of these small ears, but is occasioned principally from bad culture, and a defective nourishment; because we see that the plants raised from the same seed will have larger or smaller ears, according as they are cultivated. It might, however, be useful to know at what period of their growth those small ears are stinted, and whether they are produced from the original plant, or from the tillers. I am not furnished with experiments to determine these points, but recommend them to the enquiry of your readers.

"It is certain that the ears of wheat, in general, do not arrive to the size that they are naturally capable of: and if it was known at what period they are formed, the stinting of them might, in some degree, be prevented, by a dressing, or other culture, at that period. That there is some such period in nature, may appear from other circumstances in the growth of this plant. There is a particular season for its tillering, or spreading; another for its upright growth; and one for its blossoming and forming the seed; and probably one also for the ear being formed: and the growth of it, in respect to each of these, may be promoted by culture, or retarded by a defect of nourishment, at these periods.

"When the season of tillering is past, no culture will make this plant throw out more branches; and after the ear is shot out, it is then impracticable to make it larger, viz. to encrease the number of chests. Again, when it has blossomed, no art will cause the stem to rise higher. And, last of all, after the time of blossoming, there is no adding of one grain more than is already formed in the ear; though, in all these cases, an addition, or improvement, may be made by culture, if applied at the proper time.

"It is therefore of importance to know the periods of growth of the different parts of the plant; and that if we happen to miss assisting of it in one, we may improve it in another. If the season is lost to encrease the number of tillers, we may enlarge the ears; or, if that is also omitted, we may encrease the number of grains in the ears, and make them larger and fuller of flour.

"To shew this more plainly, with respect to the grain, let us a little consider the structure of an ear of wheat. The grain is placed in a cell, consisting of two valves, or leaves; and there is one leaf extraordinary on each outside of the chests, which seems intended as a fence, or security, against accidents to the outward grains. The chests about the middle of the ear are the largest, and usually consist of four, five, and sometimes six or seven cells: and the number of cells decreases towards the top and bottom of the ear. If the ear is examined when in blossom, we may see what number of grains each chest is formed to produce: or this may be seen afterwards by the number of double valves, which are properly the chaff; for these remain, though the grains have proved abortive; and therefore, by counting the leaves of chaff, allowing two to each grain, and two extraordinary to each chest, we shall find what number of grains each chest might have produced.

"The outward grains of the chests are commonly the largest, and smaller towards the middle, and often stinted grains, or none at all, in the middle cells; and this, notwithstanding most of these had blossoms in them, and the grains had made some progress, or begun forming. They are later than the outside grains, as if last impregnated.

The number of these deficient, or missing grains, is greater than might be supposed without examining them. In a favourable season most of the cells have grains in them; and, if examined at the time of blossoming, the grains may be seen in different degrees of maturity, many of them with the naked eye, and others with a good glass; but though they appear then in general to be fresh, and in a growing state, a considerable number of them is afterwards stinted, or die away entirely. In an ear of red Lammas wheat, of six inches long, twenty-five chests, and two hundred and eighty-six leaves of chaff, I have counted seventy-four grains some time after blossoming; by which it appears, that this ear might have produced one hundred and eighteen grains; and yet at harvest I have not commonly found above sixty grains in an ear of that length. I have likewise this season counted fifty-four grains in an ear of white Lammas wheat, of three inches and a quarter long, nineteen chests, and one hundred and seventy-four leaves of chaff; so that this ear might have yielded sixty-eight grains: but we see in the above tables, that the fullest ear, of the same sort of wheat, and the same length, yielded only forty-one grains; and three of the same length yielded but thirty-eight grains and one third each, upon an average.

"The tillage and dressing of land for wheat is done, for the most part, before the wheat is sown, and the benefit of these gradually decrease; whereas the wheat requires a gradual encrease of nourishment, both in order to form large ears, and afterwards to fill them with large grain. And hence appears the great defect of the common husbandry, and points out the advantages of top-dressing wheat in the spring with soot, or other light manure, which bring the plants a fresh supply of nourishment when they want it most; and hoeing, when they can be performed at the proper times, particularly the deep, or horse-hoeing, has the same effect of producing large ears; and for filling them, the horse-hoeing is the most effectual, as that can be performed at the critical time, and when the plants are large.

"It has been commonly supposed, by those who practise the new husbandry, that the most important hoeing, for the purpose of filling the ears with good grain, is soon after the wheat has blossomed: but this, I believe, is a mistake, and that it should be performed immediately before the wheat blows; for before that is over, the grain is considerably advanced. I have found no less than seventy-seven grains in an ear of red Lammas wheat, of four inches and three quarters long, and at the same time a considerable part of the blossoms still remaining on the outside of the ear.

"This is above one third more than usually comes to maturity in an ear of that length; so that it seems very probable the ears would produce near one third more corn than they commonly do, were they to be assisted at that time with sufficient nourishment. But this would come too late after the blossoming is over; for by that time, some

ſome of the weak grains die, and others are ſtinted, ſo as not to be recovered again by any future hoeings. A check at this critical time ſeems to have the ſame effect as it has upon a grain of corn, or other ſeed, after it has begun to vegetate: if that is put a ſtop to, it never recovers.

"From the great number of ſmall ears in a crop, and the deficient grains in all the ears, we may plainly ſee the advantage of good culture, and of taking the proper ſeaſons to apply it. The new huſbandry is, in this reſpect, much to be preferred; and alſo becauſe much fewer plants will produce an equal crop; in which there are ſeveral advantages, beſides ſaving above half the ſeed. This method of culture is, indeed, ſo much ſuperior to the common huſbandry, not only in raiſing wheat, but plants of almoſt every kind, that is to be wiſhed it was more promoted.

"I am ſenſible that ſeveral gentlemen have objections to this huſbandry, ariſing partly from a miſinformation of Mr. Tull's practice and ſucceſs, and partly from the difficulty they apprehend in overcoming the prejudices of the farmers to any new methods.

"That they are very tenacious of old cuſtoms, is readily admitted, nor are they to be too much blamed on that account: but that they cannot be prevailed with to alter them, upon rational evidence, and proper encouragement, is, it is apprehended, carrying the argument too far, as this tends to diſcourage all attempts of improvement.

"One of the reaſons aſſigned, why the farmers cannot be brought to practiſe the new huſbandry, is the difficulty of managing a drill-plough for ſowing corn, which is admitted, though that is not ſo great as ſome have ſuppoſed; for I have ſeen a huſbandman learn to manage ſuch an inſtrument, who, after one day's practice, could ſow with it four or five acres a day, with the proper quantity of ſeed, at a leſs expence than common ſowing and harrowing.

"Some have objected farther, that the farmers cannot practiſe this huſbandry, becauſe they are ignorant of its principles: but theſe principles are not many, nor hard to be underſtood, ſo far, at leaſt, as relates to practice; and, in fact, the practice of the new huſbandry is eaſier than the old, becauſe it is founded upon clear principles, which often is not the caſe in the old huſbandry.

"It ſeems that ſeveral gentlemen are not for introducing this new method, becauſe they are not convinced that it is, upon the whole, better than the old. If we may credit thoſe who have gone furtheſt in the practice of the new huſbandry, thoſe gentlemen abroad in particular, who have publiſhed their experiments, there ſeems to be no doubt of its ſuperiority: but as it is a matter of great importance, that this fact ſhould be fully eſtabliſhed to the ſatisfaction of all gentlemen, from whoſe influence and example the moſt valuable improvements are to be expected, the trial is not difficult, nor very expenſive: a ſmall farm, with ſome variety of ſoils in it, cultivated in the ſeveral methods, by way of compariſon, and exact accounts kept of the expence and produce of each, would determine this point without any reaſonable doubt.

"In matters of this ſort, ſpeculations and reaſonings are not to be relied on without experiments; and the larger they are, they will be the more convincing. Whether ſomething, like what is here propoſed, might not have the deſired effect, and likewiſe be a means of making uſeful diſcoveries in vegetation, and the culture of plants, is ſubmitted to the conſideration of thoſe who have at heart the improvement of agriculture.

"A more extenſive plan is neceſſary for introducing new methods into common practice, and which might comprehend the farmers, and alſo the huſbandmen, who execute and excel in the performance. It is recommended to your readers to conſider and propoſe what they think the moſt probable means for attaining theſe deſirable ends." *Muſeum Ruſticum, vol.* III. *pag.* 38.

"It is certain, ſays another ingenious huſbandman, that many ſtrange reports were raiſed of Mr. Tull, and his huſbandry, by prejudiced perſons; and his book being printed for the author, ſome bookſellers were much offended, and employed ſeveral hands to write againſt him, which they did in a moſt ſcurrilous manner, aſſerting many things that were falſe, and miſrepreſenting others. Some of theſe he takes notice of himſelf, in the additional parts of his work. I ſhall mention only one inſtance how ready people were to give credit to ſuch falſe reports. "Laſt ſummer," ſays he, "the vulgar in general believed, in a country but twelve miles diſtant from me, that I always carried my dung and threw it into a river: now there is no river nearer to the barton where my dung is made, than is the fartheſt part of my land; ſo that the expence of loſing my dung would be greater than ſpreading it on any part of my farm. Beſides, I live in a country where farmers buy dung at a good price; but it is known that I neither ſell nor waſte any dung. Againſt ſuch lying tongues there is no defence."

"But a principal cauſe, that the reports of his bad ſucceſs in his wheat crops have gained ſo much credit, I believe, is, that the additions to his Eſſay are out of print, and not generally known; and it is chiefly with a view to inform your readers of them that I write this letter.

"Mr. Tull began his ſcheme of ſucceſſive wheat crops with four rows. Afterwards he found that three rows were better, and was in that practice, of drilling three rows upon a ridge, when he publiſhed his Eſſay. Upon further experience he found, that two rows produced as good crops as three or four, and were more eaſily managed. This he recommends as his laſt and beſt method; and altered his drill-plough to his practice of planting only two rows upon a ridge, of which he gives a cut and deſcription in his Addenda and Concluſion. By this alteration, his drill is much leſs complicated, and leſs difficult to manage, than that for planting three rows, deſcribed in his Eſſay.

"The gentlemen abroad, who are now promoting the new huſbandry, have gone into the practice of planting three rows upon every ridge, ſuppoſing that to be the beſt method; and the drill-ploughs invented by M. Du Hamel, and M. De Chateauvieux, are conſtructed to ſow three rows.

"From the practice of the gentlemen abroad, and other inſtances that might be given at home, it is evident, that they have not ſeen the additions that Mr. Tull made to his Eſſay, in which, beſides his different method of drilling, there are ſeveral very material improvements in the manner of hoeing and cultivating wheat, and other crops; and from theſe laſt parts of his work may be alſo ſeen, that the reports of his bad ſucceſs, in repeated wheat crops, are without any juſt foundation.

"In order to ſhew this more clearly, it may be proper to premiſe a ſhort chronology of the progreſs of his huſbandry, collected from his own account of it; in which it is to be obſerved, that as the year, at that time, was by ſome reckoned to commence the firſt of January, and by others the twenty-fifth of March, and the crops at other periods, it occaſions an uncertainty of ſometimes a year in this account.

Mr. Tull began his horſe-hoeing huſbandry about the year —— ——	1723
his ſucceſſive horſe-hoed wheat crops	1726
He publiſhed his Specimen —— ——	1731
his Eſſay —— ——	1733
his Supplement to the Eſſay ——	1735
his Addenda ——	1737 or 1738
His Concluſion is dated March 31, ——	1739

(All theſe are printed in ſmall folio)

He died about the year 1741.

"As to his practice of raiſing ſucceſſive crops of wheat, he made the experiment firſt upon part of a field, which had not been dunged for ſome time, and upon this part he continued to raiſe wheat for twelve years, without the aſſiſtance of any manure. In the preface to his Eſſay, he ſays, "The particular ſcheme of raiſing annual crops of wheat, without dung or fallow, is as yet only upon probation; but, by the ſix crops I have had in that manner, I ſee nothing againſt their being continued." In the Supplement, page 249, he tells us, "There is now the eleventh crop of wheat on the ſame field, (except that in the ninth year, by accident, of having contracted to let my farm, it was drilled with white oats) and I do not yet ſee any reaſon againſt its being continued for wheat annually, as long as it is kept in this culture." In the Addenda, page 261, "The field which last year had the eleventh crop of wheat," (as in page 249) "has now the twelfth on it, very likely to be a good one." And in the Conclusion, he says, that the twelfth crop of wheat, upon this field, "was the best, I believe, that ever grew on it." "It has now the thirteenth crop, likely to be very good, though the land was not ploughed crossways;" which he mentions it was the year before, in order to alter the size of the ridges.

"I have here collected what he says of this field in particular, as it was his field of experiment, upon which he had raised the most crops of wheat, without any manure. Let us next see what crops he had upon his lands in general.

"He begins his Addenda with acquainting the reader, that he was desired to take an exact account of the crop of an acre of horse-hoed wheat, part of a field of twenty-five acres, in order to see the difference between that and the crop of a small piece of ground, drilled upon the level, and hand-hoed. This acre being measured, and the crop reaped, and threshed by itself, yielded twenty-nine bushels and three pecks of clean wheat, nine-gallon measure. But he observes that great waste was made by the reapers of this acre, and some damage was done to the corn by cattle; for which allowance being made, he reckons the real produce of this acre to have been thirty-two bushels, or four quarters, of wheat.

"He then proceeds to give an account of the crops of wheat upon his other fields, which, including the above-mentioned field, were in all one hundred and six acres. The corn was not threshed when he wrote this; but it appears, by his account of the crop, as I have computed it, that these one hundred and six acres produced, upon an average, nearly twenty bushels of wheat per acre.

"If the quality of this land is considered, none of it rich, and the greater part light, and of a thin staple, this cannot be called a bad crop. But there was another very important circumstance, which ought to be considered: Mr. Tull was now advanced in years, and in a very bad state of health; was frequently confined to his room, and sometimes to his bed; insomuch that, as he tells us, he had not seen some of his crops from the time they were sown till the spring following. And in his Supplement he says, page 225, "My agriculture having been carried on by common day-labourers, without any body to inspect them, (except when my diseases suffered me to attend them, which, for several years last past, has been very seldom) cannot be expected to be all well managed; for though they can do it well when they please, yet their will being above controul, I must be content with their doing some tolerably well every year."

The dust of the master's feet is a kind of manure so necessary in every scheme of husbandry, that no person of experience in such matters, who reflects upon these circumstances, would have reason to be much surprised, if Mr. Tull's crops had really failed as much as has been supposed; and if we also take into the account, that these day-labourers whom he employed, and who had the management of his agriculture at the critical seasons, were then generally, as such men still are, prejudiced against the new husbandry, I think his success, notwithstanding these disadvantages, is a strong argument in favour of this husbandry.

"But let us proceed to what Mr. Tull says further of these successive wheat crops. In the Addenda, page 263, he tells us, "I have now six score acres of wheat, an hundred acres of which are on the stubble of the last years wheat crop.

"And in the Conclusion, page 273, "The crop of the six score acres of wheat, that was growing at the time of publishing my Addenda, was much greater than the crop the year before it, and would have produced more grain in proportion, if the heavens had been as propitious; but the heavy rains that fell when the first-planted was most in blossom, diminished the filling of the ear and its grain, yet not so much as of most sown wheat, especially of the early-sown, which generally escapes the best in this common calamity. The burn-beaked wheat, being always early sown, I am informed had next to no grain in it; and this is the most expensive sort of husbandry, the tenants pay such exorbitant fines for the liberty of ploughing this land."

Again, page 274, "The same six score acres that was wheat the last year, is planted with wheat now, and is all of it as strong and likely for a good crop as in any of the former years, though there is but about one acre of it dunged. The whole is the freest from weeds before hoeing that ever was seen, and the sown wheat in the neighbourhood the fullest of them."

"I can shew, at this instant, one of the experiments I have recommended, which, though it be on less than two perch of ground, must convince every man who sees it (and doth not renounce the evidence of his reason and senses) that pulveration by instruments can vastly exceed the benefit of common manure.

"It is to such experiments that I leave the progress of my horse-hoeing husbandry, assuring the public, that in all my practice, which is now thirteen years, I never have met with one instance that gives me the least suspicion of the truth of the principles I have advanced; and that, I believe, they have nothing to fear from enemies, but the false relation of facts, or fallacious arguments."

"Mr. Tull mentions here, that he intended this to be his last crop. He lived about two years afterwards. Whether he continued to occupy his farm, I am not certain; but if he did, and his crops were worse than the preceding years, that could not be justly attributed to any error in the principles, but to the other causes above mentioned. We see here that he appeals to an experience of thirteen years: nor can it be supposed, or admitted, that a person of Mr. Tull's understanding would go on from year to year to enlarge his plantations of wheat to the extent of one hundred and twenty acres, had he not been fully sensible of the advantage of so doing.

"The repetition of wheat crops upon the same land may, by many persons, be supposed rather a matter of curiosity than of any great use; a change of crops being the general custom, and supposed to be the most profitable: but this is not so clear as some imagine. The custom is founded upon the supposition that change of crops is necessary; which, though it may be true in the old husbandry, is not so in the new; and, without doubt, the change is often hurtful to the farmer; for, not to insist on the extraordinary labour necessary to prepare the land, and the loss of the season, if it cannot be got into proper order in time, or, which is as bad, sowing it, though not in proper tilth to receive the seed, the main point of all is, whether the profit of these several different crops is really more than hoed successive crops of wheat, or other corn commonly propagated? In answer to this, I believe it is not very difficult to shew, by a fair comparison of both, that the hoed crops are the most profitable, even including the clover and turneps in the old husbandry. Nor is a profitable change of the crop, or the advantage of obtaining sometimes three crops in two years, peculiar to the old husbandry; for the same may be had to greater advantage in the way of hoeing.

"There is another circumstance in the old husbandry very unfavourable to the farmer. As he is under a necessity of changing his crops, he cannot adapt them to the soil. Most farms have land in them of very different qualities, and these are not equally proper for the production of plants of every kind. The strong land, that is very fit for beans, wheat, and clover, is not equally so for peas, barley, and turneps. But the farmers commonly vary their crops according to the custom of the country, and the consequence is, that most of their lands are planted in their turn with crops not the most suitable to them; which is an inconveniency that may be avoided in the new husbandry.

"Having pointed out the additional parts of Mr. Tull's work, it is hoped that we shall soon have a new impression; but as it may possibly be some time before the last parts of his work are re-published, I shall, for the benefit of such of your readers as incline to practise the new husbandry, take notice of one or two important alterations in the horse-hoeing culture.

"In the Essay, Mr. Tull directs, that the hoe-plough should be brought as near as possible to the rows at first, and when the plants are young; but that the subsequent hoeings should be at some distance from the rows, lest the plough should tear off too many of the roots, and destroy the plants; also that the last hoeing should throw the earth of the intervals up to the plants, which he thought necessary for their better nourishment, when they were grown large. His last practice was different in both these respects.

"For in the Conclusion, page 272, he says, "At the second hoeing, the plough goes in the furrow of the first, making it deeper and nearer to the wheat: the third hoeing fills up this furrow; and then, at the fourth hoeing, the plough goes in the same place as the second, turning the mould into the intervals. It is remarkable, that though the furrows of the second and fourth hoeings be deep and near to the rows, seeming to deprive the wheat of the mould which should nourish it, whereby one would imagine, that these furrows, lying long open, should weaken or starve it; but it is just the contrary, for it grows the more vigorous: and it is the observation of my ploughmen, that they cannot, at these hoeings, go too near to the rows, unless the plough should tear out the plants.

"If I may presume to assign the cause of this surprising effect, it is in my opinion the following, viz. this open furrow has a double surface of earth, which, by the nitre of the contiguous atmosphere, is pulverized to a great degree of minuteness near the row. The roots that the plough cuts off on the perpendicular side of the furrow, send out new fibres to receive the pabulum from this new-made pasture; and also part of this superfine powder is continually falling down into the bottom of the furrow, and there gives a very quick growth to those roots that are next it, and a quick passage through it into the earth of the interval, where they take likewise the benefit of the other side of this pulverized furrow. When it is said that air kills roots, it must not be understood that it kills a plant, unless all, or almost all, its root is exposed to it, as it is not in this case. Some think there are roots that run horizontally below the plough into the interval; but of this I am not convinced.

"It is not often that we plough above four times, and then the furrow is turned towards the row at the third time only.

"Whether these furrows lying long open next the rows, in very hot dry climates, may be prejudicial, cannot be known but by trials.

"The practical hoer will find this method of going close to the rows of wheat, and other plants, of great service to him; not only in the vigour of his plants, but also in the more perfect tillage of his land, and a considerable saving in hand-hoeing, weeding, and manure.

"The other circumstance, of a large plant growing more vigorous, and the seed filling better, by ploughing the earth away from one side of it, is so singular, and opposite to the common practice of gardeners, that should it succeed generally, it may lead to something new in the theory of vegetation." *Museum Rusticum, vol.* III. *p.* 159.

A comparative calculation of expence and profit between the drill and the common husbandry, taken from Mr. Baker's report to the Dublin society of his experiments in agriculture, for the year 1765. *Published by order of the society.*

An estimate of the expence upon a plantation acre of wheat, in the common husbandry.

	l.	s.	d.
To the first plowing, commonly called breaking, for fallow, eight horses eight shillings; two plowmen one shilling and four-pence; two drivers one shilling	0	10	4
To the first harrowing, four horses four shillings; a driver six-pence	0	4	6
To the second plowing, commonly called gaurowing	0	10	4
To the second harrowing	0	4	6
Carried over	1	9	8
Brought over	1	9	8
To the third plowing, commonly called stretching	0	10	4
To sowing the seed, eight horses eight shillings; two plow-men one shilling and four-pence; two drivers one shilling; the seed-man eight-pence	0	11	0
To seed wheat, one barrel	1	0	0
To rent for the year of fallow	0	18	0
To ditto, the year the crop is growing	0	18	0
	5	7	0

In this account forty shillings are charged for forty horses, employed in the culture of one acre for wheat, in the common husbandry; a charge which ought to be considered by the farmer, for he actually buys and maintains his horses for this business.

The crop which follows wheat is generally oats; but sometimes peas are sown instead of oats; with some, the practice is to let the peas follow oats, in which case they fallow only every fourth year; but where land receives no other assistance than what arises from fallow, it is a bad practice not to fallow every third year. It is the general practice to plow but once for oats, and therefore it shall be stated so; but it is a much better practice to plow the wheat stubble once before winter, and again in the spring.

An estimate of expence upon an acre of oats.

	l.	s.	d.
To plowing once	0	10	4
To seed oats, 2 barrels	0	12	0
To harrowing 4 *s.* 6 *d.* seed-man 4 *d.*	0	4	10
To one year's rent	0	18	0
	2	5	2

These two crops consume three years; after which the farmer is to begin again, and to incur every article of expence stated in the above accounts, in order to obtain two crops more.

An estimate of expence upon a plantation acre of wheat in the drill husbandry, the first year

	d.	s.	d.
To plowing 4 times, to prepare the fallow [This is the same charge as in preparing for the common husbandry.]	2	1	4
To harrowing twice for ditto [This is the same also.]	0	9	0
To rent for the year of fallow [This charge is saved after the first year.]	0	18	0
To harrowing with the drill harrows [Four acres a day may be harrowed with one horse.]	0	0	6½
To sowing with the drill plow [From 3 to 5 acres may be sown in a day.]	0	1	1
To seed-wheat, generally 5 stone, but suppose 6	0	6	0
To the first, or winter hoeing [Two acres may be hoed in a day, two horses, plow-man and driver: the design of this hoeing is to leave the plants dry, and to meliorate the earth.]	0	1	7
To the spring hoeing with the cultivator [To deepen the soil, one horse, plow-man and driver.]	0	1	1
To the 3d hoeing, *i. e.* to return the meliorated earth to the corn [To make the corn tiller, *i. e.* to encrease its branches.]	0	1	7
To the fourth and final hoeing [To fill the grain and render it large.]	0	1	1
To rent, the year the corn is growing	0	18	0
	4	19	3½

N. B. Although the drill culture for the first year is very near as expensive as the common, yet, after taking the first crop, the expence and labour of fallow, and loss of time, is is not to be incurred again, as is unavoidable in the common husbandry.

An estimate of expence upon an acre of drilled wheat, after the first crop.

	l.	s.	d.
To plowing the land once - - - -	0	10	4
[One plowing is all that is necessary.]			
To harrowing with the drill harrow - -	0	0	6½
To sowing with the drill plow - -	0	1	1
To seed-wheat - - - -	0	6	0
[Be it remembered, 5 stone is enough.]			
	0	17	11½
To four times horse-hoeing, as before stated	0	5	4
To one year's rent - - -	0	18	0
	2	1	3½

Thus the land is sown again with wheat every year, and instead of 4 *l.* 9 *s.* which is the farmer's expence in the common husbandry, exclusive of one year's rent of the land: in the drill method it is no more than 17 *s.* 11½*d.* and the total expence, instead of 5 *l.* 7 *s.* is no more than 2 *l.* 1 *s.* 3½*d.* rent included; whereby there is a saving of 3 *l.* 5 *s.* 8½*d.* an acre.

Before the account of profit and loss upon these different methods of culture be stated, it will be necessary to take notice of an objection, which may perhaps be made to the above charge of plowing in the common husbandry. It is pretended, that three quarters of an acre may be plowed in a day, with one plow: but can it be done effectually? The land may, indeed, be scratched, but cannot really be plowed as it ought to be. The farmer ought to be cautioned against a trick too frequently practised in plowing. When a plow-man enters his plow, and passes across the field, he turns a sod about a foot broad; when he is to return, he enters his plow about four feet distant from the outside of the former furrow, and so turns another sod of the same breadth, which, when turned, just meets the former sod; thus four feet of the land appear to be plowed, whereas the fact is, that the two feet lying under the sods is not touched with the plow at all. This deception, added to the practice of just skimming the ground, enables hirelings to undertake plowing at 6 and 7 *s.* an acre. But if a plantation acre of land be well and effectually plowed, 10 *s.* 4 *d.* as charged above, will not appear too much; and it is, in fact, supported by the common course of business. When wheat is to be sown, it is the general custom to send a barrel of seed into the field with two plows, which is to sow an acre of land, and that is the usual day's work for two plows in the general course of business. Let us see then, what the expence will amount to. Eight cattle will be 8 *s.* two plow-men 1 *s.* 4 *d.* two drivers 1 *s.* and the seeds-man 8 *d.* which in all makes 11 *s.* and corresponds with the above charge.

Greater profit on the drilled acre, in fifteen years	24	4	9

Which amounts to 1 *l.* 12 *s.* 3¾*d.* *per annum*, for fifteen years on the acre, more than by the common husbandry.

In the drill husbandry the crops are stated at three barrels of wheat less upon an acre than in the common husbandry, that it may not be supposed to be over-rated; but in the common husbandry, the crops are rated at the highest; fourteen barrels of oats an acre, are also allowed in the common husbandry, which every farmer must admit to be a great allowance upon the general produce.

That the drill culture will produce six barrels an acre, is fully proved in Mr. Baker's report at large, which will be shortly

ſhortly publiſhed, where it will be ſhewn, that much more has been produced.

Doubtleſs, it will be obſerved, that in fifteen years fourteen wheat crops are obtained in the drill huſbandry; in the common huſbandry only five wheat and five oat crops; the five other years are not only loſt, but are an heavy expence to the farmer.

A farmer having forty acres of tillage, ſuppoſing him to direct his attention to bringing it to the drill culture, would make in fifteen years 969 *l.* 10 *s.* more than he can in the common huſbandry; which is ſuch an advantage, that the greater profit in the drilled acre in fifteen years will purchaſe the fee-ſimple of that in the common huſbandry, at twenty-ſeven years purchaſe, valuing the land at 18 *s.* an acre.

Thus it appears, that in every fifteen years the fee-ſimple of all the tillage lands of the kingdom, is loſt to the community by the common courſe of tillage.

In ſtating theſe accounts, no mention is made of fences, water cutting the land, weeding and reaping, as theſe articles of expence depend on a variety of circumſtances, but, in general, will be more on the common huſbandry than on the drill.

