The men turning both wheels together, as in the draught, the chain AFG ſhortens, as it rolls round its axis, while the draw-back DS lengthens; then a boy placed at R catches the rope and twiſts it round a cleet, to check the ſpoon, and prevent it from ſliding over the ſurface, inſtead of biting at the bottom; the maſter and director of the machine at Q conſpires in the ſame intention, by holding the rope O H P, called the loader, in his hand, tied to the pole N M; from thence it paſſes over the roller H, under which the maſter twiſts it round the cleet P, to veer it out by degrees, as he draws it towards him, to make the ſpoon A dig itſelf in, ſo that it may fill itſelf, as it works, by the action which is communicated to it by the great wheel; the boy at R looſens his rope gradually, ſo as to let the handle become vertical, after which it falls upon the other roller I. The maſter immediately lets go the loader, and goes to T, to wait till the ſpoon A comes into the ſituation repreſented by the ſpoon B, in order to open the door of it, which he performs with the hook X by lifting up the catch which kept it ſhut; this being emptied into a lighter placed below for that purpoſe, the door of the ſpoon is ſhut again with the extremity of the hook. After this operation, the men who were placed at *a*, paſs on to V, to turn the wheels in a contrary motion to the preceding, which lets out the chain F G to lower the ſpoon which is emptied, and the rope D S draws it towards itſelf, as it winds up on its own axis; on the contrary Z Y veers out, as the chain C E draws in to bring the ſpoon B back to the ſituation in which A is exhibited, which fills in the ſame manner as deſcribed before, and the two ſpoons are worked alternately by the two contrary motions of the wheels.

To work the machine, it muſt be moored to ſix poſts anſwering to the bites Æ, and four anchors diſpoſed as in figure 2. in order to move aſide backwards or forwards, as there may be occaſion.

The maſter ſtiffens or looſens the loader, with which he governs the ſpoons according to the reſiſtance of the bottom, becauſe in ſome caſes, if this rope be held too tort, he would be in danger of breaking ſome part of the machine by the force which the great wheel communicates; and, if he holds it too ſlack, the ſpoon does not bury itſelf deep enough to fill: he likewiſe ſhortens or lengthens the chains according to the different depths of the bottom: the chains and handles are made of a ſufficient length to dig thirty feet beneath the ſurface of the water.

The

The alternate motion of the ſpoons makes two trenches on each ſide of the barge, which muſt be ſhifted to make ſeveral ſimilar trenches, which afterwards form one only, and clean out the Harbour completely, which the maſter will judge of by frequent ſoundings.

HA'RDENING *of timber*. The Venetians are famous for the ſoundneſs of their ſhips, which do not rot as thoſe of other nations, but will endure many times the common period. Tachenius tells us, that the whole ſecret of this conſiſts in the manner of their Hardening of their timber intended for this ſervice; and that this is done by ſinking it in the water while green, and leaving it there many years. This prevents the alkali, or that ſalt which furniſhes the alkali in burning, from exhaling afterwards; and by this means the timber becomes almoſt as incorruptible as ſtone. It is evident that the exhaling of this ſalt, and the rotting of wood, have ſome very great connection with one another, ſince, the more ſound any piece of timber is, the more ſalt it proportionably yields; and the wood which is rotten is found on trial to contain no ſalt at all. See the article TIMBER.

HA'RDY *ſhrubs*. The two hardeſt ſhrubs we are poſſeſſed of, are the ivy and box; theſe ſtand the ſeverity of our ſharpeſt winter unhurt, while other ſhrubs periſh, and trees have their ſolid bodies ſplit and torn to pieces. In the hard winter of the year 1683, theſe two ſhrubs ſuffered no injury any where; though the yews and hollies, which are generally ſuppoſed very Hardy, were this winter in ſome places killed, and, in others, ſtripped of their leaves, and damaged in their bark. Furze buſhes were found to be ſomewhat harder than theſe, but they ſometimes periſhed, at leaſt down to the root. The broom ſeemed to occupy the next ſtep of hardineſs beyond theſe; this lived where the others died; and, where even this died, the juniper ſhrubs were ſometimes found unhurt. This laſt is the only ſhrub that approaches to the hardineſs of the box and ivy, but even this does not quite come up to them; for, while they ſuffer nothing in whatever manner they are expoſed, the juniper, though it bears cold well under the ſhelter of other trees, yet cannot bear the viciſſitudes of heat and cold, inſomuch that ſome juniper ſhrubs were found half dead, and half vigorous; that ſide, which faced the mid-day ſun, having periſhed by the ſucceſſive thawings and freezings of its ſap; while that which was not expoſed to the viciſſitudes of heat, had bore the cold perfectly well. Such ſhrubs as are not Hardy enough to defy the winter, but appear half dead in the ſpring, may often be recovered by Mr. Evelyn's method of beating their branches with a ſlender hazel wand, to ſtrike off the withered leaves and buds, and giving a free paſſage to the air to the internal parts. Where this fails, the method is to cut them down to the quick; and, if no part of the trunk appears in a growing condition, they muſt be taken off down to the level of the ground. *Phil. Tranſ.* N°. 165.

HARE.—The ſportſmen diſtinguiſh four ſorts of this animal: the one lives in the mountains; the ſecond kind in open fields; and a third kind in marſhy grounds; and the fourth is a rambler, having no particular fixed ſpot of reſidence. It is eaſy to ſee that theſe are no diſtinctions in the eye of the naturaliſt; but they have their ſeveral properties according to theſe differences of place, which are of conſequence to the ſportſman. Thus the mountain Hares are the ſwifteſt of all, and the marſh Hares the ſloweſt; the field Hares have a middling degree of ſwiftneſs between theſe; and the rambling Hares are the moſt difficult of all to hunt, for they are not only conſiderably ſwift, but they generally know all the coverts and thickets, and have the art to make a thouſand doublings and eſcapes that the others would not think of.

Hares and rabbits are very miſchievous to new planted orchards, by peeling off the barks of the tender young trees for their food; they do alſo the ſame ſort of miſchief to nurſeries; for the prevention of which, ſome bind ropes about the trees to ſuch a height as they are able to reach; ſome daub them with tar; but, though this keeps off the Hares, it is itſelf miſchievous to the trees; but this hurtful property of it is in ſome degree taken off by mixing any kind of fat or greaſe with it, and incorporating them well over the fire. This mixture is to be rubbed over the lower part of the trees in November, and will preſerve them till that time the next year, without any danger from theſe animals. It is only in the hard weather in the winter ſeaſon, when other food is ſcarce, that theſe creatures feed on the bark of trees.

People who have the care of warrens, pretend to an odd way of making Hares fat, when they get them there. This is the ſtopping up their ears with wax, and rendering them deaf. The Hare is ſo timorous a creature, that ſhe is eternally liſtening after every noiſe, and will run a long way on the leaſt ſuſpicion of danger; ſo that ſhe always eats in terror, and runs herſelf out of fleſh continually. Theſe are both prevented by her feeding in a ſafe place, and that without apprehenſion; and they ſay ſhe will always readily be thus fattened.

HART.—Harts at one year old have no horns, but only bunches; and at two years they are very imperfect, being ſtraight and ſingle; at three years old they grow out into two ſpears; at four into three; and ſo increaſe every year in number of branches, till they are ſix years old; but after that their age is not to be known by their heads. February and March are the months in which they caſt their horns; and in general the old ones caſt them ſooner than the young ones. Thoſe that have been injured at rut, or which have been gelded, never caſt them at all; if they are gelded while young, they never have any horns; if, after their horns are grown, they keep thoſe which they had on at the time, as long as they live. The horns of ſome are reddiſh, thoſe of ſome black, thoſe of others are finally white. The red horns are generally largeſt and ſtrongeſt, the black are uſually ſhorter, and the white are worſt of all, being the leaſt ſolid or ſtrong.

This animal is the moſt cunning in its care of itſelf of all the deer kind. It is the moſt timorous of any, and by its windings and turnings and other ſubtleties, as the running among the herds of cattle, often deceives the huntſman, and puts a foil upon the dogs. In the chace, which is generally a long one, he takes over hedge, ditch, or river, or whatever comes in his way, nothing ſtopping him.

This creature loſes its horns in the ſpring time, as the other deer do; but, during the time that it is without them, does not appear, but abides in the thick woods, and only comes out in the night-time for food.

HA'RVEST-*fly*, *cicada*, in natural hiſtory, the name of a large fly, remarkable for the noiſe which it makes in the ſummer months, and particularly about the time of Harveſt. The generality of authors have very improperly tranſlated cicada by the Engliſh word graſhopper; but this is extremely erroneous, the cicada having not the leaſt reſemblance to the graſhopper. It is called the cigale in France, in the provinces of Languedoc, &c. it is very common in that country; Italy and all the hot countries abound with it; and it is in moſt of theſe places called by the common people by a name expreſſing the Harveſt-fly; but in England we have not the inſect, and few of us have any notion of what it is. It is probable, that people who found the cicada, according to the deſcription of the ancients, very noiſy, fancied the graſhopper muſt be the ſame creature, this being of all our inſects the moſt noiſy in the ſummer months.

The cicada is a large four-winged fly; its body is ſhort and thick, and its wings long and large: the great or common cicada is by far the largeſt of all the known ſpecies of ſhort-bodied flies, and the ſmaller kinds are larger than the hornet. The head of the cicada is ſhort and obtuſe; the eyes are reticulated as thoſe of other inſects of the winged kind, but they are ſmaller, in proportion to the ſize of the body, than thoſe of moſt other ſpecies; they are placed at the two ſides of the back part of the head, and leave a very large naked ſpace of forehead between them; the breadth of this plain ſpace is not leſs than that of the breaſt of the animal, and it therefore makes a very ſingular figure. The reticulated eyes are of an oblong figure, and are cut into a vaſt number of faces, and between theſe there are in the plain ſpace of the forehead three other ſmall and ſhining eyes, reſembling thoſe of ſpiders, and placed in a triangle. The corſlet, or breaſt of this fly, is divided into two; the head is fixed to the anterior diviſion, and the body to the other; the anterior has a triangular figure delineated upon it in creux, and the poſterior to which the body is fixed has a ridge in the middle, riſing above the reſt of the ſurface. *Reaumur's Hiſt. Inſ.*

HASINE'LLAS, in the glaſs-making trade, are a number of hooks faſtened to the ſides of the working furnace, by means of which the workmen are able to reſt and turn their veſſels, as they ſcald them. *Neri's Art of Glaſs.*

HA'STING *pear*, a name given, by the gardeners, to a ſpecies of pear, called alſo, by ſome, the green chiſſel pear. This is a moderately large pear, and is longiſh toward the pedicle; its ſkin is thin, and of a whitiſh green; the pulp is melting, and of a ſugary flavour. It ripens in July.

HAT (*Dict.*)—Under this article in the Dictionary we have given the whole proceſs of Hat-making, and in order to elucidate that deſcription, we ſhall give a perſpective view of the whole operation on *Plate* XXVII. Where

A, is a man bowing the ſtuff, or compoſition for Hats.

B, the bow.

C, the ſtuff.

D, a man rolling a Hat on the plank, or ſloping ſide of the baſon.

E, a man putting a piece on a thin part of a Hat.

F, a man ſhaping a Hat on a block.

G, a lamp for giving light when they work in the night.

H, the plank, or ſloping ſide of the baſon.

I, a flue which carries of the ſmoak from the fire under the baſon.

K, a man ſtiffening the Hats.

L, the ſteaming baſon.

M, a furnace containing the fire which heats the ſteaming baſon.

HA'TCHES, in mining, a term uſed, in Cornwall, to expreſs any of the openings of the earth, either into mines, or in ſearch of them. The fruitleſs openings are called eſſay Hatches; the real mouths of the veins, tin Hatches; and the places where they wind up the buckets of the ore, wind Hatches. See the article WIND-HATCH, &c.

Coamings of the HATCHES, in a ſhip. When the Hatches are raiſed up higher than the reſt of the deck, thoſe planks, or

pieces

Engraved for the Supplement.

Printed for T. Hinton in Newgate Street.

pieces of timber, which raiſe and bear them up, are called coamings of the Hatches.

HA'TCHING (*Dict.*)—The artificial method of Hatching eggs, as practiſed in Egypt, has been mentioned in the Dictionary; and Mr. Reaumur has diſcovered, that the heat, neceſſary for this purpoſe, is nearly the ſame with that marked 32 upon his thermometer or that marked 96 on Fahrenheit's. If, therefore, eggs be kept in this degree of heat, they will as certainly hatch, as if the parent hen had ſat upon them; and indeed, it is impoſſible it ſhould be otherwiſe, ſince this heat anſwers nearly to that of the ſkin of the hen, or even of mankind; ſo that the empreſs Livia, as Pliny relates, might truly hatch a chicken in her boſom, if ſhe had but the patience to keep an egg there, for the ſame number of days that it ought to have continued under a hen.

After many experiments, Mr. Reaumur, found, that ſtoves, heated by means of a baker's oven, ſucceeded equally well with thoſe made hot by layers of dung. The furnaces of glaſs-houſes, and thoſe of the melters of metals, might, no doubt, be made to anſwer the ſame purpoſe. If, therefore, an eaſy method could be found to regulate the heat of the ſtove, it would be extremely convenient for bakers or paſtry-cooks to hatch, with little or no expence, a very great number of chickens; which they might diſpoſe of to the country people to be reared up till marketable. Should a thermometer be judged neceſſary for this purpoſe, it will be ſufficient to mark on it only ſuch degrees as are abſolutely neceſſary; by which means the inſtrument will not only come cheaper, but be the more readily underſtood by the ignorant people, for whoſe uſe it is deſigned.

Such an inſtrument, however, may be wholly diſpenſed with; a lump of butter, of the ſize of a walnut, melted with half as much tallow, ſerving to indicate the heat of the ſtove with ſufficient exactneſs. When the heat is too great, this mixture, which is to be kept in a phial, will become as liquid as oil; and, when the heat is too ſmall, it will remain fixed in a lump; but it will flow like thick ſyrup, upon inclining the bottle, if the ſtove be of a right temper. Great attention, therefore, ſhould be given to keep the heat always at this degree, by letting in freſh air, if it be too great, or ſhutting the ſtove more cloſe, if it be too ſmall.

But this is not all. That all the eggs in the ſtove may equally ſhare the irregularities of the heat, it will be neceſſary to ſhift them from the ſides to the center, and vice verſa; thereby imitating what the hens themſelves do by thoſe upon which they ſit; for hens are frequently ſeen to make uſe of their bills, to puſh to the outer parts thoſe eggs that were neareſt to the middle part of their neſts, and to bring into that middle part ſuch as before lay neareſt to the ſides of the ſame.

As to the form of the ſtoves, no great nicety is neceſſary. A chamber over an oven will do very well; only, in order to aſcertain the due degree of heat, it will be neceſſary to have phials of butter, as directed above, in ſeveral parts of the room; and, when the heat wants to be either increaſed or diminiſhed, it is ſufficient to diminiſh or increaſe the communication between the air in the room and that abroad, by opening or ſhutting ſome of the openings made in the wall for that purpoſe.

In order to cheriſh the new hatched chickens, capons may be taught to tend them in the ſame manner as hens do. Mr. Reaumur tells us, that he has ſeen above two hundred chickens, at once, all led about and defended, by only three or four ſuch capons; which clucked like hens, to call in the chickens that had ſtrayed too far off; and even redoubled their call, when they found any nice bits, to invite the young brood to come and pick them up. Nay cocks may be taught to do the ſame office, which they, as well as the capons, will continue to do all their lives afterwards.

But Mr. Reaumur, not ſatisfied with the aſſiſtance he could thus procure from cocks and capons, has invented a ſort of low boxes without bottoms, and lined with furs. Theſe, which he calls artificial parents, not only ſhelter the chickens from the injuries of the air, but afford a kindly warmth; ſo that they preſently grow fond of them, and take the benefit of their ſhelter as readily as they would have done under the wings of a hen.

For a few weeks after Hatching, it will be neceſſary to keep the chickens in a room artificially heated, and furniſhed with theſe boxes; but afterwards they may be ſafely expoſed to the air in the court-yard, in which it may not be amiſs to place one of theſe artificial parents to ſhelter them, ſhould there be any occaſion.

As to the manner of feeding the young brood, they are generally a whole day after being hatched, before they take any food at all; and then a few crumbs of bread may be given for a day or two, or millet-ſeeds mixed with the crumbs; after which they will begin to pick up inſects and graſs for themſelves. People in the country, who have plenty of conveniencies for the raiſing of poultry, will hardly give themſelves the trouble to hatch chickens in this artificial manner. It is in villages near great towns, and principally in the neighbourhood of the capital city, that it would be of the greateſt importance to promote the eſtabliſhment of this kind of ſtoves. Vid. Mr. Trembley's abſtract of the art of Hatching domeſtic fowls, tranſlated from the original treatiſe of Mr. Reaumur, where he explains every difficulty.

HAUSTI'LIA *ſuccina*, in natural hiſtory, a term uſed to expreſs that kind of amber, or, more properly ſpeaking, thoſe maſſes of amber which are obtained by dragging the bottoms of the ſea near Pruſſia, or found on the ſhores, in diſtinction from thoſe pieces which are found foſſile in the ſame or other kingdoms.

HA'ZLE, *corylus*, in botany, the name of a genus of trees, the characters of which are theſe: the flower is of the amentaceous or catkin kind, being compoſed of a number of leaves affixed in a ſquamoſe order to an axis; under each of theſe there are placed a number of apices. Theſe flowers are barren, and the embryo fruits are placed in different parts of the tree; theſe finally become a hard and roundiſh ſhell, containing a ſingle kernel, and ſurrounded by a callous fimbriated cup.

HAZLE-*earth*, in agriculture, a moderately compact earth, much approaching to the nature of the chiefly ſoil, and indeed properly a ſpecies of it, but always containing a large quantity of a reſin-coloured ſand. *Morton's Northampt.*

HAY.—Whatever uplands are deſigned to be mowed for Hay, are to be ſhut up in the beginning of February, and no cattle ſuffered to come upon them afterwards; but the meadows and marſh lands, where the graſs grows quicker, need not be ſhut up till April, except the ſpring be bad; and many farmers feed thoſe meadows which are in danger of overflowing till the firſt of May, and then ſhut them up for mowing.

In ſpring, the ſtones, ſticks, and all other kinds of foulneſs that lie upon the land, are to be picked up, and the mole-hills all levelled and ſpread, becauſe they hinder the mowers. If the meadows lie any thing uneven, or if they have been trodden down in winter, they ſhould be rolled all over with a large wooden roller; the mowers will then be able to cut much cloſer; for this, and the quantity of the Hay, will very well anſwer the trouble.

The time of mowing the graſs muſt be proportioned to its ripeneſs; nothing can be more prejudicial to the crop, than the cutting it too ſoon, becauſe the ſap is not then fully come out of the root; and ſuch graſs, when dried into Hay, ſhrinks up almoſt into nothing. It is very wrong alſo to let it ſtand too long, for, when the ſeed has been ripened, and is ſhed, the moiſture of the ſap all dries away out of the ſtalks, and they become no better than ſo much ſtubble; as is plainly ſeen in thoſe graſſes which grow in hedges, and, not being mowed, die away after they have perfected their ſeeds, and become taſteleſs and very different from Hay. The middle or latter end of June is the general ſeaſon for mowing; and the red flowers of the honey-ſuckle, beginning to wither, generally give the farmer notice that the time is coming on. But he may be more aſſured of this, by the tops or heads of the graſs looking full, bending downward, and looking brown: it is then in the proper ſtate to be cut down.

If there is great plenty of the Hay, and it lie thick in the ſwarth, the Hay-makers ſhould follow the mowers, and turn the ſwarths, as they cut them, unleſs there ſeems danger of wet weather; but in that caſe it is better to let them lie in the ſwarth. At night it muſt be made up into little cocks, and theſe in the morning muſt be ſpread again and turned, ſo that the other ſide may wither. After this it is to be made into ſmall cocks again, and the next day it is to be ſpread again, and drawn into long rows, which they call winrows. From theſe it is to be made up into large cocks after a little drying; and theſe large ones, if any wet comes, are to be ſpread open once again before they are carried in.

Mowing of land too often, or continuing it too long, is a very great prejudice to it, unleſs it have the advantage of being fed and renewed by land-floods at times. The farmer who has not this advantage to his lands, ſhould feed them once in two or three years, inſtead of making Hay from them, unleſs he chuſes to lay on manure conſtantly to keep them in heart. Feeding the Hay lands is the ſame ſort of reſpite that fallowing is to corn lands, both very neceſſary and advantageous.

HEAD-*ſails*, in a ſhip, thoſe which belong to the foremaſt and boltſprit; for it is by theſe that the head of the ſhip is governed, and by which it is made to fall off, and keep out of the wind. And theſe in quarter winds are the chief drawing ſails.

HEAD-*tin*, in metallurgy, is a preparation of tin ore toward the fitting it for working into metal. When the ore has been pounded and twice waſhed, that part of it which lies uppermoſt, or makes the ſurface of the maſs in the tub, is called the Head-tin; this is ſeparated from the reſt, and after a little more waſhing becomes fit for the blowing-houſe. *Ray's Engliſh Words.*

HEART-*ſhells*, *conchæ cordiformes*, in natural hiſtory, the name of a genus of ſhells, by ſome authors referred to the pectunculus or cockle kind, but by later writers juſtly diſtinguiſhed into a ſeparate genus. The characters are theſe: it is a bivalve ſhell-fiſh of a globoſe elated form, furrowed in deep lines, and in ſome ſpecies imbricated, in others prickly, never auriculated, and always expreſſing what we call the figure of a heart. *Hiſt. Nat. Eclairc.*

HEAT (*Dict.*)—The learned Dr. Knight, after ſuppoſing a repellent

repellent fluid every where disseminated through the universe, accounts for the effects of Heat, in the following manner:

If light in a sufficient quantity enters the pores of a solid or fluid body, the quantity of repellent matter will be thereby increased, the body expanded, and the common effects of Heat produced.

Light is nothing but the repellent fluid put into very violent vibrations. When these vibrations are continued in a right-line, till they arrive near the surface of a body, they will begin to be acted upon by the repellent and true atmosphere surrounding that surface, and either be repelled thereby, or have force sufficient to penetrate within those atmospheres: if the latter, the same vibrations will be continued through the repellent atmosphere, only the direction will be changed towards the perpendicular; because the repellent particles will be acted upon by two forces, in different directions; except when the light falls perpendicular to the surface, for within the atmosphere of bodies the repellent matter it attracted towards the surface. Light will therefore move within the atmosphere of bodies, in the diagonal of the projectile and attracting force; and by the continuation and increase of that attracting force, will be made to describe a curve, and come nearer the direction of a line drawn perpendicular to the surface; where, when it arrives, it will either fall upon a pore or solid part: if the former, it will enter among component corpuscles of the body, and increase the repulsive force betwixt those corpuscles, which must make them recede farther from each other, and consequently the body will be dilated. The greater the quantity of light that thus enters amongst the component corpuscles of bodies, the greater will be their expansion: Heat therefore will be most produced, where the greatest number of repellent particles are in a vibratory motion without the body. Nor is it necessary that those vibrations should be always so violent as to excite in us the sensation of light. A very small vibration will be sufficient, when the direction of it is perpendicular to the surface. Hence we see the difference betwixt light and Heat: the first may be produced by a few vibrating rays, provided that those vibrations are brisk enough; the latter may be produced by much weaker vibrations, provided the rays are sufficiently numerous.

HEAT, in medicine.—Great Heats are not so much the immediate, as the remote cause of a general sickness, by relaxing the fibres, and disposing the fibres to putrefaction; especially among soldiers, and persons exposed the whole day to the sun; for the greatest Heats are seldom found to produce epidemic diseases, till the perspiration is stopped by wet cloaths, fogs, dews, damps, &c. and then some bilious or putrid distemper is the certain consequence, as fluxes and ardent intermitting fevers. Nevertheless, it must be allowed, that Heats have sometimes been so great, as to prove the more immediate cause of particular disorders. As when centinels have been placed without cover, or frequent reliefs, in scorching heats; or when troops march, or are exercised in the heat of the day: and when people imprudently lie down and sleep in the sun: all these circumstances are apt to bring on distempers, varying according to the season of the year. In the beginning of summer, these errors produce inflammatory fevers; and, in the end of it, or in the beginning of autumn, a remitting fever or dysentery.

To prevent, therefore, the effects of intemperate Heat, commanders have found it expedient so to order the marches, that the men come to their ground before the Heat of the day; and to give strict orders, that none of them sleep out of their tents; which in fixed encampments may be covered with boughs, to shade them from the sun. It is likewise a rule of great importance to have the soldiers exercised before the cool of the morning is over; for, by that means, not only the sultry Heats are avoided, but the blood being cooled, and the fibres braced, the body will be better prepared to bear the Heat of the day. Lastly, in very hot weather, it has been found proper to shorten the centinel's duty, when obliged to stand in the sun. *Pringle's Observations on the Diseases of the Army.*

HEATH-*moss*, *coralloides*, in botany, the name of a genus of the mosses; the characters of which are these: they are composed of stalks often branched in the manner of corals, and composed of parts of a different figure and appearance, not simple and uniform as the byssi and confervæ. On the summits of the branches there grow a sort of fleshy tubercles, which Micheli calls the receptacles of flowers; and the little atoms, which are seen adhering to the different parts of the stalks, he calls the seeds.

HE'DERA, *ivy*, in botany, a genus of plants, whose characters are:

The parasitic tendril sends forth fibres, or roots, into any thing they come near, capable of sustaining them: the leaves are angular; the flower rosaceous, and, generally, hexapetalous; the ovary, at the bottom of the flower, becomes a round berry, pregnant with seeds, which are gibbous on one side, and flat on the other.

The leaves of ivy, while they run upon the ground, are more angular and cornered; but, when the stalks rise up, and are fastened to a wall or tree, they become rounder, ending in one point: whence most of the old botanic writers have made two species; that with the cornered leaves, because it bore no fruit, while it lay on the ground, they called helix, or barren ivy; and the other corymbosa: the leaves of both are of a firm texture, and a dark green colour; those of the first frequently full of small white veins: the branches insinuate themselves, by short cirrhi, into a wall, or body of a tree, that it climbs on: the flowers grow in corymbi or umbels, consisting of small six-leaved yellowish flowers, followed by round umbilicated berries, black, when ripe; including several angular seeds: ivy grows every-where in hedges, and flowers late in the year; the berries being not ripe till January, or later.

The leaves are seldom or never used inwardly; but, outwardly, they are applied to issues, to keep them cool, and free from inflammations; as, also, to scabs, and sores, and scald heads. Mr. Boyle, in his Usefulness of Experimental Philosophy, commends a large dose of the full ripe berries, as a remedy against the plague; though Schroder says, they purge upwards and downwards. The gum of ivy is somewhat caustic, and commended to take away spots and freckles out of the face. *Miller's Bott. Off.*

The gum is a resinous, dry, hard, and compact substance; of a bay colour, inclining to that of gold, shining like glass, but not pellucid; of a subacrid and subastringent taste, and fragrant smell.

Geoffroy says, it is neither caustic nor depilatory, as the ancients imagined; but a powerful resolvent and discutient, in which intentions it is an ingredient in several plaisters.

HEDERA *terrestris*, *ground-ivy*; see the article GROUND-IVY, in the Dictionary.

HEDGE (*Dict.*)— The hawthorn is allowed to be the best of all the English shrubs for quick-set Hedges. The best method of raising this for use, is to put the haws into the ground as soon as ripe, and cover them with earth; and, by the spring twelvemonth, the young shoots will be of due size to transplant from the seed-plot into Hedge-rows. The crab-tree is a common mixture with the hawthorn in Hedges; but grows faster than the hawthorn, and requires cutting to keep the Hedge even. The young hawthorns raised from seed always thrive better than those picked up wild in the fields. *Moreton's Northampt.*

The great consideration, in making quick-set Hedges, is to bring the plants from a worse soil than that in which it is intended to set them. They must be about the thickness of one's thumb, well rooted and strong, and must be planted about four or five inches out of the ground. If there be a ditch to the Hedge, it should be three feet wide at the top, one at the bottom, and two deep; and, if wider, then deeper in proportion.

If the bank be without a ditch, the plants should be set in two rows at a foot distance below one another. The turf is to be laid with the grass side downward on that side of the ditch on which the bank is designed to be made, and some of the best mould must be laid upon it to bed the quick; then the quick is to be laid upon it a foot asunder, so that the end of it may be inclining upwards; and at equal distances of thirty feet, plant an ash, oak, crab, or elm, to grow with the quick. When the first row of quick is laid, it must be covered with mould, and the turf laid upon it as before, and some more mould upon that; so that when the bank is a foot high, another row of sets may be laid against the spaces of the lower quick. These must be then covered as the former, and the bank is to be then topped with the bottom of the ditch, and a dry or dead Hedge laid, to shade the under plantation. There should then be stakes driven into the loose earth quite down to the firm ground, at about two feet and a half distance from each other; oak stakes are accounted the best of all for this use, and, the next to this, those of black-thorn or sallow. Small bushes are to be laid below, but not too thick, only to cover the quick from being injured, as it shoots. *Miller's Gard. Dict.*

HE'GEN, Arabian name of the camel which has only one bunch on its back. Its hairs are soft to the touch, and are shorter than those of our oxen, except that there are some longer on the head, the throat and the top of the neck; and on the middle of the back, there are hairs of a foot long, and these though very soft and flexile, yet naturally standing in an erect posture, they make the most visible part of the bunch. For when these are removed by the hand, the flesh scarce appears more prominent, than that of the back of a hog, and there is not the least fleshy or callous excrescence there. See DROMEDARY.

The head is small in proportion to the body; the upper lip is divided as in the hare; the feet are not hoofed; but each terminated by two small claws; the sole of the foot is broad and very fleshy; and seems soft to the touch, though the skin is very hard and callous; the feet are indeed cloathed as it were with living shoes, which are of very great service to it in travelling over the sandy countries. It has six callous hardnesses on the knees and shoulders of the fore legs, and one on each of the hinder ones. And, beside these, there is another much larger, which adheres to the breast, on an eminence which is there, as if made to support it; this is usually eight inches long,

long, six inches broad, and about two thick. The use of these is to sustain the weight of the creatures body on occasion of his stooping to rest, or to be loaded.

Its stomach is very large, and divided into four parts as in other ruminating animals, but of a singular structure; in that at the upper part of the second ventricle, there are several square holes, which are the orifices of a great number of a sort of bags placed between the membranes which compose the stomach, and these seem to be the receptacles of water kept for the time of necessity, for the creature always drinks a vast quantity at once, and will then live a great while without drinking again. It is yet a question to be decided, whether this creature is of the retromengent kind, and whether it copulates backwards? This has been affirmed by some, but it is greatly doubted by others. See *Plate* XXVIII. *fig*. 3. *Ray's Syn. Quad.*

HELE'NIA, *bastard elecampane, or willow-leaved sun-flower*, in botany, a genus of plants whose characters are:

It hath a compound radiated flower, consisting of many florets, which are hermaphrodite, and of semi-florets, which are female: the ovaries stand on a naked placenta, each leaving an antient crown: all these parts are included in a simple empalement, which expands, and is cut almost to the bottom in several parts.

The best season to transplant the old roots, and to part them for increase, is in October, or the beginning of March, just before they begin to shoot; but, if the spring should prove dry, they must be duly watered, otherwise they will not produce many flowers the same year. These plants should not be removed oftener than every other year; for as they do not spread their roots very wide, they will very well continue two years within due compass. They delight in a soil rather moist than dry, provided it be not too strong, or hold the wet in winter: but if they are planted in a dry soil, they must be often and plentifully watered in dry weather, to make them produce plenty of flowers.

These plants generally rise about three feet and an half, or four feet high; therefore should be planted in the middle of large borders, intermixed with flowers of the same growth, where they will make a pretty variety, because they continue a long time in flower: and as they require very little care to cultivate them, they deserve a place in every large garden.

Their flowers resemble those of the smaller kinds of sunflower, and have been by some botanists ranged in that genus. The time of their flowering is from July until the frost stops them.

HE'LIOTROPE, *heliotropium*, among the ancients, an instrument or machine, for shewing when the sun arrived at the tropics and the equinoctial line. *Hoff. Lex.*

White HE'LLEBORE (*Dict.*)—The characters are:

The flower is naked, consisting of six leaves, which expand in form of a rose; in the middle of which arise the pointal, surrounded by six stamina or threads, which afterwards turn to a fruit; in which, for the most part, three membranaceous sheaths are gathered into a little head, and are full of oblong seeds, resembling a grain of wheat, and encompassed, as it were, by a leafy wing.

These plants are very pretty ornaments, when planted in the middle of open borders of the pleasure garden; for if they are placed near hedges or walls, where generally snails harbour, they will greatly deface the leaves, by eating them full of holes; and as a great part of the beauty of these plants consist in their broad folded leaves, so, when they are thus defaced, the pleasure is almost lost.

The leaves of these plants are very broad, especially if the ground is good where they grow, and are plaited somewhat resembling those of the palms; but are of a much thinner consistence. From each head of the root is generally produced a flower stem, about three feet high, having a spike of flowers about a foot in length at their top. The flowers of the first kind, being green, make not much appearance; but those of the second, which are of a dark red, or purple colour, are generally preferred by those persons who cultivate them in the pleasure garden.

They may be propagated either by parting their roots in autumn, or towards the latter end of February, or the beginning of March, just before they begin to shoot, and should be planted in a light fresh rich soil; in which they will thrive exceedingly, and produce strong spikes of flowers. These roots should not be removed oftener than once in three or four years; by which time, if they like the soil, they will be very strong, and afford many heads to be taken off; but, if they are frequently transplanted, it will prevent their increasing, and cause them to flower very weak.

You may also propagate these plants by seeds, which should be sown as soon as ripe, either in a bed or box filled with fresh light earth, and the ground kept constantly clear from weeds. In the spring the plants will appear, at which time, if the season be dry, you should now and then refresh them with water, which will greatly promote their growth; and you must carefully clear them from weeds, which, if permitted to grow, will soon overspread and destroy these plants while young. The spring following, just before the plants begin to shoot, you should prepare a bed of fresh light earth, and carefully take up the young plants, observing not to break their roots, and plant them therein about six inches square, where they may remain until they are strong enough to flower, when they should be transplanted into the borders of the pleasure garden. But as these plants seldom flower in less than four years from seeds, so this method of propagating them is not very much practised in England. See *Plate* XXV. *fig*. 2. where *e* is the flower, *f* the fruit, *g* the seed.

HE'NBANE *louse*, in natural history, a name given by some to a peculiar insect found very frequently on that plant in the summer months. It is one of the cimices of authors, and is very well described by Lister in the Philosophical Transactions. It is a very large cimex, of a fine red, spotted with black; it feeds on the juices of the Henbane, whose leaves and stalk it pierces with its trunk. It is very remarkable that the juices of this stinking plant acquire a very agreeable and aromatic flavour in the body of this insect, and on trial it may perhaps be found, that the mischievous narcotic quality of the plant may be rendered wholesome, and a good medicine, in the body of this insect. *Phil. Transf.* N°. 71.

HE'PAR *sulphuris*, brimstone melted with half the quantity of a fixed alkali. A like substance may also be produced by tartarum vitriolatum, sandiver, or other of the neutral salts containing the vitriolic acid, if, when they are red-hot in the fire, there be added to them powder of charcoal, or any other more fixed phlogistic; but the hepar sulphuris is not so strong, as otherwise, when it is made with nitre fixed with coals, or with the alkali composed of tartar and nitre, or with neutral salts with an addition of sulphur already containing the vitriolic acid. The Hepar sulphuris runs earths and stones into fusion over the fire; and when melted with the metals it makes them easily fuse, but renders them brittle, and in some degree soluble in water. *Hoffman's Observ. Phys. Chem.*

HEPA'TICA *trifolia, noble liverwort*, in botany, a genus of plants, whose characters are:

The root is fibrous and perennial; the pedicles of the leaves arise from the root; the leaves consist of three lobes, the stalks are naked, florigerous, or flower-bearing, simple, and spring from the root. The perianthium or calyx is monophyllous, deeply cut, commonly into three, rarely into four lobes, and permanent. The flower is rosaceous, polypetalous, naturally pentapetalous, and furnished with numerous stamina. The fruit is globular, and has every one of its cells furnished with a crooked tube: in other respects it resembles the lesser celandine.

The flowers of this liverwort arise out of the ground early in the spring, before the leaves; they grow on long, slender, and somewhat hairy foot-stalks, four or five inches long, inclosed in a three-leaved green calyx: they are made up of six blue roundish-pointed leaves, set about a small green head, with several whitish-blue chives in the middle; the green head afterwards is inlarged into several small naked seeds. The leaves come up when the flowers are past, consisting each of a leaf of three equal lobes, round, and somewhat pointed at the end, of a dull green colour, growing on long foot-stalks. The root is small and stringy. It is usually planted in gardens, and flowers in March.

The leaves are used, though but very rarely, here in England; but they are commended by some foreign authors, as a very good vulnerary, and useful in distempers of the liver.

It is cultivated in gardens, and flowers in the spring. As to its virtues, it corroborates the stomach by its astringent quality, and is, therefore, proper in all disorders proceeding from relaxation, and where astriction is required: hence it is of service in vulnerary drinks, in a diabetes, spitting of blood, or making of bloody urine. It is much commended in an hernia; and the leaves, pulverized, are excellent in the dysentery. A decoction of the leaves is effectual against the jaundice, itch, fetid ulcers, and the quinsey. The whole plant is of service in obstructions of the kidneys, bladder, and liver. *Boerhaave.*

These plants are some of the greatest beauties of the spring: their flowers are produced in February and March in great plenty, before the green leaves appear, and make a very beautiful figure in the borders of the pleasure-garden; especially the double sorts, which commonly continue a fortnight longer in flower than the single kinds, and the flowers are much fairer. I have seen the double white kind often mentioned in books, but could never see it growing; though I do not know but such a flower might be obtained from the seeds of the single white, or blue kinds. I have sometimes known the double blue sort produce some flowers in autumn which were inclining to white; and thereby some people have been deceived, who have procured the roots at that season, and planted them in their gardens; but the spring following their flowers were blue, as before: and this is a common thing, when the autumn is so mild as to cause them to flower. But, whether the double white sort, mentioned in the books, was only this accidental alteration in the colour of the flower, I cannot say; though it seems very probable it was, since I never could hear of any person who ever saw the double white sort flower in the spring. *Miller's Gard. Dict.*

HEPTA'NDRIA, in botany, a clafs of plants with hermaphrodite flowers, and feven male parts or ftamina in each.

* The word is formed of the Greek, ἑπτὰ, feven, and ἀνὴρ, male.

Of this clafs are the horfe chefnut, finitelis, &c.

HE'RBA *paris*, *herb paris*, in botany, a genus of plants, whofe characters are:

The calyx confifts of four leaves, which expand in rays. The flower is tetrapetalous; the petals difpofed in the form of a crofs, furnifhed with four ftamina. The fruit is foft, globular, furnifhed with four tubes, divided into four cells, and full of oblong feeds.

The roots of this herb run creeping along on the furface of the earth, being flender and of a brown colour, fhooting up here and there, being long round ftalks half a foot high; having ufually four, though, fometimes, five or fix leaves, which are pretty broad and roundifh, narroweft next the ftalk, and ending in a fharp point. From among thefe arifes a flender ftalk, two or three inches high, bearing one fingle flower, compofed of four long green leaves, with as many very narrow ones under them, of the fame colour, having feveral ftamina among them; in the middle of thefe grows a roundifh blackberry, about as big as a grape, of an infipid tafte. It is found in moift fhady woods, which have a good foil; the neareft place to London, that I know of, where it grows, is Chifelhurft in Kent, in a wood by the bog, at the entrance of it next the town.* It flowers in April and May, and the berry is ripe in July.

Though this plant was formerly accounted of a poifonous nature, being reckoned among the aconites, Fuchfius calling it aconitum pardalianches; yet authors, who have wrote fince, attribute to it quite contrary effects, efteeming it to be a counterpoifon, and an alexipharmic, and good in malignant and peftilential fevers.

Parkinfon fays, the roots, boiled in wine, help the cholic; and the leaves, applied outwardly, reprefs tumors and inflammations, efpecially in the fcrotum and tefticles, and ripen peftilential tumors.

HERNA'NDIA, in botany, the name of a diftinct genus of plants, the characters of which are thefe: the petals of the flower are multifid, and placed in a circular order; the male and female flowers ftand on diftinct plants. There is no pericarpium, but the cup of the flower is very large, fwelled, and roundifh; containing a plicated oval nut, with only one cell, and a globofe nucleus. *Linnæi Gen. Plant.*

We know only one fpecies of this genus, which is the Hernandia, with a large umbilicated ivy-like leaf, commonly called, in the Weft-Indies, Jack in a box.

HE'RON, *ardea*, in zoology, the name of a large genus of birds, the diftinguifhing character of which is, by Mr. Ray, fixed in their inteftines; they having only one inteftinum cæcum, or blind gut, as is the cuftom of nature in quadrupeds, moft other birds having two.

This bird is a great devourer of fifh, and is of more mifchief to a pond than even an otter: fome fay, that a Heron will deftroy more fifh in a week, than an otter will in three months; but that feems carrying it too far. People who have kept Herons, have had the curiofity to number out the fifh they fed them with into a tub of water, and counting them again afterwards, it has been found that they will eat fifty moderate-fized dace and roaches in a day. It has been found that in carp ponds, vifited by this bird, one Heron will eat up a thoufand ftore carp in a year, and will hunt them fo clofe as to let very few efcape. The readieft method of deftroying this mifchievous bird, is by fifhing for him in the manner of pike, with a baited hook. When the haunt of the Heron is found out, three or four fmall roach or dace are to be procured, and each of them is to be baited on a wire, with a ftrong hook at the end, entering the wire juft under the gills, and letting it run juft under the fkin to the tail; the fifh will live in this manner five or fix days, which is a very effential thing; for, if it be dead, the Heron will not touch it. A ftrong line is then to be prepared of filk and wire twifted together, and is to be about two yards long; tie this to the wire that holds the hook, and to the other end of it there is to be tied a ftone of about a pound weight; let three or four of thefe baits be funk in different fhallow parts of the pond, and, in a night or two's time, the Heron will not fail of being taken by one or other of them.

HE'SPERIS, in botany, a genus of plants, whofe characters are:

It has a long, fmooth, cylindrical, bivalve pod, divided into two capfules or cells, which are feparated by an intermediate partition, and furnifhed with cylindrical or globular feeds.

Boerhaave mentions four and twenty fpecies of this plant.

This plant is antifcorbutic and diaphoretic, and very ferviceable in the afthma, coughs, and convulfions. The outward ufe of it is recommended againft inflammations, cancers, a gangrene, fphacelus, and contagious difeafes. Bruifed, it very potently refifts putrefaction; and, applied to peftilential buboes under the arm-pits, ripens and foftens them. It is highly commended by Hildanus, in his treatife of Inflammations, Sphacelus, and Gangrene; and I myfelf have had experience of its virtues, in the following inftance: there was a ftudent, who, being on a journey, had the misfortune, not only to break, but very much bruife, both the tibia and fibula; and, before the furgeons could be ready with their affiftance, the parts were feized with a gangrene. When the furgeons were come, and had viewed the place, they fent for me, becaufe they defpaired of a cure: I bruifed this herb in wine, and applied it to the leg, which perfectly cured the patient of his gangrene. *Hiftoria Plantarum, afcribed to Boerhaave.*

HETERO'STROPHE, an epithet applied to certain fhells, the wreaths of which turn a contrary way from thofe of other fhells of the fame genera.

HEXAEDRO'STYLA *, in natural hiftory, the name of a genus of fpars.

* The word is derived of the Greek ἕξ, fix, ἕδρα, fide, and στύλος, a column.

The bodies of this genus are fpars of a columnar form, adhering to fome folid body at the bafe, and terminated at the point by a pyramid; the pyramid and column being both hexahedral, or compofed each of fix fides. Of this genus there are three known fpecies: 1. A flender one with a long pyramid; this is compofed of fo pure and clear a fpar, that it refembles cryftal, and is found in Ockey hole, on Mendip hills, and in fome other parts of England. 2. A fomewhat thick one, with a long irregular pyramid, found in the mines of Cornwall and Devonfhire, and common alfo in thofe of Germany. 3. One with a very fhort pyramid; this is found in the Derbyfhire lead mines, and in great plenty on thofe of the Hartz foreft in Germany. *Hill's Hift. of Foff.*

HEXA'NDRIA*, in botany, a clafs of plants with hermaphrodite flowers, and fix ftamina or male parts in each, which are in fome plants all of the fame length, and in others are alternately one fhorter and another longer.

* The word is derived from the Greek ἕξ, fix, and ἀνὴρ, male.

The plants of this clafs are garlic, hyacinth, meadow faffron, &c. See *Plate* XXVIII. *fig.* 1.

HEXAPYRAMI'DES *, in natural hiftory, the name of a genus of fpars.

* The word is derived from the Greek ἕξ, fix, and πυραμὶς, a pyramid.

The bodies of this genus are fpars formed into pyramids, compofed of fix fides or planes, and affixed to no column, but adhering to fome folid body by their bafes. Of this genus there are only two known fpecies. 1. A fhort one with a broad bafe; this is a very rare fpecies, and found only, fo far as is yet known, in the great mine at Goffelar in Saxony. And, 2. A long pointed one, with a narrow bafe; this is found in the figures of the alabafter quarries of the Hartz foreft. *Hill's Hift. of Foff.*

HILLS are of great ufe in a garden.

1. They ferve as fcreens to keep off the cold and nipping blafts of the northern and eaftern winds.

2. The long ridges and chains of lofty mountains, being generally found to run from eaft to weft, ferve to ftop the evagation of thofe vapours towards the poles, without which they would all run from the hot countries, and leave them deftitute of rain.

3. They condenfe thofe vapours, like alembic heads, into clouds; and fo, by a kind of external diftillation, give origin to fprings and rivers; and, by amaffing, cooling, and conftipating them, turn them into rain, and by that means renders the fervid regions of the torrid zone habitable.

4. They ferve for the production of a great number of vegetables and minerals, which are not found in other places.

It hath been found by experiment and calculation, that Hills, though they meafure twice as much as the plain ground they ftand upon, yet the produce of the one can be no more than the other; and, therefore, in purchafing land, the Hills ought not to be bought for more than their fuperficial meafure; i. e. to pay no more for two acres upon the fide of an hill, than for one upon the plain, if the foil be equally rich.

It is true, that thofe lands that are hilly and mountainous, are very different, as to their valuable contents, from what are found in flat and plain ground, whether they be planted, fown, or built upon; as for example:

Suppofe an Hill contains four equal fides, which meet in a point at the top; yet the contents of thefe four fides can produce no more grain, or bear no more trees, than the plain ground on which the Hill ftands, or than the bafe of it; and yet by the meafure of the fides there may be double the number of acres, rods, and poles, which they meafure on the bafe or ground-plot.

For, as long as all plants preferve their upright method of growing, hilly ground can bear no more plants in number than the plain at the bafe.

Again, as to building on an Hill, the two fides of an Hill will bear no more than the fame number of houfes that can ftand in the line at the bafe.

And as to rails, or park-pailing over an Hill, though the meafure be near double over the Hill to the line at the bottom, yet both may be inclofed by the fame number of pales of the fame breadth. *Miller's Gard. Dict.*

HIPPOPOTAMUS, in zoology, the name of a very singular quadruped, called in English the river horse, and by some, though less properly, the sea-horse. It approaches in figure partly to the buffalo, and partly to the bear. It is larger than the buffalo, and its legs are very much like the bear's. The full grown animal is thirteen feet long from its head to its tail, and four feet and an half in the diameter of its body, and its belly is rather flat than ridged; the circumference of its body is usually equal to its whole length; and its legs three feet and a half long, and three feet round; and its feet a foot broad; its head is very large in proportion to its body, and its mouth is capable of opening a foot wide; its eyes are small, its ears also small and thin; its teeth are as hard as flint, and will readily give fire with steel; it is usually very fat; its hoofs are black, much like those of the common cloven-footed beasts, but divided into four claws instead of two; its upper jaw is moveable in the manner of the crocodile's. Its tail is more like that of a bear or tortoise, than a hog's, to which it has usually been compared; it is very thick at its insertion, and tapers away to the end; it is not above six inches long, and so thick that it cannot twist about. Its skin is extremely hard and tough, and in colour black; and its nose is furnished with stiff hairs or whiskers, in the manner of a cat's, several stiff hairs growing from the same hole; and these are the only hairs the creature has, its whole body being naked. It has two large teeth in the lower jaw, somewhat resembling the tusks of the boar, and a little crooked, but not standing out of the mouth like the boar's tusks; these are much larger than the other teeth, and sometimes grow to a foot in length.

It is found in the Nile and Niger, and many other great rivers; it comes out of the water to bring forth its young, and feeds upon rice, herbs, and the roots of the colocasia. Its feet, being not webbed, shew that it is not intended for swimming, and probably it spends its time in walking about at the bottom of the rivers. It is very plainly proved by Bochart, that this is the creature mentioned under the name of the behemoth in the book of Job. *Ray's Syn. Quad.*

HIRUDO, *the leech.*—These are small black animals, destitute of legs, variegated with lines and points, and living in watery places. The small leeches are preferred to the large, as being less hurtful; and, among the small ones, such as are marked with lines on the back.

Leeches are a species of aquatic worms or insects, which, being applied to the body, bite through the skin, extract blood out of the veins, and are very conducive to health; for which reason they were used, in very early times, by the Greek and Roman physicians. Since there are various kinds of them, it will be proper to give some direction for the choice. Those, then, taken out of clear rivers and brooks are best; for the others from lakes, fish-ponds, and stagnating waters, are impure and malignant, exciting sometimes violent pains, inflammations, and tumors. The most experienced surgeons likewise prefer those with slender pointed heads, and greenish or yellowish streaks on their backs, with their bellies of a reddish yellow; for, when their heads are large, and from a blue they incline to a black colour all over their bodies, we look upon them to be the most malignant sort. But one observation more seems absolutely necessary, never to apply leeches lately caught in rivers, or foul waters; but let them be first put into a glass full of clean water, and often shifted, that they may purge themselves of their filth and venom. After keeping them some months in this manner, they may be used safely.

Before the leech is applied, it should be taken out of the water, and put into an empty cup, or glass, that, being thirsty, it may the more speedily insinuate itself into the skin, and draw off a greater quantity of blood. And, as for the part, it may be put to the temples, or behind the ears, if there is any disorder in the head or eyes, from a redundance of blood, and especially if the patient is delirious in a fever. They may be sometimes conveniently applied to the veins of the rectum, in the blind and painful piles; nor will this application be of less service, in hæmorrhages of the nose, and in spitting or vomiting blood; for their efficacy in promoting a revulsion, especially when an obstruction of the hæmorrhoids occasions this profusion, is very extraordinary. But, before the leech is used, the part should be rubbed, till it is hot and red; then the tail is to be taken hold of with a dry cloth, or it must be laid half over the edge of a glass, and then directed to the proper place, where, when it is once fixed, it sucks very greedily. If several are necessary, apply each successively in the same manner. When they will not adhere, as it sometimes happens, it is proper to moisten the skin with warm water, or the blood of a pigeon, or chicken; if that will not entice them, others must be substituted in their stead. The application of leeches to the caruncle in the greater canthus of the eye, after phlebotomy, has been found very serviceable, in all inflammatory disorders of that organ. Cream and sugar, rubbed upon the part, will invite leeches to bite, when other things fail.

As soon as the leeches are distended with blood, they generally fall off spontaneously; but, if a larger quantity of blood is requisite, new ones must be applied, or the tails of those already fixed must be cut off; for then, the blood running through them, they will be induced to draw more. If, after a sufficient evacuation, they do not spontaneously separate themselves from the skin, upon sprinkling a little salt or ashes, they immediately drop off; and this method is best; because pulling them away often causes an inflammation or tumor. The leech which is whole, may be put again into the clean water, and kept for future use; but that which is cut, certainly dies. The wound may be washed with warm water, and dressed with a vulnerary plaister, though it usually heals without.

When leeches fall off, the hæmorrhage generally continues for some time, as twelve hours, and frequently longer. Upon this occasion, as the blood cannot be received in vessels, bu is absorbed by linen, it makes a great appearance, and seems much more than it really is: this alarms the patient and puts the attendants into an unnecessary consternation, upon a supposition, that the hæmorrhage will be so profuse, as to occasion faintings and death, neither of which is likely to ensue; for the bleeding may, at any time, be stopped by compressure, or the application of styptics; as brandy, with a little powdered colcothar. But it is more frequently necessary to bathe the part wounded, with warm water, in order to encourage a discharge of blood, when it does not flow in quantities sufficient to answer the end proposed.

HISTRIX, *the porcupine*, an animal well known in many parts of the world, and so common in the mountainous parts of Italy, that it is brought to market at Rome, and sells but at a very low price, the flesh not being greatly esteemed.

It resembles the badger in shape, but in its nature more resembles the hare, and is properly of the leporine kind. It usually weighs between twenty and thirty pounds. Its body is often two feet long, and is all over covered with a very singular and remarkable kind of bristles. Its shoulders, legs, sides, and belly, are wholly black; and its back variegated with black and white. Its bristles more resemble those of the hog than of any other animal; its neck is short and thick; its head also short, and its nose obtuse; its nostrils very large, opening transversly, and its upper lip split, as in the hare. All about and over its nostrils, it has a number of black hairs, by way of whiskers, as the rat and mouse have; and it has, in each jaw, two large and long fore teeth, like those of the hare. The eyes are small and blue, and the ears of a very singular shape, representing those of the human species; and about these there is a grey down, very different from the covering of the rest of the creature. It has the like down upon the lower jaw; and all along the head and neck, quite to the shoulders, it has a sort of crest of very long bristles, sometimes eight inches long; this looks like an erect mane, and the bristles it is composed of are some white, some black, and others variegated with both these colours. Its legs are short, and the fore feet have each five toes, the hinder ones only four, of which the outer one is the largest, as in the bear. The bristles of the whole body are very thick, flatted at the bottom, and pointed at the extremity, and standing each on a short pedicle. Its bristles are of very different kinds; some of them are very sharp, rigid, and short; others longer, flexible, and flatted at the end; those of the first sort are white at the bottom, and chesnut-coloured at the top; the longer ones are white at both ends, and variegated with black and white in the middle.

The tail is a little more than a hand's breadth long, and is beset with spines, in several annular ranges; and at the extremity, instead of spines, it has ten or twelve tubular bodies, of the thickness of the spines, but of not more than half their length, very thin and transparent, open at the end, and placed on short pedicles. *Ray's Syn. Quad.*

HIVING, the placing a swarm of bees in a hive, in order to have the profit of their labours. When the swarm of bees has left an old hive, and is placed in form of a cluster hanging down from the branches of some shrub or loose bush, the Hiving is extremely easy, and may be done in half an hour after the time of their being still, and calm in the cluster; or it may be let alone till an hour or two before sun-set, provided that the sun do not shine too vehemently upon the place where they are, for that would disquiet them, and force them to rise; and in that case they usually take a long flight before they settle again, and are very often lost; this however may at any time be prevented, by placing an artificial screen before them, composed either of a coarse cloth, or of a few branches of trees well covered with leaves.

Those authors who speak largely of the œconomy of bees, give the new queen a set of officers, whose business it is to settle the proper places of resort; and they pretend that these bees go out of the hive a day or two before the swarm issues out, in order to fix upon a proper place. This however appears but a romantic conjecture, and we usually find the bees busied in search of a place, while the whole swarm is in the air; nor is it much to their credit, that they chuse such places as they do, for they usually fix in such as they can by no means subsist in.

It is commonly the branch of some shrub or tree that they settle upon, and we always find that they mean this as their settled habitation; for, however soon they are hived, the rudiments and beginning of combs are found on it. It is true, they

they always leave these places, if left to themselves, in five or six days; but this is not till they find them so inconvenient that they cannot keep them, either from their being too much scorched by the sun, or exposed to winds and rain. The quantity of wax and honey left in these places, when they have quitted them, abundantly proves however that they meant them for fixed abodes.

When they are placed in a hive, they very soon find themselves much better lodged than in the place they had provided for themselves, and they usually stay in it, and begin to work the next morning.

It might appear a very difficult task to get so large a number of bees into a hive, but it is much less so than it appears to be. They will often take possession of the hive of their own accord, when it is hung over them; but the shortest way is to hold the hive under the branch where they are, and then sweep them down into it. This may be done with the branch of a tree with leaves on it, or with the hand armed with a strong glove, and the face covered. But there are country fellows who will go without any sort of defence, and with their naked hand sweep them carefully off the bough into the hive, which they hold in the other hand underneath.

It is not to be expected that the whole swarm will be thus swept peaceably into the hive; many will fly away, and many clusters will fall beside the hive to the ground. All this however creates no difficulty, for, the hive being turned bottom upwards, and set on the ground near the tree, with its edges a little raised above the surface, those bees which fell in clusters to the ground, will soon scrawl to their companions in the hive, and soon after those which flew off, will descend and follow their example. If it happen however that some bees will obstinately keep to the place where they at first fixed themselves, the branch is to be rubbed over with the juice of such plants as these creatures hate the smell of; such are elder, rue, and some others. And, if this does not succeed, there must be linen rags burnt under them, the smoke of which will soon drive them off, and make them join their companions, who find themselves more at ease in the hive.

As it is necessary to render the places disagreeable to the bees from which they are to be taken into the hive, so many people think it very proper to prepare the hive for their reception, by scenting it with such things as they love the smell of. To this purpose they rub the inside of it with baum and bean flowers, and daub a little honey in some parts of it. This however does not seem necessary, those hives having been found to succeed full as well, where it was not done, as those where it was.

If it be about noon that the swarm is taken into the hive, it must not be removed from the place before evening; and in the mean time it must be sheltered from the two violent heat of the sun, by the shade of the trees; or, if that be not sufficient, a sort of screen must be made for it, either of a coarse cloth properly supported, or of branches of trees with their leaves on. In this manner it must remain till sun-set, and then the hive must be gently lifted up, and carried to the place where it is to remain, and the next morning the bees will be seen as busy at their work in it, as the old swarm in their hive.

It sometimes happens that the swarm is not placed so favourably as in the instance before-mentioned; they often hang themselves in a long cluster from the young shoots, or small branches of high trees; and in this case many different expedients are to be used to hive them, according to the circumstances of their position. The common method is for one man to climb the tree with a long staff in his hand, and another to mount a ladder placed against the tree, and hold the hive under the swarm, while the other sweeps them into it with his staff; and, when the bough on which they hang is so far from the body of the tree, that this is impracticable by the ladder, the hive is to be fixed to the end of a long pole, and by that means suspended under the swarm while they are swept into it. When all this is impracticable, by reason of the great height of the branch on which the swarm hangs, a large cloth is to be spread on some of the lower branches, and the whole swarm swept down in a cluster upon it: this is then to be thrown carefully to the ground, and another person is to be ready there, to whelm the hive over the greater part of the cluster, and the rest will usually soon creep into it, and join them. If they are slow in doing this, they are to be driven in by burning linen rags about the places where they fly, the disagreeable smell of which will send them towards the hive, where finding their companions not incommoded with it, they will naturally remain.

Another method of getting a swarm from a branch of a high tree, is to cut off the branch with a saw, as gently and with as little disturbance to the bees as possible. In this case, when the branch is off, a man may carefully descend with it, and the bees will not quit their hold, but will be all carried where he pleases with it, and may by that means be very easily put into the hive.

Sometimes the bees which go out in a swarm, fix upon a hole in a wall, or a hollow trunk of a tree, for the assembling themselves in.

This is a much better choice for them than the branch of a tree, but it is much worse for the person who is to hive them, for they are very difficult to be got out of these places. The common way of the country people is to attack these swarms in the middle of a cold night, and they then enlarge the opening from without, and, placing the hive under it, scoop the bees out of their nest with a ladle, and put them into the hive.

It usually happens that there are more than one young female in the hive, at the time when the swarm goes out; and it is not uncommon for two of them to go out with the swarm. In this case the swarm constantly divides into two bodies, and, on whatever branch it fixes, there are seen two clusters of bees, one placed near the other. Each of these is a complete swarm and has its female, but one of them is often much more numerous than the other; and, as the bees always love to live in large communities, the bees of the smaller cluster become tired of their condition, and by degrees join the larger; so that this is seen to increase, and the other to decrease in size every moment, till at length there remains no more of the smaller swarm than a few faithful creatures, forming a sort of guard about the female. In this case it is in vain for them to think of forming a community by themselves; and they finally, with the female, join the other swarm; so that the new swarm has two females. *Reaumur's Hist. Inf.*

HOACHE, in natural history, a name given by the Chinese to a peculiar kind of earth, which they have found out lately, very useful in the manufacture of their China ware.

It is called Hoache from the word hoa, which signifies soft and glutinous, and is described to us as being an earth approaching to chalk, but harder, and feeling like soap to the touch. There is great reason to believe that this is either the same earth with our soap-rock of Cornwall, or something very like it. Ours has very much the appearance of French chalk, with which they take out spots of cloaths, and which marks white in the same manner as chalk.

The word chalk is so little determinate in its general sense, and the white substance we commonly call by that name is so little likely ever to be used in earthen-ware of any kind, that there is great reason to believe French chalk is the substance to which the Hoache is compared; and, if so, all the characters agree so well, that it is probably the very same thing with our steatites. We have often attempted to make a porcelane ware with this, and that with good prospect of success. But we are to learn, in regard to the Chinese way of using it, that it is only one of the ingredients of their fine ware, not the whole matter of which it is made.

The Chinese physicians had long used this earth as a medicine, giving it in disorders of the lungs; but it is only of late times that the workmen in porcelane attempted to use it instead of kaolin. It succeeds, however, so well, that the porcelane made of it sells dearer in the Indies than any other kind. The grain of this porcelane is remarkably fine and even, so that it is fitter for receiving the finest pencilling than any other, and it may be made surprizingly light. But there is this disadvantage, that the whole is more brittle than the ordinary China, and the just degree of baking it is very difficult to hit; without which it is never strong. The Chinese sometimes make the body of their vessels of the common China ware, and dip them when dry into a thick liquor like cream in which the Hoache is dissolved. This gives a new and beautiful coat to the vessel. They give the common varnishing over this, and it succeeds to a very great perfection. *Obser. sur les Coutumes de l'Asie.*

Supposing we could not, for want of the petunse, or something analogous to it, ever arrive at making the true porcelane in England, there is yet room to hope for great advantage in making the varnish or coating of other vessels with this steatites or soap-rock. The manner in which the Chinese use it is this: they first wash it clean with river water to separate a yellow sort of earth, which lies near it in the mine where they dig it, and is often brought up with it. When it is thus cleansed, they beat it to powder, and mix it in large quantities of water; they stir the mixture well, and then, letting the coarser part settle, they pour off the thick liquor, and let it stand till a substance like cream subsides, which they keep moist and use, as before-mentioned, to dip the vessels in; or else they dry it, and use it with the petunse instead of the kaolin in the common manufactures.

It is said that a very good porcelane ware may be made with this earth alone, without any other mixture; but the workmen themselves are unwilling to do this, and always chuse, if they do not work in the common way, to add at least two parts of the petunse to eight of the Hoache, and with this mixture they make a very good ware, working it in the same manner as they do the petunse and kaolin. *Id. Ib.*

The Hoache, though ever so proper to supply the place of the kaolin, could not be used in the common works, because it costs three times the price, it being much scarcer, and brought much farther.

There is another very elegant sort of China-ware, which depends entirely on the Hoache for its beauty. It is all white; but, though the surface is perfectly smooth and polished, there are seen flowers and other ornaments on it in a very delicate manner. The method of making this is as follows: they make

make the veſſels of the common matter of the porcelane ware; they then diſſolve, in a ſufficient quantity of clear water, as much of the refined Hoache as will give it the conſiſtence of a ſyrup. With this they pencil out the figures they intend on the ſurface of the veſſel, while yet not quite dry. This penetrates the ſurface, and the lines and ſtrokes all appear very determinate. They let this dry thoroughly, and then cover the whole veſſel with the common varniſh of the porcelane. When it has been baked, the whole appears white, but the figures are very diſtinctly ſeen, and appear extremely beautiful. They are of a brighter white than any of the reſt, and ſeem formed of a thick white vapour, running with a regularity juſt under the ſurface of the veſſel. They have a way of doing this with another ſort of earth, which they call chekao; but this requires more trouble, as it muſt be roaſted and powdered before it is fit for uſe. The white of this alſo is not ſo fine when done as the other. *Obſ. ſur les Cout. de l'Aſie.*

HO'BBY, in zoology, the Engliſh name of a hawk, of the long-winged kind, called, by many authors, by the name ſubbuteo, the name by which others expreſs the ringtail and hen-harrier. The Hobby has a prominent and crooked beak, covered at the baſe with a yellow ſkin; the beak is white near this membrane; elſewhere it is blue. Its tongue is a little bifid, and the iris of its eyes hazel-coloured. It has a reddiſh brown line, mixed with white over the eyes, and its head feathers are black and brown; its neck feathers are of a whitiſh brown; its back and wings are of a blackiſh grey; its chin, and the upper part of its throat, are of a yellowiſh white, with a black ſpot on each ſide; its belly is brown; its tail is long, and pointed and variegated with brown and white. The legs and feet are yellow. It builds with us in high trees, but does not ſtay the winter with us; it feeds principally upon larks.

HOE'ING, according to Tull, is the breaking or dividing the ſoil by tillage, while the corn, or other plants, are growing thereon. It differs from common tillage, which is always performed before the corn or plants are ſown or planted, or in the time of performing it; and it is much more beneficial to the crops than any other tillage. This ſort of tillage is performed various ways, and by means of different inſtruments. Land which, before the tillage, would have yielded little, tho' the more it is tilled before ſowing, the more plenty of corn it yields, yet, if tilled only before the ſowing, will always have ſome weeds, and they will partake of the advantage of the tillage as well as the corn. This is one reaſon for an after tillage, ſuch as that by Hoeing. But there is another conſideration that yet more requires it; this is, that as ſoon as the ploughman has done his buſineſs, by ploughing and Hoeing the land, after ſowing, the ſoil, of its own accord, begins to undo it all again by tending towards its original texture and ſpecific gravity again; the altering of which was the only buſineſs of all the former tillage. The breaking the particles of the earth, and making in it new pores, and new particles, or new ſuperficies, is the great buſineſs of the plough and harrow; but, as ſoon as their uſe is over, the earth begins to coaleſce again into its own form, the particles unite together, and the artificial pores in a great meaſure cloſe up. The ſeed is nouriſhed in a worſe ground than it was firſt put into, and the more the plant grows up, and requires a larger ſupply of food, the worſe the paſture becomes. While nouriſhment is thus denied the growing plants, they are at the ſame time choaked with weeds, which, being of a hardier nature than they, will grow with leſs ſupplies, and therefore thrive more vigorouſly, and rob them of a great part of the little food the land before allowed them. Farmers in all ages have been acquainted, in ſome degree, with the uſe of tillage and dung to crops of uſeful plants; but they have ſo ill managed the time of giving theſe aſſiſtances to nature, that there is no doubt but one third part of the nouriſhment raiſed by dung and tillage, if it were given to plants and corn at many proper ſeaſons, and proportioned to the different times of their exigencies, would be of more benefit to the crop, than the whole is, when applied all together at the time of ſowing.

Nature, by what ſhe does in the animal œconomy, ſeems to point out to us ſomething like the remedying this by Hoeing; for when the teeth, as the plough, have tilled that ſoil or maſs which is earth-altered; and when the ſaliva and the juices of the ſtomach have ſerved to divide and attenuate it, as the ſalts of dung and other manure do land; after all this, the bile and pancreatic juices are ordained to farther attenuate it, at the very time when it is ready to be exhauſted by the numerous mouths of the lacteals, ſituate in the inteſtines. This laſt operation of theſe juices ſeems analogous to the meliorating the ſoil by Hoeing, after the plants are grown, and are becoming fit for uſe.

Tranſplanting is nearly allied in its nature to Hoeing, but it is much inferior. The nature of this will not admit of its being a general thing; and, even if it would, Hoeing is better. For, by tranſplanting, the plants can only be kept up to a certain period, after which they will not bear it; but Hoeing may be uſed to them with advantage, to their utmoſt ſtanding, and make them vigorous all the while.

The roots of a plant are all neceſſarily broken off in tranſplanting, and it requires ſome time for it to ſtrike a whole ſet of new ones; and, if the earth about it is not kept thoroughly moiſtened all this time, the new formed roots will not be able to ſhoot, and the plant will ſtarve in the midſt of plenty. But, on the contrary, in Hoeing, the ſame advantage of a new paſture for the plant is obtained, by the breaking the particles of the earth, and at the ſame time no more of the roots are broken off than can eaſily be ſupplied, and, the reſt remaining in their places, the plant continues growing without that ſtop or decay, which muſt happen on tranſplanting, and which it recovers only by degrees. It is obſerved, that ſome plants are the worſe for tranſplanting: lucerne and ſaintfoin are never ſo good after tranſplanting, as when they are left in their native places, at the ſame diſtances; and finochia, removed, is never ſo good and tender as when it is not. This laſt plant receives ſuch a check from tranſplanting in its infancy, that it has afterwards a diſeaſe like the rickets, which cauſes knots and ſwellings in it, that ſpoil it as a delicacy. All the tap-rooted plants ſuffer by tranſplanting, for it is neceſſary in this to cut off the long-main root, which afterwards, however good the ſoil may be, never arrives at the length it otherwiſe would have had, and which was neceſſary for the ſucceſs of the plant.

One great benefit of Hoeing is, that it keeps plants moiſt in dry weather, the advantage of which to their growth is eaſily ſeen. This good office it performs on a double account. Firſt, as they are better nouriſhed by Hoeing, they require leſs moiſture, and conſequently carry off leſs; for thoſe plants which receive the greateſt increaſe, having moſt terreſtrial nouriſhment, carry off the leaſt water, in proportion to their augment, as is proved by Woodward's experiments. Thus barley or oats, being ſown on a piece of ground well divided by tillage and dung, will come up and grow well without rains, when the ſame grains ſown on another part of the ſame land, not thus dunged or tilled, will ſcarce come up at all without rains, or, if they do, will wait wholly for the rains for their growth and increaſe.

The hoe alſo, particularly the horſe-hoe, for the other does not go deep enough, procures moiſture for the roots from the dews which fall moſt in dry weather; and theſe dews ſeem to be the moſt enriching of all moiſture, as it contains in it a fine black earth, which will ſubſide from it in ſtanding, and which ſeems fine enough to be the proper pabulum, or food for plants.

A demonſtration that the tilled earth receives an advantage from theſe dews, which the untilled does not, is this: dig a hole in any piece of land, of ſuch a depth as the plough uſually goes to; fill this with powdered earth, and, after a day or two, examine the place, and the bottom part of this earth, and bottom of the hole, will be found moiſt, while all the reſt of the ground, at the ſame depth, is dry. Or, if a field be tilled in lands, and one land be made fine by frequent deep ploughings, while another is left rough by inſufficient tillage, and the whole field be then ploughed a-croſs in dry weather, which has continued long, every fine land will be turned up moiſt, and every rough land as dry as powder from top to bottom.

Although hard ground, when thoroughly ſoaked with rain, will continue wet longer than fine tilled land adjoining to it, yet, this water ſerves rather to chill than to nouriſh the plants ſtanding in it, and to keep out the other benefits of the atmoſphere; it leaves the ground much harder alſo than before, when it is finally exhaled out of it; and when, at length, the earth is then hardened, it can receive no benefit from any thing leſs than a deluge of rain, which ſeldom falls till the ſeaſon of vegetation is over.

As fine hoed ground is not ſo long ſoaked with rain, ſo the dews never ſuffer it to become perfectly dry. This appears from the flouriſhing ſtate of plants in hoed ground, while others near them, but in ground not hoed, are ſtarved for want of nouriſhment. The common opinion is againſt this, but obſervation proves it to be true againſt the common opinion. The vulgar are guided by this, however, and will not hoe their ground in dry weather for fear of letting in the drought, as they call it; whereas Hoeing this is the only method of keeping away the drought, and without either this, or watering, they muſt periſh in theſe ſeaſons. *Tull's Horſe-Hoeing Huſbandry.*

HO'LLOWNESS *of trees.* This is one of the moſt miſchievous diſtemperatures to which trees are ſubject. It is generally occaſioned by the lopping of them in an improper manner, and leaving the wet to fall in upon them, eſpecially on their heads. When this miſchief is found out in its beginning, the only way is to cut the trunk off to the quick, ſacrificing the whole hollow part; it is, in this caſe, to be cut off ſloping, that the wet may run off from it. All ſoft woods are liable to this miſchief, after the lopping, particularly the elm; and, when it takes hold of any tree, it grows upon it daily, till the whole ſubſtance of the tree is at length eaten away, and only a coat of bark is left. The beſt way of preventing it, in the elm, is never to cut off the head or top of the tree at all, but only to lop the ſide branches; theſe will yield a very large quantity, and the body of the tree will thrive the better for their being often cut off, and will be good timber at laſt. *Mortimer's Huſbandry.*

HO'LLY, in botany. See the article AQUIFOLIUM.

HOLLY-*hedges*, are a very beautiful ever-green and ſtrong fence, but liable to periſh in hard winters. It has been ſuppoſed, that the ſeverity of the cold, in theſe ſeaſons, was the occaſion of

this;

this; but a closer observation has shewn, that the mischief is owing to the field mice, which in very severe seasons, when they can get at nothing else, disbark the roots of these shrubs. The method of preserving these hedges, in such seasons, is found to be by clearing away the weeds which are a harbour to these little animals, and placing traps and boxes in proper places, with a paste made of butter and rats-bane, daubed over their insides, and holes made in their sides no bigger than what the mice or rats, if there be any there, can creep into; and thus the vermin are destroyed, and the mischiefs which might attend rats-bane being exposed, are prevented. *Moreton's Northampt.*

HO'LLYHOCK, or *holy-oak*, in botany.—We have many species of this plant cultivated in our gardens, for the beauty of their flowers. They are all propagated from seeds, which are to be sown in March, upon a bed of light rich earth. When the plants are come up pretty strong, they should be transplanted out into nursery beds at about eight inches distance from one another. They must be watered till they have taken root, and will then require no farther care for the summer, but being kept clear of weeds. At the latter end of the September following, they should be transplanted into the places where they are to remain, and set in rows of two feet distance, and at a foot from each other in the rows where they may flower: and, when it is observed which roots produce the finest flowers, those should, the Michaelmas after, be transplanted into garden beds, where they will live four or five years; after which, they grow weak, and should be replaced by new ones. When the stalks of the plants begin to decay, they should be cut down close to the ground, otherwise they are apt to rot and destroy the roots.

HOLT-*waters*. These have been found by experience to be of admirable efficacy in all scorbutic and scrophulous cases: an account of some very remarkable cures performed by them, in these cases, was printed several years ago, and, though known to be fact in the place, was disbelieved by almost every body besides.

Mr. Lewis, the late minister of the place, confirms their efficacy from his own observation, and observes, that they are of an attenuating, astringent, and drying nature. The first of these properties they possess in common with all waters, which dilute, attenuate, and fit the juices for passing the proper vessels; their astringency they owe to the alum and iron which they contain, and their drying, absorbing, and healing qualities are probably owing to a quantity of sulphur, and a fine light ochre, which they are impregnated with. *Philos. Transf.* N°. 408.

HO'NEY-*suckle*, *caprifolium*, in botany, the name of a genus of plants, the characters of which are these: the flowers are generally placed many on the same stalk, and disposed in a circular form. The single flowers are composed of one leaf each, of a tubulated form, and divided at the end into two lips, the upper of which is divided into many segments, the lower whole, and of the shape of a tongue. The cup finally becomes a soft fruit or berry, containing a flatted and round-shaped seed.

The Virginian scarlet Honey-suckle, called the trumpet Honey-suckle, is a very beautiful flowering kind, and in great esteem. It is propagated by laying down the tender branches in spring, observing, in dry weather, to refresh them with water; and, the spring following, they will be ready to transplant, when they are to be cut off from the old plants, and carefully removed without disturbing their roots. The best time to remove them is in March, just before they shoot out; but, if the season should prove dry, they must be watered, and have a little mulch laid at their roots, to prevent the earth about them from drying too fast. They should be planted in a strong soil, and exposed to the south-east sun; but they must have a wall or pale behind them to support the branches, otherwise they will trail upon the ground. It is a native of Virginia, but will thrive very well with us, bearing all the cold of our winters, but does not succeed well near London, where the smoke commonly destroys it. *Miller's Gard. Dict.*

The propagation of all the several sorts of Honey-suckles is by laying down their branches in the spring, which, if they are supplied with water, will by the Michaelmas following have taken root so well, as to be fit to remove. They should at this time be transplanted into nursery beds for a year or two, the better to train them up, either for headed plants, or for creepers, to plant against trees, walls, &c.

They may also be propagated by planting cuttings in September, or in spring; but they sometimes fail this way, and always require much care and trouble. Their sweetness, and long continuance in flower, make them of great value in small quarters. Among flowering shrubs they are also very beautiful, when planted against the stems of old trees, where, if they are not too much shaded, they will flourish exceedingly.

The proper season for cutting them, to keep them in a regular form, is about Michaelmas, soon after they have done flowering. This is to be done with a knife, observing always to cut behind a leaf bud; for, how much soever the shoot is left longer, it will always die down to that part. They are most of them very hardy. *Miller's Gard. Dict.*

HOOF (*Dict.*)—Brittle Hoof, a name of an infirmity to which horses are subject. It comes sometimes naturally, and sometimes artificially. When it comes naturally, it is generally hereditary, the sire or dam having had the same complaint. When it comes on accidentally, it is sometimes owing to a distemper falling down into the feet; sometimes to the creature's being much foundered.

The Hoof, in this distemper, is so friable and rotten, as it were, that it cracks and flakes off on every slight occasion. The cure is to be attempted in this manner: take wax, turpentine, suet, and hog's lard, of each four ounces; sallad oil a quarter of a pint by measure, and of dog's grease half a pound; let the whole be melted together, and strained through a piece of canvas into a gally-pot. The Hoof is to be thoroughly anointed with this every day, morning and evening, especially at the root; and, if there are any large cracks, they must be filled up at every dressing with a mixture of equal parts of cow dung and hog's lard.

HORI'ZON (*Dict.*)— One great inconvenience that mariners have to struggle with at sea, is the frequent want of an Horizon: for, though the atmosphere may, at the height of ten or twelve degrees and upwards, be clear enough to give a view of the sun and other objects, yet, all below that height is often so hazy, as to hinder a distinct sight of the Horizon; and, consequently, an observation made at such a time cannot have the correctness wished for: but this defect is quite removed by a kind of horizontal speculum invented by Mr. Serson, who was lost with the Victory man of war, wherein he was sent to make trial of his machine.

The principle whereon this ingenious author founded this instrument, was derived from the consideration of a top, while spinning; for he observed that the top had a very considerable degree of steadiness in, and force to acquire an upright motion, whether the body which supported it was in motion or at rest, in an horizontal or an inclined situation: he therefore judged, that, if a circular machine, whose upper surface was a flat polished speculum, was to have a swift circular motion communicated to it, that speculum, by acquiring an horizontal situation, would shew all objects which it reflected, as much below the Horizon, as they really are above it, in the same manner as in a common looking-glass; consequently, if the image of the sun, as seen reflected from the speculum, was made to coincide with the sun's image, seen in a Hadley's quadrant, the angle given by the quadrant would in all cases be the double of the real altitude. Mr. Serson also found, that, to confine the speculum to one place, while it was spinning, it was necessary to let the point run in a hollow cup; for the horizontality of the speculum would not be altered, whatever position might be given to the cup, provided it touched the top only at the point it spun on.

This curious and useful instrument, as it is now improved by Mr. John Smeaton, F. R. S. consists in a well polished metal speculum of about three inches and a half in diameter, inclosed within a circular rim of brass; so fitted, that the center of gravity of the whole shall fall near the point whereon it spins; that is, the end of a steel axis running through the center of the speculum, above which it finishes in a square, for the convenience of fitting a roller to it, when it is to be set a going by means of a piece of tape wound round the roller. The cup in which it spins, is made of polished agate, flint, or other hard substance, and is placed on a small pillar, which is fixed to the bottom of a box, whose pyramidal cover is composed of glass panes; whereby an observation can be made on the speculum as well covered as uncovered, and thereby it will be prevented from tarnishing by the moist air or spray of the sea.

When the top is to be used in a meridian observation, it is convenient to know about what time it is proper to set it up; this may be had near enough by taking the sun's bearing from the meridian with an azimuth compass, allowing for the variation; and, if it has about five degrees to run before it culminates, it is time to spin the top, which will generally run twelve or fifteen minutes fit for observation. But, if it is likely to go down, or spin too weak, before the observation can be finished, the tape should in the mean time be got ready wound about the roller, that the top may be set up again without loss of time; and, if the box be held steady upon something nearly level, when the tape is drawn away, the speculum will be fit for observation commonly in less than two minutes.

As soon as the top is set up, put on the glass roof, if necessary; let an assistant hold the box as steady and level as he can, and in such a position as the observer may look directly through the glass roof: then let the observer place himself as near the box as he can conveniently, and look down on the sun's image in the horizontal speculum, and bring the sun's image seen in the quadrant to agree with it, so that their centers coincide; and the quadrant will give the double altitude, without any allowance for the height of the ship, or the sun's semidiameter. And although there may appear in the horizontal image a kind of trembling, yet, when the centers of the solar images are brought to coincide, the observation may be taken as truly as if there was no such trembling.

When the sun is about forty-five degrees high, the observer must look through that sight of the quadrant which is used for a back observation: but he must look down on the horizontal image, or that in the top, as it was the back Horizon; and then, making the solar images to agree, the quadrant, according as it is numbered, will give the double altitude, or double zenith distance.

As

As this latter observation is sometimes found at first more difficult to make than the former, the observer would do well to exercise himself therein in good weather, when he has an opportunity of comparing his observations with those taken from the Horizon properly corrected.

These speculum tops are as useful by night as by day; for, as the images of the smallest stars may be seen in the speculum, consequently, any object that can be seen reflected from the glasses of the quadrant, may be observed by the top; and these are all the stars of the first magnitude, the planets Venus, Mars, Jupiter, Saturn, and the Moon: so that, by having the declinations of these bodies in an ephemeris, they may be used in observations as well as the sun.

As the great distresses to which ships are sometimes drove in several parts of the world, for want of an Horizon to observe by, are by this most ingenious contrivance quite removed; it is to be hoped, that, when the use of this instrument is more generally known, few ships will be without one, although the expence should amount to five guineas.

HORIZO'NTAL *Shelters*, have, by some persons, been greatly recommended to preserve fruit trees from blights; but, with how little reason, or upon what slight experiments, every one, who has ever made use of them, will easily judge; especially those which are contrived by placing tiles in the wall at certain distances; nothing being more obvious, than that vegetables, when prevented from receiving the advantage of dews, rains, &c. those kindly benefits of heaven, grow weak, languid, and at last intirely decay: and since, from vast numbers of experiments, which have been lately made, we find that trees imbibe great quantities of nourishment through the pores of their leaves and branches, whereby they are rendered vigorous and healthy, even in such seasons, and upon such soils, where one would think it impossible they should receive much nourishment from the earth; to deprive them of this advantage is no less than destroying them; though, perhaps, if the trees are vigorous, it may not be effected suddenly; but there will be very visible signs of decay on them daily, and a few years will put a period to their lives, as I have more than once observed, where such walls were built.

The only sort of these shelters which I have observed for fruit trees, was made with two leaves of slit deal, joined over each other, and painted; this being fixed on the top of the wall with pullies, to draw up and down at pleasure, formed a sort of pent-house; which being let down in great rains, or cold nights, during the time that the trees were in flower, or the fruit was setting, proved serviceable; but these shelters were removed away soon after the fruit was set; so that the trees might enjoy all the advantages of rain, dew, &c. in the summer; which is absolutely necessary, if we would have healthy trees, or good fruit. *Miller's Gard. Dict.*

HORMI'NUM, *clary*, in botany, a genus of plants whose characters are:

It hath a labiated flower, consisting of one leaf, whose upper lip is short and crested; but the under one is divided into three parts: the middle division is hollowed like a spoon; out of the flower-cup arises the pointal, fixed like a nail to the hinder-part of the flower, and attended with four embryo's, which afterwards turn to so many roundish seeds, inclosed in the cup of the flower.

HORN.— The Horns of many animals, particularly of the deer kind, are cast every year, and new ones grow up in their places. With us the deer drop them in March, and the new Horns are full grown by the July following. Vossius very justly ranks this among the most wonderful phænomena of nature; he says, that we have nothing analogous to the growth of such hard and solid bodies of so great a bulk, in so short a time.

Many idle opinions have been formed of the cause of the falling of these parts of the animal; and worms in the head, and many other things, have been supposed instrumental to it, which have no share in it. The true reason seems, that these are a sort of vegetables growing on the animal, as our nails and hair have by many been said also to be; and there appears a great analogy between them and the sprouting of the leaves and branches in trees and plants. Trees commonly cast their ripe fruit in summer, and drop their leaves in autumn, because the sap, or nourishing juice, flows into them no longer; and in the same manner, at certain stated periods, the blood and juices cease to flow into these parts of the animal, and they drop off. The cavernous part, at the root of the Horns, probably grows hard, and the pores through which the vessels pass, grow up at this time; and then, as no juices can be carried through them to the Horn, it is not at all wonderful that it decays, and falls off, for want of nourishment.

It is probable that this stoppage of the pores, and denying of the passage of any juices, happen in the Horns, as soon as they are arrived at their full growth in July; but they are so firmly fixed to the head, that it takes a long time for them to loosen and fall, whereas in the leaves of plants the pedicles are so tender, that they wither and fall immediately on the juices ceasing to flow into them. This analogy between the operations of nature, in the casting the Horns of deer, and the falling off of the ripe fruits and leaves from vegetables, will gather great strength from observation of the orange and other trees. If the stalk, from which a ripe orange has fallen, be compared with that part of the forehead of a deer from which a horn is just fallen, there will be seen such a similarity between the one and the other, that it will appear very obvious, that nature has operated by the same laws in both. *Philosophical Transactions.* N°. 227.

HORN-*fish*, an English name for the fish which we also call the gar-fish. It is by some accounted a species of the acus or tobacco-pipe fish; but the only reason for this opinion seems to have been, that it is as long and slender as that fish.

HORN-*owl*, in zoology, the name of a sort of owl distinguished by two clusters of feathers standing up over its ears, and resembling Horns. There are two kinds of this bird, a larger and a smaller; the first distinguished by the name of the bubo, the great Horn-owl, or eagle-owl; and the other called the otus, or noctua aurita. *Ray's Ornithol.*

HOR'NET, *crabro*, in zoology; this insect is very bold and venomous, and wholly resembles the wasp, only it is twice as large, and the head is of a longer and slenderer shape, and the eyes are formed somewhat like a half-moon. They build under ground, and in winter hide themselves in hollow-trees. They feed on flesh, and, when very hungry, will seize upon a small bird. Moffet relates, that they have been seen singly to pursue and kill a sparrow, and afterwards feed on its flesh.

HORNET-*fly*, in natural history, a very large two-winged fly, which has the shape and colours of the Hornet, and is, at first sight, scarce to be distinguished from it. The principal colour of the body of this fly is yellow; but it has two long and large black lines placed transversly on its wings, and has a black corslet, and a yellow head. *Reaumur, Hist. Ins.*

HORSE, in zoology, a noble animal, too well known to need a description.

Backing of HORSES. The first backing of a Horse is a thing of great consequence, as his value afterwards very much depends on it. After a colt has been exercised some time morning and evening, and becomes somewhat obedient, he is to be taken to some ploughed lands, the lighter the better; he must be made to trot over these in the hand, by that means to tire him and abate his wantonness. When this is done, care must be taken that all the tackling be good and firm, and every thing in its due and proper place; then a person is to hold his head, and another to mount him; but this must not be done suddenly, or at a jerk, but very gradually and slowly, by several half risings and heavings. If he bears this patiently, the person is to seat himself firmly on his back; but, if he be troublesome, and not tamed enough, the person is to forbear the attempt to mount, and he is to be trotted hard in the hand over the same ploughed lands again, till he is willing to receive the rider quietly on his back. When this is done, the person who is on his back must cherish him, and the man who has his head must lead him a few paces forward; then he is to be cherished again. The feet are to be fitted well in the stirrups, and the toes turned out; afterwards the rider is to shrink and move himself in the saddle, and the person who holds his head, is to withdraw his hand a little farther from the mouth. As the rider moves his toes forward, the holder must move him forward with the rein, till he is made to apprehend the rider's motion of body and foot, which must always go together, and with spirit, and will go forward without the other's assistance, and stay upon the restraint of the rider's hands.

When this is accomplished, let him be cherished, and have grass and bread to eat; and then let the rider mount and alight several times, cherishing him between each time; and thus he is to be managed till he will go on, or stand still, at pleasure. This being done, the long rein may be laid aside, and the band about the neck, which are always used on this occasion, and nothing will be necessary but the trenches and caveson, with the martingal. A groom must lead the way before; or another Horse going only straight forwards, and making him stand still, when desired. In this manner, by sometimes following, and sometimes going before another Horse on the trot, the creature will by degrees be brought to know that it is his business to be quiet and governable.

Breeding of HORSES. In order to have a good and beautiful race of Horses, it is necessary to chuse for a stallion a fine barb, free from hereditary infirmities, such as weak eyes, bad feet, spavins, pursiness, or the like: disorders that arise from accidents are of no consequence, nor is the Horse to be at all the less valued for them as a stallion. Three months before this Horse is to cover a mare, he should be fed with sound oats, pease, or beans, or with coarse bread, and a little hay, but a good quantity of wheat straw; he should be led out twice a day to water all this time, and after every watering walked about an hour, but not over-heated. If he be not prepared and put in heart in this manner, the colts will be weakly, and the horse himself will be spoiled, growing pursy and broken-winded.

If he is put to too many mares, he will not last long; his mane and tail will begin to fall off through weakness, and it will be difficult to get up his flesh again by the next year. The number of mares should be proportioned to his strength, and twelve, fifteen, or at the most twenty, are as many as a Horse will well serve for in a season. Mares go with foal eleven months, and as many days over as they are years old. This being certainly known, it is easy to contrive so that all the foals may be brought forth at a time, when there is plenty of grass. About the end

of

of May the mares are to be put into an inclofure capable of feeding them, as long as the ftallion is to be with them, or that they are in feafon. In this inclofure all the mares are to be put together, as well thofe which are barren as others. The ftallion's hind-fhoes are to be taken off, but the fore-fhoes fhould be left on to preferve his feet; then lead him forth, and let him cover a mare twice in hand, to render him more tame and gentle. After this take off the bridle, and turn him loofe among the reft, where he will become familiar with them, and not one of them will be horfed but when they are in feafon. There fhould be a little lodge built up in fome part of the inclofure, and peafe, beans, oats, bread, and other good food, put into the manger in it, that the Horfe may retire into it in the fcorching heats, and eat what he likes beft. He muft be thus entertained during the whole time he is with the mares, which is to be about fix or feven weeks.

Mares that are very fat and grofs do not hold well, but thofe which are moderately fat conceive with the greateft fuccefs and eafe. To bring a mare in feafon, it is a common thing to give her a quart of hempfeed, or twice that quantity, night and morning, for eight days before fhe is brought to the Horfe. If fhe refufe it alone, it may be mixed with beans or oats, and will go down; and, if the ftallion eat of it alfo, it will make him the better.

The ftallion fhould not cover before he is fix years old, nor after he is fifteen. A mare fhould never be covered before fhe is three years old; they fhould be always found and healthful, and of a good breed; fuch as thefe will bring forth better and finer foals than any others. The colts produced from thefe are not to be ufed for ftallions, for they will degenerate, and the race will foon become exactly our own country breed. If a barb is not to be had, a Spanifh Horfe is to be chofen.

For the method of fattening Horfes; fee FATTENING.

HORSE-*mackarel*, in ichthyology, a name given by us to a peculiar fpecies of mackarel, called alfo in Cornwall a fcad. It is the trachurus of authors in general. Bellonius calls it the lacertus, and the old Greek writers, as Ariftotle and the reft, the faurus. Artedi diftinguifhes it by the name of the fcomber, or mackarel, with the lateral lines aculeated, and with thirty rays in the pinna ani.

HORSE-*mill*, a machine for grinding corn, &c. turned by a Horfe.

A defcription of a HORSE-*mill.—Plate* XXIV. *fig.* 1. exhibits the draught of a Horfe-mill compofed of the great wheel A which is fuppofed to contain 100 cogs which catch in the trundle-head B of 20 wallowers, the axis of which correfponds to the trundle-head D, which has fix wallowers. According to this difpofition, a horfe harneffed at the bar H making one turn the mill-ftone will make forty; but, to avoid needlefs pieces of machinery, the mill reprefented, *fig.* 2, is much more fimple, and confequently preferrable.

In order to fhew the beft manner of building a mill, we muft be determined by reafon and experience concerning the proportion of its feveral parts.

The firft point is to make the machine as fimple as poffible; yet it feems neceffary to make a wheel and trundle-head, to give the mill-ftone fufficient velocity to turn round its axis 40 times in a minute. The refiftance to be overcome muft therefore be in proportion to the main ftrength of a Horfe, which is equal to a lever of 180 pounds weight, when it acts in a horizontal direction, and the Horfe goes about 2000 fathoms an hour.

I allow eight feet for the radius of the wheel, and make 112 cogs in the periphery, which catching in a trundle-head of feven wallowers, the mill-ftone will make fixteen turns for one of the wheel; and as the fame proportion ought to be between the number of cogs and that of the wallowers, as of the radius of the wheel to that of the trundle-head, the radius of the trundle-head ought to be fix inches.

As to the arm of the lever, at which the Horfe is to be harneffed, if it be too long, the Horfe, having a large circumference to defcribe, will make fewer turns in a minute, and the mill-Houfe muft be larger: wherefore I fhould chufe to fix it at twelve feet, which is moft convenient, in which cafe, the Horfe at every turn will defcribe a circumference of twelve fathoms four-fevenths; and as he can perform 2000 of thefe in an hour, he will perform 160 turns in the fame time, which, being multiplied by fixteen, is equal to 2560, the number of turns which the mill-ftone makes in an hour at the rate of 42 per minute.

HORSE-*worm*, in natural hiftory, a fpecies of fly-worm produced of eggs depofited, by a two-winged fly of the fhape and fize of the humble-bee, in the inteftines of Horfes.

It is indeed a very ftrange place this little creature chufes for the depofiting its eggs; but as noble a creature as the Horfe feems, and as much as we may fuppofe him created for our ufe, we are to confider, that the fame great hand made both him and this little fly, and that he feems indeed more created for the fly than for us; he is ufeful to us, but to the fly he is abfolutely neceffary, fince without him fhe could not propagate her fpecies.

The worms of the human bowels have not been longer known to the world than thofe of the Horfe; and the farriers in all ages, who have undertaken the care of thefe valuable animals, have had their remedies for the long worms bred in their inteftines, and alfo for the fhort ones. The fhort ones are the creatures mentioned in this article. But, though the world has fo long been acquainted with their exiftence, it never knew their origin till Mr. Vallifnieri difcovered of late, that they were produced from one of the humble-bee flies. *Reaumur's Hift. Inf.*

HOSE *in* HOSE, a term ufed in gardening, to fignify one long hufk within another, as in the polyanthus.

HOSE-*hufk*, is a long round hufk, as in pinks, gillyflowers, &c.

HOSPITAL (*Dict.*)—Camp Hofpitals are either general or regimental.

The general Hofpitals are of two kinds, viz. the flying Hofpital, attending the camp at fome convenient diftance, and the ftationary Hofpital, which is fixed to one place. In the choice of both, it will be better to have them in towns than villages, as the former will afford larger wards, befides more of other conveniencies: thefe wards fhould be as airy as poffible.

As to the difpofition of Hofpitals, in regard to preferving the purity of the air, the beft rule is to admit but few patients into each ward. It will alfo be found a good expedient, when the cielings are low, to remove fome part of them, and to open the garret ftory. The doors and windows may likewife be opened, and ventilators ufed to purify the air of every ward. In winter Hofpitals, the wards are to be warmed with chimneys, and never by ftoves; for, though the latter may warm a large ward better, and at a lefs expence, yet, by fcarce making any draught of air, they will be apt to increafe its putrid quality; whereas a fire, kept up in a chimney, acts like a conftant ventilator.

The general Hofpital fhould receive only fuch fick as the regimental ones cannot conveniently contain, together with thofe who cannot be moved with the army. Without this difperfion of the fick, the general Hofpital, in bad feafons, would have a greater number, than could be well attended; and what is equally, if not more pernicious, it would be too much crouded, by which means the contagion would fpread, and the mortality be rendered more general.

Regimental Hofpitals are of the greateft importance, and therefore fhould be fupplied with blankets and medicines from the public ftores, with an allowance alfo for nurfes and other neceffaries. Nor are they to be maintained in the field only, but alfo in winter-quarters, as there will always be a great many more fick, than can be taken care of in the general Hofpital.

Barns, ftables, granaries, and other out-houfes, but, above all, churches, make the beft Hofpitals, from the beginning of June to October: for, as the greateft danger arifes from foul air, which cannot be compenfated by diet or medicine, we may lay it down as a rule, that, the more airy and large the Hofpitals are, the lefs danger there is of the ficknefs fpreading. *Pringle's Obfervations on the Difeafes of the Army.*

HOSPITAL *fever*, a name given to the malignant catarrhal fever, as being frequent in Hofpitals.

Dr. Pringle has given us an elaborate account of the rife, fymptoms, and cure of this terrible difeafe in his Obfervations on the Difeafes of the Army. It may be owing to a great many concurring caufes, but the principal are foul and putrid air, occafioned by filth and impurity of any kind. Hence it is no wonder that it prevails in marfhy countries after hot feafons, and in populous cities; efpecially if low, and ill-aired, unprovided with common-fhores, or where the ftreets are narrow and foul, the houfes dirty, water fcarce, and where jails or Hofpitals are crouded, and not ventilated and kept clean; when in fickly times the burials are within the towns, and the bodies not laid deep; when flaughter-houfes are alfo within the walls; or when dead animals are left to rot in the channels, or on dunghils; when drains are not provided to carry off any large body of the ftagnating or corrupted water, in the neighbourhood; when flefh-meats make the greateft part of the diet, without a proper mixture of bread, greens, wine, or other fermented liquors; from the ufe of old and mufty grain, or what has been damaged by a wet feafon; or, laftly, when the fibres are relaxed by immoderate warm bathing.

When the difeafe comes on flowly, the fymptoms are fmall interchanges of heats and cold, trembling of the hands, interrupted fleep, &c. But, when it advances faft, the above fymptoms are all in a higher degree; and befides thefe, the patient is afflicted with great laffitude, a naufea, pains in the back, a conftant pain and confufion in the head, a dejection of fpirits, and an uncommon tremor of the hands. If the fick lie warm, and have no preceding flux, the body is generally coftive; but, when they lie cold, as they often do in field-Hofpitals, the pores of the fkin being fhut, a diarrhœa is a common fymptom: in the worft cafes, a flux appears in the laft ftage; when the ftools are involuntary, colliquative, ichorous, or bloody, and of a cadaverous fmell; which are the effects of a mortification of the bowels, and the figns of approaching death: fome are never delirious, but all are under a great ftupor or confufion. The petechiæ are the frequent, but not infeparable attendants of the fever; they are fometimes of a brighter or paler red, at other times of a livid colour, but are never raifed above the fkin. For the moft part, thefe fpots are fo little confpicuous, that, unlefs looked for attentively,

Printed for J. Hinton in Newgate Street.

tentively, they may eſcape notice. They are thickeſt on the breaſt and back, leſs on the legs and arms, and the Doctor never remembers to have ſeen any upon the face. This fever, though of the continued kind, has often exacerbations at night, with remiſſions and partial ſweats next day; and, after a long continuance, is apt to change into a hectic, a remitting, or intermitting form.

Prognoſtics in it. To have a little delirium, the ſtrength a little impaired, turbid urine in the decline of the diſeaſe, and at the ſame time a gentle ſweat or moiſture diffuſed over the body, are reckoned good ſigns; and it ſeems peculiar to malignant fevers, that deafneſs is rather a good ſign.

Method of cure. This varies according to the ſtate of the diſeaſe, which may be diſtinguiſhed into three periods; the firſt continuing as long as the perſon is able to go about; the ſecond beginning with his confinement; and the third when the pulſe ſinks, and a ſtupor comes on.

In the firſt, as well as in the other periods, the cure is principally to be aimed at by removing the patient out of the foul air. When this cannot be done, the ward or room ſhould be purified by making a ſucceſſion of air by means of fires, or letting it in by doors and windows, or diffuſing the ſteams of vinegar.

The next thing to be done, is to promote a diaphoreſis, which, in this period, ſhould only be attempted by mild ſudorifics, as the ſpiritus Mindereri.

When the fever is confirmed, contrayerva-powders, with nitre, camphor, the common ptiſan acidulated, and ſuch medicines as are good in inflammatory caſes, ought to be given. Coſtiveneſs is to be prevented by emollient clyſters. But opiates are dangerous, both in this and the third ſtage, in which the pulſe ſinks, and ſtupor is greater, a delirium impends, and petechiæ often appear. When this is obſerved to be the caſe, the nitre and diaphoretic medicines are to make room for a decoction of ſnake-root, to which a ſmall quantity of ſtrong water may be added. It may alſo be given in ſubſtance from two to four ſcruples a day, with ſenſible good effects. Towards the decline of the fever, an equal quantity of Peruvian bark may be joined with the root. Wine is alſo an excellent cordial at this period, and may be given either made into whey, or added to the panado, which was the only food allowed to the ſick. It may be taken from a half pint to a quart a day, according to the ſtrength of the patient. Perhaps there is no rule of more importance, than to give ſtrict charge to the attendants of the ſick, never to let the patient, when low, remain above two or three hours without taking ſomething cordial and nouriſhing. But, however neceſſary wine, volatiles, and other cordials are in this low ſtate of the fever, it ought to be remembered, that they muſt never be given with an intention to force a ſweat, but only as antiſeptics, and to ſupport the vis vitæ. If there be danger of a phrenites coming on, it will be proper to call in the aſſiſtance of epiſpaſtics. Sinapiſms too may be uſed when the pulſe is greatly ſunk. If a diarrhœa comes on in the decline of the fever, it is to be moderated by adding a few drops of the tinctura Thebaica, to the full quantity of the alexipharmic decoction; or by giving a ſpoonful or two of an aſtringent mixture. In proportion, however, to the putrid nature of the ſtools, aſtringents are to be uſed with the more caution. When the fever is over, there are few but complain of a vertigo; and want of reſt, a continuation of the deafneſs, and other nervous ſymptoms, are frequently the conſequence of great lowneſs; in which caſe the pillulæ Matthæi are to be given at night, with analeptics and medicines of the ſtrengthening kind. *Vid. Pringle's Obſerv. on Diſ. of the Army.*

HOTTO'NIA, *water-violet*, in botany, a genus of plants, whoſe characters are:

It hath a roſe-ſhaped flower, conſiſting of one leaf, which is divided into five parts, almoſt to the bottom; in the center of the flower ariſes the pointal, which afterwards becomes a cylindrical fruit, in which are contained ſeveral ſpherical ſeeds. This plant is very common in deep ſtanding waters and ditches, in ſeveral parts of England. The leaves of this plant appear on the ſurface of the water the beginning of April; and, in May, the flowers appear on pretty long naked ſtalks, growing in a ſpike. Theſe flowers are of a fine roſe colour; which, together with their fine cut leaves, make a beautiful appearance on the water. *Miller's Dictionary.*

HOU'GHING, in gardening, is neceſſary and beneficial to plants, for two things: 1. For deſtroying of weeds. 2. Becauſe it diſpoſes the ground the better to imbibe the night dews, keeps it in a conſtant freſhneſs, and adds a vigour to the trees, whoſe fruit, by that means, becomes better-conditioned than otherwiſe it would be. See HOEING.

HOWLE, *in ſhip-building*.— When the foot-hooks of a ſhip are ſcarfed into the ground timbers, and bolted, and then the plank laid on them up to the orlop, the carpenters ſay, they begin to make the ſhip Howle.

HU'MBLE-*Bee*, in the hiſtory of inſects. See the article BOMBYLIUS.

HUMBLE-*Bee flies*, in natural hiſtory, the name of a claſs of flies of different ſizes, but all agreeing in the great reſemblance they bear to the Humble-bees, of the ſmaller or middle-ſized ſpecies. Theſe might, at firſt ſight, very naturally paſs for real Humble-bees; but a cloſer examination will ſhew them not to be ſuch, as they have not the trunk of the Humble-bee, and have only two wings. The ſpecies of the Humble-bee fly are many of them of abſolutely different genera one from another, ſome of them having trunks, and others having a diſtinguiſhable mouth.

If the figure of theſe flies, in their winged ſtate, attracts our curioſity and attention, their prior ſtate, that of the fly worm of moſt of them, ought ſurely much more to do ſo. The place nature has aſſigned the worms of theſe flies for their habitation, is indeed a moſt ſtrange one; there is no other place for them to live in under this form, to begin their deſtined growth, and be fitted for their transformation, but in the inteſtines of horſes, or under the thick and firm ſkin of oxen. In the latter caſe, the worm hatched from the egg of its parent fly, depoſited there, makes a tumor in the place, which alone furniſhes it with food and habitation. and in the middle of which it has a place to breathe. *Reaumur's Hiſt. Inſ.*

Luxated HU'MERUS.— The Humerus, from the length and laxity of its ligaments, the largeneſs of its motion, and the ſhallowneſs of its cavity in the ſcapula, into which it is articulated, is rendered, of all the bones, the moſt ſubject and eaſy to be luxated. The head of this bone may often be diſlocated, under the arm-pit; ſometimes forward, and ſometimes backward, and even below the ſcapula; but ſeldom perpendicularly downwards, and never directly upwards, unleſs the acromion and corocoide proceſſes of the ſcapula ſhould chance to be fractured at the ſame time; beſide, as long as the ſtrong deltoide and bicipital muſcles of the Humerus remain entire, they greatly reſiſt and keep down the Humerus from being luxated upwards. As ſoon as a luxation is diſcovered in the Humerus, the ſafeſt way to attempt the reduction of it, is to place the patient on the floor, or on a low ſtool; two ſtrong aſſiſtants are then to be placed on each ſide of him, one to keep firmly hold of his body, that it may not give way to the extenſion, while the other lays hold of the luxated arm with both his hands, a little above the cubitus, gradually and ſtrongly extending it. But, before that extenſion be made, the ſurgeon himſelf ſhould have a large and ſtrong napkin, of a ſufficient length, tied at the ends, and hung about his neck, ſo that the knot may hang behind, but the other part of the napkin over his breaſt. The patient's arm muſt then be put through this napkin, up to the ſhoulder, and the ſurgeon muſt lay hold of the head of the Humerus with both his hands. This done, the aſſiſtant, who has hold of the arm, is to extend it ſufficiently, and the ſurgeon is to elevate the head of the Humerus, by means of the napkin through which the arm is put, directing it with his hands, till it ſlips into its former cavity in the ſcapula.

This ſeems the moſt ſafe, ready, and commodious of all methods, for reducing luxations of the Humerus; but it is to be acknowledged, that the extenſion cannot, by this means, be made ſufficiently ſtrong, in ſome caſes, particularly when the patient is very robuſt, or when the caſe has been delayed a conſiderable time without aſſiſtance. When one or two aſſiſtants therefore are not ſufficient to make a proper extenſion, it is eaſy to employ more, by means of napkins tied about the limb, and a proper number of aſſiſtants to hold the patient's body ſteady againſt that force. And, when all this is not ſufficient, the ſurgeon is forced to have recourſe to machines with ropes and pullies; which, though the patient is uſually terrified a little at them, yet make an eaſier, and a more equal and regular extenſion, than can be done by the hands of ever ſo many aſſiſtants. *Heiſter's Surgery.*

HU'MMING-*bird*, *guainumbi*, in ornithology, a large genus of birds, many ſpecies of it having been deſcribed by authors, and many, which they have not deſcribed, having been ſent into Europe by the curious. It is the ſmalleſt of all birds, but of the moſt beautiful and lively colours of all others. It flies very ſwiftly, and in flying makes a noiſe exactly like the Humming of a bee, and ſome of the ſpecies are not much larger than the humble-bee. It can ſuſtain itſelf a long time on the wing, and in that poſture thruſts his little beak into flowers, the juices of which it ſucks and feeds on. As it has no other food but this, there is no keeping it alive, but all die that are taken; and they are preſerved and ſent over as curioſities to us. Many have reported ſtrange ſtories of their ſleeping all the winter months, and reviving at the approach of ſpring; but Marcgrave ſaw them in great plenty, in the woods, in all ſeaſons. The Indians make pictures with the feathers of theſe birds, which are ſo brightly coloured, as to vie with the fineſt paint, and ſo thin as to be as cloſe as colours on canvas. *Ray's Ornithol.*

Plate XXVIII. *fig.* 4. repreſents one of the ſpecies of this beautiful bird, which Mr. Edwards calls,

The long-tailed black-cap HUMMING-*bird*.—This bird is engraved of its natural bigneſs; it hath a very long tail, of a looſe, ſoft texture, eaſily ruffled, and flowing with the leaſt breath of air; what is remarkable in the tail is, that theſe two fine feathers are the outermoſt but one on each ſide, having a leſſer ſtiff feather under them, as well as above, the better to ſupport them, which is ſingular. So far as my obſervation reaches, all birds, whoſe tail-feathers differ in length, have either the two middlemoſt or the two outermoſt the longeſt, as in the

ſwallow

ſwallow and magpye; the bill is thicker at the baſis than in moſt of this kind, pretty long, ending in a point, a little bowed downward, of a yellow colour, with a black point; the crown of the head, and beginning of the neck behind, is of a black colour, with ſomething of a bluiſh gloſs; the throat, breaſt, and belly, are covered with green feathers, inclining to blue, of a firm ſubſtance, lying cloſe and regular, like the ſcales of fiſhes, and of ſo fine a ſurface, that they reflect the light, as doth burniſhed gold; the feathers on the back are of a looſer make, of a yellower green, not having the bright luſtre of the breaſt; the wings are of a browniſh purple, having, in ſome lights, a brighter bluiſh-purple caſt; the ridge of the wing from the ſhoulder, a good way down, is white; the tail is black or duſky, the feathers increaſing in length from the middlemoſt to the outermoſt, ſave one, which is about five times longer than any of the reſt; the legs, feet, and claws, are black. *Edward's Natural Hiſt. of Birds.*

HU'NDRED. *Docimaſtic Hundred, or centner*, in metallurgy and aſſaying, is a weight diviſible, firſt into an Hundred, and thence into a great number of other ſmaller parts; but, though the word is the ſame, both with the aſſayers and metallurgiſts, yet it is to be underſtood as expreſſing a very different quantity in their different acceptation of it. The weights of the metallurgiſts are eaſily underſtood, as being of the common proportion; but thoſe of the aſſayers are a thouſand times ſmaller than theſe, as the portions of metals or ores examined by the aſſayers are uſually very ſmall.

The metallurgiſts, who extract metals out of their ores, uſe a weight divided into an Hundred equal parts, each part a pound; the whole they call a centner or Hundred weight; the pound is divided into thirty-two parts, or half ounces: and the half ounces into two quarters of ounces, and theſe, each, into two drachms.

Theſe diviſions and denominations of the metallurgiſts are eaſily underſtood; but the ſame words, though they are equally uſed by aſſayers, with them, expreſs very different quantities; for, as the centner of the metallurgiſts contains an Hundred pounds, the centner of the aſſayers is really no more than one drachm, to which the other parts are proportioned.

As the aſſayers weights are divided into ſuch an extreme degree of minuteneſs, and are ſo very different from all the common weights, the aſſayers uſually make them themſelves in the following manner, out of ſmall ſilver, or fine ſolder plates, of ſuch a ſize, that the mark of their weight, according to the diviſion of the drachm, which is the docimaſtic, or aſſaying centner, may be put upon them. They firſt take for a baſis one weight, being about two thirds of a common drachm: this they mark 64 lb. Then, having at hand ſome granulated lead, waſhed clean, well dried, and ſifted very fine, they put as much of it in one of the ſmall diſhes of a fine balance, as will equipoiſe the 64 lb. as it is called, juſt mentioned: then, dividing the granulated lead into very nice halves, in the two ſcales, after taking out the firſt ſilver weight, they obtain a perfect equilibrium between the two ſcales; they then pour the granulated lead out of one diſh of the ſcales, and inſtead of it put in another ſilver weight, which they make exactly equiponderant with the lead in the other ſcale, and mark it 32 lb. If this ſecond weight, when firſt put into the ſcale, exceed by much the weight of the lead, they take a little from it by a very fine file; but, when it comes very near, they uſe only a whetſtone to wear off an extremely ſmall portion at a time. When it is brought to be perfectly even and equal to the lead, they change the ſcales to ſee that no error has been committed, and then go on in the ſame manner till they have made all the diviſions, and all the ſmall weights. Then to have an entire centner, or Hundred weight, they add to the 64 lb. as they call it a 32 lb. and a 4 lb. and, weighing againſt them one ſmall weight, they make it equal to them, and mark it 100 lb. This is the docimaſtical or aſſaying centner, and is really one drachm. *Cramer, Art of Aſſay.*

HU'RA, *the ſand box-tree*, in botany, a genus of plants, whoſe characters are:

It hath male and female flowers on the ſame plant: the male flowers conſiſt of one leaf, which is funnel-ſhaped, having a long incurved tube; but is ſpread open at the brim, where it is ſlightly cut into twelve parts: in the bottom of the tube are placed ſeveral ſhort ſtamina, which are collected together. The female flowers have the ſame figure with the male, but have no ſtamina; the center of the flower being occupied by the ſhort round compreſſed pointal, which afterwards becomes a round fruit compreſſed at both ends, having twelve deep furrows, and as many different cells, each containing one round compreſſed ſeed: the fruit, when ripe, burſts open with great elaſticity, and caſts the ſeeds abroad.

It is propagated by ſeeds, which ſhould be ſown early in the ſpring, in pots filled with light rich earth, and plunged into an hot bed of tanner's bark. If the ſeeds are freſh, the plants will appear in about five weeks after the plants are ſown; when they ſhould be carefully cleared from weeds, and frequently refreſhed with water. As the plants will advance very faſt, when due care is taken of them, they ſhould have a large ſhare of freſh air admitted to them in warm weather, otherwiſe they will draw up too weak. When the plants are about four inches high, they ſhould be tranſplanted each into a ſeparate ſmall pot filled with light rich earth, and plunged again into the hot-bed of tanner's bark; being careful to ſhade them from the heat of the ſun, until they have taken new root; after which time they muſt have free air admitted to them, by raiſing of the glaſſes in proportion to the warmth of the ſeaſon; and they ſhould be frequently watered. When the plants have filled theſe ſmall pots with their roots, they muſt be ſhaken out of them, and their roots trimmed, and then placed in larger pots, which ſhould be filled with the like rich earth, and plunged again into the hot-bed; where they ſhould remain till Michaelmas, provided the plants have room, without touching of the glaſſes; at which time they muſt be removed into the bark ſtove, and plunged in the warmeſt part thereof: during the winter ſeaſon they muſt be often watered, but they muſt not have it in ſuch quantities then, as is given to them in ſummer; they muſt alſo be kept very warm, otherwiſe they will not live in this country. In ſummer they muſt have a large ſhare of freſh air, in warm weather; but they muſt not be removed into the open air; for they are too tender to live abroad in the warmeſt part of the year in this country.

HU'SBANDRY. The new method of Huſbandry, called by Tull the horſe-hoeing Huſbandry, has many evident advantages over the other, or old way; but the difference between them, in regard to the former, is beſt explained by a fair compariſon. In order to do this juſtly, there are four things to be carefully conſidered: 1. The expence of a crop. 2. The goodneſs of the crop. 3. The certainty of it. And, 4. The condition in which the land is left after the crop.

The profit or loſs, ariſing from land, is not to be computed only from the value of the crop it produces, but from its value after all expences of ſeed, tillage, &c. are deducted. Thus, when an acre of land produces a crop worth four pounds, and the expences of it amount to five pounds, the loſs of the farmer is one pound upon it; whereas, when as much land produces a crop only of the value of thirty ſhillings, and the expences are only ten ſhillings, the owner receives one pound advantage. The common expence of an acre of ſowed wheat, in the uſual way, is four pounds ten ſhillings; and the common expence of an acre of wheat, in the horſe-hoeing Huſbandry, is only ten ſhillings, including all the expences that can attend it. Thus this method of Huſbandry is but a ninth part of the charge of the common way; and as no ſheep are required, as there are in the other way, the leſs ſtock will do to begin with. The goodneſs of a crop conſiſts in the quality of it as well as in the quantity, and, wheat being the moſt uſeful of all grain, a crop of this is more valuable than a crop of any other corn. Add to this, that a crop of hoed wheat has always larger ears, and a fuller body, than a crop when ſown in the common way. More wheat may alſo be obtained this way than any other, becauſe the ſame lands will thus produce crops every year; and even the land which has been exhauſted by the common Huſbandry, will produce wheat in plenty this way, without fallowing or dunging, both which would otherwiſe be neceſſary. So that, in many places, this Huſbandry can raiſe ten acres of wheat for one that the old way could produce, becauſe, where land is poor, they ſow but a tenth part of it in wheat.

The largeſt produce of an acre of wheat land, ſo far as has yet been experienced, ſeems to be ten quarters, or eighty buſhels to an acre. This is leſs indeed than the produce of an acre in the common way, according to Houghton's computation: but, to compare the different profits to the farmer, we proceed thus: the rent and expences of a drilled acre being one pound, and that of a ſowed acre in the common way being five pounds; one quarter of corn produced by the drilled bears an equal proportion to one pound in profit, as five quarters produced in the common way do to five pounds. As, ſuppoſe it to be of wheat at two ſhillings and ſix pence a buſhel, there is neither gain nor loſs in the one nor the other acre, though the drilled produce only one quarter, and the other five.

But if the drilled acre yields two quarters, and the ſown acre yields only four quarters at the ſame price, the drilled acre brings the farmer one pound profit, while the other has one pound loſs. Likewiſe ſuppoſe the drilling farmer to have his five pounds laid out in five acres of wheat, and the other to have his five pounds laid out in one dunged acre, then, let the price be what it will for the wheat, if the five acres have an equal crop to the one acre, the gain and loſs muſt be equal. But, if the price of wheat be at two ſhillings and ſix-pence, the farmer in the common way, if he have five quarters on his acre, he muſt ſell it all to pay his rent; whereas, if he who drills the land have five quarters on each acre, the produce of one acre will pay for all five. Or ſuppoſe a drilled acre to produce no more than one-third of the ſown acre, which is rating it very low indeed, the expence of the ſown acre being five times as much as that of the drilled one, it is much more profitable to the owner to have the drilled acres; becauſe a third part of five pounds is one pound thirteen ſhillings and four-pence, and, a fifth of the rent and expence, which is all his charge, being only one pound, ſuch a drilled acre

acre brings the owner thirteen shillings and four-pence profit more than the sown acre, though that brings three times as great a crop.

The certainty of a crop is greater this way than in the old way of sowing; for most of the accidents, attending wheat crops, are owing to their being late sown, which is necessary to the farmer in the old way; but in the horse-hoeing method the farmer may plough two furrows whereon the next crop is to stand, immediately after the first crop is off. In this manner of Husbandry the land may be plowed dry and drilled wet, without any inconvenience; and the seed is never planted under the furrow, but placed just at the depth which is most proper, that is, at about two inches, in which case it is easy to preserve it, and there is no danger of burying it. Thus the seed has all the advantages of early sowing, and none of the disadvantages that may attend it in the other way; and the crop is much more certain than by any other means that can be used.

The condition in which the land is left after the crop, is no less in favour of the horse-hoeing Husbandry, than all the other articles. The number of plants is the great principle of the exhausting of land. In the common Husbandry, the number is vastly greater than in the drilling way, and three plants in four often come to nothing, after having exhausted the ground as much as profitable plants; and the weeds which live to the time of harvest in the common way, exhaust the land no less than so many plants of corn, often much more. The horse-hoeing method destroys all the weeds in the far greater part of the land, and leaves that part unexhausted and perfectly fresh for another crop. The wheat plants being also but a third part of the number at the utmost of those in the sowing way, the land is so much the less exhausted by them; and it is very evident from the whole, that it must be, as experience proves that it is, left in a much better condition after this than after the common Husbandry.

The farmers who are against this method, object that it makes the plants too strong, and that they are more liable to the blacks, or blights of insects, for that season; but, as this allows that the hoeing can, without the use of dung, give too much nourishment, it is very plain that it can give enough; and it is the farmer's fault, if he do not proportion his pains so as to have the advantages of the nourishment without the disadvantages. It is also objected, that, as hoeing can make poor land rich enough to bear good crops of wheat, it may make good land too rich for it. But, if this should happen, the sowing of wheat on it may be let alone a while, and in the place of it the farmer may have a crop of turnips, carrots, cabbages, and the like, which are excellent food for cattle, and cannot be over nourished: or, if this is not chosen, the land, when thus made too rich, may soon be sufficiently impoverished by sowing corn upon it in the common old way. See HOEING.

HYA'CINTHUS, *hyacinth, or jacinth*, in botany, a genus of plants, whose characters are:

It hath a bulbous root: the leaves are long and narrow: the stalk is upright and naked, the flowers growing on the upper part in a panicle: the flowers consist each in one leaf, are naked, tubulose, and cut into six divisions at the brim, which are reflexed: the ovary becomes a roundish fruit with three angles, which is divided into three cells that are filled with roundish seeds.

All the different sorts of hyacinths are propagated by seeds or offsets from the old bulbs: the former method has been but little practised in England till very lately; but in Holland and Flanders it hath been followed for many years, whereby they have obtained a very great variety of the most beautiful flowers of this kind; and it is owing to the industry of the florists in those countries, that the lovers and delighters in gardening are so agreeably entertained, not only with the curious variety of this, but of most other bulbous-rooted flowers; few other florists thinking it worth their trouble to wait four or five years for the flower of a plant, which when produced, perhaps there might not be one in forty that may deserve to be preserved: but they did not consider, that it was only the loss of the three or four first years after sowing; for, if they continued sowing every year after they began, there would be a succession of flowers annually, which would constantly produce some sorts that might be different from what they had before seen; and new flowers being always the most valuable to skilful florists, provided they have good properties to recommend them, it would always be a sufficient recompence for their trouble and loss of time.

The method of raising these flowers from seed is as follows: having provided yourself with some good seed (which should be saved from either semi-double, or such single flowers as are large, and have good properties) you must have a parcel of square shallow boxes or pots, which must be filled with fresh light sandy soil, laying the surface very level: then sow your seeds thereon, as equally as possible, covering it about half an inch thick with the same light earth: the time for this work is about the beginning of August. These boxes or pots should be placed where they may enjoy the morning sun only until the middle or latter end of September; at which time they should be moved into a warmer situation; and, towards the end of October, they should be placed under a common hot-bed frame; where they may remain during the winter and spring months, that they may be protected from hard frosts; though they should be exposed to the open air, when the weather is mild, by taking off the glasses. In February the young plants will begin to appear above ground; at which time they must be carefully screened from frosts, otherwise they will prove very injurious to them: but you must never cover them at that season but in the night, or in very bad weather; for when the plants are come up, if they are close covered, they will draw up very tall and slender, and thereby prevent the growth of their roots. In the middle of March, if the weather proves good, you may remove the boxes out of the frame, placing them in a warm situation; observing, if the season be dry, to refresh them now and then with a little water, as also to keep them very clear from weeds; which would soon overspread the tender plants, and destroy them, if permitted to remain. *Miller's Gard. Dict.*

HYGRO'METER (*Dict.*)—*Plate* I. *fig.* 9, in the Dictionary, represents a double Hygrometer. It is made of a string either of hemp or cat's-gut, and shews the increasing moisture of the air by its twisting and shortening, and the dryness by untwisting and lengthening.

Thus, let A B C be the lower part of a twisted line or cord, hanging from the height of the room against one side thereof on the wall or wainscot; let there be described a large circle, graduated into an 100 equal parts, such as K L M N; in the center of which is a pin, with a small pulley I B, carrying an index O P. If now a cord be put round the pulley, and a small weight or ball D be suspended at the lower end to keep it straight, then, as the cord gathers moisture from the air, it will twist and become shorter; the consequence of which will be, that in contracting it will turn the pulley I B, and this by its index will point to the numbers on the graduated circle, which will shew the degree of moisture or dryness by the contraction or relaxation of the cord.

Again: if the ball D hang over the center E of another graduated circle C G H placed horizontally, carrying an index E upon its divisions, it will shew the same thing by the twisting and untwisting of the cord B C, as in the circle above.

I.

I.

JA'CEA, *knapweed, or matfellon*, in botany, a genus of plants whose characters are:

The leaves and stalks are destitute of spines, and the leaves have their margins equal, not serrated. *Boerhaave, Index alter.*

Tabernæmontanus recommends the decoction of it for ruptures: there are some that give it in powder in pottage. By the chymical analysis it yields hardly any thing but a substance loaded with acrid salt. *Martyn's Tournefort.*

It is too frequent in pasture grounds, and flowers in July and August. The herb, which is used, is effectual against tumors of the tonsils, and in hernias and wounds. *Dale from Schroder.*

I'CACO, *American plum*, in botany, a genus of plants whose characters are:

It hath a rose-shaped flower consisting of several petals, which are placed in a circular order, from whose flower cup arises the pointal, which afterwards becomes an oval, soft, fleshy fruit, inclosing a rough stone of the same form, in which is contained a round kernel.

JACOBÆ'A, *ragwort*, in botany, a genus of plants whose characters are:

It hath a radiated flower, the tube of which is almost of a cylindrical figure, and the seeds are fastened to down; to which may be added, the leaves are deeply laciniated or jagged.

JA'LAP (*Dict.*)—The characters of this genus are:

It hath a long thick fleshy succulent root: the leaves, which resemble those of nightshade, grow by pairs opposite on the branches: the stalks and branches are very full of knots: the flower consists of one leaf, and is shaped like a funnel: in the center of the flower is placed the ovary, inwrapped in one of the flower cups, which becomes an oblong five-cornered umbilicated fruit, consisting of a mealy nut. See *Plate* XXVIII. *fig.* 2. where *a* is the flower, *b*, the Jalap root of the shops.

These plants are always propagated by seeds, which should be sown upon a moderate hot-bed in March; and, when they come up, they should be transplanted into another hot-bed, at six inches distance from each other; and, when they have taken root, the glasses must be raised every day, that the plants may have a great deal of air, otherwise they are very subject to be drawn up tall and weak; nor can they be recovered to a sufficient strength again in a month's time, if once they are thus drawn. When the plants are grown to be a foot high, they should be put into pots filled with rich light earth, which should be plunged into a very moderate hot-bed, to facilitate their taking root: and, in removing them, you must be very careful to preserve as much earth to their roots as you can; for their roots have but few fibres to retain it in a ball, as many other plants will do; and it sometimes happens, when the root is left bare, it seldom takes fresh hold of the ground, at least not in a considerable time; so that the plants will make but a poor figure that season. When they are transplanted into the pots, and have taken root again, they should be hardened to endure the open air, for they are not very tender; but, on the contrary, they will not thrive well, if too much drawn or forced in the hot-bed. In the middle of May the pots may be removed into the places where they are designed to be continued for that season; observing to support the branches with a strong stake, and to water them as often as they require it. You may also in May plant some of them into the middle of the large borders of the pleasure-garden, doing it carefully; and observe to shade and water them until they have taken root; after which, they will require no farther care but to support them from being broken down by the winds, which they are very subject to be, especially when their heads are large.

The plants, thus raised, will grow to the height of three or four feet, and spread their branches very wide (especially if the roots have room in the pots;) and their flowers will begin to appear in June, and they will continue constantly flowering until the frost prevents them; which, together with the great diversity of colours in the flowers upon the same plant, renders them valuable to every curious person. The flowers of these plants never expand in the day time, while the sun is hot; but in the evening, when the sun declines, they begin to open, and continue expanded till the sun shines warm upon them the next day; so that, when it happens to be cloudy weather, as also late in autumn, when the weather is cool, the flowers will remain open most part of the day.

As the flowers are produced successively almost every day, so the seeds are in a short time after ripe, and do soon fall to the ground; so that, when your seeds begin to ripen, you must carefully look for them upon the ground twice a week: otherwise, if they lie too long upon the ground, and there should fall some rain, they will sprout, and be good for nothing. In sowing these seeds, you should be careful to take them from such plants as produced the greatest variety of flowers; for, if you save them from such as produce only plain-coloured flowers, the seeds will always produce the same sort; and those with yellow and red variegated flowers will constantly produce the same; these never varying from the red and yellow to the purple and white, though they will sometimes degenerate into plain yellow or red flowers, as will they into plain purple or white; but they will constantly retain one or both of their original colours.

JA'NSENISM, the tenets and opinions of Cornelius Jansenius (D. D. of the university of Lovain and Ypres, born at Leerdam, 1585) with relation to grace and free-will, as follows: 1. Some precepts of God are impossible to just men, though willing and endeavouring according to their present power; grace being wanting, whereby it might be possible for them to keep God's commands. 2. In the state of the fallen nature there is no resistance made to inferior grace. 3. To merit or demerit in the state of lapsed nature, there is not required in a man liberty from necessity, but liberty from coaction is sufficient. 4. The Semipelagians did admit the necessity of inferior preventing grace to every act, even to the beginning of faith; and in this they were heretics, because they would have that grace to be such as the will of man might resist or obey. 5. It is a Semipelagianism, to say that Christ died or shed his blood for all men. These propositions, though much defended in France and Flanders, were condemned by pope Innocent the Tenth in the calends of June, 1633; as likewise by Alexander the Seventh, and Clement the Ninth. Jansenism consists in maintaining this doctrine two ways, 1. By asserting that these propositions are sound and orthodox. 2. In affirming that they are evil and heretical, in the sense wherein the church had condemned them, but that this sense is not the true. *P. Simon. Sup. and Leo. de Mod.*

JAPA'NNING (*Dict.*)—The varnish, made and used in China and Japan, is composed of turpentine and a curious sort of oil they have. This they mix and boil up to a proper consistence, and this never causes any swelling in the hand or face of the people who use it. The swellings in these parts which often happen to those who work the lackered ware, and sometimes to those who only pass by the shops of these people, is from the lack and not the varnish. This lack is the sap or juice of a tree, which runs slowly out on cutting the lower part of the trunk of the tree, and is received in pots set on purpose under the incisions. This juice, as it flows from the tree, is of the colour and consistence of cream, and, as it comes in contact with the external air, its surface becomes black. As they only use it when black, their method of preparing it is to set it out in the open air, in large flat bowls, in which it looks all surface; but, that the whole may be of the same uniform colour, they continually stir it for twenty-four hours together, with a smooth piece of iron: by this means the whole becomes thicker than it was before, and of a fine deep black. When it is in this state, they powder some burnt boughs of trees, and mix them thoroughly with it, and then, spreading it thin over any board which they intend to japan, it is soon dried in the sun, and is then absolutely harder than the board it is laid on. When this is thoroughly dry, they polish it over with a smooth stone and water, till it is as smooth as glass; and then, wiping it very dry, they lay on the varnish made of oil and turpentine, and boiled to a proper consistence for this kind of work.

If the work is to be of any other colour than black, that colour is to be mixed with the varnish, and then the whole spread on very thinly and evenly; for in this laying it on depends the principal art of varnishing. When there are to be figures in gold or silver, these must be traced out with a pencil in the varnish over the rest of the work, and, when the varnish is almost dry, the leaf gold or leaf silver is to be laid on, and polished afterwards with any smooth substance.

JA'SHER, a book mentioned in ſcripture, and ſaid by ſome to be loſt. But ſome of the moſt celebrated Hebrew doctors ſay they have found it; telling us, that it is the book of Geneſis, wherein are contained the acts of Abraham, Iſaac, Jacob, and the other patriarchs, who were, by way of excellence, called jaſherim the juſt. But, that man muſt be eaſily ſatisfied, who can acquieſce with this interpretation. Dr. Lightfoot thinks the book of Jaſher is the ſame with the book of the Wars of God; but there is little foundation for it. This book, according to Grotius, was a triumphal poem; but Joſephus ſeems to bid faireſt for the truth, who ſays, that by this book are to be underſtood certain records kept in ſome place on purpoſe, and afterwards in the temple, giving an account of what happened among the Hebrews from year to year, and particularly the prodigy of the ſun's ſtanding ſtill, and directions and laws about the uſe of the bow, that is, the ſetting up of archery, and maintaining military exerciſes. If it be enquired why the title given to theſe Hebrew annals was the book of Jaſher, that is, the upright, this may be given as a reaſon, becauſe it was by all perſons reckoned as a very juſt and authentic account of all thoſe events and occurrences which it recorded; it was compoſed with great uprightneſs and truth, thence it was commonly known by the name of Jaſher's book, or chronicle. It was not the work of any inſpired perſon, but was of the nature of common civil annals; and, conſequently, we cannot infer from hence, that any book properly belonging to holy ſcripture, that is, that was written by inſpiration of the Holy Ghoſt, is at this day miſſing. *Lewis's Antiq.*

JASMI'NUM, *the jaſmine, or jeſſamine tree*, in botany, a genus of plants, whoſe characters are:

The leaves are in many ſpecies pinnated; the cup of the flower conſiſts of one leaf, but is divided at the top into five ſegments: the flower conſiſts of one leaf, is funnel-ſhaped, and divided into five ſegments: the flowers are ſucceeded by berries, which ſplit in the middle, each ſide, for the moſt part, containing a ſeparate ſeed.

The common white jaſmine is eaſily propagated by laying down the tender branches in the ſpring, which, by the ſucceeding ſpring, will be rooted ſtrong enough to be tranſplanted. They may alſo be raiſed by cuttings, which ſhould be planted in autumn in a moiſt border, where they may have the morning ſun: but they muſt be ſcreened from the violence of the ſun in the heat of the day, and frequently watered in dry weather. The cuttings, thus managed, will many of them live, and have roots fit to be removed in the following ſpring: but this method is ſeldom practiſed, the layers always making the beſt plants.

When theſe plants are removed, they ſhould be planted where they are deſigned to be continued, which ſhould be either againſt ſome wall, pale, or other fence, where the flexible branches may be ſupported; for, although it is ſometimes planted as a ſtandard, and formed into an head, yet it will be very difficult to keep it in any handſome order; or, if you do, you muſt cut off all the flowering branches; for the flowers are always produced at the extremity of the ſame year's ſhoots, which, if ſhortened before the flowers are blown, will intirely deprive the trees of flowers. Theſe plants ſhould be permitted to grow rude in the ſummer, for the reaſon before given: nor ſhould you prune and nail them until the middle or latter end of March, when the froſty weather is paſt; for, if it ſhould prove ſharp froſty weather after their rude branches are pruned off, and the ſtrong ones expoſed thereto, they are very often deſtroyed; and, this plant being very backward in ſhooting, there will be no danger of hurting them by late pruning.

The two ſtriped ſorts ſhould be planted in a warm ſituation, eſpecially the white ſtriped; for they are much more tender than the plain, and are very ſubject to be deſtroyed by great froſts, if they are expoſed thereto: therefore it will be proper to preſerve a plant of each kind in pots, which may be removed into the green-houſe in winter, leſt, by expoſing them to the cold, they ſhould all be deſtroyed, and the variety loſt.

The common yellow jaſmine was formerly in greater plenty in England than at preſent, and was planted againſt arbors, &c. to cover them, though it is not near ſo proper for that purpoſe as the white ſort, it being of much ſlower growth, nor will it ever extend its branches ſo far as that; but, however, it may have a place among the flowering ſhrubs of low growth, where it may be with more eaſe reduced to a ſtandard than the other. This plant flowers in May and June; but they have very little ſcent, which has occaſioned its being leſs regarded. It may be propagated by ſuckers, which it generally produces in great numbers; or by layers, as was directed for the common ſort; and are full as hardy. This ſort ſeldom riſes above five or ſix feet high.

The dwarf yellow jaſmine is ſomewhat tenderer than the former; yet will it endure the cold of our ordinary winters, if it be planted in a warm ſituation. The flowers of this kind are generally larger than thoſe of the common ſort, and better-ſcented; but are ſeldom produced ſo early in the ſeaſon. It may be propagated by laying down the tender branches, as was directed for the common white ſort; or by budding or inarching it upon the common yellow jaſmine; the latter of which is preferable, as making the plants hardier than thoſe which are obtained from layers; they ſhould be planted againſt a warm wall, and in very ſevere winters will require to be ſheltered with mats, or ſome other covering, otherwiſe they are ſubject to be deſtroyed. *Miller's Gard. Dict.*

The flowers only are uſed, and that but ſeldom in our ſhops; though Schroder commends them, as good to warm and relax the womb, to heal any ſcirrhi therein, and to facilitate the birth; as well as to be uſeful for a cough, difficulty of breathing, pleuriſy, and pains of the ſtomach, inteſtines, and womb. The oil, made by infuſions of the flowers, is made uſe of in perfumes.

The oil prepared of the flowers diſcuſſes crude humours, and is ſerviceable to thoſe who are ſubject to colds and catarrhs, and uſeful in the winter ſeaſon: in perſons of an hot temperature, it excites the head-ach; and, if long ſmelled to, endangers an hæmorrhage from the noſe. It is principally ſerviceable in contractions and hardneſſes of the limbs; for it heats, mollifies, and relaxes the joints, tendons, and nerves. It cures diſorders of the uterus, not only when applied to the hypogaſtrium and the pudenda, but alſo drank, or adminiſtered in a clyſter. It is no leſs effectual in the cholic proceeding from cold and viſcid humours. The flowers are principally uſed in diapaſms, and perfumes for gloves and linen. *Raii Hiſt. Plant.*

IBE'RIS, *ſciatica-creſs*, in botany, a genus of plants whoſe characters are:

The empalement of the flower conſiſts of four leaves, which are vertically oval: the flower has four leaves, which are unequal, two of them being longer, and ſpread broader, than the other; in the center of the flower is ſituated the pointal, attended by ſix ſtamina, two of which are ſhorter than the other: the pointal afterwards changes to a roundiſh compreſſed pod, having two cells, each containing one oval ſeed.

Theſe plants were commonly ſown to make edgings to large borders in the flower gardens, and are as proper for that purpoſe as any of the low annual plants: but they make a much better appearance when they are ſown in patches, intermixed with the dwarf lychnis, Venus's looking-glaſs, and other low annuals. If the ſeeds of theſe are ſown in the autumn, the plants will grow much ſtronger, and flower earlier in the year, than thoſe which are ſown in the ſpring; but, by ſowing them at different ſeaſons, they will flower at ſo many different times; by which means there will be a ſucceſſion of them in flower until the froſt puts a ſtop to them.

All the culture theſe require, is, to ſow their ſeeds in the places where they are to remain; for they do not bear removing well, unleſs it is done while the plants are young, and taken up with balls of earth to their roots: afterwards, if they are kept clear from weeds, they will thrive and flower very well. All theſe low annual flowers are very proper ornaments for the borders, or vacant ſpaces, between flowering ſhrubs; where, by the different ſorts being blended together, they will add much to the beauty.

ICE-*houſe*, a building deſigned to preſerve Ice, for the uſe of families in the ſummer ſeaſon. Theſe are more generally uſed in warm countries, than with us; particularly in Italy, where the meaneſt perſon, who rents a houſe, is not without his vault or cellar for keeping of Ice.

Ice-houſes being much more uſed with us than formerly, it may not be amiſs to give ſome general directions for the choice of the ſituation, and ſtructure of them, as alſo for the management of the Ice.

The ſituation, then, ſhould be upon a dry ſpot of ground: becauſe, wherever there is moiſture, the Ice will melt; for which reaſon, too much care cannot be taken to make drains all round them. The place ſhould likewiſe be elevated, and as much expoſed to the ſun and air as poſſible.

As to the figure of the building itſelf, the proprietor may chuſe ſuch as pleaſes his own fancy; but a circular form is the beſt for the well where the Ice is to be preſerved, which ſhould be large in proportion to the quantity to be kept.—It is beſt to have as much as may ſerve two or three years, in caſe of a mild winter, when little or no Ice is to be got. At the bottom of the well, there ſhould be a ſpace of about two feet deep left to receive any moiſture which may drain from the Ice, and a ſmall drain under ground ſhould be laid from this to carry off the wet. Over this ſpace of two feet ſhould be placed a ſtrong grate of wood; and the ſides of the well ſhould be built of brick, at leaſt two bricks thick; for, the thicker it is, the leſs danger there will be of the well's being affected by any external cauſe.

When the well is brought up within three feet of the ſurface, there muſt be another outer arch or wall begun, which muſt be carried up to the height of the intended arch of the well; and, if there is another arch turned over from this wall, it will add to the goodneſs of the houſe. The roof muſt be high enough above the inner arch, to admit of a door-way to get out the Ice. If the building is to be covered with ſlates, or tiles, reeds ſhould be placed conſiderably thick under them, to keep out the ſun and external air; the thickneſs of ſix or eight inches, with a plaiſtering of hair and lime, will be ſufficient to prevent all danger.

The external wall need not be built circular, but of what figure the proprietor pleases. Sometimes, the Ice-house is so contrived as to have an handsome alcove seat in its front.

Two feet diameter is sufficient for the aperture of the mouth of the well; which should have a stone, so contrived, as to stop it up in the exactest manner; and all the vacant space, between this aperture and the outer door, should be filled up with barley straw; and this last is to be always shut, before the inner door is opened. The building, thus finished, should have time to dry, before the Ice is put into it.

If a layer of reeds be placed smooth over the grate at the bottom of the well, on which to lay the Ice, it will do better than straw, which is commonly used; and, as to the choice of the Ice, the thinner it is, the easier it may be broken to powder: for, the smaller it is broken, the better it will unite, when put in the well. In putting it in, care must be taken to ram it as close as possible; as also to allow a vacancy of about two inches all round next the side of the well, to give passage to any moisture occasioned by the melting of some of the Ice.

When the Ice is put into the well, if a little salt-petre be mixed with it at every ten inches, or foot thickness, it will cause the Ice to join more closely into a solid mass. *Miller's Gard. Dict.*

ICHNEU'MON, in zoology, the name of an animal, of which there have been a multitude of idle and fabulous things asserted. It is a creature of the weasel kind, with a longer and narrower body than a cat, and something approaching both in shape and colour to the badger. Its nose is black and sharp, like that of a ferret. It has no beard, or whiskers: its nose is prominent, and its ears short and round. Its colour is a yellowish grey, much like that of some of the monkey class. This is its appearance when in a good humour; but, when frighted or provoked, it raises its hairs upright, and shews them variegated at intervals with grey and yellow in distinct portions. Its legs are short, and its feet have all five toes. Its tail is very long, and thick at the insertion; its teeth, and its tongue, like those of the cat. And, what is very singular, is, that in both sexes it has a large aperture situated below the anus, which it dilates and contracts at pleasure. Hence came the old opinion, that both male and female conceived, and brought forth young, in this animal. It is naturally a very cleanly animal, and is very brisk and nimble, and of great courage. It will engage a large dog, and, if it have a quarrel with a cat, will destroy that creature by three bites on the throat. Its nose is so sharp and narrow, that it can very hardly lay hold of any thing large with its teeth, and scarce can bite a man's clenched fist. It is very expert in seizing its prey; it stands erect on its hinder-legs, to descry where it is; then, throwing itself flat on its belly, crawls very slowly towards it, and, when within reach, darts violently upon it. It feeds indifferently on all animals that it can get at. Its common food are the snail, the lizard, the chameleon, such serpents as it can manage, and frogs and mice; it is also very fond of birds, and of none so much as the hen and chicken. *Ray's Syn. Quad.*

ICHNEUMON-*fly*. These flies sometimes are at great pains to destroy and carry the caterpillars, in whose bodies they intend to lay their eggs, to places where it is proper those eggs should be hatched. There is one species whose worm produced from the egg can never succeed, unless it be both bred in the body of a caterpillar, and also have that habitation buried under ground. To this purpose the parent-fly, when the time of her laying her eggs is come, forms a hole in the ground, which she covers with a little clod of earth, that no dust may fall in to fill it up; when this is prepared, she goes out in search of a caterpillar, proper for her purpose. Dr. Lister assures us, that he has often seen one of these flies seize a caterpillar much larger than herself for this intent, and, though this has been at a considerable distance from her hole, she has with great labour dragged the creature to it; as soon as she arrives with this load, she takes off the little pellet of earth from the mouth of the hole, and, going down into it to see that all is right and ready for the reception of the new guest, she returns out of it and draws in the caterpillar, which she leaves there, after giving it such wounds as, though they will not cause immediate death, yet will disable the creature so far as to make an escape impracticable. When the creature is thus lodged, she deposits her eggs in its flesh. And, this great business being done, she stops up the orifice of the hole very firmly with several pellets of dirt, and with dust carefully rammed in between, and will even fly up into gummy and resinous trees to get a cement to hold all firmly together. When the whole is thus filled up, even to the surface of the rest of the ground, she draws a leaf or two to the place, and, laying them over the mouth, flies away. There is after this no more care taken, but the young worms are hatched from the eggs, and feed on the flesh of the caterpillar till they are fully grown. They then change into the nymph state, and come out of that in form of their parent flies, in which state they easily make their way out of the ground. Some of these Ichneumons make the bodies of other smaller flies the places of hatching their eggs. They may be often met with flying with one of these small flies in their legs, the head of it being held close to their bellies. If they be watched on this occasion, they will be found usually to carry these flies to certain holes in the ground resembling worm holes. The first that they carry serves as the nidus for their eggs; the rest are for food for their young while in the state of worms; these being too voracious to be long subsisted on the body of one fly, and therefore their parents carry them more every day. The old ones on this occasion crawl backwards into the hole, dragging in the flies after them. When their young worms have fed sufficiently, they are converted into nymphæ; the cases of which are made up of the wings, legs, and other hard parts of the flies they had been feeding on. *Philos. Transf.* N°. 76.

ICHTHYO'LOGY, the science which treats of fishes.

The general division of fishes is into three classes; the cetaceous, the cartilaginous, and the spinose. The cetaceous fishes are those whose tail is so placed that, when the fish is in its natural posture, it stands parallel to the horizon. The cartilaginous fishes are those whose fins serving for swimming are sustained by cartilages in the place of the bony rays which support them in the other, and which have also cartilages in the whole body, instead of bones. These are the characters of the two first classes; and all those fish which have their fins supported by bony rays, which have their tail placed perpendicularly, not horizontally, and which have bones, not cartilages, in their bodies, are called the spinose fishes.

These are the division of the fish in general among authors.

The cetaceous fishes are arranged together, by the later writers on natural history, under the name of plagiuri. These agree in many things with the land animals, and are distinguished from one another by the same characters which serve for the distinction of the quadrupeds, particularly by the teeth. The general structure of these fishes is alike in all; and their only differences are in the teeth, and the number of fins. From the teeth and fins alone, therefore, are to be properly taken the generical characters of the plagiuri.

The cartilaginous fishes differ from each other only in the form of their body, and in the number of the foramina of the bronchia. For the number of the fins, and figure and position of the teeth, which in the former class make the only characters of generical distinctions, in these are so variable, that they frequently differ in the different species of the same genus. The characters for the distinction of the cartilaginous fishes into genera can therefore only be taken from the shape and foramina. Thus all the rays have flat or depressed bodies, and five foramina at the bronchia. All the petromyzæ have, on the contrary, rounded bodies, and seven foramina at the bronchia. The chonepterus and mola have roundish bodies, and only one foramen or hole for the bronchia; and so of the rest. The several species of the rays, though all properly belonging to the same natural genus, yet differ greatly in their number of fins, and in the shape and disposition of their teeth.