Though we, happily, in this kingdom, are not under the ſame neceſſity as ſome foreign countries, of building large edifices for public granaries, becauſe our harveſts are much leſs apt to fail us; yet as this work is, perhaps too preſumptuouſly, intended for general uſe, it is incumbent on me to ſpeak of thoſe effectual, though expenſive means of guarding againſt dearth, or even famine, as well as of the cheaper and eaſier methods, by which every farmer may be enabled to enjoy the advantage of preſerving a large quantity of corn in a ſmall ſpace, without danger of its heating and fermenting, of its being preyed upon by deſtructive animals and inſects, or of its being ſpoiled thro' the ignorance, or want of judgment, of inattentive ſervants.

Corn reaped in a dry year, and eſpecially that of the growth of a hot country, is well known to be the moſt perfect, and the fitteſt for keeping: as on the contrary, experience has proved that the ſofter and leſs ripened grains of wet years and rainy harveſts ſhould always be diſpoſed of for more immediate uſe, though their too great humidity, which would infallibly occaſion a putrefaction, if not remedied in time, may be exhaled, and they may then be preſerved a long while in very good condition, as will be ſhewn from repeated facts and proper experiments.

The ancient Romans imported annually vaſt quantities of corn from Egypt, a very hot and dry country, ſcarcely ever watered but by the periodical overflowings of the fruitful Nile; and they found this grain anſwer much better than any of their own growth, both for yielding plentiful crops, when ſown in Italy, and for keeping in their public granaries, where they frequently preſerved it many years, perfectly ſound. Pliny tells us, that, in his time, they kept corn a long while in ſubterranean caverns, made in a dry ſoil, and ſo cloſely ſtopped that not a breath of air could enter. They then covered the bottom with ſtraw, and laid upon that the corn in the ear. We have the concurrent teſtimony both of the ancients and moderns, that it will keep thus perfectly well for at leaſt ſix or ſeven years; and an accident, not long ago, diſcovered a parcel of corn thus preſerved at Amiens, where, though it had been laid up during a great number of years, it was found to be freſh and good, neither worm-eaten, rotten, nor mouldy. This was certainly owing to the moiſt air having been kept out, and with it the eggs of animals, and ſeeds of thoſe minute vegetables which we ſee in form of mouldineſs on ſuch corn as has been leſs carefully defended from their acceſs. In effect, experimental philoſophy has proved that the air is the great ſource of corruption; for even the moſt corruptible ſubſtances, ſuch as meal, butter, milk, and the like, have been preſerved freſh four months in the exhauſted receiver of an air pump.

There ſtill is, near Grand Cairo, a vaſt ſubterranean magazine of corn, defended with good walls, and called Joſeph's granaries. It is hardly to be ſuppoſed that they are quite ſo old as the days of that patriarch: but they abundantly prove the utility of ſuch places of ſtore, by the vaſt quantities of grain annually preſerved in them.

Many parts of Africa, the corn of which country, and particularly that about Algiers and Tunis, will keep much longer than the growth of any other place, abound with granaries of this kind. They are deep pits made in the ſolid rock, but juſt wide enough at their top for a man to go down into them, but they grow larger immediately after, and are uſually ſquares of from thirty to forty feet in diameter. In theſe, the great men of the country preſerve their corn. They firſt cover the floor with ſtraw, then ſpread upon that a layer of corn, upon this another, but thin, bed of ſtraw, then another couch of corn, and ſo on, till the whole cavity is filled; obſerving all the while, as the heap riſes, to place ſtraw between the corn and the ſides of the walls. When this is finiſhed, they cover the mouth of the entrance with a ſort of hurdle, over which they lay about two feet thick of ſand, and over this they raiſe a ridge of earth, well beaten together, in order to throw off the rain both ways, that none may ſettle on the place and ſoak into the magazine. The corn thus ſtored up always keeps three, four, or more years very ſound; and not unfrequently the proprietor being taken off by the cruel deſpotiſm of the Eaſtern governments, the magazine is forgotten, ſome accident diſcovers it many years afterwards, and the corn is almoſt always found perfectly good in it. All the care they take, by way of preparing the grain, is to expoſe it two or three days to the heat of the ſun, to dry it thoroughly before they carry it into the magazine.

In the dutchy of Lithuania, and in the Ukraine, the people always preſerve their corn in nearly the ſame manner, in wells or pits made in dry places: but great care muſt be taken there in the opening of theſe ſtores; for people who have deſcended into them, before they had had ſufficient communication with the freſh air, have been killed by the damps.

The Ruſſians too preſerve their corn under ground, in deep pits of almoſt the figure of a ſugar loaf, wide below, and narrow at top. The ſides are well plaſtered, and the top is covered with ſtones. They are very careful to dry their corn well, generally by means of ovens, kilns, or ſtoves, for their ſummer is too ſhort to effect it ſufficiently, before it is laid into theſe repoſitories.

The ſame thing is practiſed with unvaried ſucceſs in the iſland of Malta: and alſo in Gaſcony, the Vivarais, and other ſouthern parts of France, the corn of which is remarkable for keeping many years longer than that of any other province in the ſame kingdom. M. Duhamel tried this method in the Gatinois: but his corn was ſoon ſpoiled there by its humidity when laid up; that country being ſubject to wet and moiſture, and his grain, in this trial, not having been previouſly dried in an oven or ſtove.

Upon the whole, it is evident from theſe, and from many more inſtances, which might be alledged, of the practice of other countries, that ſubterraneous granaries properly made in a thoroughly dry ſoil, are the beſt of all repoſitories for the keeping of corn: but, at the ſame time, experience ſhews that this method will not ſucceed in our climate, the ſun here not having power to exhale the moiſture from the corn, ſufficiently to prevent its fermenting when laid in a large heap. I muſt likewiſe add, that when one of theſe ſubterranean magazines is opened and expoſed to the air, it muſt be emptied immediately, and the corn taken out of it muſt be thoroughly ſifted and ſcreened, or it will ſoon corrupt. Some think it more nouriſhing, when it has been well preſerved, than that which has been kept in granaries above ground.

The marquis of Santa Cruz, author of many excellent remarks on the political and military ſtate of different nations, obſerves, that the corn of Galicia and the Aſturias will hardly keep from one year to another, becauſe of the humidity it contains, which rots and decays it: but that the corn brought thither from Caſtile will keep good many years. This laſt is therefore the only kind that the Spaniards ever venture to lay up in their public granaries: and the ſole difference, in M. Des Landes's opinion, between it and their other ſorts, is, that it grows in a country where there is leſs rain in ſummer. They might indeed, if their religion and policy did not forbid their having intercourſe with the Moors of Barbary, once their conquerors, eaſily import from Africa plenty of ſome of the beſt corn that the world affords, perfectly ripened, thoroughly dried, and, in all reſpects, fit for keeping many years.

The great objection to public granaries, even in countries where the uncertainty of the climate, the indolence of the people, the ill-judged form of government, and various other cauſes frequently combine to render them highly neceſſary, is the expence attending ſuch eſtabliſhments; generally ſo great, that none but a monarch, or a ſtate, can properly undertake them: and they, moſt certainly, cannot do any thing more laudable, more truly noble, in countries whoſe misfortune it is to be expoſed to the dreadful calamities of want and famine, or to depend upon the precarious aſſiſtance of their neighbours.

Though ſubterranean repoſitories for the keeping of corn are preferable to all others in countries proper for them; yet, even the common granaries may, with due care, and perhaps ſome few alterations, be rendered much more ſerviceable than they generally are. The principal cautions neceſſary to this purpoſe are, 1. To guard againſt the too great humidity which always prevails in places where there are many doors and windows: 2. To prevent a too free acceſs of the external air, becauſe this brings in with it the eggs of a vaſt number of different inſects, which prey upon and deſtroy the corn: and 3. To take care that the corn be thoroughly dry, and as clean as poſſible, when it is laid up. Theſe are the three general rules to prevent its corrupting.

The chief cautions to be obſerved in the erecting of granaries are, to make them ſufficiently ſtrong, and to expoſe them to the moſt drying winds. Sir Henry Wotton, and Mr. Worlidge agree particularly in theſe; both judiciouſly adviſing a northern aſpect for theſe buildings, becauſe that quarter is cooleſt and moſt temperate; and the latter rightly obſerving, in general, that the beſt granaries are thoſe built of brick, with quarters of timber wrought in the inſide, whereto to nail well joined boards ſo cloſely to the wall, that there be no room for vermin to ſhelter themſelves. Floors of plaſter are reckoned the beſt, becauſe they are cool in ſummer, and if well made, do not retain dampneſs in the winter. There may be ſeveral ſtories one above the other; for the ſhallower the corn lieth, the better it will keep, and the more eaſily it is turned. Some have a ſmall hole in the floor of their upper granary, thro' which the corn deſcends into the lower one, like the ſand of an hour-glaſs; and after it is all come down into the loweſt granary, it is conveyed back into the upper one; ſo that it is kept in continual motion, which is a great means of preſerving corn.

The granary in the city of Schönbank, in the vale of Parinburg upon the river Elbe, which is a ſtore-houſe for the wheat of which the mum is made at Brunſwick, is built nearly in this manner. It is three hundred feet long, eighteen feet wide within, has ſeven ſtories, each of which is ſeven feet high, and large windows all around, to open and ſhut cloſe according as the wind ſits. By this means, the droſs and duſt are carried off as the corn is turned; for which a weſt wind is always preferred, becauſe it is the drieſt. At each end of this granary, and in the middle, are ſtoves for fire in damp weather, and at the going away of great froſts and ſnows, to prevent moiſture. There are alſo on each ſide of this building three long troughs or ſpouts, in the upper loft; and in fair weather men throw the corn out of this loft into thoſe ſpouts, through which it falls into others, about ten feet wide at the top, and eight or ten inches at the bottom, by which it is conveyed into the lower ſtory, from whence it is wound up again by a crane fixed in the upper loft. By thus falling from one ſtory to another, the corn is cleanſed by the wind from all duſt and chaff, and receives the benefit of the air, &c. Theſe troughs, or ſpouts, are put on and taken off as occaſion requires, to any of the windows; that when veſſels come to lade corn, it may be conveyed, through them, into the proper barges, without being carried thither by men, or cattle. The wall of the two firſt ſtories is two bricks and a half thick, that of the three next is two bricks thick, and the thickneſs of the two uppermoſt is a brick and a half. Fourteen thouſand quarters of corn may be kept in this granary.

Mr. Mortimer, who gives us this account, which is taken originally from captain Andrew Yarranton's England's improvement by ſea and land, adds, that the ears of corn, cut off from their ſtalks, and packed up cloſe in a tight caſk, will keep very well, and that this is the beſt, he indeed ſays, the only way of carrying any ſort of corn over the ſea, in order to ſow it in a foreign country.

The public granaries at Dantzick are ſeven, eight, or nine ſtories high, and have a funnel in the middle of every floor, to let down the corn from one to another. They are built ſo ſecurely, that the corn does not contract any damp, though they are ſurrounded with water on every ſide, in ſuch manner that veſſels come up to the very walls for their lading, which is let down into them, likewiſe thro' pipes or funnels, with very little labour and charge. No houſes are ſuffered to be built near them, for fear of accidents by fire.

At Zurich, in Swiſſerland, corn is kept eighty years, or more, in the public granaries, which are very ſpacious, and well aired by means of many ſquare wooden pipes which paſs through them.

The twelve companies of London, with ſome other companies and private perſons, had formerly their granaries at the bridge-houſe in Southwark, under the ſuperintendance of a juſtice of the peace, a ſteward, and two maſters. Theſe granaries were built on two ſides of an oblong ſquare (now uſed for a wharf,) one of which ſtood north and ſouth, and was near an hundred yards long. Along this ſide were lattice windows which faced the north-eaſt; and on the other ſide, which was about fifty yards long, the windows looked to the north. The oppoſite ſides had no apertures. All the windows were about a yard high, without any ſhutters, and ran on in a continued ſeries, with very ſmall partitions, ſufficient only to nail the lattices to. Each of theſe granaries was three or four ſtories high; but the loweſt, or ground ſtory, which was twelve feet high, was uſed only for a ware-houſe.

In Kent, two ſquare holes are made at the end of the floor, and a round one in the middle, by means of which the corn is thrown from the upper into the lower rooms, and back again, the better to turn and air it. The ſcreens uſed on this occaſion are made with two partitions, to ſeparate the duſt from the corn. The duſt falls into a bag, and when it is ſufficiently full, it is thrown away; the pure and good corn remaining behind. By theſe means corn has been kept thirty years in this country: and it is obſerved, that the longer it is kept, the more flour it yields in proportion, and the purer and whiter the bread is; only the ſuperfluous humidity evaporating in the keeping: for grain does not diminiſh in weight or bulk, after the firſt year.

The uſual way of preſerving it in our common granaries is, after it has been well ſifted and ſcreened, to ſpread it upon the floor about ſix inches thick, to turn it twice in a week, and to repeat the ſcreening of it once a week, during the firſt two months. It is then laid a foot thick, for two months more; and in this time it is turned once a week, or twice, if the ſeaſon be damp, and now and then it is ſcreened again. At the end of five or ſix months, it is raiſed to the thickneſs of two feet, turned once a fortnight, and ſcreened once a month, or as occaſion requires. After a year, it is laid two feet and a half or three feet deep, turned once in three weeks or a month, and ſcreened in proportion. When it has lain two years, or more, it is turned once in two months, and ſcreened once in three, and how long ſoever it is kept, the oftener it is turned and ſcreened, the better the grain will be preſerved. An empty ſpace, about two feet or a yard wide, is always left on each ſide of the corn, to prevent its running down holes or chinks at the edges of the floor, and to remove it from all moiſture that may proceed from the ſweating of the walls, or from any defect in the roof; and another ſpace is commonly left along the middle of the heap, if it be a wide one, to facilitate the turning of it as often as is needful. This is the general cuſtom; and experience has ſhewn it to be neceſſary in the uſual manner of keeping grain.

But all the foregoing methods of preſerving corn in granaries above ground are attended with very great expence, by reaſon of the vaſt buildings, which they require, and the many ſervants neceſſary to be employed to take care of theſe ſtores: beſides which, too much depends here upon the aſſiduity, ſkill, and probity of thoſe ſervants; and the grain is is ſtill liable to be preyed upon, waſted, and ſpoiled, by vermin and inſects.

To obviate theſe inconveniencies, and to point out an eaſier, cheaper, and ſurer way of keeping all ſorts of grain, is the principal deſign of M. Duhamel's excellent Treatiſe on the Preſervation of Corn; in which, after rightly noticing the ſeveral diſadvantages attending the common practice, he propoſes a method founded in reaſon, and on his own repeated experience, as well as that of others, whereby a large quantity of corn may be preſerved in a ſmall ſpace, during a number of years, without danger of its heating, fermenting, or contracting a bad ſmell or taſte, and ſecure from the ſpoil of animals and inſects, at a trifling expence, and with very little trouble. All theſe deſirable ends may be obtained, in ſome caſes, by ventilation only; in others, by drying the corn in a kiln over a ſtove; and in others again by both theſe methods. *See the article* VENTILATION.

A letter to Dr. Templeman, ſecretary to the ſociety for the encouragement of arts, manufactures, and commerce, deſcribing a new-invented granary for preſerving grain.

"SIR,

"Where public utility is in queſtion, a private apology becomes unneceſſary: accept, therefore, without ceremony, the following hints to be laid before the ſociety.

"I have long been of opinion, that a method of preſerving grain from decay is much wanting; but it muſt be, to anſwer any good purpoſe, eaſy in its execution, and cheap in its proceſs.

"The method now practiſed, of laying wheat in a room or granary, and turning it frequently with ſhovels, and ſometimes ſcreening it, is ſubject to many inconveniencies: it muſt be laid very thin, or it is apt to ferment; and by being laid thin it takes up ſo much ſpace, that to lay up and keep five hundred quarters for three years only, would be conſiderably expenſive.

"Could we preſerve our corn for a number of years, it would not only be of great ſervice to the public, but of no ſmall benefit to the farmers. For want of doing this, we find a great, and often a ſudden, variation in the price of bread-corn: wheat will one year ſell for five pounds a load, (that is, five quarters) and the next year it will riſe to fourteen or fifteen pounds or even higher.

"The rents of lands are of late greatly riſen, owing to the encreaſe of our trade; ſo is the price of all kinds of labour, inſomuch that when wheat is low in price, the great farmers are conſiderable loſers, and the poor ones are ruined: this is one reaſon why our lands are ſo much monopoliſed as they are in ſome counties. The great farmers, being rich, can afford to be loſers for ſeveral ſucceſſive years, as they are ſure that once in a while the markets will riſe, and not only repay all their loſſes, but ſecure them a large profit. The poor farmers are under a neceſſity of ſelling their corn before the winter is paſſed: if the markets are low, they fail in the payment of their Michaelmas rent, their ſtock is in conſequence ſeized, and ſome over-grown monopoliſer in the neighbourhood adds their little plot to the many formerly ſeparate farms he already holds.

"Were the intereſt of the community to be conſulted, no man ſhould be allowed to rent above three hundred acres of land: the profits of ſuch a farm will, with proper regulations, maintain a family decently and well; and it is not requiſite, or even ſalutary, that farmers ſhould acquire large fortunes.

"But to return to my ſubject. Were a proper method projected for keeping wheat good for a number of years at a ſmall expence, all this would be remedied, our lands would no longer be monopolized, and corn would from year to year vary very little in price. This ſtands to reaſon; for in a very plentiful year a farmer would not ſell his corn too cheap, if he had the power in his hands to lay it up without great charges; and when the crops by any accident failed, the price of corn would not greatly riſe upon the poor manufacturer and labourer, as what had been ſome years before laid up would now of courſe be ſold at a reaſonable price, and make up the deficiency, and this without loſs to the farmer, and with great benefit to the community in general.

"This intereſting ſubject has, for many years, employed my thoughts and attention; and I have in conſequence imagined, and even executed in miniature, or rather in ſmall dimenſions, a plan, which will, I have reaſon to think, anſwer the important purpoſes above mentioned: my whole plan conſiſts in building a proper granary, (the conſtruction of which will not coſt much) which will keep corn for any number of years ſound, ſweet, and good, and that with very little annual expence.

"I imagine the following poſtulata will be allowed.

"If we can preſerve corn from fermentation, it will be in a way of keeping.

"To keep it from damp and moiſture, is the beſt means of preſerving it from fermenting.

"To move it frequently, give it air at proper times, and ſeparate the duſt and other extraneous matter, is certainly the beſt way to keep it from being moiſt and damp.

"Deſtructive inſects are to be kept from it, which by frequent ſtirring is beſt effected.

"I imagine there are few, who have made this part of nature their ſtudy, but will allow the above poſitions: I ſhall therefore, without farther prelude, inform you in what manner I effect this at a ſmall expence.

"The granary I would recommend conſiſts of ſeven ſtories of floors, and may be built in any dimenſions, provided proper proportions are adhered to.

"The form of it is ſquare; and I ſhall at preſent ſuppoſe it to be fourteen feet ſquare within the rooms or cells; the diſtance of the floor from one cell to the floor of that above it is to be five feet: and the whole building ſhould ſtand on ſtrong poſts, more or leſs in number according to its dimenſions, at the diſtance of ſix feet from the ground: the ſmall ſtairs, or rather ladder, to go to the ſeveral cells, muſt be fixed to the outſide of the building ſide-ways, with a leading rail or rope to prevent falling.

"The whole granary is to be built of what is generally called brick-noggin; that is, the whole is firſt framed in ſtrong timber-work, and the interſtices filled up with brick-work: the floors, beams, and joiſts, muſt be made ſtrong to bear the weight of the corn; the inſide of the cells muſt be well lined with dry oak-boards, cloſe jointed, ſo as to leave no cracks; and the outſide muſt be weather-boarded, the boards being ſtrongly nailed to the timber-work of the frame, and afterwards payed over with pitch. The floors of the cells muſt be ſo contrived as to ſhelve towards the middle, in which part is to be an aperture ſix inches ſquare, to be opened, or cloſed, by means of a ſliding ſhutter, which muſt have a long handle reaching in a groove without the granary.

On three ſides of the rooms there muſt be a window, ſtrongly latticed, covered with wire to keep out larger inſects and birds, and with ſtrong ſhutters to defend the corn from the weather: on the fourth ſide is a door to each room to open from without: the windows are to be ſmall, and as cloſe as poſſible to the cieling: over the upper room or cell for the corn is a loft, on the outſide of the door of which is fixed a crane to be worked within, by a winch and flyers.

"The uſe of the windows in the ſides of the rooms, is to give the corn all the benefit it can receive from the wind and freſh air: the door, when the cell is empty, gives the workmen entry to ſweep, duſt, and clean it.

"My method of managing my corn in this granary is as follows.

"When my wheat is thraſhed and cleaned, it is put up into ſacks and carried to the granary: the apertures I mentioned above to have been contrived in the floor of the cells are then opened, except two, viz. one in the floor of the undermoſt cell, and that in the floor of the ſecond cell, reckoning from the bottom.

"The ſacks are then craned up into the loft, and emptied, through a hole made for the purpoſe, into the uppermoſt cell, whence it falls through the apertures till it reaches the floor of the undermoſt cell but one, where it is ſtopped by that aperture being ſhut.

"When this cell is filled to the height of about two feet from the floor, which may be ſeen through the lattices, the aperture in the floor of the third cell is ſhut by means of the ſlider: the workmen then continue craining up the ſacks till all the cells are filled in the like proportion,

tion, except the undermost, observing the proper opportunities of shutting the apertures.

"In this condition the corn is left for a week, or somewhat longer, if it was got in very dry.

"The first stirring it receives, occasions very little trouble: when it has been in the granary about a week, a workman, after having swept and cleaned the undermost cell, which was left empty, opens the aperture in the floor of the second cell, by drawing the slider back: this lets the corn fall from the second, into the undermost cell, the windows of which being open, the corn receives great benefit, as it falls, by the current of air that passes through the cell.

"When the second cell is empty, the aperture in the floor of it is shut, and the workman, going in at the door, by means of the stairs on the outside of the granary, sweeps it and cleans it from all impurities, in order to prepare it for receiving the corn of the third cell, the aperture of which is next opened, and the floors being all made shelving towards the middle, the corn falls gradually through, in the same manner it did from the second to the undermost cell.

"In this manner they are all managed, till at last the uppermost cell remains empty.

"It is then left for another week, when two workmen must for a small space of time be employed: one of them goes up into the loft at the top of the granary, to work the crane, and the other takes his station on the ground under the floor of the undermost cell: under the aperture in this floor he first fixes a screen, upon which the corn falls, and then, by means of a conductor at the foot of the screen, drops into the mouth of a sack which hangs to it, the bottom of the sack resting on a miller's hand-barrow: when all is prepared, he draws away the slider, and lets the corn fall on the screen.

"When the sack is full, the slider is for a moment closed, till another sack, on another barrow, is put under the conductor: the workman then wheels the first sack to the outside of the granary, and fastening the crane-rope to it, makes the signal for the other to draw it up. Whilst this is doing, the second sack is filled, which is wheeled and drawn up in the same manner; and this method is pursued till the undermost cell is empty.

"If it is necessary to screen all the corn at this time, a small screen is fixed under the aperture of the second cell, so contrived as to have a box at the back of it, which receives all the dust, trash, off-corn, and seeds of weeds that pass through the wires; and this screen is successively fixed under every aperture, as the cells are successively emptied.

"After the first month the corn need be stirred in this manner only once a fortnight, and after the first six months, only once a month, unless the weather should prove, in autumn, very hot and damp.

"This then, Sir, is the manner in which I have for some years managed my wheat, and find it answers very well, the vegetative quality of the corn being preserved in full vigour, and no signs being discoverable in it of a tendency to fermentation.

"My country hovel is at some distance from London, in a retired quarter, consequently unnoticed; and there being but little probability of this easy method's being sufficiently known by my practising it, is the reason of my troubling you with this long letter, flattering myself that by your means it may make a proper appearance in public. Had vanity been my predominant passion, I might have presented it to the society in person, which as a member I had an undoubted right to do; but this would have been encroaching on my beloved obscurity: to you, therefore, Sir, do I trust this child of my invention; and if in your hands he can be trained so as to be of public utility to my country, my every purpose is fully answered.

"I forgot to observe, that I have lately seen Monf. du Hamel's methods of preserving grain, by means of chests with false bottoms and ventilators.

"This method may in some cases be of service, I allow: but I am nevertheless of opinion, that corn cannot be properly preserved, unless the whole bulk of it be frequently stirred, which by du Hamel's method is not done: could the current of air be equally distributed over the whole chests, and in due proportion, I should still think it insufficient to preserve the corn; and if corn has been kept for some time in that manner, I should rather be apt to attribute it to Monf. du Hamel's first drying it on a kiln, before he puts it into the chests, than to any regular effect of the ventilators.

"Were I acquainted with this gentleman, I would recommend it to him, to make an experiment of his method in the following manner.

"Let him first fill a chest with dry corn that has not been on the kiln: another chest should be filled with some that had been well dried, and a third with the same dried corn: let the first and second chests, at proper intervals, be ventilated, and the third be kept without ventilating, in a dry place. Were this done, I am apt to think, that after six months, or a longer time, there would not be found so great a difference as some may imagine, betwixt the corn which was, and that which was not, ventilated.

"In my method, the expence, as well as hazard of drying is avoided, it being never necessary, unless when corn is got in very soft, in a wet harvest; and then a common malt-kiln answers the purpose very well.

"I should have mentioned, that in my method of preserving corn, when by frequent stirrings it is become hard and brittle, it may be laid to the height of three feet, on the floors of the cells, without any danger of damage ensuing; for when it is hard, it is not subject to heat and ferment; neither are insects so fond of attacking it.

"I have by this time, perhaps, tired your attention, and to be plain, am not unweary myself; shall therefore conclude with assuring you that I am, Sir,

Your very humble servant,
A Member of the Society."

"In order to form an idea of the expence of public granaries for corn, says an ingenious correspondent of the editors of the Museum Rusticum, it will be necessary to examine some of those in other countries, that are recommended for our imitation; such as that at Schoonbank on the river Elbe, which is three hundred feet long, and eighteen feet wide within; has seven stories, each story seven feet high, with a row of windows round each story, to be opened in dry weather to air the corn, and blow the dust out of it when turned. A path of a yard wide is left next the walls, all round the corn in each story; and another path across the middle, of two yards wide. In these are trap-doors, to let the corn run down from the upper to the lower stories, to screen and air it: whence it is drawn up again with cranes, or other engines. Stoves are likewise to be placed in the middle, and at each end of the granary, to dry the corn in damp weather. At first the corn is to be laid about six inches thick on the floors, and to be often turned, aired, and screened: in about a year it may be laid two feet thick; and the turning and screening being continued at proper intervals, it may, at the end of two years, be laid two and a half, or three feet thick: and being by that time perfectly dry, turning it once a quarter, will keep it sound many years.

"This is the method proposed for preserving corn in England. But as we are assured, by M. Duhamel, in his Treatise on the Preservation of Corn, that they usually lay it but eighteen inches thick in France, we cannot suppose it proper to lay it thicker in England, both on account of the greater moisture of our climate, and quality of the corn, which in wet seasons is not fully ripened in England, nor can it then be got in perfectly dry. And, though in hot dry climates, they lay it much thicker than in France: that is, because their corn is perfectly ripened; and their wheat of a different species from ours. The Lammas, which is generally esteemed in England, is a full plump fat grain; and, therefore, more difficult to be preserved sound: whereas, most of the foreign wheat, of the warmer countries that I have seen, is a drier and harder grain; and such were several parcels that I have received from Smyrna, Sicily, and Italy: being of the cone or bearded sort.