The true characters of these two great classes of fishes, the cetaceous and cartilaginous, are thus easily found; but the characters of the spinose kinds are to be sought for deeper, and do not offer themselves so readily. The multitude of these, and the great likeness between several of the different genera, render it no easy task to distinguish them one from another. Though it be a general rule, that the generical characters of fishes are to be taken from their external parts; yet, in cases where these external parts differ in themselves, in number, figure, and proportion, it is necessary that the primary characters of the genus should be taken from those parts which are the least variable of all others, and which are the most peculiar to the fish under consideration, and the least common to other genera. The utmost care and skill of the ichthyologist is necessary to the distinguishing these characters; and on a strict enquiry he will find, that those parts which seem at first most proper to found distinctions on, are in reality least of all so. The figure of the fins and tail in fish might seem one of the most essential characters for a generical distinction, yet, a farther search into their nature will shew that they can be of no use at all in this sense. Almost all the species of the cyprini, a genus constituted on essential and invariable characters, and a truly natural one, have fins acute at the end, and have forked tails; yet, had these been made characters of the genus, they would have excluded fish that are properly of it. Thus the the tench and the carassius have both obtuse fins, and tails straight or plain, not forked at the end. There are, indeed, many natural genera of fishes, in which the fins and tails are alike in all, as the pearch, the mackarel, the conger. These allow the fins and tail as very good collateral circumstances of the distinction, but even these could not well be distinguished by such marks alone, as they are common to many other genera besides.

IDO'LATRY (*Dict.*)—Dr. Owen divides the whole of idolatrous worship into Sabaism and Hellenism. Dr. Prideaux imagines the planets, as mediators, to be the first objects of Idolatrous worship: though Hellenism consists principally in the worship of dead men and dæmons, yet the Grecians at first adored the sun, moon, and stars, as even Plato owns; for, perceiving all things to run in a continual course, they called them Θεοὶ, Gods, from θέειν, to run. The Greek and Roman idolatry took its rise from that of the Egyptians, Phœnicians, and Syrians. It is a certain maxim, that religion, as well as learning, and mankind itself, had its first original in the East. We shall therefore consider that country first. Tho' the Egyptians were reputed the wisest of the Gentiles, yet they appear, in their religious

religious worſhip of beaſts, to have acted contrary to common ſenſe. It is alledged, the worſhip of brutes was the vail, under which were concealed the myſteries of their religion, as their morals were hid under hieroglyphics. But it is abominable to adore ſheep, cats, bulls, dogs, cows, ſtorks, apes, birds of prey, wolves, and ſeveral ſorts of oxen, as the Egyptians did, under any pretence whatever; the very heathens ridiculed this kind of Idolatry; each province and diſtrict in Egypt entertained a peculiar devotion for ſome beaſt or other. What was ſignified by this monſtrous Egyptian Idolatry is not eaſy to conceive; many fables have been invented to palliate its enormities. This Idolatry had footing in Egypt, in the time of Moſes and the Patriarchs. Thus much for the Egyptian Idolatry. The Phœnicians were among the moſt antient nations and firſt Idolaters; but all the account we have of their theology is in a little fragment preſerved by Euſebius little to be depended on.

It appears that the ſun, moon, and hoſt of heaven were worſhipped by the Jews, when they turned to Idolatry, after the example of neighbouring heathens, without images, by an humble proſtration before them, or their emblems, light or fire: we muſt farther remark, though the Jews were guilty of ſeveral kinds of Idolatry, eſpecially before the Babyloniſh captivity, yet the heathens very unjuſtly charged them with ſeveral acts of Idolatry of which they were innocent.

However, the long abode of the Iſraelites in Egypt left in them a ſtrange propenſity to Idolatry, which neither the miracles of Moſes, nor the rigour of his laws againſt the worſhip of idols, nor the ſplendid marks of God's preſence in the Iſraelitiſh camp, were ſufficient to overcome; they had contracted ſuch an invincible proneneſs to Idolatry, that they not only perſiſted in the worſhip of the Egyptian deities, but adopted moreover every new one which came in their way, as they became acquainted with other nations. Moſes has recorded many inſtances of their Idolatry; but they were guilty of many more, which have been preſerved by other inſpired writers, who ſeverally upbraid them with ſetting up and carrying about the idols of Remphan, Malkom, and many others of the like nature.

Saul and David, with all their authority, were not able to root out Idolatry from among this people; they ſacrificed upon high places, they conſulted divines and magicians. Solomon himſelf, whom God had choſen to build his temple, erected altars to the falſe gods of the Phœnicians, Moabites, and Ammonites, &c. and there were few of the kings his ſucceſſors who did not in this reſpect ſhew alike weakneſs; thus Jeroboam, the ſon of Nebat, king of Iſrael, introduced the worſhip of the golden calves, which took ſo deep root in the kingdom of Iſrael, that it never was intirely extirpated.

Leaving the Eaſtern nations, it is now proper to remove to the Weſt, and conſider the Idolatry of the Greeks and Romans, and other Weſtern nations, before Chriſt. Nothing can be more monſtrous than the Idolatry of the Greeks and Romans, contained in their poets and claſſics in the hands of every child, where we meet with an incredible number of them.

The ancient Britons had abundance of magical rites, and adored a multiplicity of idols. The Germans had the ſame idols as the Britons. For, from the heathen Saxons, the Engliſh learned their Idolatry.

Sozomen, with Origen, and others affirm, that, when our Saviour was carried into Egypt, to avoid the perſecution of Herod, the idols of this country, which were very numerous, and worſhipped to the greateſt degree of ſtupidity and exceſs, were moſt of them ſhaken off their baſis; however, though Idolatry was not perfectly ſuppreſſed, but was ſtill kept on foot in the ſame meaſure even in Rome, this is certain, that it began to be laid aſide after our Saviour's birth; the emperor Theodoſius, jun. deſirous to put a final end to the great work of aboliſhing Idolatry, publiſhed very ſevere edicts, wherein he ordered all things belonging to Idolatry to be deſtroyed throughout the Roman empire. At preſent Idolatry flouriſhes moſt in China.

I'LEX, *the ever-green oak*, in botany, a genus of trees, whoſe characters are:

The leaves are, for the moſt part, indented or ſinuated (and in ſome the edges of the leaves are prickly) and are ever-green; it hath amentaceous flowers, which are produced at remote diſtances from the fruit, on the ſame tree: the fruit is an acorn, like the common oak.

Theſe trees are propagated by ſowing their ſeeds: the beſt ſeaſon for this work is in the beginning of March: but then, as the acorns are ripe in autumn, they ſhould be preſerved either in ſand, or dry earth, until the ſpring, otherwiſe they will loſe their growing faculty; which is commonly the caſe with thoſe brought annually from Genoa, ſcarce one ſeed in fifty of them ever riſing; however, ſince we have many large trees now in England, which produce good ſeeds, we need not ſend to Italy for them: but, were I to adviſe, I ſhould much rather have them from Portugal than Italy; for, the voyage being much ſhorter, they are generally brought from thence in very good condition; eſpecially, if they are brought over in the packet-boat to Plymouth.

The manner in which I would adviſe their being ſown is, for large quantities, in drills at about four feet diſtance; but, for a ſmall parcel, they muſt be ſown in rows on a bed much nearer.

The ground on which theſe ſeeds are ſown, ſhould be well dug, and cleanſed from the roots of all noxious weeds, &c. and leveled even, and the great clods broken; then draw the rills with an hoe in a ſtraight line (as is practiſed in the ſowing of kidney beans) about two inches deep, laying the acorns therein three or four inches aſunder; then draw the earth over them with a head of a rake, obſerving that none of them are left uncovered; which would intice the vermin to attack your acorns, eſpecially the mice, whereby your ſeminary will be greatly injured, if not wholly deſtroyed.

Theſe trees are by many greatly eſteemed for hedges to ſurround wilderneſs quarters; but they are ſubject to grow too large for that purpoſe, becauſe we ſhould never hide the tops of the trees in ſuch places from the ſight; for they are, if rightly diſpoſed in the quarters, vaſtly more agreeable to the eye, than the fineſt ſheared hedge in the world; but they may do well enough for a large fence, to obſtruct the ſight, or to defend a new plantation of tender trees; for which purpoſe the acorns ſhould be ſown in the place where the hedge is deſigned; and, when the plants are come up, they ſhould be thinned, where they are too cloſe; and, if the ground is kept clear from weeds, and, every ſpring, dug about the plants, they will ſoon form a good hedge: but you ſhould obſerve, not to let them grow too much in height before the lower part of the hedge is well ſtrengthened, which would occaſion its bending, and the branches would be ſubject to be diſperſed with ſtrong winds, or great ſnows, and thereby become very unſightly: but, if they are regularly trained up, they will make a good thick hedge from the ground to the height of thirty-feet, and that in leſs time than any other ever-green tree whatever.

The ſoil in which theſe trees thrive beſt, is a hazelly loam, not too ſtrong, nor over light, in which they will grow to a large ſize, and reſiſt the ſevereſt cold of our climate; and, retaining their leaves all the winter, afford an agreeable proſpect in that ſeaſon: but they ſhould by no means be planted near ſuch walks, or other parts of the garden, as are intended to be kept clean; for in the month of April, when they caſt their old leaves, they make a great litter, and are apt to blow about with the wind, and become very troubleſome; and in June, when their male flowers fall off, they occaſion no leſs trouble to clean them up daily in ſuch places; and, in the pleaſanteſt ſeaſon of the year, they are the moſt unſightly trees in a garden, the old leaves decaying at that ſeaſon, and falling off; and the male flowers, which are generally in great plenty, are then produced, which renders it not ſo valuable in places much frequented: but, for larger plantations, at a remote diſtance from the habitation, ſo as to be juſt within the view, they make a very handſome appearance, eſpecially in the winter ſeaſon.

The wood of this tree is accounted very good for many ſorts of tools and utenſils, as mallet-heads, mall-balls, chairs, wedges, beetles, pins, &c. as alſo for palliſadoes; and affords the moſt durable charcoal in the world, and is the common fuel in the ſouthern parts of France and Italy. *Miller's Gard. Dict.*

ILEX *coccigera*, or holm-oak, is of much lower ſtature than the former ſorts, and ſeldom grows to the height of a tree: this, though a native of the warmeſt parts of France, yet will endure the cold of our climate in the open air. It may be propagated in the ſame manner as the former, and deſerves a place amongſt other ſhrubs of low growth, for its curioſity, as being the plant on which the kermes are bred. See *plate* XXV. *fig.* 1. where *a* is fruit, *b* the cup, *c* the kermes, *d* the catkin ſeparate. See KERMES in the Dictionary.

I'LIAC *Paſſion* (*Dict.*) — With reſpect to the Iliac paſſion, we are carefully to remember, that it is highly unſafe to exhibit draſtic purgatives, in order to render the body ſoluble; becauſe they never fail to increaſe the pains, ſpaſms, and all the other ſymptoms; nor is it expedient to uſe clyſters, prepared of exceſſively hot and carminative ſubſtances: much leſs are carminative and ſtomachic eſſences, or medicated wines, to be exhibited internally; ſince, though theſe may prove beneficial in a flatulent cholic, ariſing from a cold cauſe, as the ancients uſed to ſpeak, they are yet by no means to be exhibited, when the diſeaſe is of the acute kind, and all the fluids are in a violent and preternatural motion.

But, when the ſtrength begins to fail, and deliquiums to ſeize the patient, mild analeptics may be ſafely and advantageouſly uſed; ſuch as thoſe, for inſtance, prepared of the waters of black cherries, Turkiſh baum, lilies of the valley, and cinnamon, without wine, or a ſpoonful of generous wine, may be now and then exhibited, with ſingular advantage.

If the patient is plethoric, veneſection is forthwith to be inſtituted, and even repeated, if the caſe requires it. Great regard is, alſo, to be had to the judicious obſervations of the learned Paſcoli, who in Tom. II. uſes the following words: 'When a fever, and the ſigns of an approaching inflammation of the viſcera, are preſent, a vein is to be forthwith opened, rather in the inferior than in the ſuperior parts: hence, we almoſt always obſerve, that leeches, eſpecially when applied to the inteſtinum rectum, have been of ſingular uſe in the cure of an Iliac paſſion; ſince the blood, diſcharged from the hæmorrhoidal vein, relieves the part affected, in the moſt immediate manner of all others'.

When the uſe of quickſilver is indicated as proper and neceſſary, it is previouſly to be depurated, waſhed, and paſſed through leather: when thus prepared, it is not adviſable to exhibit more than

than a pound, or half a pound; which is most commodiously taken in fat broth. Immediately after it is taken, it is expedient the patient should lie for some time on his right side, that it may the more quickly pass through the right orifice of the stomach: besides, if his strength permits, he is to walk, or use gestation, that it may the better reach the inferior parts. But, when the inflammation is already present, and the strength much impaired, we are to abstain from the use of this medicine, lest the by-standers, and such as are not capable of forming a right judgment, should be of opinion, that the patient is destroyed by this remedy, which has the bad fortune to be suspected almost by every one.

In this disorder, great hopes of safety and recovery are justly placed in clysters, provided they are only used at proper times, and in due quantities; for these, when the large intestines are constricted by violent spasms, by relaxing their fibres, and rendering them flaccid, greatly allay the inversion of the peristaltic motion. It is most expedient, if the strength of the patient permits it, to inject a clyster of warm water, mixed with Fernelius's syrup of marshmallows, every two hours, and that during the first day of the disorder, that, by this means, the fæces may be rendered more liquid.

As for topics, I cannot help approving of the caution of Cælius Aurelianus, who advises us to abstain from heavy cataplasms, which, by their weight and roughness, increase the disorder, and the pains with which it is accompanied; for, sometimes, the inflation and distension of the abdomen are so great, that the patient cannot bear it to be moderately touched with the hand.

When the anus, in consequence of the spasmodic strictures, is so braced up, that it cannot admit a clyster-pipe, much less the nose of a pair of bellows, it is then expedient to apply to it a moderately warm fomentation, and, with a small pipe, to attempt the injection of pure tepid oil, that the spasmodically constricted coats of the intestinum rectum, being, by this means, softened, may be, afterwards, capable of receiving a larger quantity of liquor.

When the disease is upon the decline, baths are highly commodious; and may be, also, used in the first days of the disorder, when their propriety is indicated by proper circumstances; for these contribute greatly to the termination of the disease, and the expulsion of the peccant matter, by relaxing the fibres: thus baths were by the methodists, with great success, recommended in the decline of diseases, as we learn from Cælius Aurelianus.

In order to mitigate the pains which are, almost, the only cause of so many violent symptoms, and of the inverted peristaltic motion of the intestines, we are not to be afraid of using opiates, provided they are exhibited in the beginning of the disease, when the strength is as yet intire, a plethora removed, and no signs of a spacelus to be discovered. With respect to the great efficacy of opiates in this disorder, the reader may consult the sentiments of Wedelius, found in the *Miscell. Nat. Curiof. Dec.* 1. *An.* 2. *Obf. Hoffman.*

I'MAN (*Dict.*) — The Mahometans are not perfectly agreed concerning the dignity, and some other circumstances of this office. Some hold the imanate to be settled by divine right, and to be fixed, like the Aaronical priesthood, on one family: others affirm it to be of divine institution, in a qualified sense: but that it is not so unalterably tied to genealogy and descent as to hinder its passing from one family to another; the second party maintaining farther, that the Iman ought not only to be innocent of enormous crimes, such as infidelity, but also to be unblemished in lesser imputations, with which, if his character is sullied, he may be lawfully deposed, and the dignity conferred upon another: but this is denied by those who pass for good Mahometans, who affirm, that, after an Iman has been owned in his character by the mussulmen, it is reckoned downright impiety to deny he is God's immediate vicegerent; and therefore he that refuses to obey him, is reckoned as a rebel, and he that is so hardy as only to contradict him, is reproached as a very ignorant mortal. The Schiites, or the disciples of Ali, though they are not agreed among themselves concerning the person to whom this dignity belongs, yet they all maintain this privilege belongs to the family of Ali, exclusive of all others, and that it ought to be governed by laws of succession and proximity of blood, Ali being sole and apparent heir to Mahomet. This principle of the Schiites makes them not own any person for the head of religion, who cannot prove his descent in a direct line from their first Iman. The Schiites proceed farther, and maintain that the principal point of their religion, upon which all the rest is superstructed, consists in absolute and entire submission to this Iman, and an implicit belief of what he delivers. The Imans belonging to particular mosques are of the nature of our parish priests: they officiate in their public liturgy, in which they pray for the prince, and make a sort of harangue to the people. One of the principal functions of the caliph was to execute the Iman's office every Friday in the chief mosque where he resided; and, when he did not officiate himself, he used to delegate some person of condition.

IMPERATO'RIA, *masterwort*, in botany, a genus of plants whose characters are:

The leaves are not very ramous, but divided into three segments, each of which is divided into three others. The seeds are flat, oval, slightly striated, and marginated.

The roots of masterwort are long, and full of knots or joints, about a finger thick, running obliquely into the ground, shooting out many fibres from the joints, of a strong aromatic smell, and a pretty hot taste; the lower leaves are hardly a span high, somewhat like angelica, but much less, and divided into three segments of roundish leaves, crenated about the edges; the stalks seldom grow above a foot high, with but few leaves on them, and have, on their tops, umbels of small, white, five-leaved flowers, each of which is succeeded by two round, whitish, somewhat flat seeds. It is cultivated with us in gardens, its native place being the Austrian and Stirian mountains, and other Alpine countries, flowering in July.

The roots, which are the only part used, are cordial, sudorific, and alexipharmic, of great use in putrid malignant fevers, and all contagious pestilential distempers; they resist poison, and the bites of venomous creatures. They help pains of the stomach, and the cholic; in all nervine affections, and disorders of the head, they are used with good success. *Miller's Bot. Off.*

The roots are oblong, about an inch thick, wrinkled, and geniculated, brown without, white within, of an aromatic acrid taste, and fragrant smell.

The Historia Plantarum, ascribed to Boerhaave, ascribes the following virtues to these roots: they are attenuating, he says, and aperitive; provoke saliva, if held in the mouth, and are, carthartic, if taken inwardly, whence the root Imperatoria is called the countryman's purge. Taken in a lesser quantity, it proves sudorific and diuretic. In the hysteric and convulsive cholic, and the tympanitis, it often works with such violence as to require correctors, such as levisticum, meum, or some other sweet and viscid root. In intermittent fevers, especially tertians and quartans, it is a specific remedy, as well as in comatous disorders. It has the same aromatic, hot, and igneous taste and smell in every part of it; and whether it be used in infusion or decoction, is inferior to no medicine for speed in giving relief under the effects of poisons of a volatile kind, working by gentle sweat, and, if exhibited in a larger quantity, by stool. It is recommended also in the dropsy, being taken to the weight of an ounce in honey, provided the viscera be found: it is, also, an antiscorbutic. It is highly recommended in cases where any one of the viscera requires to be speedily freed from viscid matter. Baglivi very much recommends it for diseases of the breast, for the pleurisy and peripneumony, in cases where the matter is connected, but the expulsive faculty deficient: for these purposes the root is infused in water, which is afterwards sweetened with honey, and proves an excellent promoter of expectoration, to the relief of the patient from the disease. It is one of the principal ingredients in the same antidotes as angelica: being heating and aperitive, it is effectual for discussing of tumors, where there is no inflammation, or in those of the scorbutic kind. If the root be divided in the middle, you discover a multitude of vesicles full of an oily and balsamic substance, indued with an igneous quality, which renders the root more heating than angelica, and as good a corrector of a fœtid breath. The root is to be taken up in the middle of winter, in its second year. The leaves bruised are good to discuss cold tumors. The distilled oils, as well as the spirits, are carminative and stomachic. The root is justly accounted one of the best antiscorbutics, and, boiled in water, affords an excellent remedy for the gravel in the kidnies, and a stoppage of urine.

I'NCENSE (*Dict.*) — Pure frankincense is what is gathered in autumn, and is much the finest, and of the whitest colour; the ingredients it was made of were pounded severally, and, being mingled, were with great care made ready for divine service, and a quantity of it burnt every day upon the altar of Incense that was placed before the ark. It was intirely set apart for divine worship, and not to be applied to any private use, nor to be touched by any but the priests, and that only when they ministered in the sanctuary before the mercy-seat: if any man presumed to make this composition with the same spices and the same weight, with a design to burn it as a perfume, he was cut off; and it is not impossible but this excision extended not only to the trangressor, but to his whole race, that none of them should remain to keep up his name. Incense was burned every morning when the lamps were dressed, and every evening when they were lighted; and therefore it was called a perpetual Incense, because it was never intermitted twice a day. One reason why it was thus continually burnt, was, because of the vast number of beasts that were slain there and cut to pieces, and washed and burned every day at the sanctuary, which would have made it smell like a shamble, and, consequently, rather have inspired the comers with disgust and aversion than awe and reverence, if this sweet odour had not perfumed it and the garments of the priest. The odour of this Incense, the rabbins say, might be smelt as far as Jericho, and by this means the reverence due to the house of God was preserved, which would have been contemptible, if any ill smell had been constantly about it. *Lewis's Heb. Antiq.*

INDU'LGENCE (*Dict.*)—Clement VI, in his decretal, generally received by the Romish church, declares, that our Saviour has left an infinite treasure of merits and superogatory satisfaction arising from his own sufferings, together with those of the Blessed Virgin and the rest of the saints; and that the pastors and

and guides of the church, and more especially the popes, who are the sovereign disposers of this treasure, have authority given them to apply it to the living by virtue of the keys, and to the dead by way of suffrage, to discharge them from their respective proportions of punishments, by taking as much merit out of this general treasure as they conceive the debt requires, offering it to God almighty. Indulgences themselves, and the abominable abuses committed on their account, are sufficiently exposed by St. Cyprian, Tertullian, and many others. Spanheim gives us this account of the origin of Indulgences, viz. that the primitive church being very rigid in exacting penance for offences, as, first, Πρόσκλαυσις, standing and mourning before the church door. Secondly, Ἀκρόασις, admitting them to hear the word, but not to prayers. Thirdly, Ὑπόπτωσις, or protestation, when they were admitted to the word and some prayers. Fourthly, Σύστασις, when they were admitted to all the prayers, but not to the sacraments; which various steps sometimes took up a penitent's whole life, upon which many were driven to despair, or apostatised to gentilism. Hereupon a temperament was found out to remit the hardness of this canonical penance, which was afterwards abused and degenerated into those now called Indulgences, though they were but of late rise in the church of Rome.

INFLA'MMATORY *Fevers.*--These may be distinguished into two stages; the first, whilst the pulse continues hard, in which it is proper to bleed; and the second, when, the Inflammatory symptoms still remaining, the pulse is too low for that evacuation. In this last state, blisters are the chief remedy, and which, except in a few singular cases, are not to be used sooner. If the blisters are large, it is better to apply them gradually, than many at a time. It is usual to begin with the back, and, if necessary, to apply them next to the legs or thighs, reserving the arms last, that the patient may be so much the longer conveniently moved. In great lowness, attended with a delirium, sinapisms, applied to the soles of the feet, have frequently more efficacy than blisters, in raising the pulse, and relieving the head.

If the body has been costive before the disease, it is proper to open it by a laxative, after bleeding; and, after recovery, some lenient physic is generally requisite, for preventing a too hasty repletion incident to convalescents, upon indulging their appetites. There is no caution more necessary to a young physician, than to abstain from all opiates throughout these fevers, however much the patient may complain of pain or watchfulness. Indeed, if the fever be accompanied with a diarrhœa, which is not critical, the looseness is to be gradually checked by diascordium, after giving rhubarb, and endeavouring to turn the humours to the skin by the use of diaphoretics (omitting the nitre) with the use of the white decoction for common drink. *Pringle's Observ. on the Dis. of the Army.*

INK (*Dict.*)—Writing ink is commonly made of copperas and galls; but other astringent plants may serve the same purpose, such as oak-bark, red-roses, log-wood, or sumach. Mr. Boyle seems to doubt whether all astringent vegetables will do the same. *Boyle's Works abr.* Vol. I.

Filings of iron put into several of the common vegetable juices turn them instantly as black as Ink; and hence it should seem that vitriol only acts in the making Ink as a substance containing iron; which always gives a black colour to an infusion of galls, or the like vegetable substances, and that the more deep, as it is more divided in its particles by acids. According to this rule, all those vitriols which have iron for their basis, and all solutions of iron in vitriolic, sulphureous, or aluminous acids, must make Ink with galls, or a like infusion; and the blue vitriol of Cyprus, and such others as have copper for their basis, must have no such effect on these infusions; and both these deductions are confirmed by experience.

In examining separately the two principles of which the atramentitious vitriols are composed, that is, their vitriolic acid, and their basis of the matter of iron, it appears, that the acid alone, being mixed with an infusion of galls, will never make Ink; whereas the basis alone, that is, filings of iron, will always do it in a little time. Hence it appears, that the acid has no share in the effect, and that the whole is owing to the ferrugineous matter in the vitriol reviving again into iron. The manner in which this revivification of iron is so suddenly performed, on the mixing vitriol and the infusion of galls, seems to be, that this infusion acts as an absorbent on the acid which had before reduced the iron to vitriol, and the ferrugineous particles, being thus freed from the acid by which they were transformed into vitriol, appear again in their native form, and have the same effect upon the infusion that simple or pure iron would have. *Mem. Acad. Par.*

INSCRI'PTION (*Dict.*)—The customary manner of preserving the memory of considerable actions, among the ancients, was monumental remains; at first, they went no farther than erecting pillars or stones, to continue the notice of some memorable event. Thus Jacob, having had a supernatural dream at Bethel, and being assured of God almighty's protection, took the stone which had been his pillow, and set it up for a pillar, and poured oil upon it, as a token of a promise for divine protection; and that, in case of a prosperous return, the stone might put him in mind of the holy place, where he might offer the first of his substance. These stones at first conveyed but little intelligence, excepting what could be guessed by the bulk and situation. It is true, something was hinted at, but nothing explained without the help of memory; for this purpose they cut the stones in figures, gods, men, and battles, with the instructive ornaments of bass relievo, where the history was farther described; they likewise cut letters with names, Inscriptions, laws, and arts. This custom of cutting stones was very ancient among the Phœnicians and Egyptians. The Inscriptions, reported by Herodotus and Diodorus Siculus, shew sufficiently that the first way of instructing people, and transmitting histories and sciences to posterity, was by Inscriptions; and this particularly appears by Plato's dialogue, intitled Hipparchus, wherein he says that the son of Pisistratus, called by the same name, engraved, on stone pillars, precepts useful to husbandmen. Pliny assures us that the first public monuments were made with plates of lead; and the treaties of confederacy between the Romans and the Jews were written upon plates of brass, that, says he, the Jews might have something to put them in mind of the peace and confederacy concluded with the Romans.

Porphyrius mentions Inscriptions kept by the inhabitants of Crete, wherein the ceremonies of the sacrifices of the Corybantes were described. Euhemerus, as Lactantius reports, had written an history of Jupiter and the other gods, collected out of the titles and Inscriptions, which were in the temples, and principally in the temple of Jupiter Triphilianus, where, on the Inscription of a golden column, it was declared, that that pillar was erected by the god himself. Pliny assures us, that the Babylonian astrologers made use of bricks to keep their observations, and hard and solid matters to preserve arts and sciences. This was for a long time practised; for Arimnestus, Pythagoras's son, as Porphyrius relates, dedicated in Juno's temple a plate, whereon were engraved the sciences that were improved by him: Arimnestus, says Malchus, being returned home, fixed in the temple of Juno a brass table, as an offering consecrated by him to posterity; this monument was two cubits diameter, and there were seven sciences writ upon it.

Pythagoras and Plato, according to the opinion of the learned, studied philosophy from the Inscriptions of Egypt, engraven on Mercury's pillars.

Livy tells us, that Hannibal dedicated an altar with a long discourse engraven in the Greek and Punic languages, wherein he described his fortunate atchievements.

INTE'GRANT *Parts*, in philosophy, the similar parts of a body, or parts the same and of the same nature with the whole; as filings of iron are the Integrant parts of iron, and have the same nature and properties with the bar they were filed off from. The chemists distinguish, in their resolutions of bodies, between the dividing or resolving them into Integrant parts like these, and what they call constituent parts, that is, dissimilar parts, or the principles of the bodies they work upon. Thus, when crude mercury is dissolved in aqua fortis, though held imperceptibly in the menstruum, yet, when that menstruum is diluted with water, and a copper-plate is suspended in it, the menstruum leaves the mercury to work upon the copper, and the mercury subsides unaltered and in its own natural form; the mercury, therefore, in this operation, was only divided into its Integrant parts, or small parcels of the same nature and properties of the whole; but, when artificial cinnabar is resolved or divided into crude mercury and sulphur, neither of these are of the same nature and properties with the cinnabar, and are not its Integrant but its constituent parts. This therefore is the dividing a body into its constituent parts or principles. *Shaw's Lectures.*

I'NTERVAL, in music (*Dict.*)—The learned Mr. Euler defines an Interval, the measure of the difference of an acute and grave sound.

Suppose three sounds a, b, c, of which c is the most acute, a the most grave, and b the intermediate sound. From the preceding definition, it appears that the Interval between the sounds a and c is the aggregate of the Intervals between a and b, and between b and c. Therefore, if the Interval between a and b be equal to that between b and c, which happens when $a : b :: c : d$, the Interval between a to c will be double the Interval a to b, or b to c. This being considered, it will appear that Intervals ought to be expressed by the measures of the ratio's, constituting the sounds forming those Intervals: but ratio's are measured by the logarithms of fractions, the numerators of which denote the acute sounds, and the denominators the grave. Hence the Interval between the sounds a and b will be expressed by the logarithm of the fraction $\frac{b}{a}$, which is usually denoted by $l\frac{b}{a}$, or, which comes to the same, $lb - la$. The Interval therefore of equal sounds, a to a, will be null, as $la - la = 0$. The Interval, called an octave or diapason, will be expressed by the logarithm of 2; and the Interval of the fifth, or diapente, will be $l\frac{3}{2} = l3 - l2$. From whence it appears, that these Intervals are incommensurable: so that no Interval, however small, can be an aliquot part, both in the octave and fifth. The like may be said of the Intervals $l\frac{5}{4}$ and $l\frac{6}{5}$, and others whose logarithms are dissimilar. But Intervals expounded by logarithms of numbers, which are powers of the same root,

may

may be compared.—Thus, the Interval of the sounds 27 : 8, will be to the Interval of the sounds 9 : 4, as 3 is to 2: for $l\,\frac{27}{8} = 3\,l\,\frac{3}{2}$, and $l\,\frac{9}{4} = 2\,l\,\frac{3}{2}$.

But, though the logarithms of numbers, which are not powers of the same root, be incommensurable, yet an approximating ratio of such may be found. Thus the measure of the octave is $l\,2 = 0.3010300$, and the measure of the fifth is $l\,3 - l\,2 = 0.1760913$. Hence the Interval of the octave will be to that of the fifth, nearly as 3010300 to 1760913; which ratio, being reduced to smaller terms, will give us these simpler expressions for the ratio of the octave and fifth, 2 : 1, 3 : 2, 5 : 3, 7 : 4, 12 : 7, 17 : 10, 29 : 17, 41 : 24, 53 : 31, which last is very near the truth. *Euler. Tentam. Nov. Theor. Mus.*

INTERVALS, in husbandry, a term used to express the spaces left between the several rows of plants sown or set in a garden or field. The method of horse-hoeing husbandry, so strongly recommended by Mr. Tull, is objected to by many, on account of the largeness of the intervals which are to be left between the rows of corn. These are required to be about five feet wide, and it is thought such wide spaces are so much lost earth, and that the crop is to be so much the less for it. But it is to be observed, that the rows of corn separated by these Intervals need not be single; they may be double, triple, or quadruple, at the pleasure of the farmer; and four rows, thus standing as one, will have the five feet Interval but one fourth of its bigness as to the whole quantity, and it will be but as fifteen such Intervals to plants in single rows. Corn that is sown irregularly in the common way, seems indeed to cover the ground better than that in rows; but this is a mere deceptio visus, for the stalks of corn are never so thick as when they come out of one plant, or as when they stand in rows; and a horse-hoed plant of corn will have twenty or thirty stalks in a piece of ground of the same quantity, where an unhoed plant will have only two or three stalks. If these stalks of the hoed plant were separated and planted over the Intervals, the whole land would be better covered than it is in the common way; and the truth is, that, though these hoed fields seem to contain a much less crop than the common sown fields, they yet, in reality do contain a much greater. It is only the different placing that makes the sown crop seem the larger, and even this is only while both crops are young. *Tull's Horse-hoeing Husbandry.*

INTESTINAL *Fever, febris intestinalis*, in medicine, a name given by Heister to a peculiar species of acute fever passed over in silence by the generality of authors, but by some called the mesenteric fever, and by our Sydenham the new fever, nova febris. This differs from other acute fevers, in that it is attended always with a diarrhœa, which however is salutary, and which it is very dangerous to stop; and in that it is not relieved by the attemperating or diaphoretic medicines useful in other fevers, much less by the hot sudorifics; all these things exasperate and make it worse, and the only things that give relief in it, are gentle cathartics, and vomits that operate without violence. This fever, therefore, evidently shews the error of those hasty reasoners, who declare, that all acute fevers are to be cured by diaphoretics.

This peculiar species of fever, though unknown to many of the late writers, and called by Sydenham a new distemper, was not unknown to the antients. Hippocrates has left many things concerning it, as have also the later Greeks and Celsus: and, among the moderns, Duret, Sennertus, Forestus, Riverius, Etmuller, Baglivi, Stahl, Hoffman, and Lancisci, have all met with it, though they have given but very short and imperfect descriptions of it in their writings.

The generality of those who have written of this fever have referred it to the malignant kinds, from its being usually attended with severe and uncommon symptoms from the beginning, or from such being brought on in the course of an irregular treatment: the common method of curing fevers by diaphoretic medicines bringing on in this anxieties and streightness of the precordia, with pains about the stomach, loss of appetite and deliriums, with efflorescences of various kinds, particularly petechial spots; and these symptoms are not unfrequently attended with death. But it is to be observed, that diseases are to be carefully distinguished in their own symptoms, those which the physician brings on being often very different from what nature would offer.

These fevers have their seat in the stomach and intestines; or, if they have it any where else, it appears at least that their origin, which is in a putrid colluvies, is always much more easily reduced and evacuated by these, than by any other passages. Many of the distempers, mentioned by authors under peculiar names, are properly to be referred, as to their causes, to this species of fever. The dysenteric fever is absolutely of this kind, and many of the petechial ones. The catarrhal fevers also are referable to this kind; and the continual quotidian and tertian, with the fevers described by the antients under the names of hemitritæus, assodes, elodes, epiala, and lipyria, with the tritophyæ nearly allied to the hemitritæi, and by some authors confounded together, the words being used as synonymous.

The method of cure. All hot medicines must be avoided, and the discharge of the peccant matter by the diarrhœa promoted by clysters and by purging medicines. Some advise aloes, and other medicines of that kind; others sena and manna; some the purging salts; but most prefer rhubarb, given in often repeated small doses. Large draughts of the lubricating decoctions, such as barley water and water gruel, are to be given, and emulsions of sweet almonds and of the cold seeds. Small quantities of oil of sweet almonds are also to be given at times, and juleps of the cooling waters and syrups moderately acidulated, and powders of nitre, cinnabar, and the common absorbents, as crabs-eyes and the like, are to be given to take off the pains and spasms, and to attemperate the acrid matter. Bleeding in this fever is not necessary, unless in plethoric habits; and in those cases it must be done on the access of the disease, for, if done after the third or fourth day, it is usually found to do more harm than good.

The diet in these fevers is not to be so very thin and weak, as in other acute fevers; but moderate nourishment is to be allowed, that the patient may hold his strength sufficiently to go through it; in the beginning of the disease however, the patient has usually an aversion for food, and then it is not to be forced upon him; but, when the stomach begins to require it, then it is to be given in a moderate quantity; and great care is to be taken that nothing astringent or difficult of digestion be allowed, but light and innocent meats, and with these a little good wine to promote digestion. Some also have given frequent vomits, by small doses of ipecacunaha, in these fevers, and that with very good success; and it is remarkable, that the purple fever mentioned by Stahl, and others, as particularly affecting lying-in women, and being very frequent in Saxony, for a long time, was by Dr. Wagner, and others, cured by this method: its origin being found to be a viscous matter, putrifying in the stomach and intestines; and therefore the distemper, being properly one of these intestinal fevers, was curable by the same methods with them, that is, by emptying the primæ viæ. *Heister's Compend. Med.*

INTESTINES (*Dict.*)—The intestinal canal, like all other parts of the body, may be seized with a true inflammation, the signs and effects of which are generally these following: a burning, fixed, and pungent pain in the stomach; an exacerbation of this pain, at the very time any thing is taken into the stomach; a painful vomiting immediately after eating or drinking, accompanied with a tormenting hiccup; a violent and perpetual uneasiness about the precordia, and an acute continual fever. The causes of this disorder are either general inflammations, the contiguity of the stomach to the other parts inflamed, or the taking acrid substances into the stomach.

An inflammation of the stomach generally soon proves mortal, unless expeditiously cured, in consequence to the injury done to the important function of this part, and the incredible number of nerves connected with it.

Like other inflammations, it terminates either in health, in suppuratory, scirrhous, cancerous, or gangrenous disorders, or in the sudden death of the patient, accelerated by convulsions.

As soon as the disorder is, from its signs before enumerated, known to be present, we are forthwith, and with the greatest care, to use liberal venefection, which is to be repeated as necessity requires; highly mild, nutritive, emollient, and antiphlogistic liquors, of a quality opposite to the causes of the disorder: as, also, clysters and fomentations of a like nature. But all acrid substances, and especially vomits, are carefully to be abstained from.

A mild and lenitive drink.—Take, of the recent leaves of wood sorrel, three ounces; of the leaves of mallows, an handful and an half; of entire oats, an ounce; boiled with a sufficient quantity of whey; to every twelve ounces of which add two yolks of eggs, and one ounce of the rob of currants.

A clyster.— Take of the recent leaves of endive, succory, fumitory, mallows, and marsh-mallows, each an handful: boil with whey, and, after expressing the decoction, use ten ounces of it for a clyster, twice or thrice a day.

If an inflammation of the stomach terminates in a suppuration, many seemingly misfortunes ensue; but especially a nausea, vomiting, and pain, which, when their cause is unknown, are rarely cured; but, when it is known, they are to be treated in the same manner with abscesses.

When an inflammation of the stomach produces a scirrhus, or a cancer, it then excites excessive vomitings, and intolerable pains, which are heightened and protracted by taking the least thing into the stomach, of a fixed nature, and are generated by all acrid medicines.

By mild and lenient medicines alone, this species of the disorder may be alleviated, but rarely cured. Medicinal waters are, however, in this case, the most efficacious means of relief.

From what has been said above, and under the article LIVER, the origin, nature, effect, knowledge, prognostic, cure, and palliative cure of inflammations, suppurations, gangrenes, scirrhuses, and cancers, of the spleen, pancreas, and omentum, may be deduced.

Inflammations of the INTESTINES.—Not only the stomach, but also the Intestines, especially small ones, are often subject to an acute inflammation in their membranes. This misfortune is is produced by the common cauſes of an inflammation, conveyed to the inteſtines, either, for inſtance, by the acrid matter of liquor drank, of aliments, ſpices and pickles, medicines, or poiſons, taken into the ſtomach, conveyed thence into the Inteſtines, and there retained in their valvulous folds.

This misfortune may, alſo, be produced by an acrid, putrid, fetid, purulent, ichorous, gangrenous, bilious, or atrabilious matter conveyed from the œſophagus, ſtomach, liver, ſpleen, pancreas, and omentum, to the Inteſtines, where it remains and corrodes them. And, laſtly, an inflammation of the Inteſtines may be produced by violent previous convulſions, which create flatulences, ſtop the motion of the fluids, and by that means produce an inflammation.

This diſorder contracts the Inteſtines, cloſes up their cavities, prevents the paſſage of what is conveyed to them, produces highly acute, burning, and fixed pains; excites violent convulſions, when the inflamed part is irritated by the things conveyed to it; renders the patient coſtive, excites a vomiting of the aliments, and of things conveyed to the affected part, ſooner or later, according as the inflammation is near the ſuperior or inferior parts of the Inteſtines; produces painful flatulences, acute gripes accompanied with rumblings, the iliac paſſion, that diſorder called volvulus, an abſceſs, a gangrene, a ſcirrhus, a cancer, a highly acute fever, exceſſive weakneſs, in conſequence of the intenſe pain, and ſudden death.

So long as the diſorder continues in its inflammatory ſtate, it is, by the ignorant and unſkilful, taken for a twiſting of the Inteſtines; and, being, through a dangerous miſtake, aſcribed to cold, flatulences, and wind, is, for that reaſon, treated with hot medicines, a practice which proves fatal to the patient.

But a genuine inflammation of the Inteſtines is known from its concomitant continual acute fever, intenſe thirſt, exceſſive heat, a hard pulſe, a burning pain, high-coloured urine, and the induction of a ſudden weakneſs.

When an inflammation ſeizes the flexure of the colon, the diſorder reſembles the cholic; but, if it ſeizes the extremity of the inteſtinum rectum, it is generally taken for the blind hæmorrhoids; in which caſe, its moſt happy termination is by a mild, bloody, and bilious dyſentery.

As ſoon as an inflammation of the Inteſtines is known to be preſent, from the ſigns before enumerated, we are, in its firſt ſtage, with the greateſt expedition, to attempt its cure; which is to be obtained, firſt, by liberal and repeated venſection, as in a pleuriſy; ſecondly, by the careful injection of laxative, diluting, and antiphlogiſtic clyſters, repeated three, four, or more times a day; thirdly, by the frequent drinking of liquors of a laxative, diluting, and antiphlogiſtic nature, with a prudent addition of opium, and ſuch things as are oppoſite to the particular known cauſe of the diſorder; fourthly, by fomentations prepared of ſubſtances of like qualities applied to the whole abdomen, and eſpecially fomentations conſiſting of young, vigorous, and ſound animals; fifthly, by carefully abſtaining from all kinds of drink, aliments, or medicines which are of an acrid, hot nature, or capable of increaſing the impetus of the fluids; as, alſo, by avoiding exerciſe, and the exorbitancies of the paſſions: and, ſixthly, by perſiſting in the uſe of theſe things, till the intire diſorder is removed, and does not return in three days.

If this diſeaſe is not cured by proper remedies, and continues to rage with violence longer than three days, the pain, heat, and diſtraction, are ſucceeded by a ſhivering through the whole body, without any apparent cauſe, and by an obtuſe pain, with a ſenſation of weight in the part affected; theſe are ſigns, that the abſceſs is forming in it: within fourteen days after, the abſceſs breaking, the pus will be diſcharged: if this pus is diſcharged into the cavities of the abdomen, it produces many diſorders ſimilar to thoſe ariſing from the diſcharge of pus from the liver, and mentioned under the article LIVER: but, if this pus is diſcharged into the cavities of the Inteſtines, it produces a purulent dyſentery, ſmall or great, ſhort or long, according to the nature of the ulcer formed. In this caſe, intire membranes of the Inteſtines are frequently diſcharged, and a conſumption is often brought on.

As ſoon as an inflammation of the Inteſtines is known to be preſent, all ſuch aliments are carefully to be abſtained from, as are capable of generating a large quantity of hard and thick fæces: the patient is only to be nouriſhed with broths boiled with gently detergent roots; balſamic detergent decoctions are to be copiouſly drank, and injected by way of clyſters; or medicinal waters are to be copiouſly drank, and their uſe perſiſted in till a perfect cure is brought about.

The following aliment ſhould be uſed in this diſorder:—Take, of the roots of viper's graſs, goat's beard, ſkirret, parſley, and ſuccory, each two ounces: boil in fleſh broth, and, with every thirty ounces of the broth, mix two yolks of eggs, and a ſufficient quantity of ſalt.

The following decoction will be alſo of great ſervice:

Take, of the roots of garden valerian, two ounces; of the leaves of lovage, two handfuls; of the flowers of St. John's wort, one handful, and of the flowers of agrimony, two ounces: boil with two pints of water; of which let the patient drink two ounces every hour. This decoction is alſo to be uſed as a clyſter.

INVOLU'CRUM, among botaniſts, expreſſes that ſort of cup which ſurrounds a number of flowers together, every one of which, has, beſide this general cup, its own particular perianthium. The Involucrum conſiſts of a multitude of little leaves diſpoſed in a radiated manner. See the article CALYX.

JOINT, in anatomy; ſee ARTICULATION, in the Dictionary.

Pains in the JOINTS.—Thoſe pains of the Joints, which are accompanied with inflammation and tumor, have an affinity with the gout. The proper method of curing them is by bleeding, bliſtering the parts affected, and, unleſs the fever runs high, by purging. If there be no fever, or but a ſlight one, a mixture of equal parts of gum guaiacum and cinnabar of antimony will produce a very good medicine, both to open the body and correct the acrimony of the tumors. It ſhould be given ſo as to procure two ſtools at leaſt every day.

Of all theſe pains, the moſt ſevere is that which the Greeks name *ἰσχιάς* (and we corruptly ſciatica) becauſe it ſeizeth the hips; and it is attended with the greater difficulty, becauſe it is moſt commonly the conſequence of chronical diſeaſes, by the morbid matter being thrown on this part. This diſeaſe, when grown inveterate, weakens the thigh and leg, and makes the patient lame; and ſometimes alſo the head of the thigh-bone ſlips out of the ſocket, and then the thigh ſoon waſtes away.

In this diſeaſe little is to be expected from cupping or bliſtering the part: for the acrid humour lies too deep fixed in the membrane ſurrounding the bone, to be drawn out by theſe means. More efficacious is the volatile epithem, or a plaiſter compoſed of Burgundy pitch, with about an eighth part of euphorbium, and a ſufficient quantity of Venice turpentine. But nothing gives ſo much relief, in an obſtinate caſe eſpecially, as a ſeton paſſed below the part affected, in order to give vent to the morbid humour. But, if this operation be thought too cruel and troubleſome for the neceſſity of it, it will be of uſe to make an iſſue with a cauſtic in the inſide of the thigh above the knee; which muſt be kept open till the diſorder is quite removed. Hippocrates adviſes to apply the actual cautery in three or four places upon the hip. And indeed no remedy would be more efficacious than this, if patients could be reconciled to it: for, how terrifying ſoever the ſight of red-hot iron may appear, the pain from the application of it would be much ſooner over, than that which is raiſed by the common cauſtics.

The fleſh-bruſh ought likewiſe to be uſed ſeveral times every day, in order to facilitate the digeſtion and diſſipation of the concreted humour; and more eſpecially on the very hips, if practicable. But fomenting the part affected with warm water is generally prejudicial: becauſe this brings on a relaxation of the fibres, whereby the pain is increaſed.

I now paſs to internal remedies, the chief of which are bleeding and purging. Of cathartics, the moſt efficacious are dulcified mercury ſix times ſublimed, and the electuary of ſcammony; either of which muſt be often repeated, according to the patient's ſtrength. And, in the intermediate days of purging, the proper medicines are ſuch as are diuretic and laxative at the ſame time. Of this claſs I give the preference to the volatile tincture of gum guaiacum, or the balſam of guaiacum. *Mead's Monita & Præcepta.*

JOINT *cartilage, or articulating cartilage.* An articulating cartilage is an elaſtic ſubſtance, uniformly compact, of a white colour and ſomewhat diaphanous, having a ſmooth poliſhed ſurface covered with a membrane, harder and more brittle than a ligament, but ſofter and more pliable than a bone. *Phil. Tranſ.* N°. 469.

IO PÆ'AN, among the ancients, an exclamation uſed on account of a victory, or ſome proſperous event. Hoffman thinks that Io Pæan is a contraction of the Hebrew Jao, from Jehovah, and פקד, reſpexit; and was the ſame with Jehovah penoch, i. e. Dominus reſpiciat in nos. Something like this exclamation ſtill remains among the Symerones, a people of the Weſt-Indies, who, on any joyful occaſion, frequently cry out Yo Peho. *Hoff. Lex. in voc.*

IO'TA, a letter in the Greek alphabet, which derives its name from the jod of the Hebrew, or rather of the joda of the Chaldeans. Our Saviour mentions it, by ſaying, there ſhould not be an Iota, or tittle in the law, but ſhould be accompliſhed: ſo that whatever was foretold by Moſes, and the prophets, ſhould be exactly fulfilled; meaning nothing ſhould be wanting, becauſe Iota was the ſmalleſt letter in the Greek alphabet, as jod is in the Hebrew: they both ſtand for 10, in numbering.

JOU'I. This is an alimentary and reſtorative liquor, prepared in Japan, and capable of being preſerved ten or a dozen years. It is fluid like broth, aqueous, black, of an agreeable ſmell, and good taſte, ſalt, and ſavoury. With reſpect to the manner of preparing it, no more is known, than that it is made of the gravy of beef, expreſſed when half roaſted: the Japoneſe keep the reſt a ſecret, and ſell it very dear. This liquor is very rare in Europe: ſome, however, is imported either on account of curioſity or luxury. It is thought to be a reſtorative after diſeaſes, and, on this account, is eſteemed greatly all over the Eaſt.

I'RIS (*Dict.*)—Mr. Sharp gives the following account of an operation

operation upon this membrane, which he calls cutting the Iris.

There are two cafes, fays he, where this operation may be of fome fervice; one, when the cataract is from its adhefion immoveable; and the other when the pupil of the eye is totally clofed up by a diforder of the mufcular fibres of the Iris, which, gradually contracting the orifice, at laft leaves the membrane quite imperforate. This laft diftemper has hitherto been deemed incurable. The adhefion of the cataract I have confidered as a fpecies of blindnefs not to be relieved: but Mr. Chefleden has invented a method of making an artificial pupil, by flitting the Iris, which may relieve in both the inftances here ftated.

In performing this operation, the patient muft be placed as for couching, and the eye kept open, and fixed by the fpeculum oculis, which is abfolutely neceffary here, for the very reafon I would difcard it in the other, fince the flaccidity of the membrane from the iffue of the aqueous humour would take away its proper refiftance to the knife, and make it, inftead of being cut through, tear from the ligamentum ciliare; then, introducing the knife in the fame part of the conjunctiva you wound in couching, infinuate it, with its blade held horizontally, and the back of it towards you, between the ligamentum ciliare and the circumference of the Iris, into the anterior chamber of the eye; and, after it is advanced into the farther fide of it, make your incifion quite through the membrane; and, if the operation fucceeds, it will, upon wounding, fly open, and appear a large orifice, though not fo wide as it becomes afterwards.

The place to be opened in the Iris will be according to the nature of the difeafe: if the membrane itfelf be only affected with a contraction, the middle part of it, which is the natural fituation of the pupil, muft be cut; but, if there be a cataract, the incifion muft be made above or below the cataract, though I think it more eligible to make it above.

The contracted Iris, from a paralytic diforder, is fo often complicated with an affection of the retina, that the fuccefs is very precarious in this cafe. This operation, by what I have feen, has anfwered beft in adhefions of the cryftalline humour; though, to fpeak truly, but very feldom even there. As I would not miflead any one in an operation not yet much known in the world, I do confefs, that either the danger of the Iris feparating from the ligamentum ciliare, or of the wound not inlarging fufficiently, do, upon the whole, make the event very doubtful. I once performed it with tolerable good fuccefs, but, a few months after, the very orifice I had made, contracted, and brought on blindnefs again.

I have not here once ufed the word uvea, but have made mention of the ligamentum ciliare; both which parts are little underftood, for want of proper explanation; but which muft be rightly conceived of, in order to underftand what has been faid.

The generality of anatomifts call that membrane, which I have fpoke of under the name of Iris, the uvea, and its anterior lamina, the Iris: others, again, call the membrane uvea; and the colour of it, Iris: but both one and the other diftinction confound learners exceedingly, and take their rife from a want of proper attention to the hiftory of anatomy. The antients, who have given moft of the names we now employ in the defcription of the eye, were verfed principally, if not altogether, in the diffection of brutes; among which, thofe of the graminivorous kind have a party-coloured choroides, one half of it being dark, and the other of a light fhining green: this laft, from its refemblance to an unripe grape, was called the uvea; but the fucceeding writers, among the moderns, applying themfelves to human diffections only, and not duly confidering the difference of the human choroides, which is nearly of an uniform colour, and of that above defcribed, have retained the appellation, though we have not the thing. Hence has arofe the great variety of mifapplications of this word, which ought no more to be fpoke of in the anatomy of the human eye, than the tunica nictitans, which is proper to certain beafts and birds.

The ligamentum ciliare is that circular line on the globe of the eye, where the fclerotis, choroides, retina, cornea, proceffus ciliares, and Iris, terminate and unite together, forming a whitifh ring fomewhat denfer than any other part of the coats; but, fince the inftitution of this term, the defcription of the part it implies has been very much neglected, and the term itfelf confounded with the proceffus ciliares: wherefore it was neceffary to define it, that the procefs of the operation of the Iris might be better underftood. *Sharp's Surgery.*

IRIS, in botany, a genus of plants, whofe characters, according to Tournefort, are thefe: the flower is liliaceous, confifting of one leaf, and being of a tubular fhape at the bottom: hence it is expanded and enlarged, and forms fix parts, three of which point upwards, and three downwards. The piftil arifes from the bottom of the flower, and is furnifhed with three petals, which are arched, and fo bent down upon the reflex leaves of the flower, that they refemble a fort of palate: the flower cup finally becomes an oblong fruit, which opens into three parts at the end, and is feen to be divided into three cells, which contain roundifh and fometimes flattifh feeds. To this it is to be added, that the root is flefhy, oblong, and of the creeping kind, and not covered with coats.

We have a great many fpecies of this plant preferved in gardens, and moft of them very beautiful: their roots are tuberous, and increafe very faft, and all the fpecies are eafily propagated by parting them. The beft feafon for doing which is in Auguft, when their flower leaves are decayed, and the whole plant begins to change colour; but this fhould always be done when the weather is moift, fo that, if the month of Auguft fhould prove very dry, it fhould be deferred till September, though it is beft to do it fooner, if it can be. They all love a fhady and moift place. If too much dung is ufed to the ground, it rots their roots; and, if they ftand expofed to the fun, their flowers are but of very fhort duration. They fhould be taken up once in two years, to prevent their extending their roots too far; for they are very apt to fpread, and to harbour all forts of vermin.

The curious may raife their feveral fpecies from their feeds, which if taken from the choiceft flowers, and cultivated with care, ufually afford a fine variety in the flowers of the plants thus produced: they fhould be fown, foon after they are ripe, on an eaft border; they will come up in fpring, and the year following will flower. *Miller's Gard. Dict.*

IRON (*Dict.*)— Iron may be produced from its ore in a clofe veffel, in the following manner: roaft, for a few minutes, in a teft, placed under a muffel in a pretty ftrong fire, two centners of iron ore grofly powdered, that the volatile particles may be in part diffipated, and the ore foftened, in cafe it be too hard. When it is grown cold, beat it to a very fine powder, and roaft it a fecond time in a ftronger fire till it emits no fmell; then take it out of the fire.

Compofe a flux of the parts of the common white flux, and one part of powdered glafs; and add of fandiver and coal-duft of each one half part. Add of this flux three times the quantity of the roafted ore, and mix the whole very well together; then take a good crucible well luted within, and put into it the ore mixed with flux; cover it with common falt, and fhut it clofe with a tile, and with the lute applied to the joints. Put the common wind furnace upon its bottom part, having a bed made of coal-duft; introduce into the furnace a fmall grate fupported on its Iron bars, and a ftone upon it whereon the crucible may ftand; furround the whole with hard coals, not very large, and light them at top. Make the fire very ftrong, and continue to add frefh fuel, that the veffel may never be naked at top. When the fire has thus been continued in its full ftrength for an hour, take out the veffel, and ftrike on the floor where it ftands, to collect all the particles of Iron into a body; and, when cold, break the veffel, and you will find the pure Iron. *Cramer's Art of Affaying.*

Several attempts have been made to run Iron ore with pit coal, but we meet with no account of the fuccefs of fuch attempts: however, Mr. Mafon informs us, that, at Colebrook-Dale in Shropfhire, Mr. Ford makes iron brittle or tough as he pleafes, from Iron ore and coal, both got in the fame dale; there being cannon, thus caft, fo foft as to bear turning like wrought Iron. *Phil. Tranf.* N°. 482.

For the method of cafting Iron; fee FORGE.

IRON *furnaces.*— Thefe furnaces, as they are employed in running the moft difficult of all metals, fo they are, of all others, contrived the largeft, and capable of carrying heat to the greateft degree. When they are to be ufed, they are firft filled up to the top with coals; and, the lower part being lighted, the top, and all other parts of the furnace where the air could have paffage, are clofed firmly up with Iron-plates laid one over another. The confequence of this is, that the fire is put out, and the whole is kept in this ftate ten or twelve days. At the end of this time the furnace is opened, and the coals are found all black, without a fingle fpark of fire in any part, yet extremely hot, and reduced to a tenth part of their quantity. When the furnace has been thus opened about a quarter of an hour, the matter begins to take fire of itfelf by the mere contact of the air. The firft appearance of this is very remarkable; there arifes a very bright flame from fome of the coals, which plays about their furface, and fpreads itfelf from one to another, without the appearance of the leaft fpark of fire in any part of any of the coals. The ore of the Iron is, for the firft day, put only in the middle of the furnace, and that but in fmall quantity; the next day more, and every day afterwards more and more is put on, and by degrees it is fpread over the whole furface of the furnace to the edges. This is the method of working the ore to the utmoft advantage, and with the moft difpatch. The whole procefs for one furnace of ore is finifhed in about eight days from the time of opening the top; all the ufe of the firft quantity of coal is only thoroughly to warm the fides and walls of the furnace; and it is, after this, to be kept carefully fupplied with fuel, and the ore only out toward the fides, as the extreme heat, moft fenfibly in the center, increafes. If too much be laid on of the ore at firft, there is always a lofs from the quantity of metal. The quantity of the coals, neceffary to any given quantity of the ore, differs in proportion to the advantageous or faulty ftructure of the furnace. In the very beft conftructed ones, the weight of the coals and of the ore need be no more than

than equal. The flame which makes its way out of the bottom of the furnace, is of different colours, according to the natures of the ore and of the coals; ſometimes red, ſometimes yellow, and ſometimes green. That which iſſues out from the top of the furnace is of a red colour, and aſcends in a ſort of ſpiral line, reſembling the ſound of diſtant falls of waters, as it mounts up. With all the care that can be taken to heat the ſides of the furnace, and to keep them hot, the middle is always greatly the hotteſt, and the ore ſooneſt runs into metal there. *Swedenberg. de Ferro & Igni.*

IRON *works.* See FORGE.

IRREDU'CIBLE *caſe*, in algebra, is uſed for that caſe of cubic equations where the root, according to Cardan's rules, appears under an impoſſible or imaginary form, and yet is real. Thus, in the equation, $x^3 - 90x - 100 = 0$, the root, according to Cardan's rule, will be $x = \sqrt[3]{50 + \sqrt{-24500}} + \sqrt[3]{50 - \sqrt{-24500}}$, which is an impoſſible expreſſion, and yet one root is equal to 10; and the other two roots of the equation are alſo real. Algebraiſts, for two centuries, have in vain endeavoured to reſolve this caſe, and bring it under a real form; and the queſtion is not leſs famous among them, than the ſquaring of the circle is among geometers.

It is to be obſerved, that, as in ſome other caſes of cubic equations, the value of the root, though rational, is found under an irrational or ſurd form; becauſe the root in this caſe is compounded of two equal ſurds with contrary ſigns, which deſtroy each other; as, if $x = 5 + \sqrt{5} + 5 - \sqrt{5}$, then $x = 10$; in like manner, in the Irreducible caſe, when the root is rational, there are two equal imaginary quantities, with contrary ſigns, joined to real quantities; ſo that the imaginary quantities deſtroy each other. Thus the expreſſion: $\sqrt[3]{50 + \sqrt{-24500}} = 5 + \sqrt{-5}$; and $\sqrt[3]{50 - \sqrt{-24500}} = 5 - \sqrt{-5}$. But $5 + \sqrt{-5} + 5 - \sqrt{-5} = 10 = x$, the root of the propoſed equation.

Dr. Wallis ſeems to have intended to ſhew, that there is no caſe of cubic equations Irreducible, or impracticable, as he calls it, notwithſtanding the common opinion to the contrary.

Thus, in the equation, $r^3 - 63r = 162$, where the value of the root, according to Cardan's rule, is, $r = \sqrt[3]{81 + \sqrt{-2700}} + \sqrt[3]{81 - \sqrt{-2700}}$, the doctor ſays, that the cubic root of $81 + \sqrt{-2700}$ may be extracted by another impoſſible binomial, viz. by $\frac{9}{2} + \frac{1}{2}\sqrt{-3}$; and in the ſame manner, that the cubic root of $81 - \sqrt{-2700}$ may be extracted, and is equal to $\frac{9}{2} - \frac{1}{2}\sqrt{-3}$; from whence he infers, that $\frac{9}{2} + \frac{1}{2}\sqrt{-3} + \frac{9}{2} - \frac{1}{2}\sqrt{-3} = 9$ is one of the roots of the equation propoſed. And this is true: but thoſe who will conſult his Algebra, p. 190, 191, will find that the rule he gives is nothing but a trial, both in determining that part of the root which is without a radical ſign, and that part which is within: and if the original equation had been ſuch as to have its roots irrational, his trial would never have ſucceeded. Beſides, it is certain, that the extracting the cube root of $81 + \sqrt{-2700}$ is of the ſame degree of difficulty, as the extracting the root of the original equation $r^3 - 63r = 162$; and that both require the triſection of an angle for a perfect ſolution. *See M. de Moivre in the Appendix to Saunderſon's Algebra.*

ISA'TIS, *woad*, in botany, a genus of plants, whoſe characters are:

The flower conſiſts of four leaves, which are diſpoſed in form of a croſs; out of whoſe flower-cup riſes the pointal, which afterward turns to a fruit in the ſhape of a tongue, flat at the edges, gaping two ways, having but one cell; in which is contained, for the moſt part, one oblong ſeed.

Woad is commonly ſown upon a lay, which they plow into high ridges, except the land be very dry; and they harrow the turf till they break it to pieces, and pick out all the graſs, weeds, and lumps of earth, and fling them into the furrows to rot.

The land for this ſeed ought to be finely plowed and harrowed, and all the clods and turfs broken, and the ſtones picked up, and carried off.

The beſt time for ſowing it is the latter end of July, ſoon after the ſeed is ripe; which will come up in Auguſt, and muſt be hoed out, as is practiſed for turneps, leaving the plants ten or twelve inches aſunder; by which means they will grow ſtrong, and produce much larger leaves; and beſides, that ſown at this ſeaſon doth ſeldom miſcarry; whereas that which is ſown in the ſpring will be very liable thereto; and if it doth not, the plant will not have half the ſtrength the firſt ſummer.

It ought to be kept conſtantly weeded; but if it come up good, it will need the leſs weeding: the ordinary price of weeding is eight ſhillings per acre.

Some recommend the ſowing of it about the beginning of February; for which they give this reaſon, that whereas it is apt to be ſpoiled by the fly and grub, it eſcapes the better being early ſown; and if they do kill any of it, they have the better opportunity of ſowing more.

They do this by making holes with a ſtick about ſeven or eight inches aſunder, and put five or ſix ſeeds into each hole. They ſeldom or never ſow it more than two years upon the ſame piece of land; becauſe, if it be long continued, it robs the ſoil: but if it be moderately uſed, it prepares land for corn; and where the ſoil is rank, it abates the too great fertility of it.

It is ripe, when the leaf is come to its full growth, and retains its perfect colour and lively greenneſs; which is ſometimes ſooner, and ſometimes later, as the year proves dry or moiſt.

As ſoon as it is fit to cut, it ſhould be done with all the ſpeed that poſſibly may be, that it may not fade, or grow pale; and when it is cut, it ought to be immediately carried to the mill. The manner of doing which, and the way of ordering it, is beſt learned from experienced workmen, and is not to be truſted to a verbal deſcription of it.

In plowing it up, and ſowing it again, they pick up all the old roots, as they harrow it, except what they deſign for ſeed, which they let ſtand to the next year: it many times produces fifty quarters upon an acre.

They always keep a good quantity of ſeed by them, to plant the ground that fails: the ſeed of two years will ſometimes grow; but as it is apt to fail, it is better to ſow that of the firſt. And if they ſow or plant it late, if the ground be dry and hard, they ſteep it in water the day before they ſow it, which cauſes it to come up the ſooner.

Good woad may yield five or ſix crops in a plentiful year; though it ordinarily yields but four, ſometimes but three; eſpecially if it be let ſtand to grow for ſeed: but what grows in winter they do not uſe, though it is very good and very cheap. The two firſt crops are the beſt, which are uſually mixed in the ſeaſoning. The latter crops are much the worſe; which, if mixed with either of the former crops, ſpoil the whole.

It many times ſells from ſix pounds to thirty pounds a ton, an acre commonly yielding about a ton. *Miller's Gard. Dict.*

ISCHNA'MBLUCIS *, in natural hiſtory, the name of a genus of foſſils of the claſs of the ſelenitæ, but one of thoſe which are of a columnar form, not of the common rhomboidal one.

* The word is derived from the Greek, ἰσχνὸς, thin, ἀμβλὺς, blunt or obtuſe, and κίων, a column; and expreſſes a body in form of a thin or flatted column, with obtuſe ends.

The characters of this genus are: that the bodies of it are of a flatted columnar form, and octohedral in figure, conſiſting of ſix long planes, and two abrupt or broken ends; the whole being of a flatted figure. The top and bottom planes are much broader than the reſt; the four other planes, called the ſides, are narrower than theſe, but are uſually of very near the ſame breadth with one another, as are alſo theſe tops and bottoms, ſo that the whole figure comes very near an hexaedral priſm. *Hill's Hiſt. of Foſſ.*

I'SIA, feaſts and ſacrifices antiently ſolemnized in honour of the goddeſs Iſis. The Iſia were full of abominable impurities; and for that reaſon, thoſe who were initiated were obliged to take an oath of ſecrecy. They held for nine days ſucceſſively, but were ſo abominable, that the ſenate aboliſhed them at Rome, under the conſulate of Piſo and Gabinius. Two hundred years after, they were re-eſtabliſhed by the emperor Commodus, who himſelf aſſiſted at them. *Dict. Trevoux.*

I'SLAND *Cryſtal*, a body famous among the writers on optics for its property of a double refraction; but very improperly called by that name, as it has none of the diſtinguiſhing characters of cryſtal, and is plainly a body of another claſs. Dr. Hill has reduced it to its proper claſs, and determined it to be of a genus of ſpars, which he has called, from their figure, parallelopipedia, and of which he has deſcribed ſeveral ſpecies, all of which, as well as ſome other bodies of a different genus, have the ſame properties. Bartholine, Huygens, and Sir Iſaac Newton, have deſcribed the body at large, but have accounted it either a cryſtal or a talc; errors which could not have happened, had the criterions of foſſils been at that time fixed; ſince Sir Iſaac Newton has recorded its property of making an ebullition with aqua-fortis, which alone muſt prove that it is neither talc nor cryſtal, both bodies being wholly unaffected by that menſtruum.

It is always found in form of an oblique parallellopiped, with ſix ſides, and is found of various ſizes, from a quarter of an inch to three inches or more in diameter. It is pellucid, and not much leſs bright than the pureſt cryſtal, and its planes are all tolerably ſmooth, though, when nicely viewed, they are found to be waved with crooked lines made by the edges of imperfect plates. What appears very ſingular in the ſtructure of this body is, that all the ſurfaces are placed in the ſame manner, and conſequently it will ſplit off into thin plates, either horizontally or perpendicularly; but this is found, on a microſcopic examination, to be owing to the regularity of figure, ſmoothneſs of ſurface, and nice joining of the ſeveral ſmall parallellopiped concretions, of which the whole is compoſed; and to the ſame cauſe is probably owing its remarkable property in refraction. *Hill's Hiſt. of Foſſ.*

ISOPERIME'TRICAL (*Dict.*)—Iſoperimetrical lines and figures have greatly engaged the attention of mathematicians, ſince the invention of fluxions. The analyſis of the general problem concerning figures, that all thoſe of the ſame perimeter

perimeter produce maxima and minima, was given by Mr. James Bernouilli, from computations that involve second and third fluxions. And several inquiries of this nature have been since prosecuted in like manner, but not always with equal success. Mr. Mac Laurin, to vindicate the doctrine of fluxions from the imputation of uncertainty, or obscurity, has illustrated this subject, which is commonly considered as one of the most abstruse parts of this doctrine, by giving the resolution and composition of these problems by first fluxions only; and in a manner that suggests a synthetic demonstration, serving to verify the solution.

ISO'RA, *the screw-tree*, in botany, a genus of trees, whose characters are:

It hath a spreading anomalous flower, consisting of one or many leaves, divided into several parts, and appearing like two lips: from the bottom of the flower arises the pointal, whose apex afterwards becomes a twisted fruit, consisting of many cells, which are intorted like a screw; in which are contained several almost kidney-shaped seeds.

The name Isora, which father Plumier has given to this genus, is the Indian name for the plant; but by the English inhabitants of America, it is called screw-tree, from the form of the fruit, which is twisted like a screw.

JU'GLANS, *the walnut*, in botany, a genus of trees, whose characters are:

It hath male flowers or catkins, which are produced at remote distances from the fruit on the same tree: the female flowers grow two or three together, close to the branches: these are divided into four acute segments: the pointal is situated in the bottom of the empalement, which turns to a large nut covered with a thick green coat: the nut is deeply furrowed, and divided in the middle, containing a kernel having four lobes, which is covered with a thin skin.

This genus of plants has been universally intitled nux juglans, till Dr. Linnæus altered it to this of Juglans, the other being a compound name.

All the sorts of walnuts which are propagated for timber, should be sown in the places where they are to remain; for these trees always incline downwards; which, being stopped or broken, prevent their aspiring upward; so that they afterwards divaricate into branches, and become low spreading trees: but such as are propagated for fruit, are greatly mended by transplanting; for hereby they are rendered more fruitful, and their fruit are generally larger and fairer; it being a common observation, that downright roots greatly encourage the luxuriant growth of timber in all sorts of trees; but such trees as have their roots spreading near the surface of the ground, are always the most fruitful.

The nuts should be preserved in their outer covers in dry sand until February; when they should be planted in lines, at the distance you intend them to remain; but in the rows they may be placed pretty close, for fear the nuts should miscarry; and the young trees, where they are too thick, may be removed, after they have grown three or four years, leaving the remainder at the distance where they are to stand.

In transplanting these trees, you should always observe never to prune either their roots or branches, both which are very injurious to them; nor should you be too busy in lopping or pruning the branches of these trees; for it often causes them to decay: but when there is a necessity of cutting any of their branches off, it should be done early in September, that the wound may heal over before the cold increases; and the branches should always be cut off quite close to the trunk, otherwise the stump which is left will decay, and rot the body of the tree.

The best season for transplanting these trees is as soon as the leaves begin to decay; at which time, if they are carefully taken up, and their branches preserved intire, there will be little danger of their succeeding, although they are eight or ten years old, as I have several times experienced.

This tree delights in a firm rich loamy soil, or such as is inclinable to chalk or marl; and will thrive very well in stony ground, and on chalky hills, as may be seen by those large plantations near Leatherhead, Godstone, and Carshalton in Surry, where are great numbers of these trees planted upon the downs; which annually produce large quantities of fruit, to the great advantage of their owners; one of which, I have been told, farms the fruit of his trees, to those who supply the markets, for thirty pounds per annum.

The distance these trees should be placed, ought not to be less than forty feet, especially if regard be had to their fruit; though, when they are really designed for timber, if they stand near, it promotes their upright growth. The black Virginian walnut is much more inclinable to grow upright than the common sort; and the wood, being generally of a more beautiful grain, renders it preferable to that, and better worth cultivating. I have seen some of this wood, which hath been beautifully veined with black and white; which, when polished, has appeared at a distance like veined marble. This wood is greatly esteemed by the cabinet-makers for inlaying, as also for bedsteads, stools, tables, and cabinets; and is one of the most durable woods for those purposes yet known, it being rarely infected with insects of any kind, which may proceed from its extraordinary bitterness: but it is not proper for buildings of strength, it being of a most brittle nature, and exceeding subject to break very short, though it commonly gives notice thereof, by its cracking some time before it breaks.

The general opinion, that the beating of this fruit improves the trees, I do not believe, since, in the doing of this, the younger branches are generally broken and destroyed: but as it would be exceeding troublesome to gather it by hand, so in beating it off, great care should be taken that it be not done with violence, for the reason before assigned. In order to preserve the fruit, it should remain upon the trees till it is thorough ripe; when it should be beaten down, and laid in heaps for two or three days; after which they should be spread abroad, when, in a little time, their husks will easily part from the shells: then you must dry them well in the sun, and lay them up in a dry place, where mice or other vermin cannot come to them: in which place they will remain good for four or five months: but there are some persons who put their walnuts into an oven, gently heated, where they let them remain four or five hours to dry; and then they put them up in oil jars, or any other close vessel, mixing them with dry sand; by which method they will keep good six months. The putting of them in the oven is, to dry the germ, and prevent their sprouting: but, if the oven is too hot, it will cause them to shrink; therefore, great care must be had to that. *Miller's Gard. Dict.*

Concrete JUICES, in minerology, a name given by many authors to such substances found in the bowels of the earth, as have once been in a state of fluidity, and are capable of being rendered fluid again by art, by means of heat, moisture, or other common agents.

Others apply the word concrete to all those substances which may be separated from fluids by chemical operations, whether they are afterwards soluble in them again or not; such are the principles of spar separated from water by a slow distillation, and remaining at the bottom of the vessel.

Mineral JUICES.— Many countries afford these, and give marks by them of treasures that might be turned to great account, were the proper manner of assaying them known; which is, by first properly reducing them to a dry substance, so as to come at the solid matter they contain. With a view to the discovery of metallic veins, the erection of salt works, vitriol works, allum works, borax works, and the like, the curious on this subject may find many excellent hints for further discoveries in the close of Agricola's work, De re metallica; and the view is farther carried on by Boyle, Becher, Stahl, and Homberg. The Royal Academy of Paris have also given some hints that may be of use, in their Memoirs; and some practical things are recorded in the Philosophical Transactions.