"It is, also, to be remarked, that the quantity, which can be kept in such granaries, has been greatly over-reckoned. Mortimer has implicitly copied from Yarranton, and others from both, that such a granary as the above, would contain fourteen thousand quarters of corn. But a quarter, nine gallon measure, being 11.2 cubic feet, and each ſtory, after deducting the paths round and acroſs the middle, being only three thouſand four hundred and fifty-ſix ſquare feet, all the ſeven ſtories will contain no more than three thouſand two hundred and forty quarters of corn, laid eighteen inches thick; which is but about one-fourth of the quantity they have ſuppoſed. Mr. Dobbs is more moderate, when he reckons, in his Eſſay on the Trade of Ireland, that a granary of the above dimenſions will contain fourteen thouſand barrels; but he ſuppoſes the corn to be laid two and a half, or three feet thick. He calculates the expence of erecting ſuch a granary, built with bricks, and of a ſufficient thickneſs and ſtrength, at fifteen hundred pounds; and eight or ten pounds a year each to ſix men, to turn and ſcreen the corn, and forty pounds a year to a clerk. This calculation was made for Ireland about thirty-five years ago, but is much too low for England; eſpecially as ſuch granaries are erected near cities and populous towns, where materials and labour are dear: for the building would coſt conſiderably more in England, and the wages double: alſo the clerk would deſerve a ſuitable appointment for the care and conſtant attendance neceſſary in a buſineſs of ſuch truſt and importance; nor would one clerk and ſix men be ſufficient, to do all the buſineſs, and alſo to take in and deliver out the corn: and therefore the clerk and men, at a moderate reckoning, would coſt two hundred pounds a year.

"But there is another article that Mr. Dobbs has omitted, which cannot, nor is it proper to be done by the clerk. One or more perſons muſt be employed to buy the corn; which, at the rate of the uſual commiſſion for buying in private trade, will coſt one ſhilling per quarter: to this is to be added the expence of fuel, of repairs, intereſt of money, and alſo for the waſte of corn in drying and ſkreening, which, according to M. Duhamel's experiments, amounts to about a tenth part of the whole.

"The expence of erecting granaries in France, is by this gentleman computed at a much higher rate than the above. For, he ſays, that a granary, to contain two thouſand ſeven hundred cubic feet of corn, which is about two hundred and fifty quarters, will coſt in France eight or nine hundred pounds. So that if the corn was bought at twenty-four ſhillings per quarter, the granary would coſt near three times as much as the corn contained in it.

"The principal corn, to be preſerved in granaries, is wheat: of which, the quantity produced in England is uncertain. The author of the Eſſays on Huſbandry computes the wheat, barley, and rye, annually produced, at near fifteen millions of quarters, over and above what is uſed for feeding and fattening cattle, &c. and for malting, diſtilling, and ſeed: and, as probably about a third part of theſe crops is wheat, the quantity of wheat remaining for bread, and other domeſtic uſes, may be about five millions of quarters; and this would be the proviſion of wheat for a year, to be laid up in public granaries, beſides rye, and ſuch other ſorts of corn as might be kept for a ſhort time. But I ſhall ſtate a year's proviſion of wheat at no more than four millions of quarters, and charge nothing for keeping any other ſort of corn.

"I do not find, that thoſe, who recommend public granaries, have determined what quantity of corn they thought neceſſary to be laid up in them. The ſtate of Genoa had always, in their public granaries, ſeven years proviſion of corn before hand. This ſeems to be a very ample proviſion; and I ſhall, in favour of theſe granaries, ſuppoſe, that leſs than half this, or only three years proviſion, may be ſufficient for England, at a medium of the granaries being full when corn is cheap, and near empty in a dear time of the longeſt continuance. But to have this quantity always before-hand, or even leſs than this, it is neceſſary to provide ſtore-room for more than three years proviſion, to be laid up in cheap times; and alſo room to ſpare, in order to lay the corn thin at firſt; and for it to run from the upper to the lower ſtories, when ſcreened and aired. And, therefore, if we ſuppoſe, that room for only four years proviſion may be ſufficient, this will alſo be allowed as favouring the ſcheme of granaries. But after all theſe abatements, to have room for four years proviſion of wheat at firſt, or when the granaries are quite full, there muſt be four thouſand ninehundred and thirty-eight ſuch granaries, as that above deſcribed: for ſo many will be neceſſary to contain ſixteen millions of quarters.

"To determine what advantage theſe granaries may be of to the public, we muſt fix ſome price for the prime coſt; and, alſo, how much it may probably ſell for. The markets are governed by the quantity produced: which, being variable, the prices will be ſo likewiſe; and the granaries cannot be always filled when wheat is cheapeſt. For, in that caſe, much more room would be neceſſary than is here ſuppoſed. But, in general, the granaries are to be filled, when wheat is under the middle price; and ſold out when above it: and, therefore, the prime coſt will be nearly the mean between the common and loweſt prices; and the ſelling price the mean between the common and higheſt. Theſe, according to Windſor market, for ſeventy-five years, ending in 1762, (admitting wheat to fall five ſhillings per quarter, upon diſcontinuing the bounty) are nearly twenty-ſix ſhillings and ſix-pence half-penny, and forty-four ſhillings one penny half-penny per quarter; and the difference between theſe, being ſeventeen ſhillings and ſeven-pence per quarter, is the profit accruing to the public from theſe granaries, upon ſo much as is ſold every year.

"Howmuch this profit would amount to every year, is uncertain, as it depends upon the quantity ſold in a year, which cannot be determined: but, if the whole quantity, lodged in theſe granaries, were to be ſold once in ſeven or eight years, the annual profit would fall very much ſhort of the expence: as will appear from the following ſtate of it, viz.

	£
To firſt coſt of erecting four thouſand nine hundred and thirty-eight granaries, at fifteen hundred pounds each - - - - - - - - - -	7,407,000
To three years proviſion of wheat, being twelve millions of quarters, at twenty-ſix ſhillings and ſix-pence half-penny per quarter - - - - - - - - - - - - - - - -	15,925,000
To commiſſion for buying, at one ſhilling per quarter - - - - - - - - - - - - -	796,250
	24,128,250

To intereſt of this ſum - - - - - - - - - - -	1,206,912
To clerks and men - - - - - - - - - - -	987,600
To repairs, fuel, &c. and waſte of corn, above - - - - - - - - - - - - - - -	305,488
	2,500,000

"Thus there is above twenty-four millions ſunk, and two millions and a half a year expence. The profit upon the wheat ſold, and the bounty together, will ſcarce pay half this expence: and though it is not pretended that this eſtimate is accurate in every particular; yet, if upon the whole, it is any thing near the truth, the ſcheme of public granaries will not, I think, be either expedient or practicable.

"The next thing to be conſidered is, whether, after all this expence, corn would be cheaper; and if it were, what effect this would have upon agriculture?

"It has been ſuppoſed, that, upon diſcontinuing the bounty, wheat would of courſe fall five ſhillings per quarter; and likewiſe that the ſame quantity would be ſtill exported. Now it is certain, that all the wheat produced in England, is either conſumed at home, or exported: and, therefore, the wheat exported is all that can be ſpared for the granaries. The quantity exported yearly, at an average of twenty-five years, ending in 1756, was three hundred and forty-five thouſand eight hundred and twenty-three quarters: ſo that, if all the wheat exported were to be lodged in theſe granaries, they would not be full in leſs than thirty-five years, even if none were to be ſold out of them, in all that time: which is a further argument, that ſuch granaries are impracticable; or, that, if they could be introduced, they would put an entire ſtop to the exportation; and, conſequently, occaſion a further and very great loſs to the nation.

"It is often ſaid, in favour of theſe granaries, that they would be a ready market for the farmers, when corn was cheap. But the intention of them being to ſink the price of corn in general, it is but poor encouragement to the farmers, that they must always sell at a low price. This, however, could be but temporary; for the bounty being taken away, the price sunk, and the farmers confined to one market, corn would become an unprofitable crop to them: for which reason they would undoubtedly raise less corn than they do now; and then, of course, it would be dearer. Those, who advise the bounty to be discontinued, and to erect public granaries, are sensible this would be the consequence; and, therefore, propose, that other encouragements should be given to agriculture in lieu of the bounty. But, till it is shewn what other can be given equal to the bounty, and a free trade, it will be safest to pursue the same measures, that have been found so long successful.

"Though it is the practice of several countries, to lay up corn in magazines, it may not be proper to do so in England. In large kingdoms, where the interior parts are remote from the sea, or navigable rivers, it may be necessary to save corn in magazines; and also in populous states, that have a small extent of territory, such as Holland. As the policy of the Dutch, in this respect, has been greatly magnified, and their example recommended for England, it may be proper to take notice here, that their circumstances being very different, what is necessary to one, may be not only improper, but very prejudicial to the other.

"The province of Holland, though only about a fifth part larger than Kent, is computed to contain above two millions of people. The soil, in general, is of a bad quality, and improper for corn; of which it is reckoned, they do not raise enough for a tenth-part of the inhabitants. So that about two millions of them must have corn from other countries; and, therefore, they are under necessity of laying up enough in magazines for their constant supply But their magazines are not intended solely for the use of their own people; but also to lay up corn, when they can buy it cheap, to sell it again wherever they can get a profit by it. So that if they did not want to buy for their own people, they would, notwithstanding, have magazines of corn for trade; as they have for all kinds of merchandize: and, therefore, if we ought to imitate the Dutch in erecting magazines for corn, why not for all other goods, and make all our ports free?

"And herein lies the mistake of those, who recommend the same policy for both countries, though their circumstances are widely different. Holland is but a small tract of bad land, and produces very little for manufactures, or trade. England, on the contrary, with about three times the number of people that are in Holland, contains about thirty times the quantity of much better land, in a better climate; and has a large native product, sufficient for the inhabitants, and, also, for a considerable foreign trade. The land and product of England, are a large part of the riches of the state, and of individuals: and, therefore, in all deliberations concerning the public, they are to be considered; and land and trade are to be made subservient to each other, so far as is consistent with the good of the whole.

"For this reason, public granaries cannot be for the interest of England, unless the benefit, arising from them to trade, were of more consequence to the public, than the loss occasioned by them, in sinking the value of land: which does not appear in the present case. But the bounty is advantageous to land, and to trade also, as may be seen from the following observations.

"England was not considerable in foreign trade and shipping, till about 1600; nor had made great progress in husbandry. For money was then at ten per cent. and the current price of land was twelve years purchase. In these circumstances, no great improvements would be made: when those, who had money, could make ten per cent. of it without that trouble. The shipping was, also, very low at that time: for, by an account taken in 1582, by order of the lord high-admiral, there were then only two hundred and seventeen ships and vessels, above eighty tons, belonging to England: and about thirty years after this, not above three merchant-ships, of three hundred tons, and upwards: as we are informed by Sir Josiah Child, in his Discourse of Trade.

"But, about 1660, trade had made a quick progress, interest of money was fallen to six per cent. and the value of land very much advanced; and it appears, that wheat had risen above thirteen shillings per quarter: this was the consequence of a growing trade, for that makes every thing dearer. And hence it is evident, that to make corn cheap, a further encouragement is necessary, than what arises from trade.

"Hitherto a considerable part of the trade of England had been carried on by foreign ships, and chiefly by the Dutch; and, for this reason, the Act of Navigation was made, to exclude the Dutch and others; and to encourage English shipping. At the same time, an act passed, laying a duty upon corn imported, and permitting also a free exportation of it; which, with the additional duties laid soon afterwards upon corn, and granting a bounty upon the exportation of it, laid the foundation of the improvements in husbandry, that have been made since.

"The trade of England is now much greater than it was in 1660: and though it has been interrupted by war, and other accidents; yet, if upon the whole, it has increased in the last hundred years, as much as it did in the former sixty, the price of corn would have advanced in proportion, as in fact the prices of other things have done: and in that case, the mean price of wheat in 1662, would have been nearly sixty-nine shillings per quarter, whereas it was really less than thirty-nine shillings: and, therefore, this difference of thirty shillings per quarter, is clear profit to the public upon wheat; and a profit in proportion, upon all the corn produced in England. This is an important fact in the present argument; nor is it material whether the price of wheat is so much lower as is here stated: but it is certainly very much cheaper; and thence we may draw the following conclusions. First, that public granaries are unnecessary: for the end, that was proposed by them, is attained by the bounty. Secondly, the bounty does not make wheat dearer to our own people, five shillings per quarter, as has been supposed: but, on the contrary, they have it, by that means, thirty shillings per quarter cheaper. And, thirdly, this points out the reason of the demand for our corn abroad: as we can afford to sell it to foreigners forty per cent. cheaper, than we could have done, had agriculture received no other assistance, than it does from an extended commerce. All these sufficiently prove the utility of the bounty.

"But it is objected, that now we are got into the tract of improvement, the bounty may be discontinued: this might be true in a profitable trade, wherein we had no competitors; which cannot be said here: and it may be a sufficient answer to the objection, to shew the danger of such an experiment in a parallel case. "A large bounty," says Mr. Gee's Treatise upon Trade, p. 212, "was given for several years, to encourage the making of pitch and tar in America, till it came to be imported in such vast quantities, that we had not only enough for our own consumption, but even to export to our neighbours; from which great plenty, we were ready to persuade ourselves, that the business was effectually established; and thereupon neglected the continuance of the bounty: since which, the importation of these commodities from Russia, Sweden, and Norway, is re-assumed."

"Was it indeed true, what has been frequently asserted, in support of some favourite scheme, that foreigners must have corn of us, a bounty would be unnecessary, in respect to foreign trade. Thus, Sir Matthew Decker, speaking against the bounty, says, p. 54, "The pretence of encouraging tillage, by a bounty on corn, can have no weight now, since our great improvements in husbandry: much less, if we erected magazines of corn in every county, against times of scarcity. Foreigners never buy provisions till they want them, and then they must have them, whether we give bounties or no."

"If this be the case, we have got the monopoly of corn; and may set our own price upon it: but, if we only fancy so, and should act as if it were real, we shall fall into a dangerous error. The profit upon corn exported, is a matter of great consideration to England, in a national view: but it is a strange conceit, that we have the monopoly of it against all Europe, though all that we export,

export, is ſcarce ſufficient for one-third of the people in the province of Holland.

"Beſides, it is well known, that all countries produce corn, from about twenty-five or thirty, to ſixty degrees of latitude; and though we have no reaſon to complain, yet it is certain, that ſeveral other countries are more fertile than England; and that the principal reaſon, why all of them, of any conſiderable extent, do not produce corn enough for the inhabitants, is a want of induſtry: which it is the intereſt of England to encourage, by ſupplying them with cheap corn.

"Moſt of the countries in the Baltic, and Mediterranean, abound in corn; and, from thence, the Engliſh were ſupplied, before they raiſed enough of their own. It is quite unneceſſary to enlarge upon a thing ſo generally known; and, therefore, I ſhall only mention a circumſtance, reſpecting the fertility of Barbary, ſpoken of by the curious and learned Dr. Shaw, who lived twelve years in that country. The ſoil is ſo light, that a pair of ordinary oxen uſually plough an acre of it a day: "and one buſhel yields ordinarily from eight to twelve, though ſome diſtricts may perhaps yield a much greater increaſe: for it is common to ſee one grain produce ten or fifteen ſtalks." Travels, p. 137. This is a much greater increaſe, than is common in England; and with this additional advantage, in favour of that part of Africa, that the corn is in no danger of receiving damage by wet: for there is ſeldom, or never, any rain there in harveſt. But, what is ſtill more remarkable, theſe plentiful crops of corn, are conſtantly produced without any manure. "The plains of Africa," ſays our author, p. 399, "are never manured; yet the ſame fertility in the ſoil, and the like plenty and abundance, that have been recorded of their crops, for above theſe two thouſand years, continue to this day."

"If we look towards the Baltic, we ſhall not only find ſeveral large countries, that have been long noted for plenty of corn, but alſo ſome others, which may probably come in for a large ſhare of that trade; and very much ſink the general price of corn in Europe. For, I obſerve, that among other countries, where your Muſeum is circulated, Ruſſia is mentioned, where you remark, gentlemen, "that great encouragement is given to agriculture." If this is continued with ſpirit, it may have great effects, in regard to corn, and other articles of commerce.

"The great river Wolga takes its courſe for many hundred miles through the fertile parts of that vaſt empire: and captain Perry, who was employed by the late czar, in ſeveral great works, and in different parts of that country, fourteen years, did at laſt take a ſurvey of that river, in order to make a communication between it and the Nieva, that falls into the gulph of Finland, at Peterſburgh. This he found very practicable, and would have performed it, had not the ill-uſage he met with, obliged him to leave the country. The great importance of this communication, he mentions in his State of Ruſſia, p. 245. "If the Czar," ſays he, "lives to perform the communication, which it is his intention to make, for free water carriage, between the Wolga and Peterſburgh, he will then be able to bring oak and timber, with plenty of corn, to that place, at very eaſy rates: that the ſame may both pay a conſiderable duty to the czar, and turn very much to the advantage of his country, by the being exported from thence to other parts of Europe: for corn may then be loaded much cheaper there, than can be delivered, either at the ports of Riga, Dantzick, or Koningſberg; from whence, and other places in the Baltic, the Hollanders alone, load every year eight hundred or a thouſand ſail of ſhips with corn.

"The Ruſſes make the moſt part of their bread with rye, which they reckon to be the moſt ſtrengthening for men: and in many places on the Wolga, between the mouth of Shackſna and Caſan, rye is uſually ſold for the value of an Engliſh ſix-pence, or ſeven-pence per buſhel, according to Engliſh meaſure: wheat is about nine-pence per buſhel; and all other grain is there in price proportionable."

"When theſe things are duly weighed, together with the improvements in huſbandry now carrying on in many neighbouring countries; there is great reaſon to expect, that the general price of corn in Europe, will be lower than it has hitherto been; and of courſe a leſs demand for it from England: which will check the progreſs of Engliſh agriculture; and hence the neceſſity of a public encouragement to tillage and exportation, and of introducing new methods and improvements. It is to thoſe already made, in conſequence of the bounty, that the farmers have hitherto been enabled to continue raiſing ſtill larger quantities of corn, though the price has been ſinking upon them for one hundred years; and though during that time, the price of labour, and of the neceſſaries of life, have been advancing; as alſo the rent of land, taxes, and coſt of implements of huſbandry.

"Though I am of opinion, that public granaries would be very prejudicial in England, I would not be underſtood to mean, that no proviſion ſhould be made againſt times of ſcarcity. On the contrary, I think this highly neceſſary: but that ſuch proviſions ſhould be in the hands of private perſons; and more eſpecially, of the growers of corn: and this for ſeveral obvious reaſons; but chiefly, becauſe the poor are thus ſupplied at firſt hand; and, therefore, in the cheapeſt manner. Likewiſe, as this is the moſt certain way, to prevent engroſſing, in every degree hurtful to the public. For, of the ſeveral cauſes, that have been aſſigned of the high price of corn, there is none, in my opinion, ſo groundleſs, as that of its being engroſſed by the farmers. That ſuch a great number of perſons, of ſmall capitals, diſperſed over the whole kingdom, who have no foreign correſpondence, and very little at home further than their own neighbourhood; that theſe perſons, ſo circumſtanced, can combine together, to raiſe or keep up the price of corn, is altogether incredible; and contrary to every idea of engroſſing.

"By keeping wheat in ricks, the farmers loſe the immediate benefit of the ſtraw: and the corn is liable to be damaged, by vermin, and otherwiſe. Sometimes they have not convenient room to houſe, and threſh their wheat, when the market is riſing; and, at other times, they muſt pay an advanced price for threſhing it. Theſe inconveniencies might be avoided, if they had granaries to lodge it ſafely; and it would then be ready for market, upon the ſhorteſt notice. The granaries, contrived by M. Duhamel, are, in my opinion, by much the cheapeſt and beſt hitherto propoſed; and very convenient for the uſe of farmers, or others, who might incline to lay up ſome corn upon ſpeculation; eſpecially if made of plank, and ſo conſtructed, that they could be eaſily taken to pieces, and carried from one place to another, where the owner might think proper to ſet them up again: and probably they might be contrived ſo as to be made larger or ſmaller occaſionally.

"But, whatever methods may be thought of, to preſerve corn, in a cheaper or more compendious manner than has been commonly practiſed, they will not invalidate the objections to public granaries, as they lie againſt the whole ſcheme, for other and the ſtrongeſt reaſons, beſides the expence. And, as it is of great importance to the community, that there ſhould be corn in private hands, and in all parts of the kingdom, againſt times of ſcarcity, it is, I apprehend, a matter worthy of the conſideration of the London Society, by what means the farmers and others may be encouraged and enabled, to preſerve corn in a cheap and ſafe manner." *Muſeum Ruſticum, vol.* VI. *pag.* 404.

WHEE, *or* WHEY, a heifer.

WHINS, the ſame with furze. *See the article* FURZE.

WHISKET, a baſket.

WHITE-CLOVER, a well known plant, and reckoned the ſweeteſt feed of any of the ſown graſſes; and it is of moſt advantage to the farmer, becauſe it is perennial, or laſts a great number of years on the land.

This plant ſends forth roots at every joint, ſo that it thickens, and ſoon makes a thick ſward. When land is to be laid down for paſture, the farmer will reap great profit, if, with about four buſhels of clean-ſifted hay-ſeed to an acre, he ſows eight pounds of this clover; but it is to be remarked, that it is never to be ſown with corn.

It may be ſown either in ſpring or autumn; if in ſpring, it may be cut about the latter end of July; if ſown in autumn;

tumn; the crop will be much earlier. As ſoon as ever the hay is off the land, it ſhould be rolled with a heavy roller. In laying down land with theſe graſſes, it will be proper for the farmer to be very careful that he cleans the land of all ſorts of weeds; and the hay-ſeeds are to be ſown firſt, immediately after which the clover is to be regularly ſcattered. After ſowing, the land ſhould be lightly harrowed, with a ſhort tined harrow, to bury the ſeed; and a few days afterwards, if the weather is dry, it ſhould be rolled, to break the clods, and cloſen it.

It will be good huſbandry, if, after the plants are come up, the farmer ſhould ſend in ſome weeders, to pull up all the tall rampant weeds which might injure the crop, for, if they are ſuffered to ſeed, they will ſoon ſtock the land.

It will be proper to take the advantage of dry weather, and roll the land three or four times, after the plants have attained ſome ſize; for the clover, as is already obſerved, taking root at every joint, the ſward will thereby be greatly thickened.

If a farmer knows his own intereſt, he will ſow ſome of this white clover-ſeed by itſelf, in order to ſupply himſelf with what ſeed he may want, for it is ſometimes very dear. The beſt ſeaſon for ſowing is autumn, upon dry lands, about the beginning or middle of September; but in open, cold lands, much expoſed, a month ſooner is better: all the caution required in this autumnal ſowing is to let the land be very well rolled in the month of October, before the froſts come on, and again in March.

WHITE-SCOUR, a diſeaſe with which ſheep are too often affected, and by which great numbers of them die.

The following medicine has been often given with ſucceſs, provided the ſheep are at the ſame time removed into a dry paſture.

> Take a pint of old verjuice, half a pound of common or bay ſalt, dried well before the fire, pounded, and ſifted through a ſieve. Then mix the verjuice with the ſalt by degrees; and add half a pint of common gin, and bottle it up for uſe. When any of your ſheep are ſeized with this diſorder ſeparate them from the flock, and give each of them three large table ſpoonfuls of the mixture for a doſe, repeating it two days after, if they are not better.

WHITE-LANDS, chalky lands.

WILDS, a term uſed by our farmers to expreſs that part of a plough by which the whole is drawn forwards.

WILDERNESS, a kind of grove of large trees, in a ſpacious garden, in which the walks are made either to interſect each other in angles, or have the appearance of meanders and labyrinths.

Wilderneſſes, ſays Mr. Miller, ſhould always be proportioned to the extent of the gardens in which they are made; for it is very ridiculous to ſee a large wilderneſs planted with tall trees, in a ſmall ſpot of ground; and, on the other hand, nothing can be more abſurd, than to ſee little paultry ſquares, or quarters of wilderneſs work, in a magnificent large garden. As to the ſituation of wilderneſſes, they ſhould never be placed too near the habitation, nor ſo as to obſtruct any diſtant proſpect of the country; there being nothing ſo agreeable as an unconfined proſpect; but where from the ſituation of the place, the ſight is confined within the limits of the garden, nothing can ſo agreeably terminate the proſpect, as a beautiful ſcene of the various kinds of trees judiciouſly planted; and if it is ſo contrived, that the termination is planted circularly, with the concave towards the ſight, it will have a much better effect, than if it end in ſtrait lines or angles. The plants ſhould always be adapted to the ſize of the plantation; for it is very abſurd for tall trees to be planted in the ſmall ſquares of a little garden; and in large deſigns ſmall ſhrubs will have a mean appearance. It ſhould alſo be obſerved, never to plant ever-greens amongſt deciduous trees; but always to place the ever-greens in a wilderneſs in a ſeparate part by themſelves, and that chiefly in ſight.

As to the walks, thoſe that have the appearance of meanders, where the eye cannot diſcover more than twenty or thirty yards in length, are generally preferable to all others, and theſe ſhould now and then lead into an open circular piece of graſs; in the center of which may be placed either an obeliſk, ſtatue, or fountain; and, if in the middle of the wilderneſs there be contrived a large opening, in the center of which may be erected a dome or banquetting-houſe, ſurrounded with a green plot of graſs, it will be a conſiderable addition to the beauty of the whole. From the ſides of the walks and openings, the trees ſhould riſe gradually one above another to the middle of the quarters, where ſhould always be planted the largeſt growing trees, ſo that the heads of all the trees may appear to view, while their ſtems will be hid from the ſight. Thus in thoſe parts which are planted with deciduous trees, roſes, honey-ſuckles, ſpiræa frutex, and other kinds of low flowering ſhrubs, may be planted next the walks and openings; and at their feet, near the ſides of the walks, may be planted primroſes, violets, daffodils, &c. not in a ſtrait line, but ſo as to appear accidental, as in a natural wood. Behind the firſt row of ſhrubs ſhould be planted ſyringas, althæ frutex, mezereons, and other flowering ſhrubs of a middle growth: and theſe may be backed with many other ſorts of trees, riſing gradually to the middle of the quarters.

The part planted with ever-greens, may be diſpoſed in the following manner, viz. in the firſt line next the great walks, may be placed the laurus-tinus, boxes, ſpurge-laurel, juniper, ſavin, and other dwarf ever-greens. Behind theſe may be placed laurels, hollies, arbutuſes, and other ever-greens of a larger growth. Next to theſe may be planted alaternuſes, phyllireas, yews, cypreſſes, Virginian cedars, and other trees of the ſame growth; behind theſe may be planted Norway and ſilver firs, the true pine, and other ſorts of the fir growth; and in the middle ſhould be planted Scotch pines, pinaſter, and other of the larger growing ever-greens, which will afford a moſt delightful proſpect, if the different ſhades of the greens are curiouſly intermixed.

But beſide the grand walks and openings (which ſhould always be laid with turf, and kept well mowed) there ſhould be ſome ſmaller ſerpentine walks through the middle of the quarters, where perſons may retire for privacy; and by the ſides of theſe private walks may alſo be ſcattered ſome wood flowers and plants, which, if artfully planted, will have a very good effect.

In the general deſign for theſe wilderneſſes, there ſhould not be a ſtudied and ſtiff correſpondency between the ſeveral parts; for the greater diverſity there is in the diſtribution of theſe, the more pleaſure they will afford.

WILLOW, the name of a well known tree, of which there are ſeveral ſpecies, ſome of which may be propagated to great advantage, particularly that known by the name of the Norfolk willow, as demonſtrated by the late Mr. North, in an Appendix to a little Treatiſe on Graſſes, publiſhed by him ſome years ago. As this pamphlet may have reached the hands of but few of our readers, and will, now the author is dead, be ſcarcely ever republiſhed; we were perſuaded it merited a place in our work, eſpecially as it may ſerve as an example of a profitable method of cultivating trees of this kind, that may be applied to ſeveral others, alſo obſerving a due regard to the difference of circumſtances.

Directions for propagating the ſound-growing Norfolk willow.

"This willow (I dare affirm) will prove very profitable to the planter, and of great utility to the kingdom in general. It will grow taller and larger in twenty or thirty years, than moſt other ſorts of trees will in ſixty or ſeventy. It grows very kindly, and great quantities may be propagated at a ſmall expence. A very conſiderable profit from it will come to the planter in five or ſix years after planting: in eight or ten years more another profit will ariſe much larger than the firſt; and at laſt, which will be in about twenty or thirty years after planting, the profit will be ſurpriſing, as I will make it appear in the ſubſequent account.

"In order to begin with this willow-plantation, the land muſt be ſecurely fenced from all kinds of cattle, and muſt be well ploughed or dug in winter, to make the ſurface looſe, and to kill the graſs and weeds. The ſeaſon for planting is from November to April, and ſometimes later. The dryeſt land ſhould be planted firſt.

"One year's ſhoots are beſt for ſets when they are deſigned to make large trees. The ſets ſhould be cut to eighteen or twenty inches long; about eight or nine inches

of

of the thick or lower ends must be thrust into the ground. A strong shoot of one year's growth will frequently make three or four good sets, but I would not advise cutting any sets from the very tops of the rods, because they will be too weak to make strong shoots the first year.

"The proper distance these sets should be planted, is about three feet promiscuously. An acre will require about five thousand. In June, after planting, the sets should be all looked carefully over; and such, as have more than one shoot, should be reduced to one, and it should be minded, to leave the uppermost and strongest. The superfluous shoots should be cut off close to the set, that the bark may sooner cover the wound.

"At the same time the ground should be hoed over to kill the weeds, and to loosen the surface, in order to sow turneps, which will no ways hurt the sets, but rather be of service, provided they are properly hoed, and set out at good distances, and not suffered to grow within a foot of the sets. The winter following, when the turneps are gone, the ground should be dug all over, and, the summer after, the weeds cut down with hooks; which is the last, and all the labour of cleaning they will ever want. The best instrument to dig these plantations with, is the sort of broad-trined fork they use in Kent to dig their hop grounds. The price, by the acre, is twelve shillings for once digging.

"When these sets have grown four or five years, about three-fourths of them must be dug up, in order to leave space for the others to thrive. If they have throve well, in five years they will be above a foot in circumference, and twenty or thirty feet high. These young trees will be very proper for many uses, as for chair-makers, hoops, gates, hop-poles, &c. and will surely be worth three-pence a piece, upon an average.

"From five thousand sets which are planted upon an acre, at about three feet apart, certainly three thousand may be very properly taken away, and the remaining ones will not be left quite six feet apart. If these young trees are valued at but three-pence a piece, they will be worth thirty-seven pounds, but I rather believe, they will be worth more. Eight or ten years after the first thinning, three parts in four should again be took up, which will be about one thousand five hundred; and five hundred or more will be left at about twelve feet apart, which should grow twelve or fifteen years longer, when they will be in fine maturity. The second thinning will be of much more value than the first; upon an average, no doubt but they will be worth half a crown a tree at least, as they will be tall and large, and may be put to divers uses. Many of them will be very proper for masts for small vessels, as the wood is light and tough.

"In twelve or fifteen years more, the remaining five hundred trees will be very tall and large, perhaps above sixty feet high, and five or six feet in circumference. The least value one may conceive must be twenty shilling a tree; so that, at the lowest profit one can set upon the produce of an acre of land, planted with this noble willow, in about thirty years at most, it will be worth six hundred pounds, and all the rent, &c. paid at the rate of twenty shillings a year. I really think I have allowed too low prices for the growth, and that it is very probable they will be worth more. The wood of this tree is very white and tough, and without pith or sap; so must be very proper for carvers, turners, &c. Boards of this wood are as good for floors, or wainscoting common rooms, as any other. I am told, by a man of great veracity and judgment, that posts of this wood, set in the ground, will outlast all other sorts, except yew, or heart of oak. He also affirms, that there is no tree upon the earth so proper for ships masts as this, as it is light and tough, and will not splinter, as fir does.

"This tree has oblong, pointed, saw-edged leaves, of a most refreshing light green: at the bottom of each footstalk grow two small wings, which almost environ the young shoots.

"This willow will thrive upon almost any soil, so it be not too dry.

"It is also the best kind to plant, in large sets, by the sides of rills, &c. where they will produce larger lopping, and in less time than any other sort of willow will do.

"If any gentlemen, &c. have a mind to make plantations of this profitable tree, it would be well worth their while to lay out the ground in some gentle meander-walks; which will be but little extraordinary expence, and, in few years, will give both shade and shelter.

"This willow will make the most profitable coppice woods, to cut every six or eight years, for hop poles, and many other very useful purposes.

"They should at first be planted about two feet and a half a part; and, after five or six years, three parts in four should be dug up, and the remainder cut down within six or eight inches of the ground, to remain for stubs.

"This is also one of the best sorts of willow for basket-makers, as it grows freely, and is very tough.

"In many countries, where firing is scarce, this willow would turn to great advantage, merely for fuel; as it will grow into large billets, in three or four years, and will burn very well both green and dry.

"Since I wrote this, a gentleman told me, that he knew of three willow-trees being sold for fifteen pounds, but he could not inform me what kind they were; I fancy them to be the bright swallow-tail willow; for, next to the Norfolk kind, it is the largest growing sort; and best for most uses."

Mr. North calls this the Norfolk willow; but that is only a local name for this tree. It is by some called the Hertfordshire willow, and has had various other names in different places. The description he has given of the leaves, and the firm sound texture of the wood, without pith or sap, will, however, sufficiently ascertain the species to those who may not before know it. When he published this account, he advertised, that he would furnish sets to any who might want them. As he is very lately dead, who may be his successors in his business, or whether they will continue to provide for the demand of sets, we are at present ignorant. But it would be a matter of regret, that the difficulty of procuring them, should be any discouragement to those who may be disposed to make plantations of this tree.

There is an addition, which might be made to Mr. North's plan of deriving an intermediate profit from a plantation of these trees, while the principal of them are growing to due maturity. It is this, to leave at the second thinning one tree in the middle of every four, that are intended to grow to maturity; which middle tree will consequently be at more than six feet distance from any other, being in the diagonal line of the four. The trees so left should be then cut down, within six or eight inches of the ground, and suffered to shoot afterwards as stubs or pollards. In which state they will afford hop-poles, billets, twigs, for basket-work, &c. if cut at proper periods, from seven years to every other year, respectively to the purposes, for which the shoots may be wanted. This kind of plantation, of pollards, with tall trees, is not so proper in a drier, as in a moist situation; because the crouding the roots may, in dry seasons, injure the growth of the trees intended to stand for wood, where there is a want of moisture in the ground. But in a wet soil, it will rather assist than retard them; and will be a constant source of profit during the whole continuance of the plantation.

Other trees may be treated in the same manner, allowing for the respective differences of each, with very great advantage, in swampy and marshy ground, as in the low parts of meadows, or the waste of manors; and the plantations will often prove a beauty and convenience in other respects. In such cases the twenty shillings per year, allowed for rent in Mr. North's account, may be wholly or mostly saved.

WIND-GALL, a flatulent swelling which yields to the pressure of the finger, and recovers its shape on the removal thereof: the tumor is visible to the eye, and often seated on both sides of the back sinew, above the fetlocks, on the fore-legs; but most frequently on the hind legs; though they are met with in various parts of the body, wherever membranes can be so separated, that a quantity of air and serosities may be included within their duplicatures.

When they appear near the joints and tendons, they are generally caused by strains, or bruises on the sinews, or the sheath that covers them; which by being over-stretched, have some of their fibres ruptured; whence probably may

may ouze out that fluid which is commonly found with the included air: though where these swellings shew themselves in the interstices of large muscles, which appear blown up like bladders, air alone is the chief fluid; and these may safely be opened, and treated as a common wound.

On the first appearance of wind-galls, their cure should be attempted by restringents and bandage; for which purpose let the swelling be bathed twice a day with vinegar, or verjuice alone, or let the part be fomented with a decoction of oak bark, pomegranate, and allum boiled in verjuice, binding over it, with a rowler, a woollen cloth soaked in the same. Some for this purpose use red wine lees, others curriers shavings wetted with the same, or vinegar, bracing the part up with a firm bandage.

If this method, after a proper trial, should not be found to succeed, authors have advised the swelling to be pierced with an awl, or opened with a knife; but mild blistering has in general the preference given to these methods; the including fluids being thereby drawn off, the impacted air dispersed, and the tumor gradually diminished. A little of the blistering ointment should be laid on every other day for a week, which brings on a plentiful discharge, but generally in a few days is dried up, when the horse may be put to his usual work; and the blistering ointment renewed in that manner once a month or oftener, as the horse can be spared from business, till the cure is compleated. This is the only method to prevent scars, which firing of course leaves behind, and unless skilfully executed, too often likewise a fullness on the joint, with stiffness; the mild blistering ointment, where the sublimate is left out, is the properest for this purpose. *Bartlet's Farriery, p.* 276.

WIND-ROW, the green parts, or borders of a field, dug up, in order to carry the earth on the land to mend it; so called because it is laid in rows, and exposed to the wind.

WINE, a general name given to any brisk, agreeable cordial liquor drawn from vegetable bodies, and fermented, particularly that procured from the juice of the grape. *See the article* FERMENTATION.

One and the same kind of grape proves greatly different in taste and flavour, according to the climate and exposure to the sun. In cold countries the vine, if it grows at all, never ripens its fruit; and even in France and Italy it is constantly observed, that the grapes produced on the south sides of hills are notably sweeter than those which grow on plane grounds. Among the Tockay wine-hills, there is but one which directly fronts the south, and the advantage of it's situation are not a little remarkable: from the extraordinary sweetness of its grapes, it is called the sugar-hill. It affords the most delicious of all the Hungarian wines, and is appropriated to the use of the imperial family.

In very warm dry seasons, the grapes at the bottoms of the hills are best; in warm and moist ones, those at the top; such as grow in the mid-region being always good. In dry summers, the grapes are sweetest, but least juicy: in rainy ones they abound with juice, which proves proportionably weaker and more dilute. Frosts in autumn promote their ripening; but frost succeeding heavy rains makes them apt to burst and shed their juice.

The grapes in America are remarkably apt to burst; which Mr. Miller imputes, either to the too great moisture of the air in that country, or to their receiving too much nourishment from its over rich soil. But gentlemen of America think that their air, except in marshy places, is drier than ours; and are therefore of opinion, that the bursting of their grapes is not owing to the too great moisture of the air. If it proceeds from too much nourishment, the remedy would seem to be easy, by training up a great number of branches to consume that nourishment. Others, perhaps with more reason, impute their bursting to their ripening too early, while the heavy rains, frequent in autumn, continue to fall. In this case, they may be raised against lofty trees, as was the method of the ancient Romans, and as still is the practice in many parts of Languedoc and Provence. The reflection of the heat, from the earth, would then be less, and the leaves of the trees would shelter the grapes from the sun. By this means, being later before they fill, they would not be so apt to burst; and as the latter end of the autumn is generally fair, they may then have an opportunity of coming to their full maturity, without the danger of bursting. Or if it be thought more advisable to quicken their ripening, the warmest soil and situation should be chosen for the vines, and they should be kept low.

A due degree of maturity is essentially necessary in every kind of fruit, the juice of which is to be made into wine; because the juice of unripe fruit is a rough acid liquor, which cannot be made to undergo a vinous fermentation, without great difficulty. In some instances, as in verjuice, it will remain in the same state for years together. Nor is there less danger from the fruit's being over ripe; because the least taint or putrefaction will, as before observed, run through the whole process of the wine, in spite of every art that can be used to correct or remove it.

When a considerable portion of the grapes have attained their full maturity, these should be gathered with great skill and care; leaving the unripe for a future gathering. Most vintagers make it an almost general rule, to gather their grapes at a certain stated time, according to the custom of the country, without attending to their various degrees of ripeness; therein imitating other rustics, who seldom vary their operations as the seasons vary. Thus, in some countries they make it a general rule to gather their grapes when dry; and in others they as carefully gather them when they are wet with dew. In both, the circumstances of the seasons should perhaps vary this custom: for example, when a warm kindly season has brought the grapes to a due maturity, such juice wants no addition; and if, on the other hand, the dryness of the season should have thickened their juice too much, the dew may remedy that defect. If a cold or rainy season has prevented their ripening thoroughly, and they still continue in an acid watery state, surely the warmest and driest hours should be chosen for gathering them.

In some places, the grape is concentrated or rendered richer, by suffering it to remain on the tree till great part of its watery moisture has exhaled; the stem of each cluster being cut half through, when the fruit is ripe, to prevent the afflux of any fresh juice, from the plant. The sweet Hungarian and Spanish wines are made from grapes that have been thus half dried.

In order to make good wine, the grapes of the same vine should be gathered at three different times. The first gathering should consist of the ripest, finest and most open bunches. They should be cut as close as possible to the fruit, the better to avoid the austere sharpness and bitterness of the stalk, and all their rotten or green berries be carefully picked off, or rather cut off with a pair of sharp scissars. Some are even so nice as to cut off the grapes at the end of the bunches, because they are always weaker in quality, as well as less ripe, than those which grow higher up on the stalk. By this means, they indeed diminish the quantity of their wine; but what they do make, is thereby vastly improved. An inferior wine is, however, made of the grapes that are so cut off. This practice is, indeed, attended with some trouble; but it answers extremely well, and deserves to be much recommended, as a means of obtaining at least some good wine, in years when, and places where, the grapes do not ripen perfectly. The second gathering should be of the large, close, and less ripe bunches; for close bunches never ripen thoroughly: and the third will of course consist of the refuse of the former gatherings; but no rotten grapes should ever be mixed with either. Each of these three cuttings should be pressed separately. It is highly necessary always to employ a sufficient number of gatherers, each of which should be provided with a basket and knife, and should lay the bunches, as fast as they are cut, gently in the baskets, without bruising or squeezing them: for the more expeditiously they are gathered, the finer will be the colour of the wine; and the sooner they are pressed the better will be its quality. Women are most commonly employed for gathering the grapes, because their labour is cheaper than that of men, and this does not require any great exertion of strength.

This first work, which is of the utmost importance to the making of good wine, may be still more completely performed by duly attending to the following circumstance. The fruits of different vineyards are of different qualities: some,

ſome, ſituated on very light and ſtony land, yield exceedingly delicate and high flavoured wine, which ſeldom is ſtrong; whilſt the grapes of vines growing on a richer ſoil, where they receive more nouriſhment, afford a wine which has more body. Both theſe good qualities may be united in the ſame wine, either by mixing the grapes of the different growths before they are preſſed, or by mixing the different wines that have been obtained from them: but the ſureſt way is to mix the grapes, becauſe it is thought that theſe liquors do not eaſily incorporate perfectly after they are made: the weakeſt of them is ſaid to change its colour, and to communicate its defects to the other, inſtead of being mended by the ſuperior quality of that with which it is blended: ſo that, according to many who pretend to have had long experience in theſe matters, the leaſt evil, and that leaſt is a very great one, which can ariſe from thence, is a cloudineſs in the liquor, a ſort of floating lees which will always tarniſh the beauty of its colour, ſpoil the perfection of its taſte, and prevent its ever becoming perfectly bright. This does not happen when the perfect grapes of one vineyard are mixed with the perfect grapes of another: for, from the juices of theſe different fruits preſſed out and fermented together, proceeds an exquiſite, ſound, delicate, fragant, and bright coloured liquor, which will keep ſeveral years without the leaſt alteration. It is by a knowledge of the good effects produced by a judicious mixture of the grapes of three or four vineyards of different qualities, that the celebrated Champagne wines of Silleri, Aï, and Hautvilliers, have been brought to the perfection for which they are ſo famed. Every thing that can delight the palate ſeems to be united in them. But this knowledge can be acquired only by many repeated trials and long experience.

One of the ways of making wine in the higheſt perfection of which it is ſuſceptible, is to ſtrip the grapes from off their ſtalks before they are thrown into the vat. By this means all the auſtere roughneſs which the ſtalks would communicate to the liquor is guarded againſt, and the muſt may be ſuffered to ferment, without danger, till the fermentation has ſufficiently opened the body of the fruit. The wine which is thus obtained is the melloweſt, beſt coloured, ſoundeſt, and fitteſt for keeping.

The above directions for gathering and ſorting the grapes are equally proper, whether white wine is to be made, or red; for either of theſe differently coloured wines may be, and generally is, obtained from the ſame grapes, that is to ſay, from black ones. As to the white wine which white grapes yield, it ſeldom has much ſtrength or flavour, ſoon grows yellow, and, for want of body, rarely keeps well even till the next ſummer. All the white wines of Champagne, which look as bright and as clear as cryſtal, are made from the blackeſt grapes, and never preſerve their colour better than when all the plants of white grapes have been rooted out of the vineyard. Formerly, the wine of Aï would hardly keep a year; the thin ſweet juice of the white grapes, of which the quantity was great in the vineyards of that diſtrict, turning yellow, gained the aſcendant, and altered the whole maſs of the wine. But ſince white grapes have been no longer uſed in the white Champagne wines, that of the mountain of Reims laſts ſeven or eight years, and that of the river Marne keeps well for four or five.

The wine of black grapes may be made of almoſt any depth of colour that one pleaſes. They who deſire to have it perfectly white, proceed thus. The gatherers go into the vineyard very early in the morning, and ſelect the fineſt bunches, which they cut as cloſe as poſſible to the fruit, then lay them gently in their ſmall hand baſkets, and when theſe begin to be full, put them, ſtill as gently as can be, into panniers, commonly called dorſers, in which men or women carry them, with the greateſt care not to tumble or bruiſe them in the leaſt, to the end of the vineyard, where they are put carefully into large panniers, with all their bloom, or azure, as it is technically termed, and all the dew upon them. This dew increaſes greatly the quantity of the wine; but at the ſame time it weakens it conſiderably.

If the ſun begins to be a little powerful, the vintagers ſpread wet cloths over the baſkets, whether dorſers or panniers; becauſe, if the grapes ſhould be heated, the liquor drawn from them would be apt to contract a reddiſh teint. If the place where they are to be preſſed is not far from the vineyard, men or women carry the dorſers gently on their backs to the preſs; but if the diſtance is conſiderable, the panniers, into which the grapes are in that caſe put, are loaded upon quiet eaſy going beaſts, which carry them ſlowly, and without ſhaking, to the cellar, where they remain covered and cool. When the heat of the ſun is but moderate, the vintagers continue their work ſafely till eleven o'clock: but when it ſhines ſtrongly, they leave off at nine.

For the making of white wine, of which we now ſpeak, the grapes are thrown, as faſt as the panniers arrive with them, not into the vat, as would be done for red wine, but into the preſs, of whatever form it be, and the firſt preſſing is given immediately. The wine which runs from this preſſing is the moſt delicate of any. The French call it *vin de goutte*, becauſe it rather drops than runs, as but little force is uſed in preſſing it. After this firſt preſſing, which is but gentle, for fear of diſcolouring the liquor, the preſs is raiſed, the ſcattered grapes are thrown up upon the cake, and the ſecond preſſing, called the turning up *(la retrouſſe)* is given. Here the preſs is ſcrewed down with much greater force than before, and if this ſecond running is not quite ſo plentiful as the firſt, though it ſometimes is more ſo, it is at leaſt but little inferior to it in flavour or colour, and preferable in this, that it has a ſtronger body, and will keep a conſiderably longer time. The wine of the firſt preſſing is, however, always ſet apart, if it has been drawn from quite ripe grapes and in very warm weather; becauſe the juice of the fruit then runs very plentifully, and there might be danger of reddening it by mixing it with that of the ſecond preſſing: but this mixing of them is uſeful, and ſometimes neceſſary, on account of the greater ſtrength of the ſecond running when the year is not a warm one, and when the firſt preſſing has not yielded plentifully.

After the two firſt preſſings, the ſides of the cake of grapes are cut down perpendicularly, with a ſteel ſpade, ſo far as they exceed the breadth of the upper part of the preſs which is let down upon the fruit; the grapes thereby ſeparated are thrown up on the top of the cake; and the third preſſing, commonly called the firſt cutting, is given. The juices of this firſt cutting are excellent, to make a perfect liquor; and they may alſo be added to the red wine, if any of this is made ſeparately. A fourth preſſing, a fifth, and ſo on of others, which are called the ſecond, third, and fourth cutting, are given after this; the ſides of the cake being cut down and thrown up each time, till the grapes ceaſe to yield any more juice. The liquor of the cuttings becomes gradually more and more red, becauſe the action of the preſs becomes more and more forcible upon the thin ſkin which envelops the berry, and the particles detached from thence are what render the wine red. Sometimes too the heat of the ſun, or the ſhaking of the fruit in the carriage, are ſo great, and act ſo powerfully upon the outſide of the grapes, that the tinging particles which are in the ſkin of the berries, being let looſe, mix immediately with the juice of the grape at the very firſt preſſing, and then a perfectly white wine cannot be made; but it will be of the colour of a partrige's eye, or even deeper. The wine itſelf is not, in fact, at all the worſe for this: but the faſhion is to have it either perfectly white, or of a full bright red.

The wines of theſe different cuttings (as the latter preſſings are called) are collected ſeparately, and afterwards mixed according as they contain more or leſs of the quality that is wanted. Thoſe who have many grapes preſs them at two, three, or even four different times, and collect each of the runnings ſeparately. For the firſt they conſtantly chooſe the moſt perfect grapes, and this wine is always worth a third part more than the ſecond, and ſo on in proportion.

It is eſſential to obſerve that the preſſings for white wine, if it be wiſhed to have it very pale, ſhould be performed as quick as poſſible one after the other, in order that the grapes may not have time to heat, nor the liquor remain long upon the murk. Particular attention ſhould be paid to this for the two firſt runnings, becauſe they yield the fineſt wine.

Of the ſame black grapes, namely the black morillons, the pineaus, and the Auvernats, with which we have ſeen that

that white wine is made in Champagne, red wine is made in Burgundy; and indeed the same has, of late years, been attempted also in Champagne, with no bad success; though not so as by any means to equal the fine white wines of that country, or the best red wines of Burgundy.

As much as the heat of the sun is avoided by the vintagers who make white wine, so much it is sought after and wished for by those who make red wine. These always choose to gather their grapes when the sun shines hottest; because they find that its action upon the outside of the berries produces more effect than several days steeping in the vat would do; for that the grapes then ferment very speedily. As to the rest, the cautions before directed for gathering the grapes for white wine, in regard to their ripeness, the sorting of them, cutting the bunches off with as short stalks as possible, clearing them of all damaged, rotten, and unripe berries, &c. should be equally observed here. Some express the juice of these grapes in the open air, either in the vineyard itself, or close to it, by throwing the bunches into large tubs, and there mashing or bruising them to pieces, with sticks, or by putting children into the tubs to tread out their juice. Others carry them home, with care not to bruise them by the way, and put them in a vat, in which they are trodden and mashed. This, in either of these cases, is repeated till the vessel is full; and after that the broken grapes are let lie in their liquor more or less time, according to the heat of the weather, the flavour of the must, and the degree of colour that is intended to be given to the wine. During this time, the whole must be frequently stirred together, the better to raise a fermentation, and tinge the liquor with a due degree of red; for it is known by experience, that the redness of wine proceeds from the more or less intimate mixture of the colouring which is in the skin of the grape, with the juice which is contained in the pulpy body of the berry. It is, in fact, chiefly to give this dye to the wine, that the trodden grapes are let lie to ferment in the tub or vat before they are pressed.

Some advise, as a general rule for all red wines, to let the grapes lie in their liquor forty-eight hours; whilst others, going on in the beaten track of their forefathers, without daring even to suspect that there may possibly be errors in the stated practice of their country, talk of letting the grapes infuse during seven or eight days, or even longer, and act accordingly: but the authors of the Maisons Rustique, who seem to have taken their directions from more judicious and more accurate observations, say positively, that the duration of this infusion of the husks should be proportioned, not only to the heat of the weather, but also to the natural quality of the grapes, and to the usual, or intended colour of the wine that is to be made. Thus, for the Coulange wine, which is one of the most esteemed growths of Burgundy, only four hours, or at most five, are allowed for the steeping of the husks, unless the weather be chilly and rainy, in which case they are sometimes suffered to remain all night in the liquor. This is likewise, now, the practice of the best vintagers throughout the whole province of Burgundy, in most parts of that of Orleans, and, in short, in almost every part of France where the finest, highest flavoured, and most spirituous red wines are made: and the reasons for it are, that this time is found to be sufficient to give the wine a duly deep colour; that it is apt to contract a roughness from the stalks if it remains too long upon them (to guard against which, as much as can be, care is taken to pull the stalks out with the rake, or stick, with which the must is stirred in the tubs or vat, whilst others, more cautious, pick the grapes from off them before it is trodden out); and also, because too much fermenting of the must always renders the wine harsh and coarse, deprives it of its most volatile parts, and the quantity of the must is considerably diminished by the loss of what flies off, or is otherwise wasted in the fermentation. Others again make it a rule not to draw off their must till its head begins to fall. But in this they are evidently wrong; because a great part of the most active spirits of the liquor is certainly evaporated thereby. It may indeed be true, and probably is, that the liquor which has lain long upon the murk acquires the most strength, and is therefore fittest for keeping: but at the same time it also acquires a roughness and bitterness of taste, communicated from the stones and stalks of the grapes, which are far from rendering it the more palatable.

Might not the surest way of judging when the liquor has lain a sufficient time upon the bruised grapes be, to thrust one's hand pretty deep into the vat, to take from thence a handful of the murk, and to smell to it, as the dyers do, to judge of the disposition of their vats? One might then, perhaps, especially with the help of some experience, know pretty exactly whether the liquor be sufficiently concocted, and whether it has acquired colour enough. If it smells sweet, it should be let work a little longer in the vat; at least till it has lost that smell, and has acquired so strong a scent as to affect the nose. Then may probably be the right time for drawing it off. A good bodied wine will never taste of the grape stone, if it be taken in its proper degree of the vat; but it will keep sound for many years, and be always fit to drink.

To the different ways of managing the must is certainly owing, in a great measure at least, that some people make much better wine than others from grapes of the very same sort, of equal ripeness, and of the growth of equally good and well situated vineyards. Indeed, for thicker, heavier, and coarser wines, than those of either Burgundy or Orleans, of which, chiefly, we have now been speaking; such, for example, as the Bourdeaux claret, of which we are so fond in this country, and of which the French themselves do not drink any at home, a whole day is frequently allowed for the steeping of the husks, and sometimes more, before the press is recurred to. But as to the rule of letting the grapes lie to steep in their liquor forty-eight hours, and much less the longer time which some recommend and practice; we cannot, for the above reasons, think it properly applicable to any sort of wine, unless it may, perhaps, be in very cold unfavourable weather, or for such thick, heavy, dark coloured, and very heady wines, as those of Oporto, which, as is well known, are scarcely drinkable even here, till age has depurated them and softened their natural roughness. It is true, that wine which has fermented long upon the murk may always be best for keeping; but it will never be the most pleasing to drink.

We consequently do not approve of this part of the method of making red wine in Chianti, from whence we may probably judge of the general practice in Italy. When the grapes there are of a due ripeness, and the weather warm and dry, they are cut as soon as the sun or wind has dried up the dew that was on them, and are put into little barrels, commonly called piggins, in which they are carried to the wine vat, on mules if it be distant, but between two men if it be near. They are then bruised to mash in those barrels with a club, and thrown directly into the vat, or else into a kind of very large hopper placed over the vat, with a grate lengthwise, through which the juice, husks, stones, and stalks all pass into the vat, upon their being trodden; and this is continued till the vat is full; when immediately, or sometimes even hours before it is full, the must thus made ferments. By this means the husks, stalks, and stones are thrown up to the top of the liquor, where they form a thick crust; and this ebullition, which will continue for many days if the liquor be strong, for its duration depends on the strength of the must as well as on the temperature of the air, is suffered to proceed till the wine is judged to be fit for drawing off. This fitness is determined by the palate; and herein consists the greatest skill in the art of making wine. Old practitioners know precisely, by the colour, smell, and taste of the must, the exact time that best suits their method of proceeding: but it cannot be learnt without great attention, and long experience. The wines of the plains are generally deemed ready for tunning in about ten days, those of the hills in about fifteen, and those of the mountains in Chianti in about eighteen or twenty, or sometimes more; for in this way of proceeding, the weather has always a very great influence on the ripening of the must. When it is judged to be near ready for tunning, those who are skilled in those matters taste it every eight hours. The longer the ebullition is continued, the drier and deeper coloured will the wine be; and the less it is continued, the sweeter and paler will be the liquor.

The vats are proportioned to the quantity of wine that is to be made at one preffing, and there frequently are feveral of them in the fame vineyard; for the Italians prefs all their red grapes in the open air. The vats on which the hoppers are fet are covered with boards, and a coarfe linnen cloth, the better to prevent the evaporating of the wine, and other accidents.