I'VORY (*Dict.*)—A green dye may be given to Ivory by steeping it in aqua-fortis tinged with copper or verdigrease.

And by converting the aqua-fortis into aqua-regia, by dissolving a fourth part of its weight of sal ammoniac in it, ivory may be stained of a fine purple colour. *Boyle's Works abr.*

JUSTI'CIARY *court*, in Scotland. The court of Justiciary, has supreme jurisdiction in all criminal causes. It came in place of that of justice eyre, or justice general, which was last in the person of the earl of Argyle, who transacted for it with king Charles the First, and was made justice general of all the islands; which raising great debates between him and some hereditary sheriffs there, the jurisdiction was taken away in 1672, and this court of Justiciary erected instead of it, consisting of a justice general, alterable at the king's pleasure; a justice clerk, and five other judges, who are likewise lords of the session.

This court commonly sits on Mondays, and has an ordinary clerk, who has his commission from the justice clerk. They have four ordinary macers and a doomster, appointed by the lords of the session.

JUSTS, a combat on horseback, man against man, armed with lances. Antiently justs and tournaments made a part of the entertainment at all solemn feasts and rejoicings. The Spaniards borrowed these exercises from the Moors, and call them the cane plays. This is the same with the ludus Trojanus, antiently practised by the youth. The Turks use it still, and call it lancing the gerid. The difference between justs and tournaments consists in this, that the latter is the genus, of which the former is the species. Tournaments were all kinds of military races and engagements, made out of gallantry and diversion. Justs were such particular combats, where parties were near each other, and engaged with lance and sword: the tournaments were frequently performed by a number of chevaliers, who fought in a body. The Justs was a single combat of one man against another; though the Justs were usually made in a tournament, after the general re-encounter of all the cavaliers, yet they were sometimes single and independent of any tournament. He who appeared for the first time at a Just, forfeited his helmet or casque, unless he had forfeited before at a tournament.—The word is derived from the Latin, *juxta*, near, because combatants fought near one another: some derive it from *justa*, which, in the corrupt age of the Latin tongue, was used for this exercise; this being supposed a more just and equal combat than the tournament.

K.

KA'BIN, or Kebin, a kind of marriage permitted in Turkey and Persia, by which a man may take a wife for a certain term of time; having entered his promise, before a cadi, of giving the woman such a sum of money at his leaving her; for Kabin, in the Turkish language, signifies a dowry: some historians tells us, that this half marriage is only allowed among the Persians that are of the sect of Hali, and that it is condemned by the Turks; but it is very common with some nations of the negroes. *Ricaut. Pietro Della Valle, Tome* III.

KA'MAN, in natural history, a name given by many authors to a stone found about the burning mountains, and at some times used to engrave seals on. It is described as a white stone variegated with several colours.

KA'OLIN, the name of one of the two substances, which are the ingredients of China-ware. The other, which is called petuntse, is easily vitrifiable, and this Kaolin is scarce at all so. Whence the fire composes, from a mixture of them both, a semivitrification, which is China ware.

Mr. Reaumur had an opportunity of examining this substance, not in its native state, but only in form of small bricks, made out of a paste of the powder of the native Kaolin and water. He found it of a white colour, and sprinkled all over with fine glittering particles; but these he did not judge to be fragments of a different substance mixed among the mass, as are the small flakes of talc in our clays and sands; but that the whole mass was composed of some stone reduced to powder and made into a paste with water, and that these larger spangles were only coarser particles of the powder; the examination of which he promised himself would discover what the stone was of which they were formed. And this was the more worthy a diligent enquiry, since the petuntse might easily be supplied by many of our own earths and sands; nothing being required of that but a substance easily running into a white glass. But the difficulty of vitrifying this other ingredient renders it a thing much more difficult to be supplied by one of the same nature among ourselves. The comparison of these with other mineral substances soon proved that they were of the nature of talc; or, in other words, that Kaolin was talc powdered, and made up into a paste with water. And, to be assured whether the whole mass was talc powdered, or any thing else with a mixture of talc, he separated the particles of the Kaolin by water, and found the small ones wholly the same with the larger, and that the larger, when reduced to powder alone, made with water a paste wholly the same with the Kaolin. It is well known, that the fragments of talc have a great resemblance to the pearly part of some shell fishes; and hence unquestionably has arisen the opinion of porcelain being made of sea-shells; ignorant persons having seen the talc or Kaolin, and taken it for shelly matter. Talc has not yet been successfully used in any of our European manufactures of porcelain; but it is easy to see, from many unanswerable reasons, that, since China porcelain is made of a mixture of a vitrifiable and an unvitrifiable matter, nothing is so likely to succeed with us, in the place of the last of these, as talc.

1. We know no substance in the fossil world so difficult to reduce to glass as talc, which, if put into the strongest of our fires, in a crucible, is not to be vitrified, nor even calcined. 2. We know no substance which keeps so much brightness after having passed the fire as talc, or is of so pure a white; whence we may also learn that it is not to the petuntse alone, that the China ware owes its whiteness, but that the Kaolin is instrumental to the giving it that colour. 3. Talc is transparent, nay, and in some degree keeps its transparence after the action of the most violent fire. If we are to make porcelain of a vitrifiable and an unvitrifiable matter mixed together, yet it is necessary that the unvitrifiable matter should retain its transparence, otherwise it would obscure the mass; and talc is therefore the only known substance qualified for this purpose. Persons who have been at the China works, say, that the porcelain is made of equal quantities of petuntse and Kaolin, and it is therefore a just and exact semi-vitrification. 4. Talc is well known to have a great flexibility and toughness, and, as it is found to preserve this even after it has passed the fire, it is very probable, that it is owing to this property of the Kaolin, that the China ware is so much less brittle than glass. *Mem. Acad. Par.*

KE'RMES *Mineral.* The Kermes mineral was a preparation of Glauber, which the king of France bought of Mr. de la Ligerie, and made public in 1720. That receipt was in the following form: take a pound of Hungarian antimony, broken into thin pieces, according to the direction of its spicula; four ounces of nitre, fixed by charcoal; and a pint of rain water: boil them two hours: then filtre the warm liquor, and, when it cools, the Kermes precipitates. The same antimony undergoes the same operations with the remaining liquor, to which three ounces of fixed nitre, and a pint of water, are added. In a third boiling, two ounces of nitre, and a pint of water, are to be added to the former lixivium. The Kermes thus obtained is about a drachm, which after being well edulcorated by washing it in water, and burning spirit of wine on it, is dried for use.

Mr. Geoffroy shews, by many experiments, that the Kermes is the reguline part of the antimony, joined to a sort of hepar sulphuris. He teaches us a much easier way of preparing this medicine, thus: mix intimately the fine powder of two parts of antimony, and one of any fixed alkaline salt; melt those materials in a crucible; then, having powdered them while hot, boil them two hours in a large quantity of water; after this, pass the hot liquor through paper, receiving it into a vessel, in which there is hot water; the Kermes separates, when it cools. The grosser parts, which do not pass through the paper, are to be boiled again, and filtrated again; and the operation is to be repeated a third time, by which six or seven drachms of Kermes may be got out of every ounce of antimony. He says, he has seen effects, like to those of mild Kermes from antimony, reduced to such a fine powder, that none of the shining spicula are to be seen; and that the magistery of antimony, made by pouring spirit of nitre, or aqua regia, on the powder of antimony, and then edulcorating the mass with water, has the same effects as Kermes. *Mem. de la Acad. des Sciences.*

Half a grain, or a grain, of this powder, given every three or four hours, produces no violent effects; but, by increasing the dose, it may be made to vomit, purge, and sweat. Some commend this medicine as the most universal resolvent and deobstruent; assuring us, that it almost infallibly cures pleurisies, peripneumonies, asthmas, catarrhs, anginæ, small-pox, and many other diseases. Others are as positive, that it heats and thickens the blood, thereby increasing obstructions, and is particularly hurtful in all inflammatory diseases.

This preparation was famous in France, and known by the name of poudre des Chartereux, because a Carthusian monk, who got it from Mr. de la Ligerie, first brought it into vogue. See *Hist. de l' Acad. des Sciences* 1720, and the Memoirs for the same year, where it is said that Glauber was looked upon as the first inventor of this remedy.

Its effect, like that of many other antimonial preparations, is very various, which is frequently owing, as Mr. Geoffroy observes, to the different manner and care of making it. He adds, that, the more the Kermes contains of a regulus easily revivified, the more it proves emetic. He also shews how to make a cinnabar with Kermes and mercury, and to disengage the vitriolic acid from the Kermes. *See Mem. de l' Acad. des Sciences* 1734.

KERN, in the English salt-works, a word used to signify the crystallizing, or shooting of salt in the brine, when sufficiently evaporated in the boiling pan. The word is also used by the seamen for the first forming of the bay salt, made by the sun's heat in the isle of May.

KETTLE-*Drums*, are formed of two large basons of copper or brass, rounded at the bottom, and covered over with vellum or goat skin, which is kept fast by a circle of iron, and several holes fastened to the body of the drum, and a like number of skrews to skrew up and down, with a key for that purpose. The two drums are kept fast together by two straps of leather, which go through two rings, and are fastened, the one before, the other behind the pommel of the Kettle-drummer's saddle. They have each a banner of silk or damask, richly embroidered with the sovereign's arms, or those of the colonel, and are fringed with silver or gold; and, to preserve

preserve

preserve them in bad weather, they have each a cover of leather. The drum-sticks are of crab-tree or other hard wood, of eight or nine inches long, with two knobs on the ends, which beat the drum-head, and cause the sound. The Kettle-drum with trumpets is the most martial sound of any; each regiment of horse has a pair.

KING *of sacrifices*, a Roman magistrate, who had the disposing of all that was necessary for the sacrifices they offered to their deities, and the solemnities of their festivals: he was set up, after the expulsion of their kings, because there were certain sacrifices, wherein it was customary for the king himself to officiate, that there might be somebody to represent the royal character: however, to preserve their liberty, he had the administration of nothing but what appertained to religion, and even in that the pontifex maximus was above him.

KIRK-*Sessions*, the name of a petty ecclesiastical judicatory in Scotland. Each parish, according to its extent, is divided into several particular districts, every one of which has its own elder and deacon to oversee. A consistory of the ministers, elders, and deacons, forms a Kirk-sessions. This meets once a week, the minister being moderator, but without a negative voice: it regulates matters relating to public worship, elections, catechising, visitations, &c. It judges in matters of less scandal; but greater, as adultery, are left to the presbytery; and, in all cases, appeal lies from it to the presbytery.

KITCHEN-*Garden*, a garden appropriated to herbs and plants used at the table.

The Kitchen-garden should always be situated on the side of the house, so as not to appear in sight, but must be placed near the stables, for the conveniency of dung; which ought always to be considered in the disposition of the buildings, and the laying out of the garden: for, if this garden be placed at a great distance from the stables, the labour will be very great in wheeling the dung; and such expences should ever be avoided, if possible.

As to the figure of the ground, that is of no great moment, since in the distribution of the quarters all irregularities may be hid; though, if you are at full liberty, an exact square, or an oblong, is preferable to any other figure.

The great thing to be considered is, to make choice of a good soil, not too wet, nor over-dry, but of a middling quality; nor should it be too strong or stubborn, but of a pliable nature, and easy to work: and, if the place where you intend to make the Kitchen-garden should not be level, but high in one part, and low in another, I would by no means advise the levelling it; for by this situation you will have an advantage which could not be obtained on a perfect level, which is, the having one part of dry ground for early crops, and the low part for late crops, whereby the Kitchen may be the better supplied throughout the season with the various sorts of herbs, roots, &c. And in very dry seasons, when in the upper part of the garden the crops will greatly suffer with drought, then the lower part will succeed, and so vice versa; but I would by no means direct the chusing a very low moist spot of ground for this purpose; for, although in such soils garden-herbs are commonly more vigorous and large in the summer season, yet they are seldom so well tasted or wholesome as those which grow upon a moderate soil: and especially, since in this garden your choice fruits should be planted, it would be wrong to have a very wet soil. This garden should be fully exposed to the sun, and by no means overshadowed with trees, buildings, &c. which are very injurious to your Kitchen-plants and fruit-trees; but, if it be defended from the North wind by a distant plantation, it will greatly preserve your early crops in the spring; as also from the strong South-west winds, which are very hurtful in autumn to fruit and garden-herbs.

The quantity of ground necessary for a Kitchen-garden must be proportioned to the largeness of the family, or the quantity of herbs desired: for a small family, one acre of ground may be sufficient; but, for a large family, there should not be less than three or four acres; because, when the ground is regularly laid out, and planted with espaliers of fruit-trees, as will hereafter be directed, this quantity will be found little enough, notwithstanding what some persons have said on this head.

This ground must be walled round; and, if it can be conveniently contrived, so as to plant both sides of the walls, which have good aspects, it will be a great addition to the quantity of wall-fruit: and those slips of ground, which are withoutside of the walls, will be very useful for planting of gooseberries, currants, strawberries, and some sorts of Kitchen-plants; so that they may be rendered equally useful with any of the quarters within the walls: but these slips should not be too narrow, lest the hedge or pale which incloses them should shade the borders where the fruit-trees stand: the least width of these slips should be twenty feet; but, if they are double that, it will be yet better, and the slips will be more useful; and the fruit-trees will have a larger scope of good ground, for their roots to run. These walls should be built about twelve feet high, which will be sufficient height for any sort of fruit.

If the soil where you intend to place your Kitchen-garden be very strong, then you should plow or dig it three or four times, before you plant any thing therein; and, if you throw it up in ridges, to receive the frost in winter, it will be of great service to meliorate and loosen its parts.

The manure which is most proper for such soils, is sea-coal ashes, and the cleansing of streets and ditches, which will render it light much sooner than any other dung or manure; and, the greater quantity of ashes, the better, especially if the ground be cold; and, where these ashes are not to be obtained in plenty, sea-sand is very proper, or rotten wood, or the parts of vegetables rotted are very good: all which will greatly loosen the soil, and cause it to be not only easier to work, but also more advantageous for the growth of plants.

But, on the contrary, if your soil be light and warm, you should manure it with rotten neats-dung, which is much preferable to any other, for hot soils; but, if you use horse-dung, it must be well rotted, otherwise it will burn up the crops, upon the first hot dry weather.

The soil of this garden should be at least two feet deep; but, if deeper, it will be still better, otherwise there will not be depth enough for many sorts of esculent roots, as carrots, parsneps, beets, &c. which run down pretty deep in the ground, and most other sorts of esculent plants delight in a deep soil: and many plants, whose roots appear short, yet if their fibres, by which they receive their nourishment, are traced, they will be found to extend to a considerable depth in the ground; so that, when these are stopped by meeting with gravel, chalk, clay, &c. the plants will soon shew it, by their colour and stinted growth.

You should also endeavour to have a supply of water in the different parts of the garden, which, if possible, should be contained in large basons or reservoirs, where it may be exposed to the open air and sun, that it may be softened thereby; for such water as is taken out of wells, &c. just as it is used, is by no means proper for any sort of plants.

In the distribution of this garden, after having built the walls, you should lay out banks or borders under them, which should be at least eight or ten feet broad, whereby the roots of the fruit-trees will have greater liberty than in such places where the borders are not above three or four feet wide; and upon these banks you may sow many sorts of early crops, if exposed to the south; and upon those exposed to the north you may have some late crops: but I would by no means advise the planting any sort of deep-rooting plants too near the fruit-trees; especially pease and beans; though, for the advantage of the walls, to preserve them in winter, and to bring them forward in the spring, the gardeners in general are too apt to make use of those borders, which are by the best aspected walls, to the great prejudice of their fruit-trees; but for these purposes it is much better to have some reed-hedges fixed in some of the warmest quarters, under which you should sow and plant early pease, beans, &c. where they will thrive as well as if planted under a wall; and hereby your fruit-trees will be entirely freed from such troublesome plants.

Then you should proceed to dividing the ground out into quarters, which must be proportioned to the largeness of the garden; but I would advise, never to make them too small, whereby your ground will be lost in walks; and, the quarters being inclosed by espaliers of fruit-trees, the plants therein will draw up slender, and never arrive to half the size as they would in a more open exposure.

The walks of this garden should be also proportioned to the size of the ground, which in a small garden should be six feet, but in a large one ten; and on each side of the walk should be allowed a border three or four feet wide between the espalier and the walk, whereby the distance between the espaliers will be greater, and the borders, being kept constantly worked and manured, will be of great advantage to the roots of the trees; and in these borders may be sown some small sallad, or any other herbs, which do not continue long, or root deep; so that the ground will not be lost.

The breadth of these middle walks, which I have here assigned them, may by many persons be thought too great; but my reason for this is to allow proper room between the espaliers, that they may not shade each other, or their roots interfere, and rob each other of their nourishment; but, where the walks are not required of this breadth, it is only inlarging of the borders on each side, and so reducing the walks to the breadth desired.

But the walks of these gardens should not be gravelled; for, as there will constantly be occasion to wheel manure, water, &c. upon them, they would soon be defaced, and rendered unsightly; nor should they be laid with turf, for, in green walks, when they are wheeled upon, or much trodden, the turf is soon destroyed; and those places, where they are much used, become very unsightly also: therefore the best walks for a Kitchen-garden are those which are laid with a binding sand; but, where the soil is strong, and apt to detain the wet, there should be some narrow under-ground drains made by the side of the walks, to convey off the wet; otherwise there will be no using the walks in bad weather: and, where the ground is wet, if some lime-rubbish, flints, chalk, or any such material as can be procured with the least expence, is laid at the bottom of these walks, and the coat of sand laid over it, the sand will be kept drier, and the walks will be found in all seasons: these sand-walks are by much the easiest kept of any; for,

for, when either weeds or moſs begin to grow, it is but ſcuffling them over with a Dutch hoe in dry weather, and raking them over a day or two after, and they will be as clean as when firſt laid.

The beſt figure for the quarters to be diſpoſed into is a ſquare, or an oblong, where the ground is adapted to ſuch a figure; otherwiſe they may be triangular, or of any other ſhape, which will be moſt advantageous to the ground.

When the garden is laid out in the ſhape intended, if the ſoil is ſtrong, and ſubject to detain the moiſture, or is naturally wet, there ſhould always be under-ground drains made, to convey off the wet from every quarter of the garden: for otherwiſe moſt ſort of Kitchen-plants will ſuffer greatly by moiſture in winter: and, if the roots of the fruit-trees get into the wet, they will never produce good fruit; ſo that there cannot be too much care taken to let off all ſuperfluous moiſture from the Kitchen-garden.

Theſe quarters ſhould be conſtantly kept clear from weeds; and, when any part of the ground is unoccupied, it ſhould always be trenched up into ridges, that it may ſweeten, and imbibe the nitrous particles of the air, which is of great advantage to all ſorts of land; and the ground will then be ready to lay down, whenever it is wanted.

The ground in theſe quarters ſhould not be ſown or planted with the ſame crop two years together: but the crops ſhould be annually changed, whereby they will prove much better than when they conſtantly grow upon the ſame ſpot. Indeed, the Kitchen-gardeners near London, where land is dear, are often obliged to put the ſame crop upon the ground for two or three years together; but then they dig and manure their land ſo well every year, as to render it almoſt new: though, notwithſtanding all this, it is conſtantly obſerved, that freſh land always produces the beſt crops.

In one of theſe quarters, which is ſituated neareſt to the ſtables, and beſt defended from the cold winds; or, if either of the ſlips without the garden-wall, which is well expoſed to the ſun, lies convenient, and is of a proper width; that ſhould be preferred, for a place to make hot-beds for early cucumbers, melons, &c. The reaſons for my giving the preference to one of theſe ſlips, are, firſt, there will be no dirt or litter carried over the walks of the Kitchen-garden in winter and ſpring, when the weather is generally wet; ſo that the walks will be rendered unſightly: ſecondly, the view of the hot-beds will be excluded from ſight: and, laſtly, the convenience of carrying the dung into theſe ſlips; for, by making of a gate in the hedge or pale, wide enough for a ſmall cart to enter, it may be done with much leſs trouble than that of barrowing it through the garden: and, where there can be a ſlip long enough to contain a ſufficient number of beds for two or three years, it will be of great uſe, becauſe by the ſhifting of the beds annually, they will ſucceed much better than when they are continued for a number of years on the ſame ſpot of ground. As it will be abſolutely neceſſary to fence this melon-ground with a reed-hedge, it may be ſo contrived as to move away in panels; and then that hedge which was on the upper ſide the firſt year, being carried down to a proper diſtance below that which was the lower hedge, and which may remain, there will be no occaſion to remove more than one of the croſs-hedges in a year; therefore, I am perſuaded, whoever will make trial of this method, will find it the moſt eligible. *Miller's Gard. Dict.*

KNEE.—The mucilaginous glands of the Knee, which lie near the edges of the patella, are very remarkable: they are diſpoſed in fringes, and ſupported by a great quantity of fatty matter, which in ſome meaſure makes one maſs with them. This common maſs is contained within the capſular ligament, and on the ſide of the joint is covered by a very fine membrane, which likewiſe lines the inner ſurface of the ligament. The glandulous ſubſtance is eaſily diſtinguiſhed from the fat by the reddiſh colour of the capillary veſſels, which ſurround the glands. The ſuperior portion of this maſs is, as it were, ſupported by a ſmall ligament, fixed in the anterior part of the great common notch of the condyles of the os femoris, and which from thence runs from the upper part of the patella. There are alſo other mucilaginous glands, both above and below the edges of the ſemilunar cartilages, and likewiſe in the ham: ſome of theſe ſerve for a joint, and the others for the crucial ligaments. Theſe laſt lie in folds, formed by the internal membrane of the capſular ligament, which give particular coverings to the crucial ligaments, and to the other bundles of ligamentary fibres near them. *Winſlow's Anatomy.*

Luxated KNEE. A luxation of the Knee is a receding of the tibia from under the femur. The leg is ſometimes thus luxated from the baſis of the thigh-bone, on the outſide, ſometimes on the inſide, and ſometimes backward, but very rarely or never forwards, unleſs it be forcibly driven with great violence that way; for the patella is bound againſt the articulation forwards, by the ſtrong tendons of the muſcles which extend the leg; nor is it indeed eaſy for the bones of the leg to be wholly diſplaced from that of the thigh, ſo as to make a perfect luxation of the Knee, by reaſon of the great ſtrength of the ligament, and the two deep ſinuſes, which receive the head of the thigh-bone, unleſs thoſe ſtrong ligaments ſhould happen to be broken aſunder at the ſame time. This is the reaſon alſo why people, who ſuffer a perfect luxation of the Knee, are generally tortured with violent and excruciating pains and convulſions; and, if they eſcape the miſchiefs uſually attending ſuch ſymptoms, they are generally troubled afterwards with a lameneſs and ſtiffneſs of the joint; but ſlight or imperfect luxations of this joint are uſually very ſpeedily and eaſily cured. The patient in this caſe is to be ſeated on a bed, bench, or table, and one aſſiſtant is to hold the thigh firmly above the Knee, and another ſtrongly to extend the leg, while the ſurgeon replaces the bones by his hands and Knee, in their natural places. If the hands and ſlings are not ſufficient, in this caſe, to make a proper extenſion, recourſe muſt be had to the pullies, generally uſed on ſuch occaſions; but, in children and young perſons, great care muſt be taken not to make the extenſion ſo violent, as to ſeparate the epiphyſes from the bones, to which they are, in ſuch ſubjects, not yet firmly united. After the luxation is properly reduced, the Knee is to be bound up with a proper bandage, and placed in a frame or caſe, ſo as to be kept at reſt for a proper time. *Heiſter's Surgery.*

L.

LA'BYRINTH, in gardening, a winding, mazy, and intricate turning to and fro, through a wilderness, or a wood.

The design of a Labyrinth is, to cause an intricate and difficult labour to find out the center; and the aim is, to make the walks so intricate, that a person may lose himself in them, and meet with as great a number of stops and disappointments as is possible, they being the most valuable that are most intricate.

As to the contrivance of them, it will not be possible to give directions in words; there are several plans and designs in books of gardening: they are rarely met with but in great and noble gardens, as Hampton-Court, &c.

There are two ways of making them; the first is with single hedges: this method has been practised in England. These, indeed, may be best, where there is but a small spot of ground to be allowed for the making them; but, where there is ground enough, the double are most eligible.

Double ones, or those that are made with double hedges of a considerable thickness of wood between hedge and hedge, are approved as much better than single ones; as is the manner of making them in France, and other places; of all which, that of Versailles is allowed by all to be the noblest of its kind in the world.

It is an error in Labyrinths in making them too narrow, for by that means the hedges must be kept close clipped: whereas, if the walks be made wider, according to the foreign practice, they will not stand in need of it.

The walks are made with gravel, usually set with hornbeams: the palisades ought to be ten, twelve, or fourteen feet high: the hornbeam should be kept cut, and the walks rolled. *Miller's Gard. Dict.*

LACE'RNA, the name of a garment worn by the ancients, being a kind of cloke made of wool, only used by the men. They wore it over the toga or tunica; it was at first very short, but, growing popular in the Roman army, was soon lengthened. The Lacerna was scarce known in Rome till the time of the civil wars and the triumvirate; then indeed it came into fashion; for, the soldiers being frequently in the city-gates, the sight became familiar to the citizens, and they fell into the use of it; so that it became a common dress of the knights and senators, but Valentinian and Theodosius prohibited the senators wearing it in the city. Some will have this garment the same with the chlamys.

LACTU'CA, *lettuce*, in botany, a genus of plants whose characters are:

It hath a fibrose root, which is, for the most part, annual: the leaves are smooth, and grow alternately upon the branches; the stalks are, for the most part, slender and stiff, and commonly terminate into a sort of umbel: the cup of the flower is oblong, slender, and scaly: the seeds are oblong, depressed, and generally terminate in a point.

It would be beside my purpose to mention in this place the several sorts of lettuce that are to be found in botanic writers, many of which are plants of no use, and are never cultivated but in botanic gardens for variety; and some of them are found wild in many parts of England. I shall therefore pass over those here, and only mention the several sorts which are cultivated in the kitchen-garden for use: 1. Common or garden lettuce. 2. Cabbage lettuce. 3. Cilicia lettuce. 4. Dutch brown lettuce. 5. Aleppo lettuce. 6. Imperial lettuce. 7. Green capuchin lettuce. 8. Versailles or upright white cos lettuce. 9. Black cos. 10. White cos. 11. Red capuchin lettuce. 12. Roman lettuce. 13. Prince lettuce. 14. Royal lettuce. 15. Egyptian cos lettuce.

The first of these sorts is commonly sown very early for cutting, to mix with other small sallad-herbs, and is only different from the second sort, in being a degeneracy therefrom; or, otherwise, the second is an improvement by frequent cultivation from the first: for, if the seeds are saved from such plants of the second sort as did not cabbage closely, the plants produced from that seed will all degenerate to the first sort; which is by the gardeners called lapped lettuce, to distinguish it from the other, which they call cabbage lettuce. The seeds of the first, which are commonly saved from any of the plants, without having any regard to their goodness, are generally sold at a very cheap rate, especially in dry seasons, when these plants always produce the greatest quantity of seeds; though sometimes this seed is sold in the seed shops, and by persons who make a trade of selling seeds, for the cabbage lettuce; which is often the occasion of people's being disappointed in their crop: so that this sort should never be cultivated, but to be cut up very young; for which purpose this is the only good sort, and may be sown any time of the year; observing only in hot weather to sow it on shady borders, and in the spring and autumn upon warm borders; but in winter it should be sown under glasses, otherwise it is subject to be destroyed by severe frosts.

The cabbage lettuce may also be sown at different times of the year, in order to have a continuation of it through the whole season. The first crop is generally sown in February; which should be upon an open warm spot of ground, and, when the plants are come up, they should be thinned out, to the distance of ten inches each way; which may be done by hoeing them out, as is practised for turneps, carrots, onions, &c. provided you have no occasion for the superfluous plants; otherwise they may be drawn up, and transplanted into another spot of good ground at the same distance; which if done before the plants are too large, they will succeed very well, though they will not be so large as those which were left upon the spot where they were sown; but they will come somewhat later, which will be of service, where people do not sow every month.

The Cilicia, imperial, royal, black, white, and upright cos lettuces may be sown at the following times: the first season for sowing these seeds is at the end of February, or the beginning of March, upon a warm light soil, and an open situation; i. e. not overshadowed with trees; and, when the plants are come up, they should be either hoed out, or transplanted into another spot of ground, as was directed for the cabbage lettuce, observing to leave these sorts fifteen or sixteen inches apart each way; which will be full near enough for these plants, especially if the soil be good; and you must carefully keep them clear from weeds, which is the only culture they will require, except the black cos lettuce, which should be tied up when they are full grown, to whiten their inner leaves, and render them crisp; otherwise they are seldom good for much, rarely cabbaging without this assistance.

You may also continue these sorts through the season, by sowing them in April, May, and June; observing to sow the late crops in a moist shady situation, otherwise they will run up to seed before they grow to any size; but in August, toward the latter end, you may sow of these sorts, to abide the winter; which plants should be transplanted either under glasses, or into a hot-bed, which should be arched over with hoops, in order to be covered in winter, otherwise in hard winters they are often destroyed; but you must constantly let these plants have as much open free air as possible, when the weather is mild; only covering them in hard rains, or frosty weather; for if they are kept closely covered in winter, they will be subject to a mouldiness which soon rots them.

The most valuable of all the sorts of lettuce in England are the Egyptian green cos, and the Versailles or white cos, the Cilicia, and black cos; though some people are very fond of the royal and imperial lettuces; but they seldom sell so well in the London markets as the others, nor are so generally esteemed. Indeed of late years, since the white cos has been commonly cultivated, it has obtained the preference of all the other sorts, until the Egyptian green cos was introduced; which is so much sweeter and tenderer than the white cos, that it is by all good judges esteemed the best sort of lettuce known. This sort will endure the cold of our ordinary winters full as well as the white cos; but at the season of its cabbaging, if there happens to be much wet, this sort, being very tender, is very subject to rot.

The brown Dutch and green capuchin lettuces are very hardy, and may be sown at the seasons as was directed for the common cabbage lettuce; and are very proper to plant under a wall or hedge to stand the winter; where many times these will abide, when most of the other sorts are destroyed; and, therefore, they will prove very acceptable, at a time when few other sorts are to be had; they will also endure more heat and drought than most other sorts of lettuce, which renders them very proper for late sowing; for it often happens, in very hot weather, that the other sorts of lettuce will run up to seed in a few days after they are cabbaged; whereas these will

will abide near three weeks in good order, eſpecially if care be taken to cut the forwardeſt firſt, leaving thoſe that are not ſo hard cabbaged to be laſt. In ſaving of theſe ſeeds, the ſame care ſhould be taken to preſerve only ſuch as are very large, and well cabbaged, otherwiſe the ſeeds will degenerate, and be good for little.

The red capuchin, Roman, and prince lettuces are pretty varieties, and cabbage very early; for which reaſon a few of them may be preſerved; as may ſome of the Aleppo, for the beauty of its ſpotted leaves; though very few people care for either of theſe ſorts at table, when the other more valuable ones are to be obtained; but, in a ſcarcity, theſe may ſupply the place pretty well; and theſe ſorts are very proper for ſoups. The ſeeds of theſe muſt alſo be ſaved from ſuch as cabbage beſt, otherwiſe they will degenerate, and be good for little. *Miller's Gard. Dict.*

LA'DLE-*boards*, thoſe boards diſpoſed on the circumference of the water-wheels of over-ſhot mills; forming hollows, or receptacles not unlike ladles, to receive the water that falls upon the wheel.

LA'MMAS-*day*, *quaſi lamb-maſs*, the firſt of Auguſt, ſo called from a fond conceit the Popiſh people had, that St. Peter was patron of the lambs, becauſe our Saviour ſaid to him, Feed my lambs; upon which account they thought the maſs of this day very beneficial to make their lambs thrive.

LAMP, λαμπὰς, a ſort of luminary, conſiſting of oil diſpoſed with a wick in a proper veſſel for burning.

The uſe of lighted Lamps in churches, and places of devotion, is very antient.— In the city of Fez is a moſque, wherein are nine hundred brazen Lamps burning every night. — In Turkey, all the illuminations are made with Lamps.— Polydore Virgil aſcribes the firſt invention of Lamps to the Egyptians; and Herodotus deſcribes a feaſt of Lamps held annually in Egypt.

Kircher ſhews the manner of preparing Lamps, which ſhall diffuſe a light ſo diſpoſed, as to make the faces of thoſe preſent appear black, blue, red, or of any other colour.

There has been a great diſpute among the learned, about the ſepulchral Lamps of the antients: ſome maintain, they had the ſecret of making Lamps that were inextinguiſhable, alledging ſeveral that had been found burning, at the opening of tombs, fifteen or ſixteen hundred years old. But others treat theſe relations as fables; and others think that the Lamps which before were extinguiſhed, took light afreſh upon the admiſſion of freſh air.

Dr. Plott, however, is of opinion, ſuch perpetual Lamps are things practicable, and has himſelf made ſome propoſals of this kind. The linum aſbeſtinum, he thinks, may do pretty well for the wick, and that naphta, or liquid bitumen, conſtantly ſpringing into ſome of the coal mines, will anſwer for the oil.

If the aſbeſtos will not make a perpetual wick, he thinks there is no matter in the world that will; and argues, that the tradition of ſuch Lamps muſt be fabulous, or that they made them without wicks.

Such a Lamp he thinks it poſſible to make of the bitumen ſpringing into the coal mines at Pitchford in Shropſhire; which, he ſays, like other liquid bitumens, will burn without a wick. Thoſe Lamps that kindle on the immiſſion of freſh air, the ſame author thinks, might be imitated by incloſing ſome of the liquid phoſphorus in the recipient of an air-pump; which, under thoſe circumſtances, will not ſhine at all; but on letting in the air into the recipient, there will poſſibly, ſays he, appear as good a perpetual Lamp, as ſome that have been found in the ſepulchres of the antients.

Cardan's LAMP, is a contrivance of the author of that name, which furniſhes itſelf with its own oil.

It conſiſts of a little column of braſs, tin, or the like, well cloſed every-where, excepting a ſmall aperture at bottom, in the middle of a little gullet or canal, where the wick is placed.

Here the oil cannot get out, but in proportion as it ſpends, and ſo opens the paſſage of that little aperture.

This kind of Lamp was in much uſe ſome years ago; but it has ſeveral inconveniencies; as that the air gets into it by ſtarts and gluts; and that, when the air in the cavity comes to be much rarefied by heat, it drives out too much oil, ſo as ſometimes to extinguiſh the Lamp.

Dr. Hook and Mr. Boyle have invented other Lamps, that have all the conveniencies of Cardan's, without the inconveniencies.

LA'MPADARY, an officer in the antient church of Conſtantinople. His buſineſs was to ſee the church well lighted, and he bore a taper before the emperor, the empreſs, and the patriarch, when they went to church or in proceſſion. There were alſo Lampadaries in the emperor's palaces; the word is from the Latin, *lampas*, a lamp.

LANCE, an offenſive weapon, borne by the antient cavaliers, in form of a half-pike; it conſiſts of three parts, the handle, the wings, and the dart. Pliny attributes the invention of Lances to the Etolians. Varro and Aulus Gellius ſay the word Lance is Spaniſh, whence others conclude the uſe of this weapon was borrowed by the people of Italy from the Spaniards.

LAND.— There are various methods of improving Lands, as, 1. By incloſing and dividing the ſame into ſeveral fields, for paſture or tillage, which is one of the moſt principal ways of improvement; firſt, by aſcertaining to every man his juſt property, and thereby preventing an infinity of treſpaſſes and injuries, that Lands in common are ſubject unto, beſide the diſadvantage of being obliged to keep the ſame ſeaſons with the other people who have Land in the ſame field; ſo that the ſowing, fallowing, and tilling the ground, muſt be equally performed by all the Land-holders; and, when there happens a ſlothful, negligent perſon, who has Land intermixed with others, it is one of the greateſt nuiſances imaginable. Secondly, it being of itſelf a very great improvement: for, where Land is properly incloſed, and the hedge-rows planted with timber trees, &c. it preſerves the Land warm, and defends and ſhelters it from the violent cold nipping winds, which in ſevere winters deſtroy much of the corn, pulſe, or whatever grows on the open field, or champain grounds. And, where it is laid down for paſture, it yields much more graſs than the open fields, and the graſs will begin to grow much ſooner in the ſpring. The hedges and trees alſo afford ſhelter for the cattle from the cold winds in winter; as alſo ſhade for them in the great heats of ſummer. And theſe hedges afford the diligent huſbandman plenty of fuel, as alſo plough-boot, cart-boot, &c. and, where they are carefully planted and preſerved, furniſh him with timber, and maſt for his ſwine: or, where the hedge-rows are planted with fruit-trees, there will be a ſupply of fruit for cyder, perry, &c. which, in moſt parts of England, are of no ſmall advantage to the huſbandman.

By this method of incloſing, there is alſo much more employment for the poor, and is therefore a good remedy againſt beggary; for in thoſe open countries, where there are great downs, commons, heaths, and waſtes, there is nothing but poverty and idleneſs to be ſeen amongſt the generality of their inhabitants. It is very obſervable of late years, how much advantage the incloſing of the Land in Worceſterſhire, and ſome other counties at a diſtance from London, has been to the inhabitants; for, before this method was introduced amongſt them, the Lands, for the moſt part, lay in commons, &c. Upon which the poorer ſort of people built themſelves cottages with mud walls, where they contented themſelves with a cow or two, and ſome ſwine: and thoſe of them who were more induſtrious than the reſt, travelled to the neighbourhood of London every ſpring, where they were employed in the gardens and fields for the ſummer ſeaſon; and in autumn they returned to their native countries, where they lived, in winter, upon what money they had ſaved in ſummer. But, ſince they have converted their waſtes and commons into incloſures, there are but few of the inhabitants of thoſe countries, who come to London for work, in compariſon to the numbers that formerly came; ſo that moſt of the labourers, who come to London for employment, are either Welch, or inhabitants of ſome diſtant counties, where this improvement hath not as yet been introduced.

The advantages of incloſing Land are now ſo generally known, that there is no occaſion for us to enumerate them here; ſince the improvements which have been made of late years, in ſeveral parts of England, and the increaſe of rent, that is every-where made by thoſe that incloſe, are ſufficient arguments to enforce the practice, and render it general; more eſpecially in the north, where it is much neglected; becauſe it would greatly ſhelter the Lands, and render them much warmer than they now are.

In incloſing of Land, there ſhould be regard had to the nature of the ſoil, and what it is intended for; becauſe corn Land ſhould not be divided into ſmall parcels; for, beſides the loſs of ground in hedges, &c. the corn ſeldom thrives ſo well in ſmall incloſures, as in more open fields; eſpecially where the trees are large in the hedge-rows. The graſs alſo in paſtures is not ſo ſweet near hedges, or under the drip of trees, as in open expoſures; ſo that where the incloſures are made too ſmall, or the Land is overplanted with trees, the herbage will not be near ſo good, nor in ſo great plenty, as in larger fields: therefore, before a perſon begins to incloſe, he ſhould well conſider how he may do it to the greateſt advantage: as, for inſtance, it is always neceſſary to have ſome ſmaller incloſures near the habitation, for the ſhelter of cattle, and the conveniency of ſhifting them from one field to another, as the ſeaſon of the year may require; and hereby the habitation, barns, ſtables, and outhouſes, will be better defended from ſtrong winds, which often do great damage to thoſe that are expoſed to their fury. Theſe ſmall incloſures may be of ſeveral dimenſions; ſome of them three, four, ſix, or eight acres in extent; but the larger diviſions for corn ſhould not contain leſs than twenty or thirty acres, or more, according to the ſize of the farm.

The uſual method of incloſing Land is, with a ditch and bank ſet with quick. But in marſh Land, where there is plenty of water, they content themſelves with only a ditch, by the ſides of which they uſually plant ſallows or poplars, which, being quick of growth, in a few years, afford ſhade to the cattle; and, when they are lopped, produce a conſiderable profit to their owners. In ſome counties the diviſion of their Lands is by dry walls made of flat ſtones, laid regularly one upon another,

ther, and laying the top courfe of ftones in clay, to keep them together, the weight of which fecures the under ones. But in fome parts of Suffex and Hampfhire they often lay the foundation of their banks with flat ftones, which is of a confiderable breadth at bottom; upon which they raife the bank of earth, and plant the hedge on the top, which in a few years make a ftrong durable fence, efpecially if they are planted with holly, as fome of thofe in Suffex are. See the article FENCES.

2. The draining of Land is alfo another great improvement to it: for though meadows and paftures, which are capable of being overflowed, produce a greater quantity of herbage than dry Land; yet, where the wet lies too long upon the ground, the grafs will be four, and extremely coarfe; and, where there is not care taken in time to drain this Land, it will produce little grafs, and foon be over-run with rufhes and flags, fo as to be of fmall value. The Land which is moft liable to this is cold ftiff clays, where the water cannot penetate, but is contained as in a difh; fo that the wet which it receives in winter, continues till the heat of the fun exhales the greateft part of it.

The beft method of draining thefe Lands is, to cut feveral drains acrofs the Land, in thofe places where the water is fubject to lodge; and from thefe crofs drains to make a convenient number of other drains, to carry off the water to either ponds or rivers in the lower parts of the Land. Thefe drains need not be made very large, unlefs the ground be very low, and fo fituated as not to be near any river to which the water may be conveyed: in which cafe, there fhould be large ditches dug at proper diftances, to contain the water; and the earth which comes out of the ditches fhould be equally fpread on the Land, to raife the furface. But, where the water can be conveniently carried off, the beft method is, to make under-ground drains, at proper diftances, which may empty themfelves into large ditches, which are defigned to carry off the water. Thefe fort of drains are the moft convenient; and, as they are hid from the fight, do not incommode the Land; nor is there any ground loft where thefe are made.

The ufual method of making thefe drains, is to dig trenches, and fill the bottoms with ftones, bricks, rubbifh, or bufhes, which are covered over with the earth, which was dug out of the trenches: but this is not the beft method, becaufe the water has not a free paffage through the drains; fo that, whenever there is a flood, thefe drains are often ftopped by the foil which the water frequently brings down with it. The beft method I have yet obferved to make thefe drains, is, to dig trenches to a proper depth for carrying off the water, which fhould be three feet wide at their tops, and floped down to about a foot wide at their bottom; then, having prepared a quantity of good brufh wood, the larger fticks fhould be cut out to pieces of about fixteen or eighteen inches in length, which fhould be laid acrofs the lower part of the drain, at about fourteen inches diftance from the bottom, driving them down at both ends, fo as that they may have firm hold of the ground on each fide; fo as to leave a foot of the lower part of the drain open, through which the water is to pafs; then cover thefe fticks with the fmaller brufh-wood, furz, broom, or any other kind of brufh, laying it lengthwife pretty clofe; on the top of thefe may be laid rufhes, flags, &c. and then the earth laid on to cover the whole. Thefe forts of drains will continue good for a great number of years, and are never liable to the inconveniencies of the other drains; for the water will find an eafy paffage through them; and, where there is plenty of brufh-wood, they are made at an eafy expence: but, in places where wood is fcarce, it would be chargeable to make them: however, in this cafe, it would be a great advantage to thefe Lands, to plant a fufficient number of cuttings of willow, or the black poplar, on fome of the moift places, which would furnifh brufh-wood for thefe purpofes in four or five years; and, as the expence of planting thefe cuttings is trifling, there cannot be a greater advantage to an eftate which wants draining, than to practife this method, which is in every perfon's power, fince there is little expence attending it.

In countries where there is plenty of ftone, that is the beft material for making thefe under-ground drains; for when thefe are properly made, they will never want repairing.

The beft time of the year for making thefe drains is about Michaelmas, before the heavy rains of autumn fall; becaufe, at this feafon, the Land is ufually dry; fo that the drains may be dug to a proper depth: for, when the ground is wet, it will be very difficult to dig to any depth; becaufe the water will drain in, wherever there is an opening in the ground.

When the drains are made, and the water carried off the Land, it will be proper to pare off the rufhes, flags, &c. which may be laid in heaps in proper places to rot, and will afford a good manure for the Land. The ground muft alfo be plowed, to deftroy the roots of noxious weeds; and if it be laid fallow for one feafon, and plowed two or three times, it will greatly mend the Land. The rufhes and flags, which were pared off the ground, when rotten, fhould be fpread over the furface, and the grafs feed fown thereon, which will greatly forward the grafs, fo that it may foon be brought to a good turf; which Land, thus mended, has been let at four times the rent it was let at before.

There are fome perfons, who, after they have pared off the flags, rufhes, &c. from their Land, lay them in fmall heaps, and burn them in dry weather, then fpread the afhes on the Land to improve it; which is a good method, where a perfon is in hafte to have grafs again: but, where the ground can be fallowed one year, it will loofen the foil, and more effectually deftroy the roots of all noxious weeds; and the rufhes, &c. when rotted, will afford a much larger quantity of manure for the Land, than when it was burnt; befides, this can only be practifed in the fummer feafon, when the weather is very dry; for, if there fhould fall much rain, the fires will go out, and it will be impracticable to burn it. But, where the method of burning is practifed, the heaps fhould not be too great, and it fhould burn very flowly: which will render the afhes a much better manure, than where the fire is too violent, or the heaps too large; for, in this cafe, the inner part will be over burnt, before the fire reaches the outfide of the heap.

As the draining of cold wet Lands is a great improvement to them, fo the floating or watering of dry loofe Lands is not a lefs advantage to them. This may be eafily effected where there are rivers, or refervoirs of water, which are fituated above the level of the ground defigned to be floated, by underground drains, made after the manner of thofe before directed for draining of Land, through which the water may be conveyed at proper feafons, and let out on the ground; in order to this, there muft be good fluices made at the heads of the drains, fo that the water may never get out, but at fuch times as is required; for, if this be not taken care of, the water, inftead of improving the Land, will greatly damage it.

But where the Land lies fo high, as that there is no water in the neighbourhood lying above its level, it will be more expenfive; becaufe, in fuch cafe, the water muft be raifed, by machines, from refervoirs or ftreams which lie below it. The moft common engine ufed for this purpofe is the PERSIAN WHEEL (which fee.) Yet, notwithftanding the expence of raifing the water, it has been found greatly advantageous, in many parts of England, to drown the Lands; for the profit has many times more than doubled the charge.

The time for drowning of Land is ufually from November to the end of April: but, though this is the general practice, yet I cannot approve of this, for many reafons: the firft is, that, by the wet lying continually on the ground in the winter, the roots of the finer forts of grafs are rotted and deftroyed; and, by letting on of the water, at the feafon when the feeds of docks, and other bad weeds, which commonly grow by river-fides, are falling, thefe feeds are carried upon the Land, where they remain and grow, and fill the ground with bad weeds; which is commonly the cafe with moft of the water meadows in England, the grafs in general being deftroyed; fo that rufhes, docks, and other trumpery, make up the burden of thefe Lands: but if thefe meadows were judicioufly managed, and never floated till March or April, the quantity of fweet good grafs would be thereby greatly increafed, and the beautiful verdure of the meadows preferved: but there is little hope of convincing thofe perfons by arguments, who are fo much wedded to their own prejudices, as to fhut their eyes and ears againft experiments or reafon.

Where the Land is very hot and dry, and it lieth convenient to be watered at a fmall expence, it fhould be repeated every week in dry hot weather, which will prove a great advantage to the Land. But, whenever this is done, there fhould no cattle be admitted, while it is wet; for they will poach, and fpoil the turf.

3. Another great improvement of Land is by burning of it; which, for four, heathy, and rufhy Land, be it either hot or cold, wet or dry, is a very great improvement: fo that fuch Lands will, in two or three years after burning, yield more, exclufive of the charges, than the inheritance was worth before. But this is not to be practifed on rich fertile Land; for, as the fire deftroys the acid juice, which occafions fterility in the poor Land, fo it will in like manner confume the good juices of the richer Land, and thereby impoverifh it; fo that it hath been with great reafon difufed in deep rich countries. See the article BURNING *of land*.

4. It is alfo a very great improvement, where Land is overgrown with broom, furz, &c. to ftub them up by the roots; and, when they are dry, lay them on heaps, and cover them with the parings of the earth, and burn them, and fpread the afhes over the ground. By this method vaft tracts of Land, which at prefent produce little or nothing to their owners, might be made good at a fmall expence, fo as to become good eftates to the proprietors.

LANTERNISTS, the name of the members of an academy of learned men fet up at Touloufe in France. The occafion of the name was as follows: fome counfellors of the parliament of this town, with other gentlemen of feveral diftinctions, projecting to form a fociety for clofe correfpondence and communicating their notions to each other, appointed a fet day to meet at each other's houfes; and here, to prevent interruption from foreign company, they chofe to meet in the evening, after the hours for common vifits were over; and, to to make their meeting more private, they took no flambeaux along with them, but lighted themſelves with ſmall lanthorns. Thus they carried on their converſation with a great deal of pleaſure and improvement, and kept it private for a conſiderable time; but, there being few things which time does not diſcover, their meeting broke out at laſt, and all people of ſenſe and regularity commended the deſign: and now, being no longer incog, they puſhed the project further; they increaſed the ſociety, and made a company in form. Upon the ſcore of their ſmall lanthorns, ſome pleaſant men called them the Lanterniſts; and they took their denomination in good part, as the learned academies in Italy had done before them. Thus theſe Lanterniſts, to preſerve the memory of their original, took a ſtar for their device, with this motto, Lucerna in nocte. Afterwards they ſettled a prize to be given every year to the man or woman who made the beſt rhiming copy of verſes in commendation of the king, to be publiſhed by the company: the prize is a very fine medal, with a ſtar and legend as abovementioned; and, on the reverſe, Apollo playing upon the harp, ſitting on the top of Parnaſſus, with this motto, Apollini Toloſano. *Mercure galant, Juin*, 1698.

LA'PATHUM, *the dock*, in botany, a genus of plants whoſe characters are:

The empalement of the flower is compoſed of three ſmall leaves, which are reflexed: the flower hath three leaves, which are larger than thoſe of the empalement, and are coloured: in the center of the flower is ſituated the three-cornered pointal, ſupporting three ſmall ſtyles, and is attended by ſix ſtamina: the pointal afterwards becomes a triangular ſeed, incloſed by the petals of the flower.

LA'PWING, in ornithology, the Engliſh name of the black-breaſted tringa with a hanging creſt. Were the Lapwing leſs common, it would be highly eſteemed for its beauty. It is very frequent in our fenny countries, and in the wet places of moſt other parts of Europe.

Authors have deſcribed it under the names of vanellus, capra, and capella.

LA'RIX, the *larch-tree*, in botany, a genus of trees, whoſe characters are:

The leaves, which are long and narrow, are produced out of little tubercles, in form of a painter's pencil: the cones are produced at remote diſtances from the male flowers on the ſame tree: the male flowers are very like ſmall cones at their firſt appearance, but afterwards ſtretched out in length.

Theſe trees are propagated by ſeeds, which ſhould be ſown in the beginning of March, upon a bed of light ſoil, expoſed only to the morning ſun: or otherwiſe it may be ſown in pots or boxes of light earth, and placed near an hedge, where they may have the morning ſun only. The ſeed ſhould be be covered about half an inch thick with fine light earth, and in very dry weather ſhould be gently refreſhed with water. In about ſix weeks, if your ſeeds were good, your plants will come up, at which time you ſhould carefully guard them againſt the rapacious birds, which would otherwiſe pull off the heads of the plants, as they thruſt themſelves out of the ground with their covers on them; and obſerve to refreſh them with water in dry weather, eſpecially if they are ſown in pots or boxes; as alſo to keep them clear from weeds, which, if ſuffered to grow among the young plants, will ſoon deſtroy them: nor ſhould they be too much expoſed to the ſun, or ſtrong winds; both which are very injurious to theſe plants, while they are young: but in October you ſhould (if they are in boxes or pots) remove them into a ſituation where they may be defended from ſharp winds, which are ſometimes hurtful to them, while young; but afterwards they will endure the ſevereſt weather of our climate.

Theſe trees are very proper for the ſides of barren hills, where few other ſorts will thrive ſo well; nor is this tree very delicate in its ſoil, but will grow much better on poor ſtrong ſtony land, than in rich ground: and, during the ſummer, they appear very beautiful; but in autumn they caſt their leaves, whereby ſome people have been deceived, by ſuppoſing them dead, and have deſtroyed them.

From the wounded bark of this tree exudes the pureſt Venice turpentine; and on the body and branches of it grows the agaric, which is a drug uſed in medicine: the wood is very durable, and (by ſome) reported to be very difficult to burn. But I do not know how this ſhould be, to a tree which abounds with turpentine; though it is ſaid alſo to be ſo ponderous as to ſink in water. It will poliſh exceeding well, and is by the architects abroad much coveted, both for houſes, and building of ſhips. Witſen, a Dutch writer upon naval architecture, mentions a ſhip to be long ſince found in the Numidian ſea, twelve fathoms under water, being chiefly built of this timber and cypreſs, both which woods were reduced to that hardneſs, as to reſiſt the ſharpeſt tools; nor was any part of it periſhed, though it had lain above a thouſand years ſubmerged. And it was upon tables of this wood that Raphael, and ſeveral of the greateſt artiſts, eterniſed their ſkill, before the uſe of canvas was introduced. *Miller's Gard. Dict.*

LASERPI'TIUM, *laſerwort*, in botany, a genus of plants, whoſe characters are:

It hath an umbellated flower, compoſed of five heart-ſhaped leaves, which are equal, and expand in form of a roſe, and reſt on the empalement, which afterwards turns to a fruit compoſed of two ſeeds, which are gibboſe on one ſide, with four large foliaceous wings, which extend the length of the fruit, and are ſhaped like a water-mill.

Theſe plants are extreme hardy; ſo will thrive in moiſt ſoils and ſituations. They are propagated by ſeed, which if ſown in the autumn, the plants will come up the following ſpring; but, when they are ſown in the ſpring, the ſeeds commonly remain in the ground a whole year. The plants ſhould be tranſplanted the following autumn, where they are deſigned to remain; for they ſend out long deep roots, which are frequently broken; when the old plants are removed, they ſhould be planted three feet aſunder; for the plants grow very large. They decay to the ground every autumn, and come up again the following ſpring; but the roots will continue many years, and require no other culture, but to clear them from weeds, and to dig between the roots every ſpring.

LATHE (*Dict.*)—The Lathe is compoſed of two wooden cheeks, or ſides, parallel to the horizon, having a groove or opening between; perpendicular to theſe, are two other pieces, called puppets, made to ſlide between the cheeks, and to be fixed down at any point at pleaſure.

Theſe have two points, between which the piece to be turned is ſuſtained; the piece is turned round, backwards and forwards, by means of a ſtring put round it, and faſtened above to the end of a pliable pole, and underneath to a treddle or board moved with the foot. There is alſo a reſt which bears up the tool, and keeps it ſteady.

As it is the uſe and application of this inſtrument that makes the greateſt part of the art of turning, we refer the particular deſcription thereof, as well as the manner of applying it in various works, to that head. See TURNING.

LATHY'RUS, *chichling vetch*, in botany, a genus of plants, whoſe characters are:

It hath a papilionaceous flower, out of whoſe empalement riſes the pointal, covered with a membranaceous ſheath, which afterwards becomes a pod, ſometimes round, ſometimes cylindrical, and at other times angular: to which may be added, it hath a compreſſed ſtalk, with a raiſed rib, and a leafy border; and has only one pair of leaves, growing on the nerves, which terminates in a tendril.

LATIFO'LIOUS *, in botany, an epithet applied to ſuch trees and plants as have broad leaves.

* The word is formed from the Latin, *latus*, broad, and *folium*, a leaf.

LAT'TIN, a name formerly given to the plates of iron covered with tin, and now uſually called tin, of which our mugs and ſuch other things are made.

The method of preparing theſe plates of tin, as they are called, is as follows: plates of iron are prepared of a proper thinneſs; theſe are cut into ſquares fitted to receive the tinning, but it is not every kind of iron that will ſerve for this purpoſe, but only ſuch as is moſt diſtenſible, eaſily beating out to any degree of thinneſs when hot, and malleable even when cold, without danger of flying to pieces. Of this the Germans have large quantities, which they always ſelect for this purpoſe. This ſort of iron is firſt formed into ſquare bars of an inch in diameter; theſe they beat out a little into flatneſs, and then cut into pieces, which they call ſemelles, or ſoles. They fold theſe together, and having made them into parcels, containing forty pieces each, they beat them all at once with a hammer, which weighs ſix or ſeven hundred weight. When they have done this, the principal part of the whole work is to prepare the leaves, now beat out to a proper thinneſs, ſo as that they ſhall readily receive the tin; for, if there be but the ſmalleſt particle of duſt on them, or only the ſlighteſt ruſt in any part, the tin will never fix there.

This ſmoothing of the plates may be brought about by filing them, but that would be too expenſive, wherefore they do it by ſteeping them in acid waters. Thus, preparing a great number at a time, they leave them in this liquor till the ſurface is a little preyed upon by it, and then they are ſcowered with ſand, which makes them very ſmooth and fine. By this means a woman cleans more plates in an hour, than the moſt expert workman can do in many days. Mr. Reaumur, to whom the world owes the diſcovery of this proceſs, mentions ſeveral waters, any one of which will ſucceed; but the Germans themſelves uſe nothing but common water, made eager with rye. This they make a great ſecret of, but the preparation is very eaſy. After they have ground the rye groſly, they leave it to ferment in common water for ſome time; and they are thus ſure of a ſharp and eager menſtruum, excellently fitted for their purpoſe. With this liquor they fill certain troughs, or tons, and into theſe they put ſeveral bundles of the plates of iron: and to make the liquor be more eager, and act the better on them, they keep it in ſtoves, where it has little air, and is kept warm with ſmall charcoal fires. The workmen go into theſe vaults once or twice a day, to turn the plates, that they may be the better wrought upon by the acid, and to take out thoſe which are moſt wrought upon, and put in others in their room. The more acid the liquor is, and the warmer the ſtove; the ſooner the plates are cleanſed: it requires, however, at leaſt two days to effect this, and oftener ſomething more.

This was the method which the German labourers, employed in the tin works in France, always made uſe of, in order to prepare the iron to receive the covering of tin ; but the authors, finding that this was a very laborious employ, and that the heat in the ſtoves was ſo great, that they could hardly bear it, propoſed ſome other methods in the place of this, which were attended with much leſs trouble, and as ſmall an expence, if not leſs ; and theſe, upon trial, were found to ſucceed equally well.

Having obſerved that the iron leaves, or plates, are covered with a ſmall layer of a ſort of ruſt, which they contract in the fire, and which the acid liquor took very little hold of ; he judged it might be better to expoſe the plates to ruſt, in order to the cleanſing them eaſily of it ; as ruſt is always accompanied with a ſort of fermentation, and the particles of ruſt, found on the ſurface of the iron, would be ſure to raiſe up every thing in their way. To this purpoſe he ſteeped the plates of iron in waters in which were ſeparately diſſolved alum, common ſalt, and ſal armoniac. Some other plates he did not ſteep in theſe liquors, but only juſt dipped them in, and then expoſed them to the air to ruſt. All theſe liquors, thus uſed, cauſed the iron to ruſt very freely, but the ſal armoniac beſt of all. After two days, during which every plate had been dipped into this menſtruum only twice or thrice, he ordered both theſe, and thoſe which had been left ſteeping during the ſame ſpace of time, to be ſcowered ; and on comparing them together, it was found, that thoſe which had been dipped, and expoſed to the air, became much cleaner than thoſe which had been all the time ſteeped. The ruſt covered all the ſurface in the latter, without raiſing the ſcale ; whereas, in the former, the ſurface was raiſed into bliſters of ruſt, which carried it wholly off with them. The diſſolvents, though very weak, are obſerved to produce the deſired effect, as well as ſtronger, which muſt be much dearer ; but, among the latter, he prefers vinegar in France, which ſucceeds very well, and, being plentiful there, is very cheap. This operates ſo quick on the iron, that the plate need only be once dipped into it, and immediately taken out again, and ſet in a moiſt place, where it will ruſt in eight and forty hours. If the dipping is repeated three or four times, the ruſting will be ſtill more expeditious, and, eſpecially, if a ſmall quantity of ſal armoniac be diſſolved in the vinegar about a pound to the puncheon. This will make a very efficacious menſtruum, the vinegar diſſolving iron very well, and the ſal armoniac ruſting it ſooner than any other ſalt. This, however, muſt be uſed very moderately, and the plate muſt be ſteeped in cold water afterwards, to take off any particle that might yet remain upon it, otherwiſe it would be ſubject to ruſt after it was tinned.

There are ſeveral other ways of making iron ruſt, as keeping it in a moiſt cellar, expoſing it to the dew, ſprinkling it with ſimple water, or, which is ſtill better, with water in which ſal armoniac has been diſſolved, ſeveral times a day ; and, in thoſe countries where the pyrites is common, the vitriolic waters, which partake of it, will do it very well. This water may be prepared at little or no expence, only by heaping up large quantities of the pyrites, and letting it moulder in the air, then putting it into common water, and making a lixivium of it.

The leaves of tin, when they are finiſhed, are always found to be more bright and gloſſy on one ſide than on the other, which is owing to the plates of iron having always ſeveral roughneſſes on one ſide, where it has been moſt expoſed to the hammer. Theſe roughneſſes are what are principally to be eaten down by the menſtruums ; for which reaſon Mr. Reaumur greatly prefers ſprinkling, or wetting them, to ſteeping ; becauſe, in ſteeping, as both ſides are equally expoſed to the force of the menſtruum, the ſmooth ſide muſt be conſequently eaten away too far, while the other is but eaten barely enough ; this occaſions a loſs of the iron, which the author propoſes to ſave by ſprinkling, or ſimply wetting, as the bad ſide only might be ſubjected to the action of the menſtruum.

There are two other cautions, very neceſſary to be obſerved in this part of the work. The firſt is in the management of the plates, before they come to be prepared ; which is, in the beating of them, to turn them continually about, ſo that all parts of every plate may be equally extended. And the other is, to plunge them into ſome ſoft clay, or fuller's earth, before they are heated, that they may not ſolder themſelves together.

Which ever method of ruſting the plates be uſed, it is always neceſſary to ſcower them with ſand, as ſoon as it is done ; and, when they are thus cleaned, they muſt be immediately plunged into water, to prevent their ruſting again ; and they are to be left in this water till the inſtant in which they are to be tinned, or, in the language of the workmen, blanched. The people employed in this part of the operation are called blanchers, and the others who, aſſiſt at the cleaning the plates, the ſealers.

The blancher makes as great a ſecret of his art, as the ſealer does of his ; and it was with great difficulty that Mr. Reaumur obtained it. The manner of doing it is this :

They flux the tin in a large iron crucible, which has the figure of an oblong pyramid with four faces, of which two oppoſite ones are leſs than the two others. The crucible is heated only from below, its upper part being luted with the furnace all round. The crucible is always deeper than the plates, which are to be tinned, are long ; they always put them in downwright, and the tin ought to ſwim over them. To this purpoſe artificers of different trades prepare plates of different ſhapes, but Mr. Reaumur thinks them all exceptionable. But the Germans uſe no ſort of preparation of the iron, to make it receive the tin, more than the keeping it always ſteeped in water till the time ; only, when the tin is melted in the crucible, they cover it with a layer of a ſort of ſuet which is uſually two inches thick, and the plate muſt paſs through this before it can come to the melted tin. The firſt uſe of this covering is to keep the tin from burning ; as, if any part ſhould take fire, the ſuet would moiſten it, and reduce it to its primitive ſtate again. The blanchers ſay, this ſuet is a compounded matter. It is indeed of a black colour, but Mr. Reaumur ſuppoſes that to be only an artifice to make it a ſecret, and that it is only coloured with ſoot, or the ſmoke of a chimney ; but he found it true ſo far, that the common unprepared ſuet was not ſufficient ; for after ſeveral attempts, there was always ſomething wanting, to render the ſucceſs of the operation certain. The whole ſecret of blanching, therefore, was found to lie in the preparation of this ſuet ; and this he at length diſcovered to conſiſt only in the firſt frying and burning it. This ſimple operation not only gives it the colour, but puts it into condition to give the iron a diſpoſition to be tinned, which it does ſurpriſingly.

The melted tin muſt alſo have a certain degree of heat, for, if it is not enough, it will not ſtick to the iron ; and, if it is too hot, it will cover it with too thin a coat, and the plates will have ſeveral colours, as red, blue, and purple ; and, upon the whole, will have a caſt of yellow. To prevent this, by knowing when the fire has a proper degree of heat, they might try with ſmall pieces of iron ; but, in general, uſe teaches them to know the degree, and they put in the iron when the tin is at a different ſtandard of heat, according as they would give it a thicker or a thinner coat. Sometimes, alſo, they give the plates a double layer, as they would have them very thickly covered. This they do by dipping them into the tin, when very hot, the firſt time, and, when leſs hot, the ſecond. The tin which is to give the ſecond coat, muſt be freſh covered with ſuet, and that with the common ſuet, not the prepared. *Philoſophical Tranſactions*, Nº. 406.

LAVEN'DULA, *lavender*, in botany, a genus of plants whoſe characters are :

It is one of the verticillate plants, whoſe flower conſiſts of one leaf, which is divided into two lips ; the upper lip, ſtanding upright, is roundiſh, and, for the moſt part, bifid : but the under lip is cut into three ſegments, which are almoſt equal : theſe flowers are diſpoſed in whorles, and are collected into a ſlender ſpike upon the top of the ſtalks.

Theſe are propagated by cuttings or ſlips ; the beſt ſeaſon for which is in March, when you ſhould plant them in a ſhady ſituation, or at leaſt ſhade them with matts until they have taken root ; after which they may be expoſed to the ſun, and, when they have obtained ſtrength, may be removed to the places where they are deſigned to remain. Theſe plants will abide the longeſt in a dry, gravelly, or ſtony ſoil, in which they will endure our ſevereſt winters ; though they will grow much faſter in ſummer, if they are planted upon a rich moiſt ſoil ; but then they are generally deſtroyed in winter ; nor are the plants half ſo ſtrong-ſcented, or fit for medicinal uſes, as thoſe which grow upon the moſt barren rocky ſoil.

LA'VERS, ſacred veſſels in the temple of Solomon at Jeruſalem ; they were a ſort of baſons which received the water that fell from another ſquare veſſel above them, from which they drew it by cocks ; each Laver contained ten barrels ; they were uſed in waſhing the victims, veſſels, &c. They were ten in number, placed five on each ſide the court, over-againſt the altar or place of ſlaughter.

LAVI'GNON, the name of a French ſhell fiſh common on the coaſt of Poitou. It is of the chama kind, having a very thin pair of ſhells for its covering, which are eaſily cruſhed to pieces between the fingers, and which never can ſhut cloſe, in the manner of the oyſter or muſcle, or other common bivalve ſhells. The fiſh, therefore, always buries itſelf in the mud by way of ſecurity. The ſhells are very ſmooth and poliſhed, eſpecially, on the inſide, and they are naturally white. This colour they always retain within, though their outer ſurface is often tinged black with the mud.

LAU'NDER, in minerology, a name given, in Cornwall, Devonſhire, and other places, to a long and ſhallow trough, which receives the powdered ore after it comes out of the box or coffer through the iron ſtrainer, at the foot of the ſtamping-mills ; the waſte or light part of the ore is waſhed away by a gentle ſtream of water, but the more ponderous part ſtays behind, which is ſent to the melting-houſes after it is dreſſed, at the frames, or waſhing-places, then dried, and made fit for the furnaces.

LAU'RA *, a place where monks anciently dwelt.

* The word is derived from the Greek λαύρα, a village.

Authors are divided about the difference between a Laura and a monaſtery. Some pretend that a Laura was a monaſtery, wherein lived at leaſt 1000 monks ; but this is no ways creditable. But the Lauræ were a kind of villages, whereof each ſeveral houſe was inhabited by one or two monks at the moſt. The term Laura was only underſtood of the religious places in Egypt and the Eaſt, where their houſes ſtood apart from each other,

other, and were not joined by any common cloister, the monks that inhabited them only meeting in public once a week.

LAURE'OLA, *the small spurge laurel*, in botany, is the same with the thymelæa, with laurel-shaped leaves.

Laureola is a very rough purge; it operates both upwards and downwards, and usually carries off a great quantity of matter, but it is apt to erode, and inflame the stomach and intestines. The leaves are somewhat milder than the bark of the stem; that of the root is strongest of all. Many have given it in drops with success; but it is so rough and dangerous a medicine, that, while there are others capable of answering all the purposes intended by it, it is unpardonable to bring it into use.

LAU'RO-*cerasus*, the laurel, in botany, the name of a genus of trees, the characters of which are these: the flower is of the rosaceous kind, being composed of several petals arranged in a circular form. The cup is hollowed, and funnel-fashioned, and from it there arises a pistil, which finally becomes a fruit, resembling a cherry, soft, and inclosing a stone with a roundish kernel.

This was discovered to be poison by the accident of two women dying suddenly at Dublin, after drinking some of the common distilled laurel water. Several experiments were then made on dogs, and communicated to the Royal Society by Dr. Madden, and afterwards confirmed by Dr. Mortimer, which plainly shewed the poisonous effect of laurel water. See *Philosophical Transactions*. N°. 418, 420.

LAU'RUS, *the bay-tree*, in botany, a genus of trees, whose characters are:

It hath a flower consisting of one leaf, which is shaped like a tunnel, and divided into four or five segments: the male flowers (which are produced on separate trees from the female) have eight stamina, which are branched into arms: the ovary of the female flowers becomes a berry, inclosing a single seed within an horny shell, which is covered with a skin.

These trees are very proper to plant upon the warm sides of dry hills, where they may be protected from the severe blasts of the north and east winds; in which situations I have seen some of these trees upwards of thirty feet in height, which is a plain indication of their large growth.