When the Italians make their ftrong white wines, or mufcadines, they gather their grapes carefully, and lay them in the fun for three or four days, or more; always houfing them at night, or at leaft covering them then fo that no dew may fall on them. They call the ebullition which thefe undergo in the vat a fhort one, becaufe it does not exceed five or fix days; after which they tun up the wine, and fhift it twice or thrice from one cafk to another, to make it become fine. As to the Verdea or white Florence, as it is called, they draw it off from the vat almoft as foon as an ebullition begins to rife in it, and has thrown up the hufks, ftones, &c. fo as to form a cruft at top. They then let the ebullition continue for a day and a half, or at moft two days, in the cafk into which it has been drawn, from which they afterwards fhift it into another, and in a few hours more into a third and fourth, to check and prevent the fermentation. By this means it is made to retain that fweetnefs which the ladies in moft countries are fond of: but wine thus managed never is perfectly fine.

When the muft has fermented upon the hufks of the grapes in the tubs, or vats, as long as is thought proper, it is poured off from the former into other veffels, and drawn off from the latter by means of a brafs cock placed about three or four inches above the bottom of the vat, from whence it runs into a receiver, which, as well as that under the prefs, generally is a very large cafk, open at one end, and placed upright directly underneath the cock or channel through which the liquor flows. A bundle of pretty clofe-tied twigs, commonly of vine cuttings, or of the haulm of afparagus run up to feed, is placed within the vat, before the grapes are put into it to be trodden, clofe to the entrance of the cock, to prevent the hufks from running into it fo as to choak it up; and a large ftone or two is laid upon this bundle, to keep it down. Befides this precaution to retain the hufks, &c. of the grapes, and prevent their mixing with the liquor that is drawn off, fome, for greater fecurity, let their muft run from the cock through a fieve, into the receiver, from whence (as alfo from the abovementioned tubs, in the ufing of which the fame precaution of keeping back the hufks, &c. is carefully obferved when the liquor is poured out of one into another), it is laded by hand, in bowls, jugs, jets, or pails, and poured into the cafks, through pewter funnels.

After the muft has been thus poured or drawn off, the murk, that is to fay, the remainder of the grapes at the bottom of the tubs or vat, is collected together and put into the prefs, where it is fqueezed very hard, three or four times, in fhort, till it is perfectly dry, its fides being cut down each time, and thrown up, as before directed for the latter preffings of the grapes; and the liquor obtained from thence, efpecially if the prefs be fcrewed fo tight as to crack the feeds of the grapes, has a ftronger body than any of the preceding runnings, but not any part of their fine, high, or delicate flavour. Some, however, mix a little of it with their other wines, to ftrengthen them, and thereby make them keep the better: but certainly not to mend their tafte.

Others, in whom the fpirit of oeconomy is very prevalent, pour as much water as they think proper upon the murk in the vat, immediately after the muft has been drawn off. They do this immediately, for fear of the murk's turning four, as it would be very apt to do, if they fhould wait longer. They then ftir it about, and leave it upon the murk a longer or fhorter time, according to the heat of the weather, till they find it pretty highly coloured, and judge that it has incorporated all the remaining particles and fpirit of the wine. They then draw this water off into another veffel, and carry the remaining murk to the prefs, where they fqueeze it till not a drop of moifture remains in it. The liquor thus extracted is mixed with that which was drawn off before, and is then barrelled. This is principally intended for common ufe, or rather for fervants: but it muft be drank in the enfuing winter; for it will turn four by the next fummer. It is brifk and pleafant enough whilft it lafts good, and is much preferable to water cyder; though not equal to the refufe wine, as it is called, of which a vat, or more, is generally made by itfelf, of the damaged, rotten, or unripe black grapes that were left at the laft gathering, as not being fit for the finer wines.

Another ufe too which the French make of the murk of their grapes after the muft has been drawn off from the vat, is, to amend fuch of their wines, whether red or white, old or new, as are deficient in colour or ftrength. To this end, they empty them out of their cafks into the vat, immediately after the muft has been drawn off, ftir the murk up fo as to mix it thoroughly with them, and then let them remain upon it, at moft twenty-four hours if it be new-wine, and twelve hours if it be old. When they find that it has taken a fufficient degree of colour, and that it is not fweet to the tafte, but agreeable to drink, they draw it off, barrel it up feparately, in order to know it again, and then put the remaining murk in the prefs, where it is fqueezed as dry as poffible.

As to the white grapes that were rejected at the former gatherings, they are let hang upon the vines till the latter end of October or beginning of November, that they may be a little bitten by the froft. They are then gathered, and a wine is made of them which is fold quite warm from the vat, and does well enough to mix with coarfe red wine.

The newly preffed murk of grapes foon contracts a heat; and as it contains many fpirituous parts, it is then ufed as an effectual remedy for rheumatic pains, ftiffnefs of the joints, and numbnefs of the limbs. The way of applying it is, to bury the part affected under a heap of fermenting murk.

By the time that the murk has undergone the utmoft dint of preffing, it will be as hard as a ftone: but even then it will yield, when diluted with water, fermented, and diftilled, a fpirit which has its medicinal, as well as domeftic, ufes. Or it makes a good manure for land; particularly, fay fome, for vines and for afparagus.

The too great propenfity to fermentation in hot countries has laid the inhabitants of thofe parts under the neceffity of ufing means to retard it: but the method which they practice for this purpofe renders their wines, as Dr. Neumann juftly obferves, fcarcely deferving of that name; becaufe they hardly undergo any degree of fermentation at all, and are, in fact, no better than boiled muft. Several of the Italian wines are of this fort, and are called by the general name of *vino cotto*, "boiled wine." It is to thin watery juices, extremely prone to ferment, and in which fermentation, when once begun, can fcarcely be fuppreffed till it has run beyond the vinous ftate, that the procefs of boiling over a fire is applied. The fermentative quality is thereby reftrained, and the liquor becomes richer, and continues fit for drinking at leaft a year or two, though it is never fo wholfome as the fermented wines. The effects of muft and of wine upon animal bodies are diametrically oppofite: for muft relaxes and liquefies, and, if drank immoderately, is apt to produce dangerous fluxes; whereas perfect wine, on the contrary, corroborates and conftringes. This the doctor reckons the firft of three claffes into which he very properly divides wine, with refpect to its fermentation.

The fecond clafs comprehends thofe wines which have undergone fermentation, but not a complete one. Of thefe there are two kinds. The firft is the thin fweet wines; which are no other than muft partially fermented, or whofe fermentation is checked, while it can be checked, before the fweetnefs has gone off. Thefe wines can fcarcely be kept above a year. Such as the Tyrol, fome of the Savoy, and feveral of the Italian. The fecond fort is the ftrong, full-bodied, rich, fweet wines, which are generally a mixture of fermented and infpiffated muft; the latter being added to increafe the richnefs of the liquor, and prevent the fermentation from running beyond its due limits. Thefe kinds of wines greatly heat the conftitution, and ought to be very fparingly drank: fuch are Malmfey, Canary, and fome of the Spanifh and Hungarian wines.

To the third claſs belong thoſe wines which have been completely fermented, and have thrown off their groſs matter. Theſe are the moſt perfect wines, and for common uſe the moſt wholſome.

In cold countries, where, for want of the ſun's having force enough to mellow and enrich the juice of the grape, the muſt is thin and poor; ſugar, or dried grapes, ſhould be added to the muſt, to give it a body. Authors name a variety of other ingredients for this purpoſe; but they are uſeful only as they contain a ſaccharine ſubſtance. It is therefore moſt adviſable to uſe good ſugar, which requires no other care than diſſolving it in the juice in the proportion deſired, or found to be wanted. If part of the juice is evaporated by fire, as is ſometimes practiſed, a ferment muſt be added, to make up for the inaptitude to ferment, which experience has ſhewn to be in all juices that have been boiled.

When we here adviſe the adding of ſugar, in particular, we do it on a ſuppoſition of its being the ſubſtance moſt eaſily come at; and alſo becauſe it has been proved by ſome late experiments, that all juices are more or leſs fermentable in proportion to the quantity of ſaccharine matter contained in them.

If the juice is ſo ſour that it will not ferment kindly, no alkaline ſalts ſhould be recurred to, though greatly recommended by ſeveral authors; becauſe they raiſe ſo ſtrong an effervescence, that they deprive the liquor of much of its moſt volatile and active principles, and thereby leave it vapid. Inſtead of theſe, ſuch calcarious ſubſtances as will give the leaſt taſte to the liquor, or diſſolve the leaſt in it, ſhould be preferred. Such are, extremely well cleaned oyſter or other ſhells, and hard lime-ſtone or marble reduced to powder. Theſe ſhould not be calcined or burnt; becauſe they would then communicate a diſagreeable taſte to the liquor, and be beſides attended with the diſadvantage of raiſing too great an effervescence. Next to theſe, chalk bids the faireſt to anſwer the deſired end. But a caution neceſſary to be obſerved when theſe or any other ſuch like ſubſtances are uſed, is, that the too great acidity of the liquor ſhould be only leſſened; for a certain degree of acidity is eſſentially neceſſary in all wines. If the juice is otherwiſe rich in ſubſtance, and faulty only in being too acid, warmth alone has, in many inſtances, been found to be a ſufficient cure. Madeira, for example, is always harſh, till it has been mellowed by heat: and thus again, ſome gentlemen in England and America, when the juice of their grapes has not fermented kindly, have obtained a very good wine by expoſing the containing veſſels, in a warm ſituation, to the ſun, with an intention of turning it to vinegar. Chemiſts know that all vegetable acids are volatile in certain degrees of heat; and it is highly probable that the effect of this ſummer expoſure may be the evaporation of the acid, and thereby the converſion of the whole into a mild vinous fluid. Inſtances are not wanting, of the roughest verjuice being turned to a ſtrong pleaſant cider, or vinous fluid, by means of a warm ſituation accidentally given it. Habit has made a gently acid even deſirable in ſome wines, as in rheniſh.

In ſeveral parts of Germany where the grapes ſeldom come to full maturity, and are therefore gathered ſomewhat green, the makers of wine have iron ſtoves in their cellars, and keep in them a conſtant fire, at leaſt during the time of fermentation. This, by heightening the fermentation, ripens and meliorates the wines, and renders them much more palatable and agreeable than they would otherwiſe be. We have already ſeen that keeping the wines in places conſiderably warmed either by the ſun, or by fire, will have the ſame effect, even ſo late as in the ſummer after the vintage: for acid liquors remain long without either fermenting thoroughly, or putrifying.

As the wines drawn from the laſt gathering of the grapes cannot be ſo perfect as the others, for want of due maturity in the fruit, the people of Champagne and Burgundy have recourſe to the following method, to accelerate their ripening. When the wines have been about three weeks in the caſks, and have been drawn off their firſt lees, they roll them up and down for ſome time, five or ſix times a day, for four or five days running; then two or three times a day, for three or four days; and afterwards twice a day, for about four days; then once a day, for about a week; and after that, once in four or five days. If the grapes were gathered very green, the rolling in this manner is continued, in all, for about five or ſix weeks: but if they were tolerably ripe when gathered, rolling once in four or five days, for about a month or ſix weeks, is found to be ſufficient. This rolling of the liquor in the caſks is intended to ſupply the defect of its firſt fermentation.

It now appears evidently, from the foregoing account of the practice of making wines in hot and cold countries, that a means to counteract the inconveniences of the climate is wanting in each. If they had proper cellars and vaults, as before obſerved, the too quick and too great fermentation in hot countries might be reſtrained and kept within due bounds; and a proper degree of heat during the fermentation in a cold country, might give the juice that rich mellowneſs which the too weak ſun could not.

The new wines will generally ferment of themſelves, within a few days after they have been put into the caſks. Thoſe that do not ſhould be helped, by putting into them a little of the froth, or yeaſt, which works from the others. The fineſt wines will ferment the ſooneſt: and this fermentation will continue for about ten or twelve days, according to the ſort of the wine, and the ſeaſon of the year.

While the wine ferments, the bung-hole of the caſk muſt be left open, or only covered with a thin linen cloth, to prevent any dirt from falling in: and this cloth ſhould be laid hollow, ſo that the froth ariſing from the fermentation may have room to work off.

When the fermentation is pretty well over, which is known by the froth's ceaſing to riſe ſo faſt as before, the bung may be cloſed down, after filling up the caſk with liquor to within two inches of the top; and a vent-hole ſhould then be opened and left, to carry off whatever may be thrown up by any ſubſequent fermentation. This filling up of the caſk to within two inches of the vent-hole ſhould be regularly performed every two days, for about ten or twelve days running: for the fermentation will continue a conſiderable time, though in a leſs degree; and if the caſks are not kept ſo full as that the foulneſs thrown up by the fermentation may be carried off at the vent-hole, it will fall back again into the wine, and prevent its becoming clear. After filling up each caſk in this manner to within two inches of the bung, for about ten or twelve days, it muſt be filled up to within an inch every fifth or ſixth day, for the ſpace of a month; after which, once a fortnight will be ſufficient during the next three months.

Though the fermentation will be over long before this laſt mentioned time, yet the caſks muſt be filled up once a month ſo long as they remain in the cellar: for as the wine will waſte inſenſibly in them, it will grow flat and heavy, if they are not kept conſtantly filled up. It were needleſs to ſay, that the vent-holes muſt be ſtopped when the fermentation is over.

About the middle of December, the wines may be drawn off from their lees into freſh caſks, for the firſt time; taking care to fill the caſks up, and to place them ſo that they may not be ſhaken or diſturbed until the middle of February, when it will be right to draw them off again into other caſks. If the quantity of lees is then found to be ſo conſiderable as to endanger their contracting a putrid taint by remaining too long mixed with the wine, it may be adviſable to draw it off again after a proper interval of time; or ſometimes it may be neceſſary to repeat this racking even more frequently, though hardly ſo often as is practiſed in Champagne, viz. even twelve or thirteen times in the ſpace of four years; becauſe, though this may render the wine very clear, bright, and pleaſing to the eye, it muſt ſurely diminiſh its ſtrength, and conſequently make it be the leſs fit for keeping.

A leathern pipe, about ſix or ſeven inches in circumference, well ſewed with a double ſeam, to prevent the wine's running out, is, at the diſtance of every five or ſix feet, very tightly bound with ſtrong waxed twine around braſs rings of the ſame dimenſions, made to ſcrew into other rings faſtened in the ſame manner to other ſimilar pipes. The number of theſe pipes may be ſuited to whatever diſtance is found proper or neceſſary: or, when the diſtance between the caſks is always nearly the ſame, the leathern pipe may be made of one ſingle piece, with only a braſs ſcrew-ring at each of its ends. To theſe ſcrews a the extremities of the leathern pipe ſhould be fitted, ſo as to ſcrew exactly on or into them, two ſtrong braſs cocks, which are however first to be thrust as lightly as possible, by their more taper ends, the one into the usual tapping place of the cask which is to be emptied, and the other into the usual tapping place of that which is to be filled; that is to say, each of these cocks is to be firmly and closely fixed at about two or three inches above the lowest part of the head of the cask to which it is applied. It were needless to observe that these cocks must be quite strait, the better to complete the communication from one cask to the other. When every thing is thus prepared, the cocks, being duly fixed in their respective casks, are both opened, and the wine then flows naturally from the full cask into the empty one, till the liquor becomes of an equal height in each, without in the last disturbing the lees of the wine in the cask that is to be emptied. When the wine ceases to run spontaneously, the rest of it is forced out by means bellows constructed as follows.

These bellows are about three feet long, and a foot and an half broad at their widest part. They are made and shaped in the common manner to within about four inches of their smaller end, from whence the remainder of them is but three or four inches wide. In the inside of the place where their breadth is thus altered, the air passes through a hole of an inch bore; and upon this hole, on the side of it that is next the nozzle of the bellows, is a piece of leather, like the valve of a pump, so fitted that when the bellows are lifted up to take in fresh air, that valve instantly closes upon the hole, in such manner that none of the air which has passed through this hole, and entered into the cask, can be drawn back again; but the bellows take in fresh air, by their holes below.

Instead of ending with a strait nozzle like other bellows, these terminate in a tube or pipe of wood, a foot long, closely jointed into their smaller end, and there well glued and strongly fastened by good pegs, in a direction perpendicular to that of the body of the bellows, in order to its conducting the air downward. This nozzle, for such we shall now call it in compliance to custom, is round, and about nine or ten inches in circumference over its outside at the top, from whence it diminishes gradually towards its other end, the better to fit it for entering some inches in at the bung hole of the vessel, and also to close up that hole so exactly, that no air may get in, or come out, at its sides. The upper part of this nozzle rises about two inches above the level of the small end of the bellows, and is there cut somewhat flat, that it may be the more easily struck with a wooden mallet, and thereby forced the closer into the bung-hole of the cask: and also, at about two fingers breadth below the upper part of this nozzle, is nailed an iron ring, thro' which is passed an iron hook, or brace, a foot long, by means whereof the bellows are cramped down to the hoops of the cask: for without this precaution, the force of the air would drive the bellows out of the bung-hole, and the operation of emptying the broached vessel would not be performed.

It now is easy to conceive the manner in which these bellows force the remaining wine out of the cask that is to be emptied: for, upon opening the bellows, the air rushes in at the holes in their bottom; and upon shutting them, it is forced through their nozzle into the cask: the valve just above their nozzle prevents its returning back; and thus a quantity of air sufficient to counter-act the weight of the atmosphere on the wine in the cask that is to be filled, is easily forced into that which is to be emptied.

When the wine is drawn off to within about two or three gallons, a hissing is heard in the cock of the then almost empty cask. The cock in the other should then be turned, so as to close it, and the pipe of communication should be taken away. That done, all the remaining clear wine is drawn off from the cask that is to be emptied, but with great care to stop when it becomes in the least cloudy. This bright wine is then poured into the bung-hole of the cask that is to be filled, and the entire filling of it up is completed with sound wine of the same quality as that which has been drawn off. It is then closely bunged down; and when this has been done, the cock may be taken out, and a plug put in, with very little loss of wine. Or, if the owner be so curious as to desire not to lose any of his liquor, the little air necessarily left near the bung-hole may be drawn off with a small hand-air-pump, and then scarcely a drop of wine will run out when the cock is drawn.

At every racking of this kind a peg-hole is made in the cask, if there be not one before, in order to examine the degree of wasting of the wine: for wine wastes sensibly in keeping, how closely soever the cask be stopped; a part of it transpiring through the pores of the wood: but, as Dr. Neumann observes, it is not the spirituous, but the watery part that is thus lost; for the remaining wine proves stronger than at first, and the strength continues to increase as the quantity diminishes. In filling up the vessels, for it is necessary that they should be kept full, care must be taken never to mix wines of dissimilar qualities.

The Hungarian, for example, does not well bear any other wine, particular rhenish: for if the spontaneous diminution of a cask of Hungarian wine be made up with rhenish, though both of them keep extremely well by themselves, the mixture will presently spoil: and so it is of other wines.

The lees in the several casks that have been racked off may be collected together, and when their thicker part has subsided, a spirit may be drawn from the thinner.

Distempers seldom happen to fermented liquors, but from some fault in the manner of managing them. If the fermentation has been duly carried on, the wine racked off the lees before they can contract a putrid taint, and afterwards kept in an equal degree of heat; the wine will answer the expectation of the maker. When it is to be transported, and thereby necessarily brought into a warmer air, brandy is often added, to check the propensity to a new fermentation. This is also sometimes done to give strength to the wine: but it is not a practice by any means to be recommended.

It is necessary for the preservation of some wines, particularly of such as are apt to be frequently on the fret, to fumigate the casks with burning brimstone, to which some add, perhaps uselesly, vinous spirits and aromatic ingredients. The fumes of brimstone strongly resist fermentation, but wines which are largely impregnated with them cannot be recommended as wholesome. The colour of red wine is destroyed by them. What is called stum, is no other than must whose fermentation has been prevented, or prematurely suppressed, by fumigation with sulphur.

The colour of wine is frequently artificial. A pale yellow may be natural, but a fine deep yellow proceeds from an addition of burnt-sugar, or other colouring matters, or from the oaken cask in which the wine has been kept. Wine may be naturaly of a pale dilute red; but a deep red is almost always the effect of artificial additions, as of the red-woods, elder-berries, bilberries, &c. In France, no secret is made of these practices, the colouring matters being publicly thrown out after they have been used. Turbid wines are fined by a mixture of whites and shells of eggs, powdered alabaster, and isinglass. The use of the shells and alabaster is to correct any small degree of acidity that the wine may have contracted: and indeed if we look into the many compositions made use of by vintners, we shall see that they are all framed upon this principle; wherefore it would be needless here to particularise them. If the wine is grown very sour, the best way of correcting it, so as to preserve the spirit and flavour, is, by adding a quantity of salt of tartar sufficient to neutralize the acid, just before it is to be used. It then becomes a pleasant wholesome liquor: but if salt of tartar is mixed with any fermented liquor long before it is to be used, the effervescence which it raises will deprive the liquor of its spirit, and leave it quite vapid. Isinglass is used only for clarifying the wine. Weak wines are improved by an addition of spirit, particularly before the fermentation is completed; for after this period it is apt to spoil the vinosity. Poor wines are enriched by sweets, and flavoured by various additions so as to emulate the more costly: thus elder-flowers give the flavour of Moselle, and the flowers of the yellow clary will make almost any common white wine resemble new rhenish. Even the most delicious wines have been imitated also without a drop of the juice of any grape; with solutions of sugar, juice of currants, figs, and other fruits.

After the wine, and particularly that of countries where the sun is not very powerful, has passed its fermentation in the

the vat, and is drawn off into casks, it will require something to feed upon. To this end, it will be right always to preserve a few bunches of the best grapes, which may be hung up in a room till there be occasion for them; when they should be picked off the stalks, and two or three good handfuls of them should be put into each cask, according to its size.

The French recommend strongly the two following methods; the one for giving additional strength and colour to red wine, and the other for clarifying wines in general.

For the former, a sound well-hooped cask is set upright on one of its ends, the other end is taken out, and a layer of vine-cuttings is spread at the bottom of the cask, to the depth of about three inches. Some of the finest and ripest black grapes are then chosen, and their berries are cut off from the stalks, as close as possible to the fruit, which the utmost care is taken not to burst or damage. The grapes thus selected are put gently upon the layer of vine-twigs, and the cask is filled with them up to the beginning of the bung-hole. Another layer of vine-cuttings is placed gently upon these grapes, till it reaches the upper part of the bung-hole, and the cask is then filled with grapes, culled as before, to within a foot of the top, where another layer of vine-cuttings is spread over them, and the head of the cask is then replaced. The cask thus prepared is filled with good coarse red wine, to within three fingers breadth of the bung-hole, that the liquor may have room to ferment without much loss, and in this state it is carried gently to the place where it is to remain. Great care is taken to keep this vessel constantly filled up with wine of the same sort, both whilst it ferments, and afterwards as it is used: for if the grapes in it were at any time to be left long without a sufficient quantity of wine upon them, the whole would grow vapid and be spoiled. The principal use which the vintners make of this liquor, is to supply their customers constantly with wine of the same taste and colour, by mixing it with what they sell.

The other method, which is practised only when wine is to be fined very speedily, consists in this. A parcel of very thin chips, the longer the better, or of pretty thick shavings, of new but well dried beech, is steeped for two days in water, which is changed at least twice a day, the better to take off the taste of the wood. These chips are then well drained; and after they have been thoroughly dried in the air, as many of them are put lightly into a cask, of which the head has been taken out for this purpose, as will fill it to within about a finger's breadth of the top. The head is then properly replaced in the cask, so as to fit it for holding liquor, and a pint of good brandy is poured in at the bung-hole, upon the chips. After this, the bung-hole is stopped closely with a bung, and the cask is rolled about till the chips have imbibed all the brandy. The cask is then carried to its allotted place, and immediately filled with some of the wine that is to be speedily fined. The wine will soon be fit for drawing off; and when that is done, the cask with the chips in it should be filled up again directly, because the chips, like the grapes and vine-cuttings beforementioned, will loose all their virtue if they are left long without a sufficiency of liquor upon them.

When the wine that is poured upon these chips begins to require a length of time in order to its becoming fine, it is a sign that they are over-loaded with lees. The head of the cask is then taken out anew, the chips are washed in water till they are cleared of the lees, they are then dried in the air as before, and after being again soaked with brandy, or washed in perfectly clear wine, they are replaced in their former cask; after that this also has been well washed and cleaned, and they continue to answer the same purpose as at first.

All the abovementioned practices are innocent enough: but, as Dr. Neumann rightly observes, some of the dealers in wines have had recourse to such dangerous artifices as have been pernicious to thousands. They have sweetened acid wines by litharge, or other preparations of lead; and impregnated sweet ones with mercury-sublimate and with arsenic. Lead is discovered in wines by adding a decoction of orpiment made in lime-water. If the wine is genuine, it does not sensibly change its colour on this addition, though on standing, a yellowish white powder falls to the bottom: but if it has any saturnine impregnation, its colour becomes immediately darker, brown, reddish, or blackish. Arsenic may be detected by a solution of lead in aqua fortis; and mercury-sublimate, by volatile alkaline spirits, or by a solution of fixed alkaline salts.

As to the concentrating of wines by cold, commonly called condensing or congealing of them, it seems to us so much a matter of mere curiosity, rather than of use, that, though Dr. Stahl has taken the pains to give a full and accurate account of the manner of performing this process, by which the wine is not only freed from its superfluous humidity, so as to be greatly diminished in bulk, and of course rendered more convenient for transportation, but also, say the advocates for this practice, infinitely enriched and ennobled in its quality, and rendered so much more perfect and durable, as to be from thenceforth unalterable by any accident or changes of the weather (for by this means "the philosophic spirit of the wine", to use the language of the adepts, is obtained).

"When wines, says Dr. Neumann, are exposed to the action of a freezing air, a part of their water congeals, and the unfrozen part proves proportionably stronger and more spirituous. By repetitions of this process, first pointed out by Paracelsus, and since carried to a greater length by Stahl, the best wines are reduced to about one sixth of their original volume. Wines thus concentrated or freed from their redundant phlegm, are no longer the delicate liquors they were before. They are too unpleasant, as well as too strong, to be drank by themselves; and when mixed with other wines, they communicate to them also a disagreeable taint. The phlegm which congeals retains a part of the truly vinous matter, as appears from its being convertible into vinegar; but this phlegm, mixed with the unfrozen wine, does not restore its pristine qualities: both the phlegm by itself, and the mixture, soon corrupt. When once the principles of wine are separated from one another, no art can reproduce wine by joining them together again. When barely the inflammable spirit has been distilled off, the addition of that spirit to the residuum does not restore its vinosity. The residuum itself often suffers a new separation upon this addition, its tartareous parts precipitating."

When the wine is of an age at which it usually is bottled, care should be taken to examine whether it be sufficiently bright; because a natural brightness is the most certain indication of the liquor's having undergone a due fermentation, and consequently of its being rendered most wholesome. If any small degree of cloudiness is observed in it, the whites of eggs will easily remove that imperfection; and if it inclines to tartness, the shells of the eggs should be mixed with their whites: but if the degree of cloudiness is thought to be greater than the whites of eggs will cure, recourse is had to isinglass, the quantity of which should be proportioned to the quantity of the liquor, and to its degree of foulness; for wine that becomes bright of itself does not need any. The proper way of using the isinglass, is to dissolve it over the fire in so much water as will form it into a jelly; then to dilute it sufficiently with some of the same wine as it is intended to clarify, afterwards to strain it through a flannel bag, and finally to pour it into the cask, and stir it well about with a whisk that reaches only to about half way down the cask. For wine that is very tart, the proper corrective is powdered marble, alabaster, or un-burnt lime-stone, as before directed.

A quite fashionable gentleman would hardly have vouchsafed, a few years ago, to taste a glass of Champagne which did not sparkle or froth strongly: but that notion of its excellency is now pretty much laid aside. Opinions have been so greatly divided in regard to the cause of this sparkling, some ascribing it wholly to the force of drugs used for that purpose by the dealers in this wine; others imputing it to the un-ripeness, or, as some call it, the tartness of the wine, because, in fact, most of the wines that do sparkle and froth are extremely tart; and others again attributing this effect to the influence of the moon, according to the times of bottling these wines; that we cannot do better than copy here the substance of what the authors of the Maison Rustique have said on this subject.

"It is true that many dealers in wine, seeing how immoderately fond most people were of this sparling liquor, did

did often put into it alum, ſpirit of wine, pigeon's dung, and many other drugs, to make it froth exceedingly; but it is certain, from experience, that the bottling of it at any time between the vintage and the month of May, will alſo make it froth. Some pretend that it froths moſt when it has been bottled neareſt to the time of gathering the particular ſort of grapes of which it was made: but many deny this. There is no time of the year in which it froths more than at the end of the ſecond quarter of the moon in March; and that without any artifice at all. One may always be ſure that the Champagne wine which has been bottled between the tenth and the fourteenth days of the ſame moon will froth perfectly. This has been proved by ſuch reiterated experience, that it cannot be doubted. It is, however, proper to obſerve, that the wine does not froth immediately after its having been bottled. It muſt have been at leaſt ſix weeks, and often two months in bottles, before it will froth well. If it has been tranſported to any diſtance, it muſt be let reſt for a month in the vault, eſpecially in ſummer, to recover itſelf.

" But as the Champagne wines, and particularly thoſe of the mountain of Reims, are not in general ſufficiently ripe for bottling at the abovementioned time, but ſtill retain too much tartneſs, or hardneſs, if the ſeaſon has been cold and moiſt; or too much ſweetneſs, if it has been hot; the ſureſt and beſt way to have exquiſite wine which ſhall froth perfectly, is not to bottle it till the riſe of the ſap in Auguſt. Experience has certified, that it froths exceſſively when bottled between the tenth and the fourteenth of the moon in Auguſt: and as it will by that time have loſt its too great tartneſs, or its over great ſweetneſs, one may be aſſured that the wine which is bottled then will be the ripeſt and moſt frothy.

" Another experiment has been tried, which is, not to bottle the Champagne mountain wine till the ſpring of the ſecond year, that is to ſay, eighteen months after it has been made; and it has been found to froth ſufficiently, though not above half ſo much as that which was bottled while the ſpring-ſap of the preceding year was riſing. It is not thought that the river wine, which has leſs body than that of the mountain, can froth ſo much in the ſecond year.

" They who would have Champagne wine that does not froth at all, muſt bottle it in October or November of the year after the vintage. If it be bottled in June or July, it ſtill will froth a little, though but very little.

" As theſe wines, eſpecially in their firſt year, work continually in the cellars and vaults, and ſtill more in bottles than in caſks, according to the different ſeaſons and the different impreſſions of the air; it is not ſurprizing that the ſame wine, particularly the new, ſhould ſometimes appear different to the taſte. A wine, for example, which is fit for drinking in January and February, ſhall ſeem hard in March and April; becauſe of the riſing of the ſap which then agitates it: and this ſame wine, after ſeeming to be perfectly ripened in the next June and July, ſhall again have, in Auguſt and September following, a hardneſs which could not be perceived in either of the two preceding months; becauſe the riſing of the ſap in Auguſt will have increaſed the motion of its parts, or, in other words, have ſet it on the fret. Thus the ſame Champagne wine, of the firſt year, if it be of the river growth, and frequently that of two years old if it be of the growth of the mountain, will appear more or leſs ripe or mellow, more or leſs exquiſite, more or leſs forward, according to the different motions it receives from the different impreſſions of the air, which vary moſt ſenſibly in the different ſeaſons of the year."

What is here implied, though perhaps not quite clearly expreſſed, is, we apprehend, the true cauſe of the ſparkling or frothing of wine; namely, its not having been perfectly fermented, and conſequently not had a thorough aſſimilation of its conſtituent parts. The want of this certainly makes it fret in the bottle: and accordingly we ſee, that, the better to ſecure its ſparkling, the people of Champagne bottle it in the very ſeaſon when it is moſt likely to be on the fret; viz. at the time of the weather's turning from cold to warm. Several other cauſes may likewiſe put wine on the fret, and among theſe a principal one is the want of cellars in which an equal temperature of the air is preſerved all the year round. This, and the imperfectneſs of the fermentation of the liquor, are undoubtedly the real cauſe of the ſparkling or frothing of wine.

As a general rule, if it be intended that the wine ſhould not froth, the beſt time for drawing it off, whether into bottles, or into caſks, is when the weather is extremely fair and clear, the barometer high, and, of choice, during a northerly wind; becauſe the air is then cooleſt, and the wine leaſt apt to be on the fret. By inverting theſe rules, and drawing off the wine in warm damp weather, when the barometer is low, and the wind ſoutherly; what is bottled at this time will froth; for wine in the caſk is always cloudy then, and conſequently diſpoſed to fret.

It may not be uninſtructive, and certainly cannot be unentertaining to our readers, if we copy here Dr. Neumann's account of, and curſory remarks on, the principal wines that are drank in Europe. " 1. The Madeira iſlands, and Palma, one of the Canaries, afford two kinds: the firſt called Madeira Sec; the latter, which is the richeſt and beſt of the two, Canary or Palm Sec. The name Sec (corruply written Sack,) ſignifies dry; theſe wines being made from half dried grapes. There is another ſort of Sec wine, inferior to both the foregoing, prepared about Xeres in Spain, and hence called, according to our orthography, Sherris, or Sherry. 2. The wines of Candia and Greece, particularly the latter, are of common uſe in Italy. Malmſey was formerly the produce of thoſe parts only, but is now brought chiefly from Spain: it is a ſweet wine, of a golden or browniſh-yellow colour: the Italians call it *Manna alla bocca e balſamo al cervello*, " Manna to the mouth and balſam to the brain." Zant and Cephalonia ſend alſo to Venice ſome good, and no ſmall quantity of indifferent wines: almoſt all the wines indeed made uſe of in the Venetian territories come from Greece and the Morea; of which there are ſome ſorts ſo bad, and ſo cheap, that large quantities are made into vinegar for the preparation of ceruſſe. 3. Italy, not Greece, produces the *vino Greco*: this is a gold-coloured unctuous wine, of a pungent ſweetneſs, the growth of Mount Veſuvious, greatly ſophiſticated by the Neapolitans. In the neighbourhood of Veſuvious is made the Mangiaguerra wine, as alſo a thick blackiſh one called Verracia; and at the foot of the hill, the delicious *vino vergine*. The Italians apply this laſt name likewiſe to all the other wines made without preſſure. The kingdom of Naples affords the Campania or Pauſilippo and Muſcatel, the Surentine, Salernitan, and other excellent wines, as alſo the Chiarello, much drank at Rome. But the principal of all theſe wines is the red, fat, ſweet, and gratefully poignant one, called *Lacbryma Chriſti*. The eccleſiaſtical ſtate produces the light, pleaſant Albano; and the ſweet Monteſiaſcone, a yellowiſh not very ſtrong wine, which comes the neareſt to good Florence, but does not keep well; together with ſeveral of leſs note, as the Nomentan, Monteran, Velitrin, Prænetic, il Romaneſco, d'Orvieto, &c. 5. In Tuſcany are the excellent white and red Florence; the celebrated, hot, ſtrong red wine of Monte Pulciano; the Montalneo, Porte Hercole, &c. But along the coaſt of the Adriatic, at Ancona, Rimini, Peſaro, and as far as Bologna, one meets with exceeding bad wines, chiefly of the boiled unfermented kind, heavy, diſagreeable, and unwholeſome. 6. In Lombardy alſo there is abundance of bad wines: the Modeneſe and Monſerrat are tolerable; the Marcemino, produced about Vicenza and Padua, pretty good. The other wines moſt commonly drank in that province are the Breſcian, Veroneſe, Placentine, Lumelline, and Pucine; and in the Genoeſe, the Vino di monte vernaccia, vino amabile or vino di cinque terre, and Vino razzeſe. Between Nizza and Savona is produced an incomparable Muſcadine; near Aquileia is the Roſatz, and near Pavia the Vino Piccante. 7. Piémont and part of Savoy have excellent light wines. 8. The Sicilian, Sardinian and Corſican wines are alſo good: the firſt, as particularly the Catanian, Panormitan, Meſſinian, and Syracuſan, are accounted the beſt, and are chiefly bought up by the Knights of Malta. 9. Moſt of the Spaniſh wiſhes are compoſed of fermented or half fermented wine, mixed with inſpiſſated muſt and variouſly manufactured, or of an infuſion of dry grapes in weak muſt. No wines freeze more difficultly than the Spaniſh; theſe abounding both

both with unctuous matter and with inflammable spirit. The principal of them are, the Alicant, which is a thick, strong, very sweet, and almost black as well as nauseous wine; Sherry, Spanish Malmsey, Malaga, commonly called Mountain, and what is simply termed Spanish wine. These, at least, are the sorts most generally imported here: but in Spain itself there are many more, such as, the Tarragon, Salamanca, Cordova, Galicia, Andalusia, sundry bastards, vino de toro, &c. 10. In Portugal there is plenty of red Port, a cheap but not a very excellent wine, drank in large quantities in England, and often dreadfully sophisticated. The best vino tinto, a blackish red wine used by the coopers for colouring other wines, is said by some to be the produce of Portugal. So largely do the Portuguze deal also in Madeira, that their king receives yearly twelve thousand pipes of this wine by way of tythes. 11. In France, there is a great variety of wines; of which the strong, sweet, full-bodied, spirituous ones are called *Vins de liqueur*. There is scarcely a province in France that does not produce wine: Languedoc and Provence afford the sweetest; and the same provinces, with Champagne and Burgundy, the strongest. The wines of the northern parts of that kingdom, as Picardy and Bourdeaux, are the worst; and those about its middle, as Paris and Orleans, of a middling kind. The most celebrated of the French wines are those of Champagne and Burgundy, the Cote rotie, St. Laurence, Frontignac, Muscat de Lion, Cahors, Hermitage, Grave, &c. 12. In Swisserland, the best are the Neufchatel, Velteline, La cote, and Reiff wines. The Velteline straw-wine, so called from the grapes being laid for some time upon straw before they are pressed, is particularly celebrated. 13. The dry-grape wines of the Upper-Hungary are in general excellent, and greatly superior to those of the Lower. They have a delicious aromatic smell and taste, a notably diaphoretic, and corroborating virtue, and when drank freely occasion no head-ach, heaviness of the limbs, or other inconveniencies. They do not easily become vinewed even in open vessels; and retain their sweetness and agreeableness for a length of time, though they lose a little of it from year to year. 14. Among the German wines, the Tyrol are very delicate, particularly those of Tramin and Etsch; but they do not keep. 15. Good Austrian wine is not to be rejected. Those of Kloster-Neuburg and Brosenberg are accounted the best, and, in the opinion of some, excel in taste that of Edenburg in Lower Hungary. There are also good wines in several other parts of the imperial dominions. 16. In the Palatinate, the best wine is that of Worms, especially the sort called women's milk; and next to this, those of Edinghoff and Ambach. 17. Among the more esteemed German wines are to be reckoned also Rhenish, Mayne, Moselle, Neckar, and Elsass. A certain writer calls the Rhenish made in Hockheim (hock) the prince of the wines of Germany. 18. The Bohemian, Silesian, Thuringian, Misniam, Naumberg, Brandenburg, and other German wines, are generally inferior to the foregoing. Some however, of those of Misnia and the Marche, made from ripe picked grapes, have this advantage, that they are greatly meliorated by age, so as to be preferred by many to the Rhenish, Neckar, and Franconia wines, and frequently mixed with other of greater note. The tartish German wines keep the longest of any: some of them have been kept two or three hundred years; and in Strasburg there is a cask of it fourteen hundred years old, and many above seventy; the wine being occasionally racked off into smaller and smaller casks, that the vessel may be constantly full. These very old wines are preserved rather for curiosity than use, as they not only grow too strong for drinking, but at last quite disagreeable. The best are those of a middle age, from twenty to about fifty years."

We cannot close more properly, than with the above quoted excellent chemist's definition of the characters of good wine.

"The goodness and wholesomeness of wines are judged of, from their being bright, clear, and sparkling in the glass; of an agreeable reviving smell and taste; leaving, when held in the mouth for some time, a slight sense of astringency; being moderately strong and spirituous; passing freely by urine; exciting appetite; producing a gentle sweat in the night; keeping the belly open next day; without being followed by any head-ach, heaviness of the limbs, or other uneasiness. Such a wine, moderately used, is a very valuable cordial. The sweet rich wines are either new, or very strong and fiery: they heat the body much more, and, if drank to any degree of excess, their effects continue much longer than those of the thinner wines, which contain an equal quantity of spirit. The red wines, in general, have the greatest astringency."

The following directions for making domestic wines, taken from the Museum Rusticum, will, we are persuaded, be agreeable to our readers.

"As to the art of making wine, I think the rendering it more generally known, and practised here, may not only afford a convenience with regard to expence, and a security with regard to health, to private persons; but an advantage to the public, in the balance of trade: a principle, at present, overlooked: though, in a short time, it will probably be seen in a more interesting light.

"Among the various articles of foreign luxury, wine certainly makes one of the most capital; and yet, what with the taking such extreme great quantities, as oblige us to receive, as well the product of inferior, as good vintages; and what with adulteration, as well practised before the wine is imported hither, as after; we in general drink very indifferent natural wines, or very exceptionable artificial mixtures of liquors, called so. Though for these, we either pay great annual sums to foreign countries, or to those, who make it their business to impose upon us at home.

"This is the more to be regretted: because we have it in our power wholly to avoid it: and, by a little attention and trouble to provide ourselves with wine, that is superior in flavour, cordial effect, wholesomeness, and every other quality, with a saving of at least fifty or sixty *per cent.* of the expence. The means, by which, I suggest it to be in our power to do this, is, by the domestic production of wine in our own families: which, were the art well known, and the advantages, as I have here enumerated them, well understood, could not surely fail to be a much more general practice than it is at present.

"It may be said to appear from experience, that wine thus made here, is not so good as the foreign: and that, we find, in the instances of those, who have tried to introduce it, the success is not equal to my representation. To this, I answer, that experience has verified what I advance, in the few instances of those, who have made domestic wine with skill; and kept it to be of a due age: without which, even foreign wine would not be good. But the reasons, why greater numbers do not succeed, is the want of knowledge; a sordidness, with respect to expence; or the drinking the wine before it be fit: which is almost universally the case. For, where this art has been practised without any of these disadvantages, such wine has been produced, as not only has equalled the foreign, in all general good qualities; but has even been mistaken for several of the most valuable kinds, even by the most skilful judges.

"The want of knowledge in the art of making domestic wine, being, therefore, one principal cause of the neglect of doing it more frequently, I shall here endeavour to remove it, by furnishing such instructions, as can scarcely fail to enable any attentive person to practise it, with ease and certainty. And, I am persuaded, that, to middling people, especially those living in villages and places remote from sea-ports, where it is difficult to procure even indifferent wine in small quantities, I shall do a material kindness: tho' the advantage of making domestic wines is by no means, confined to such persons, or situations; but even all others might find their account in it, both with respect to expence and health.

"I will, therefore, first give a recipe for making the most perfect wine, that can be produced, by composition, in this country. By composition, I mean, such as is not made of the simple native juice, of any one kind of fruit. But this kind is, indeed, in a great degree native, as the water added to the dry fruit is only, in fact, the restoration of what evaporated in the drying and ripening the fruit: and the produce of this process is, therefore, in reality, a natural wine, and superior to any, that can be made of the native juices of the fruits of our country; or perhaps equal to the beſt of thoſe of any other. This recipe will ſerve, alſo, as a baſis, for the ſhowing afterwards how other, and cheaper kinds, may be made.

" Take thirty gallons of ſoft water, either rain, or river water. It ſhould be obtained in as clear a ſtate as poſſible, but boiling is needleſs. Put this water into a veſſel, at leaſt, one-third bigger than will contain that quantity: and then add to it one hundred weight of Malaga raiſins, groſsly picked from their ſtalks. Mix the whole well together, that the raiſins may not remain clotted in lumps: and then cover it partly, but not intirely, with a linen cloth; and let it ſtand in a warm place, if the ſeaſon be not hot. It will ſoon begin to ferment; and muſt be well ſtirred about, twice in twenty-four hours, for twelve or fourteen days. It muſt be then examined, by the taſte, to try if the ſweetneſs be nearly gone off: and if that be found ſo, and the fermentation be greatly abated, which will be perceived by the raiſins beginning to lie quietly at the bottom, the fluid muſt be ſtrained off; and preſſed out of the raiſins, firſt by the hand, and afterwards by a preſs, if ſuch be eaſily procured. But, if there be no preſs, two boards may be uſed with the aſſiſtance of a large weight, or other ſtrong compreſſive force; which muſt be continued as long as any fluid can be made to drop from the maſs. The fluid, thus ſeparated from the ſkins, or marc of the raiſins, muſt be then put in a good ſound wine caſk, well dried and warmed, together with eight pounds of Liſbon ſugar, and a little yeaſt: but ſome part of the liquor muſt be kept out, to be added, from time to time, as the abatement of the fermentation, that will come on again, may admit, without the wine riſing out of the caſk. In this ſtate it muſt continue for a month, with the bung-hole open: and then, the whole of the liquor kept out, having been now put in the veſſel, muſt be cloſely ſtopped up; ſo that no air may enter: and in this ſtate it muſt be kept for a year, or longer. At which time, it may be bottled off.

" This wine may be drunk, and will be very good at the end of a year and half: but it will be much better, if kept longer: and will improve for four or five years. When it has a proper age, it will equal any of the ſtrong cordial foreign wines: and may, by the addition of proper ſubſtances to flavour and colour it, be made to reſemble them.

" This is the moſt perfect kind, of what may be called artificial wine; but others may be made cheaper. There are two methods of making a ſaving in the expence. The one is, to ſubſtitute, inſtead of the whole quantity of raiſins here directed, a greater proportion of ſugar: leaving out four pounds of raiſins for one of ſugar added: or the quantity of both ſugar, and raiſins, may be diminiſhed; and a proportion of clean malt-ſpirits added, when the bung of the caſk is cloſed up. The uſe of diſtilled ſpirits, in this manner, is not ſo objectionable, as it may at firſt appear to perſons, who are not acquainted with theſe matters. For ſuch ſpirits will loſe their fiery quality, and be rendered ſoft and mellow, by their incorporation with the oily part of the wine. And there is nothing more certain, than that the practice of uſing them is general in the preparation of all the foreign wines, for our market: and moſt particularly thoſe ſtronger kinds, which are moſt eſteemed by us.

" Any other kind of large raiſins, which are cheap, may be uſed, as well as the Malaga: and the thinner the ſkins, and the ſweeter the pulp, the ſtronger will be the wine.

" It has been practiſed formerly to bruiſe the raiſins; but it is unneceſſary with reſpect to the common ſorts, as they will ſoon burſt with the fermentation; and freely give out their contents. But there are ſome ſmall kinds with tough ſkins, which, if employed for this purpoſe, ſhould be bruiſed: or they will reſiſt the penetration of the water. Theſe kinds are not, however, ſo good for the purpoſe of making wine as the larger; or, at leaſt, if they be choſen for any particular flavour, they may give the wine, there ſhould be only a certain proportion mixt, added to ſome of the other kinds: and, in this caſe, they ſhould be firſt bruiſed.

" The practice of a double fermentation, as here directed, firſt of the raiſins themſelves, and afterwards of the ſugar, is not the common method: and very good wine may be made, by fermenting both at the ſame time. But this method is, nevertheleſs, preferable; for it ſometimes happens, from ſome unknown circumſtances in the fermentation, when ſuch method is not practiſed, that the wine will turn out cloudy, and not admit of being fined, by any means at preſent underſtood: which accident is prevented by this double fermentation remaining, as the ſecond perfectly works all the remaining half fermented part of the pulp. Moreover, in conſequence of this more perfect fermentation, the wine is lighter, and becomes wholeſome and perfect with leſs age: the glutinous matter of the raiſins being intirely reſolved.

" Of this wine, by adding the proper flavour, may be formed, imitations of all the natural wines, of a very ſtrong body: and, by abating the proportion of raiſins, ſugar, or both, other ſmaller kinds, may, by the ſame means, be produced.

" If this wine be perfectly fermented, and kept a long time, ſo that no ſweetneſs remain, it will reſemble Madeira: and has very frequently paſſed for it.

" An imitation of Frontiniac may be made, by the wine, in which the proportion of ſugar, or of malt-ſpirits, to the raiſins, is large; and the whole body weaker. The muſcadel flavour of Frontiniac, being exactly to be imitated, by an infuſion of the flowers of meadow-ſweet, in ſome of the wine: and added in that proportion, which may be found ſufficient to raiſe the due degree of the flavour. In the making this artificial Frontiniac, the fermentation ſhould be ſtopt, by cloſing the caſk, and adding the ſpirit, while a conſiderable ſweetneſs yet remains: and the wine may be drunk after it has been a ſhort time in bottles.

" Cyprus wine may be imitated, alſo, by the ſame means: the infuſion of the meadow-ſweet being added to the wine prepared in the beſt manner above directed. But, in this caſe, three or four pounds more of ſugar, than the quantity given in the recipe, ſhould be uſed; and the fermentation ſtopt, while a conſiderable degree of ſweetneſs remains. This kind will be the better for age: and, if properly managed, can never be diſtinguiſhed, even by actual compariſon, from the true Cyprus: as I can aſſert from the fact itſelf.

" The imitation of mountain is to be made, by preſerving a ſmall degree of ſweetneſs, giving the nut-like flavour, and keeping the beſt kind of the above wine to a due age. This nut-like flavour may be obtained, by the infuſion of the Florentine orris-root, powdered with a very ſmall proportion of orange and lemon-peel: and the wine may be rendered more dry or ſweet, by continuing the fermentation a greater or leſs time; and adding a correſpondent proportion of clean malt-ſpirits, when the fermentation is ſtopt ſooner. The adding ſome of the ſtony ſeeds of the raiſins well bruiſed, alſo, gives the nut-like flavour: and the putting in a part of the ſtalks of the raiſins, gives a ſharpneſs, found in general in this kind of wine.

" The racy taſte of canary, now commonly called ſack, may be counterfeited by the addition of a proper quantity of the juice of white currant-berries to the wine, made with a large proportion of ſugar to the raiſins; and left very ſweet in the fermentation. But it is ſaid, that a ſpirit, diſtilled from the leaves of clary and clean malt-ſpirits, and put to the wine, will give to it ſuch a ſtrong reſemblance of ſack, as renders it abſolutely undiſtinguiſhable from that wine.

" It is ſaid, alſo, that the juice of the bramble-berries, added to the mixture of the wine, before the fermentation, gives both the exact colour, and flavour of claret. But, in this caſe, the quantity of raiſins ſhould be conſiderably diminiſhed, and that of the ſugar increaſed, though not to the full proportion: as the fermentation muſt be continued till all ſweetneſs be deſtroyed; and this wine is not intended to have ſo great a body as the others.

" It is better, therefore, for this imitation of claret, to work it only of moderate ſtrength; and to add ſome proportion of diſtilled ſpirit: it will be perfect at the end of two years. This, and the imitation of ſack by the ſpirit of clary, I have never ſeen tried: but have them on very good authority. I ſhould be apt to believe, a ſmall proportion of red-argol, or tartar, diſſolved in ſome of the wine, and added together with the ſpirit, when the bung is cloſed up, would aſſiſt the imitation very m ateriall.

" Any

"Any intelligent perſon may eaſily collect, from theſe inſtructions, ſufficient lights to qualify them to make better or cheaper kinds of wine, according to their inclination. But whatever kind is made, at leaſt a year ſhould be given to it: and, in moſt caſes, a longer time. For nothing has ſo much contributed to the diſcrediting, and excluding the uſe of domeſtic wines, as the drinking them too new: eſpecially after an injudicious, and undue management of the fermentation; by which means they have been made to appear flatulent, aceſcent, and foul. But the very oppoſite of theſe qualities will be found in them, when properly treated and kept."

To WINNOW, to clear corn from the chaff, &c. *See the article* THRASHING.

WITHERS, the part of a horſe where the ſhoulder bones join at the bottom of the neck and mane.

All pinches of the ſaddle on the withers, ſhould be treated with repellers; for this purpoſe bathe the tumor well with hot vinegar three or four times a day: if that does not ſucceed alone, an ounce of oil of vitriol may be put to a quart of vinegar, or half an ounce of white vitriol diſſolved in a little water, and added to the ſame quantity. Theſe are generally very effectual repellers for this purpoſe in horſes, and will frequently prevent impoſthumation: when the ſwelling is attended with heat, ſmarting, and little hot watery pimples, the following mixture will then be more proper to bathe with.

> Take two ounces of crude ſal ammoniac, boiled in a quart of lime water, where that cannot be had, a handful of pearl or wood aſhes may be boiled in common water; pour off the decoction when ſettled, and mix with it half a pint of ſpirit of wine: anoint the part afterwards with linſeed oil, or elder ointment, to ſoften and ſmooth the ſkin.

But when theſe ſwellings are critical, the conſequence of a fever ſettled on this part, you muſt avoid the repelling method, and aſſiſt in bringing the ſwelling to matter, by means of ſuppurating poultices: experienced farriers, adviſe, never to open theſe tumors till they break of themſelves; for if they are opened before they are ripe, the whole ſore will be ſpongy, and diſcharge a bloody ichor, which ſoon degenerates into a ſordid ulcer. But take care to inlarge the openings and pare away the lips, that your dreſſings may be applied eaſily; and avoid the ligament which runs along the neck to the withers: if a gathering forms on the oppoſite ſide, open it in the ſame manner, but take care they incline downwards, for the ſake of depending orifices, and letting the matter flow off eaſily, and if the bones ſhould be found foul, they muſt be dreſſed with tincture of myrrh till they ſcale off: if the fungus is very troubleſome, and the diſcharge, oily, yellow and viſcid; pledgits ſoaked in the following, made hot, have been found very effectual, bathing the ſwelling round with ſpirit of wine and vinegar.

> Take half an ounce of blue vitriol, diſſolved in a pint of water; oil of turpentine, and rectified ſpirit of wine, of each four ounces; white wine vinegar, ſix ounces; oil of vitriol and Ægyptiacum, of each two ounces.

Theſe ſharp liquid applications are often found more efficacious dreſſings than ointments with precipitate, or verdigreaſe, or indeed any other digeſtives; as they inſinuate themſelves more readily into the interſtices of the funge, or little quag-holes, ſo commonly obſerved in theſe kind of ulcers; and at the ſame time, level and deſtroy the riſing, and exuberant pupillæ; whereby the ulcer grows more ſmooth and dry, ſoon heals up, and cicatriſes.

When the cavities are truly fiſtulous, the calloſities muſt be cut out, where it can be done, with a knife; and the remainder deſtroyed by corroſives; viz. precipitate, burnt allum, and white vitriol. *Bartlet's Farriery, pag.* 273.

WITH-WIND, *ſee the article* BIND-WEED.

WOAD, the Engliſh name of a plant, called by botaniſts *Iſatis ſativa, vel latifolia.*

This plant puts forth ſtems about three feet high, and of the thickneſs of a man's finger: theſe divide at their top into ſeveral branches loaded with many leaves irregularly placed; and theſe leaves, which reſemble pretty much thoſe of dog's-tongue, are ſleek, and of a bluiſh green colour. The branches bear alſo great numbers of flowers compoſed of four yellow petals diſpoſed croſs-wiſe: the pointal becomes a capſule flattened on the edges, and each capſule contains two oblong ſeeds: the root is large, woody, and penetrates deep into the ground. This plant delights in a warm climate, ſuch as Italy and the ſouthern parts of France; though it has likewiſe been cultivated in Normandy, and is ſaid to ſucceed in Germany; as experience has ſhewn that it does alſo in this country.

A light, black, kindly, and rich ſoil, or a meadow newly broken up, is choſen for the cultivation of woad; but it muſt not by any means be ſown on ſtoney or ſhallow land. It thrives well in plains, but ſtill better on the ſouth ſide of a hill: the eſſential point is, that the ſoil be good, and that it have the above-mentioned qualities.

Though the land which is intended for woad be never ſo good, it muſt be dunged a year before it is ſown with this plant, and be made firſt to bear a crop of wheat, or of onions, &c. After theſe are taken off, three deep ſtirrings ſhould be given with the plough, or, which is much better, with the ſpade: the firſt ſtirring ſhould be in November, and the other two in February, March, or April. If the land which is intended for woad lies flat, and has not ſlope enough to carry off the wet, channels muſt be cut of a greater or leſs ſize, according as the ground is more or leſs diſpoſed to retain the water.