But I know it will be objected, that these trees are often destroyed in hard winters, and so are improper to make large plantations of in England. That they have been sometimes killed by severe winters, I cannot deny: but, if they are brought up thus hardy, as has been directed, and not sheared, I dare affirm, they will resist the severest cold of our climate, when grown to a moderate age, provided they are planted in a dry soil; in which, though their leaves should be intirely shrivelled by extreme cold, yet, if permitted to remain undisturbed, and not cut, they will shoot again the succeeding summer, as I have more than once experienced. And in the hard winter, anno 1728, when most of the bay-trees seemed to be destroyed which grew abroad, and many people were so inconsiderate as to dig them up, and throw them away, it was observable, that all those which were permitted to stand did shoot out again in the succeeding summer, and recovered their usual verdure. Which should caution every person, not to be over hasty in condemning trees to the fire, but to wait for the success of a whole season, before they are pulled up. *Miller's Gard. Dict.*

Canon LAW, a public regulation for the deciding ecclesiastical affairs. The canon Law is made up of these following parts: first, the holy scriptures; secondly, the constitutions of councils, properly called canons; thirdly, the decrees and decretal epistles of popes; and, fourthly, the opinions of the fathers: besides these constituent parts, the civil Law is likewise taken in, in some cases, i. e. extracted from the Theodosian or Justinian codes, and sometimes from the capitularies of the ancient kings of France. The time, in which the several collections were put together, which make up the canon Law, is divided into three divisions: the first comprehends the old Laws, by which the church was governed for above 1000 years, and which is contained in the ancient collections and ecclesiastical constitutions. The second division consists of that which the French call cours, canon; being composed of collections, which were made since the year 1150 to 1483; and the third division of time takes in all the additions made since the period above-mentioned, either by the constitutions of new councils, the decrees of later popes, or by other provisions which are owned to have the force of Law in ecclesiastical matters. To say something of the progress of this matter, upon each division of time; to begin with the first with respect to what was collected either in Greek or Latin: the first collection of the Greeks was published about the year 385; the author of the performance being Stephen bishop of Ephesus, or, as others will have it, Sabinus bishop of Heraclea. This work took in the canons of the two general councils of Nice and Constantinople, together with those made by the five provincial councils of Ancyra, Neo-Cæsarea, Gangra, Antioch, and Laodicea, held in Asia much about the same time. The second collection was made a little after the general council of Chalcedon, held in 458; and here most of the canons of the general council of Ephesus, and of that of Chalcedon, were added to the canons of the first collection; the greatest part of the learned are of opinion that this collection was drawn up by Stephen bishop of Ephesus. To this body were added, the canons of the council of Sardica, the apostles canons, and those of St. Basil. The third Greek collection was ordered to be drawn up by the council in Trullo, held at Constantinople in 692. This was afterwards augmented in the year 790; some canons of the second general council of Nice, as Morery calls it, being added to it. The fourth Greek collection was compiled by Photius, patriarch of Constantinople, about the year 880; besides these four Greek collections, in which the canons were ranged according to the order of the councils, or the epistles of the fathers made use of; besides these collections, I say, John of Antioch made another in the year 550, in which, the canons were disposed into heads according to the subject-matter under fifty titles or divisions; the same John of Antioch, being preferred to the patriarchate of Constantinople in 554, drew up the first nomo-canon, divided likewise into fifty titles or heads, in which he cites the civil Laws from Justinian's codes and novels, i. e. so much of them, as the canons are concerned in. Photius drew up another nomo-canon, where the resembling Laws and canons are placed together, for view and comparison, about the year 883. Arsenius, a monk of Athos, and, afterwards, patriarch of Constantinople, made a new nomo-canon in 1255, and Matheus Blastares, a monk of St. Basil's order, made another in 1335: so much for the Greeks. We shall say something of the Latin collections, of which the most considerable are four. The oldest was drawn up by the order of pope Leo, in 460. The second Latin collection was made by Donysius Exiguus, who was likewise the author of the paschal cycle, and the christian æra; this collection was published in 496, to which, in the year 500, Dionysius added a supplement consisting of popes decrees. The third Latin collection was made in Spain by Isidore, bishop of Seville, in the year 620. The fourth appeared in 790, under the name of Isidorus Peccator, or Mercator: besides these collections, in which the order of time in the councils or decretal epistles is generally observed, there have been several others drawn up, in which, the division is made, according to the diversity of the subject-matter; and of this kind are those drawn up by Ferrandus, deacon of the church of Carthage, in the year 527; by Martin archbishop of Braga in Portugal, 572; by Cresconius, an African bishop, in 670; and by Regino Abbot of Prûm, in the diocese of Treves, in the year 900; this last added the civil Laws to the canons and opinions of the fathers where they had any relation to them; so that, in reality, this collection may pass for a nomo-canon. About the year 1020, Burchardus, bishop of Wormes, made a new collection of canons, vulgarly called the decretum of Burchard (instead of a book or collection of decreta) some likewise call this work Brocardica, by mistake for Burchardica. In the year 1100, Ivo Carnutensis, or bishop of Chartres, drew up two bodies of canon Law, one of which was commonly called the decretum, and the other panormia, or rather pannomia, that is to say, a collection of all the Laws. And likewise, among the collections of canon Law, may be added the orders and constitutions of bishops, and pœnitentials, or books in which penance and discipline are stated; as likewise Gregory, a Spanish priest, his Polycarp, which compiler lived some little time after Ivo Carnutensis; (and thus much for the first division of time, with reference to the common law. The second period of the canon law takes in that commonly called the Cursus Canonicus. This consists of three parts, the first of which contains Gratian's Decretum; the second takes in the great Decretals collected by order of pope Gregory IX, in 1230; the third comprehends the four lesser collections of Decretals, i. e. the Sextus, the Clementines, the Extravagants of John XXII, and the common Extravagants. The Decretum of Gratian is a collection of ecclesiastical constitutions, and of those ancient regulations which passed for Law in the church, till the middle of the XIIth century. This Gratian was a Benedictine, who employed twenty-four years in this work, which he published in the year 1150; the performance is divided into three parts, the first of which contains 101 distinctions, in which ecclesiastical persons are his principal subject; the second part contains 36 causes, in which, the matter and form of trial and sentence are handled; and the third consists of five distinctions, concerning consecration of holy things. (This Decretum of Gratian was received and corrected by pope Gregory XIII, and a new edition published in 1580.) After the Decretum of Gratian, there was a collection of the decretal epistles drawn up, which were written by popes living after Gratian's time. Bernard Circa, afterwards bishop of Fayenza, compiled a new body of canon Law in 1188; and Johannes Valensis drew up another about twelve years after. Peter of Beneventum finished a third collection which was approved by pope Innocent the IIId, in 1210. After the IVth council of Lateran, held in the year 1215, under the same pope Innocent the IIId, there appeared a fourth collection, the author of which is not known. Tancred, archdeacon of Bologne, made a fifth, in the year 1226. The second part of the Cursus Canonicus, or Course of Canon Law, being a collection of the Decretal Epistles, drawn up by the order of pope Gregory the IXth, takes in the epistles of several popes, and particularly those epistles which were written from the year 1150, the time in which Gratian published his decree, till the year 1230, in which this collection of Decretals was published; to this second part likewise

wise are added the constitutions of councils, and some decisions of the fathers: this collection was put in order by Raymond de Pegnafort, the pope's penitentiary, and is divided into five books. The first book treats principally of the ecclesiastical Law in general, and of the several sorts of judges who have jurisdiction in the church. The second treats of civil process, or the forms of prosecuting an action. The third and fourth give directions about sentence and passing judgment in civil matters, taking in the cases in which the clergy are concerned, together with those relating to marriage. The fifth enlarges both upon the matter and form, concerning trial and judgment in criminal causes. The third part of the Cursus Canonicus, or Course of Canon Laws, consists of a collection of new decretals, and contains the Sextus, the Clementines, and the Extravagants. The Sextus, i. e. the sixth book of the decretals, was drawn up by pope Boniface the VIIIth's order in the year 1298: this collection is divided into five books, like that of Gregory the IXth, the matter being thrown into the same order, and divided under the same heads. The Clementines were formed into a body by pope Clement the Vth, some time after the celebration of the council of Vienna, held in 1311, and published in the year 1317, by his successor John the XXIId. The Extravagants of John the XXIId are the decretal epistles of that pope, which were so called, because, being not yet inserted into the body of the Law, they seemed as it were outliers, and to range out of the confines of the Cursus Canonicus, which name has continued upon them; afterwards the decretals of several popes were called the Common Extravagants, to the year 1483, and, in this latter body of the canon Law, there are more of the constitutions of pope John the XXIId, than in the collection that goes under his name. The third period of the canon Law takes in the constitutions of councils and popes made since the last collections of the decretals, with other regulations which have the force of Law in ecclesiastical affairs; this last division of Law is either common, i. e. as Morery speaks, received by all Catholics, or else particular to some community. There are two sorts of common Law; the one relates to discipline, and the other to the forms and process of courts. The first consists of the decrees of general councils, held since Clement the Vth, and the bulls of popes, not yet taken into the body of the Law, the greatest part of which has been put together by Laertius and John-Mary Cherubins; from whence Petrus Matheus, a lawyer of Lyons, has extracted a collection, which he calls the seventh book of the decretals. The second part of this common Law takes in the forms and regulations of the apostolic Chancery, made since John the XXIId, amounting to the number of seventy-one, the three principal of which are received in France, upon the score of being founded upon natural equity. That branch of the civil Law, which is called proper or particular, is that, which besides the general Law of the whole church, is peculiar to particular nations, provinces, churches, dioceses, chapters, and communities: as to France, continues Morery, that part of the canon Law, which is particular to us, is, in the first case, taken from the antient decrees, usages, or customs of the universal church, being preserved by our forefathers with greater care, than by the neighbouring nations; and in these usages and regulations that which we call the privileges or immunities of the Gallican church principally consists. In the second place, that part, which makes the canon Law particular to France, consists of royal ordinances made by the kings of the third race, either with the concurrence of the states of the realm, or their own proper authority, or else in concert with the holy See, such as the pragmatic sanction, the ordinances of Orleans, Blois, and others, so far as the church is concerned; the concordat, made in the year 1516, between pope Leo the Xth and Francis the Ist, which was concluded to soften that which shocked the court of Rome, in the pragmatical sanction: to this we may add the German concordat, made in the year 1447, between pope Nicholas the Vth and the emperor Frederic the IIId, and which is still observed in Lorraine and Alsace. The third branch of ecclesiastical Law, which, though particular to France, is not observed all the kingdom over, is made up of the canons of late provincial courts, synodal constitutions, and regulations of corporations or communities. *Doujat Histoire du Droit Canonique.*— There is a new edition of the body of canon Law, and decretals, printed in 1687, with notes and corrections of Petrus and Franciscus Pithæus, two eminent lawyers, printed from an original in the library of M. le Pelletier, minister of state, comptroller general of the finances, and great grandson to Petrus Pithæus; this edition was some time since printed at Paris.

Roman or Civil LAW.— Under this denomination, we are to understand Laws made by the Romans for the support of their government, and the administring justice to private persons. Romulus, who built Rome, gave the first beginning of these regulations in his leges curiatæ, so called, because they were made by the consent of a general meeting of the people, divided into thirty parts or wards, called curiæ. The other kings, who succeeded him, made several Laws during their respective reigns, which, in all, lasted 244 years. These Laws being drawn into a body, by Sextus Papyrius, in the 245th year of Rome, the collection was called Jus Papyrianum. But, these Laws being soon after repealed by the Lex Tribunitia, there are none of these royal Laws to be met with, in the books of the Jus Romanum. About the year of Rome 303, there were ten learned men pitched upon to travel to the republics of Greece, and to transcribe all the Laws which they believed serviceable to their own government. These ten men, called decem-viri, made ten Laws, to which, the year after, they added two more. These Laws being engraven upon plates of ivory, and hung up in public places of the town, were called the Laws of the twelve tables. But, notwithstanding this publication, the people, were obliged in several cases, to apply to the lawyers for explanation and direction; whose opinions, upon cases put, being approved by custom, came, at last, to be called Law. Much about the same time, there were forms of process settled, for the grounding of actions, and stating the method of prosecution; and these they called actions of Law. These forms, being published by Cn. Flavius, made them be called the Flavian civil Law. Some time after, Sextus Ælius wrote another book of actions, or forms of process, which were called Jus Ælianum. And thus, at that time of the day, the Roman Law was made up of the twelve tables, the civil Law, and, as they called it, the actions of the Law. The people of Rome, falling afterwards into a misunderstanding with the senate, and retiring to mount Aventine, made, during this separation, Laws called plebiscita, which were afterwards received by the whole commonwealth. After the people or plebeians had yielded the senate the power of making Laws, the senatus consulta appeared, i. e. the ordinances or statutes made by the senate. To these, in the year 387 of Rome, were added the edicts of prætors, who were magistrates, chosen every year for the administration of justice, whose edicts or decrees were called jus honorarium; Julianus, an eminent lawyer, made a collection of these decrees, which was called the perpetual edict, and approved by the emperor Adrian in the year 130, according to the Christian computation. The form of the Roman government being changed a little before the birth of our Saviour, the authority of making Laws devolved upon the emperors, whose constitutions were drawn into two codes, by Gregorius and Hermogenes, two learned lawyers, under the reign of Dioclesian, in the year 290. These two collections, called the Gregorian and Hermogenian code, took in the imperial constitutions, from Adrian to Constantine the Great. The emperor Theodosius the younger ordered a third collection to be drawn up, called the Theodosian code, in which all the constitutions of the succeeding emperors, from Constantine to himself, were inserted. The writings, likewise, and opinions of some eminent lawyers, made part of the Roman Law: for, since the reign of Augustus, there were several of that profession named by the emperors, to give their judgment upon cases put, whose resolutions, upon the point, were looked upon as Law, because they were authorised by the princes commission to give their opinions. The most considerable of these lawyers, were Publius Papyrius, Appius Claudius, Sempronius, Sextus Ælius, Q. Mutius Scævola, Ateius Capito, Antistius Labeo, Papinianus, Ulpianus, Junius Paulus, Pomponius, Modestinus Africanus, &c. In the year of our Lord 530, the emperor Justinian, perceiving the civil Law very confused, ordered a review of it, that the insignificant part of it should be cut off, and put into the method and condition it is in at present. In this great work, he employed the ablest lawyers of his time; the names of which were, Trebonianus, Constantinus, Theophilus, Dorotheus, Anatolius, Cratinus, with some others. This committee, after having selected what was most useful in the XII tables, in the plebiscita, and senatus consulta, in the edicts of prætors, the resolutions of eminent lawyers, the constitutions, or rescripts of emperors; after having done this, I say, they divided the body of Law into four books, viz. the Digest, the Institutes, the Code, and the Novels. The Digest, otherwise called the Pandects, is a collection which contains the old Law, together with the resolutions of eminent lawyers. The Institutes contain the elements or principles of the Roman Law. The Code is a collection of all the constitutions, from Adrian to Justinian, for there are few imperial constitutions older than Adrian; so that it takes in the three codes, the Gregorian, Hermogenian, and Theodosian. It was called the Justinian Code, from that emperor's name, who got it drawn up. The Novels is a supplemental book to the Code, and contains the constitutions of Justinian, which were made after the Code was published. These Novels are faithfully translated from the Greek into the Latin, and commonly called Authenticæ, to shew the exactness of the version, and to distinguish them from the epitome of Julianus, consul of Constantinople, and likewise from those which Irenerius, a lawyer, inserted into the Code in the reign of the emperor Frederick the Ist, in the year 1155; which performance is often, not very carefully and judiciously, managed. The civil Law of the Romans, being put in this good condition by the care of the emperor Justinian, took place only in Greece, Illyricum, and part of Italy; because the Goths, Lombards, Vandals, Franks, and other barbarous nations, had possessed themselves of the western parts of the Roman empire. About the year 868, the emperor Basilius made an abridgment of the Justinian

nian code, and his son Leo, the philosopher, published the Basilicæ, in 888, which passed for Law, till the ruin of the eastern empire, which happened in the year 1453, Justinian's body being no longer read in the schools, nor pleaded at the bar in Constantinople. After these Basilicæ, the emperor Leo set forth an hundred and thirteen new constitutions, which treat of several things undecided by the Laws of Justinian. The Greek lawyers made glosses and explanations upon the Basilicæ, but not so voluminous as those of the Latins upon the civil Law. Michael Attaliottes, a lawyer, who flourished in the year 1070, published another abridgment of the Justinian code, which he called the Abridgment abridged, i. e. an abridgment of what Basilius the emperor had set out before. About the same time, Michael Psellus made another little collection of the Basilicæ, afterwards translated by Leunclavius in the year 1580. And, lastly, in 1143, Constantine Herminopulus furnished out another abridgment of the whole Law, which he called Promptuarium: but the taking of Constantinople by Mahomet the IId, in 1453, put an end to the eastern empire, and to the use of the Laws observed there. And thus we have seen the state of the Roman or civil Law in Greece: as for Italy, as has been remarked already, it was little observed there, for the space of 506 years, after the death of the emperor Justinian: for the Goths made themselves masters of Italy about sixty years after the reign of that emperor, and the Lombards, having chaced the Goths out of that country, reigned there about 200 years. During this time, the Visigoths and Vandals held the government of Spain; and the Goths, Huns, and other barbarous people, seized upon part of Gaul; Charlemaigne, having conquered Desiderius king of the Lombards, in the year 774, was chosen emperor of the Romans, by the senate and people of Rome, in the pontificate of Leo the IIId. This emperor had then a design of reviving the practice of the Roman or civil Law, but the men of that profession could not furnish him with a copy of what Justinian had published; but at last, in the year 1137, in the reign of Lotharius the IId, emperor of the West, and in the popedom of Innocent the IId, they found a copy of the Digests at Amalfi in Puglia, which was called the Florentine pandects, for a reason to be given by and by. The emperor Lotharius and pope Innocent, joining in a war against Roger, king of Sicily and Naples, desired assistance from the then republic of Pisa. In the course of this war, the town of Amalfi being taken by storm, and plundered, Justinian's copy abovementioned, being found there, was given to the Pisans, for the good services they had done on this occasion. These books remained in the hands of this commonwealth, till they were conquered by the Florentines, who carried off the pandects, from Pisa, to Florence; where they are still carefully preserved, as the only, or at least the most authentic original of the Roman law. After the discovery of these pandects, the emperor Lotharius the IId publishes an edict, commanding the Roman or civil Law to be taught in public schools, and that causes should be tried by it; and, in the year 1150, gave Irenerius leave to read upon it, in the university of Bononia, after whom, it was taught and cultivated, in the same place, by several eminent professors, as, Placentinus, Azo, Accursius, &c. There have been, likewise, a great many other famous civilians in several parts of Europe, as Bartholus, at Pisa and Perugia; Baldus, at Bononia and Pavia; Alciat, Coverruvius, Antonius Augustinus, &c. The most eminent civilians among the French, are, Budæus, Duarenus, Du Moulin, Cujacius, Hottoman, Brissonius, Tiraqueao, Chopinus, Pithæus, &c. The Roman or civil Law was not received in Germany till the XVth century, but since that time, it has made its way farther there than elsewhere, upon the account of the emperors of this country stiling themselves the Roman emperors. *Histoire du Droit Romaine.*

LAWN (*Dict.*)— Many persons have preferred the lime-tree for this purpose, on account of their regular growth: but as the leaves of this tree often change their colour, and begin to fall very soon in the autumn, occasioning a great litter in the garden; and from the end of July the trees make but an indifferent appearance; so they are not to be esteemed for these plantations.

The elm, oak, beech, and chesnut, among the deciduous trees, are to be preferred to all others, as they keep their leaves late in autumn: and these are all of them large-growing trees; so are very proper for this purpose.

If there are some clumps of ever-green trees intermixed with the deciduous trees in this plantation, it will add to the beauty of it, especially in the winter season: the best sorts for this purpose, are, the lord Weymouth's pine, the silver and spruce firs, which will grow fast, and become large trees: and, as the two latter sorts always grow pyramidically, so they will have a good effect to the sight, when properly disposed with the deciduous trees: but, as these generally feather out their branches near the ground, they should be planted where they do not obstruct the view of any distant objects.

But, as most persons who take pleasure in beautifying their seats in the country, are in haste for shade, they generally plant the trees too close together, and often in such a manner, as to render it difficult, when the trees are advanced, to reduce their number, without injury to the design; therefore those trees should be first planted, which are designed to remain; and then there may be some few others planted for present shade, which may afterwards be taken away. When persons who are beautifying their seats meet with full grown trees on the spot, it is a great pleasure; for these should not be destroyed, if they can possibly stand. *Miller's Gard. Dict.*

LA'YING *of trees*, a very necessary operation, and thus performed:

1. Take some of the boughs, and lay them into the ground about half a foot deep in fine fresh mould, leaving them with the end of the layer about a foot or a foot and a half out of the ground, and keep them moist during the summer-season, and they will probably have taken, and be fit to remove, in autumn; and, if they have not by that time taken root, they must lie longer.

2. Tie a piece of wire hard round the bark of the bough, at the place you intend to lay in the ground; and twist the ends of the wire, so that they may not untie; and prick the place above the wire, through the bark, with an awl in several places; and then lay it in the ground, as before directed.

3. Cut a slit upwards at a joint, as is practised in Laying of carnations, which, by gardeners, is called tonguing the layers.

4. Twist the place which you design to lay in the ground like a withy, and lay it into the ground, as directed in the first way of Laying.

5. Cut a place round about the bough, that is designed to be laid, an inch or two, at the place that is most convenient to lay into the ground, and manage it, as is directed in the first method of Laying.

The season for Laying hardy trees, that shed their leaves, is in October; but, for such as are tender, in March; for evergreens, June or August are good seasons.

Though layers may be laid at any time in the year, the before-mentioned seasons are most proper, for the reasons following: because they have the whole winter and summer to prepare and draw root; for at those times of the year the sun has sufficient power on the sap of the tree, to feed the leaf and bud, but has not power sufficient to make a shoot.

And if that small quantity of sap that does arise be hindered, as it will by some of the preceding ways of Laying, the leaves and buds will gently crave of the layer, and, by that means, will prepare the layer to take root, or put forth roots a little to maintain itself, finding it cannot have it from the mother-plant.

And, therefore, because it wants but little nourishment at that time of the year, it is better to lay layers of trees, or to set cuttings, than at other times, either in the winter, when the sap stirs but little, or in the summer, when the sap abounds, or in the spring, when it begins to rise; because it is then apt to come too suddenly to draw sap from the layer, before the layer has drawn or prepared for root.

However, the spring or summer may do well for small plants; because such plants, being but short-lived, draw root the quicker.

If you would lay young trees from an high standard, the boughs of which cannot be bent down to the ground, then you must make use of osier-baskets, boxes, or pots, filled with fine sifted mould, mixed with a little rotten willow-dust, which will keep moisture to assist the layer in taking root: this basket, box, &c. must be set upon a post or tressel, &c. and the bough must be laid according to either of the four first ways of Laying; but too much head must not be left on, lest that be injured by the wind, or by its own motion rub off the tender root; and the smaller the boughs are, the less way they should be set out of the ground, and care must be taken to keep them clear from weeds.

The harder the wood is, the better will the young wood take root; but if the wood be soft, the older boughs will take root the best. *Miller's Gard. Dict.*

LEACH *brine*, a word used by the English salt-workers, to express the brine, which runs out from the salt, when it stands in the baskets to drain, immediately after being taken out of the pan: and also the liquor left in the pan, when no more salt will shoot. This is also called the mother brine, and bittern. In the German salt works they always throw this liquor away. In our brine salt works in Cheshire they always preserve it, and add it to the next boiling; and, in the Newcastle, and other sea-water salt works, they save it for the making the bitter purging salt, called Epsom salt.

LEAD (*Dict.*)— This metal may be procured from its ore, of whatever kind that be, by a stratification with charcoal. The method of doing it in assay is this: take for a docimastical centner of the ore a hundred half ounces, or three pounds and four half ounces, that, by this means, each half ounce may stand in lieu of the docimastical pound; beat this to a coarse powder, or lumps not larger than a pea. Put it at first into a large earthen or iron frying-pan, and heat it first by a gentle fire, which must be increased gradually, that the greatest part of the sulphur may be dissipated. Now, have at hand a melting furnace, with its bed made of lute and dust of charcoal. Apply to this, on the outside, another bed, joined to it by lute, that the matter running out of the inferior hole, when open, may be received into it. Surround this outer bed

 with

with burning and fresh coals; and fill the whole furnace with the same fuel, that it may be dried. Then, with a pair of bellows, excite the fire for a quarter of an hour, then put in the ore at several times; nor will it be amiss to add to it some scales of iron; but the ore must be put in so as to be above the coals, facing the hole, through which the blast of the bellows is made; but let it not touch the wall of the furnace. Fill the furnace at least two thirds with charcoal, and let it be in pieces of a moderate bigness; and, after every portion of ore is put in, add a larger of charcoal above it. When all the ore is put in, continue to blow till all the fire is consumed; then pour water upon the foremost bed, drop by drop, to cool the Lead gathered in it, and see among the scoriæ if there be any Lead lodged among them; and, if there be, separate it, and weigh all together, and you will, from this, know the value of the ore, and what the smelter may obtain from it. *Cramer's Art of Assay.*

It has been proved, by the experiments of different chemists, that Lead contains a real running mercury. Kunkel and Becher both separated mercury from it; and Mr. Grosse, of the Paris academy, has justified their experiments, by producing the same effect, by means, not only very different from theirs, but absolutely opposite and contrary. They suppose that the mercury contained in Lead is fixed there, either by acids or by sulphurs, and therefore they used alkaline materials to disengage and support it. On the contrary, Mr. Grosse used only acids, and by means of these procured a pure running mercury from this metal. His method was to dissolve thin plates of Lead in spirit of nitre, weakened with an equal quantity of water. He then observed a grey-coloured powder precipitate, which, when tried on gold or copper, shewed itself to be mercurial, and even in the powder he saw small globules of quick-silver. *Mem. de l'Acad. des Scienc.* 1733.

LEAF (*Dict.*)— The distinction of Leaves, made by those who have written on botany, are:

A simple Leaf is that which is not divided to the middle.

A compound Leaf is divided into several parts, each resembling a simple Leaf, as in liquorice, &c.

A digitated Leaf is a compound Leaf divided into several parts, all of which meet together at the tail, as in the hemp, black hellebore, &c.

A trifoliated Leaf is a digitated Leaf, consisting of three fingers, as the trefoil, &c.

A quinquefoliated Leaf is a digitated Leaf, consisting of five fingers, as in the quinque folium.

A pennated Leaf is a compound Leaf divided into several parts, each of which is called a lobe, placed along the middle rib, either alternately, or by pairs. When the middle rib is terminated by an odd lobe, it is said to be unequally pennated, as in the goats rue, &c. and equally pennated, when it is not terminated by an odd lobe, as in the cassia: when the lobes are all nearly of the same form and bigness, it is called an uniform pennated Leaf, as in the liquorice; when they are not so, it is said to be difform, as in the agrimonia.

A winged Leaf is, as it were, divided into several pennated Leaves, as in the orobus, &c.

A ramose Leaf is that which is still farther divided than the winged Leaf, as in the osmund royal, female fern, &c.

An entire Leaf or lobe is that which has no division on its edges, as in the apple-tree, &c.

A sinuated Leaf is that which is cut about the edges into several long segments, as in common mallows.

A serrated Leaf is that which is cut about the edges into several acute segments, resembling the teeth of a saw, as in the nettle, &c.

A crenated Leaf is that which is cut about the edges into several obtuse segments, as in the betony, &c.

A laciniated or jagged Leaf is that which is cut about the edges into several pretty deep portions, in an irregular manner, as in the horned poppy, &c.

Leaves are a part of a plant that is ordinarily very thin and flat, growing in the spring, and falling off at the autumn; though there are some plants without Leaves, as the truffles and mushrooms. *Miller's Gard. Dict.*

The Leaves of plants are of the utmost consequence to the life of the whole. Air evidently passes in at the Leaves, and goes through the whole plant, and out again at the roots. If the Leaves have no air, the whole plant will die, as is easily proved by the air-pump; but, in these experiments, if the Leaves be left on the outside of the receiver, and parted by a hole cemented with wax, and have air, the plant will thrive, and grow, though its roots and stalk are kept in vacuo in water. The Leaves of plants perform the necessary work of altering the water, received in at the roots, into the nature of the juices of the plant; and hence it is, that the life of the plants depends so immediately upon their Leaves. The husbandman often suffers for want of this knowledge. A crop of saintfoin is a very valuable thing, and, its root being perennial, will yield him increase many years; but it is often destroyed at first, by suffering it to be indiscreetly fed upon by the sheep, which eating up all the leaves, the root remains without the means of a supply of air, and the whole perishes.

Leaves being thus necessary to plants, nature has, in all perennial plants, provided a reversionary stock of them. The Leaves of these plants are always formed in autumn, though they are not unfolded till the following spring. They then open and increase gradually, in proportion to the motion of the sap, and the quantity of pabulum it then receives to be circulated. These Leaves may also, though not wholly appearing out of the bud, be sufficient for the extremely small motion of life, which the sap of perennial plants, that drop their Leaves, has in winter. *Tull's Horse-hoeing Husbandry.*

LEA'O, in natural history, a mineral substance approaching to the nature of the lapis lazuli, found in the East-Indies, and of great use in the Chinese porcelain manufacture, being the finest blue they are possessed of. This is found in the strata of pit coal, or in those of a yellowish or reddish earth in the neighbourhood of the veins of coal. There are often pieces of it lying on the surface of the ground, and these are a sure indication, that more will be found on digging. It is generally found in oblong pieces, of the size of a finger, not round, but flat. Some of this is very fine, and some coarse, and of a bad colour. The latter is very common, but the fine sort is scarce, and greatly valued. It is not easy to distinguish them at sight, but they are found by experiment, and the trying one piece is generally sufficient for judging of the whole mine; for all that is found in the same place, is usually of the same sort.

Their manner of preparing it for use is this: they first wash it very clean, to separate it from the earth, or any other foulness it may have; they then lay it at the bottom of their baking furnaces; and when it has been thus calcined for three or four hours, it is taken out and powdered very fine in large mortars of porcelain with pestles of stone faced with iron. When the powder is perfectly fine, they pour in some boiling water, and grind that with the rest; and, when it is thoroughly incorporated, they add more, and finally pour it off, after some time settling. The remainder at the bottom of the mortar, which is the coarser part, they grind again with more water, and so on, till they have made the whole fine, excepting a little dirt or grit. When this is done, all the liquors are mixed together, and well stirred. They are suffered to stand two or three minutes after this, and then poured off, with the powder remaining in them. This is suffered to subside gradually, and is the fine blue they use in their best works, our common smalt serving for the blue of all the common low-priced China ware. *Observat. sur les Coutumes de l'Asie.*

LECH, in metallurgy, a term used by the miners, to express the gold ore which has been powdered, and washed, and afterwards run with the assistance of lime-stone. The Lech is afterwards burnt in a fire of charcoal, in order to render it fit for the separation of the metal, by means of lead, which, absorbing and scorifying the extraneous matter, renders the gold pure.

LEECH. See HIRUDO.

LEEK, *porrum*, in botany.—We have two kinds of Leek commonly cultivated amongst our gardens, the one called the common Leek, and the other a broader-leaved one, commonly called the London Leek. There are some reasons to suspect that these are only varieties of the same species of plant, both arising from the same seed.

The method of propagating these is by seeds, and they are commonly sown along with onions. The onions grow up first; and after they are pulled up, the Leeks have time enough to grow to their size. *Miller's Gard. Dict.*

LEER, in glass-making, a sort of third furnace, intended to anneal and cool, by proper degrees, the vessels when made. This properly comprehends two parts, the tower and Leer. The tower is that part which lies directly above the melting furnace, with a partition between them of a foot thick; in the midst whereof there is a round hole, placed exactly over the furnace, through which the flame and heat pass into the tower. On the floor of this tower the vessels are set to anneal. There are two openings, by which the vessels are put into this tower, and after standing there some time, they are put into iron pans, which, by degrees, are drawn out all along that part of this furnace, which is properly called the Leer; which is five or six yards long, that the vessels may cool by degrees. This Leer is continued to its tower, and arched all along, and is about four feet wide, and high within. The glasses are cool by that time they are come to the mouth of this, which enters into a room where the glasses are placed, when taken out. *Neri's Art of Glass.*

LEETCH *of a sail*, in a ship, the outward edge or skirt of the sail from the earing to the clew, or rather the middle of the sail between these two.

LEETCH-*lines*, in a ship, small ropes fastened to the Leetch of the top-sails (only) and then reeved into a block at the yard, just by the top-sail ties. Their use is to hail the Leetch of the sails, when the top-sails are to be taken in; which is always first done, and then the sail can be taken in with the greater ease.

LE'GATE-*note*, in the Italian music. Notes are said to be Legate when this ⌒, or this ⌣ mark is found over or under the heads of them. This is what we call tying them, and is done, when they are properly but one note, but obliged to be separated into two, because part is found at the end of one bar, and

and the other part in the beginning of the following bar; or because the two halves of a note are in different parts of the measure.

LE'GER-*line*, in music, is used to signify a line added to the staff of five lines, when the ascending and descending notes run very high or very low. We often meet with several of these lines both above and below the staff.

LEMU'RIA, a feast of ghosts and phantoms, solemnised the ninth day of May, to pacify the manes of the dead, who were the lemures that came in the night to torment the living. The institution of this feast is ascribed to Romulus, who to rid himself of the phantom of his brother Remus, whom he had ordered to be murdered, ordained a feast called after his name, Remuria and Lemuria. They offered sacrifices for three nights together, during which time all the temples of the gods were shut up, and there was no wedding.

LE'NÆA, Λήναια, in antiquity, a festival of Bacchus, surnamed Lenæus, from ληνὸς, i. e. a vine-press. Besides the usual ceremonies at feasts sacred to this god, it was remarkable for poetical contentions, and tragedies acted at this time. *Potter, Archæol.*

LE'NTES *lapidea*, *fossil lentils*, the name given by many writers to a very remarkable fossil substance, usually found immersed in hard stone, and of a roundish but flatted shape, resembling, not unaptly, a pea or lentil flatted by pressure.

LENTI'SCUS, *the lentisk or mastich-tree*, in botany, the name of a genus of trees, very nearly allied to the terebinthus or turpentine-tree in its characters, but differing, in that the leaves are pinnated; but there is no single leaf to terminate the end of each compound one. *Tourn. Inst.* See MASTICH in the Dictionary.

LEO, *the lion*, in zoology. See LION.

LEO-*pulex*, a name given by Mr. Reaumur to a species of insect which feeds on the pulex arboreus, or common tree-puceron, in the same manner that the creature, called the formica Leo, does on the ants: this being also, like that, an animal, yet in an imperfect state, and finally to be changed into a different creature, this author has kept up the remembrance of this analogy between them, by giving this a similar name.

LE'OPARD, in zoology, the English name of a voracious beast of prey, beautifully spotted, and virgated.

This creature, when carefully examined, is found to be very like a cat; particularly its head, teeth, tongue, feet, and claws. Its actions also are all like a cat's; it boxes with its fore feet, as a cat does her kittens; leaps at its prey, as the cat does; and will spit much in the same manner.

All the Leopard kind, as they walk, keep the claws of their fore feet turned up from the ground, and sheathed, as it were, in the skin of the toes, whereby they preserve them sharp for the seizing of their prey.

Notwithstanding the natural fierceness of the Leopard, numbers of them are bred up tame, and kept for the great cham of Tartary's use, for the hunting of deer and other beasts.

They are most numerous in Africa and Syria. *Grew's Muf.*

LE'TTUCE; see LACTUCA.

LERICOI'UM, *stock-gilliflower*, in botany, a genus of plants, whose characters are:

The flower is composed for the most part of four leaves, which are placed in form of a cross: out of the flower cup rises the pointal, which becomes a long flat pod, divided into two cells by an intermediate partition, to which the valves adhere on both sides, and are furnished with flat smooth seeds, which are orbicular, and bordered round their edges: to which may be added, the flowers are specious, and sweet-smelling.

All the sorts of stock-gilliflowers are propagated by seeds: the best time for sowing them is in the beginning of April, upon a border of fresh light earth, where they may be exposed to the morning sun; for, if they are too much exposed to the sun in the heat of the day, they are very subject to be eaten by a sort of fly; as they often are, while young, upon an hot dry soil. To remedy which, you should always sow a few radishes amongst them, which will secure them from this mischief: for the flies will always prey upon the radishes, whereby your gilliflower plants will be preserved; but then you must not suffer the radishes to be too thick amongst them; for that would draw them up very weak, and cause them to be long-shanked. When your plants have gotten six leaves, they must be transplanted into other borders of the like fresh earth, and exposed to the morning sun at about four inches distance; observing to water and shade them until they have taken root; after which they will require no farther care, than only to keep them clear from weeds until the latter end of August, or the beginning of September, when you must transplant them into the borders of the pleasure-garden; which should be done, if possible, in moist weather, that they may the sooner strike root, whereby they will be securely fastened in the ground before the frost comes on; which would prevent their taking root, and thereby either quite destroy them, or at least cause them to flower very weak the succeeding spring.

LE'WING, in metallurgy, the sifting the ores of metals in water. This is done in fine sieves moved backwards and forwards under water; and is the method of separating the finer part of the ores which had subsided among the larger lumps, under that part of it separated for use in the various washings. The coarser matter, left in the sieve, is powdered again with the larger masses, and all thus sifted together for the blowing-house. *Ray's English Words.*

LIBE'LLA, in natural history, the name of a very large genus of four-winged flies, called by us adder-flies and dragon-flies.

These flies have also two very large and reticulated eyes, covering the whole surface of the head. They fly very swiftly, and prey upon the wing, being of great use to mankind, in clearing the air of innumerable little flies.

LI'BRARY (*Dict.*)— Some authors refer the origin of Libraries to the Hebrews, and observe, that the care they took for the preservation of their sacred books, and the memory of what concerned the actions of their ancestors, became an example to many other nations, and particularly the Egyptians. Osymandrias, king of Egypt, is said to have taken the hint first, and had a Library built in his palace with this inscription over the door ψυχῆς ἰατρεῖον. The Ptolemies of that country were also very curious in books. The scripture, Esdras the Vth and VIth, speaks of a Library of the kings of Persia, which some imagine to have consisted of the historians of that nation, and of memoirs of the state; but it appears rather to have been a depository of laws, charters, and ordinances of the kings. The first who erected a Library at Athens was the tyrant Pisistratus; yet, Strabo says, Aristotle was the first. That of Pisistratus was transported by Xerxes to Persia, and afterwards brought by Seleucus Nicanor to Athens. Long after it was plundered by Sylla, and re-established by Hadrian. Plutarch says, that, under Eumenes, there was a Library at Pergamos containing 200,000 books. Tarannion, a celebrated grammarian, cotemporary with Pompey, had a Library of 3000 volumes. That of Ptolemy Philadelphus, according to Ammianus Marcellinus, contained 7000 all in rolls, burnt by Cæsar's soldiers. Constantine and his successors erected a magnificent one at Constantinople, which, in the eighth century, contained 300,000 volumes, all burnt by order of Leo Isauricus, and, among the rest, one wherein the Iliad and Odyssey were written in letters of gold on the guts of a serpent. The most celebrated Libraries of ancient Rome were the Ulpian and the Palatine. Antiently, every large church had its Library. One of the most complete Libraries in Europe is said to be that erected, at Florence, by Cosmo Medicis: though it is now exceeded by that of the French king, begun by Francis the First. The Emperor's Library, according to Lambecius, consists of 80,000 volumes, and 15,940 curious medals. The Bodleian Library at Oxford, built on the foundation of that of duke Humphrey, exceeds that of any university in Europe, and even those of all the sovereigns of Europe, except the emperor's and French king's, which are each of them 100 years older; it was first opened in 1602, and has since found a great number of benefactors. The Vatican, the Medicean, as that of Bessarioni at Venice, and those just mentioned, exceed the Bodleian in Greek manuscripts, which yet out-does them all in Oriental manuscripts. As to the printed books, the Ambrosian at Milan, and that at Wolfenbuttel, are two the most famous, and yet both inferior to the Bodleian. The Cotton Library consists wholly of manuscripts, particularly such as relate to the History of Antiquities in England, which, as they are now bound, make about 1000 volumes.

LI'CHEN, *liverwort*, in botany, the name of a genus of mosses, the characters of which are these: they have the most perfect fructification of all the mosses, having evident flowers as well as seeds. Their flowering heads are of various figures, and have a number of monopetalous flowers in them, divided into a different number of segments; these have several filaments, and among them have a large quantity of farina, which, when examined by the microscope, appears of a globular figure. The seeds are produced in other parts of the plant, and are contained in certain cups, which stand without pedicles on the surface of the leaves; these are sometimes on the same individual plant with the flowering heads, but sometimes they are on different plants of the same species.

LICHENOI'DES, in botany, the name of a genus of mosses, the characters of which are these: they are composed of parts of different figure and structure, not simple and uniform as the byssi; they have usually no stalk, but grow on the branches of trees, on stones, and other bodies, either in form of a mere crust, or of leaves variously divided and raised. They have tubercles on the several parts of these, serving in the place of flowers or seeds, and growing closely upon the leaves without pedicles. Micheli has described the flowers and seeds of these plants from microscopic observations, but these are too minute to form generical distinctions on. These plants have the name Lichenoides, from their resemblance to the lichen, or liverwort, as they consist, like it, of leaves diffused every way. They have hence been called by some lichens; but the difference between the two genera is very great, these having very imperfect flowers, the others the most perfect of all the mosses.

LI'CTORS, among the ancient Romans, were officers who attended the magistrates, when they appeared in public.

They were twelve in number, and carried bundles of rods, in which was tied up an ax, the head whereof appeared a-

mongst

mongſt the rods. Their office was to go before the king and clear the way for him. Afterwards, when Rome was become a commonwealth, the conſuls, dictators, and prætors, and other magiſtrates who had a right to command the Roman armies, had alſo Lictors going before them; the conſuls and dictators twelve; the prætors ſix. At triumphs the Lictors marched before the conqueror's chariot, carrying their bundles wreathed about with laurels, and holding a branch of the ſame in their hands. They were alſo common executioners: I, Lictor, colliga manus, expedi virgas, plecte ſecuri. They were ready to undo their bundle of rods, whether it were to whip, or to cut off the head of the condemned offender: they were thus called a ligando, becauſe they bound the hands and feet of the condemned perſon before his execution. *Rollin's Roman Antiquities.*

Expectation of LIFE, a term uſed by Mr. De Moivre, for the time which a perſon of a given age may juſtly expect to continue in being, that is, when the chance for his living or dying becomes equal.

According to that gentleman's calculation, upon the ſuppoſition of an equal decrement of Life, the expectation of Life would be expreſſed by $\frac{1}{2} n$, if n denotes the complement of Life. Thus the expectation of Life for a man of 50 years of age will be $18 = \frac{36}{2}$: that is, he had an equal chance, or of 1 to 1, of living 18 years. But, if that interval be once attained, there ariſes a new expectation of $\frac{1}{2} n$, and afterwards of $\frac{1}{2} n$, &c.

Hence he gives the ſolution of the following problem: to find the expectation of two joint Lives, that is, the time which two Lives may expect to continue together in being.

For this, the rule is, from one half of the ſhorteſt complement ſubtract the ſixth part of its ſquare divided by the greateſt complement, the remainder will expreſs the number of years ſought.

Thus, ſuppoſing a Life of 40, and another of 50; the ſhorteſt complement will be 36; the greateſt 46; $\frac{1}{2}$ of the ſhorteſt will be 18; the ſquare of 36 is 1296, whereof the ſixth part is 216, which being divided by 46, the quotient will be $\frac{216}{46} = 4.69$; and this being ſubtracted from 18, the remainder 13.31 will expreſs the number of years due to the two joint Lives.

LIFTING-*pieces*, in a clock, are thoſe parts which lift up and unlock the detents in the clock part.

LIFTS, in a ſhip, ropes belonging to the yard-arms of all yards. Their uſe is to ſtop the yard-arms, i. e. to make the end of the yards hang higher or lower, as occaſion ſerves.

LIGHT (*Dict.*)—It is evident that the intenſeneſs of the ſun's Light, falling upon any given ſurface, is greater or leſs, according as his rays fall in greater or leſs quantity; or, in other words, any ſurface is more or leſs illuminated, according as the light falls thicker or thinner upon it; now, that this denſity of the ſun's Light is reciprocally, as the ſquares of the diſtances of the illuminated bodies from the ſun, is thus demonſtrated: let S (*Plate* XLI. *fig.* 10, in the Dictionary) be the ſun ſending forth rays of Light every way round, in the ſtraight lines S A, S B, S C, S D, &c. all theſe rays, at the diſtance S *a*, are ſpread uniformly over the ſpherical ſurface *a b c d e*; at the diſtance S A, the ſame rays are ſpread uniformly over a larger ſpherical ſurface A B C D E; the Light then muſt be as much thinner upon this larger ſpherical ſurface than it is upon the ſmaller one, as the larger ſpherical ſurface is greater than the ſmaller one: now the ſurfaces of ſpheres are as the ſquares of their diameters; that is, the ſpherical ſurface A B C D E is to the ſpherical ſurface *a b c d e*, as the ſquare of S A is to the ſquare of S *a*: therefore the Light at A is to the Light at *a*, as the ſquare of S *a* is to the ſquare of S A: which was to be proved.

The prodigious velocity of Light has always been looked upon as one of the greateſt difficulties attending the Newtonian ſyſtem. This difficulty the learned Dr. Knight has attempted to remove, by ſuppoſing that Light is propagated by the progreſſive motion of a repellent fluid; and has ſhewn that all the phænomena of Light and colours will be the ſame, whether we ſuppoſe the propagation of Light performed by a progreſſive motion of its particles, or by the vibrations of a repellent fluid. See REPELLENT *Fluid*.

For, ſays this ingenious author, it makes no difference, in reſpect to the action of a body impinging upon another, whether the impinging body has moved already through a great ſpace, or is only juſt put in motion, provided the velocity and direction be exactly the ſame in both caſes. Therefore a particle of Light will ſtrike upon the retina of the eye with the very ſame effect, when it receives its motion from the next contiguous particle, as when it has moved all the way from the ſun, with the ſame direction and velocity. And it is much eaſier to comprehend how a tremor may be propagated from one end of a ſeries of elaſtic bodies to the other, in the ſame time that Light takes up in coming from the ſun to us, than to conceive how a particle of Light can continue its motion and direction unaltered, through ſo vaſt a ſpace, and with ſo great a velocity; whilſt innumerable other particles are everywhere moving in different and often contrary directions. Is it poſſible that it can move ſo far, and not frequently impinge upon other particles, when every minute part of ſpace muſt contain thouſands of them? What confuſion muſt neceſſarily ariſe in the direction of its motion from ſuch a variety of percuſſions! But, ſuppoſing the motion propagated through our repellent fluid, theſe difficulties immediately vaniſh. In that caſe, the motion may be conveyed in all directions at once, without danger of confuſion; becauſe, as before obſerved, the motion of the intermediate particles from their places will be inconſiderable; and from the nature of percuſſion, amongſt equal elaſtic bodies, one particle is no ſooner removed from its place, but the particle which removed it, takes poſſeſſion of the ſame, and remains there at reſt. The moſt obvious objection to this doctrine is, that in a repellent fluid a particle in motion will not only act upon the next that lies exactly in the direction of that motion, but alſo upon all thoſe that are placed but a very little way out of that direction; and by this means ſeveral other vibrations will commence, which will be communicated in ſuch directions as correſpond with the degrees of obliquity with which the particles act: whereby Light will not only be propagated from one body to another, in right-lines, but will at the ſame time be communicated ſide-ways, in almoſt all directions. And this will not only create confuſion in regard to viſion, but alſo make it impoſſible that there ſhould be any darkneſs in the night. To this I anſwer, that, even granting a particle of the repellent fluid will act upon ſuch particles as lie but a little way out of the direction of its own motion, yet it will not act on them with the ſame force as it does on thoſe directly in its way; therefore theſe lateral vibrations will be much weaker than the direct ones, which give us the ſenſation of Light: however, though theſe vibrations may be too weak for our organs, yet they may be well enough ſuited to the delicate ſtructure of the eyes of many inſects and animalcula, and even of ſome larger animals; for doubtleſs what is darkneſs to us, is not ſo to many of them. The ſame thing happens in regard to ſounds: for, if all the vibrations of the air were capable of affecting our organs of hearing, there could be no ſuch thing as ſtillneſs or ſilence; becauſe the particles of air muſt be put in continual vibrations in all directions, by every little percuſſion that happens among bodies. All nature is perpetually in motion; and every motion, in ſuch an elaſtic fluid as the air, muſt be attended with a greater or leſs vibration of that fluid. As to the objections that may be drawn from the analogy betwixt the waves in water, and the undulations of an elaſtic fluid, they will be anſwered all at once, by denying the exiſtence of theſe undulations; at leaſt with regard to the propagation of ſound or Light. I will not ſay, that the air is never made to undulate: the winds themſelves have often a wave-like motion; but this is not ſound: a large body in motion through the air may make undulations in it. The oſcillations of a pendulum, or the ſtring of an inſtrument, may do the ſame. But none of theſe are the immediate cauſe of ſound. The moving body, pendulum, and ſtring are all ſilent. Only it generally happens in the laſt caſe, that, whilſt the ſtring performs its oſcillations, its component corpuſcles, being elaſtic, are put into a tremulous motion, which motion they communicate to the circumambient air. Touch the ſtring with a ſoft unelaſtic body, and the tremulous motion of the parts ceaſes. But the ſtring continues to oſcillate for a long time after with as much ſilence as a pendulum.

From the whole of what has been ſaid, I think it is ſufficiently evident, that the effect of Light will in all caſes be the ſame, when its motion is propagated through a repellent fluid, as when it is progreſſive, in the manner that Sir Iſaac Newton has ſuppoſed. So that the whole theory of optics, demonſtrated by that excellent philoſopher, continues the ſame as before. Only one thing, that is of any conſequence, remains to be reconciled, I mean his doctrine of colours. He ſhews the diverſity of colours to be owing to the different momenta of the particles of Light, and ſuppoſes their momenta to differ on account of their different magnitudes. I have ſuppoſed all the particles of Light to be of the ſame ſize. This was done for the ſake of ſimplicity, which muſt always take place, as far as the nature of things will admit. And the momenta of the particles of Light will differ, though their ſizes are the ſame, if Light be propagated by vibrations. For in the ſame manner as the tones in muſic make a difference in ſound, according as thoſe vibrations are quicker or ſlower; ſo the momenta of the particles of Light will differ, according as they vibrate with more or leſs force. A great many will be ready to object, that if the particles of Light are equal, and yet their momenta different, they muſt move with different velocities: and, conſequently, that the red rays will come from Jupiter to us, in leſs time than the blue. I grant the premiſſes, but deny the conſequence: for ſound moves with equal velocities, let the tone be what it will. What I advance may at firſt ſight appear a very great paradox. But it ſeems evident to me, that, in two different ſeries of equal and elaſtic bodies, thoſe of one ſeries may move with greater velocity than thoſe of another, and yet the propagation of motion from one to the other be performed in equal times. *Knight's attempt to demonſtrate that all the phænomena in nature may be explained by two ſimple active principles, Attraction and Repulſion.*

LILIACEOUS, in botany, a term uſed to expreſs the flowers of of some plants, which approach to those of the lily in shape. The characters of a Liliaceous flower are these: it is composed of six leaves, or else of three leaves divided into six, but this is more rarely the case; the pistil, or cup of this flower, always becomes finally a seed vessel divided into three cells.

Of this sort are the flowers of the tulip, hyacinth, asphodel, ephemerum, and the like; many of which, though they less resemble the lily flowers than the others, yet are to be distinguished by this title, because they leave behind them the Liliaceous seed-vessel, which is long, and divided into three cells. *Tourn. Inst.*

LI'LIUM, *the lily*, in botany, the name of a large genus of plants, the characters of which are these: the flower is a sort of bell-fashioned shape, but is composed of six leaves which are more or less expanded and bent back. The pistil stands in the center of the flower, and finally becomes an oblong and trigonal fruit, which is divided into three cells, and contains a number of marginated seeds, arranged in a double order one on another. To this it is to be added, that the root is of a bulbous form, and is composed of a number of fleshy scales affixed to an axis.

All sorts of lilies and martagons are propagated by sowing their seeds; and, if the seeds are carefully saved from good flowers, the martagons very frequently afford very beautiful varieties.

The manner of sowing them is this: some square boxes should be provided of about six inches deep, with holes bored in the bottoms to let out the wet; these must be filled with fresh light sandy earth, and the seeds must be sown on them pretty thick in the beginning of August, soon after they are ripe, and covered over about half an inch deep with light sifted earth of the same kind. They should be then placed where they may have the morning sun; and, if the weather prove dry, they must be watered at times, and the weeds carefully picked out. In the month of October, the boxes are to be removed to a place where they may have as much sun as possible, and be secured from the north and north-east winds. In spring the young plants will appear, and the boxes are then to be removed into their former situation; they should be watered at times during the summer, and in August the smallest roots are to be emptied out of these boxes, and strewed over a bed of light earth, and covered with about half an inch depth of light earth sifted over them; they must here be watered and shaded at times, and defended from the severity of the winter, by a light covering of straw, or pease-haulm, in the hardest weather. In February the surface of the bed should be cleared, and a little light earth sifted over it. When the leaves are decayed, the earth should be a little stirred over the roots, and in the month of September following a little earth sifted on. In the September of the following year, the roots must be transplanted to the places where they are to remain, and set at eight inches distance, the roots being placed four inches below the surface: this should be done in moist weather. They will now require the same care as in the preceding winters; and, the second after they are transplanted, the strongest roots will begin to flower. The fine ones should then be removed at the proper season into flower-beds, and planted at great distances from one another, that they may flower strong. *Miller's Gard. Dict.*

The roots of the white lily are emollient, maturating, and greatly suppurative. They are used externally in cataplasms for these purposes with success. The common form of applying them is boiled and bruised; but some prefer the roasting them till tender, and then beating them to a paste with oil, in which form they are said to be excellent against burns. Gerard recommends them internally in dropsies.

Water-Lily. See Nymphæa.

LI'MBERS, in artillery, a sort of advanced train joined to the carriage of a cannon upon a march. It is composed of two shafts wide enough to receive a horse betwixt them, which is called the fillet horse; these shafts are joined by two bars of wood, and a bolt of iron at one end, and have a pair of small wheels; upon the axle-tree rises a strong iron spike, upon which the train of the carriage is put. But, when a gun is upon action, the Limbers are run out behind her.

Limber-*holes*, in a ship, are little holes cut through her floor timbers, serving to let the water to the well of the pump, which otherwise would lie between those timbers where the keel rope runs.

LIME (*Dict.*)—Lime makes the greatest improvement upon light sandy lands, or upon a dry gravel: but a cold clay is seldom much benefited by it. If it be mixed with dung, or with mud drawn from the bottom of rivers, it makes an excellent mixture, especially where the soil is very sandy; and in Westmoreland they procure fine crops of barley from their sandy lands, by manuring them with Lime and cow-dung mixed together. The nature of Lime on land is like that of chalk, it works downwards, as the farmers express it; it is therefore best to treat it in the same manner, laying it upon a lay the year before it is to be plowed up. Lime is reckoned to make corn grow with a thick husk; but it is not a lasting manure, seldom holding for more than five crops. When Lime is used to land which lies upon a descent, it should be mixed with dung, and laid principally on the higher part of the land; the consequence of which will be, that the rain will wash out the virtue of the Lime and dung together, and carry the whole to the lower parts, as it runs down. Dung and Lime mixed together will do better for any land, than either of them alone.

Lime is made of chalk, or of any stone, that is not too cold, or sandy, as free-stone, and the like. All the soft stones that are of a tolerable close texture, will burn to good Lime, as will also marble, slate, sea-shells, corals, and flints; but this last kind of stone is more difficult to be burnt to Lime than the others, except in a reverberatory kiln, for they are apt to run to glass. The harder the stones of which Lime is made, the better the Lime is; and, when it is made of chalk, that is much better which is made of the hard stony kind, than that which is made from the soft; but, the harder the stones are, the more fire is required to burn them: both sorts may be burnt with wood, coals, turf, or fern, which makes a very fierce fire. The kilns used for chalk, or stone, they commonly make in a large pit, which is dug either round or square, according as they have convenience; and is of such a size, as will be proper for the quantities they intend to burn. They are widest at the top, and narrower, by degrees, as they come nearer the bottom. The inside of this pit is lined with a wall built of Lime-stone; at the outside, near the bottom, they have a hole, or door, by which they take out the ashes, and, above that, some have an iron grate, which comes close to the wall all about it: but others arch it over with stone, or large pieces of chalk; and upon this they lay a layer of stone, or of whatever else they burn in the pit; upon this they place a layer of wood, or coals, and so on, layer over layer, to the top of the pit; only they observe, that the outermost layer be always of the fuel, not of the stone. When the kiln is thus filled, they give fire at the hole underneath, and the Lime is finished in a different time, according to the nature of the substance. That made of chalk is commonly burnt into Lime in twenty-four hours; but Lime stone generally takes sixty hours in burning. Ten bushels of sea-coal, or one hundred of faggots, three feet long, will burn forty bushels of chalk, and this will yield thirty bushels of unslaked Lime. Where chalk is scarce, they work up the chalk rubbish into a sort of stiff paste with water, and make it into a sort of bricks, which they dry in the air, and then burn them into Lime in the common way; but this is not quite so good as the other. Hot Lime taken out of the kiln, and mixed into a very soft paste with water, and then mixed with sand, makes a kind of mortar very much superior to the common sort. *Mortimer's Husbandry.*

All Lime is a very good manure, but that made of stone is much better than what is made of chalk. The common allowance is a bushel to a pole square, or a hundred and sixty bushels to an acre.

This they cover with earth, and so leave it till the rains fall and slake it, and after that they spread it as evenly as possible upon the ground. They always find that, if it be carried hot out of the kiln, and laid upon the land to cool, it does much better than in any other way.

The improvement it makes upon land is owing chiefly to its heat, and the salt it contains. It is in much the same manner that coal-ashes and the soot of coal become useful upon the like sort of lands; but the farmers always find that a mixture of good earth and Lime, that has lain a considerable time together, is better for this purpose than fresh Lime alone. *Morton's Northampt.*

Lime-*galls*, in natural history, a sort of galls or vegetable protuberances, formed on the edges of the leaves of the Lime-tree in spring-time; they are very common in the plantations of Limes, and are irregularly shaped, but usually oblong and rugged, and of a reddish colour; they occupy only the edges of the leaves, and are of a red colour, sometimes very beautiful. As these are very plentiful, Mr. Reaumur was of opinion, that they might be of service in the dying trade; he made trial by rubbing them on some parts of his linen, and found that they gave a very beautiful red colour, which did not come out in the first washings afterwards. It is extremely probable, that there wants only inquiry to prove that we have many valuable productions of this kind, which, though disregarded at present, might prove of great use in the several mechanical arts as well as in medicine.

These galls of the Lime leaves are formed by a worm, which inhabits them during its term of life, being found in them of all sizes, from the most minute to that of the full growth, which is about half an inch in length; but, when its period of life, as a worm, draws near, it deserts this habitation, and goes elsewhere to pass into its chrysalis state. This also is the case with the worms that inhabit many galls, which are frequently found to contain them in the worm state, but never in that of the chrysalis, which they always pass into elsewhere. *Reaumur's Hist. Inf.*

Lime-*tree*.—The several species of the tilia, or Lime-tree, are all easily propagated by layers, which in one year will take good root, and should then be removed to the nursery, planting them at four feet distance in rows, and the plants two feet asunder in each row. The best season for removing them is Michaelmas. They should remain four or five years in the nursery, and should afterwards be removed to the places where

where they are to remain. The foil they love beft is a ftrong fat loam, in which they will grow very faft. *Miller's Gard. Dict.*

LI'MMA λεῖμμα, *refiduum*, in the antient mufic, is the difference of the diatefferon and the ditonus. It is expreffed by $\frac{243}{256}$.

LI'MON, the lemon-tree, in botany, a genus of trees whofe characters are thefe:

It hath large ftiff leaves like the citron, without any appendage at the bottom; the flower confifts of many leaves which expand in form of a rofe: the fruit is almoft of an oval figure, and divided into feveral cells, in which are lodged hard feeds furrounded by a thick flefhy fubftance, which, for the moft part, is full of an acid juice.

All forts are propagated by budding or inarching them either on ftocks of lemons or citrons produced from feeds, but they will not fo readily unite on orange ftocks; for which reafon the citrons are preferable to either oranges or lemons for ftocks, as they readily join with either fort; and, being of larger growth, caufe the buds of the other forts to be much ftronger than if they were on ftocks of their own kind.

The culture of the lemon being the fame with that of the orange-tree, it would alfo be needlefs to repeat it here: therefore I fhall only obferve, that the common lemons are fomewhat hardier than the oranges, and will bring their fruit to maturity with us better than they will do, and require to have a greater fhare of frefh air in winter; for which reafon they fhould always be placed nearer to the doors or windows of the green-houfe: and in fome curious gardens thefe trees have been planted againft walls, where, by covering them with glaffes in winter, and protecting them from fevere froft, they have produced plenty of large fruit: as thefe trees do generally produce ftronger fhoots, fo they require more water to be given them than the orange; but, as to the tender forts, they muft be treated with a little more care, otherwife their fruit will fall off in winter, and come to nothing. See the article ORANGE in the Dictionary.

LIMO'NIUM, *fea-lavender*, in botany, a genus of plants whofe characters are:

It hath a fibrous root; the ftalks are naked and branched; the cup of the flower is long and tubulofe, but expanded at the top; the flower in fome fpecies confifts of one leaf, but in others of feveral, and is fhaped like a clove-gilli-flower: the pointal, which arifes out of the flower-cup, becomes an oblong fruit, wrapped up in the flower-cup, as in an hufk.

LIN'ARIA, *toad-flax*, in botany a genus of plants whofe characters are thefe:

The leaves are oblong, and produced alternately on the branches: the cup of the flower confifts of one leaf, which is divided into five long acute fegments; the flower, which confifts of one leaf, is of an anomalous perfonated figure, ending in a tail behind, and in the fore-part divided into two lips, of which the upper is cut into two or more parts, and the under into three: the ovary (which rifes from the center of the flower-cup) becomes a roundifh fruit or hufk, divided into cells or apartments by an intermediate partition, and full of feeds, which are fometimes flat and bordered, fometimes cornered and roundifh, adhering to the placenta.

LINA'RIA, in zoology, the name of the linnet, a genus of birds, of which there are feveral fpecies. The general characters of the genus are thefe: the birds of it are fomewhat fmaller than the chaffinch; their general colour is a greyifh brown; their tail is a little forked, the outer feathers of it having white extremities; they all fing very fweetly. We have in England four fpecies of this bird. 1. The common brown linnet, well known to every one. 2. The Linaria rubra major, or greater red-headed linnet. This has a fine red head, a grey neck, a dufky reddifh brown back, and its breaft and belly are fomewhat reddifh. The female of this fpecies, however, has no rednefs on its head, or breaft, but has fomewhat of a greenifh caft among the brown of her back, and is yellowifh on the breaft, with fome brownifh fpots. 3. The Linaria rubra minor, or leffer red-headed linnet. This is fmaller than the former, and on the back is of the fame colour with the common linnet. The back part of its head is red, as is alfo its breaft, but the lower part of its belly is whitifh. In this fpecies the female, as well as the male, has a red head, and both have their beaks much fharper, and their feet and legs blacker than in the larger kind. This alfo is a gregarious bird; the larger kind commonly flies fingle. 4. The laft fpecies is the Linaria montana, or mountain linnet. This is the largeft of all the linnets. Its beak is very fmall; its head and back are of the fame colour with thofe of the common linnet, and the feathers of the breaft and belly are black in the middle, and edged with a whitifh colour. The rump is of a fine and beautiful red, and is the only part of the bird which is fo. This is common in Derbyfhire, but feems not fo frequent in other places. *Ray's Ornitholog.* See LINNET.

Angling LINE.—The beft materials for making thefe Lines are fine and even horfe-hairs: the hair fhould be round and twifted even, for that greatly ftrengthens it; and all the hairs fhould be of an equal bignefs, or as nearly fo as may be. They fhould be laid in the water about a quarter of an hour after twifting, that it may be feen which will fhrink: they are then to be twifted over again. In this laft twifting fome intermingle filk among them, but that is not fo well. The beft colours for a Line are forrel, white, and grey; the two laft are beft for angling in clear waters; the former in muddy ones. The pale watery green is alfo a very good colour, and may be made thus: boil in a quart of alum water a large handful of marygold flowers; there will arife a fcum, which muft be taken off; then add to this liquor copperas and verdigreafe, of each half a pound, beat to powder together; boil thefe up together; then put the hair into this liquor, and let it lie ten or twelve hours; it will obtain a watery bluifh green colour, which will not wafh out afterwards.

LINES, in heraldry, the figures ufed in armories to divide the fhield into different parts, and to compofe different figures.

They are of different forms, and, were it not for this, many arms would be one and the fame; for a chief wavey differs from a plain chief, by the lines which compofe them, and the heralds fhew particular reafons for all thefe different forms of Lines.

LING, in ichthyology, the Englifh name for a kind of fifh, which is a fpecies of the afellus, according to the generality of authors, and is generally called afellus longus. According to the new Artedian fyftem, it is a fpecies of the gadi, and is diftinguifhed by the expreffive name of the gadus, with two fins on the back, with a bearded mouth, and with the upper jaw longeft.

Ling is efteemed, both frefh and cured, for the table. It is a long-bodied fifh, more approaching to the merlucius or hake than to any other fpecies. It is covered with very fmall fcales which are fcarce vifible, as they adhere fo clofely to the fkin. The back and fides are of a bluifh or greenifh brown, and the belly white. Its head is flat and large, and its fnout confiderably long. The upper jaw is longer than the under, and both are furnifhed with feveral rows of fhort teeth, and the lower with one range of longer; and in the palate there are a large number of fmall teeth, among which there are four or five large and long ones intermixed. The mouth opens very wide, and in the angle of the lower jaw has a fingle fhort beard. It has two fins upon the back, one near the head, the other not far behind it, and reaching down almoft to the tail. The gill-fins are fmall, the belly fins are placed high, and the tail is not forked. *Ray's Ichthyog.*

LI'NNET, *linaria*, in zoology, the name of a well known finging bird.

It is remarkable of this bird, that when it builds in hedges, and when in furz bufhes on heaths, in both which places the nefts are very common, they are made of different materials. When they build in hedges, they ufe the flender filaments of the roots of trees, and the down of feathers and thiftles; but, when they build in heaths, they ufe mofs, principally, for the outer part, finifhing it within with fuch things as the place will afford. Thefe birds will have young ones three or four times a year, efpecially if they are taken away before they are able to leave their nefts.

When they are intended to be taught to whiftle tunes, or to imitate the notes of any other bird, they are to be taken from the old one when they are not more than four days old; for at this time they have no idea of the note of the old ones, and will readily be taught to modulate their voice like any thing that is moft familiar to their ears, and within the compafs of their throats. There requires more care in the feeding them when they are taken thus young, than when they are left in the neft till nearly fledged; but they will be reared very well upon a food half bread, half rape-feed, boiled and bruifed: this muft be given them feveral times a day. It muft be made frefh every day, and given them fufficiently moift, but not in the extreme. If it be in the leaft four, it gripes and kills them; and, if too ftiff, it is as mifchievous by binding them up.

LI'ON, *leo*, in zoology.—The head of the Lion appears very large, in proportion to its body, and is the moft flefhy of the heads of all the known animals. Its jaw bones alfo are remarkably large. The beaft alfo appears very large, but this is only owing to the great quantity of long hair that covers it, for the fternum is fmaller than that of moft animals of the fame fize. The tail, which is very long, appears alfo of the fame thicknefs all the way, but this is wholly owing to the growth of the hair. The tail itfelf is largeft at the bafe, and thence goes taper to the point; but the hair, being very fhort near its bafe, and continuing to grow longer all the way, as that decreafes in thicknefs, is fo exactly proportioned in this growth, that it always gives the whole tail this regular appearance. See *Plate* XXXII. *fig.* 5.

The long hair that grows about the neck and breaft, and makes what is called the mane of the Lion, only differs from the hair of the reft of the body in length, having no greater thicknefs, or rigidity, like that of the manes of other animals. The claws of the Lion have no cafes, as Pliny pretends that they have, for the animal to withdraw them into in walking; but Plutarch, Solinus, and fome others, are much more in the right, in faying that the Lion draws them up backwards when he walks, and places them clofely among the articulations of the toes.

It is certain that the laft joint but one of every toe in this creature has a peculiarly eafy joint for motion, and by means of of this the laſt joint, with the claw that is affixed to it, are very readily drawn up, and hid upon the foot, and placed wholly out of the way of being hurt in walking. This creature, therefore, does not put the extremities of its toes to the ground in walking, but the termination of each toe, as to its touching the earth, is the joint of the laſt piece with the laſt but one. This drawing up of the laſt joint of every toe, by means of which each claw is hid between the toe it belongs to and the next, is the effect of a ligament, which in its natural ſtate is ſo ſhortened, as to keep them in this poſition; and it is only by the action of a very ſtrong muſcle, that this joint can be pulled downward, when the claws are to be uſed, the ligament beforementioned always drawing them naturally into their firſt poſition again, as ſoon as the force of the muſcle is over.

The Lion has fourteen teeth in each jaw, four inciſores, four canine, and ſix molares. The inciſores are ſmall; the canine are unequal in ſize, two being very large, and two very ſmall; the large ones are an inch and half long, and are the only ones the antients allowed to be canine teeth. The molares alſo are irregular in ſize, the anterior ones being very ſmall, the others large, and terminated by three or four points, forming a ſort of flower-de-luce.

Ariſtotle, Ælian, and others ſay, that the neck of the Lion is all compoſed of one unjointed bone. It appears indeed very rigid in this creature, but it does not proceed from ſo ſtrange a cauſe, but is found owing to this, that the ſpinoſe apophyſes of the vertebræ of the neck are long, and faſtened together by extremely ſtrong and rigid ligaments.

The tongue of the Lion is very rough and rigid, being covered with a great number of prominences of a hard matter, reſembling that of a cat's claws, and nearly of the ſame ſize, the baſe of each being a round fleſhy prominence on the ſurface of the tongue.

The eyes of the Lion are clear and bright, even after the creature is dead. The common obſervation that this creature ſleeps with its eyes open, is founded on this, that it has a very thick membrane lodged in the greater canthus of the eyes, which it can extend over the whole eye upon occaſion, as birds do their membrana nictitans, and thus will have no occaſion to ſhut its eye-lids, in order to exclude the light. It is very remarkable that the common cat has all the ſingular ſtructure of the ſeveral parts as the Lion has, its claws, feet, tongue and eyes, being of the ſame kind, and its internal parts bearing as ſtrong a reſemblance.

The heart of the Lion is greatly larger than that of any other creature of the ſame ſize, being ſix inches long, and four in diameter, in the largeſt part, and terminating in a very ſharp point. The brain is as remarkably ſmall; and, upon the compariſon of this with the great quantity of brain in a calf, and purſuing the obſervation through ſeveral other creatures, as to the proportion of brain they have, it does not appear that a ſmall quantity of brain is a mark of folly, but uſually of great ſubtlety, and of a cruel diſpoſition. *Mem. pour l'Hiſtoire des Anim.*

LION-*puceron*, in natural hiſtory, the name given by Mr. Reaumur to a genus of worms which deſtroy the pucerons in the ſame manner that the formica leo does the ants.

Theſe little inſects are prey alſo to a ſort of worm hatched from the egg of a two-winged fly. This has no legs, and is of ſeveral colours.

Though theſe Lion-pucerons be all hexapodes, yet they are of different origin; ſome being produced from the eggs of a four-winged fly, others from thoſe of a beetle. As the formica leo has two horns, the extremities of which ſerve him by way of mouth, our Lion-puceron has the ſame kind alſo; but as the former of theſe inſects can only move backwards, but is forced to make ſnares for his prey, not being able to hunt it; this creature runs very nimbly in the common way, and ſeizes its prey, without having recourſe to ſuch ſtratagems. The body of the Lion-puceron is longer than that of the formica leo, and is flat; the breaſt is the thickeſt and broadeſt part of it, and from this it gradually tapers off to a point at the tail. It has two legs fixed to the breaſt, the other four to the anterior rings of the body, and, when it moves, the poſterior end of the body ſerves it in the place of a ſeventh leg, for it always bends it downward, and draws it along the ſurface it walks upon. The back of this creature is not ſmooth or gloſſy, but is every-where rough, and full of wrinkles, and ſeems as if every ring of it was compoſed of ſeveral other ſmaller rings.

Mr. Reaumur put twenty of theſe creatures together into a box, where they had no other food, and where they could not eſcape one another, and theſe were very ſoon reduced to three or four. It is eaſy to conceive that a creature, which feeds ſo very faſt, muſt ſoon arrive at its full growth; and this is the caſe with theſe animals, for, within five or ſix days of their being hatched from the egg, they are ready for their final transformation, or the putting on the form of the animals to whoſe eggs they owed their origin. In order to this, the creature leaves the place where he has hitherto fed, and ſeeks the folds of a leaf, or ſome other ſuch convenient receptacle, where it ſpins a web of very fine ſilk, every way ſurrounding its body with it, and, under this cover, paſſes the ſtate of a nymph or chryſalis. The ſilk of this web is not only very ſtrong, but the threads are very cloſely laid together, ſo that it is much firmer than the webs of any of the caterpillar kind. It is of a roundiſh figure, and is ſomewhat ſmaller than a pea.

The eggs of this fly are a very ſingular object, and cannot have eſcaped the eye of any perſon who is converſant among the inſects which live on trees; though, of the many who have ſeen them, perhaps few or none ever found what they really were. It is common to ſee on the leaves and pedicles of the leaves of the plum-tree, and ſeveral other trees, as alſo on their young branches, a number of long and ſlender filaments, running out to about an inch in length, and being of the thickneſs of a hair; ten or twelve of theſe are uſually ſeen placed near one another, and a vaſt number of theſe cluſters are often found on the ſame tree. The end of each of theſe filaments is terminated by a ſort of ſwelling or tubercle of the ſhape of an egg. People who have obſerved theſe, have generally ſuppoſed them to be of vegetable origin, and that they were a ſort of paraſitical plants, growing out of others, as the miſletoe, moſſes, &c. from the oak and other trees. They very much reſemble in figure thoſe ſpecies of mouldineſs, which Malphigi and others have figured under the ſhape of little muſhrooms, only they are much larger than thoſe little plants, and bear the heat of the ſun and other accidents uninjured, which would deſtroy the tender plants of that kind. There is a time, when theſe egg-like balls, which terminate every one of theſe filaments, are found open at their ends, and in this ſtate they very much reſemble flowers; and they are in this ſtate figured by ſome authors, under the name of flowers of a ſingular kind, found on the leaves of the willow. All this, however, is wholly erroneous, and the purſuing the hiſtory of our Lion-pucerons ſhews their true origin to be from the fly of that creature. What theſe authors took for flowers of the willow, were only the eggs of this fly, out of which the young animals had been hatched, and had made their eſcape. The leaves and branches on which theſe eggs are found, are uſually ſeen covered over with the pucerons; and the creature, providing a place where her young ſhall find nouriſhment as ſoon as hatched, places her eggs in the midſt of theſe harmleſs and defenceleſs animals, fixing each on a ſlender pedicle, yet ſufficiently ſtrong to ſupport its weight. If theſe eggs be nicely examined, a worm may be diſcovered in them while yet whole; but the moſt certain way of judging them, is, to put ſeveral of them into a box, in which caſe every one of them is found at a proper time to hatch, and to give an inſect; which, when viewed by the microſcope, appears plainly to be a Lion-puceron in all its parts, and requiring only increaſe in ſize, without any change of ſhape, to be one of thoſe we have already deſcribed, as feeding ſo voraciouſly on the pucerons.

The manner in which the parent fly places her eggs in this ſingular way on the trees, is a ſubject that greatly excited the curioſity of Mr. Reamur. He often watched the animals in vain, in order to ſee them employed in it; and, in fine, ſhut up ſeveral of them in boxes. The conſequence of which was, that they fixed their eggs on long pedicles, to the ſides of the box, in the ſame manner that they before had to the ſides of the branches, or leaves of trees; but he never could find them employed about it. The manner in which he ſuppoſes it done, however, appears very rational, and is as follows: The egg is ſuppoſed, while in the body of the inſect, to be covered with a tough glutinous matter, capable of drying very ſuddenly in the air. The creature, when the egg begins to come forth, applies the extremity of it to ſome ſolid body, as a leaf, or ſtalk of a plant; and, then drawing herſelf away, there follows a thread or filament of this viſcous matter, which is faſtened at one end to the leaf, and at the other to the egg in her body. When ſhe has drawn this out, to an inch in length, ſhe ſtops a moment, and the whole will harden into a ſolid matter; and, on her next motion, will draw out the egg from her body, and will become a pedicle to it. In this condition it will remain till the egg is hatched, and then the young inſect needs only to deſcend downward on the leaf, on which the pedicle is fixed, and it will find itſelf in the midſt of plenty of food. *Reaumur's Hiſt. Inſ.*

LI'ONESS, *leæna*, a female lion. See LION.

The Lioneſs has no mane, or long hairs upon the neck and breaſt, which ſo remarkably characteriſes the lion. The noſe alſo is longer in the Lioneſs, and the head more flatted in the upper part; the claws alſo much ſmaller than thoſe of the male lion. This creature, when full grown, is about three feet high, from the fore feet to the ridge of the back; and about five feet long from the end of the noſe to the inſertion of the tail, which is about two feet and a half long. The claws are of a fibroſe texture, the fibres being very hard in themſelves, but eaſily ſeparable from one another. In other particulars, the Lioneſs very little differs from the lion. See *Plate* XXXII. *fig.* 6.

LIPOTHY'MIA, in medicine, the name of a diſeaſe uſually confounded with the ſyncope, but really different from it in many particulars.

The Lipothymia is a very conſiderable abolition of the vital and animal faculties, at leaſt to appearance: and the ſyncope is a plenary or total abolition of them, as far as appears to us at the time. It is eaſy to ſee, however, that theſe are only two

two different stages of the same distemperature. The lipothymy is sometimes an idiopathic, sometimes a symptomatic disease, and most frequently attends the scurvy, malignant fevers, and other disorders; the syncope is idiopathic, and attacks persons in health as well as those that are diseased. The lipothymy is always easily distinguished from a convulsed state of the body, by this, that the limbs are all flaccid in it. The syncope differs from death only in degree; and the body being flaccid in this, and growing rigid under the last convulsions in death, is the only distinction of them in extreme cases.

Anodyne mineral LIQUOR, the name given by Hoffman to a liquor of his own invention, famous at this time in Germany, and supposed by Burggrave to be made in this manner: take oil of vitriol and Indian nitre, of each four ounces; distil the spirit gradually from this by a retort; pour two ounces of this spirit cautiously and successively into fifteen ounces of spirit of wine highly rectified; distil this, and there comes over a very fragrant spirit. This is to be again distilled, to render it perfectly pure, adding first to it a small quantity of oil of cloves, and a quantity of water, equal to that of the spirit; after this, as soon as the watery vapours begin to arise, the whole process is to be stopped, and the spirit kept alone in a bottle well stopped. This has great virtues, as an anodyne, diaphoretic, antiseptic, and carminative. It is not certain, that it is exactly the same with Hoffman's, that author having never published his manner of making it; but it appears the same to the smell and taste, and has the same virtues.

LI'QUORICE (*Dict.*)— The ground designed for Liquorice must be well dug, and dunged the year before, that the dung may be thoroughly rotted in it; and, just before it is planted, the earth is to be dug three spades deep, and laid very light. The plants to be set should be taken from the sides or heads of the old roots, and each must have a very good bud, or eye, or otherwise they are subject to miscarry; they should also be about ten inches long, and perfectly sound. The best season for planting them is the end of February, or the beginning of March, and this must be done in the following manner: the rows must be marked by a line drawn a-cross the bed, at two feet distance; and the plants must be set in these by making a hole of their full depth, and something more, that the eye of the root may be an inch below the surface: they must also be set two feet distance from each other in the rows. When this is done, the ground may be sowed over with onions, which, not rooting deep, will do the Liquorice roots no injury for the first year. In October, when the stalks of the Liquorice are dead, a little very rotten dung should be spread over the surface of the ground. Three years after the time of planting, the Liquorice will be fit to take up for use; and this should be done just when the stalks are dead off; for, if taken up sooner, the roots are very apt to shrink greatly in their weight. The roots about London look browner than those which have been propagated in a less rich soil, but then they are much larger, and grow quicker to their size. *Miller's Gard. Dict.*

LIS, *or Notre Dame de Lis*, an order of knighthood of Navarre, instituted, in 1408, by Garcius IV, king of Navarre, upon occasion of an image of the blessed virgin found in a flower-de-luce at Nagera, and whereof he declared himself and his successors the sovereigns. The order consisted of 38 knights, of noble extraction, that took a vow to oppose the Moors, the enemies of the kingdom. They wore upon their breasts an embroidered flower-de luce of silver, and, on solemn festivals, a collar, interlaced with divers Gothic M's, with a flower-de-luce of gold, enamelled white, and springing from a green plat, hanging at the end of it, and a great M over it. *Favin. Hist. de Navarre, & Theatr. de Honneur & de Cheval.*

LI'TÆ, Λιται, according to Homer, are goddesses, the daughters of Jupiter, whose office was to procure for men the good things they desired either of God, or of other men. Homer represents them to be lame, squint-eyed, and wrinkled, the allegorical meaning whereof is not to be rejected. These Litæ are nothing else but our prayers and supplications; for that is the signification of the Greek word λιτη, whence comes the word λιτανεια, or litany, and the Latin word litare, which imports the offering up an acceptable service or prayer to God. Now our prayers are represented lame, to denote, that God doth not immediately grant men their desires, and therefore the need we have of fervour and perseverance in our prayers; they are squint-eyed, to represent the corrupt and selfish respects of our prayers, as in them we commonly do not purely and directly regard the glory of God; and they are wrinkled and shrivelled, to set out to us the weakness, staggerings, and doubtings wherewith they are accompanied, as commonly wanting the strength, vigour, and liveliness of faith. If we would apply this picture of prayer to those petitions we address to men, they also are lame, to declare to us the difficulty we have to approach persons of whom we would desire any favour or kindness. They are squint-eyed, by reason of the dissimulations, flatteries, by-ways, and sinister respects we are fain to make use of, to obtain of them what we desire; and they are wrinkled, to give us an idea of the trouble, disappointment, grief, and vexation it costs us, either before we can resolve to desire any thing of men, and, when we have desired it, before we can obtain it.

LITHAN'THRAX, in natural history, is used as the name of the common pit-coal

LITHI'DIA, in natural history, the name of a large class of fossils, including the flint and pebble kinds.

LITHO'LABON, a name given by some chirurgical writers to an instrument used in the operation of lithotomy; it is a forceps intended for taking hold of the stone.

LITHONTRI'PTICON *Tulipii*, the name of a famous diuretic medicine, invented by Tulipus, and given with great success in cases of the stone, but requiring great judgment and caution in the administring it.

The preparation is this: take a drachm of cantharides without their wings, and a drachm of lesser cardamoms without their husks; powder them fine, and pour upon them an ounce of rectified spirit of wine, and half an ounce of spirit of nitre: set them to infuse, without heat, for five or six days, stirring them from time to time. The phial must not be stopped close; because, if it be, the continual fermentation will burst it. The dose is from fourteen to fifteen, or twenty drops, in a glass of wine and water; it is to be taken in a morning, an hour after the eating a mess of broth, and may be repeated for three or four days.

It is remarkable, that this mixture never ceases fermenting for many years; but, if it be too fast corked, will break the glass; if but slightly stopped, it only throws out the cork with an explosion. *Mem. Acad. Par.*

LITHO'PHYTON, *coral*, in botany; see CORAL.

LITHOPHO'SPHORUS *fublensis*, in natural history, a name given by some authors to a species of spar, which, when it has been heated over the fire, retains a property of giving light in the dark. This is a quality that seems more or less in degree to be inherent in several sorts of spars.

LI'TTER.—When a horse comes tired into a stable, fresh Litter has the virtue always to occasion him immediately to stale. This is known to be a very great advantage to a horse in a tired state; and when the Litter is old and dirty, it never has any such effect upon him. If the owner knew how refreshing it is to a horse to discharge his urine on his return from labour, they would be more careful in giving him all means and occasions of it than they do. This staling, after fatigue, prevents those obstructions in the neck of the bladder or urinary passages, which horses are subject to; the bladder being often inflamed by the long retention of the heated urine in it, and the creature perishing by it. Some of our farmers act wrong in this case of the Litter, not through carelessness or accident, but by principle; they order the old Litter to be left a long time in the stables, that it may be impregnated with more and more of the urine, &c. of the animal, and be made richer for the fields. It is not to be doubted but the manure is greatly improved by this; but the damage done to the horse, by it, is greatly over-proportioned to the benefit. The heat which the dung acquires, by thus lying together, spoils the feet of the creature, and makes it unfit for any service, and occasions many distempers, which are ignorantly continued and increased by the continual addition of heat in the fermenting dung, till at length the horse perishes.

LI'VER (*Dict.*)— From the structure of the Liver, duly considered, it will be easy to understand the distempers to which this organ is subjected in a particular manner: the first, and most acute of these, is an inflammation, called hepatitis; which, perhaps, occurs more frequently than is generally apprehended; but, however, not so often as one would be subject to imagine, from the conformation of the part, unless it were considered, that the hepatic artery is not very large, and, therefore, cannot convey to the Liver a great quantity of blood; and that the force of the blood, circulating through the ramifications of the vena portæ, is not so considerable as to subject this organ very much to inflammations.

An inflammation of the Liver is seated in the extremities of the ramifications of the vena portæ, or hepatic artery; and it is evident, from the disposition of these vessels, that an inflammation in either of them must soon be succeeded by one in the other.

The antecedent causes of both these species of inflammation are the same as the general causes of inflammations (see INFLAMMATION) determined to this organ. But there are other causes, which are local, and relate more immediately to the particular part: thus an extraordinary degree of fatness, in the omentum, may raise an inflammation in the Liver, not only by compressing it, but this fat may also dissolve by exercise, motion, and heat, and, being absorbed by the vessels, and conveyed to the Liver in too large quantities, may there cause an inflammation.

This effect may, also, be produced by an atrabilarious temperament of the blood or bile; for when such a temperament is induced by an intimate union of the earth and oil, and a dissipation of the spirituous and aqueous particles of the blood or bile, either of these humours become subject to form concretions and stagnations in the minute extremities of the branches of the hepatic artery, or vena portæ.

The Liver, also, suffers from disorders in remote parts of the body; for, if acrimonious pus, ichor, or a scorbutic sanies, is deposited in any other organ or member, these, upon the accession of heat, a fever, violent motion, an improper diet, ill-

ill-applied medicines or poisons, are colliquated, moved, returned into the circulation, and, by this means, conveyed to, and deposited in, the Liver.

Besides these causes, the bile, when pinguious, acrimonious, and exalted, or what the ancients called adust, if put in motion by adequate causes; a stone, chalky concretions, a scirrhus, callus, steatoma, abscess, or worms, occupying any part of the Liver, gall-bladder, or biliary ducts, upon the accession of any cause sufficient to put them in motion, by compressing the small ramifications of the hepatic artery and vena portæ, excite therein an inflammation.

Cold, also, applied to the Liver, when, by any means overheated, contracts the vessels, inspissates the fluids, and thus produces an immediate inflammation; and this cold has much the same effect, whether it is applied by means of the air, liquors drank, or bathing.

An abstinence from diluting liquors, during excessive motion, great heat, and profuse sweating, will also cause an inflammation of the Liver; for, when the blood is deprived of its aqueous parts, without a fresh supply, it becomes thick, and, consequently, inclining to stagnate in the capillary vessels. Abstinence, likewise, especially from drink, in burning fevers, will, for the same reason, produce a like effect: and the same disorder may be brought on by violent passions and perturbations of the mind, which induce spasmodic strictures in the vessels of the Liver, and an irregular circulation; as it frequently happens, in some degree, during hysteric disorders, as Sydenham remarks.

Among the causes of an inflammation in this organ, excessive motion, excited by emetics, must, farther, be reckoned as one; for, by these, some vessels in the Liver may be ruptured; or the blood, contained in all the abdominal viscera, may be impelled with violence into the vena portæ, and thence being conveyed, in too large quantities, into the Liver, or too forcibly, or both, in either case excite an inflammation.

Lastly, inveterate hypochondriac disorders will produce inflammations of the Liver.

The effects of inflammations of the Liver, arising from any of these causes above specified, are various, and determined by the various preceding dispositions of the Liver, the variety of the matter which is moved and fixed upon the Liver, the material cause of the inflammation, and the different causes which excite the matter to action, and impel it upon the Liver.

When the case is only a simple inflammation, the small vessels are obstructed; and, in consequence of this, the fluids, which ought to circulate through them, are stopped in the part: hence a tumor arises, which compresses the adjacent parts, and, by that means, propagates the tumor to them; thus it proceeds, till almost the whole organ is affected, which then compresses the stomach, and is again compressed by the stomach when full; which compression is attended with pain in the inflamed Liver. It also affects the diaphragm, and sometimes excites pain and inflammation in that part by compressing it, on account of its near situation. Besides, all the blood received by the cœliac artery, and the two mesenteric arteries, is intercepted and stopped at the Liver; and, in consequence of this, the circulation of all the venous, arterial, and lymphatic fluids, in the principal viscera of the abdomen, is utterly obstructed; and the generation, secretion, excretion, and circulation of the bile are entirely hindered. Hence a jaundice is produced, with all its consequences; putrefactions of the abdominal viscera, together with their contained fluids; and a great number of ill consequences, which are obvious; for the uses of the bile, and the functions of the parts are thus destroyed.

LI'VERWORT; see LICHEN in the Dictionary and Supplement.

LIXI'VIUM *martis*, a new form of medicine introduced into practice in the late London Dispensatory. The manner of preparing it is to set the matter remaining in the retort after the subliming the flores martis, in a damp place, where, by means of the moisture of the air, it will run into a liquor. *Pemberton's Lond. Dis.*

LIXIVIUM *tartari*, the name given in the London Dispensatory to the liquor called, by most authors, oil of tartar per deliquium. This is made of tartar which is to be calcined to a whiteness, and then set in a damp place, where it will liquify by the moisture of the air. The liquor thus procured is more pure, than if the calcined tartar were dissolved directly in water. *Pemberton's Lond. Dis.*

LI'ZARD *lacertus*, in zoology, the name of a large genus of animals, comprehending all those quadrupeds which are oviparous, and have long tails continued from their bodies. The term oviparous is to be understood however in a larger sense, expressing some among these, which, though they have true and proper eggs within them, yet never deposit them as such, but keep them in their bodies till they are hatched, and bring forth living young ones. Some of the serpents, as well as some of the Lizards, are of this kind, and the observation is as old as Aristotle, who calls the creatures, whose generation is of this kind, internally oviparous, externally viviparous. *Ray's Syn. Quad.*

LOAD, in mining, is used, especially in the tin mines, for a vein of ore.

In Cornwall and Devonshire the Loads all hold their course from eastward to westward, though, in other parts of England, they frequently run from north to south. The miners report, that the sides of the Load never bear in a perpendicular, but always over-hang either to the north or south. The mines seem to have been so many channels, through which the waters pass within the earth, and, like rivers, they have their small branches opening into them, in all directions; these are by the miners termed the feeders of the Load. Most mines have streams of water running through them, and, when they are found dry, it seems owing to the water having changed its course, which it seems sometimes to have been compelled to by the Load's having filled up the course, and sometimes to have fallen into other more easy channels. *Philos. Transact.* Nº. 401.

LOAM, in husbandry, a common superficial earth, that is a mixture of sand and clay, commonly of a yellowish colour, though there is some Loam that is blackish. Some call Loam the most common superficial earth met with in England, without any regard to the proportion it bears to sand or clay; but most generally the appellation of the Loam is applied to a soft fat earth, partaking of clay, but easy to work.

It is found by experience, that plants of all sorts will grow in it; and, where-ever it is found, it appears to be a more beneficial soil to plants than any other. A clay used in grafting is also called Loam.

LO'CKSPIT, among miners, is the small cut or trench made with a spade of about a foot wide, to mark out the first lines of a work.

LO'CRIAN, in ancient music, the seventh species of the diapason. It was also called hypodorian and common.

LOCU'LAMENTS, in natural history, little distinct cells, or partitions, within the seed-vessels of plants.

LO'CUSTS, *locustæ*, a genus of insects, comprehending the Locust, simply so called, the several species of other Locusts and grasshoppers, with the crickets of the house and field.

Willughby observes, that in these animals there are always more males than females, which is contrary to the order of nature in other insects, where the females are much the most numerous; and Swammerdam observes, that it is only the males that make a noise, which he says they do by a swift vibration of their wings, either against one another, or against their legs.

The nympha, or worm of the Locust, scarce at all differs from the creature in its perfect state. It moves and eats in the nymph state, and all the visible difference is, that the wings are not expanded as in the perfect Locust, but are gathered up in a small compass, and form four little buttons on the shoulders. Swammerdam observes, that the want of attention to this particular, in former writers, had been the occasion of a very unnecessary multiplication of names; as Aldrovand, Johnson, Mouffet, and others, have described these Locusts in the nymph state under the names of bruchi, attebali, and aselli, supposing them to be so many distinct species of animals. It is observed, that towards the end of summer the males are very tender of the females, three or four of them being frequently seen gathered about one of that sex, and seeming to do her all the kind offices in their power, fluttering about with their wings, and rubbing her with their fore legs. The males are always more brisk and nimble than the females; and, amongst all the kinds of Locusts, there are a great many naturally imperfect; particularly, many have only one hinder leg, yet these hop almost as well as the rest.

The country of the Cossacks or Ukrain is, in dry summers, much infested with swarms of Locusts driven thither by an east or south-east wind. The number of these insects is so great, that they darken the air, and devour all the corn of the country. They lay their eggs in autumn, and then die. It is said that each of these creatures lays two or three hundred eggs, which hatching the ensuing spring, produce such a number of Locusts, that they do far more mischief than before, unless the rains fall, which kill both the eggs and the insects, or unless a strong north or north-west wind arises, which drives all into the Euxine sea. The hogs of the country are fond of these eggs, and devour great quantities of them. In the night, when these insects rest on the ground, they cover it to the height of three or four inches. If a wheel passes over them, they emit an intolerable stench. *Phil. Transf.* Nº. 8.

Water LOCUST, *locusta aquatica*, the name given by authors to a species of water insect, somewhat resembling the Locust kind in shape. It is about three inches long, its tail an inch and a quarter, and its legs are of different lengths; the anterior pair being shortest of all. Its body is slender, and its fore legs are always carried straight forward, so as to reach beyond the head in the form of antennæ. These, as well as the other legs, end each in two claws. The eyes are small and not very prominent, and the upper wings are crustaceous, the under ones membranaceous, thin, and transparent. The middle joint of the leg is such, that the creature can only move them upwards, not downwards; and there runs an acute tongue or

proboscis

proboscis under the belly, as is the case in the water scorpion and notonecta. *Ray's Hist. Inf.*

LOG, in the Jewish antiquities, a measure which held a quarter of a cab, and consequently five sixths of a pint. There is mention of a Log, 2 Kings VI. 25, under the name of a fourth part of a cab. But, in Leviticus, the word Log is often met with, and signifies that measure of oil, which lepers were to offer at the temple after they were cured of their disease.

Dr. Arbuthnot says, that the Log was a measure of liquids, the seventy-second part of the bath or ephah, and twelfth part of the hin, according to all the accounts of the Jewish writers.

To rectify the LOGA'RITHMIC *Curve*. Let it be required to find the length of the Logarithmic arc E *e* (*Plate* XXX. *fig.* 1.) draw the perpendiculars L L A, *e l a*, to the asymptote, and having drawn the tangents E F, *e f*, take A L equal to the excess of the tangent above the sub-tangent A F; and *a l* equal to the excess of the tangent *e f* above *a f*; then having drawn L M, *l m*, parallel to the asymptote, if the difference of the tangents E F — *e f* be added to the difference of the parallels *l m* — L M, the aggregate will be equal to the arc E *e*. *Cote's Harm. Mens.*

LO'GARITHMS (*Dict.*)—Under this article in the Dictionary, we have shewn, that if the infinite root be extracted out of any number, the difference between that root and unity will be the Logarithm of that number.

But because the infinite root of $1-x,^{\frac{1}{n}}$ or $\overline{1-x}\,^{\frac{1}{n}}$, is $1-\frac{1}{n}x-\frac{1}{2n}x^2-\frac{1}{3n}x^3-\frac{1}{4n}x^4$, &c. therefore $\frac{1}{n}$ multiplied into $x+\frac{1}{2}x^2+\frac{1}{3}x^3+\frac{1}{4}x^4+\frac{1}{5}x^5$, &c. will be the Logarithm of the ratio of 1 to $1-x$, or the Logarithm of a number less than unity; and, whereas the infinite index n may be taken at pleasure, the several scales of Logarithms to such indexes will be reciprocally as $\frac{1}{n}$, or the several indices, and if the index be taken 10000000, &c. the respective Logarithms will be, simply,

$$x \mp \frac{1}{2n}x^2 + \frac{1}{3n}x^3 \mp \frac{1}{4n}x^4 + \frac{1}{5n}x^5, \text{ \&c.}$$

Let a represent the least of any two given numbers, and b the greatest, z the sum of the two numbers, and d the difference; and let us suppose the ratio of a to b to be divided into that of a to $\frac{1}{2}z$, and of $\frac{1}{2}z$ to b; that is, into the ratio of a to the arithmetical mean between the two numbers and the ratio of the said arithmetical mean to the greater number b; then, because $\frac{a}{\frac{1}{2}z}\times\frac{\frac{1}{2}z}{b}=\frac{a}{b}$, the log. of $\frac{a}{\frac{1}{2}z}$ + log. $\frac{\frac{1}{2}z}{b}$ = log. $\frac{a}{b}$, or because $\frac{\frac{1}{2}z}{a}\times\frac{b}{\frac{1}{2}z}=\frac{b}{a}$, the log. of $\frac{\frac{1}{2}z}{a}$ + log. $\frac{b}{\frac{1}{2}z}$ = log. $\frac{b}{a}$, that is, the sum of the Logarithms of these two ratio's will be Logarithms of the ratio of a to b; and to find the value of each of these ratio's, in the terms of 1 and $1\pm x$, we must say, $\frac{1}{2}z : a :: 1 : 1-x$, whence $x=\frac{\frac{1}{2}z-a}{\frac{1}{2}z}=\frac{d}{z}$, and again as $\frac{1}{2}z : b :: 1 : 1+x$, whence $x=\frac{b-\frac{1}{2}z}{\frac{1}{2}z}=\frac{d}{z}$ and substituting $\frac{d}{z}$ in the room of x, in each of the former series, we shall have $\frac{1}{n}\times\frac{d}{z}+\frac{d^2}{2z^2}+\frac{d^3}{3z^3}+\frac{d^4}{4z^4}+\frac{d^5}{5z^5}$, &c. for the Log. of the ratio of a to $\frac{1}{2}z$, and $\frac{1}{n}\times\frac{d}{z}-\frac{d^2}{2z^2}+\frac{d^3}{3z^3}-\frac{d^4}{4z^4}+\frac{d^5}{5z^5}$, &c. for the Logarithm of the ratio of $\frac{1}{2}z$ to b; and consequently the sum of these two series $\frac{1}{n}\times\frac{2d}{z}+\frac{2d^3}{3z^3}+\frac{2d^5}{5z^5}$, &c. or $\frac{1}{n}\times 2\times\frac{d}{z}+\frac{d^3}{3z^3}+\frac{d^5}{5z^5}+\frac{d^7}{7z^7}+\frac{d^9}{9z^9}$, &c. will be the Logarithm of the ratio of a to b, whose difference is d, and sum z; whence, to find the Logarithm of any prime number, we have this general rule:

To the given number add 1 for a denominator or divisor, and subtract 1 from the same given number for a numerator or dividend; then, of the vulgar fraction thence resulting, compose all the odd powers thereof, these will form a series of numbers, which being divided by their respective exponents, viz. 1, 3, 5, 7, 9, &c. will produces a series of quotients, whose sum will be the natural Logarithm of the number proposed, according to Neper's form.

This rule is not only very easy to be retained in the memory, but very proper for the practice of making Logarithms, which it performs with very great expedition, as will appear hereafter; and is so very plain that it may be taught to persons of a mean capacity.

It was first published by Mr. James Gregory, in a treatise of his, written by himself, and printed in the year 1668, wherein that excellent geometrician has shewn the analogy between the Logarithms and certain hyperbolic spaces, and by shewing us how to square the one, has taught us how to construct the other; and the truth of the same law has long since that time been demonstrated independent of the hyperbola, from a consideration of the properties of the Logarithms only, and by the help of Sir Isaac Newton's general theorem, for extracting of roots and raising of powers.

Let it be required to find the Logarithm of 2, the first prime number.

Because $a=1$, and $b=2$, therefore, $d=b-a=2-1=1$, and $z=a+b=1+2=3$; wherefore $\frac{d}{z}=\frac{1}{3}$, and $\frac{d^2}{z^2}=$:

Hence $\frac{1}{3}+\frac{1}{3}\times\frac{1}{27}+\frac{1}{5}\times\frac{1}{243}+\frac{1}{7}\times\frac{1}{2187}$, &c. equal to $\frac{1}{3}+\frac{1}{81}+\frac{1}{1215}+\frac{1}{5209}$, &c. will be the natural Logarithm of 2, and consequently $\frac{2}{3}+\frac{2}{81}+\frac{2}{1215}+\frac{2}{15309}$, &c. will be the Logarithm of the same number in Neper's form, wherefore if the several fractions be added together, and reduced into an equivalent decimal, we shall have the Logarithm of the number given; but because to multiply by $\frac{1}{9}$, and divide by 9, will produce the same effect, if the first fraction be reduced into a decimal fraction, and that be divided by 9, and each successive quotient by the same, we shall have a series of quotients, which being divided by the several co-efficients 1, 3, 5, 7, 9, &c. the sum of these last quotients will give the Logarithm of the number given; and in order to obtain the Logarithm true to any number of places, it is necessary to continue the fraction to one or two more places than the intended number of places the Logarithm is to consist of; so that, to have the Logarithm true to 10 places, it will be convenient to find the value of $\frac{1}{3}$ in decimals to 11 or 12 places.

The operation is as follows.

$\frac{1}{3}$ =	333.333.333.333 =	333.333.333.333	+
$\frac{1}{9}$	37.037.037.037 its $\frac{1}{3}$ =	12.345.679.012	+
$\frac{1}{9}$	4.115.226.337 its $\frac{1}{5}$	823.045.268	—
$\frac{1}{9}$	— 457.247.371 its $\frac{1}{7}$	— — 65.321.053	
$\frac{1}{9}$	— 50.805.263 its $\frac{1}{9}$	— — 5.645.029	+
$\frac{1}{9}$	— 5.645.029 its $\frac{1}{11}$	— — 513.185	—
$\frac{1}{9}$	— 627.225 its $\frac{1}{13}$	— — 48.248	
$\frac{1}{9}$	— 69.691 its $\frac{1}{15}$	— — 4.646	
$\frac{1}{9}$	— — 7.743 its $\frac{1}{17}$	— — 456	—
$\frac{1}{9}$	— 860 its $\frac{1}{19}$	— — 45	+
$\frac{1}{9}$	— — 96 its $\frac{1}{21}$	— — 5	—
The nat. Logarithm of 2 is		346.573.590.280	
		2	
The Neper's Log. of 2 is	—	693.147.180.560	

Hence 346. 573. 590. 280. the natural Logarithm of 2 being doubled, will give 693. 147. 180. 560. for the natural Logarithm of 4; and this again, being doubled, will give 1386. 294. 361. 120, &c. for the natural Logarithm of 16, &c. in like manner 1386. 294. 361. 120. the double of 693. 147. 180. 560. the Neper's Logarithm of 2 will give the Neper's Logarithm of 4, and this again, being doubled, will give 2772. 588. 722. 240. for the Neper's Logarithm of 16, &c.

Again, as the natural Logarithm of 2 being multiplied by 3, will produce 1039. 720. 770. 840. for the natural Logarithm of 8; so the Neper's Logarithm of 2 being trebled, will give 2079. 441. 541. 680. for the Logarithm of 8, &c.

Again, if the Logarithm of 8 be multiplied by the Logarithm of 1 $\frac{1}{4}$, we shall have the Logarithm of 10; and to find the Logarithm of 1 $\frac{1}{4}$, we have given $a=1$, $b=1\frac{1}{4}$, $=\frac{5}{4}$, whence $z=\frac{9}{4}$, and $d=\frac{1}{4}$, and consequently $\frac{d}{z}=\frac{1}{9}$, and $\frac{d^2}{z^2}=\frac{1}{81}$

$\frac{1}{9}$ =	111.111.111.111 =	111.111.111.111	
$\frac{1}{81}$	1.371.742.112 its $\frac{1}{3}$	— 457.247.371	
$\frac{1}{81}$	— 16.935.087 its $\frac{1}{5}$	— — 3.387.017	
$\frac{1}{81}$	— 209.075 its $\frac{1}{7}$	— — 29.868	
$\frac{1}{81}$	— — 2.581 its $\frac{1}{9}$	— — 287	
$\frac{1}{81}$	— — 32 its $\frac{1}{11}$	— — 3	
The natural Log. of 1 $\frac{1}{4}$ =		111.571.775.657	
		2	
The Neper's Log. of 1 $\frac{1}{4}$ =		223.143.551.314.	

As 1039. 720. 770. 840. the natural Logarithm of 8 being added to 111. 571. 775. 657. will give 1151. 292. 546. 497. for the natural Logarithm of 10; so 2079. 441. 541. 680. the Neper's Logarithm of 8 being added to 223. 143. 551. 314. the Neper Logarithm of 1 $\frac{1}{4}$ will give 2302. 585. 092. 994. for the Neper's Logarithm of 10.

As these Logarithms which are called Neper's Logarithms, were those that were first published by Neper the inventor himself, in the year 1614; so these that are called the natural Loga-

Logarithms were those that were published, in the year 1619, by John Spidel, then a professor of mathematics in London, to which they fixed tables of artificial sines, tangents, and secants; but as these being found not so proper for the business as could be wished for, the inventor himself, with the assistance of Mr. Henry Briggs, altered the form, and made the Logarithm of 10 to be 1,0000000000, &c. and not 2,30258509299, &c. that is, he made the number 10 the 10000000000th, &c. term is the series, whence the Logarithm of 100 will be 20000000000, &c. that is, the number 100, will be placed in the 20000000000th place in the series, and the Logarithm of 1000 will be the 30000000000, &c. that is, the number 1000 will be the 30000000000th term in the series, &c. whence the Logarithms of all numbers between 1 and 10 will begin from 0, that is, they will have 0, for the first term towards the left hand, inasmuch as they are each of them less than the Logarithm of 10, which has unity in the first place; in like manner the Logarithm of all numbers between 10 and 100 begin from unity, inasmuch as they are all greater than 1,000000000, &c. and less than 2,0000000000, &c. for the same reason, the Logarithms of all numbers between 100 and 1000 begin from 2, since they are all greater than the Logarithm of 100, which is fixed at 2, and less than the Logarithm of 1000, which is made equal to 3; after the same manner the Logarithms of all numbers between 1000 and 10000 will begin from 3, and the Logarithms of all numbers between 10000 and 100000 will begin from 4, that is, they will have a 4 for the first figure towards the left hand, &c. The first figure of every Logarithm towards the left hand, which is separated from the rest by a point, is called the index or characteristic of that Logarithm, inasmuch as it shews or points out the highest or remotest place of that number from the place of unity in the infinite scale of proportionals towards the left hand. Thus, if the index of the Logarithm be 1, it shews that its highest place towards the left hand is the tenth place from unity. If the index be 2, it shews that its highest place towards the left hand from the place of unity is the hundredth place; and as all the Logarithms that have 1 for their index will be found between the 10th and 100th place from unity, in the order of numbers; so all the Logarithms which have 2 for their index, will be found between the 100th and 1000th place, in the order of numbers, &c. whence the index or characteristic of any Logarithm is always less by one than is the number of figures, which correspond or answer to the given Logarithm.

Now, inasmuch as all scales of Logarithms are made up of similar quantities, it will be easy from any scale of Logarithms whatsoever to form another scale of Logarithms in any given ratio, and consequently to reduce any table of Logarithms into another of any given form, by saying, as any one Logarithm in the given form is to its correspondent Logarithm in the new form; so is any other Logarithm in the given form to its correspondent Logarithm in the required form; and hence we are taught how to reduce either Neper's or the natural Logarithms into the form of Briggs's and the contrary.

For as 2,302, 585, 092, 994, the Neper's Logarithm of 10, is to 1.0000000000, the Brigg's Logarithm of 10; so is any other Logarithm in Neper's form to the correspondent tabular Logarithm in Briggs's form; and, inasmuch as the two first numbers constantly remain the same, if the Neper's Logarithms of any one number be divided by 2.302, 585, &c. or multiplied by 434, 294, 481, 903, the ratio of 1,000,000, &c. to 2, 302, 585, &c. as is found by dividing 1,000,000, &c. by 2302, 58, &c. the quotient in the first case, and product in the last case, will give the correspondent Briggs's Logarithm, and the contrary.

It has been already shewn, that $\frac{1}{n} \times x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4$, &c. equal to $\overline{1+x}^{\frac{1}{n}} - 1$, will be the Logarithm of the ratio of 1 to $1+x$, where n represents an infinite index, and x any number taken at pleasure. Now, if L be put for the Logarithm itself, then $\overline{1+x}^{\frac{1}{n}} - 1$ will be equal to L, consequently, $\overline{1+x}^{\frac{1}{n}}$ will be equal to $L+1$, and $1+x$ equal to $\overline{L+1}^{n}$; and because $\overline{L+1}^{n} = 1 + nL + \frac{nn-n}{2}L^2 + \frac{n^3+3n^2+2n}{6}L^3 + \frac{n^4-6n^3+11n^2-6n}{24}L^4$, &c. by the general theorem, when n is finite, when n becomes infinite to $\overline{L+1}^{n}$ will be equal to $1 + nL + \frac{1}{2}n^2L^2 + \frac{1}{6}n^3L^3 + \frac{1}{24}n^4L^4 + \frac{1}{120}n^5L^5 + \frac{1}{720}n^6L^6 + \frac{1}{5040}n^7L^7$, &c. $= 1+x$. In like manner, because $\frac{1}{n} \times x + \frac{1}{2}x^2 + \frac{1}{3}x^3 + \frac{1}{4}x^4 + \frac{1}{5}x^5 + \frac{1}{6}x^6$, &c. equal to $1 - \overline{1-q}^{\frac{1}{n}}$ is the Logarithm of the ratio 1 to $\overline{1-x}$, $1 - \overline{1-x}^{\frac{1}{n}}$ will be equal to L, consequently $\overline{1-x}^{\frac{1}{n}} = \overline{1-L}$, and $1-x = \overline{1-L}^{n}$, wherefore, by the same general theorem, $1-x = \overline{1-L}^{n}$ will be equal to $1 - nL + n^2L^2 - \frac{1}{6}n^3L^3 + \frac{1}{24}n^4L^4 - \frac{1}{120}n^5L^5 + \frac{1}{720}n^6L^6 - \frac{1}{5040}n^7L^7$, &c.

Whence $1 \pm x = 1 \pm nL + \frac{1}{2}n^2L^2 \pm \frac{1}{6}n^3L^3 + \frac{1}{24}n^4L^4 \pm \frac{1}{120}n^5L^5$, &c. which is a general theorem for finding the number from the Logarithm given, of any form whatsoever.

And because $n = 1000000$, &c. in Neper's form, $1 \pm x = 1 \pm L + \frac{1}{2}L^2 \pm \frac{1}{6}L^3 + \frac{1}{24}L^4 \pm \frac{1}{120}L^5$, &c. will give the number answering to any Logarithm in Neper's form.

Hence any one term of the ratio whereof L is the Logarithm, being given, the other term will be obtained readily; for, putting a for the lesser of the two terms, and b for the greater, $a \times 1 + L + \frac{1}{2}L^2 + \frac{1}{6}L^3 + \frac{1}{24}L^4 + \frac{1}{120}L^5$, &c. will give the greater; and $b \times 1 - L + \frac{1}{2}L^2 - \frac{1}{6}L^3 + \frac{1}{24}L^4 - \frac{1}{120}L^5$, &c. will give a the lesser, in Neper's form. Or, $a \times 1 + nL + \frac{1}{2}n^2L^2 + \frac{1}{6}n^3L^3 + \frac{1}{24}n^4L^4 + \frac{1}{120}n^5L^5$, &c. $= b$: and $a \times 1 - nL + \frac{1}{2}n^2L^2 - \frac{1}{6}n^3L^3 + \frac{1}{24}n^4L^4 - \frac{1}{120}n^5L^5$, &c. $= a$, in any form.

Let d stand for the difference between the given Logarithm, and the next nearest tabular Logarithm; then will $a \times 1 + d + \frac{1}{2}d^2 + \frac{1}{6}d^3 + \frac{1}{24}d^4 + \frac{1}{120}d^5$, &c. $=$ N. Or, $b \times 1 - d + \frac{1}{2}d^2 - \frac{1}{6}d^3 + \frac{1}{24}d^4 - \frac{1}{120}d^5$, &c. $=$ N, the number required in Neper's form. Or, $a \times 1 + nd + \frac{1}{2}n^2d^2 - \frac{1}{6}n^3d^3 + \frac{1}{24}n^4d^4 - \frac{1}{120}n^5d^5$, &c. $=$ N. And, $b \times 1 - nd + \frac{1}{2}n^2d^2 - \frac{1}{6}n^3d^3 + \frac{1}{24}n^4d^4 - \frac{1}{120}n^5d^5$, &c. $=$ N, the correspondent number in Logarithms of any species.

Let it therefore be required to find the number answering to 7.5713740282 in Briggs's form.

Because 7.5713710453, the nearest tabular Logarithm to this, is less than the given number, put 37271000 the number answering to it, equal to a, and the difference between the two Logarithms 0000029827 equal to d, then will n equal to 230258, &c. multiplied by d, produce 0000068683; which being increased by 1, and multiplied by 37271000, the next nearest number in the table will give 37271255.988 for the number answering to the given Logarithm: or, if 0000068683 be multiplied by a, equal to 37271000, the product 255.998 increased by a, equal to 37271000, will give 37271255,988 for the number required, and after the same manner may the number answering to any given Logarithm be found.

Hence, and from the general theorem, may the number answering to any Logarithm be found, and consequently an antilogarithmic canon be constructed, shewing the natural numbers answering to every Logarithm, set down in a natural order from 1 to 100.000, whence the number answering to any Logarithm might be found with the same ease as we find the Logarithm for any number in the logarithmic canon.

Imaginary LOGARITHM, is used for the Logarithm of negative and imaginary quantities, such as $a - \sqrt{-a}$, &c. Thus also the fluents of certain imaginary fluxionary expressions, such as $\frac{\dot{x}}{x\sqrt{-1}}$, $\frac{a\dot{x}}{2bx\sqrt{-1}}$, &c. are imaginary Logarithms.

The expression $\frac{\dot{x}}{x}$ represents the fluxion of the Logarithm of x, and the fluent thereof $\frac{\dot{x}}{x}$ is the Logarithm of x; but no Logarithm can represent the fluent of $\frac{\dot{x}}{x\sqrt{-1}}$, which is therefore called an imaginary Logarithm.

However, when these imaginary Logarithms occur in the solutions of problems, they may be transformed into circular arcs or sectors; that is, the imaginary Logarithm, or imaginary hyperbolic sector, becomes a real circular sector.

LONGITU'DINAL *Vessels*, in plants, are such as are extended in length through the woody part of trees and plants, into which the air is supposed to enter, and mix with the juices of the plant, and thereby augment its bulk.

LONI'CERA, *upright honeysuckle*, in botany, a genus of plants, whose characters are:

The flower is tubulous, and of one leaf, which is deeply cut into several segments, which are reflexed: from the empalement arise six long stamina, surrounding the pointal, which are extended the length of the petals: the ovary rests on the empalement, which afterwards turns to a berry, in which are included one or two compressed seeds, surrounded by a glutinous pulp.

LOOL, in metallurgy, a vessel made to receive the washings or ores of metals. The heavier or more metalline part of the ores remaining in the trough in which they are washed; the lighter, and more earthy, running off with the water, but settling in the Lool. *Ray's English Words.*

LOOME, at sea. If a ship appears big, when seen at a distance, they say she Loomes, or appears a great sail.

LOOP, in the iron works, is a part of a sow or block of cast iron broken or melted off from the rest, and prepared for the forge

forge or hammer. The usual method is, to break off the Loop of about three quarters of a hundred weight. This Loop they take up with their slinging tongs, and beat it with iron sledges upon an iron plate near the fire, that so it may not fall to pieces, but be in a condition to be carried under the hammer. It is then placed under the hammer, and, a little water being drawn to make the hammer move but slowly, it is beat very gently, and by this means the dross and foulness are forced off, and after this they draw more and more water by degrees, and beat it more and more till they bring it to a four-square mass, of about two feet long, which they call a bloom. *Ray's English Words.*

LOO'PING, in metallurgy, a word used by the miners of some counties of England, to express the running together of the matter of an ore into a mass, in the roasting, or first burning, intended only to calcine it so far as to make it fit for powdering. This accident, which gives the miners some trouble, is generally owing to the continuing the fire too long in this process. *Ray's English Words.*

LO'PPING.—It is very observable that most old trees are hollow within; which does not proceed from the nature of the trees, but is the fault of those who have the management of them who suffer the tops to grow large before they lop them; as the ash, elm, hornbeam, &c. and persuade themselves, that they may have the more great wood; but, in the mean time, do not consider that the cutting off great tops endangers the life of a tree; or, at best, wounds it so, that many trees yearly decay more in their bodies, than the yearly tops come to; and, at the same time that they furnish themselves with more great wood, they do it at the loss of the owner. And, indeed, though the hornbeam and elm will bear great tops, when the body is little more than a shell; yet, the ash, if it comes to take wet at the head, very rarely bears more top after the body of the tree decays. Therefore, if once these trees decay much in the middle, they will be worth little but for the fire; so that, if you find a timber-tree decay, it should be cut down in time, that the timber be not lost.

The Lopping of your trees, that is, at ten or twelve years old at most, will preserve them much longer, and will occasion the shoots to grow more into wood in one year, than they do in old tops at two or three. Great boughs, ill taken off, often spoil many a tree; for which reason they should always be taken off close and smooth, and not parallel to the horizon; and cover the wound with loam and horse-dung mixed, to prevent the wet from entering the body of the tree.

When trees are at their full growth, there are several signs of their decay; as the withering or dying of many of their top branches; or if the wet enters at any knot; or they are anywise hollow, or discoloured; if they make but poor shoots; or if woodpeckers make any hole in them.

This Lopping of trees is only to be understood for pollard-trees; because nothing is more injurious to the growth of timber-trees, than that of Lopping or cutting off great branches from them. Whoever will be at the trouble of trying the experiment upon two trees of equal age and size, growing near each other, to lop or cut off the side branches from one of them, and suffer all the branches to grow upon the other, will in a few years, find the latter to exceed the other in growth every way; and this will not decay near so soon.

All sorts of resinous trees, or such as abound with a milky juice, should be lopped very sparingly; for they are subject to decay, when often cut. The best season for Lopping these trees is soon after Bartholomew-tide; at which time they seldom bleed much, and the wound is commonly healed over before the cold weather comes on. *Miller's Gard. Dict.*

The Lopping of young trees, that is, of such as are ten or twelves years old, will preserve them much longer, and will occasion the shoots to grow more into wood in one year, than they do in old tops in two or three. The taking off of large boughs in a careless manner destroys many a tree; they should therefore always be lopped with great care, and the wound covered with some loam to keep it from rotting, and prevent the wet from entering and getting into the body of the trees.

All sorts of resinous trees, or such as abound with a milky juice, should be lopped but very sparingly, for they are very subject to decay, when cut. The best season for the Lopping these is the end of August, when they will not bleed very much, and the wounds will heal before the hard weather.

The generality of the world are against pruning timber trees at all, and, where they naturally grow straight and regular, it is much better let alone. But all the common faults in shape may be regulated by this Lopping them while young, and it can be attended with no ill consequence to the timber; for the cut not lying near the timber pith cannot affect it, when grown up, and squared in the working for beams and other uses, or to be quartered; for all the defects, occasioned by such wounds, are in the superficial parts, and all the four quarters are perfectly sound within.

As to the large forest trees, they should not be lopped at all, except in cases of great necessity, and then the large boughs must not be cut, but only the side branches, and even these must be cut off close, that the bark may soon cover the wound, and yet a little slanting, that the water may run off, not lodge upon the cut part.

If there is a necessity of cutting off a large bough, as by its being broken or cankered, let it be cut off slanting at about four feet distance from the body of the tree, and that if possible near some place where there is a young shoot from it, which may receive the sap, and grow up in its place. No stump must be left standing out farther than this, because they are wounded parts which never can heal, and which will always be letting in the water, and will serve as pipes to convey that water into the heart of the body of the tree, and by degrees will utterly spoil it. All that grow upright, whether they be large or small branches, must in cutting be taken off slanting, never evenly, for the same reason; those boughs that bear from the head are to be cut with the slope on the lower side, and on any occasion that great wounds are given to a tree, they should be covered with a mixture of clay and horse-dung, which will make them heal much sooner than they otherwise would do. *Mortimer's Husbandry.*

LO'RICA, a name given by some chemical writers to a peculiar lute made for the coating over vessels, which are to bear a very vehement fire.

This is ordered to be made of the powdered glass of broken retorts mixed up into a paste with potters clay by means of warm water: the retort, or other vessel, to be loricated, is to be covered a third of an inch thick with this matter, and if it cracks in the drying, which must be done gradually before it is to be used, the cracks must be filled up with the same paste, and this must be left to dry as the former. *Collect. Chym. Lond.*

LO'RIMERS, one of the companies of London, that make bits for bridles, spurs, and such-like small iron ware.

LORE'TTO, the name of an order of knights, instituted by pope Sixtus V. in 1587, where he made the church of our lady of Loretto, a bishop's see; during his papacy, he made no less than 260 of them; the popes conferred this order indifferently on sword-men and lawyers, and honoured them with the titles of count palatines; they had all of them pensions, with a power of making doctors in all faculties, as also public notaries, and that of legitimating bastards.

LOT, or LOTH, in mining, is the thirteenth dish, measure, or part of the miner's ore, which the bar-master takes up for the king. *Houghton's Compl. Miner, in the explanation of the term.*

LO'TION, *lotio saponacea*, the saponaceous Lotion, the name of a form of medicine prescribed in the late London Pharmacopœia, being properly soap in a liquid form. It is ordered to be made thus: take damask rose water, three quarters of a pint; oil of olives, a quarter of a pint; ley of tartar, half an ounce in measure; rub the ley and oil together till they are mixed, and then gradually add the water. *Pemberton's Lond. Disp.*

LO'TUS, *bird's-foot trefoil*, in botany, a genus of plants, whose characters are:

It hath a papilionaceous flower: the ovary, which rises out of the flower cup, afterward becomes a pod; sometimes distinguished, as it were, into cells, by transverse partitions, which are full of seeds, for the most part roundish: to which may be added, the leaves grow by threes, but have two wings or little leaves at the origin of their foot-stalks.

There are two or three varieties of this bird's-foot trefoil, which grow wild in most parts of England: when these are upon dry gravelly and chalky land, they are very low humble plants, spreading on the surface of the ground: but in rich moist land they grow much larger; and one of the sorts will sometimes produce branches near two feet in length: the seeds of these plants have been sold, and recommended as profitable to sow for fodder, by some husbandry-quacks, by the name of ladies-finger-grass: but I never could yet find any animal that would eat it, either green or dry.

LOVE *Apple*, is the English name for the fruit of the lycopersicon, a plant cultivated in gardens with us, for the singularity of its appearance. The Portuguese call it tomato, and eat the fruit, either raw or stewed, as do also the Jew families in England.

LOW'ERING, is the distillers business, a term used to express the debasing the strength of any spirituous liquor by mixing water with it. The standard and marketable price of these liquors is fixed, in regard to a certain strength in them called proof; this is that strength, which makes them, when shook in a phial, or poured from on high into a glass, retain a froth or crown of bubbles for some time. In this state spirits consist of about half pure, or totally inflammable spirits and half water; and, if any foreign or home spirit is to be exposed to sale, and is found to have that proof wanting, scarce any one will buy it, till it has been distilled again, and brought to that strength; and, if it be above that strength, the proprietor usually adds water to it, to bring it down to that standard. This addition of water, to debase its strength, is what is called Lowering it. People well acquainted with the goods will indeed buy spirits at any strength, only Lowering a sample to the proof strength, and by that judging of the strength of the whole; but the generality of buyers will not

not enter into this, but muſt have it all lowered for them. *Shaw's Eſſay on Diſtillery.*

There is another kind of Lowering in practice among the retailers of ſpiritous liquors to the vulgar; this is the reducing it under the ſtandard of proof. They buy it proof, and afterwards increaſe their profit upon it, by Lowering it with water one eighth part. The quantity of ſpirit is what they generally allow themſelves for the addition of water; and whoever has the art of doing this, without deſtroying the bubble proof, as this is eaſily done by means of ſome addition, that gives a greater tenacity to the parts of the ſpirit, will deceive all that judge by this proof alone; that is, very nearly all who are concerned in the ſpirit trade. Such an additional quantity of water, as one eighth, makes the ſpirit taſte ſofter and cooler, and will make many prefer it to the ſtronger ſpirit which is hotter and more fiery; but, unleſs the ſpirit, thus lowered, were tolerably clean, or the proof be ſome other way preſerved, the addition of the water lets looſe ſome of the coarſe oil, which makes the liquor milky, and leaves a very nauſeous taſte in the mouth. *Shaw's Eſſay on Diſtillery.*

LO'XIA, in zoology, the name of a bird, called in Engliſh the croſs bill, and in ſome places the ſhell apple, ſuppoſed to be the tragon of the ancients.

LU'CERNE, in huſbandry, the name of a plant frequently cultivated by our farmers in the manner of clover. It is the ſame plant which the ancients were ſo fond of under the name of medica, and in the culture of which they beſtowed ſuch great care and pains.

Its leaves grow three at a joint, like thoſe of the clover; its flowers are blue, and its pods of a ſcrew-like ſhape, containing ſeeds like thoſe of the broad clover, but longer, and more kidney-ſhaped.

The ſtalks grow erect, and, after mowing, they immediately grow up again from the parts where they were cut off. The roots are longer than thoſe of the ſaint-foin, and are not ſingle, but ſometimes they run perpendicularly in three or four places from the crown.

It is the only plant in the world, whoſe hay is preferable to the ſaint-foin for the fattening of cattle; but its virtues, in that reſpect, are ſo great, that they are not to be credited by any that have not tried the plant. It is the ſweeteſt graſs in the world, but muſt be given to cattle with caution, and in ſmall quantities, otherwiſe they will ſwell and incur diſeaſes from it.

Though the common method of huſbandry will not raiſe Lucerne to advantage; yet, the horſe-hoeing huſbandry will raiſe it annually, increaſing in value to the owner, and make one of the moſt profitable articles of his buſineſs.

The ſoil to plant it on muſt be either a hot gravel, or a very rich and dry land, or ſome other rich and dry land that has not an under ſtratum of clay, and is not too near ſprings of water. The natural poorneſs of gravel may be made up by dung and the benefit of the hoe, and, the natural richneſs of the other lands being increaſed by hoeing and cleanſing them from graſs, the Lucerne will thrive with leſs heat; for what is wanted in one of theſe qualities muſt be made up in the other. The beſt ſeaſon for planting it in England is early in the ſpring, the earlier the better; for then there is always moiſture enough in the earth to make it grow, and not ſo much heat as would dry up its tender roots, and kill it after the firſt ſhooting. About a pound and a half of ſeed will be enough for an acre; and, if this be ſown in February, though ſome of the young plants will be deſtroyed by the froſts in March, yet there will be enough left of them for the making as thick a crop as is neceſſary. The planting it in autumn might do very well in hotter countries, but with us the long winters would kill a great part of the tender plants, and greatly ſtunt and injure thoſe they did not kill.

The number of Lucerne plants ſhould be leſs than thoſe of ſaint-foin to an acre, becauſe they grow much larger in this way of management, and each occupies a greater ſpace of ground, and produces a larger quantity of hay. The quick growth of this plant requires that it ſhould have large ſupplies of nouriſhment, and good room to grow in; and it is better in all things of this kind to err in ſetting the plants too far diſtant, than in ſetting them too near.

The moſt fatal diſeaſe incident to Lucerne is ſtarving; for this reaſon, good culture is neceſſary to it, and the often turning the earth with the hoe all about it. By this means, a plant, that in the common way of ſowing, would not have been more than four or five inches high, will be three feet, and will ſpread every way, ſo as to produce a quantity of hay, more like the cutting of a ſhrub than a plant.

The plants ſhould ſtand at five inches diſtance in ſingle rows, and the intervals between theſe rows muſt be left wide enough for the uſe of the hoe plough.

The rows of Lucerne plants muſt not be thinned till they are grown up to ſome height; for, while young, they are ſubject to be eaten by the fly, like turnips; and, if this deſtroyer ſhould ſeize them, after they are reduced to only a competent number, the crop would be rendered much too thin. The hoe plough is the only inſtrument that can bring this plant to perfection, and it muſt be frequently had in proportion to the number of crops it produces; but then it muſt be ſtill ſome years, leſt the plowed ground injure the hay that is made upon it; and when it is come to a turf, and the Lucerne wants renewing, the four-coultered plough is the only inſtrument that can prepare the turf to be killed, and cure the Lucerne. This plough muſt be uſed in the following manner: turn its furrows towards one row, and from the next; that is, plow round one row, and that will finiſh two intervals; and ſo of the reſt. The next plowing muſt be towards thoſe rows from which they were turned the firſt time, and care muſt be taken that the firſt furrows do not lie long enough on the rows to kill the plants, which will be much longer in winter than in ſummer.

Lucerne is to be made into hay in the ſame manner as ſaint-foin; but this is to be obſerved, that it is always to be cut, juſt before it comes to flower. The richeſt Lucerne hay of any is that cut while the ſtalks are ſingle, without any collateral branches, and in this caſe there uſually is not ſo much as the bud of a flower to be ſeen on the plants.

Lucerne can never be expected to ſucceed well any where, let the ſoil be ever ſo good, unleſs it be kept clean from natural graſs. *Tull's Huſbandry.*

LU'CIUS, in zoology, the name of the common river fiſh, called in Engliſh the jack, or pike, and by ſome the pickerel.

LUCIUS *terreſtris*, the land pike, in zoology, the name of a very ſingular ſpecies of American lizard, which has the ſhape, ſcales, &c. of the pike fiſh. In the place of the fins of that fiſh it has four legs, but theſe are ſo weak and ſlender that it makes no uſe of them in walking, but crawls along upon the ground in the manner of a ſnake, and draws its legs after it. It grows to about fifteen inches long, with a proportionable thickneſs. It is all over covered with ſmall, ſtrong, and gloſſy ſcales, of a ſilvery grey. In the night they retire into holes and caverns, and make a very diſagreeable and loud noiſe, much louder than the croaking of frogs. They ſeldom ſtir out of their holes, unleſs in the duſk of the evening; and, if they are ever met with in the day time, their ſtrange motion ſurprizes all that ſee them. *Rocheſort's Hiſt. Inſ. Antill.*

LU'FFA, *Egyptian cucumber*, in botany, a genus of plants, whoſe characters are:

It hath a bell-ſhaped flower, conſiſting of one leaf, which is divided into five parts to the center: there are male and female flowers on the ſame plant: the male flowers are produced on ſhort foot-ſtalks, having no embryo's; but the female flowers reſt on the top of the embryo's, which afterwards becomes a fruit like a cucumber to outward appearance, but is not fleſhy, the inner part conſiſting of many fibres, which are elegantly netted: and there are three cells, which are filled with ſeeds, which are almoſt of an oval ſhape.

This plant may be propagated after the ſame manner as cucumbers and melons, by ſowing the ſeeds on a hot-bed the beginning of March: and, when the plants are come up, they muſt be pricked into a freſh hot-bed to ſtrengthen the plants, obſerving to let them have freſh air every day in warm weather, and to refreſh them frequently with water.

The fruit, when it is young, is by ſome people eaten, and made into mango's, and preſerved in pickle; but it hath a very diſagreeable taſte, and is not accounted very wholſome: wherefore theſe plants are ſeldom cultivated in Europe, except by ſuch perſons as are curious in botany, for variety. *Miller's Gard. Dict.*

LUGS, the Engliſh name for a peculiar ſpecies of inſect, found in great plenty on the ſhores of Cornwall. It is of the nature of the ſcolopendra, and is called by Mr. Ray vermis ſcolopendroides. It grows to twelve inches long, and has inſtead of legs nineteen pair of ſtiff briſtles; theſe all ſtand towards the head part of the creature, the tail being of at leaſt five inches long when full grown, and having no mark of them. Its body is rounded, and much reſembles the body of the common earth worm, and is of a fleſh colour, or of a pale red; it has no forceps.

LUME'LLA, in the glaſs trade, the round hole in the floor of the tower of the leer, which is directly over the working furnace, and by which the flame is let into the tower. *Neri's Art of Glaſs.*

LU'MPUS, in zoology, the name of a thick and ſhort ſea fiſh, called in Engliſh the lump fiſh, and ſea own, and by the Scotch the cock paddle.

LUNA'RIS *Cochlea*, in natural hiſtory, the name of a genus of ſhells of the ſnail kind, the diſtinguiſhing character of which is their having a perfectly round mouth. Theſe are univalve, umbilicated ſhells, with a depreſſed clavicle, and a ſurface ſometimes ſmooth, but more frequently ſtriated, furrowed, laciniated, or covered with tubercles.

LU'PIA, in ſurgery, a name given by ſome authors to that ſort of ſwelling, called by others talpa and teſtudo; this is an encyſted tumor, more diſtinguiſhed by its ſituation than by its nature, ſince of whatever kind it be, whether aſteatomatous, or atheromatous, &c. if ſituated under the ſcalp, it is called by theſe names. *Heiſter's Surgery.*

LU'PUS, *the wolf*, in zoology. This is a beaſt of prey, but wholly of the dog kind, and the largeſt and fierceſt of that race of animals. It is extremely like the domeſtic dog in ſhape, and, if the head did not differ a little in figure, one would be apt to declare it the very ſame animal. It has a very fierce look about the face, its eyes are glaring and ſavage, and its teeth and the opening of its mouth fierce and frightful. The ancients

ancients had an opinion, that the neck of the wolf was all of one ſolid bone; but, on the contrary, this creature is able to turn and twiſt about better than the dog kind. *Ray's Syn. Quad.*

LUPUS, is alſo the name given by authors to a peculiar claſs of ſpiders, from the manner of their taking their prey, which is by open hunting and running down, and not by means of webs as the common ſpiders do theirs. Theſe are diſtinguiſhed into two kinds, the one properly the Lupus, or wolf ſpider; the other the crab ſpider.

All the ſpiders of the Lupus kind have large eyes and four ſmall ones. Their hinder pair of legs are longer than any of the others; and they uſually live upon the ground, ſeldom climbing into trees. Of the firſt kind, or the Lupi, properly ſo called, there are four principal ſpecies. Firſt, the black ſpider. This is of a middle ſize, the male and female are both black, the head is ſmall, and the legs are beautifully ſpotted. Secondly, the brown ſpider, with oblique ſtreaks upon the body: this is of a middle ſize, and has a black head. Thirdly, the plain yellowiſh ſpider, with a long-ſhaped pointed body. This is a very large ſpider, and its legs are long and robuſt; it lives among buſhes. Fourthly, the livid ſpider, with a long-pointed body undulated with white. This is a very larger ſpecies, and lives among trees and under hedges. *Ray's Hiſt. Inſ.*

LUPUS *marinus*, the ſea wolf, a voracious ſea fiſh, caught ſometimes in our ſeas, but more frequently in the Mediterranean, and very fierce and voracious. Its head is larger, in proportion to its ſize, than that of the ſhark and rounder. This, as alſo the back, ſides, and fins, are all of a bluiſh colour. The belly is white, the ſkin is ſmooth and ſoft, but his teeth ſo remarkably hard and ſtrong, that, if he bites againſt an anchor of a ſhip, or other iron ſubſtance, they make a loud noiſe, and leave their mark in the iron. In the rim of his under jaw, he has ten ſharp and round teeth diſpoſed in two rows, and twelve grinders on each ſide behind theſe, diſpoſed in the ſame manner in two rows. The upper jaw has twelve ſharp and round teeth before, and there are three orders or rows of grinders in his palate; the middle one conſiſting of twelve teeth, as the others, and having them harder than the human teeth, and running farther towards the jaw, and in the upper jaw he has two roughs and ſharp bones; to which a rough part near the roof of the tongue anſwers, and this like thoſe is beſet with ſharp teeth. *Willughby's Hiſt. Piſc.*

LUSTRA'TION (*Dict.*)—Lomeir has a volume expreſs on the Luſtrations of the ancients: Joh. Lomeieri Zutphanenſis Epimenides, ſive de veterum Gentilium Luſtrationibus; firſt printed at Utrecht in 1681, and ſince, with additions, in 1702, in quarto.

All perſons, ſlaves only excepted, he ſhews, were miniſters of ſome ſort of Luſtration.—When any one died, the houſe was to be ſwept after a particular manner, by way of purification; the prieſt threw water on new married people, with the like intention.—To purify themſelves, people would even ſometimes run naked through the ſtreets; ſuch was their extravagance. And, as if fancy was not fertile enough in inventing modes of Luſtration, they even uſed inchantments to raiſe the dead, in order to get inſtructions what they muſt do to purge themſelves of their ſins. Add, that they frequently raiſed the opinion of the ſanctity of their expiations by fictitious miracles. The birds, ſay they, practiſe Luſtration, both by waſhing themſelves, and throwing water on their neſt. The hen takes ſtraw, and uſes it to purify her chickens. — There was ſcarce any action, at the beginning and the end of which the Gentiles did not perform ſome ceremony to cleanſe themſelves, and appeaſe the gods. When they had no animals to ſacrifice, they made the figure of the beaſt they would offer in dough, metal, or other matter; and thus ſacrificed in effigy.

Some expiations were performed in the water; for which reaſon, certain fountains and rivers were in great reputation: others were performed in the air. — A certain heathen cauſed himſelf to be ſeriouſly ſifted in a ſieve, as we now ſift corn: another hung himſelf by a cord, and was toſſed backwards and forwards: another ſhut his eyes, and ſet himſelf blindfold to find out a noſegay tied to a cord: others played at ſee-ſaw, as a more efficacious way of appeaſing the gods.

Fire was much uſed for expiation: ſometimes the penitents were caſt into the fire; at others, only brought to the flame, or ſmoke.

It was common, on theſe occaſions, to ſhed human blood: The prieſts of Cybele, Bellona, and Baal, made cruel inciſions on themſelves. — Erectheus, king of Attica, ſacrificed his daughter to Proſerpina. Several had their throats cut at Rome, to obtain the emperor's health from the gods. Thoſe who commanded armies, offered one of their ſoldiers to appeaſe the anger of the gods, that he alone might ſuffer all the wrath the army deſerved.

All ſorts of perfumes, and odoriferous herbs, had place in Luſtration.—The egg was much uſed among them, as being the ſymbol of the four elements; its ſhell, they ſay, repreſents the earth; the yolk, a globe of fire; the white reſembles the water; and, beſides, it has a ſpirit which repreſents the air. For this reaſon it is, that the Bonza's, or Indian prieſts, believe to this day that the world came out of an egg.—There is ſcarce any pot-herb, pulſe, tree, mineral, or metal, which they did not offer the gods by way of expiation: nor did they forget milk, bread, wine, or honey: what is more, they made uſe of the very ſpittle and urine.

The poets had feigned that the gods purified themſelves, and they did not omit to purify their ſtatues.—They made a Luſtration for children, the eighth day after their birth.—When a man, who had been falſely reputed dead, returned home, he was not to enter his houſe by the door. — It was a ſettled cuſtom to offer no expiation for thoſe who were hanged by order of juſtice, or that were killed by thunder. Neither did they offer any for thoſe who were drowned in the ſea; it being the common opinion, that their ſouls periſhed with their bodies. And hence it was, that perſons in danger of ſhipwreck ſometimes thruſt their ſwords through their bodies, that they might not die in the ſea; where they thought their ſoul, which they ſuppoſed to be a flame, would be totally extinguiſhed.

The moſt celebrated expiatory ſacrifice was the hecatomb, when they offered an hundred beaſts; though they commonly did not offer ſo many, but contented themſelves with killing twenty-five; but, thoſe being quadrupeds, their feet came to an hundred.

Luſtrations and luſtratory ſacrifices were not only performed for men, but alſo for temples, altars, theatres, trees, fountains, rivers, ſheep, fields, and villages. When the Arval brothers offered a victim for the fields, their ſacrifice was called ambarvalia.

Cities were all to be purified, from time to time: ſome walked the victim round their walls, and then ſlew him.—The Athenians ſacrificed two men, one for the men of their city, and the other for the women. The Corinthians ſacrificed the children of Medea ſo; though the poets ſay, Medea killed them herſelf. The Romans performed the ceremony of purifying their city every fifth year; whence the name of luſtrum, given to the ſpace of five years.

Divers of the expiations were auſtere: ſome faſted; others abſtained from all ſenſual pleaſures: ſome, as the prieſts of Cybele, caſtrated themſelves; others, that they might live chaſte, eat rue, or lay under the branches of a ſhrub called agnus caſtus.

The poſtures of the penitents were different, according to the different ſacrifices: they ſometimes joined prayers to the ſolemnity; at other times, a public confeſſion of ſins was made. —The Indians, when they ſacrifice to Hercules, call him a thouſand reproachful names; and think they incur his anger, if any reſpectful term comes out of their mouth.

The prieſts changed their habits, according to the ceremonies to be performed: white, purple, and black, were the moſt uſual colours. They had their heads always covered, and long hair, except in the ſacrifices of Saturn, Hercules, Honour, and a few others: only the prieſts of Iſis were ſhaven, becauſe that goddeſs underwent the ſame operation, after the death of her huſband Oſiris. — In ſome ceremonies the prieſts were ſhod, in others barefoot: the poets expreſs the former by the word vincula. They had no girdles; nay, they durſt not pronounce the word ivy, becauſe ivy cleaves to every thing.—In the ſacrifices of Venus, and the moon, every one took the habit of the contrary ſex.— Every thing was to be done by odd numbers; becauſe they looked on an even number, which may be equally divided, as the ſymbol of mortality and deſtruction. The odd number was with them holy: hence Neptune's trident, Cerberus's three heads, and Jupiter's thunder-dart, with three points.

They caſt into the river, or at leaſt out of the city, the animals, or other things that had ſerved for a Luſtration or ſacrifice of atonement; and thought themſelves threatened with ſome great misfortune, when by chance they trod upon them. —At Marſeilles, they took care to feed a poor man for ſome time; after which, they charged him with all the ſins of the country, and drove him away: thoſe of Leucade faſtened a number of birds to a man charged with their ſins, and in that condition caſt him headlong from a high tower; and, if the birds hindered his being killed, they drove him out of the country.

Part of theſe ceremonies were aboliſhed by the emperor Conſtantine, and his ſucceſſors; the reſt ſubſiſted till the Gothic kings were maſters of Rome, under whom they expired; except that ſeveral of them were adopted by the popes, and brought into the church, where they make a figure to this day: witneſs the numerous conſecrations, benedictions, exorciſms, ablutions, ſprinklings, proceſſions, feaſts, &c. ſtill in uſe in the Romiſh church.

LU'STRICUS *Dies*, among the ancients, the day on which young children underwent the ceremony of luſtration and received their names.

LUTE'OLA, in zoology, a name given by many to a ſmall bird, called by others aſellus, and by others regulus non criſtatus; but this laſt is a name that has occaſioned ſome confuſion, as many have erroneouſly called our common wren the regulus, and, as it has no creſt, imagined it to be the bird meant by this name.

It is, excepting the creſted wren, the ſmalleſt of all European birds, and it very little exceeds that in ſize. Its head, neck, and back, are of a greeniſh brown; the rump is greener than the reſt. It has a yellow line on each ſide, extended from the noſtrils,

noſtrils, beyond the eyes, to the hinder part of the head. The breaſt, throat, and belly, are yellow, with a very faint caſt of green. The wings and tail are brown, and all their feathers are tipped with green at their ends: the under part of their wings has much of a very fine green. The beak is extremely ſlender, and half an inch long; the mouth yellow within. It makes a loud noiſe, like that of a graſshopper, and is principally found among willows: it is continually creeping, and ſinging among the branches of trees. It builds with ſtraw and feathers, and lays five eggs, which are white, and ſpotted with red. There is a conſiderable variation in the colours of theſe birds; ſome of them being much greener on the back, and much whiter on the belly, than others. *Ray's Ornitholog.*

LUTEOLA, *weld, would, yellow-weed*, or *dyer's-weed*, in botany, a genus of plants, whoſe characters are:

The leaves are oblong and intire: it hath an anomalous flower, conſiſting of many diſſimilar leaves: the fruit is globular, hollow, and divided into three parts.

The common weld is accounted a rich dyers commodity, and is of great advantage, conſidering the ſmall expence of its culture: it will grow upon the pooreſt ſort of land, provided it be dry; though, upon a middling ſoil, it will grow much larger. The ſeeds of this plant ſhould be ſown the beginning of Auguſt, ſoon after they are ripe; when it will come up with the firſt moiſt weather, and will grow very ſtrong the ſame autumn, provided it be ſown by itſelf; for moſt people ſow it with corn, which is very wrong; for that hinders its progreſs greatly, and occaſions the loſs of one whole year. When the plants are come up pretty ſtrong, you ſhould hoe them (as is practiſed with turneps) in order to deſtroy the weeds, as alſo to cut up the plants where they grow too thick, which will greatly improve them; and the ſucceeding ſpring, if the ground produces many weeds, you ſhould give it a ſecond hoeing in April, which will preſerve it clean from weeds; after that, the weld will grow, and prevent the weeds from coming to an head afterwards.

You muſt be very cautious, in the gathering of it, that the ſeed be not over-ripe, ſo as to fall out, and that neither the ſtalk or ſeed be under-ripe; becauſe, if it be, both will be ſpoiled. It muſt be pulled up and bound in little handfuls, and ſet to dry, as you do flax; and then houſe it carefully, that you ſhake not out the ſeed, which is eaſily beat out, and ſhould be ſown (as was before directed) ſoon after it is ripe.

This ſeed is commonly ſold for about ten ſhillings per buſhel, or more, a gallon of which will ſow an acre; for it is very ſmall. There are ſome who recommend the ſowing this ſeed in the ſpring, mixing it with a crop of barley or oats, and only harrowed in with a buſh, or rolled with a roller. But this is not a good method; for the barley or oats will ſtarve the weld, and make it very poor: and, many times, the ſeeds which are ſown in the ſpring do not grow or not come up, till the autumn following; whereas that ſown, in the beginning of Auguſt, rarely fails to come up ſoon after, and will be much ſtronger, and fit to pull the ſucceeding ſummer, when the other is always two years before it is pulled. The dyers uſe it for dying bright yellows and lemon colours. It is much ſown in Kent, eſpecially about Canterbury, and often yields, from forty ſhillings, to ten or twelve pounds an acre. This is ſuppoſed to be the plant that the ancient Britons dyed themſelves with. *Miller's Gard. Dict.*

LUTRA, in zoology, *the otter*. See OTTER.

LY'CIUM, in the materia medica, the name of a fruit called by the French baye d'Avignon, the Avignon berry, and by many authors the pyxacantha. The ſhrub which produces it, is the Lycium five pyracantha of Gerrard. The fruit is about the ſize of a grain of wheat, and is not round, but of an angular form when dried, ſometimes of three, ſometimes of four angles, and ſometimes dented in at one end like a heart. It is of a yellowiſh green colour, and of a bitter and aſtringent taſte. It ſhould be choſen freſh dried, and large. There was formerly a rob, or inſpiſſated juice made from theſe berries, much in uſe in medicine; but this was generally adulterated with a rob made of the berries of the woodbind, privet, ſloe, or other ſhrub, and is now quite out of uſe. The dyers of France and Holland uſe it for a yellow; and the Dutch have another uſe for it, which is, that they boil it in alum-water, and, mixing it with whiting, form it into twiſted ſticks, which they ſell to the painters in water colours, under the name of ſtil de grain. *Lemery Dict. de Drog.*

LYCOPE'RSICON, *love-apple*, or *wolf's-peach*, in botany, a genus of plants, whoſe characters are:

It hath a flower conſiſting of one leaf, which expands in a circular order, as doth that of the night-ſhade: the ſtyle afterwards becomes a roundiſh ſoft fleſhy fruit, which is divided into ſeveral cells, wherein are contained many flat ſeeds.

LYCOPODIOI'DES, in botany, the name of a genus of moſſes, the characters of which are theſe: it produces ſeeds in ſpikes, in the manner of the lycopodium, or wolf's claw moſs, but that in two ways; for ſome of the capſules incloſe a powder, which ſeems only a farina; others ſeem to contain true ſeeds; theſe always ſtand to the number of three in each capſule. It differs from the lycopodium alſo, in its general appearance and manner of growth, the leaves being all placed in the ſame plane, and expanded in the manner of fins, with an intermediate ſeries of ſmall leaves, which cover the upper ſide of the middle rib, or ſtalk.

LYCOPO'DIUM, in botany, the name of a genus of moſſes, the characters of which are theſe: it produces capſules in the alæ of certain leaves, which are very unlike the capſules of the other moſſes, having neither calypha, operculum, nor pedicle. Theſe do not ſtand as thoſe of the ſelago, in all the alæ of the leaves, but are collected together into a ſort of ſpike of a ſcaly ſtructure, and one capſule ſtands under every ſcale, or leaf. Theſe capſules are of the ſhape of a kidney, and, when ripe, they ſeparate longitudinally into two parts, and throw out a powder, conſiſting of round globules. It has been ſuppoſed by many, that this powder is the farina of the flower; but, as there are no ſeeds found in any other part the plant for it to impregnate, it ſeems a much more probable opinion, that this powder, as well as that of the capſules of all the other moſſes, is the true and genuine ſeed of the plant. In moſt of the ſpecies of this plant, the ſpikes are compoſed of leaves of a different figure from thoſe of the reſt of the plant, and are therefore called ſcales; but in ſome they are made of leaves of the ſame figure with thoſe of the other parts of the moſs. See *plate* XXXII. *fig.* 1.

LYNX, in zoology, the name of a very fierce beaſt of prey called in Engliſh the ounce, and by many Latin authors the lupus cervarius, or dear wolf, from its loving to feed on deer. The hairs of this creature, as well ſuch as appeared reddiſh, as thoſe which were grey, when nicely examined, are all found to be truly of three colours in each ſingle hair; the middle part being of a reddiſh tawny, the bottom grey, and the top white; but thoſe which compoſe the black ſpots are only of two colours, there being no white at their ends.

This creature's eyes are extremely bright and vivid, and ſhew plainly that it has a very piercing ſight. Its ears are like thoſe of a cat, but have this peculiarity, which diſtinguiſhes the creature from all the animals of the ſame claſs: they have a fine pencil of black hairs growing out at their extremities, ſmooth, and of a deep black like velvet, and two fingers long. Its tongue is rough like that of the lion. The Lynx is found wild in Italy and Germany, but the greater number are in Aſia, and theſe are much finer-coloured than the European. They all differ conſiderably from one another, at times, in the number and diſpoſition of their ſpots. *Ray's Syn. Quad.*

LY'RA, the name of a beautiful ſea ſhell of the genus of the concha globoſa, or dolium. There are three ſpecies of the lyra, or harp ſhell. Firſt, the common lyra, which has thirteen roſe-coloured ribs running along its body. Secondly, the eleven-ribbed Lyra. And, thirdly, the noble harp, or Lyra nobilis. This is a moſt elegantly variegated ſhell; its ground colour is a deep brown, and its variegations very elegant and black.