In warm climates, woad is ſown ſo early as the beginning of April, unleſs the weather chances then to be too cold, in which caſe this ſowing is deferred till the beginning of May: but for countries like ours, where the ſpring is attended with froſts, particularly in the night, Mr. Miller is certainly right in adviſing to lay the land up in narrow high ridges juſt before winter, that the froſt may mellow it; to croſs-plow it in the ſpring, laying it again in narrow ridges, and between this time and the enſuing month of June to harrow it well twice, at different intervals, in order to root up whatever weeds may have appeared; then, in June, to give the ground a third plowing as deep as the plough will go, making the furrows narrow; after this, to harrow it again when any new weeds are come up; and finally, towards the end of July, or the beginning of Auguſt, to plow it for the laſt time, laying it as ſmooth as poſſible. A good harrowing after this will fit it completely to receive the ſeeds, which, if rain falls ſoon after their being ſown, or if they are ſteeped in water during the night before the ſowing, as Mr. Miller adviſes, will appear in a fortnight, if the ſeaſon be favourable. They ſhould be but lightly covered, and ſhould be ſowed ſo thin as that the plants may ſtand ſix inches aſunder. Some ſtrew pigeon's dung on the land juſt after having ſown it with woad, and the plants become much the finer for this manure.

It is a common cuſtom to ſow woad in broad-caſt: but all plants which require being hoed ſhould certainly be ſowed in rows, becauſe this method greatly leſſens the labour and time of hoeing; and beſides, it is much eaſier, in this caſe, to give each plant its due diſtance.

When the woad is grown large enough to be diſtinguiſhed, it ſhould be carefully cleared of all weeds, for theſe would hurt it greatly; and at the ſame time the plants ſhould be thinned wherever they ſtand too cloſe: without this precaution, the woad would produce but very few leaves, and would remain extremely ſtinted in its growth.

The intervals between the plants ſhould be ſtirred whenever the ſeaſon requires it; and in the doing of this, by which the weeds thereby rooted out will ſoon be deſtroyed in dry weather, care ſhould be taken to lay a little earth up around the ſtems of the woad. M. Du Hamel, whoſe account we have here reſumed, ſays he has been aſſured, that, in countries where there is a conveniency of water, the woad-grounds are flooded: but to reap any benefit from this practice, the water ſhould be in ſufficient plenty for the huſbandman to be able to repeat the flooding frequently; for otherwiſe the heat of the ſun, after

having

having exhaled the water too foon, would harden the furface of the earth, and thereby greatly injure the plants.

Woad generally affords two crops in the fame year, and fometimes, when the feafon has been favourable, it has yielded even four. The two firft are the beft, and thefe are commonly mixed together in the manufacturing of this plant: but the after-crops are always kept feparate; for if thefe are mixed with the other, the whole will be fpoiled. The two firft crops will fell for from twenty-five to thirty pounds a ton; but the latter will not bring more than feven or eight pounds, and fometimes not fo much. An acre of land well hufbanded will produce a ton of woad, and in good feafons near a ton and a half. The firft crop is gathered towards the end of Auguft, and the laft at the end of October, or in the beginning of November: but this laft crop muft be got in before the firft frofts come on; for the leaves that might be gathered afterwards would not be worth any thing. When the plant is ripe, which is known by its firft leaves beginning to dry, all the leaves are cut off by a man who grafps the plant by handfuls, and they are then laid in a heap to wither. Whilft they are in this fituation, they muft be fheltered from the fun and rain, and they muft be frequently turned, in order that they may heat equally: they are then carried to a mill fomewhat like that which is ufed for preffing the oil out of linfeed, and are there ground till they are reduced into a pafte, which is afterwards formed into cakes of about a pound weight, and thefe are laid to dry in a covered place where neither the fun nor rain can come at them. This pafte is dried thus for about a fortnight, that is to fay, till it has acquired confiftence enough to be formed into fmall roundifh lumps, by means of little wooden moulds into which it is put for that purpofe. As faft as thefe lumps are taken out of the moulds, they are laid upon wicker hurdles loofely woven, fo as not to touch one another, and in fuch manner that the air may come at every part of them, as is practifed in the drying of ftarch. Thefe lumps become very hard, and in this condition it is that they are fold. When they are to be ufed, they muft be fteeped a long while in water before they can be broken.

The woad thus prepared yields an excellent blue dye, very lafting, and with which all the degrees of this colour may be made. It is not long fince this plant was preferred to indigo: afterwards, through a kind of toleration, the dyers were allowed to put a fmall quantity of indigo into their vats of woad; but now that the making and manner of ufing indigo have been greatly improved, it is looked upon as a matter of indifference whether that or woad be ufed for dying blue.

At the laft cutting of the woad, and with that cutting, the crown of the root is taken off; whereas only the leaves were gathered in the preceding cuttings. When it is intended to fave the feeds of woad, a fmall portion of the plantation fhould be allotted for this purpofe at the laft cutting, and then a part only of the leaves there fhould be taken from the plants: but it is proper to retrench fome of them, becaufe experience has fhewn that the plants on which all their leaves are left run to feed too foon, and that their feeds have in this cafe often been deftroyed by the cold of the enfuing fpring. Thus woad, being a biennial plant, fhould not be fuffered to feed before the month of Auguft in the fecond year after it has been fown; and therefore fome of its leaves fhould be cut off in October, to prevent its being too forward.

Befides cold, weeds, and drought, which are very pernicious to woad, locufts will fometimes devour a whole field of it in an evening. When thefe enemies are obferved, all the leaves fhould be immediately cut off, that the plants may put forth new ones.

The fame field fhould not be made to bear a fecond crop of woad immediately after the firft; for this plant is a great impoverifher of the ground: but after it has been taken off, wheat may be fown the firft year, millet the fecond, and in the third it may be laid down again to woad, if it has been well manured.

WOLVES TEETH, a name given to thofe teeth, which grow in fuch a manner, that their points prick, or wound either the tongue, or gums, in eating. Old horfes are moft liable to this infirmity, and whofe upper overfhoot the under teeth in a great degree.

To remedy this evil, you may either chop off the fuperfluous parts of the teeth with a chizzel and mallet, or file them down, which is the better way, till you have fufficiently wafted them.

WOOD, a large and thick plantation of trees.

Woods and groves are the greateft ornaments to a country feat; therefore every feat is greatly defective without them, wood and water being abfolutely neceffary to render a place agreeable and pleafant. Where there are woods already grown to a large fize, fo fituated as to be taken into the garden or park, or fo nearly adjoining, as that an eafy communication may be made from the garden to the wood; they may be fo contrived by cutting of winding walks through them, as to render them the moft delightful and pleafant parts of a feat, efpecially in the heat of fummer, when thofe walks afford a goodly fhade from the fcorching heat of the fun.

Where perfons have the convenience of grown woods near their habitation, fo as that there may be an eafy communication from one to the other, there will be little occafion for wilderneffes in the garden; fince the natural woods may be fo contrived, as to render them much pleafanter than any new plantation can poffibly arrive to within the compafs of twenty years, where the trees make the greateft progrefs in their growth; and in fuch places where their growth is flow, there cannot be expected fhade equal to the grown woods in double that number of years; but there is not only the pleafure of enjoying a prefent fhade from thefe woods, but alfo a great expence faved in the planting of wilderneffes, which, if they are large, and the trees to be purchafed, will amount to no fmall fum.

If the wood is fo fituated, as that the garden may be contrived between the houfe and that, then the walk into the wood fhould be made as near to the houfe as poffible, that there may not be too much open fpace to walk through in order to get into the fhade; if the wood is of fmall extent, then there will be a neceffity for twifting the walks pretty much, fo as to make as much walking as the compafs of the ground will admit; but there fhould be care taken not to bring the turns fo near each other as that any two walks may be expofed to each other, for want of a fufficient thicknefs of wood between; but where the wood is large, the twifts of the walks fhould not approach nearer to each other than fifty or fixty feet; or in very large woods they fhould be at a greater diftance; becaufe, when the underwood is cut down, which will be abfolutely neceffary every tenth or twelfth year, according to its growth, then the walks will be quite open until the underwood grows up again, unlefs a border of fhrubs, intermixed with fome evergreens, is planted by the fides of the walks; which is what we would recommend, as this will greatly add to the pleafure of thefe walks.

Thefe wood walks fhould not be lefs than eight or nine feet broad in fmall woods; but in large ones fifteen feet will not be too much; and on each fide of the walks, the border of fhrubs and evergreens may be nine or ten feet broad; which may be fo managed, as to fhut out the view from one part of the walk to the other at thofe times when the underwood is cut down; at which times there will be an abfolute occafion for fuch plantations, and at all times they will afford great pleafure by adding to their variety, as alfo by their fragrant odour.

The former method, which was practifed in cutting thefe walks through woods, was to have them as ftraight as poffible; fo that there was much trouble to make fights through the woods, for direction how to cut them; but where this was practifed, every tree which ftood in the line, good and bad, was cut down, and many times boggy or bad ground was taken into the walks, fo that an expence of draining and levelling was neceffary to render them proper for walking on; befides this, there were many other inconveniences attending thefe ftraight cuts through woods, as, firft, by letting in a great draught of air, which in windy weather renders the walks unpleafant; and thefe cuts will alfo appear at a great diftance from the woods, which will have a very bad effect; therefore the modern practice of twifting the walks through woods is to be preferred. In the cutting of thefe walks there fhould be particular care taken to lead them over

the

the ſmootheſt and ſoundeſt part of the ground, as alſo to avoid cutting down the trees; ſo that whenever theſe ſtand in the way, it will be better to lead the walk on one ſide than to have the tree ſtand in the middle; for although ſome perſons may contend for the beauty of ſuch trees which are left ſtanding in walks, yet it muſt be allowed, that unleſs the walk is made much broader in thoſe places than in the other, the trees will occaſion obſtructions to the walkers or riders, eſpecially when ſeveral perſons are walking together; ſo that it will be much better to have the walks entirely clear from trees; and where any large ſpreading tree ſtands near the walk, to cut away the ſmall wood ſo as to make an opening round the trees, where there may be ſome ſeats placed for perſons to reſt under the ſhade. The turns made in theſe walks ſhould be as eaſy and natural as poſſible; nor ſhould there be too many of them, for that will render the walking through them diſagreeable; therefore the great ſkill in making of theſe walks is, to make the turns ſo eaſy as not to appear like a work of art, nor to extend them ſtraight to ſo great length, as that perſons who may be walking at a great diſtance may be expoſed to the ſight of each other; both theſe extremes ſhould be avoided as much as poſſible, ſince they are equally diſagreeable to perſons of true taſte. When a wood is properly managed in this way, and a few places properly left like an open grove, where there are ſome large trees ſo ſituated as to form them, there can be no greater ornament to a fine ſeat than ſuch a wood.

We ſhall now treat of the culture of woods for profit to the poſſeſſor, and public benefit of the nation.

The great deſtruction of the woods and foreſts which has been of late years made in this country, ſhould alarm every perſon who wiſhes well to it; ſince there is nothing which ſeems more fatally to threaten a weakening, if not a diſſolution, of the ſtrength of this once famous and flouriſhing nation, than the notorious decay of its timber: and as this devaſtation has ſpread through every part of the country, ſo unleſs ſome expedient be ſeriouſly and ſpeedily reſolved on, to put a ſtop to this deſtruction of the timber, and alſo for the future increaſe of it, one of the moſt glorious bulwarks of this nation, in a few years, will be wanting to it.

And as there are ſmall hopes of this being remedied by thoſe entruſted with the care of public woods, ſince their private intereſt is ſo much advanced by deſtroying the timber, which they were appointed to preſerve; therefore, unleſs private perſons can be prevailed on to improve their eſtates, by encouraging the growth of timber, it is greatly to be feared, that in an age there will be a want of it for the ſupply of the navy; which, when ever it happens, muſt put a period to the trade of this country.

It has been often urged, by perſons whoſe judgment in other affairs might be depended on, that the great plantations, which for ſeveral years paſt have been carried on in ſeveral parts of this kingdom, will be of public benefit by the propagation of timber; but in this they are greatly miſtaken, for in moſt of the plantations which have been made for years paſt, there has been little regard had to the propagation of timber, preſent ſhade and ſhelter have been principally conſidered; and in order to obtain theſe ſoon, great numbers of trees have been taken out of woods, hedge rows, &c. which, if they had remained in their firſt ſituation, might have afforded good timber, but being tranſplanted large, are abſolutely rendered unfit for any uſe but fuel; ſo that the great quantity of plantations which have been made, I fear, will rather prejudice than be of uſe to the improvement of timber; nor is there any other method of increaſing the uſeful timber of this country, than by ſowing the ſeeds in the places where they are to remain, or in ſuch ſituations where there are plenty of oaks in the neighbourhood; if the ground is properly fenced, to keep out cattle and vermin, the acorns which drop from thoſe trees will ſoon produce plenty of young trees, which, if properly taken care of will ſoon grow to be large.

The two moſt ſubſtantial timbers of this country are the oak and cheſnut; though the latter has been of late years almoſt entirely deſtroyed in England, ſo that there are ſcarce any remains of trees of ſize in the woods at preſent; but there can be no doubt of this tree having been one of the moſt common trees in this country, as may be proved by the old buildings in many parts of England, in which the greateſt part of the timber is cheſnut. Next to theſe, the elm is eſteemed as a profitable timber; but of theſe there are few cultivated in woods, eſpecially in the ſouth part of England, where they chiefly grow in hedge-rows, or plantations, near houſes; but in the north-weſt part of England, there are numbers of very large trees of the witch-elm growing in parks, and ſome in woods, as if that tree was a native of this country, which has been much doubted; though as this tree propagates itſelf by ſeeds, it may be deemed an indigenous plant in England.

The beech is another tree common in the woods, eſpecially upon the chalky hills of Buckinghamſhire, Kent, Suſſex, and Hampſhire, where there are ſome very large woods entirely of this ſort; ſome of which have been of long ſtanding, as appears by the age of the trees; but whether this tree is a native of this country, has been a point often diſputed.

The aſh is a very profitable tree, and of quick growth; ſo that in leſs than an age, the trees will arrive to a large ſize from the ſeeds, therefore a perſon may hope to reap the profits of his labour, who ſows the ſeeds; but this is not a beautiful tree to ſtand near a habitation, being late in the ſpring in putting out its leaves, and the firſt that ſheds them in autumn; nor is it a friendly tree to whatever grows near it, the roots drawing away all the nouriſhment of the ground, whereby the trees or plants which grow near are deprived of it; ſo that where the aſh grows in hedge-rows, the hedges in a few years are entirely deſtroyed; and if they are in paſture-grounds, and the cows browze on them, the butter made with their milk will be bad; for which reaſon the aſh ſhould be ſown ſeparate in lands which are incloſed, where cattle are not permitted to come, and at a diſtance from the habitation.

Upon ſandy or rocky ſoils, the Scotch pine will thrive exceedingly, and turn to great advantage to the planter, provided the plants are planted young, and treated in a proper manner. There are alſo ſeveral aquatic trees, which are very profitable to thoſe who have low marſhy lands, where the harder kinds of timber will not thrive; theſe are the poplars of ſeveral ſorts, the willow, alder, &c.

Where there are young woods, great care muſt be taken of the fences; for if cattle ſhould get in among the trees, they will, in a ſhort time, do infinite damage to them, by browzing on their branches, or barking the trees; and during the firſt ten years of their growth, they ſhould be ſecured from hares and rabbets, otherwiſe, in ſevere froſt, when the ground is covered with ſnow, whereby they are deprived of other food, they will get into the woods, and eat off the bark from the young trees, and gnaw all the branches within their reach; ſo that in a few days, where there are plenty of theſe animals, there may be ſuch deſtruction made among the young trees, as cannot be retrieved, but by cutting them down to the ground, which will be a loſs of ſeveral years; therefore thoſe perſons who have the care of young woods ſhould be very diligent in froſty weather in looking over the trees and ſtopping holes in the fences, to keep out all vermin.

Another care to be taken of young woods, is the thinning the trees from time to time, as they increaſe in their growth; but in doing of this, there muſt be great caution uſed, for it ſhould be gradually performed, ſo as not to open the trees too much, to let the cold air among them, which will greatly retard their growth; nor ſhould the trees be left ſo cloſe, as to draw each other up like Maypoles, but rather obſerve a medium in this work, cutting down a few each year, according as there may be neceſſity for it, being careful not to permit thoſe to ſtand, which may ſpoil the growth of the neighbouring trees, always obſerving to leave thoſe trees which are the moſt promiſing.

The young trees in theſe woods ſhould not be lopped or pruned, for the more they are cut the leſs they will increaſe in bulk; every branch which is cut off will rob the tree of its nouriſhment, in proportion to the ſize of the branch; therefore the hatchet ſhould not be ſuffered to come into young woods, unleſs in the hands of ſkilful perſons.

Where perſons have more regard to the future welfare of the timber than their immediate profit, the underwood ſhould be grubbed up as the trees advance, that the roots may have the whole benefit of the ſoil, and their ſtems enjoy the free air, without which their ſtems are generally covered

covered with mofs, and their growth greatly ftinted; as may be obferved in all fuch woods where there is any quantity of underwood remaining, in which places it is rarely found that the trees do ever grow to a large fize; therefore when large timber is defired, the trees muft have room to extend their roots and branches, without which it cannot be expected: but from a covetous temper, many people let their underwood remain as long as it will live; for as the timber increafes, the underwood will be gradually decaying by the fhade and drip of the large trees, fo that by this method the timber fuffers more in a few years than the value of the underwood; therefore by endeavouring to have both, neither of them can be fo good as where they are feparately preferved.

If perfons who have eftates would be careful to nurfe up trees in their hedge rows, it would in time become a fortune to their fucceffors; as hereby the timber growing in the hedges may be worth more than the freehold of the eftate, which has often been the cafe with eftates from which their poffeffors have cut down timber for fortunes for their younger children; the frequency of this fhould encourage perfons to be a little more attentive to the growth and prefervation of young woods, fince the expence and trouble is not great, and the future profit very certain; befides, the pleafure of feeing trees of a man's own fowing make yearly advances, muft be very great to thofe who have any relifh for country amufements.

There are feveral perfons who plant copfes for cutting every ten or twelve years, according to their growth. Thefe are ufually planted in autumn, either with ftools or young plants, which are drawn out of the woods; the latter fhould always be preferred to the former. Thefe copfes are commonly planted with feveral forts of trees, as oak, beech, chefnut, afh, birch, willows, &c. but the afh and chefnut are the moft profitable, where they grow kindly, becaufe the poles of afh are very valuable; thefe alfo are good for hoops, fo that there is no danger of having fale for thefe copfe woods when they are fit for cutting; but where the copfes are intended to remain, there fhould be no ftandard trees left for timber, becaufe as the heads of the trees fpread, and over-top the underwood, it will caufe that fo decay, and where the ftandards are left upon the ftumps of the copfe wood they will never grow to a large fize, nor will the timber be fo valuable as that produced immediately from a young root; therefore whoever will make the experiment, will be convinced that it is more for the advantage of both to keep them in diftinct woods.

But where perfons plant copfes upon land free from trees, it will be the better method to fow the feeds, efpecially if chefnut, oak, or beech, are the trees intended; for although it is a prevailing opinion with the generality of perfons, that by planting they fave time, yet I am fure of the contrary; for if the feedling plants are kept clear from weeds, they will, in eight or ten years, out-grow thofe which are planted; and thefe unremoved copfes will continue much longer in vigour than the other; fo that for either timber or copfe wood, the beft method is to prepare the ground well, and fecure the fences and fow the feeds, which is fo far from lofing, that in twenty years it will be found to gain time, which is what every planter wifhes to do.

The ufual time of felling timber is from November to February, at which time the fap in the trees is hardened; for when the fap is flowing in the trees, if they are cut down the worm will take the timber, and caufe it to decay very foon; therefore if the durablenefs of the timber is confidered, the trees fhould always be cut in the winter months; but as the bark of the oak is fo very valuable for tanning leather, there has been a law paffed to oblige perfons to cut thefe trees during the fpring-feafon, when the bark will readily peel off, by which the timber is rendered unfit for building either fhips or houfes, as it will be very fubject to caft, rift, or twine, and the worm will foon take it; therefore it would be more for the public benefit, if a law was enacted to oblige every perfon to ftrip off the bark of fuch trees, as are defigned to be cut down in the fpring, when the bark will run, leaving the trees with their branches ftanding till the following winter, which will be found to anfwer both purpofes well. *Miller's Gard. Dict.*

Wood-Cock *Soil*, ground whofe foil under the turf is of the colour of a wood-cock, and is not good.

Wood-Land, ground covered with woods. It is alfo a term ufed, by the farmers of many counties of England, for a fort of foil, from its conftant humidity and dark colour, refembling the foil in woods, which, of whatever nature it originally is, will always be made to appear thus from the continual dropping of trees, and the want of a free air and fun, together with the fall of leaves, deftroyed and wafhed to pieces by the wet.

This foil in the open countries has a confiderable quantity of clay in it, and holds the water a long time that once falls upon it: in wet weather it fticks firmly to the ploughfhare; and, in dry, is very apt to crack. In uncultivated places it ufually produces rufhes and rufh-grafs. A moift and dripping year is extremely detrimental to this fort of land.

WOODY, abounding with wood.

WOOL, the covering of fheep. Each fleece confifts of wool of feveral qualities and degrees of finenefs, which the dealers therein take care to feparate.

The Englifh and French ufually feparate each fleece into three principal forts, viz. 1. Mother-wool, which is that of the back and neck. 2. The wool of the tails and legs. 3. That of the breaft and under the belly. The wool moft efteemed is the Englifh, chiefly that about Leominfter, Coltfwold, and the Ifle of White; the Spanifh, principally that about Vegovia; and the French, about Berry.

An account of three experiments made to difcover whether wool, laid up in the fleece, alters in its weight.

It has been a matter of fome doubt amongft grafiers, farmers, and dealers in wool, whether or not wool, after it is fhorn and laid up in the fleece, alters in its weight. The following experiments were made to decide this queftion.

Experiment I.

This wool was fhorn dry, and laid up in a two-pair-of ftairs room, on a boarded floor.

	Weight lb.	oz.
1746, Aug. 10	76	6
Sept. 7	76	8
Oct. 14	77	11
Nov. 18	78	0
1747, Jan. 26	80	0
Feb. 20	80	4
Mar. 23	79	8
Apr. 18	77	13
June 24	76	8
July 28	76	8
Sept. 16	75	15
Nov. 2	78	1
Dec. 8	78	14
1748, Feb. 15	79	1

The weight was increafed from Auguft 10, 1746, (when it was firft laid up) to February 20, 1747, in the proportion as 100 to 105.

Experiment II.

This wool was fhorn dry, and laid in a lower room, with a brick floor one foot above the floor.

	Weight lb.	oz.
1746, Oct. 15	100	4
Nov. 18	101	2
1747, Jan. 26	102	8
Feb. 20	102	11
Mar. 23	102	9

The weight increafed from October 15, 1746, to February 20, 1747, as 100 to $102\frac{1}{2}$.

N. B. It is fomething difficult to account for this parcel of wool not encreafing more in its weight, as it lay fo near the ground floor; but very probably the air had been very damp and raw from the time it was fhorn till the 15th of October, 1746, when it was firft weighed, fo that the wool had then very likely gained weight confiderably.

Experiment III.

This wool was fhorn dry, and laid up in a two-pair-of-ftairs room, with a boarded floor.

	Weight lb.	oz.
1756, Aug. 30	36	9
Nov. 19	37	2
1757, Feb. 19	37	12
Mar. 24	37	6
April 1	37	4
D°. 21	36	14
May 2	36	13
June 1	36	$8\frac{1}{2}$
D°. 13	36	4
July 8	36	$1\frac{1}{2}$
D°. 27	35	12
Sept. 30	36	4
1758, Jan. 25	37	$11\frac{1}{4}$

The weight of this wool encreafed from the time it was laid up, Auguft 30, 1756, to February 19, 1757, as 100 to $103\frac{1}{4}$.

Both wool, and woollen rags, make an excellent manure. The rags should be chopped small, about an inch or two square, and scattered on the earth at the second plowing; for being thereby covered, they will begin to rot by seed time. They imbibe the moisture of dews and rain, retain it long, and, as Dr. Home observes, thereby keep loose soils in a moist state. They cost about fourpence a bushel at London, from whence many loads are sent every year to Dunstable (which is thirty miles), where they are laid even on stiff lands, just after the sowing of the corn, allowing to the acre four sacks of six bushels each.

WORMS are very prejudicial to corn fields, eating up the roots of the young corn, and destroying great quantities of the crop. Sea-salt is the best of all things for destroying them. Sea-water is proper to sprinkle on the land, where it can be had; where the salt springs are their water do; and were neither are at hand, a little common or bay-salt does as well. Soot will destroy them in some lands, but is not to be depended upon, for it does not always succeed. Some farmers strew on their lands a mixture of chalk and lime; and others trust wholly to their winter-fallowing to do it, if this is done in a wet season, when they come up to the surface of the ground, and some nails with sharp heads be driven into the bottom of the plough. If they are troublesome in gardens, the refuse brine of salted meat will serve the purpose, or some walnut leaves steeped in a cistern of water for a fortnight or three weeks, will give it such a bitterness that it will be a certain poison to them. A decoction of wood-ashes, sprinkled on the ground, will answer the same purpose; and any particular plant may be secured both from worms and snails by strewing a mixture of lime and ashes about its roots. It is a general caution among the farmers to sow their corn as shallow as they can, where the field is very subject to worms.

WORMS, a well known species of insects, very troublesome to horses.

Authors have described three different sorts of worms that affect horses, *viz.* bots, which young horses are often troubled with in the spring: the rotundi, or those resembling earth-worms; and the ascarides, or those about the size of the largest sewing needle, with flat heads.

For the method of curing the bots, *see the article* BOTS.

As the source of worms in general proceeds from a vitiated appetite and a weak digestion, recourse must first be had to mercurials, and afterwards to such things as are proper to strengthen the stomach, promote digestion, and by destroying the supposed ova, prevent the regeneration of these animals. Thus, two drams of calomel may be given with half an ounce of diapente, and mixed up with conserve of wormwood over night; and the next morning the above purge: these may be repeated in six or eight days. Or the following mercurial purge may be given, which will be less troublesome, and no less efficacious.

> Take crude quicksilver, two drams; Venice turpentine, half an ounce; rub the quicksilver till no glistening appears; then add an ounce of aloes, a dram of grated ginger, thirty drops of oil of savin, and a sufficient quantity of syrup of buckthorn to make a ball.

One of these balls may be given every six days, with the usual precautions in regard to mercurial physick; and these powders intermediately.

> Take powdered tin and Æthiops mineral, of each half an ounce: give every night in a mash, or his corn.

The various preparations of antimony and mercury must be given several weeks together, in order to get entire riddance of these vermin. The Æthiops mineral may be given to the quantity of half an ounce a day; the mercurius alkalisatus to two drams a day, incorporated with a bit of cordial ball. The cinnabar powders, as directed in the farcy, are no less effectual: and when worms are bred from high feeding, or unwholsome food; rue, garlick, tansy, savin, box, and many other simples, may be given successfully; being for that purpose mixed with their food; as also, cut tobacco, from half an ounce to an ounce a day.

As the generation of worms perhaps principally proceeds from a weak stomach, and bad digestion, if the horse be of a tender constitution, and a bad feeder, the following bitter drink should be given to strengthen his stomach, and mend his digestion; which will prevent the formation of these animals, interposing now and then a gentle stomach purge, prepared with an ounce and half of hiera picra made up into a ball, with syrup of buckthorn.

> Take gentian root, zedoary and galangals, of each two ounces; chamomile flowers, and tops of centaury, of each two handfuls; Jesuits bark powdered, two ounces; filings of iron half a pound; juniper berries four ounces: infuse in three gallons of ale for a week, shaking the vessel now and then: and give a pint of this night and morning.

To answer this purpose also, an ounce of filings of steel finely powdered, has been successfully given every day for a fortnight, or longer, in the horses corn. *Bartlet's Farriery, pag.* 150.

WOUND, a hurt given by violence.

In all fresh wounds made by cutting instruments, there is nothing more required than bringing the lips of the wound into contact by suture or bandage, provided the part will allow of it; for on wounds of the hips, or other prominent parts, and across some of the large muscles, the stitches are apt to burst on the horse's lying down and rising up in the stall; in such cases the lips should not be brought close together; one stitch is sufficient for a wound two inches long; but in large wounds, they should be at an inch or more distance; and if the wound is deep in the muscles, care should be taken to pass the needles proportionably deep, otherwise the wound will not unite properly from the bottom.

Should the wound bleed much from an artery divided, the first step should be to secure it, by passing a crooked needle underneath, and tying it up with a waxed thread: if the artery cannot be got at this way, apply a button of lint or tow to the mouth of the bleeding vessel, dipped in a strong solution of blue vitriol, styptic water, oil of vitriol, or hot oil of turpentine, powdered vitriol, or colcothar, &c. and remember always to apply it close to the mouth of the bleeding vessels, and take care that it is kept there by proper compress and bandage, till an eschar is formed; otherwise it will elude your expectations, and frequently alarm you with fresh bleedings.

In a memoir presented to the Royal Academy of Sciences by M. La Fosse, he gives an account of the success he had met with, in stopping the bleedings of very considerable arteries in horses, by the application of the powder of puff balls, the arteries cicatrizing by this means only, without any succeeding hæmorrhage. This lycoperdon, or puff ball was made use of for this purpose in human subjects, about one hundred and sixty years ago, by Felix Wurtz, a famous old surgeon in Germany; but he does not seem to have a thought of trusting to it in such considerable arteries, as M. La Fosse mentions, viz. those of the leg and thigh, the bleedings from which divided vessels, he stopt in a few minutes by the use of this powder only. The agaric of the oak may also be used for this purpose, where it can be retained by a proper bandage.

These applications, as indeed all styptics, seem to act by constringing the extremity of the vessel, or choaking it up, till a grume of blood is formed internally, which plugs up the orifice; and has been found to adhere to it so, as to constitute one body with the vessel. M. La Fosse has proved this by slitting an artery up longitudinally, when he found, that the little grume of clear blood, was of a firm consistence, of a lively red, in form of a cone or sugar loaf, the basis of which adhered to the little inclosing membrane, which shut up the artery without; the pocat of which floated in the cavity of the vessel.

I purposely avoid setting down any famous receipts for fresh wounds, whether ointments, or Fryar's balsams, being well assured, that in a healthy sound constitution, nature furnishes the best balsam, and performs herself the cure, which is so often attributed to the medicine; when it is otherwise, and the blood is deprived of its balsamic state, as will appear from the aspect of the wound, and its manner of healing, it must be rectified by proper internal medicines, before a good foundation for healing can be laid by any external applications whatever.

The lips of the wound then being brought together by the needle or bandage, it needs only to be covered with rags dipped in brandy, or a pledgit of tow spread with the wound ointment, and the wounded part kept as much as possible from motion.

Remember to dress all wounds of the joints, tendons, and membranous parts, with terebinthinate medicines: to which may be added honey and tincture of myrrh; and avoid all greasy applications whatever; fomentations and poultices are also generally here of great use; the former thin and attenuate the impacted fluids, greatly promote a free perspiration in the limb, and facilitate the unloading the surcharge on the vessels, by quickening the motion of the fluids; while the latter, by relaxing the vessels, abate their tension, and relieve the obstruction, by promoting digestion.

Punctured wounds from thorns, or any other accidents, should be treated in the same manner; applying the beer, or bread and milk poultice over the dressing, till some signs of digestion appear; and fomenting the part well every day. This method is also very successfully used to those swellings, which often arise on the neck from bleeding, the sores being sprinkled with precipitate, and burnt allum powdered, to fetch out the core, or fungus, which choaks up the orifice. The usual method is to introduce a piece of vitriol, or sublimate, which often brings on a plentiful discharge, fetches out the core, and makes a cure; but it is often with the loss of the vein, and it sometimes leaves a large swelling and imposthumation.

In gun-shot wounds, when the ball has not penetrated too deep, it should be extracted, if it can be fetched away without disturbance, together with any extraneous bodies that might pass in with it; the wound should be dressed with the old digestive of Venice or common turpentine, divided with the yolks of eggs, to which may be added some honey and tincture of myrrh. The entrance of these wounds frequently requires to be enlarged, and a depending orifice should always be procured if possible; and if the wound should not digest kindly, apply the beer poultice, and foment with the discutient fomentation.

In scalds, or burns from gunpowder, or any other cause, when the skin remains intire, bathe the part well, and keep it soaked with rags dipped in spirit of wine camphorated: salt bound thick on the part has been found very effectual for this purpose: and indeed all saline and spirituous applications excel others, while the skin is yet unbroke; but when the skin is separated, anoint the part, and keep it constantly supple with linseed or sallad oil, and a plaister spread with bees-wax and oil; if the skin is so scorched, that sloughs must be digested out, dress with the wound ointment and oil of turpentine, and finish the cure with any drying ointment. Should the horse be feverish from the pain, bleed him, give cooling glysters, and treat him as we have directed in simple fevers.

The fire supposed to be left in the part after injuries of this kind, is nothing more than the inflammation, which is the natural effect of such causes; so that the whimsical notions and conceits concerning fire remaining in the burnt part, is extremely absurd.

Wounds in the feet from nails, gravel, &c.

Accidents of this sort are very common, and sometimes for want of early care, prove of bad consequence; for the parts being naturally tender, are very susceptible of inflammation; and when matter is once formed, if a free discharge is not procured, the bone, which is spongy, soon becomes affected, and the whole foot is then in danger.

When any extraneous bodies, such as nails, stubs, thorns, &c. have passed into the horse's foot, you should endeavour to get them out as soon as possible; and after washing the part with oil of turpentine, dress the hole with lint dipped in the same, melted down with a little tar; the foot may be stopped up with bran and hogs-lard heated together, or put it into the turnep, or any soft poultice: this method is generally succesful, when the nail, &c. is intirely removed; but if any piece, or particle, should remain behind, which may be suspected by the degree of pain, and discharge of matter; after paring away the sole as thin as possible, introduce a bit of sponge tent, in order to inlarge the hole, that it may be drawn out by a small pair of forceps, or brought away by digestion: if this method should not succeed, but the lameness continues, with a discharge of a thin, bloody, or stinking matter, you must no longer delay opening the wound with a drawing knife to the bottom, and then dress as above directed, or with the turpentine digestive, divided with the yolk of an egg, and a little tincture of myrrh afterwards with the precipitate medicine. *Bartlet's Farriery, pag.* 246.

Y.

YARD-LAND, a quantity of land, in some countries fifteen acres, in some twenty, and in others, twenty-four, thirty and thirty-four acres.

YELLOWS, a disease incident to horses and other cattle, and more properly called the jaundice. *See the article* JAUNDICE.

" Having, says a correspondent of the editors of the Museum Rusticum, noted the frequent fatal effects of the disease in cattle, called the yellows, I, some years since, resolved to let no opportunity slip of being acquainted with this complaint, in order to assign its cause, inasmuch as I apprehend it to be the forerunner of most chronical diseases, to which great cattle are subject, as the murrain in the guts, scowering, asthma, or wheezing, dropsy, and loss of milk, &c.

" I have not hitherto been able to find any author who has treated of this complaint in a manner suitable to the consequence thereof, so as to trace the symptoms in its several stages, in order to effect a cure; and, where this complaint has been quite neglected or ill cured, to point out the consequence, by shewing how it may appear under the abovementioned shapes, which, being mistaken for originals when they are only consequents, are rarely cured, through the first cause being unknown.

" This complaint, I apprehend, proceeds from a waste of bile, that is, a preternatural running out of what is called gall; occasioned by the rugæ, which are in the inner membrane of the neck of the bilious duct, becoming, by some accident, too weak to perform their office, so that the gall runs out of the bladder nearly as fast as it runs in; by which means it forceth itself, or a considerable part at least, into the porus bilarius, instead of being discharged by the ductus communis cholidochus into the intestines, and, by the means of the vena porta, mixes again with the blood, filling that with its sharp pungent quality; which causeth that fluid to become of a sizy nature, and, consequently, to move slowly in the channels through which it passes; whence arises that sluggish disposition the beast in this complaint is subject to, and which is one of the first symptoms of the disease.

" And the liver, being deprived of the natural heat and weight thereof, is, together with the siziness of the blood, rendered incapable of performing its office, so that the supply of bile is not equal to the expence; nor is the blood purified from it as it ought, but passes on together till it fixes in some part, and there (if not timely prevented) forms a tumor very prejudicial to the beast.

" These tumors I have seen appear externally in the glands behind the ears, of the shoulders, and of the flank, in the dewlap, round the cornet of the hoofs, and in the udder, or milk-bag; internally, in the form of water, in the veins of fat between the muscular parts of the body, in the kidney fat, and even between the coats of the guts.

" When these tumors, which appear externally, come to suppuration, the beast commonly recovers, though frequently it be a long time first.

" The seasons of the year in which cattle are most subject to this complaint, are for about the five first weeks after they are put out to grass in the spring, during which time the season is apt to be very warm at days and cold at nights; the grass being also tender, and abounding with moisture: and, in like manner in autumn; at which time the days are also warm and nights cold; and the grass, on account of autumnal rains, tender as in the spring, and more so, if the preceding summer was tolerably dry.

" The cattle at these seasons being faint are very subject to perspire much, by which the pores are greatly opened in the day, and sudden cold coming on at night hastily contracts them; and before the warmth of the next day becomes sufficient to set the parts thus contracted at liberty, the matter, which should have been discharged by perspiration, returns into the blood in order to pass off by urine, by which means a much greater quantity of bile is secreted than otherways would; which passing into its receptacle, the gall-bladder, causes it to extend to a preternatural size; thereby extending the passage by its pressure, till the rugæ are scarcely to be seen: whereby the resistance made by them is not equal to the pressure of the bile, which, consequently, forces its way hastily into the blood, in the manner before observed, instead of passing off as excrement by the guts.

" The early symptoms attending this disease, are, a shaking of the beast in a morning, and more particularly the hinder parts, as the loins, thighs, and legs; hollowness of the eyes, and the hair staring; a dry nose, and if the cold taken be great, hanging of the ears, the swelling of the dewlap, of the glands of the ears, the shoulders, or the flanks, and of one or more quarters of the udder, or milk-bag in cows; with a sudden decrease of milk, what remains becoming, after a few days, more yellow than usual, and will, if boiled, curdle: the fore teeth are generally loose, as though they would drop out.

" If these symptoms, especially the first, remain unobserved, as is often the case in barren cattle, and such as range at large, it frequently happens that the disorder settles in some inward part; as on the pericardium, which causes wheezing, and the hask, and uncommon poverty; when in the guts and mesentery, (or sweet-bread) causes the lask and scowering; and when in the vein of fat, between the muscles, causes the dropsy and uncommon weakness.

" In this last complaint, on opening a beast, the melt or spleen was very small and thin, not half so large as in a healthy state, as was also the liver; but otherways found and perfect, the gall-bladder of an uncommon thickness, and its contents very little.

"In opening a beaſt which was waſted, and ſubject to wheezing and the haſk, the pericardium was become hard, and inclined to calloſity towards the part which joined the heart: the heart unuſually large, but ſound: the lights very ſound, but ſmall: the melt or ſpleen thin and withered: and the liver dryiſh, with a few ſmall hard knots therein: the gall-bladder near as the former.

"I have obſerved theſe knobs in others, and generally found the gall-bladder, liver, and ſpleen, leſs or more affected; thoſe which had the laſk, and ſcowered, generally having their guts covered, the inſide with a large quantity of mucus reſembling frogs ſpawn: the fleſh of theſe is always of a yellow caſt.

"Having ſaid thus much of what I apprehend the cauſe, I will now preſcribe what I have very many times known uſed with good ſucceſs for a cure.

"Firſt, Suffer no blood to be taken away from the beaſt.

> "Take a handful of rue tops, the like quantity of the greater celendine; ſhred them ſmall, and mix with them one ounce of turmerick root in powder (or inſtead thereof red ſanders); put theſe in three pints of ſtale old ale or beer, and cauſe it juſt to boil up; when it is cold enough, give it the beaſt warm: there is no occaſion to keep the beaſt in before or after, unleſs the inclemency of weather oblige.

"Two of theſe drinks, at forty-eight hours diſtance, will perfect a cure, if the diſeaſe be not of long ſtanding.

"Should a ſcowering be come on, then, after the firſt drink, give the following on the intermediate days.

> Take two pounds of oak-bark, boil it in one gallon of water till one fourth be conſumed; ſtrain it; in this water boil two pounds of rice till it be ſoft; mix with it half a pound of the burnt cruſt of bread, taken from the underſide of the loaf; and to all this put two quarts of milk; let it boil for twenty minutes; divide it in two parts, and give one to the beaſt at a time warm." *Muſeum Ruſticum, vol.* II. *pag.* 144.

YEOMAN, the firſt, or higheſt degree of the plebeians of England. The yeomen are properly freeholders, and who cultivate their own lands.

YEW-TREE, the name of a well known tree, common on cold ſoils in many parts of England. The timber of the yew-tree is much eſteemed for various uſes.

There is hardly any ſort of ever-green tree, which has been ſo generally cultivated in the Engliſh gardens as the yew, upon the account of its being ſo tonſible, as to be with eaſe reduced into any ſhape the owner pleaſed; and it may be too often ſeen, eſpecially in old gardens, what a wretched taſte of gardening prevailed formerly in England, from the monſtrous figures of beaſts, &c. we find theſe trees reduced into; but of late this taſte has been juſtly exploded by perſons of ſuperior judgment; for what could be more abſurd than the former methods of planting gardens? where, thoſe parts next the habitation were crouded by a large quantity of theſe and other ſorts of ever-green trees, all of which were clipped into ſome trite figure or other, which beſides the obſtructing the proſpect from the houſe, filled up the ground; ſo that little room was left for other ſhrubs and flowers. Beſides, it occaſioned an annual expence to render the trees diſagreeable; for there never was a perſon who had conſidered the beauty of a tree in its natural growth, with all its branches diffuſed on every ſide, but muſt acknowledge ſuch a tree infinitely more beautiful than any of thoſe ſhorn figures ſo much ſtudied by perſons of a grovelling imagination.

The only uſe this tree is fit for in gardens, is to form hedges for the defence of exotic plants; for which purpoſe, when it is neceſſary to have hedges, it is the moſt proper of any tree in being; the leaves being ſmall, the branches are produced very cloſely together; and if carefully ſhorn, they may be rendered ſo cloſe, as to break the winds better than any other ſort of fence whatever, becauſe they will not be reverberated, as againſt walls, pales, and other cloſe fences; therefore conſequently, are much to be preferred for ſuch purpoſes.

Theſe trees may be eaſily propagated by ſowing their berries in autumn, as ſoon as they are ripe, upon a bed of freſh undunged ſoil, covering them over about half an inch thick with the ſame earth.

In the ſpring the bed muſt be carefully cleared from weeds, and if the ſeaſon prove dry, it will be proper to refreſh the bed with water now and then, which will promote the growth of the ſeeds; many of which will come up the ſame ſpring, but others will remain in the ground until autumn or ſpring following; but where the ſeeds are preſerved above ground till ſpring before they are ſown, the plants never come up till the year after, ſo that by ſowing the ſeeds as ſoon as they are ripe, there is often a whole year ſaved.

Theſe plants, when they come up, ſhould be conſtantly cleared from weeds, which, if permitted to grow amongſt them, would cauſe their bottoms to be naked, and frequently deſtroy the plants when they continue long undiſturbed.

In this bed the plants may remain two years; after which, in autumn, there ſhould be a ſpot of freſh undunged ſoil prepared, into which they ſhould be removed the beginning of October, planting them in beds about four or five feet wide, in rows about a foot aſunder, and ſix inches diſtance from each other in the rows, obſerving to lay a little mulch upon the ſurface of the ground about their roots, as alſo to water them in dry weather until they have taken root; after which they will require no farther care, but to keep them clear from weeds in ſummer, and to train them according to the purpoſe for which they are deſigned.

In theſe beds they may remain two or three years, according as they have grown, when they ſhould again be removed into a nurſery, placing them in rows at three feet diſtance, and the plants eighteen inches aſunder in the rows, obſerving to do it in autumn, as before directed, and continue to trim them in the ſummer, for what they are intended; after they have continued three or four years in this nurſery, they may be tranſplanted where they are to remain, always obſerving to remove them in autumn where the ground is very dry; but on cold moiſt land it is better in the ſpring.

Theſe trees are very ſlow in growing, but yet there are many very large trees upon ſome barren cold ſoils, in divers parts of England.

YOAK, *or* YOKE, a frame of wood, fitted over the necks of oxen, whereby they are coupled together, and harneſſed to the plough.

Horſes and oxen are the animals uſed for drawing ploughs. Sometimes the one, ſometimes the other, and ſometimes both together. It is impoſſible to determine which of theſe is the moſt proper. This depends upon the kind of food moſt eaſily obtained, the other kinds of work required, and the expenſe of breeding, or purchaſing. If the real labour is to determine this without any other conſideration, then oxen are to be preferred; becauſe as they ſtand to the draught, they will overcome a reſiſtance which horſes will yield to.

As it cannot be determined, what kind of cattle are moſt proper for the plough; ſo neither can it be determined, what number is neceſſary. This depends upon the ſtrength of the cattle, and the nature of the ſoil. The number varies according to the work in which the plough is to be employed, and often according to the cuſtom of the place, and fancy of the farmer.

The methods of yoking cattle in ploughs vary almoſt as much as the number uſed. Some of them at firſt ſight are ſo aukward, that it is needleſs to conſider them. The only thing worthy of being inquired into, is, whether the cattle ſhould be yoaked in pairs, or in a line before each other? We ſhall therefore conſider the advantages and diſadvantages attending each way, and compare them together.

The moſt common way of yoaking cattle in ploughs is in pairs. There are ſome diſadvantages attending this way that are obvious. In ploughing the furrows betwixt ridges, the land-cattle go upon the ploughed land, and tread

tread it down with their feet: this, eſpecially if the land is wet, hurts it very much.

There is another diſadvantage very obvious. When there is but as much of the ridge unploughed as to allow the land-cattle to go upon it with difficulty, they are frequently either going into the oppoſite furrow, and thereby giving the plough too much land; or, which is worſe, they are juſtling the furrow-cattle upon the ploughed land.

To remove theſe inconveniencies that attend the ploughing with cattle yoked in pairs, ſome yoke them in a line before each other. It is obvious, that cattle yoked in this manner, going always in the furrow, neither tread upon the ploughed land, nor joſtle one another. In theſe reſpects the yoaking the cattle in a line before each other, ſeems to have the advantage.

It is to be obſerved, however, that this method is not quite free from inconveniencies. When examined, it may perhaps be found attended with as great inconveniencies as the other.

When cattle are yoked in a line, they go all in the furrow. This makes it neceſſary to give the plough more land and than ordinary, either by the ſoke or the muzzle: for if this is not done, the head and ſoke being in the ſame direction with the beam, and the cattle yoaked to the middle of it, the plough will directly follow the cattle, without taking any thing off from the land. Now, it is inconvenient to be obliged to give the plough land either by the ſoke or muzzle; for, when the ſoke is turned out of the plane of the beam, it makes the plough heavy to draw; and when the muzzle puts the draught too much to one ſide of the beam, it prevents the plough from going upright. The yoking the cattle in pairs is attended with none of theſe inconveniences: for, in this caſe, the quantity of land, which the plough has naturally, when right made, is ſufficient to make it take off a proper furrow.

There is another inconveniency that attends yoking cattle in a line, ariſing from the nature of the animals. Horſes and oxen, like men, love their eaſe, and are diſpoſed to throw the burden upon their fellows. This they have a better opportunity of doing when yoked in a line before each other, than when yoaked in pairs. When yoked in a line, each pulls by the traces of the one behind him; and therefore, though it may be known when the foremoſt neglects his work, by the ſlackening of his traces, yet it cannot be known when any of the reſt neglect their work; for though one of them does this, yet by the pulling of the one before him his traces may be fully ſtretched. But this is eaſily diſcovered, when the cattle are yoked in pairs; for then every one of them has a ſeparate draught. The goadman or driver knows, by the poſition of the yokes or croſs-trees, whenever one of them does not draw equally with his fellow; and the ploughman perceives, by the going of the plough, whenever any of the two pairs does not draw equally with the other: for if the pair that goes foremoſt neglect their work, the plough is pulled out of the ground; and if the pair that go hindmoſt neglect their work, the plough is pulled in too deep. The reaſon is obvious; the plough is made to go at a proper depth, when the two forces by which different directions are given the plough, act at the ſame time. If one of them then ſhould ceaſe to act, the plough cannot go right. If the foremoſt pair ſhould ceaſe to draw, the plough having too little eard for the direction of the draught of the hindmoſt pair, will come out of the ground: and if the hindmoſt pair ceaſe to draw, the plough having too much eard for the direction of the draught of the foremoſt pair, will go in too deep. This does not hold in an ox-plough: for as the ſoam by which the foremoſt pair draw is fixed to the yoke of the hindmoſt pair, the whole force applied to the plough is in the ſame direction; and therefore, though any of the pairs ceaſe to draw, there is no alteration in the going of the plough.

There is yet another inconveniency that attends the common way of yoaking cattle in a line before each other. When the fore cattle are all yoked to the traces of the hindmoſt, it is obvious, that as the beam, to which the draught is fixed, is much lower than his ſhoulders, by which the reſt pull, ſuch a weight muſt be laid upon his back or ſhoulder, as muſt render him incapable of giving any aſſiſtance. Beſides, as the whole force is applied in the direction of the traces of the hindmoſt horſe, it cannot have ſuch influence on the plough, as when a part of it is in a direction more horizontal. When a body is to be moved forward in any direction, the nearer that the direction of the force applied approaches to the direction of the body, it acts with the greater influence. And therefore, as the plough moves horizontally, and as the direction of the united draught of a plough with the cattle yoked two abreaſt, is more horizontal than the direction of the draught in a plough with cattle yoked in a line, the ſame force applied will have greater influence.

When theſe two different ways of yoking cattle in ploughs are thus conſidered and compared together, it is difficult to determine which ought to be preferred. Each of the two ſeems preferable to the other in a certain ſituation. When the land is ſtiff and the labour ſevere, the yoking the cattle in pairs ſeems preferable, as it is certainly the ſtrongeſt draught; and when the land is wet, and in danger of being much hurt by the treading of the cattle, the yoking them in a line before each other ſeems preferable; as thereby they are confined to the bottom of the furrow, which is the firmeſt part of the land, and prevented from doing harm.

When a perſon uſes two or more ploughs, it is a very proper way to have one with the cattle yoked in a line, and the reſt with the cattle yoked in pairs. The ploughs with the cattle yoked in pairs continue as long as the land-cattle have room to go eaſily upon the firm land; and the plough with the cattle yoked in a line, follows, and clears up the furrows. In this way the cattle yoaked in pairs do no damage, and the cattle yoaked in a line are never uſed but where they are of real benefit.

To perſons that incline to yoke the cattle in a line before each other, it will not be amiſs to point out a way to remove the inconveniency laſt mentioned, and ſhow how the cattle may be yoked ſo as to lay no additional weight on the back or ſhoulders of the hindmoſt horſe, and to make the direction of the draught more horizontal. This is done by making the traces of the horſe next to the plough but one very long, and fixing them, not to the ſhoulders of the horſe behind him, but to the croſs-tree, and by fixing the traces of the horſe before him, not to his ſhoulders, but to his traces at the place where the back-rope is fixed. By this the hindmoſt horſe is delivered from the burden laid upon him in the other method, as his draught is entirely independent of that of the reſt. There is indeed ſome weight laid upon the horſe immediately before him, to whom the others are yoked. But this is but ſmall; for his traces are nearly in the ſame direction with theirs, and they are yoked to him at a place lower than his ſhoulders. By this, likewiſe, the direction of the united draught is more horizontal, when there are three or more horſes yoked; it is even more horizontal than when the cattle are yoked in pairs. In a four-horſe plough yoked in pairs the two forces are equal; but in a four horſe-plough, yoked in this manner, the force moſt horizontal is to the other, as three to one.

The traces of the horſe hindmoſt but one being long, will incommode the hindmoſt horſe in turning, if they have nothing to ſupport them. To prevent this, two links muſt be fixed to the ſhoulders of the hindmoſt horſe, and the traces paſſed through them; the links long enough to allow the traces to be ſtretched.

When two horſes are ſufficient for the draught, the yoking them in this manner deſcribed for the two hindmoſt, removes alſo the ſecond inconvenience mentioned, that attends the yoking the cattle in a line: for the ploughman diſcerns, by the going of the plough, when any of them neglect their work, in the ſame manner as when there are four horſes in the plough yoked in pairs

The ordinary method of yoking oxen, is attended not only with all the inconveniencies of yoaking cattle in pairs, but alſo with the laſt-mentioned inconveniency, of yoking cattle in a line. For the ſoam, by which the foremoſt cattle draw, is fixed to the yoke of the hindmoſt pair. Their yoke being higher than the beam, a great weight is laid upon their necks by the drawing of the foremoſt cattle. This inconveniency may be removed, and the oxen yoked

in

in such a manner, as to give two directions to the plough, as is done when horses are yoked in pairs; by which the draught will likewise be made stronger. To do this, the soam of the pair immediately before the hindmost must be fixed, not to their yoke, but to the beam; and, to prevent this soam from incommoding the hindmost in turning, a link must be fixed to their yoke for it to pass through, the link long enough to allow the soam to be fully stretched. When there are more than two pair in the plough, as is most common, the largest-sized cattle should be placed next the plough, and the smallest-sized immediately before them. For the lower that the yoke of these last is placed, the nearer will the direction of their soam be to the soam of those before them; and thereby the less weight laid upon their necks. This method of placing the cattle is contrary to the ordinary way: for it may be observed, that the smallest-sized oxen are always placed next to the plough. But these different ways of placing the cattle are both founded upon the same reason: for the smallest-sized oxen are placed next the plough in the ordinary way of yoking, that so their yoke, to which the soam of the pair before them is fixed, may be as low as possible: for the lower that it is placed, the nearer the directions of the two soams approach each other, and the less weight is laid upon the necks of the hindmost pair. And, for the same reason, the lowest-sized oxen should be placed in the middle, when yoaked in the manner proposed, that so they may be less incommoded by the pair before them.

If, in considering the most proper method of yoking cattle in ploughs, we had nothing in view but the strength of the draught, and conveniency of the cattle; we would always recommend the yoaking the cattle in such a way, as to apply two forces to the plough in different directions. But as we must also have in our view the going of the plough, hence it becomes necessary to observe, that sometimes it is an advantage, to have the draught of the whole cattle in the same direction.

In ploughing lea, where the sward is tough, or any kind of land, where there are interruptions from roots, or the hardness of the bottom; the plough, if two forces are applied to it in different directions, goes very unsteadily, sometimes too deep, and at other times too shallow; and is very difficult to manage. The reason is obvious: when the plough meets with such interruptions, as tend to make it go deeper, or shallower, than its ordinary way of going; if at the same time, the force that acts contrary to the interruption ceases; then the plough, in spite of all the attention of the ploughman, will either start out of ground, or go in too deep, according to the tendency of the interruption. But when there is only one force acting upon the plough, it is, in some respect, like the wheeled plough; it goes steadily, and at a certain depth; at least, it is not so difficult to manage it, as when there are two forces acting in different directions: for though some of the cattle, at the time when the interruption is given, should cease to draw, yet the draught continues still in the same direction, and the ploughman has only the alteration occasioned by the interruption, to rectify. Every person knows, that an ox-plough goes much more steadily than a horse-plough: and this is occasioned, not only by the nature of the animals, oxen being more steady in drawing than horses; but also by the manner of yoking them, oxen being yoked in such a manner, as that one force only is applied to the plough.

Thus it apppears, that no absolute determination can be given, which of these two ways of yoking cattle in ploughs is to be preferred. Men must weigh the advantages and disadvantages attending each way, and determine according to circumstances. If the land is of a kind not easily ploughed, the cattle not well trained, and the ploughmen not expert, the work will be best performed, if there is only one force applied to the plough. But if the land is easily ploughed, that is, has few things in it to incommode the plough in going; if the cattle are well trained, and the ploughmen expert, the work will be well enough performed, and the labour less severe upon the cattle, if two forces are applied to the plough in different directions.

YOAK *of land*, the quantity of land which a yoak of oxen might plough in a day.