M.

M.

MACA'W, or MACAO, in zoology, the name of a large species of parrot, distinguished also by the length of its tail. There are three different species of this bird brought over into Europe, which not only differ in size and other particulars, but also in colour. The first is the largest, and is finely variegated with blue and yellow. The second is somewhat smaller than this, and is principally red and yellow; and the third is red and blue. It is not uncommon also to see the Macaw perfectly white, and it is to that particular colour we give the name of cockatoon; though with some it is made the synonymous name of all the Macaw tribe.

MA'CKAREL, the English name for the scombrus, or scomber. See the article SCOMBER.

Horse MACKAREL. See the article HORSE-*Mackarel*.

MACRO'PTERA, in zoology, the name of a genus of birds of the hawk kind, remarkable for the length of their wings. The word is derived from the Greek μακρὸς, long, and πτέρον a wing.

The hawks of this genus have their wings so long, that, when closed, they reach to the end of the tail, or nearly so. Of this genus are the bald buzzard, the kite, the hen harrier, the honey buzzard, and common buzzard, the sacre, the jerfalcon, &c. *Willughby's Ornitholog.*

MACROTELO'STYLA, in natural history, the name of a genus of crystals, which are composed of two pyramids joined to the end of a column, both the pyramids, as also the column, being hexangular, and the whole body consequently composed of eighteen planes. The word is derived from the Greek μακρὸς, long, τέλειος, perfect, and στύλος, a column; expressing a perfect crystal with a long column. See *Plate* XXXII. *fig.* 2.

MA'DDER, (*Dict.*) — The method of cultivating this useful plant, as practised by the Dutch, is as follows:

In autumn they plow the land, where they intend to plant Madder in the spring, and lay it in high ridges, that the frost may mellow it; in March they plow it again; and at this season they work it very deep, laying it up in ridges eighteen inches asunder, and about a foot high; then about the beginning of April, when the Madder will begin to shoot out of the ground, they open the earth about their old roots, and take off all the side-shoots, which extend themselves horizontally, just under the surface of the ground, preserving as much root to them as possible: these they transplant immediately upon the tops of the new ridges, at about a foot apart, observing always to do this when there are some showers, because then the plants will take root in a few days, and will require no water.

When the plants are growing, they carefully keep the ground hoed, to prevent the weeds from coming up between them; for, if they are smothered by weeds, especially when young, it will either destroy or weaken them so much, that they seldom do well after. In these ridges they let the plants remain two seasons, during which time they keep the ground very clean; and at Michaelmas, when the tops of the plants are decayed, they take up the roots, and dry them for sale.

This is what I could learn of their method of cultivating this plant; to which I will subjoin a few observations of my own, which I have since made upon the culture of Madder in England. And, first, I find there is no necessity for laying the ground up in ridges in England, as is practised by the Dutch (especially in dry land) because the places where I saw it, were very wet land, which is often floated in winter; so that, if the plants were not elevated upon ridges, their roots would rot in winter. Secondly, they should be planted at a greater distance in England; the rows should be at least three feet distance, and the plants eighteen inches asunder in the rows; for, as they extend themselves pretty far under ground, so, where they are planted too near, their roots will not have room to grow. And, thirdly, I find, that, if all the horizontal roots are destroyed from time to time, as they are produced, it will cause the large downright roots to be much bigger, in which the goodness of this commodity chiefly consists: for, if the upper roots are suffered to remain, they will draw off the principal nourishment from the downright roots, as I have experienced; for I planted a few roots upon the same soil and situation, which were of equal strength, and rooted equally well: half of these I hoed round, and cut off the horizontal roots; and the other half I permitted the horizontal roots to remain on; and, when I took them all up, those which I had hoed about, and kept clear from horizontal roots, were almost as large again as the other, and the roots were double the weight; which plainly proves it necessary to cut off those superfluous roots: so that, where this plant is cultivated in quantity, it will be an excellent method to use the hoeing-plough, to stir the ground, and destroy the weeds; for with this instrument a large quantity of ground may be kept clean at a small expence: and, as this will stir the ground much deeper than a common hoe, it will cut the superficial roots, and thereby improve the principal roots.

The crop of Madder should be shifted into fresh land; for the ground which has had one crop, will not be fit to receive another in less than four years; during which time any other annual crop may be cultivated on the land.

The manner of drying and preparing these roots for use I am not acquainted with, having never had an opportunity of seeing that part, so can give no instructions concerning it: but whoever shall have curiosity enough to cultivate this useful plant, might easily inform themselves, by going over to Holland at the season of taking up the roots.

What I could learn from the people with whom I conversed in Holland on this affair, was, that they pared off the outside rind of the roots, which is dried by itself, and is called mull-Madder. Then they pared off another fleshy part of the root, which is made into another Madder, and is called number O: but the inside, or heart of the root, is called crop-Madder. The first sort is not worth above fifteen or sixteen shillings per hundred weight: the second sort is sold for about forty shillings; but the third sort will sell for five pounds per hundred. I have since been informed, that there is no necessity of dividing it into three sorts for use; for, if the whole is dried and ground together, it will answer the dyer's purpose full as well. These roots must be dried on a kiln, before they are ground to powder; for which purpose, I suppose, the same as are used for drying of malt might be made useful for this commodity.

By some few experiments which I made, I imagine that one acre of good Madder, when fit to take up for use, will be worth above one hundred pounds: so that if it were to stand three years in the ground, and to be planted on land of three pounds per acre, it would pay exceeding well; considering the annual culture (if performed by a plough) will be no great expence; the principal charge being in the first preparing of the land, and the planting: but whoever has a mind to cultivate this plant, might rent very good land for this purpose, for twenty-five or thirty shillings per acre, at a distance from London, but near some navigation.

MADRE'PORA, in botany, a genus of sea plants intirely like the coral, as to its hardness, which is equal to bone or marble. Its colour is white, when polished. Its surface is lightly wrinkled, and the wrinkles run lengthwise of the branches. Its inside is of a particular organization, having in the center a sort of cylinder, which is often pierced through its whole length by two or three holes.

From this cylinder are detached about 17 laminæ (*Plate* XXX. *fig.* 2. *k*, *k*) which run to the circumference in straight lines, *m*, *m*, *m*, *m*.

These laminæ are transversely intersected by other laminæ, *q*, *q*, which form many irregular cavities throughout the whole plant. The branches (*fig.* 3. *g*, *g*) are conical; and the basis of the cone is formed by the summit of the branch *e*, *e*. Every one of these summits has wrinkles on its outside, which runs in the longitudinal direction of the branches (*fig.* 4. *c*, *c*) and each wrinkle answers to a lamina (*fig.* 5. *c*, *u*, *c*, *u*) and each lamina is of the shape of a prism (*fig.* 6.) the basis of which is warty, and faces the outside (*fig.* 5. *c*, *u*) and its point is cut into teeth (*fig.* 6. *n*, *n*, *n*) and belongs to the inside. The cellule (*fig.* 4. *a*, *a*, *a*, *c*, *c*, *fig.* 5. *c*, *c*, *u*, *u*) which is of the shape of a chalice, is composed of these laminæ ranged into a circle.

In every one of these cellules is found a little polypus, represented in *fig.* 7. but considerably magnified; the mechanism of which is this:

Three different parts, unlike each other, compose this animal; *viz.* the feet, *a*, *i*, a trough, and an head (*fig.* 8. *n*.) Each foot begins by two conical appendices (*fig.* 9. *a*, *a*, *a*, *fig.* 10. *a*.) By the union of these appendices a rounded part is formed, which, in some degree, resembles the belly of a muscle

muscle (*fig.* 9. *i*,) by means of which the foot is shortened and lengthened. To this part (*fig.* 10. *x*) is annexed a little cylinder (*fig.* 10. *u*, *fig.* 9. *c*) the length of which is indeterminate.

These feet are ranged all around in great number, and annexed to the laminæ (*fig.* 4. *a*, *a*, *c*, *c*) and are all united to the trough (*fig.* 9. *c*) on the outside of which are seen ten cavities, with an equal number of prominences *t*, *t*, *t*, *s*, *s*, *c*, and in these is lodged the animal's head (*fig.* 8.) which has prickly rays, the precise number of which I could not determine, on account of the extreme velocity of the continual oscillatory motion of the head from right to left, and from left to right: yet I thought I could perceive the number of these rays to be eight, and the use of them may be for the animal to catch and hold its food. This part is not always to be observed, because it sometimes hides itself, by closing up the trough (*fig.* 9. *s*, *s*, *t*, *c*) about it; and, by thus covering itself, it is safe in its habitation.

As the figure of this animal bears no resemblance to the urtica marina, I cannot see, how one could class the polypus of the madrepora with the urtica.

This animal is extremely tender, and generally transparent, and very beautiful for its variety of colours. I have observed it in spring and autumn in the neighbourhood of Rovigno and Orsera, where it is often fished up. *Philosophical Transactions*, Vol. XLVII.

MAGELLA'NIC *Clouds*, whitish appearances like clouds, seen in the heavens towards the south pole, and having the same apparent motion as the stars.

They are three in number, two of them near each other. The largest lies far from the south pole; but the other two are not many degrees more remote from it than the nearest conspicuous star, that is, about eleven degrees.

Mr. Boyle conjectures, that, if these clouds were seen through a good telescope, they would appear to be multitudes of small stars, like the milky-way. *Boyle's Works abr.* Vol. I.

MA'GI (*Dict.*)—The priests of the Magi were the most skilful mathematicians and philosophers of the ages in which they lived, insomuch, that a learned man and a magian, became equivalent terms. This proceeded so far, that the vulgar, looking on their knowledge to be more than natural, imagined they were inspired by some supernatural power, and hence those who practised wicked and diabolical arts, taking upon themselves the name of magians, drew on it that ill signification which the word magician now bears among us. The royal family among the Persians, as long as this sect subsisted, was always of the sacerdotal tribe. There is a remnant of these magians still subsisting in Persia and India, called by the natives geberrs. See GEBERRS.

MA'GIC (*Dict.*)—Pliny gives the reason why this science, vain and deceitful as it is, should have gained so much authority over men's minds. It is, says he, because it has possessed itself of three sciences of the most esteem among men, taking from each all that is great and marvellous in it. No body doubts but it had its origin in medicine, and that it insinuated itself into the minds of the people, under a pretence of affording extraordinary remedies. To these fine promises it added every thing in religion that is pompous and splendid, and that appears calculated to blind and captivate mankind. Lastly, it mingled judicial astrology with the rest, persuading people, curious of searching into futurity, that it saw every thing to come, in the heavens.

MAGNI'FICAT, the name or title of an hymn used by the virgin Mary, after the salutation of the angel; in which she expresses her great joy and gratitude for the great honour conferred upon her. It begins, Magnificat anima mea, &c. My soul doth magnify the Lord, &c. This hymn was so respected among the primitive Christians, that they used it as a part of their devotions; and the christian church has always retained it in her divine service, as proper to express the pious affections of godly and devout minds.

MAGNI'SSA, in minerology, a name given by some of the antients to the white pyrites, called by others leucolithos and argyrolithos. Many have supposed the Magnissa to be the same with the magnesia, that is, magnese, but this is an error; nor is there the least similitude between the two stones. It is plain, indeed, that the antients called a white and silvery-looking stone also by the name magnesia; but neither does this appear to have been the Magnissa here described, for Theophrastus describes it as a stone that artificers used for turning things out of, which is utterly impossible to be done with the pyrites; the shattery texture of which would make it fall to pieces, on the slightest attempt to cut it into shape by the wheel. The chemists of the preceding ages have plainly understood this word Magnissa of the pyrites, and have made these two words and the sory synonymous. Pliny mentions a gold-coloured and silver pyrites; these therefore were distinctions sufficient for the white and yellow pyrites; but Dioscorides has only mentioned one kind of the marcasite or pyrites, which is the yellow or brassy one, the most common of all the species. When the word pyrites, therefore, was only the name of this yellow stone, it is not wonderful that the white one should be called by another name, as Magnissa.

MAG'NETISM (*Dict.*)—The magnet can communicate directive and attractive qualities to iron, and we ought to consider the iron which has imbibed these qualities, as a real magnet, which can communicate its virtue to other iron. A vigorous magnet will give virtue to a weak magnet, and render its effects as sensible and lively as those of a good load-stone. It is in general sufficient to touch, or even hold the pole of a good stone near the body, to which we design to communicate the magnetic virtue, and it immediately becomes magnetical: the iron indeed which only receives its virtue from a momentary touch of the load-stone, loses it almost as soon as it is separated from it; but its virtue may be rendered more durable by keeping the iron longer near the magnet, or heating it red-hot and suffering it to cool in that situation; in this case the part, presented to the north pole of the magnet, becomes a south pole, and would in like manner become a north pole, on the application of the south pole of the magnet. But, as these simple means do not procure any great virtue, other means more efficacious are made use of.

1st. It has been discovered that iron, rubbed on one of the poles of the magnet, acquires much more virtue than when rubbed on any other part of the stone, and that the virtue, communicated to the iron by the pole, is stronger when the magnet is armed, than when it is naked. 2dly. The more slowly the iron is rubbed on the pole of the magnet, and the more it is pressed upon it, the more it imbibes of the magnetic virtue. 3dly. It is better to render the iron magnetical on one pole of the load-stone, than successively on both, because the iron receives the magnetic virtue of both poles, in contrary directions, the effects of which destroy each other. 4thly. A piece of iron is better made magnetical by passing it uniformly and in the same direction on the pole of the magnet, its whole length, than by rubbing it only in the middle; and it is observed that the extremity retains most strength, which touches the pole last. 5thly. A piece of polished steel, or iron, receives more magnetic virtue than an unpolished piece of the same figure; and, all other things being equal, a piece of iron which is long, thin, and pointed, imbibes more magnetic virtue, than one of any other form; as, for example, a piece of a blade of a sword, or knife, imbibes much more virtue than a square piece of steel of the same weight, which has no other points but its angles. A piece of iron or steel, as we have observed, only imbibes or retains the magnetic virtue to a certain degree, and it is evident that this quantity of magnetic virtue, imbibed, is determined by the length, breadth, and thickness of the magnetised piece of iron or steel. 6thly. Since iron receives the magnetic power in proportion to its length, it is necessary this length should be somewhat considerable, if we would convey a great deal of the magnetic virtue to the iron or steel; the blade of a sword therefore receives more virtue than the blade of a knife rubbed upon the same stone. But there are certain proportions of thickness and length, without which the iron receives less magnetic virtue; as, for example, we magnetised six iron laminæ, four inches long and about $\frac{1}{16}$ parts of an inch thick; their respective breadth was 1, 2, 3, 4, 5, and 6 lines; these were rubbed three times each, in the same manner, on the pole of an excellent load-stone, and we made an experiment of the different weights they could lift.

The first which was the least raised	1	grain	[illegible]
The second 2 lines broad	10		[illegible]
The third 3 lines broad	7		[illegible]
The fourth 5 lines broad	2		
The fifth 5 lines broad	1		[illegible]
The sixth 6 lines broad	1		[illegible]

The following experiment will demonstrate that the magnetic power, which a piece of iron receives from a load-stone, depends also on its length; we took an iron lamina $\frac{1}{100}$ part of an inch thick, five lines broad, 13 inches $\frac{1}{2}$ long; rubbed it three times on the pole of a magnet, and it carried 25 grains; we reduced the length to 10 inches, magnetised it three times more, and it carried 33 grains; when reduced to 9 inches, it carried 19 grains, to 8 inches 17 grains, to 4 inches 1 grain and [illegible]; from whence it is evident, that the length of the bar ought to be determined at 10 inches, or between 10 and 13 $\frac{1}{2}$, with the given breadth and thickness, to imbibe or receive the largest quantity of the magnetic virtue.

When a lamina of iron or steel of a certain breadth and thickness is too short to receive a large quantity of the magnetic virtue by communication, it may be remedied by tying it on a longer piece of iron, nearly similar in breadth and thickness, so that the whole may be of a proper length to receive the greatest quantity of magnetic virtue possible, by rubbing it on the pole of a load-stone: you will then find, on separating the little bar from the great one, that its magnetic force is considerably augmented: the following experiment plainly demonstrated the increase of the magnetic force, by this method of application. The end of a sword-blade one foot in length, being magnetised on another piece of a blade 2 feet, 7 inches, and eight lines in length, lifted 7 ounces, 3 drachms, and 36 grains, which, when magnetised alone, would lift no more than 4 ounces, 2 drachms, and 36 grains.

We must observe however, that two laminæ, being thus magnetised together, do not receive so much magnetic virtue, as one whole lamina of similar dimensions and equal length; this

this was proved by dividing a bar into two equal parts, one of which was kept whole, the other fawed into feveral fquare pieces; thefe pieces we put as clofe together as we could, to make the fame length nearly equal to that before they were fawed, and fixed them in this pofition; by the fide of them was placed the half which had not been fawed; thefe were both magnetifed equally: we found the whole part received much more magnetic virtue than the other, and that the part which had been cut into pieces, received more or lefs of the virtue of the load-ftone, as its parts were more or lefs contiguous.

Exclufive of thefe methods of communicating the magnetic virtue to iron by means of the load-ftone, there are others which we have mentioned under the article *Artificial* MAGNET, in the Dictionary: but we cannot pafs over in filence a method of communicating a very confiderable magnetic virtue to iron, and even increafing that of weak magnets, to fuch a degree as to make them very ftrong. The learned Dr. Knight is the author of this difcovery, though he has not yet made it public: the following experiments fhew the great quantity of magnetic virtue he communicated to bars of fteel, which could not have been procured by means of the beft load-ftones in the ordinary method. 1ft. A fmall bar of fteel about 3 inches $\frac{7}{10}$ long, weight about half an ounce, took up at one of its ends eleven ounces, without being armed. 2dly. Another bar of fteel in the form of a parallelopiped 5 $\frac{8}{10}$ of an inch long, $\frac{4}{10}$ of an inch broad, and $\frac{2}{10}$ of an inch thick, weighing 2 ounces 8 pennyweights and $\frac{1}{2}$, lifted 20 ounces at one of its extremities, without being armed. 3dly. Another bar of the fame form, and 4 inches long, armed with fteel like a load-ftone, contained within a hoop of filver, weighing in all 1 ounce 14 pennyweights, took up, at the bottom of its mounting, 4 pounds. 4thly. A bar of fteel in the figure of a parallelopiped, 4 inches long, $\frac{3}{10}$ broad, and $\frac{1}{10}$ thick, armed at its extremities with a brafs hoop to keep on the mounting, the whole weighing 14 ounces 1 pennyweight, took up, by the feet of the mounting, 14 pounds 2 ounces and $\frac{1}{2}$. He alfo made an artificial magnet, with twelve bars of fteel armed in the common manner, which lifted, by the feet of the mounting, 23 pounds 2 ounces and $\frac{1}{2}$. Thefe 12 bars were each fomewhat more than four inches long, $\frac{1}{2}$ of an inch broad, and $\frac{15}{100}$ of an inch thick; each of thefe laminæ weighed about 25 pennyweights, and were placed one upon another, fo that they formed a parallelopiped of about two inches in height: all thefe bars were bound very tight with cramps of brafs, and, mounted in fteel in the ordinary method, the whole weighed 20 ounces. Dr. Knight's particular method of communicating the magnetic virtue, in a furprizing manner, is not confined to iron and fteel; he alfo increafes the virtue of a weak load-ftone to fuch a degree, as to make it become excellent; he exhibited one before the Royal Society, which, when it was mounted, weighed in all feven pennyweights fourteen grains, which could hardly lift two ounces; but, after he had magnetifed it in his manner, it lifted almoft 7 ounces. He communicates the magnetic virtue to a weak dead ftone fo powerfully, that he quite effaces the virtue of its poles, and fubftitutes new ones in their ftead, which are more powerful and directly oppofite; he changes the fouthern into the northern pole, places the poles of a load-ftone where the equator was before, and vice verfa. In a cylindrical magnet he places the northern pole, all round the circumference of the circle, which makes one of its bafes, and the fouthern pole in the center of the fame circle, fo that all the circumference of the other bafis is a fouthern pole, and the center a northern pole. He places the poles of a magnet at pleafure in any part defired, as, for example, he makes the middle of a ftone the northern pole, and the two extremities the fouthern pole: in a parallelopiped magnet he places the poles at the two extremities in fuch a manner, that the upper half of the furface becomes the fouthern pole, and the lower half the northern pole; the upper half of the other extremity is the northern, and the lower half the fouthern pole.

Thefe experiments are performed by the help of large artificial magnets, of his own making, whofe magnetic virtue prodigioufly exceeds that of the natural load-ftone.

The communication of the magnetic virtue does not fenfibly exhauft the magnet from which the virtue is borrowed; whatever number of pieces of iron are magnetifed by the fame ftone, it lofes nothing of its ftrength; though inftances have been known of a magnet's communicating power to a piece of iron, of a greater weight than the magnet itfelf could raife, yet the power of the ftone has not appeared at all leffened.

Neither is the iron at all enriched at the expence of the load-ftone, whatever virtue it acquires, as the niceft fcales have proved. It is obferved thofe magnets which lift the greateft weights, do not communicate the greateft virtue; experience has taught us that fome magnets, though very weak in themfelves, yet communicate great virtue; it is true, fome kinds of iron imbibe very little virtue from a good ftone, while others imbibe a great deal. But this truth is moft evident in artificial magnets, which in general communicate a great deal of virtue, though they lift but a fmall weight of iron.

MAGNO'LIA, *the laurel-leaved tulip-tree*, in botany, a genus of plants, whofe characters are:

The flower hath no empalement, but is compofed of an uncertain number of petals, which expand in a circular order; and greatly refembles the flower of the water-lily; having a great number of ftamina clofely embracing the conical pointal, which is fituated in the center of the flower: the pointal afterwards becomes a conical fruit, having many fcaly protuberances, each being a cell including a large flattifh feed, which, when ripe, fall out, and are fufpended by threads.

MA'HOMET *Pigeon*, the common Englifh name of a fpecies pigeon, called by Moore the columba Numidica alba. It is of the fame fhape and fize with the Barbary pigeon, and has all the characters of that fpecies, but is always perfectly white, which gives the red circle about the eyes a more lively look. *Moore's Columbarium.*

MAHO'METANS, (*Dict.*)—The Mahometans divide their religion into two parts, viz. faith, or theory; and religion, or practice. Faith, or theory, is contained in this formulary, There is but one God, and Mahomet is his prophet. This confifts of fix diftinct branches, viz. belief in God, in his angels, his fcriptures, his prophets, in the refurrection and judgment, and in God's abfolute decrees. They reckon five points relating to practice, viz. prayer, wafhings, alms, faftings, and pilgrimage to Mecca. The Mahometans have very juft notions of God and his attributes, as appears very plain from the koran itfelf, and the writings of the Mahometan divines; notwithftanding what fome fuppofe, that their God is only a fictitious deity or idol. They believe the angels to have pure and fubtile bodies, created of fire, and that they have various forms and offices: they affign to each perfon two guardian-angels. Mahomet borrowed his whole doctrine concerning the angels from the Jews, who had it of the Perfians. As to the fcriptures, the koran teaches, that God, in divers ages of the world, gave revelations of his will in writing to feveral prophets. They reckon 104 facred books, which, however, are all loft, except the pentateuch, pfalms, gofpel, and koran; and the three firft of thefe, they fay, have undergone fo many alterations and corruptions, that very little credit is to be given to the prefent copies of them: as to the koran, God has promifed to take care of that, having left the others to the care of men. They reckon they have 224,000 prophets, of whom 313 were apoftles, fent with fpecial commiffions to reclaim mankind; and fix of them brought new laws or difpenfations, which fucceffively abrogated the preceding; thefe were Adam, Noah, Abraham, Mofes, Jefus, and Mahomet. The Mahometans have a high opinion of Chrift. They allow that he was a greater prophet than Mofes; that he was the fon of a virgin, who conceived by the fmell of a rofe prefented to her by the angel Gabriel: they believe that he never finned; nay, in their koran, they term him the breath and word of God; they punifh all that blafpheme him; and no Jew is capable of being a Turk, but he muft be firft made a Chriftian: they believe a general refurrection, and a future judgment; but, before thefe, they think there is an intermediate ftate both of the foul and body after death. Mahomet borrowed his doctrine of the refurrection from the Jews: he alfo taught, that the body is intirely confumed by the earth, except only the rump bone, which is to ferve as a bafis of the future edifice of a new body, or as a feed from which the whole is to be renewed. This is to be effected by a forty days rain, which will cover the earth to the height of twelve cubits, and caufe the bodies to fprout forth like plants. For this likewife he is beholden to the Jews, who fay the fame thing of the bone luz. The fixth great point of the Mahometan faith is God's abfolute decree and predeftination of good and evil. Of this doctrine Mahomet made great ufe for the advancement of his defigns, as it was one of the ftrongeft motives to induce his followers to fight without fear, and even defperately, for the propagation of the faith. The koran forbids the drinking of wine and ftrong liquors, and alfo gaming: indeed the Mahometan cafuifts except chefs, becaufe it depends wholly on fkill and management, and not at all on chance. They comply better with the prohibitions of gaming, than that of wine. The koran prohibits the eating blood and fwine's flefh, and whatever dies of itfelf, or is ftrangled, or killed by a blow, or by another beaft; which prohibitions he plainly copied from the Mofaical law; as he did likewife that of ufury, which is ftrictly forbidden.

MAJORA'NA, *marjoram*, a genus of plants whofe characters are: It is a verticillate plant, whofe flower is compofed of one leaf: the galea, or creft, is upright, roundifh, and divided into two parts: the barba, or beard, is cut into three fegments, fo as to appear almoft like a quinquefid flower: the flowers are collected into a fhort thick round head, and come out of a four-fold order of leaves, which are placed like fcales or plates.

Marjoram is an attenuant, diffolvent, and detergent. It is good in nervous cafes, and diforders of the breaft and lungs. Its flowery tops, dried and powdered, and given a fcruple for a dofe, are greatly recommended in epileptic cafes. The dried plant is only kept in the fhops.

The common fweet-marjoram, though a plant fo commonly cultivated with us, never ripens its feeds in England: and, as it is an annual plant, we are obliged yearly to have a fupply of its feeds from Marfeilles, and other places in the fouth of France, where it grows wild in great abundance.

PLATE XXIX. *Engraved for the Supplement.* *Facing Malt-distillery.*

Printed for J. Hinton in Newgate Street.

MA'KING-UP, a term used by the distillers to express the bringing spirits to a certain standard of strength by the additions of water.

MAIZ.—The Indians in New England, and many of our other settlements in America, had no other vegetable but Maiz, or Indian corn, for the making their bread of. They call it weachin; and, where our colonies are at this time numerous, there is yet much of the bread of the country made of this grain, not of the European corn.

The ear of the Maiz yields a much greater quantity of grain than any of our corn ears. There are commonly about eight rows of grains in the ear, often more, if the ground be good. Each of these rows contains at least thirty grains, and each of these gives much more flour than a grain of any of our corn. The grains are usually either white or yellowish, but sometimes they are red, bluish, greenish, or olive-coloured, and sometimes striped and variegated.

The manner of planting Maiz is in rows, at equal distances, every way about five or six feet. They open the earth with a hoe, taking away the surface to five or six inches deep, and of the breadth of the hoe; they then throw in a little of the finer earth, so as to leave the hole four inches deep, or thereabouts; and in each of these holes they place four or five grains at a little distance from one another.

If two or three of these grow up, it is very well; some of them are usually destroyed either by the birds or other animals. When the young plants appear, they hoe up the weeds from time to time; and, when the stalk gathers some strength, they raise the earth a little about it, and continue this at every hoeing, till it begins to put forth the ears; then they enlarge the hill of earth, round the root, to the size of a hop-hill, and after this they leave it till the time of harvest without any farther care.

When they gather the ears, they either immediately strip off the corn, or else hang up the ears, tied in traces at distances from one another; for, if they are laid near together, they will heat and rot, or else sprout and grow; but, kept cool and separate, they will remain good all the winter. The best method of all others is to thrash out the corn as soon as the harvest is over, and then lay it up in holes of the ground, well lined with mats, grass, or the like, and afterwards covered at top with more earth. The most careful among the Indians use this method, and this sort of subterranean grainary always proves good.

The uses of this plant among the Indians are very many. The great article is the making their bread of it; but, besides this, the stalks, when cut up before they are too much dried, are an excellent winter food for cattle; but they usually leave them on the ground for the cattle to feed on. The husks about the ear are usually separated from the rest, and make a particular sort of fodder, not inferior to our hay. The Indian women have a way of slitting them into narrow parts, and they then weave them artificially into baskets and many other toys.

The original way of eating the grain, among the Indians, was this: they boiled it whole in water till it swelled and became tender, and then they fed on it either alone, or eat it with their fish and venison, instead of bread. After this, they found the way of boiling it into a sort of pudding, after bruising it in a mortar; but the way of reducing it to flour is the best of all. They do this by parching it carefully in the fire, without burning, and then beating it in mortars, and sifting it. This flour they lay up in bags, as their constant provision, and take it out with them when they go to war, eating it either dry or with water.

MA'LOPE, *bastard mallow*, in botany, a genus of plants, whose characters are:

The flower which is shaped like that of the mallow, hath a double empalement, the outer being composed of three heart-shaped leaves, and the inner is of one leaf cut into five segments: the flower is of one leaf, divided into five parts to the bottom, where they are joined; but it seems to have five leaves: in the center arises the pointal, having a great number of stamina surrounding it, which are joined closely, and form a sort of column: the pointal afterward becomes a fruit composed of many cells, which are collected into an head; in each of which is lodged a single seed.

MALPI'GHIA, *Barbadoes cherry*, in botany, a genus of plants, whose characters are:

It hath a small quinquefid calyx, which consists of one leaf, having bifid segments: the flower consists of five leaves, which expand in form of a rose, having several stamina collected in form of a tube: the ovary in the bottom of the flower-cup becomes a globular fleshy soft fruit, in which is a single capsule, containing three stony winged nuts.

As these plants are natives of the warmest parts of America, they will not live through the winter in England, unless they are preserved in a warm stove: but, when the plants have obtained strength, they may be exposed in the open air, in a warm situation, from the middle or latter end of June, till the beginning of October, provided the weather continues so long mild; and the plants so treated will flower much better than those which are constantly kept in a stove.

They are all propagated by seeds, which must be sown upon a good hot-bed in the spring; and, when the plants are fit to transplant, they must be each put into a separate small pot filled with rich earth, and plunged into an hot-bed of tanner's bark, and must be treated in the same manner as hath been directed for other tender plants of the same country: and, for the two first winters, it will be proper to keep them in the bark-bed in the stove; but afterwards they may be placed upon stands in the dry stove in winter, where they may be kept in a temperate warmth, in which they will thrive much better than in a greater heat: these must be watered two or three times a week, when they are placed in the dry stove; but it must not be given to them in large quantities. *Miller's Gard. Dict.*

MALT (*Dict.*)—Almost every master has his secret of making Malt; but there are some necessary cautions to be observed by all, which will ensure success in the work; as, first, that the barley be newly thrashed, or at least newly winnowed. Secondly, that the whole be of one kind, not mixed up with several sorts. Thirdly, that it be not over steeped in the cistern, or so long as to make it soft. Fourthly, that it will be well drained. Fifthly, that it be carefully looked after in the wet couch, so as not to stop the first tendency of the blade to shooting. Sixthly, to turn the wet couch inside outermost, if the barley comes, that is, shoots more in the middle than on the sides. Seventhly, to keep it duly turning after it is out of the wet couch. Eighthly, to give it the proper heat in the dry heap. Ninthly, to dry and crisp it thoroughly on the kiln, but without a fierce fire, so as to be several days in drying a kiln of pale Malt. *Shaw's Lectures.*

Good Malt may be made of the grain of the maiz or Indian corn, but then a particular method must be taken for the doing it. Our barley Malt-makers have tried all their skill to make good Malt of it in the ordinary way, but to no purpose; that is, the whole grain will not this way be malted or rendered tender or floury, as in other Malt; for it is found, by experience, that this corn, before it be fully malted, must sprout out both ways, that is, both root and blade, to a considerable length, that of a finger at least, and, if more, the better. For this purpose, it must be laid in a heap a convenient time; and in this process, if it be of a sufficient thickness for coming, it will quickly heat and grow mouldy, and the tender sprouts will be so entangled, that the least moving of the heap will break them off; and the farther maturation of the grain into Malt, will be hindered by this means; and on the other hand, if it be laid thin, and often stirred and opened to prevent too much heating, those sprouts which have begun to shoot cease growing, and consequently the corn again ceases to be promoted to the mellowness of Malt. *Philos. Trans.* N°. 142.

To avoid all these difficulties, the following method is to be used: take away the top of the earth in a garden or field, two or three inches, throwing it up half one way, and half the other; then lay the corn for Malt all over the ground so as to cover it; the earth that was pared off is now to be laid on again, and nothing more is to be done till the field is all over covered with the green shoots of the plant. The earth is then to be taken off, and the roots of the grain will be found so entangled together, that they will come up in large cakes or parcels; it must be gently washed in order to take off all the dirt, and then dried on a kiln, or in a clean floor exposed to the sun. Every grain of the maiz will be thus transmuted into good Malt, and the beer brewed with it will be very pleasant and very wholesome, and of an agreeable brown colour, but very clear.

It may be worth trying whether the same process is not with due care applicable to the malting of turneps, potatoes, carrots, parsneps, and the like. It might possibly be of service also to attempt this less laborious way of making Malt of barley and other small grains; the disadvantages would be the not so easily separating the dirt from the grain as in that larger kind; and as barley requires the root only, not the ear, to shoot in order to the making of Malt, it would be some difficulty to know the exact time of taking it up; but with all these disadvantages, the method is worth a trial.

MALT-*distillery*, the art of converting Malt liquors into a clear inflammable spirit.

The reader will find every thing relating to brewing and fermenting Malt-liquors intended for distillation, under the articles BREWING, FERMENTING, and WASH.

Malt-wash being of a mucilaginous or somewhat glutinous nature, requires a particular encheiresis to prevent its scorching, and to make it work kindly in the still. If it should happen to be burnt in the operation, this would give the spirit a most disagreeable flavour, or empyreuma, that cannot be got off again, without the utmost difficulty, or some very particular treatment. To prevent any such ill effect, 1. The wash should be made dilute; 2. The fire be well regulated; and, 3. The liquor kept in a constant agitation.

The constant agitation of the wash, may be effected three different ways; viz. 1. By stirring it with a paddle or oar, till the liquor begins to boil, then immediately luting on the head. This is the common way. 2. By putting some moveable solid bodies into the still. And, 3. By placing some proper matter at the bottom and sides, or where the fire acts the strongest.

1. The

1. The usual method of stirring with the paddle is very defective, as being of no use after the still is once brought to work; whereas it often burns in the working. This method is greatly improveable by an addition to the structure of the still; whence the agitation may be commodiously continued during the whole operation: and this though the wash were made very thick, or wine-lees themselves were to be distilled. The method is this: solder a short iron or copper-tube in the center of the still-head; and below, in the same head, place a cross-bar, with a hole in the middle, corresponding to that a-top; through both which, is to run an iron-pipe, deep down into the still; and through this an iron rod: to the bottom whereof wooden sweeps are to be fastened; so that, this rod being worked a-top, backwards and forwards, with a winch, they may continually rake and clear the bottom plate and adjacent sides of the still: the interstices of the tubes being at the same time well crammed with tow a-top, to prevent any evaporation thereat.

2. The same effect may in good measure be secured by a less laborious way; viz. by placing a parcel of cylindrical sticks lengthwise, so as to cover the whole bottom of the still; or else by throwing in a parcel of loose faggot-sticks at a venture: for thus the action of the fire below, moving the liquor, at the same time gives motion to the sticks, and makes them continually act like a parcel of stirrers upon the bottom and sides of the still, so as to prevent the liquor from scorching.

3. But a better method still is upon a parcel of large cylindrical sticks to lay loose hay, to a considerable thickness; securing it from rising by two ash-poles laid a-cross, and pressing hard against the sides of the still; which might, if necessary, be furnished with buttons or loops, to secure the poles from starting. But care must here be had, not to press the hay against the sides, for that would presently make it scorch; which being otherwise defended by the sticks, it is not apt to do.

These are simple but effectual contrivances, which, in point of elegance, are easily improveable at pleasure.

There is a farther inconvenience attending the distillation of Malt-spirit, when all the bottoms or gross mealy feculent substance is put into the still, along with the wash: which thus coming to thicken a little, like starch in the boiling, and losing the thinner liquor, wherewith it was diluted, as the still works off; the mealy mass at length grows so viscous, as sometimes to scorch towards the end of the operation. To prevent this ill effect, it is very proper to have a pipe, with a stop-cock, leading from the upper part of the worm-tub into the still; so that, upon a half or a quarter turn, it may continually supply a little stream of hot water, in the same proportion as the spirit comes off, by which means the operation will be no ways checked or hindered.

But in Holland, where they work their wash thick, with all the Malt and meal along with it, they commonly use no art at all to prevent burning; only charge whilst the still is hot and moist, after having been well washed and cleansed. And yet they very rarely scorch, unless it be now and then in the winter. When such an accident happens, they are extremely sollicitous to scrape, scrub, and wash off the least remains of the burnt parts; by which means they effectually avoid the danger there would otherwise be of burning a second time.

But most effectually to prevent any accident of this kind, there is nothing comparable to the way of working by the balneum mariæ, if the distillers could have the address to find their account in it.

All simple spirits may be considered in the three different states of low-wines, proof-spirit, and alcohol: the intermediate states being of less general use, and to be judged of according as they approach to or recede from these. Low-wines, at a medium, contain a sixth part of totally inflammable spirit; five times as much water as perfect spirit necessarily rising in the operation with a boiling heat. Proof-goods contain about a half of the same totally inflammable spirit, and alcohol entirely consists of it.

Malt-low-wines, prepared in the common way, are exceeding nauseous, fulsome, and disagreeable. They have however a natural vinosity, or pungent acidity, that would render the spirit agreeable, were it not for the gross oil of the Malt, abounding therein. When this oil by suitable contrivances, as mentioned above, is kept from running in among the low-wines, they prove considerably sweeter, both to the smell and taste; and less thick and milky to the eye.

When distilled over gently, in order to their rectification into proof-spirit, they leave a considerable quantity of this gross fœtid oil behind, with the phlegm, in the still. But, if the fire be made fierce, this oil is again thrown over, mixed with the spirit; and, being now broke somewhat fine, impregnates it rather in a more nauseous manner than at first. And this is the usual fault commited not only by the Malt-stiller, but even the rectifier; who, instead of separating and keeping back the foul parts, according to the design of the operation, really brings them over in greater vigour. Whence it is not unusual, after repeated rectifications, as they call them, both simple and compound, to find the spirit much more nauseous and disagreeable than it came from the hands of the Malt-stiller. The remedy is, plainly, either gentle and soft working in the common engine, or the prudent use of the balneum mariæ.

Malt-low-wine, when brought into proof-spirit, appears bright and clear, without the least cloud or milkiness; no more oil being contained in the mixture than is perfectly dissolved by the alcohol, weakened with its own quantity of phlegm. Its taste also is much cleaner for the same reason; viz. because no gross parts of the oil can, in their own form, hang upon the tongue, but now pass readily and slightly over it: which is not the case in low-wines and faints, where the oil remains distinct and undissolved.

When proof Malt-spirit is distilled over again, in order for alcohol, if the fire be raised when the faints begin to come off, a very considerable quantity of oil will be brought over, and run in the visible form of oil, from the nose of the worm. Though this is not peculiar to Malt-spirit, but others also, and even French brandies do the same; so that sometimes half an ounce or more of this oil may be collected from a single piece of brandy.

Malt-spirit, more than almost any other, requires to be brought into the form of alcohol, before it can be used internally; especially, as it is now commonly made up, with as much fulsome oil in it as will give it the strongest proof. On which account it is, that in all compound waters, not excepting those of the apothecary, an indifferent judge will easily find the predominant flavour of this fulsome spirit, through that of all their ingredients. For this reason, it ought at least to be rectified, in balneo mariæ, to a perfect alcohol, before it is used in the finer compositions.

And, when once brought, with a due care and art, to a perfect alcohol indeed, it is then preferable to the French brandies for all curious internal uses; as being a much more uniform, hungry, tasteless, and impregnable spirit than those usually are.

This alcohol ought to be kept in close earthen vases or jars; not only to prevent its evaporation, but also its colouring itself with the resinous parts of the oak, which it dissolves powerfully, when preserved in casks.

The quantity of pure alcohol obtainable from a certain quantity of Malt differs according to the goodness of the subject, the manner of the operation, the season of the year, and skilfulness of the workman: according to which variations, a quarter of Malt may afford from eight or nine, to thirteen or fourteen gallons of alcohol; which should encourage the Malt-stiller to be careful and intelligent in this business. As, after each operation in the common way, there is always a remainder of faints, which never ought in their foul state to be mixed among the cleaner spirit; they should either be converted to other uses, or treated in a particular manner, so as to make a pure alcohol: the uses they are otherwise fit for being principally external, or, when redistilled to a proper height, burning in lamps: for which purpose they may have their disagreeable odour corrected by proper aromatics, or other ingredients, used in distillation.

But to make them into pure and perfect alcohol is a work of greater difficulty; yet practicable, though not perhaps to advantage. One way of effecting it is by slowly rectifying them from water into water; by which operation several times repeated, a pure alcohol may be obtained from the foulest and most oleaginous faints. But of this method, and others for the like purpose; see RECTIFICATION.

The œconomical use of the still-bottoms of the Malt-wash is sufficiently understood by the Malt-stiller; and, being so profitable an article, may, perhaps, render him less sollicitous about the improvement of the other branches of the business.

But these bottoms might have some farther, if not more advantageous uses than feeding of animals. Thus, in particular, they might, in a chemical way, afford a large proportion of an acid spirit, an oil, a fewel, and a fixed salt; and, with some address and good management, a vinegar or a tartar. Besides this, one uncommon use thereof has been already touched upon, where the refuse wash is observed to be very advantageously employed, instead of water, in the next brewing: as more readily disposing the subject to ferment; giving the spirit a vinosity, and somewhat increasing its quantity. But the proportion for this purpose should not exceed that of a fifth or sixth of the whole liquor employed.

The liquor left behind in the still, upon rectifying the low-wines, is little more than mere phlegm or water, impregnated with a few acid and some oily parts, not worth separating, unless for curiosity. And the same is to be understood of the liquor left behind upon distilling proof-spirit into it.

Explanation of *plate* XXIX, being a section of part of a Malt still-house.

a, A worm-tub, or refrigeratory belonging to the still *f*, *g*.
b, A man pumping water into the still *f*.
c, A common pump.
d, A pipe which conveys the water from the pump into the still *f*.
e, A cock to the pipe *d*.
f, The body of a still.
g, The head of the still *f*.
h, The nose or beak of the still-head, by which the vapour arising by distillation is conveyed into the worm, where it is condensed into a fluid.
k, An iron door, which confines the fire under the still.

l, A

l, A tackle for lifting off the ſtill-head *g*,
m, The head of another ſtill.
n, A machine for ſtirring the liquor, or, as the brewers call it, waſh, in the ſtill.
o, A man turning the machine.
p, A tackle for lifting off the ſtill-head *m*.
q, The beak or noſe of the ſtill *m*.
r, The door to the fire-place belonging to the ſtill *m*.
s, A copper for brewing the waſh for diſtillation.
t, A maſh tun, which receives the liquor from the copper *s*.
u, A cock, by which the liquor is let out of the copper *s* into the maſh-tun *t*.
w, A man maſhing, or ſtirring the Malt in the maſh-tun.

MALT-*duſt*.—This is accounted a great enricher of barren ground: it contains in it a natural heat and ſweetneſs, which gives the earth whereon it is laid a proper fermentation, as thoſe who live in malting countries have found by experience. Some are of opinion, that there is not a greater ſweetener than Malt-duſt, where the grounds are natural clay, and have contracted a ſourneſs and auſterity, whether by reaſon of its having lain long untilled, and unexpoſed to the air, or by reaſon of water having ſtood long thereon.

MA'LVA, *mallows*. See MALLOWS, in the Dictionary.

MALVA *marina*, *the ſea mallow*, in botany, a name not very judiciouſly given by ſome writers to a ſpecies of ſubmarine plant, ſuppoſed, in ſome degree, to reſemble the common mallow. It is very common in the places where they fiſh for coral, and grows to the rocks without any regular roots; it is found at different depths, but moſt uſually far from the ſurface, and its height is uſually about two inches. It is of a duſky greeniſh colour, with an admixture of a faint yellow; it is compoſed of ſeveral leaves of about half an inch broad, and a little more than that in length. Each of theſe is faſtened to a pedicle of about an inch and a half long; the leaves are of a fine thin membranaceous ſubſtance, but their ſtalks or pedicles are thick and tough like horn. When examined by the microſcope, many glandules diſcover themſelves upon the ſurfaces of the leaves, but the ſtalks or pedicles are entirely covered with glandules in form of ſmall protuberances, which make it as rough in thoſe parts as the common chagrine. The ſtalks, when cut tranſverſly, ſhew an infinite number of pipes or veſſels running up to every part of the leaves. Count Marſigli has given an elegant figure of this, both as it appears to the naked eye, and by the microſcope. *Marſigli, Hiſt. de la Mer.*

MA'LVA *roſea*, *roſe mallow*, *or hollyhock*; the characters are:
It hath a large and more expanded flower than the mallow, which cloſely adheres to the ſtalk; and in many ſpecies, the flowers are double, where the petals occupy the place of the ſtyle: it is in every reſpect larger than the common mallow: the leaves are rougher, and the plant grows almoſt ſhrubby.
Theſe plants are propagated from ſeeds, which ſhould be ſown upon a bed of freſh earth in April: and when the plants are come up pretty ſtrong, they muſt be tranſplanted out into nurſery-beds at about eight inches diſtance from each other, obſerving to water them until they have taken root; after which they will require no farther care until the Michaelmas following, but only to keep them clear from weeds; at which time they ſhould be tranſplanted into rows two feet aſunder, and a foot diſtance in the rows; in which place they may continue until they flower, when you ſhould mark all thoſe with double flowers, which have good colours, with ſticks, that they may be tranſplanted into the borders of large gardens at Michaelmas, where they will remain four or five years, and produce their flowers very ſtrong: but when the roots are much older, they begin to decay, and do not produce their ſtems ſo ſtrong, nor are their flowers ſo large; wherefore there ſhould always be a ſupply of young plants raiſed from ſeeds every third or fourth year, in order to have the flowers in perfection: but it is the better way to change the ſeeds every three or four years, with ſome perſon of integrity who lives at a conſiderable diſtance, and is exact to ſave ſeeds from none but double flowers, and ſuch as are well coloured, by which means you may preſerve the ſorts well from degenerating: but if you conſtantly ſave the ſeeds in the ſame place, they will in a few years become of little worth.

MA'LUS, *the apple*. See APPLE.

MA'MEI, *the mammee-tree*; a genus of plants, whoſe characters are:
It hath a roſaceous flower, which conſiſts of ſeveral leaves placed in a circular order; from whoſe cup ariſes the pointal, which afterwards becomes an almoſt ſpherical fleſhy fruit, containing two or three ſeeds incloſed in hard rough ſhells.

MA'MMOTH'*s Teeth*, or MAMMOUT *Bones*, in natural hiſtory, a name given by travellers and other writers to certain foſſil teeth, and other bones, found in Ruſſia and ſome other parts of the world, and that uſually at great depths in the earth. The Ruſſians and other people give them this name, ſuppoſing them to have belonged to an animal which they deſcribe as being of a monſtrous ſize, and living in caverns under ground. But the true account of them is, that they are in reality the teeth and other bones of elephants, there being no ſuch beaſt as theſe people deſcribe.

MA'NDARINES (*Dict.*)—There are in China nine orders of Mandarines, or nine degrees of nobility, which have as many different animals for their characteriſtics. The firſt is diſtinguiſhed by a crane, the ſecond by a lion, &c. There are in all 32 or 33,000 Mandarines in China. There are Mandarines of arms, and Mandarines of letters, who are judges; they both paſs ſeveral examinations. They are ſo much reſpected, that no body ſpeaks to them but on the knee. They are diſtinguiſhed from each other by different ſorts of precious ſtones in their caps and girdles; and there are great lords who are ſuperior to theſe Mandarines, who are alſo known by round jewels in their girdles, and a ſapphire in the middle.
The Chineſe alſo call the learned language of the country the Mandarine tongue; this is, in China, what the Latin is in Europe, and is common to all the learned men in the empire. Their public officers, as notaries, lawyers, judges, &c. write and ſpeak the Mandarine.

MANDRA'GORA, *mandrake*, in botany, a genus of plants, whoſe characters are:
The flower is monopetalous, bell-ſhaped, and multifid; the fruit is ſoft, globular, and contains ſeeds, which are for the moſt part kidney-ſhaped.
The mandrake has a large browniſh root, ſometimes ſingle, and ſometimes divided into two or three parts, growing deep in the earth, from which ſpring ſeveral large dark green leaves, a foot and more in length, and four or five inches broad, ſharp-pointed at the ends, of a fœtid ſmell; from among theſe ſpring the flowers, each on a ſeparate foot-ſtalk, about the height and bigneſs of a primroſe, of a whitiſh colour, of one bell-faſhioned leaf, cut into five ſegments, ſtanding in a large five-cornered calyx; and are ſucceeded by ſmooth round fruit, about as big as a ſmall apple, of a deep yellow colour when ripe, and of a very ſtrong ſmell. It grows wild in Spain, Italy, and Turkey, but in cold countries only in gardens. The leaves and roots are uſed.
This plant is rarely uſed inwardly, many eſteeming it to be a narcotic, and of a poiſonous nature; though others deny it and ſay, that the fruit may be eaten without any ill effects. Outwardly, it is uſeful in all kinds of inflammations, hot tumors, and ſcrophulous ſwellings: the juice, dropped in the eyes, is good to take away their heat and redneſs. It is ſeldom to be met with; and, though an ingredient in the unguentum populeon, its place is generally either ſupplied by henbane, or Engliſh tobacco. *Miller's Bot. Off.*
The mandrake is commonly reckoned among narcotics and hypnotics; whether this be true of the bark of the root, which is the part uſed in the ſhops, I am not certain; but the fruit is without doubt unjuſtly ſuſpected. Caſpar Hoffman confeſſes himſelf unable to determine, whether the apple, either with or without the rind, may be eaten with ſafety or not. Aetius ſeems to aſcribe all the malignity to the ſeeds, as if the pulp, without them, was harmleſs, unleſs eaten in an exceſſive quantity. That the pulp, however, may be eaten together with the ſeeds, without injury, appears from the example of I. Faber Lynceus, profeſſor of botany at Rome, who, as we are aſſured by J. Torrentius, in his Notes on Hernandez de Plantis Mexicanis, before his auditors, eat up a large mandrake apple, ſeed and all, in the morning faſting, without any conſequent ſleeping, or any the leaſt ill ſymptom. And that the experiment might be the ſurer, he continued, he ſays, without taking any thing elſe till dinner-time, which was ſome hours. J. Torrentius ſays, he has very often tried the ſame experiment.

MA'NGANESE, *magneſia*, in natural hiſtory, a very poor kind of iron ore.
It is a denſe, ponderous, and heavy ſubſtance, in its pureſt pieces, approaching greatly to the texture of the lapis hæmatites, being compoſed of regular parallel ſtriæ, diverging from a center to the circumference. This kind, however, is rare; beſides this, there is another ſomewhat of a leſs pure kind, of an iron grey colour, and irregularly ſtreaked like the ſteel-grained lead ores. But the common Manganeſe is of a perfectly irregular ſtructure. It is very heavy, moderately hard, and of a deep duſky grey, approaching to black, though ſometimes of a ferrugineous brown. It is found in large maſſes of no determinate ſhape, and of a rude, rugged, and unequal ſurface. Manganeſe gives fire but difficultly with ſteel, and makes no effervеſcence with aqua-fortis. It is found in many parts of England and Germany.
This ſubſtance is of vaſt uſe in the glaſs trade, but neither the induſtrious Neri, nor any others who have written of the art, can ever deliver the true proportions in which it is to be mixed with the glaſs metal on the ſeveral occaſions. The ſame thing is alſo to be obſerved in regard to zaffer, another ſubſtance in continual uſe among them. And the reaſon of this is, that there is vaſt difference in the quality of theſe bodies, ſome which are ſold being very pure and rich, others good for almoſt nothing, and much of middle degrees of purity between theſe. For this reaſon there is no determining how much of each is to be added to the glaſs, but the conciator adds them at ſeveral times, and in ſmall quantities, and takes frequent proofs by his eye, till he knows that they are properly proportioned. *Merret's Notes on Neri.*

MA'NGO *Tree*, in botany, the name of a vast tree, forty feet in height, and eighteen in thickness, and spreads its numerous branches all around at a great distance, being always green, and bearing fruit once or twice a year, from six or seven years old to an hundred. It is propagated by insition, or sowing the seed, in Malabar, Goa, Bengall, Pegu, and many other countries in the East-Indies.

The fruit is of a round oblong figure, flat, slightly sinuated, or hollowed at the sides, and shaped much like a kidney, bigger than a goose egg, smooth, shining, first green speckled with white, then inclining to yellow, and at last of a gold-colour: it has a yellowish and succulent pulp, not unlike that of a peach; or rather a plum, first acid, then acido-dulcid, and pleasant to the taste. Within the pulp is contained an oblong, compressed, and lanuginous stone, thin, yet very hard and tenacious, and including a callous oblong kernel, very like an oblong almond, and of the same bigness, and of a bitterish, though not unpleasant taste.

There are various sorts of this fruit, as there are of our apples and pears, which are very different, according to the countries where they grow: that species, which is without a stone, and is very grateful to the palate, seems to us only a variety, or a degenerate fruit The fruit is cut into slices, and eaten either without wine, or macerated in wine; it is also candied, in order to its preservation. Sometimes they open it with a knife, and fill up the middle with fresh ginger, garlic, mustard, and salt, with oil or vinegar, that they may eat it with rice, or after the manner of pickled olives.

As to its temperament, this fruit is cold and moist, though the Indian physicians affirm the contrary. We make use of pickled Mangoes, which are imported to us, as we do of pickled cucumbers, for sauce to roasted meat. The stones roasted are said to cure a looseness, which Garcias found to be true. The wood of the tree, with cinders, is used for burning the carcases of the pagans, as being consecrated to this rite; whence it serves also for coffins, in which they reposit their dead; but it is but of a soft substance, and of short duration.

The stalks supply the place of arequa or caunga, in the chewing of betel; the same, calcined and reduced to powder, take away warts. Of the tender leaves, with the bark of the avanacoe, that is, the ricinus, the seed of cummin and parpadogam, is made a decoction, which is highly beneficial in the cough, asthma, and other affections of the thorax. The bark of the tree pulverised, and taken in chicken-broth, is an excellent dissolvent of extravasated and coagulated blood, occasioned by a fall, in any part of the body. The juice of the bark, with the white of an egg, and a very little opium, taken inwardly, is a present remedy against the diarrhœa, dysentery, and tenesmus. Of the gum of the tree, and the flowers of rice, with the addition of a small quantity of opium and pepper, are prepared pills, which also cure all sorts of fluxes of the belly. Of the flower of the dried kernels the natives have the art of preparing various kinds of food.

MANIFE'STO (*Dict.*)—Manifesto's were substituted in the room of that august and solemn ceremony, by which the ancients introduced the divine Majesty in declarations of war, as witness and avenger of the injustice of those who undertook war without reason and necessity. Motives of policy have, besides, rendered these Manifesto's necessary, in the situation of the princes of Europe with regard to each other, united by blood, alliances, and leagues. Prudence requires the prince who declares war against his enemy, to avoid drawing upon him the arms of all the allies of the power he attacks. It is to prevent these inconveniences that Manifesto's are published.

MANU'RING.—Sea sand is often made use of by way of manure, in some parts of Cornwall, near the sea shore. When the sand is notably shelly, that is, much mixed with the broken pieces of sea shells, it is reckoned best. It is spread upon such land as is intended for wheat, or usually in the first crop of four, whatever be the grain; for, after four crops, it is the custom, in Cornwall, to leave the land six or seven years for pasture before it is tilled again, and the grass will be so good the first year, where this manure is used, as to be fit for mowing: this is called mowing of gratten by the people there. The Cornish acre is eight score yards, at eighteen feet to the yard. In one of these acres, the farmers bestow, according to the distance from the sea shore, from three hundred sacks to one hundred, each sack containing thirteen gallons, which is called a horse-load, the roads in many parts of this country being so bad, that they are forced to carry the sand on horse-back from the water-side to the land, though eight or ten miles distant. In this case the sand costs them in the whole about eight pence per load. Where the land lies very distant from the shore, and from all water carriage, they bestow very little of this manure, but they do not care to be any where wholly without it. In some of these places they lay twenty loads on an acre, and find a proportionable advantage from it. Where much sand is used, the corn is large and plentiful, and the straw little. Hence has grown the old Cornish phrase of a bushel of corn to a peck of straw; which is not miraculous in a place where the ears of barley are frequently found as long or longer than the stalks they grow on.

Where little of this sand is used, there is generally a great deal of straw, and but little and hungry ears of small grain. After the corn is taken off, the grass that naturally comes up is a white clover; and, where the land is any thing deep, a red kind comes up among it. This is usually but short the first year, but it grows thick, and affords good feeding for the cattle; and they are found to thrive better, and give better milk, than when they are fed on the high grass, which generally succeeds where there has been less sand used.

Another great advantage of the lands where much sand is used, is, that no snow lies upon them; there is a continual winter spring, and an early harvest, usually six weeks before the neighbouring lands that do not use it in proper quantities; so that all the expence of procuring it in quantities is many ways amply repaid to the farmers.

We have, about Erith, and many other places, the same sort of sand in great abundance in the Thames, that is used with this great advantage in Cornwall; and, if it should be found on trial to answer as well, probably there would be found few places where this river would not afford it at some depth, or in some part of its bed. The coral sand of Falmouth is dredged up from under a stratum of ouze of about a foot in thickness; and perhaps in the Thames, where the bottom seems of another nature, the same sand, or some of equal efficacy, may be found underneath. The sand taken up out of the Thames at Erith is used by the brick-makers, and they observe that the grass always grows particularly fresh and strong about the edges of their heaps of it, and that clover naturally grows there among the other grass. *Phil. Transf.* N°. 113.

MA'PLE *tree*, *acer*, in botany, the name of a tree common in most parts of England.

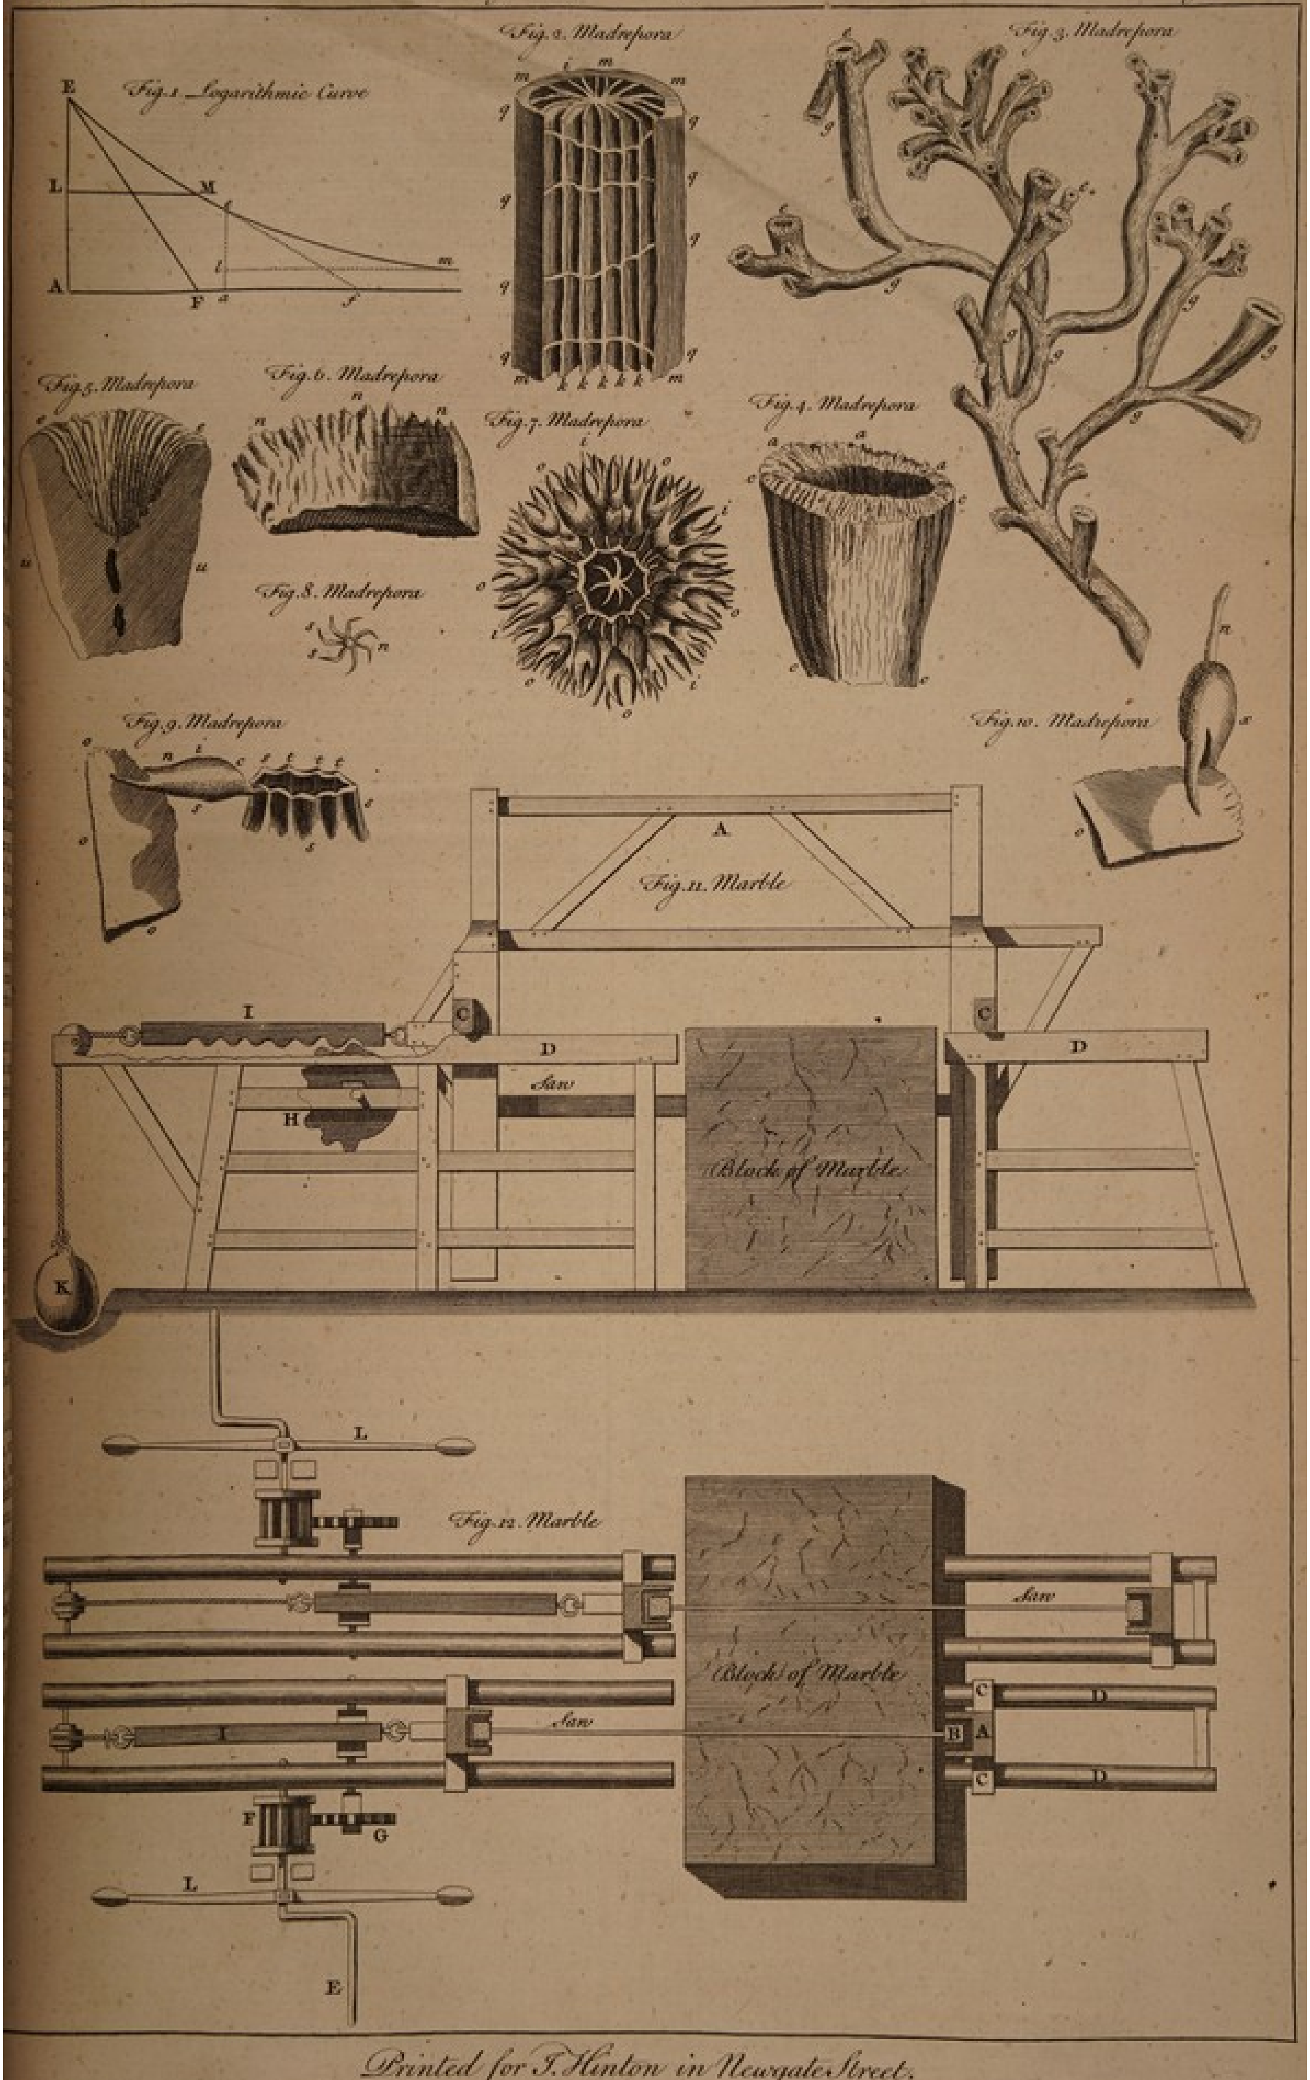
These trees are easily propagated by sowing the seeds, soon after they are ripe, in an open bed of common earth, covering them about half an inch thick, with sandy light earth: the spring following they will appear above ground, and, if kept clear from weeds, will grow above a foot high the first summer: the Michaelmas following, if they are thick in the seed-bed, you may take out a part of them, and transplant into a nursery, in rows at three feet distance, and two feet asunder in the rows; in which place they may remain three or four years, when, they will be large enough to plant out for good. The timber of the common Maple is far superior to the beech for all uses of the turner, particularly dishes, cups, trenchers, and bowls; and when it abounds with knots, as it very often doth, it is highly esteemed by the joiners for inlayings, &c. and also, for the lightness of the wood, is often employed by those that make musical instruments; and, for the whiteness of the wood, is in great request for tables.

Egyptian MA'RBLE, a name given by our artificers to a very beautiful green and white Marble, greatly in use among us, and brought in great quantities from Egypt and other places. It was also in frequent use, and in great esteem among the Romans, who received it also from Egypt, and distinguished too lightly two kinds of it, from the different disposition and order of its variegations, and honoured them with the names of two of their emperors, in whose reigns they were first brought into use. These were the marmor Augusteum and Tiberianum. Those pieces, in which the variegations were waved and thrown into arches and circular figures, they called the Augustan; and those, which were marked with more diffused and scattered veins, they called the Tiberian. These were the whole differences between the two; and, if we were to acknowledge different species from such differences as these, we must allow almost as many different species as we see blocks of Marble. *Hill's Hist. of Foss.*

Colouring of MARBLE.—The colouring of Marble is a nice art, and in order to succeed in it, the pieces of Marble, on which the experiments are tried, must be well polished, and clear from the least spot or vein. The harder the Marble is, the better it will bear the heat necessary in the operation; therefore, alabaster, and the common soft white Marble, are very improper to perform these operations upon.

Heat is always necessary for the opening the pores of the Marble, so as to render it fit to receive the colours; but the Marble must never be made red-hot, for then, the texture of the Marble itself is injured, and the colours are burnt, and lose their beauty. Too small a degree of heat is as bad as too great; for, in this case, though the Marble receive the colour, it will not be fixed in it, nor strike deep enough. Some colours will strike even cold, but they are never so well sunk in as when a just degree of heat is used. The proper degree is that which, without making the Marble red, will make the liquor boil upon its surface. The menstruums, used to strike in the colours, must be varied according to the nature of the colour to be used. A lixivium made with horse's or dog's urine, with four parts quick-lime, and one part pot-ashes, is excellent for some colours; common ley of wood-ashes does very well for others: for some, spirit of wine is best; and, finally, for others, oily liquors, or common white-wine.

The colours which have been found to succeed best with the peculiar menstruums, are these: stone-blue dissolved in six times the quantity of spirit of wine, or of the urinous lixivium; and that colour which the painters call litmouse, dissolved in common ley of wood-ashes. An extract of saffron, and that colour made of buckthorn berries, and called by the painters sap



Printed for J. Hinton in Newgate Street.

sap green, both succeed well dissolved in urine and quick-lime, and tolerably well in spirit of wine. Vermilion, and a fine powder of cochineal, succeed also very well in the same liquors. Dragon's blood succeeds very well in spirit of wine, as does also a tincture of logwood, in the same spirit. Alkanet root gives a fine colour, but the only menstruum to be used for this is oil of turpentine; for neither spirit of wine, nor any lixivium, will do with it. There is another kind of fanguis draconis, called dragon's blood in tears, which, mixed with urine alone, gives a very elegant colour. *Philos. Transact.* N°. 268.

Besides these mixtures of colours and menstruums, there are some colours which are to be laid on dry and unmixed. These are dragon's blood, of the purest kind, for a red; gamboge for a yellow, green-wax for a green, common brimstone, pitch, and turpentine for a brown colour. The Marble, for these experiments, must be made considerably hot, and then the colours are to be rubbed on dry in the lump. Some of these colours, when once given, remain immutable; others are easily changed or destroyed. Thus the red colour given by dragon's blood, or by a decoction of logwood, will be wholly taken away by oil or tartar, and the polish of the Marble not hurt by it.

A fine gold colour is given in the following manner: take crude sal armoniac, vitriol, and verdigrease, of each equal quantities; white vitriol succeeds best, and all must be thoroughly mixed in fine powder.

The staining of Marble to all the degrees of red or yellow, by solutions of dragon's blood or gamboge, may be done by reducing these gums to powder, and grinding them, with the spirit of wine, in a glass mortar; but, for smaller attempts, no method is so good as the mixing a little of either of these powders with spirit of wine, in a silver spoon, and holding it over burning charcoal. By this means a fine tincture will be extracted, and, with a pencil dipped in this, the finest traces may be made on the Marble, while cold, which, on the heating it afterwards, either on sand, or in a baker's oven, will all sink very deep, and will remain perfectly distinct in the stone. It is very easy to make the ground colour red or yellow by this means, and leave white veins in it. This is to be done by covering the places where the whiteness is to remain, with some white paint, or even with two or three doubles only of paper, either of which will prevent the colour from penetrating in that part. All the degrees of red are to be given to Marble by means of this gum alone; a slight tincture of it, without the assistance of heat to the Marble, gives only a pale flesh colour, but the stronger tinctures give it yet deeper; to this the assistance of heat adds yet greatly; and, finally, the addition of a little pitch to the tincture gives it a tendency to blackness, or any degree of deep red that is desired.

A blue colour may be given also to Marble by dissolving turnsol in a lixivium of lime and urine, or in the volatile spirit of urine; but this has always a tendency to purple, whether made by the one or the other of these ways. A better blue, and used in an easier manner, is furnished by the canary turnsol, a substance well known among the dyers: this needs only to be dissolved in water, and drawn on the place with a pencil; this penetrates very deep into the Marble, and the colour may be increased by drawing the pencil, wetted afresh, several times over the same lines. This colour is subject to spread and diffuse itself irregularly; but it may be kept in regular bounds, by circumscribing its lines with beds of wax, or any other such substance. It is to be observed, that this colour should be always laid on cold, and no heat given even afterwards to the Marble; and one great advantage of this colour is, that it is therefore easily added to Marble already stained with any other colours, and it is a very beautiful tinge, and lasts a long time. *Mem. Acad. Par.* 1732.

A description of a machine for sawing MARBLE, from a draught of M. Morel's. See *Plate* XXX. *fig.* 11, 12.

Few are ignorant of the common manner of sawing blocks of Marble; they make use of a smooth saw without teeth, which sometimes employs two men one on each side, who cast fine sand into the track of the saw frequently, to wear the Marble, and let water trickle into it to prevent the saw from heating. The frame of the saw is represented by the letter A. The arms of the saw are hollow in the form of cullices, about five feet in height, to answer to the biggest blocks of Marble; and as the saw cannot act upon the Marble, but by the efforts it makes to penetrate it, the extremities are both loaded with a cube of lead, the weight of which must be sufficient to make the saw descend. Besides the parts which compose it, this machine is also fortified with two ears C C to strengthen it and make it slide on the tressels D D placed in a right-line, and at such a distance, that the frame of the saw may easily pass between them.

Though several saws may be made to work at the same time, I shall only speak of one of the two in the plan: the power must be applied to the handle E, whose crank is twelve inches, which continues to the trundle-head F eight inches in diameter, which communicates with the cog-wheel G sixteen inches diameter; at the axis of the wheel G is another wheel H which can be seen only in the eleventh figure, being hid in the plan under the piece I. This wheel which is twenty inches radius to the extremity of the cogs, has cogs only on the half of its circumference, which indent with the notches in the piece I, fixed at one of its extremities to the frame of the saw; at the other is a cord, which, after having passed on a pulley, is fastened to the weight K.

When the power turns the handle, the teeth of the wheel H, meeting those of the piece I, force it, notwithstanding the weight K, to move 30 inches from the left to the right, and the saw is impelled in the same manner, so that, when the wheel H has made an half-turn, as it presents no more cogs to catch in the notches of the piece I, the saw is retracted from the right to the left by the action of the weight K; the handle therefore must be turned twice round to carry the saw once backwards and forwards, and in one of these turns it has plainly no resistance but what proceeds from the friction of the parts.

The diameter of the trundle-head F being only half the diameter of the wheel G, the saw moving thirty inches at every half-turn of the wheel H, for which the handle is obliged to make a turn, the velocity of the acting power will be to that of the saw, in winding up, nearly as seventy-five to thirty, or as five to two; wherefore the resistance of the saw will be in the same proportion as five to two, to the power applied to the handle.

As two men are generally wanted to move the saw, whose joint effort I suppose equal to fifty pounds, we may reckon, subtracting the weight K, the power applied to the handle ought to be twenty pounds; but as an equal power is required to bring the saw back again, as that which carried it forward, and the two cubes of lead with which it is loaded act with equal gravity, the weight K must be at least fifty pounds: but this weight which renders the acting power of no effect, in one of the two turns of the crank, becomes contrary to it in the other, as it re-unites itself to the resistance of the saw, which will be in winding up equal to 100 pounds, taking two-fifths of which for the power applied to the handle, there will remain forty pounds, for which two men are required; so that, hitherto, this machine seems of no advantage, because two men must be employed at the machine as well as in the common method; unless you reckon the intervals when the weight K operates alone a benefit.

But this defect may be remedied by working two saws together instead of one, as may be seen in *fig.* 12, where are two handles on a common axis, but their cranks bent opposite. One saw may be made to go backward as the other goes forward, and, setting a man to each handle, they will divide between them the power necessary to impel one of the saws, while the weight K retracts the other; the resistance will not exceed 40 pounds at most, which will be equally divided between them, because, the two wheels H having their cogs disposed contrarywise, as soon as one leaves its piece I, the other catches in his: thus two men may perform the work of four, by applying the machine to saw two blocks at once; it may be said this machine is rather curious than useful, but we chose to exhibit it, because the principles of its construction may be applied to several uses.

Coralloide MARBLE, in natural history, the name given by authors to such Marbles as have specimens of the marine corals or bodies of that kind immersed in them, as the sea-shells are buried in, and make a part of the body of others.

MARBLE *colour*.—To give this variegated colour to glass is a very easy operation: there needs no more than to put crystal frit into a pot in the furnace, and to work it before it has stood the usual time to purify in the fire. *Neri's Art of Glass.*

MA'RBLED *China ware*, a name given by many to a species of porcelain or China ware, which seems to be full of cemented flaws. It is called by the Chinese, who are very fond of it, tsou tchi.

It is generally plain white, sometimes blue, and has exactly the appearance of a piece of china which had been first broken, and then had all the pieces cemented in their places again, and covered with the original varnish. The manner of preparing it is easy, and might be imitated with us. Instead of the common varnish of the China ware, which is made of what they call oil of stone and oil of fern mixed together, they cover this with a simple thing made only of a sort of coarse agates, calcined to a white powder, and separated from the grosser parts by means of water, after long grinding in mortars. When the powder has been thus prepared, it is left moist, or in form of a sort of cream, with the last water that is suffered to remain in it; and this is used as the varnish. Our crystal would serve fully as well as these coarse agates, and the method of preparation is perfectly easy. *Obs. sur les Cout. de l' Asie.*

MARLE (*Dict.*)—It is a very material circumstance in the marling of land, to find out how much the land requires of this manure; and, till experience has thoroughly shewn this, it is better to err in laying on too little, than too much; because the latter is a fault not to be remedied. It is to be observed also, that Marle never makes so great an improvement on land the first year, as it does afterwards.

In Staffordshire they lay two hundred loads of Marle upon an acre of land of the common kind; but, where the soil is black,

loose,

loose, and sandy, or full of worms, they will lay on three or four hundred loads to an acre; it being a rule with them, that this sort of soil cannot be marled too much. If the mould be thin, the less Marle does; if deep, it must have the more.

It is best sowing of marled lands under furrow; because, if these lands are well husbanded, they will be very mellow and hollow, which will occasion the earth's sinking from the roots of the corn, if it stand too high. If Marle fattens land, or makes it stiff or binding, it must be well dunged, and laid down for grass. In Staffordshire, after their land is marled, their way is to take the crops following. After the first crop of wheat is off, they plow in the wheat stubble in December, and, if the weather proves frosty, to mellow it, they do not plow it again till April. They then sow it with barley, allowing three bushels of seed to an acre. The common produce of this is thirty bushels. After this they sow pease, for which they plow once in the February following, allowing only three bushels of seed to an acre, as in the barley. Next after this, if they intend six crops, they sow wheat again upon the pease-crop; the fifth crop is barley again; and the sixth year's is red oats. Some sow two or three crops more, when the ground has been well marled, but that is much better let alone.

In digging for the Marle, they use in manuring their lands, in Ireland, they meet with fossil horns, and other curious fossils. The Marle always lies in the bottom of low bogs. It is never met with in any other places, and is found by boring with augres made for that purpose. It usually lies at five, seven, or nine feet depth. The obtaining it in many places is attended with very considerable expences, in draining off the water. The manner of digging it is this: they employ six able labourers and a supernumerary; and these cut up a hole of twelve feet square; which is supposed a pit that this number of men can manage in a day. Two men dig, two throw it up, and two throw it by, and the supernumerary supplies defects on all occasions. For the first three feet they dig through a fuzzy earth, fit for making a turf for fuel. Under this lies a stratum of gravel, of about half a foot. Under this often, for three feet more, there is a more kindly moss, which would make better fuel. This lower stratum of turf is always full of fossil wood, which is usually so soft, that the spade cuts as easily through it, as through the earth it lies in. Under this, for about three inches, is found a series of leaves, principally of the oak; these appear very fair to the eye, but fall to pieces on touching; and this stratum is sometimes interrupted with vast heaps of seed, which seem to be of the broom or furz. In some places there appear berries of different kinds; and in others, several species of sea plants, all lying in the same confused manner as the oak leaves. Under this vegetable stratum, there lies one of blue clay, half a foot thick, and usually full of sea shells. This blue clay is not so tough as the common sort, but is thrown carefully up, and used as Marle in some places. Under this always appear the right Marle; the stratum of this is usually from two to four feet thick, and sometimes much more. *Philosophical Transactions.* N°. 394.

Dice MARLE, in husbandry, a name given by the people of Staffordshire to a reddish Marle, that breaks into small square pieces like dice, or else into thin flakes, in the manner of lead ore, and looks smooth on the surface.

MARI'NE *Remains*, a term used by many authors to express the shells of sea fishes, and parts of crustaceous and other sea animals, found in digging of great depths in the earth, or on the tops of high mountains. Their being lodged in these places is an evident and unquestionable part of the sea's having once been there, since it must have covered those places where it has left its productions.

It has been a favourite system with many, and particularly with the late Dr. Woodward, that all these Marine bodies were brought, to the places where they now lie, by the waters of the universal deluge; which, as we are informed by holy writ, covered the whole surface of the globe, and even the highest mountains. But, though this is a very ready expedient to account for many of the natural phænomena, yet there are evident proofs that it cannot have been the cause of all that is attributed to it, and there must necessarily have been some other cause of many of these remains having been placed where we now find them. Neither does the opinion of some particular authors, that partial inundations of different places have left these Marine bodies behind them at the recess of the waters, seem sufficient to account for the multitudes of these remains, many of which we find thrown upon places inaccessible to such floods. *Moro de Crustaceis in Montib. deprehens.*

Signior Moro has attempted to account for these phænomena on a new plan of reasoning. He observes, that it is the best basis of argument to begin from facts, and that, if we can certainly find how some part of these animal remains come to be deposited at such great distances from their natural residence, we may very rationally conclude, that by the same means, be they what they will, all the rest were also brought thither. He adds, that the earth, once the bottom of the sea, or the level surface of a plain, may be, and frequently has been, in the memory of man, raised up into a mountain by subterranean fires, earthquakes, and volcano's. He mentions the famous instances of the new island raised out of the sea near Santorini, in the year 1707, which became of circumference not less than six miles, and of the new mountain raised near Pozzuoli, in 1538.

These, and many other like facts, prove that the origin of mountains and islands may have been such, and that the matter they consist of may have been the same with what was once the bottom of the sea; and that the Marine bodies, found in these mountains, were such as were living, or remaining of living fish, at the time when the islands or mountains were so raised above the surface of the water which before covered it.

This is no new opinion; but this author has set it in a new and much stronger light than it ever had appeared in before, by the instances and examples he has brought in proof of it. Some have been fond of believing that the bodies we call Marine remains, were never indeed any parts of living animals, but that they are mere lusus naturæ, formed in the places where they are found; but Fabius Columna proved this to be an error, shewing that the shark's teeth, or glossopetræ, of the island of Malta, when calcined by a strong fire, yielded ashes, the same as those from animal bodies, and by no means of the same nature with those produced from calcined stones.

MARMO'TTE, *marmotta*, the mountain rat, a creature very common in many parts of Europe, and frequently carried about as a shew by the poor Savoyards. It is of the size of a leveret, or between that of the hare and the rabbit; and is larger-bodied than the cat, but much shorter-legged. Its whole figure and appearance are like the common rat, whence it has its name.

They will play with one another in the manner of kittens, and make a soft and not disagreeable noise on those occasions; but when they are provoked, or when they are affected, as they always are by change of weather, they make a very shrill and disagreeable squeaking. They feed on vegetables, and are very fond of the roots of several plants; they are very fond also of milk, butter, and cheese. They sit on their buttocks to eat, and use their fore-feet as hands to reach their food to their mouths, in the manner of the squirrel. They lie hid in the winter in holes which they dig in the earth, and sleep away a great part of that season. They make their holes in a very nice and artful manner, and make themselves a bed of straw, and other soft matters, that they may lie the softer and the warmer. It is a creature easily bred up tame, and will be perfectly good-humoured and familiar, but it hates dogs.

MARRU'BIUM, *white hore-hound*, in botany, a genus of plants, whose characters are:

The leaves are wrinkled; the calyx is long, and generally furnished with five aculeated appendicula; the galea is erect, with two horns; the beard tripartite, with oblong slender fauces.

Horehound has square, white, hoary stalks, about a foot high, having two leaves at a joint, which are rugged, white, and downy, roundish and blunt-pointed, and serrated about the edges, standing on pretty broad foot-stalks: among these grow very thick whorles, of white, labiated, and galeated flowers, standing in stiff hoary calyces, which end in nine or ten hard, and almost prickly, spinulæ; each calyx contains four small longish seeds; the root is woody, hard, and full of fibres: it grows by the sides of roads, and in lanes; and flowers in June.

The leaves and tops are used.

They are hot and dry, pectoral, and good to free the lungs from hot viscid phlegm, and thereby to help old coughs, especially in cold moist constitutions; the juice being made into a syrup, with sugar or honey, they open obstructions of the liver and spleen, and are very serviceable against the dropsy, jaundice, green-sickness, and obstructions of the catamenia, and suppression of the lochia, and other distempers of the female sex; for which few herbs go beyond it. *Miller's Bot. Off.*

The leaves of the white horehound give no tincture of red to the blue paper; they are very bitter, and have a penetrating smell. It is probable, that in Flanders this smell may approach to that of musk, for Dodonæus affirms it does so. The bitter natural salt of the earth, composed of marine salt, sal ammoniac, and nitre, seem to be united in this plant, with a considerable quantity of sulphur, phlegm, and terrestrial parts.

This plant, by the chemical analysis, yields a great deal of acid phlegm, oil, and earth; a little urinous spirit; some concreted, volatile, and fixed salt; a little lixivial.

Thus it is no wonder, if the white horehound should be a great dissolver, and a good aperitive, and excellent for those who have the asthma or jaundice. The juice of this plant is given to drink, from two ounces to six, for rheums and stubborn coughs: one glass-full of the infusion in white-wine, and several glass-fulls of ptisan, two pugils of the tops of white horehound, are sufficient for one decoction: but the fat must first be taken off, by straining it through a wet cloth, and dissolving it in half a drachm of chalybeated soluble tartar, or twenty grains of the chalybeated flowers of sal ammoniac; one or two ounces of the syrup of horehound, two drachms of the tincture of steel, and two ounces of orange-flower-water may be prescribed for the suppression of the menses. *Martyn's Tournefort.*

MA'RSHY *Countries*.—It is to be observed, that neither canals, nor even large inundations, where the water is deep, are nearly so dangerous in regard to people's health, or exhale so much noxious vapours, as Marshy grounds, or meadows that have

have been once floated, and but lately drained; and that fields, though dry in appearance, may neverthelefs be moift, by the tranfpiration of fubterraneous water.

By this exhalation, as well as by that of ditches and canals, in all which innumerable plants and infects die and rot, the atmofphere is filled, efpecially during the latter part of the fummer and autumn, with moift, putrid, and infalutary vapours. Add to this, that, Marfhy countries being low, and without hills to receive the winds, or direct them in ftreams upon the lower grounds, the air is apt to ftagnate and corrupt. The common water too, being either collected from rains, and preferved in cifterns, or drawn from fhallow wells, is, in hot and dry feafons, foon corrupted; fo that every thing confpires, in fummer, not only to relax the folids, but to difpofe the humours to putrefaction.

In Marfhy countries, rainy and moift feafons differ greatly; fince intenfe and continued heats occafion the greateft moifture in the atmofphere, by the immenfe exhalations they raife; whereas frequent fhowers, during the hot feafon, cool the air, check the excefs of vapours, dilute and refrefh the corrupted ftagnating water, and precipitate all putrid and noxious effluvia. But, if heavy rains, in the beginning of fummer, are fucceeded by great and uninterrupted heats, thofe rains, by overflowing the meadows, ferve only for matter of more exhalation, and to make the feafon more fickly, and the diftempers more fatal.

The epidemic of the hot feafon, and the great endemic of Marfhy countries, is a fever of an intermitting nature, commonly of a tertian fhape, but of a bad kind; which in the damper places, and worft feafons, appears in the form of a double tertian, remittent, continued putrid, or even an ardent fever. Marfhy countries are likewife fubject, more than any others, to the cholera morbus, dyfentery, and a kind of fcurvy, peculiar to a moift and corrupted air; the fymptoms of which laft agree fo much with the fea-fcurvy, that they may be accounted the fame difeafe; the exhalations of the canals and Marfhes, in hot weather, acting like the vapours which rife from the bildge-water of a fhip.

As to the diet neceffary in moift places, it may be obferved in general, that thofe who can afford to live above the common rate, keep freeft from the difeafes of the Marfhes. For fuch climates require dry houfes, the apartments raifed from the ground, proper exercife, without labour in the fun, or in the evening damps; a juft quantity of vinous liquors, and victuals of good nourifhment. Without fuch helps, not only ftrangers, but the natives themfelves, are extremely fickly after hot and clofe fummers. *Pringle's Obfervations on the Difeafes of the Army.*

MARSHY *lands*, a name given by our farmers to a fort of pafture land, or grazing ground, which lies near the fea, rivers, or fens.

As to lands lying near rivers, the great improvement of them is their being overflowed, which brings the foil of the uplands upon them, fo that they need no other mending, though kept conftantly mowed. The great inconveniency of thefe lands is their being fubject to floods, which high hills near the fides of rivers, and the long courfe of them, befpeak to be frequent: and, though the richeft land generally lies near fuch rivers, yet there is the greateft danger of the crops being fpoiled, efpecially, when they are not inclofed, and therefore cannot be fed with cattle. This, when feeding bears any thing of a price, would be the very beft way of managing thefe uncertain lands; and inclofing them would be highly beneficial, on this account. *Mortimer's Hufbandry.*

The Marfh-lands in Lincolnfhire, and many other parts of England, produce a fort of grafs, which feed fheep in a better manner than that of almoft any other land, in regard to their fize, and the quantity of wool. The fheep about Grimfby, and fome other places in this county, produce fuch lufty wool, or, as they call it, wool of fo large a ftaple, that three or four fleeces ufually make a tod of twenty-eight pounds weight. Several hundred loads of this wool are yearly carried from thefe places to Norfolk, Suffolk, and other parts of the kingdom, for the cloth manufacturers. They fend this in large packs, which they call pockets, each containing about five and twenty hundred weight. *Philof. Tranf.* N°. 223.

When Marfh lands lie flat, it is neceffary for the owner to keep all the water he can from them. The fea water, in particular, is to be kept from them as much as poffible; and this is ufually done at a very great expence, by high banks and walls.

Two things greatly wanting in thefe lands, in general, are good fhelter for the cattle, and frefh water. The careful farmer may, however, in a great meafure, obviate thefe, by digging, in proper places, large ponds to receive the rain water, and by planting trees and hedges in certain places towards the fea, where they may not only afford fhelter for the cattle, but keep off the fea breezes, which often will cut off the tops of all the grafs in thefe places, and make it look as if mowed.

Thefe lands fatten cattle the fooneft of any, and they preferve fheep from the rot. It would be of great advantage to them, if there were raifed, in the middle of every large Marfh, banks of earth in a crofs, or in the form of two femi-circles, and thefe planted with trees; thefe would ferve as a fhelter for cattle, let the wind blow from what quarter it would, and would foon repay the expence of making.

There are, in different parts of England, very large quantities of land upon the fea-coafts that would be worth taking in, tho' no one has yet thought of doing it. The coafts about Bofton, Spalding, and many other parts of Lincolnfhire, give frequent inftances of this, where the fea falls from the land, fo that on the outfide of the fea walls, on the owfe, where every tide the falt water comes, there grows a great deal of good grafs, and the owfe is firm to ride upon when the water is upon it.

This owfe, when taken in, hardly finks any thing at all, and they dig the walls from the outfide of it, all the earth they are made of being taken from thence, and the fea, in a few tides, filling it up again: and, though the fea, at high-water, comes only to the foot of the bank, yet, once in a year or two, fome extraordinary tides go over the banks, though they are ten feet high. Thefe banks are fifty feet broad at the bottom, and three feet at the top; and the common price of making them is three fhillings a pole, the earth being all carried in wheelbarrows, and face towards the fea, where the greateft flope is, being turfed. *Mortimer's Hufbandry.*

MARTEA'U, the name given by French naturalifts to a peculiar fpecies of oyfters, called alfo malleum by others. It is one of the moft curious fhells in the world. Its figure is that of a hammer, with a very long head, or rather of a pick-ax. It has a body of a moderate thicknefs, and two long arms. It is of a brownifh colour, with a beautiful tinge, of a violet blue. Notwithftanding the ftrange fhape of thefe fhells, they clofe very exactly.

MA'RTES, *the martin, or martlet*, in the Hiftory of Quadrupeds, the name of a creature of the weafel kind, called alfo by fome fogua. There are two fpecies of this creature, the one called the Martes abietum; or fir martin, the other the Martes fagorum, or beech martin. The beech martin is diftinguifhed from the other by having a larger and blacker tail, and being all over of a darker colour, and being white on the throat, whereas the others are yellow; but the fpecies are fcarce kept up diftinct, the creatures mixing with one another in the breed. When diftinct, the beech martin is found to be a much tamer creature than the other, and may be kept about houfes like a cat; and often lives of its own accord about houfes, and among old walls. Their fkins make a valuable fur; and that of the fir martin, or yellow kind, is much the moft valuable. *Ray's Syn. Quad.*

MA'RTLET (*Dict.*) — Some heraldifts fay that this mark of diftinction is more peculiarly applied to the fourth brother or family. See *plate* XXI. *fig.* 37. in the Dictionary.

MA'RVEL *of Peru*, a name given to the plant more ufually called jalap. See the article JALAP.

MA'RUM *Syriacum, Syrian maftich*, in botany, a genus of plants, whofe characters are:

It is a plant with a lip-flower, confifting of one leaf; but has no galea (or creft) the ftamina fupplying the place of it; but the under lip is divided into five large fegments, the middlemoft of which is hollow like a fpoon: thefe flowers are produced fingle from the wings of the leaves: to which may be added, it has the appearance of a fhrub, and an hot volatile fmell.

This plant is propagated by planting cuttings, in any of the fummer-months, upon a bed of frefh light earth, obferving to water and fhade them, until they have taken root; after which they may be tranfplanted either into pots or borders of the fame frefh light rich earth: but the greateft difficulty is, to preferve it from the cats; which will from a great diftance tear this plant in pieces, and from which there is fcarcely any guarding it, efpecially near towns and cities, where there are many of thefe animals, unlefs by planting large quantities of it: for it is obfervable, that, where there are but few of them, the cats will not leave them until they have quite demolifhed them; whereas, when a large quantity of the plants are fet in the fame place, they will not come near them.

Thofe plants which are put into pots, fhould be fheltered in winter; but thofe in the full ground will abide the cold of our ordinary winters very well, provided they are planted on a warm dry foil; and may be clipped into pyramids or balls; in which figures I have feen fome plants of this kind near three feet high, which have endured the open air feveral years without any covering.

The common herb maftich is a cephalic, and is of fervice in all diforders of the nerves. It has alfo an aftringency, by means of which it is of fervice in hæmorrhages, of all kinds, particularly in profluvia of the menfes.

MA'RYGOLD, *caltha*, in botany, the name of a genus of plants, the characters of which are thefe: the flower is of the radiated kind; its difk is compofed of feveral flofcules, and its outer circle of femi-flofcules; thefe are all placed upon the embryo feeds, and contained in a common cup. The embryo's finally become flat, crooked, and marginated capfules, containing a long-fhaped feed.

The flowers of the common marygold are cordial and alexipharmic; they promote fweat, and are good to throw out the fmall-small-pox, or any other eruption. They also promote the menses, and are so far aperient, that they are found of service in the jaundice, and indurations of the spleen. The midwives burn them under women whose labour does not come on properly, and suppose they are of great virtue in promoting the pains. They also distil a water from them, as a remedy for sore eyes; but these last virtues are not so well warranted.

MA'SONS, the name of a mechanic trade, called also stone Masons, or stone-cutters, whose business is the stone-work in buildings, tombs, broad pavements, &c. a most curious art, taken in all its parts, and not hard work; (for they have labourers under them, who saw and do the drudging part) and a lad, to be properly qualified for learning this trade, ought to have an insight in geometry and architecture.

They take with an apprentice ten pounds, whose working hours are from six to six; a journey-man's wages fifteen or eighteen shillings a week; and to set up a master two hundred pounds will be sufficient, though some employ a good deal more.

They are a society so long as the year 1410, in the reign of king Henry the IVth, and with whom the marblers, or statuaries, joined; but not incorporated into a company till 1677, by king Charles the IId. livery-fine five pounds.

Their hall is in Mason's-alley, in Basinghall-street; and their court-day on the first Thursday after quarter-day.

They have also a stand in St. Paul's church-yard, in which they sit, to attend the lord mayor, on the day of his installation.

Arms. Azure, on a chevron argent, between three castles argent, a pair of compasses, somewhat extended, of the first. Motto. In the Lord is all our trust.

MA'TCHING, in the wine trade, the preparing vessels to preserve wines and other liquors, without their growing sour or vapid.

The method of doing it is this: melt brimstone in an iron ladle, and, when thoroughly melted, dip into it slips of coarse linen cloth; take these out, and let them cool. This is what the wine coopers call match. Take one of these matches, set one end of it on fire, and put it into the bunghole of a cask; stop it loosly, and thus suffer the match to burn nearly out; then drive in the bung tight, and set the cask aside for an hour or two. At the end of this time examine the cask, and you will find that the sulphur has communicated a violently pungent and suffocating scent to the cask, with a considerable degree of acidity, which is the gas, and acid spirit of sulphur. The cask may, after this, be filled with a small wine, which has scarce done its fermentation, and, bunging it down tight, it will be kept good, and will soon clarify. This is a common and very useful method; for poor wines would scarce be kept potable, even a few months, without it. Nor could stums be prepared in large quantities without this help. *Shaw's Lect.*

MA'STER *Load*, in mining, a term used to express the larger vein of a metal, in places where there are several veins in the same hill. Thus, it often happens, that there are seven, sometimes five, but more usually three veins or loads, parallel to each other, in the same hill. Of these, the middle vein is always greatly the largest. This is called the Master load; and the others which lie there, two, or one, on each side of this, are called the concomitants of the Master load.

The general breadth of the Master loads, in Cornwall, is from three to seven feet. They are seldom larger than this, except in certain peculiar places, as where all the veins meet together, as they sometimes do, and form a knot, from which they separate again, and each takes its peculiar course. The size of such a knot is easily determined, and it is usually very rich in tin, or the other metal of the mine. The several parts, even of the Master load, are not at all regular in breadth, but, from six feet, it will, in some places, dwindle to one, or even to an inch broad, in a very small space; but the miners are not disheartened at this, for they know it will soon grow wider again, unless really worked out. *Phil. Transf.* N°. 69.

The Master load usually lies in a hard rocky or shelfy stratum, made up of metalline matters, spars, mundic, and other unprofitable substances, or weeds, as the miners call them, and is, as it were, all along a continued rock; but has many veins and joints, as they are called. In some places the matter in which the ore lies is softer, and then it is much more easily worked. In Cornwall they usually allow two shovel-men to three beele men or pickers; but, where the load runs in a softer substance, there must be a greater proportion of shovellers or carriers away.

There is generally water found about the loads of the metal. In most places it is met with at some feet deep from the loady surface; and it often runs through the heart of the load, not in a direct channel, but windingly, in and out, insensibly, through the veins and joints of the load. When the miners have followed a load to some depth, and the water begins to be troublesome, as it generally soon is, if there be any in the work, they descend to the bottom of the hill, where they have that conveniency, and at the lowest place begin as little adrift, as the convenience of working or driving will permit, scarce half so big as that for a load; they carry this on, on a level, till they come to the work itself. In this the use of the dial is needful, which they term plumming and dialling.

By this means the exact place of the work is known, where to bring the adit, or to sink down to make an air-shaft. Tho' the water is troublesome in the loads, yet there is always some great convenience attending it, which is, that, where there is water, there is never want of air for the respiration of the miners, and the candles always burn well. But it is also to be observed, that, in a soft, loose, quagmire country, the earth sometimes falls in after the workmen, in such a manner as, though it does not choak up the whole shaft, yet it so far stops it, as to render the current of air less free, and the miners find the utmost necessity of opening a shaft for air to respire from the surface. If the soil be so soft as not to be able to support itself in the working, as is sometimes the case in these wet clayey hills, it is necessary to prop it up, as they go on, with boards, posts, and the like. This adds greatly to the expence of mining; but, in working a Master load, it is often worth while. When the miners are out of heart at the trouble of walling and propping, on this occasion, it sometimes happens, that a dipping of the load carries them down into a firmer stratum, and they are at once relieved from all that trouble and danger.

MATRICA'RIA, *feverfew*, in botany, a genus of plants whose characters are:

The root is annual and fibrous; the leaves are cut many ways, and by conjugations; the calyx is hemispherical and squamous; the flowers are collected into bunches, or form umbella's, and are generally marked with white rays.

The leaves of the feverfew are large and winged, divided into several sections, usually about seven, that at the end being the largest; they are deeply cut in, or laciniated, of a pale yellow green colour. The stalks are stiff, round, or striated, two feet high, or more, cloathed with smaller leaves, and pretty much branched towards the top, on which grow large flat umbels of flowers, made of several white petals, broader and shorter than those of the chamomile, set about a yellow thrum. The root is thick at the head, having many fibres under it; the whole plant has a very strong, and, to most, an unpleasant smell. It grows in hedges and lanes, and flowers in June and July. The leaves and flowers are used.

This is a herb particularly appropriated to the female sex, being of great service in all flatulent disorders of the womb, and hysteric affections; procuring the catamenia, and expelling the birth and secundines. The juice to the quantity of two ounces, given an hour before the fit, is good for all kinds of agues. It, likewise, destroys worms, provokes urine, and is good for the dropsy and jaundice. *Miller's Bot. Offic.*

MATTS, on board a ship, a kind of broad, thick clouts, wove out of spun yarn, sinnet, or thrums; and used to preserve the main and fore yards from galling against the masts at the ties, and at the gunnel of the loof. They also serve to keep the clew of the sail from galling there; as also to save the clews of the foresails from doing so at the beak-head and boltsprit.

MAT'TAGESS, in zoology, the English name of the larger species of the lanius or butcher bird.

The word Mattagess is borrowed from the Savoyards, and signifies the murdering pye; and has been given it from its savage disposition, and its resemblance to the magpye, in the shape of its tail.

It is barely of the bigness of a thrush; its beak is moderately long, black, and hooked at the end, but straight all the way to that. Its tongue is bifid and hairy, and there are several black and short bristles at the top of the beak. Its head, back, and rump are grey. Its chin and belly are white, and its throat and breast variegated with dusky streaks. Its feet and legs are black; it is very common in Germany, and is sometimes seen in the northern parts of England, but with us it is not very frequent. It lives among low bushes, and builds in them; its nest is made of moss, wool, and soft herbs, and the tender branches of heath; it has seven young ones at a brood, which are of a greenish colour, and very little resemble their parent; it feeds on thrushes, and smaller birds, and is a very terrible destroyer among them. *Ray's Ornithology.*

MA'VIS, in zoology, the common name of the song thrush, or throstle, called by authors the turdus viscivorus minor, to distinguish it from the larger species, called in English the missel bird; and usually known among us also by the simple name thrush. It is called viscivorus by authors, from its resemblance in colour to the viscivorus, not from its feeding on the misletoe berries, as that does.

It is much smaller than the missel bird, and of a middle size, between the fieldfare and red-wing. Its back is of a greyish brown, somewhat like the colour of the Spanish olives; its belly white, and its breast yellowish, and spotted with brown and blackish spots, and it is spotted round about the eyes; its under small feathers of the wings are of a yellowish or reddish brown, and those under the tail whitish; its legs are brown. It feeds on worms, snails, and small insects, and remains with us the whole year; it builds with moss and stubble, and lines the nest with mud. On this it lays five or six eggs, which are of a bluish green, variegated with a few black spots; it sits on hedges and bushes, and sings very agreeably. *Ray's Ornithology.*

MAU'MY *Soil*, in argiculture, an earth confifting of a white marly clay, chalk, and fand, which caufes it to work very fhort, as the farmers call it, when any thing dry. This fort of land is ufually fowed with wheat, mifcellan, or barley, and requires the fame tillage that the clay land does, and muft be kept dry and warm.

Its moft proper manure is the rotteneft dung: as they frequently fow beans next after wheat in clayey grounds, fo in thefe they chufe to fow peafe, chufing a fair and fettled feafon for their feed time; for, if there happen a fmart fhower foon after their fowing, the earth will bind fo firmly together after it, that moft of the feed will be loft. *Plot's Oxfordfhire.*

MEA'DOW.—There are two forts of Meadows in England, one of which is ftiled water-Meadows, and the other are fimply called Meadows.

Water-Meadows are thofe which lie contiguous to rivers or brooks, from whence the water can be carried to overflow the grafs at pleafure. Of thefe there are large tracts in feveral parts of England; which, if fkilfully managed, would become much more profitable to their owners, than they are at prefent; as hath been already mentioned in another place: for nothing can be more abfurd than the common practice of flowing thefe low grounds all the winter; whereby the roots of all the fweeteft kinds of grafs are deftroyed, and only fuch graffes left, as are natives of marfhes, which are coarfe and four; and, if people were curious to examine the herbage of thefe water-Meadows, they would find the bulk of them compofed of bad weeds, fuch as grow by the fides of rivers, brooks, and ditches; of which the feveral forts of docks make no fmall fhare; and, although many of thefe Meadows produce a great burden of what the country-people call hay, yet this is only fit for cows, cart-horfes, and other animals, which by hard labour and hunger are driven to eat it; for horfes which have been accuftomed to feed on good hay, will ftarve before they will touch it: and after the grafs is mown off thefe Meadows, and cattle turned in to graze upon them, how common is it to fee the land almoft covered with thefe rank weeds, which the cattle never will eat? Which muft always be the condition of fuch Meadows, where the water is let over them in autumn and winter; for, as the fides of rivers and brooks do every-where abound with thefe rank weeds, whofe feeds ripen in autumn, falling into the water, they are carried by the ftream, and depofited on the land, where they grow, and fill the ground in every part: but fo incurious are the generality of farmers in this refpect, that, if the ground is but well covered, they care not what it is; few of them ever taking any pains to weed or clean their paftures.

The method which I propofe for the management of thefe Meadows is, never to flow them till the middle or latter end of March, excepting once or twice in winter, when there may happen floods, which may bring down a great fhare of foil from the upper lands; at which times it will be of great fervice to let water upon the Meadows, that the foil may fettle there; but, the fooner the wet is drained off, when this is lodged, the greater advantage the Meadows will receive by it: but, from the end of March to the middle of May, by frequently letting on of the water, the growth of the grafs will be greatly encouraged; and at this feafon there will be no danger of deftroying the roots of the grafs: and after the hay is carried off the ground, if the feafon fhould prove dry, it will be of great fervice to the grafs, if the Meadows are flowed again; but, when this is practifed, no cattle fhould be turned into the Meadows, till the furface of the ground is become firm enough to bear their weight without poaching the land; for otherwife the grafs will fuffer more from the treading of the cattle, than it will receive benefit by the flowing: but thefe are things which the country people feldom regard, fo that thefe Meadows are generally very unfightly, and rendered lefs profitable.

I would alfo recommend the weeding of thefe Meadows twice a year; the firft time in April, and again in October; at which times, if the roots of docks, and all bad weeds, are cut up with a fpaddle, the Meadows will foon be cleared of this trumpery, and the herbage greatly improved.

Another great improvement of thefe lands might be procured by rolling them with a heavy roller, in fpring and autumn. This will prefs the furface of the ground even, whereby it may be mown much clofer; and it will alfo fweeten the grafs: and this piece of hufbandry is of more fervice to pafture, than moft people are aware of.

As to thofe Meadows which cannot be flowed, there fhould be the fame care taken to weed and roll them, as hath been directed for the water-Meadows: a ralfo never to let heavy cattle graze upon them in winter, when they are wet; for the cattle will then poach them, and greatly injure the grafs: therefore thefe fhould be fed down as clofe as poffible in the autumn, before the heavy rains fall to render the ground foft; and thofe paftures which are drier may be kept to fupply the want of thefe in winter; and, where there are not cattle enough of their own to eat down the grafs in time, they had much better take in fome of their neighbours, than fuffer their fog (as it is called) to remain all the winter. When thefe Meadows are fed in the autumn, the greater variety of animals are turned in, the clofer they will eat the grafs: and I am fully convinced, the clofer it is eaten, the better the grafs will come up the following fpring: therefore if, during the time while the cattle are feeding, the Meadows are well rolled, the animals will eat the grafs much clofer, than they otherwife would.

MEA'SURE, (*Dict.*)—We have lately had fome acute comparifons between fome of the French weights and meafures and thofe of England, the refult of which is, 1. The Paris half toife, as fet off on the ftandard kept by the Royal Society, contains of Englifh inches, by the fame ftandard, 38,355; whence it appears, that the Englifh yard and foot are, to the Paris half toife and foot, nearly as 107 to 114; for, as 107 to 114, fo is 36 to 38. 35514.

2. The Paris two marc, or fixteen ounce weight, weighs Englifh troy grains 7560; whence it appears, that the Englifh troy pound of twelve ounces, or 5760 grains, is to the Paris two marc, or fixteen ounce weight, as 16 to 21; that the Paris ounce weighs Englifh troy grains 472.5; and that confequently the Englifh troy ounce is to the Paris ounce, as 64 is to 63.

3. The Englifh avoirdupoife pound weighs troy grains 7004; whence the avoirdupoife ounce, whereof fixteen make a pound, is found equal 437.75 troy grains. And it follows, that the troy pound is to the avoirdupoife pound, as 88 to 107 nearly; for, as 88 to 107, fo is 5760 to 7003.636; that the troy ounce is to the avoirdupoife ounce, as 80 to 73 nearly; for, as 80 to 73, fo is 480 to 438. And, laftly, that the avoirdupoife pound and ounce are to the Paris two marc weight and ounce, as 63 to 68 nearly; for, as 63 to 68, fo is 7004 to 7559.873.

4. The Paris foot, expreffed in decimals, is equal to 1.0654 of the Englifh foot, or contains 12.785 Englifh inches. *Philof. Tranf.* N°. 465.

MECHA'NICS. (*Dict.*)—The term Mechanics has been formerly, and ftill is ufed in a double fenfe in very different fciences, both with refpect to their objects and principles. For the name Mechanics is applied equally to that fcience which treats of the equilibrium and comparifon of powers, and to that fcience, in which the nature, generation, and alteration of motion are explained. To avoid ambiguity, therefore, it would be proper to give the name ftatics to the fcience of equilibrium and comparifon of powers, and to reftrain the term Mechanics to the fcience of motion.

Thefe two fciences not only differ as to their objects and principles, but alfo with refpect to the times in which they have been cultivated. Some of the principles of ftatics were eftablifhed by Archimedes; but Galileo laid the firft foundation of Mechanics, when he inveftigated the defcent of heavy bodies; and, fince his time, by the affiftance of the new methods of computation, a great progrefs has been made, particularly by Sir Ifaac Newton in his Principia. This admirable work is now rendered more acceffible to beginners by the learned comment of the fathers le Seur and Jacquier, printed, with the text, at Geneva, 1739, 4to, 1742, 4 Vols. 4to. We have alfo the fciences of ftatics and Mechanics treated of, under the name of phoronomia, by the late learned profeffor Herman, Amft. 1716, 4to. Mr. Euler's Mechanica, five de Motus Scientia, is fufficiently recommended by the name of the author, well known as one of the moft eminent mathematicians in Europe. This work, however, did not efcape the cenfure of a late ingenious writer; but, granting the juftnefs of his remarks, it may be faid, that a few inaccurate expreffions, owing to analogies carried too far, and to the ftyle of infinitefimals, are but fmall flaws in fuch a work. As to ftatics, the fubject has been almoft exhaufted by Varignon, in his Mecanique Paris, 1725, 2 Vols. 4to.

ME'DAL. (*Dict.*)—Impreffions of Medals. A very eafy and elegant way of taking impreffions of Medals and coins, not generally known, is this: melt a little ifinglafs glue, made with brandy, and pour it thinly over the Medal, fo as to cover its whole furface; let it remain on for a day or two, till it is thoroughly dry and hardened, and then, taking it off, it will be fine, clear, and hard as a piece of Mufcovy glafs, and will have a very elegant impreffion of the coin. *Shaw's Lect.*

We have an eafy method of procuring the true impreffion or figure of Medals and coins, by Mr. Baker in the Philof. Tranf. N°. 472.

Take a perfect and fharp impreffion, in the fineft black fealing-wax, of the coin or Medal you defire; cut away the wax round the edges of the impreffion; then with a preparation of gum-water, of the colour you would have the picture, fpread the paint upon the wax impreffion with a fmall hair pencil, obferving to work it into all the finking or hollow places, thefe being the rifing parts of the Medal; and the colouring muft be carefully taken from the other parts with a wet finger. Then take a piece of very thin poft paper, a little larger than the Medal, and moiften it quite through. Place it on the wax impreffion, and on the back of the paper lay three or four pieces of thick woollen cloth or flannel, of about the fame fize; the impreffion, with its coverings, fhould be placed between two fmooth iron plates, about two inches fquare, and one tenth of an inch thick. Thefe muft be carefully put into a fmall prefs, made of two plates of iron, about five inches and an half long, one inch and a half wide, and half an inch in thicknefs, having a couple of long male fcrews,

running

running through them, with a turning female ſcrew on each, to force the plates together. Theſe being brought evenly together, by means of the ſcrews, will take off a true and fair picture of the Medal; which, if any deficiencies ſhould appear, may eaſily be repaired with a hair pencil, or pen, dipped in the colour made uſe of.

If a relievo only be deſired, nothing is neceſſary, but to take a piece of card, or white paſte-board, well ſoaked in water; then placing it on the wax mould, without any colouring, and letting it remain in the preſs for a few minutes, a good figure will be obtained.

MELÆNA'CTOS, *the black eagle*, a ſpecies called alſo aquila Valeria by ſome authors. It is a ſmall eagle, of twice the bigneſs of a crow. Its jaws and eye-brows are deſtitute of feathers, and look reddiſh: its head, neck, and breaſt, are black, and in the middle of his back he has a large triangular ſpot, of a pale browniſh red, with ſomething of whiteneſs intermixed. His rump is a reddiſh brown, and his wings variegated with black, white, and grey; his beak is not large, black at the end, the ſkin covering the noſtrils red, and the iris of his eye hazel-coloured. His legs are feathered a little below the knee, and below that red, and the claws very ſharp. *Willughby's Ornithology.*

ME'LANCHOLY (*Dict.*)—The cauſes evidently productive of Melancholy are obſerved to be,

1. All things which fix, exhauſt, or diſturb the nervous fluid of the brain; ſuch as violent and ſudden frights, intenſe thinking upon any object, exceſſive love, watchings, ſolitude, fear, and hyſteric diſorders.

2. Such things as hinder and diſturb the generation, reparation, circulation, and various ſecretions and excretions of the blood, eſpecially in the ſpleen, ſtomach, omentum, pancreas, meſentery, inteſtines, liver, uterus, and hæmorrhoidal veſſels: ſo that, of conſequence, Melancholy may be produced by the hypochondriacal diſorder; by acute diſeaſes ill cured, and eſpecially a phrenitis and burning fever; by an exceſs of all the ſecretions and excretions; by ſuch aliments and drinks as are cold, tenacious, terreſtrial, tart, and aſtringent; by violent heat long protracted and parching the blood; as alſo by a ſtagnant, moiſt, and cloudy air.

3. A naturally black, hairy, dry, ſlender, and robuſt conſtitution of body, a middle age, a quick, penetrating, and diſcerning genus.

If this diſorder continues long, it produces ſtupidity, epilepſies, apoplexies, madneſs, convulſions, blindneſs, ſurpriſing fancies, laughter, weeping, ſinging, ſighs, eructations, flatulences, anxieties; an urine ſometimes copious and limpid like water, and at others highly thick; a retention, accumulation of the excrementitious blood in the veſſels of the abdominal viſcera, and often a ſudden excretion of it; obſtinate coſtiveneſs, frequent ſpitting of a thin matter, and an incredible ability of enduring watchings, hunger, and cold.

This diſorder has often been cured by a ſupervening unſeemly itch, ſometimes reſembling an elephantiaſis; by numerous and large varices; by a copious diſcharge from the turgid hæmorrhoidal veins; and an evacuation of the black bile by vomit and ſtool.

Patients labouring under this diſorder are generally injured by all medicines which impair the ſtrength, and evacuate too forcibly; as alſo by thoſe which throw the humours into too violent commotions, whether cordials, or medicines of whatever other denomination.

Hence the beſt method of curing this diſorder is, after a due obſervation of the firſt cauſes and the variety of patients conſtitutions, to accommodate various medicines to theſe cauſes, and various conſtitutions.

The ſeveral intentions of cure to be purſued, therefore, are,

1. To rouſe, augment, and regulate the fluids of the brain and nerves; which is done, firſt, by diverting the mind from its uſual object to others of an oppoſite nature: ſecondly, by inducing cautiouſly another diſpoſition, or affection of mind, oppoſite to Melancholy: thirdly, by humouring the perverſe and falſe turn of the imagination: or, fourthly, by frequently oppoſing it with great vigour.

2. To remove thoſe obſtructions which are either the cauſe, or the effect, of a perverted imagination, by ſoftening, inciding, and ſtimulating the obſtructing matter, by means of mineral waters, whey, viſceral, hepatic, and antihypochondriac decoctions, waters invigorated with lixivial or compound ſalts, laxative preparations of mercury, emetics, motion, exerciſe, riding, ſailing, uterine medicines, and ſuch as promote the lochia, remedies which procure hæmorrhoidal diſcharges, baths, liniments, and plaiſters.

3. They alleviate the ſymptoms by veneſection, immerſion in cold water, and the uſe of carminatives and opiates.

4. After due evacuations, to exhibit ſuch things as are from experience known to exhilarate the mind, and corroborate all the parts of the body.

From what has been ſaid, it is obvious that the perfect cure of this diſorder, as well as of great many others falſly accounted incurable, conſiſts in the correction of the bilis atra, or melancholic humour.

When Melancholy increaſes ſo far as to bring on an agitation of the fluids of the brain, capable of driving the patient into a raging fury, the diſorder is called madneſs.

This only differs in degree from a dejected Melancholy, is its offspring, ariſes from the ſame cauſes, and is generally to be cured by the ſame medicines.

In madneſs the muſcles are generally ſurpriſingly ſtrong, the patient is afflicted with watchings, incredibly capable of enduring hunger and cold, diſtracted by terrible imaginations, and ſubject to thoſe diſorders called lycanthropia and cynanthropia; which ſee.

It is obſervable, that, upon diſſecting thoſe who have died of madneſs, the brain has been found dry, hard, and friable, with its cortical ſubſtance of a yellow colour, and its veſſels turgid, varicoſe, and diſtended with black and viſcid blood.

It is alſo obſervable, that, during this diſorder, all the excretions have, in like manner, almoſt ceaſed.

Unexpected precipitation into the ſea, and a ſubmerſion in it, continued as long as poſſible, conſtitute the principal remedy for it.

Madneſſes, obſtinate againſt all remedies, have often been removed upon the approach of varices, hæmorrhoidal diſcharges, dyſenteries, dropſies, copious ſpontaneous hemorrhages, tertian and quartan fevers.

Such a ſort of madneſs ſometimes ariſes after the body is, by an autumnal, violent, and long-continued intermittent fever, weakened and exhauſted, both by the force of the diſeaſe, and repeated veneſections and purgings. The madneſs is alſo generally brought on again by theſe very means.

This ſpecies of the diſorder is only to be cured by the uſe of reſtoratives, cardiacs, and corroboratives, long perſiſted in: but, if it is treated with evacuation, it brings on an atrophy, a weakneſs, and an unſurmountable fooliſhneſs.

But a madneſs ariſing in robuſt vigorous perſons in the flower of their age, or of hot and plethoric habits, is to be cured by repeated veneſections, interpoſing a briſk purge between each; and, when the diſorder is alleviated, it is to be treated with opiates and cardiacs. *Boerhaave's Aphoriſms.*

ME'LON, *melo*, in botany, makes a diſtinct genus of plants, the characters of which are theſe:

The flowers conſiſt only of one leaf each, and are wide at the mouth, and divided into ſeveral ſegments, wholly reſembling the flowers of cucumbers. Of theſe alſo ſome are male or ſterile flowers, having no embryo fruit; others are fruitful or female flowers, having an embryo which ripens into a large fruit of an oval figure, ſometimes ſmooth, ſometimes rough, divided into three cells, and containing oblong ſeeds; each of theſe cells ſeems alſo divided into two. See *Plate* XXXII. *fig.* 4. where *a* is the flower, *b* the fruit.

The proper management and culture of Melons is this: the ſeeds ſhould be procured from good Melons, produced in ſome diſtant garden; for, if ſowed on the place where it was raiſed and ripened, it is very apt to degenerate. This ſeed ſhould be kept three years before it is ſowed, and it ſhould be ſowed at two ſeaſons. The firſt for the early crop, to be raiſed under frames, ſhould be ſown in January or the beginning of February; the ſecond, to be raiſed under bell or hand glaſſes, is to be ſowed in March, and this is the ſowing which produces the general crop of Melons, which ripen in July and Auguſt. About a week before the time of ſowing the ſeed, ſome dung ſhould be prepared in a heap with the litter, or ſome coal aſhes, and the ſame methods uſed in the early cucumbers, for the firſt crop; but for the ſecond, which is of more general uſe, the ſowing may be on the upper ſides of the hot-beds that were for the early Melons or cucumbers, or on a freſh moderate hot-bed. When the young plants are come up, they muſt be removed to another hot-bed, and covered with hand glaſſes, and watered and ſhaded till they have taken root; and, after this, they muſt have as much air and ſun as the ſeaſon will permit, and their ſtalks ſhould be earthed up as they grow, which will vaſtly ſtrengthen them.

In the beginning of April the plants will begin to ſhew their rough leaves; a parcel of dung is then to be prepared with litter and coal aſhes. The common quantity is a load to five holes; a trench muſt then be dug, which ſhould be ten inches deep, if the ſoil be dry, but only three, if it be wet. The dung muſt be evenly laid in this, and heaped up to three feet high: then the place intended for the holes muſt be marked out, at each of which muſt be laid a baſket full of light rich earth, thruſting a ſtick of two feet long into the middle. Then cover the dung all over with the earth, which was dug up out of the trench, laying it ſmooth, and about three inches thick; then the glaſſes are to be placed cloſe down over the place where each of the ſticks is, and in two days the earth will be warm enough to receive the ſeedling plants. The ſticks are now to be taken out, and the earth formed in the places into a hollow like a baſon, that it may retain the water which is given to the plants. The plants are then to be taken up, and two ſtrong and thriving ones put into each of theſe holes, which muſt be watered and ſhaded till they have taken root. The plants having taken root, and thruſt out a fourth leaf, the top of each of them ſhould be pulled off, in order to force out ſhoots from the bottom; and, as the weather becomes warmer, the glaſſes muſt be raiſed with ſtones on the ſouth fouth fide, to give them air, and about twice a week they fhould have a little water.

About the middle of May the ftalks of the plants will begin to prefs upon the glaffes on every fide, and the glaffes are then to be raifed up on bricks, to give them room to run out; and they fhould be pegged down with forked fticks, and turned into a proper direction for their running, fo that they may be out of the way of tangling one with another: they fhould now, if the weather be fevere, be fheltered with mats in the night, and watered gently at times. When the ftalks of the plants are grown to the edges of the bed, the earth muft be raifed with old dung buried under it, till it be upon a level with the beds, for two feet wide on each fide. The branches are here to be trained in a proper courfe, and the glaffes are to be left over the roots of the plants; and, after this, what water is given them is to be fprinkled all over the plants. When the fruit begins to appear, the waterings muft be very gentle on the plants; but it will be proper to foak the earth well with large quantities of water about the beds, which will fpread a moifture even to the roots of the plants; from this time the plants fhould be gently watered twice a week, and that always in the evening. When the Melons are grown of the fize of a tennis ball, a piece of tile fhould be laid under each to keep them from the ground. As they afterwards approach to ripenefs, they fhould be turned feveral times, that they may ripen equally every fide; and if, the weather be not very favourable, they fhould be covered with glaffes.

If the Melon is defigned to be eaten as foon as cut, it fhould be fuffered to remain on the plant till it changes pretty yellow, and the ftalk begins to feparate from the fruit; but, if it is to be kept two or three days after cutting, it muft be always cut proportionably earlier.

It is a practice with many to take off the leaves about the fruit, that it may have more fun; but it is wrong, and the fruit is always the worfe tafted for it, and the fkin is hard and tough. *Miller's Gard. Dict.*

When a Melon is perfectly fine, it is full, without any vacuity: this is known by knocking upon it, and, when cut the flefh muft be dry, no water running out, only a little dew, which is to be of a fine red colour. Large Melons are not to be coveted, but firm and well-flavoured ones. Our gardeners, who raife Melons for fale, fow the feeds of the large rather than the good kinds, and they increafe the fize of thefe by much watering the roots, but this fpoils the tafte. Some of the French raife at this time particularly fine Melons, by a method kept as a fecret, but which we find, on a ftrict enquiry, is no other than the ingenious Mr. Quintiny's, of that nation, publifhed near eighty years ago in our Philofophical Tranfactions.

The Melons, particularly proper to be treated in this manner, are thofe which have a thin and fomewhat embroidered fkin, not divided by ribs, and have a red pulp, dry and melting on the tongue, not mealy, and of a high flavour.

Petrified MELONS, a name given by the people who have written books of travels, &c. to certain ftones found on mount Carmel, which refembles Melons.

MELTING *Cone*, in affaying, is a fmall veffel made of copper or brafs, of a conic figure, and of a nicely polifhed furface within. Its ufe is to receive melted metals, and ferve for their precipitation, which is effected, when two bodies melted together, and yet not mixing perfectly with one another in the fufion, feparate in the cooling into two ftrata, on account of their different fpecific gravity. This precipitation might be made in the fame veffel in which the fufion is performed; but then the melting pot or crucible muft be broken every time to get it out, whereas the conic fhape, and polifhed furface of this veffel, makes it eafily got out without violence. The fhape of this veffel is alfo of another ufe in the operation; for, by means of it, the heavy matter, fubfiding to a point, is formed into a perfect and feparate regulus, even where the whole quantity, as is very frequently the cafe, has been but very fmall.

When the quantity of the melted matter is great, it is common to ufe, inftead of this cone, a large brafs or iron mortar, or any other conveniently fhaped brafs or iron veffel. It is neceffary, when the cone is of brafs, to be cautious that it be not made too hot; for the brittlenefs of that metal, when hot, makes it eafily break, on the ftriking with any force on that occafion, to make the melted mafs fall out.

Thefe, and all other moulds for receiving melted metals, muft always be well heated before the mafs is poured into them, left they fhould have contracted a moifture from the air, or have been wetted by accident; in which cafe the melted metal will be thrown out of them with great violence and danger. They ought alfo to be fmeared over with tallow on their infide, that the regulus may be the more eafily taken out of them, and the furface of the mould not corroded by the melted mafs poured in.

If a very large quantity of a metal is, however, to be received into them, and efpecially if any thing fulphureous have place among it, this caution of tallowing the moulds does not prove fufficient; for the large quantity of the mafs makes it continue hot fo long, that this becomes but a flight defence to the furface of the mould. In this cafe the affayer has recourfe to a lute, reduced to a thin pap with water, which, being applied in form of a very thin cruft, all over the infide of the cone or mould, foon dries up indeed, but always preferves the fides of the veffel from the corrofion of the mafs. And this caution is found neceffary, even when pure copper is melted alone, without any mixture of fulphur. See *Plate* XXXI. *fig.* 1. *Cramer's Art of Aff.*

Weaknefs of the MEMORY, in many cafes, is to be confidered as a difeafe, and is looked on in that light by the medical writers, who have prefcribed various remedies for it. The principal caufes of this debility, are a too frequent and conftrained ufe, or rather abufe of it, in the getting by rote numbers of words and fyllables, particularly in the learning different languages; a paralytic affection in the head; violent external injuries in the fame part; violent pains in the head, attended with deliriums, or attending a phrenitis. And to thefe are to be added drunkennefs, and an abufe of venery.

Prognoftics. All debilities of Memory are cured, with great difficulty, by medicines alone; and indeed this complaint is feldom removed, unlefs the whole frame of mind and courfe of life be altered; all paffions avoided, and excefs of every kind left off. But, of all other kinds, that debility of Memory which proceeds from a paralytic diforder of the head, particulary when that diforder affects the tongue, is found to be the moft obftinate and difficult of cure. Much fleep, or exceffive waking, are equally hurtful to the Memory, and frequently bring on an almoft total lofs of it.

Method of treatment. All fuch medicines as are of an agreeable tafte or odour, are generally fuppofed to be of fervice in ftrengthening the Memory; and lignum aloes, ambergreafe, and fome other of the fcented drugs, have been known to do great good. The aromatic, volatile, and fpirituous medicines alfo all help in this cafe, if taken in fmall dofes, and continued for a long time together. The analeptics and nervine medicines are alfo greatly recommended, but they are feldom found of ufe; for, among people afflicted with a debility of Memory, many are thofe of robuft conftitutions and ftrong appetites, who eat already more than nature requires, and have therefore very little ufe for analeptics or nutritive things. Bleedings in fmall quantities frequently repeated, in cafes where there is no contrary indication, frequently prove of great fervice in this cafe; but the primæ viæ are firft to be cleanfed before fuch a courfe is entered upon. Many greatly recommend bags of aromatics to the head, to be conftantly worn in caps; but it is much to be feared thefe can have but very little effect. *Junck. Confp. Med.*

MENSTRUUM (*Dict.*)—*Action of* MENSTRUUMS.—The changes, wrought upon bodies by the diffolving power of Menftruums, feem greatly to depend upon the minute particles of the Menftruum now ftrongly cohering with the particles of the folvend; and can fcarcely be attributed to an effential alteration introduced by the Menftruum into the diffolved particles. Though pure metals, fuch as gold, filver, and mercury, diffolved, feem entirely changed; yet they may be eafily feparated from the Menftruums in the form of a calx, which being fufed in the fire, the metal is recovered unchanged. Hence it appears, that the Menftruums have no other effect, than barely adhering to the furfaces of the metallic particles, while divided: many more inftances of this kind may be given.

But it may be objected, that folution produces new bodies; becaufe, if red lead be diffolved in diftilled vinegar, there arifes fugar of lead, when the acid of the vinegar is attracted into the particles of the lead; and, though this falt of vinegar be diftilled in a retort with a ftrong heat, the fpirit of vinegar is not recovered, but a particular liquor obtained, which will burn in the fire. There are many more inftances of the like kind; but we muft confider, that the adhering parts of the Menftruum cannot always clearly extricate themfelves, but remain united. Hence, fome imagine, that the nature of bodies is deftroyed, while there only happens fuch a fimple conjunction of unchanged particles, under a new appearance.

Thus the blade of a lancet or knife, when naked, has the appearance of the power of cutting; but, when in the fheath, it has not, then, the fame appearance; though, in themfelves, the knife, or lancet, is ftill the fame. The eafier they are to be unfheathed, the fooner the appearance of their cutting power becomes manifeft; but, if the fheath was firmly connected with the blade, we fhould not fcruple to fay, that the blade was changed. So, if a little cylinder of pure filver be gilt, and fo put into aqua-fortis, the filver will be perfectly diffolved, and leave the hollow covering of gold entire, floating like a black film in the Menftruum; whence the acid parts of vinegar may be fo united to certain parts of lead, as not to feparate upon diftillation, but eafily rife together. It would, therefore, be wrong to affert, that the acid of the vinegar was thus converted into a new kind of inflammable liquor by the contact of lead: it is highly probable, that this difference much oftener happens from combination, than from any change of the fubftance; and the like holds, alfo, in feparation. For the fubftance diffolved often confifts of very different parts, fome of which are perfectly taken up by the Menftruum, while others have been rejected, and left feparate: whence, after the Menftruum is abftracted from the folution, there

there remains a different fubftance from what was employed as the folvend. And hence, without caution, one might be ready to infer, that the fubftance thus procured was a new one, produced by the changing power of the folvent; whereas, in reality, it is only produced by a bare feparation.

Hence we may learn, that the action of all known Menftruums depends upon motion: for, if a Menftruum did not change the motion of the parts upon which it acts, thofe parts would remain as they were; in which cafe the Menftruum, contrary to fuppofition, could have no action at all. The origin of this motion we cannot fairly attribute to the common caufes of motion, fuch as impulfe, gravity, elafticity, magnetifm, and the like; but there is a particular caufe, not common to all bodies, exerted between the folvent and folvend. An enquiry fhould be carefully made into this fubject, to which we are the more incited, as fome great philofophers have conceived, that all the actions of bodies muft be accounted for mechanically.

When a folvent divides its folvend by a mere mechanical motion, this motion muft be generated in the particles of the folvent by fome caufe, and this caufe is generally fire. The particles of the Menftruum, thus agitated, muft ftrike againft the furfaces of the united particles of the folvend, communicate to them their motion, and loofen and feparate them from the folid, whether this action be exerted externally, on the furface of the folvend, or internally, by penetrating the folvend.

Though this mechanical manner of acting may have fome effect, it is, perhaps, lefs than is generally imagined: for fluids can produce little alteration in a folid, by means of their quantity, hardnefs, figure, and weight; and the force they receive from the fire is but fmall, and always as capable of acting upon themfelves: the power of folution, therefore, muft depend upon fome other caufe. Thus a wedge could never cleave wood by being barely applied to it, or kept floating about it; but muft firft be fixed into the fubftance, and then driven farther by an external force; an action not to be expected from the particles of a yielding fluid.

Thofe Menftruums alone appear to act mechanically, which, by a bare mechanical motion, arifing from their magnitude, hardnefs, figure, weight, and impulfe, firft attenuate bodies, then directly feparate from them again, according to their fpecific gravities; by which kind of folution no great change can arife. By this mark we may diftinguifh Menftruums which act mechanically from others.

Repulfion, alfo, may caufe bodies to feparate, after having been mixed together by fhaking; as in oil and water, or alcohol and oil of tartar per deliquium; where not only gravity, but, alfo, repulfion occafions a feparation, and fuffers fimilar things to unite with fimilar.

When, after folution, the diffolved particles remain equally mixed with thofe of the folvent, though, at firft, they differed remarkably in their weight, fuch a folution may partly be afcribed to the general mechanical power, which here almoft univerfally occurs; but principally to another action, arifing from the peculiar properties of the folvent and folvend, with refpect to each other: as, by this power, the particles of the one attract the particles of the other; thus both are feparated from their former concretions, and afterwards permix or unite with each other, fo as to form numerous new fpecies of bodies.

To illuftrate this doctrine by an example: if a ball of foft clay be put into water, and fet over the fire to boil, the parts of the water put in motion by the fire will divide the clay into fmall particles, and permix them with the body of the water, while the boiling continues; but when the external force of the fire ceafes, and the water comes to reft, and grows cool, all the clay falls to the bottom: this I would call a mere mechanical folution.

But if a ball of fal-gem be boiled in four times its quantity of water, all the falt immediately diffolves fo perfectly as to remain totally imbibed, fufpended, and uniformly diffufed in the water, even after it grows cold, and is thoroughly at reft; although the gravity of the falt is much greater than that of the water. Whence it appears, that the water has a power, by which it unites to itfelf the particles of the falt, fo that they cannot be feparated from it by their own gravity, but remain fufpended. The clofer or loofer degrees of adhefion of the particles of different Menftruums with the particles of the body diffolved are almoft infinite; and hence arife numerous differences in the corpufcles produced by Menftruums.

Calcined MERCURY, *mercurius calcinatus*, a new and more expreffive name for the preparation of Mercury, commonly called precipitate per fe. It is made by fetting purified quickfilver, for feveral months, in a fand-heat, in a glafs veffel with a broad bottom, and opening it to the air by a fmall hole, till it is reduced to a red powder.

The quickfilver muft have a communication with the external air, as is neceffary to the calcining of all the metals. This opening is beft made, not as in the common bolt-heads, but at the lower end of a ftem, going into the body of the glafs; that, if the quickfilver rife with the heat, it may not, by afcending into the ftem, be removed out of the heat that is to calcine it. *Pemberton's London Difpenfatory.*

Coralline MERCURY, *mercurius corallinus*, the name given, in the London Difpenfatory, to a preparation of Mercury, commonly known by the name of arcanum corallinum. It is prepared in this manner: pour upon the red corrofive Mercury, commonly called red precipitate, thrice its weight of rectified fpirit of wine; digeft them together in a gentle heat for two or three days, often fhaking the phial; then fet fire to the fpirit, and continue ftirring the powder till the fpirit is burnt away. *Pemberton's Lond. Difp.*

This operation proceeds upon the principle of fpirit of wine's dulcifying acid fpirits.

Oil of MERCURY, the name given by the chemifts to a preparation of Mercury in a fluid form, by means of a ftrong acid. The preparation is this: calcine Mercury with oil of vitriol to a dry fnowy calx; fuffer it to cool, then put it into a glafs, and pour upon it an equal quantity of oil of vitriol; let this boil away almoft to a drynefs, carefully avoiding the poifonous fumes; then increafe the fire, and by degrees reduce it to a drynefs again; which is, in this ftate, a very difficult and tedious tafk. When the powder is dry, put the fame quantity of oil of vitriol to it again, and proceed as before: at length it will fcarce dry by means of ever fo long or ftrong a fire, but only ceafe flowing freely, and become fomewhat rigid, like a fixed oil. It is then highly fharp, cauftic, and not to be touched, like the ignis gehennæ of Paracelfus. By this means the Mercury is fo fixed with the oil of vitriol, as not to be evaporated, or fly off, by the action of a very violent fire.

By this procefs we fee the method of impregnating, faturating, and incerating metals by acids to any degree, and alfo of fixing, in a great degree, volatile Mercury by them; but no metal is hence to be expected, for, in whatever manner Mercury is fixed with acids, it is always recoverable again in its priftine ftate, by grinding it with twice its weight of iron filings, and diftilling it in a glafs retort, with the greateft degree of a fand-heat. *Boerh. Chem.*

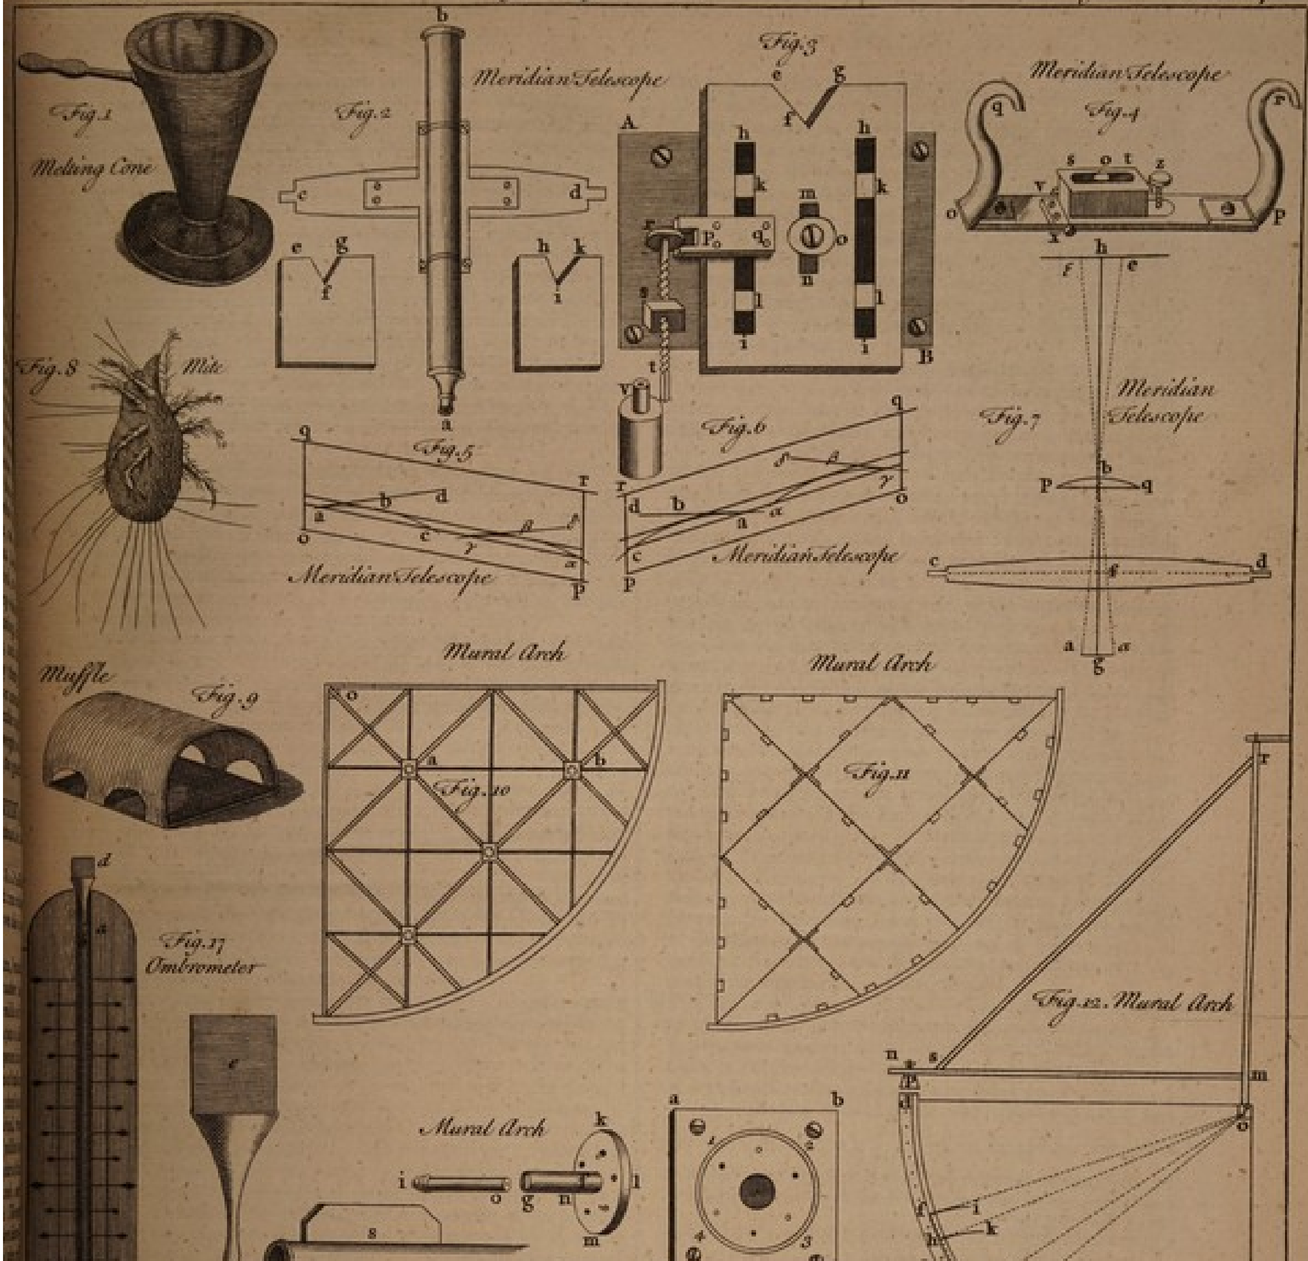
MERIDIAN *Telefcope*, a telefcope, as *a b* (*Plate* XXXI. *fig.* 2.) fixed at right-angles to an axis *c d*, and turned about it in the plane of the Meridian.

The vulgar ufe of it is to correct the motion of a clock or watch, by obferving, day after day, the exact time when the fun or a ftar comes to the Meridian. It ferves alfo for other ufes to be mentioned hereafter.

The axis *c d* confifts of a ftrong brafs plate, broader in the middle than towards the ends, having another long plate placed edgeways and foldered along the middle of the backfide of it from one end to the other. This plate is alfo broader in the middle than towards the ends, to prevent its fpringing. To the ends of thefe plates two folid pieces of brafs are firmly jointed and foldered; and, the whole being placed in a turning lathe, the folid ends are turned truly cylindrical, to an equal thicknefs, and are alfo well fmoothed and polifhed with oil and proper powders. Flat upon the broader plate of the axis, there lies another brafs plate, in the fhape of a crofs; one bar of it being parallel, and firmly fkrewed to the axis. The ends of the other bar, being turned up at right-angles, have femicircular notches filed in them, to receive the cylindrical tube of the telefcope, which is made of brafs, to prevent its warping; and is firmly fixed in thefe notches by two half-collars of brafs, which go over the tube, and are fkrewed to the ends of the femicircular notches, as reprefented in the figure. The cylindrical ends of the tranfverfe axis *c d* are to be placed upon two angular notches *e f g* and *h i k*, filed in two thick brafs plates, and well planed and polifhed, for the axis to turn very fmoothly upon them. In order to bring the axis *c d* exactly perpendicular to the plane of the Meridian, each of the notched plates are contrived to be moveable by a fkrew, one upwards or downwards, and the other fideways, by fliding them upon the furfaces of two other brafs plates immoveably fixed to two pofts or free-ftone pillars.

In order to move the notched plate *e f g*, *fig.* 3, up or down, two long upright flits *h i* are cut through it; in each of which, at *k* and *l*, are two fquare ftuds of brafs firmly riveted to the fixed back-plate A B, being exactly as broad as the flits that flide by them. In the middle between them there is alfo a fhorter parallel flit *m n*, through which a broad-headed fkrew-pin is fkrewed into the back-plate, having a round fpringing plate under the head of it; thus the two plates are preffed together or relaxed, according as the notched plate is to be fixed or moved. To perform this motion gradually, *p q* reprefents a fmall piece of another brafs plate, laid upon the fore-plate and riveted to the middle of one of its upright fides. In the end *p*, which projects over this fide, there is a fmall fquare notch, which receives the circumference of a fmall circular plate *r*, like a fkrew-head, fixed perpendicular to a long fkrew *r s t*, placed parallel to this upright fide of the notched plate. This fkrew works round in a concave fkrew in the middle of a thick brafs ftud at *t*, firmly riveted to the back-plate, and being turned by a hollow key *v*, put upon the fquare end of it, it gradually raifes or depreffes the notched plate *e f g*; which is fixed more firmly, at its proper height, by turning the middle fkrew at *o*, abovementioned.

The angular notch that fupports the other end of the tranfverfe axis is moveable fideways, by the fame contrivance; as will appear



Printed for T. Hinton in Newgate Street.

appear by supposing the notch efg to be cut in the side opposite to the skrew rst, and this side to be turned upwards.

The transverse axis is to be placed horizontal upon the angular notches by a spirit level, consisting of a hollow glass tube st, *fig.* 4, five or six inches long; not quite straight, but as little incurvated as possible; and filled with spirit of wine, or any liquor that will not freeze or grow foul, all but a bubble of air; which, by the laws of hydrostatics, will always move to the highest place in the cavity of the tube. The tube, with its convexity upwards, is placed in a long slender brass box, made fit to receive it, and is fastened in it by very hard cement. This box is laid lengthways upon a long ruler op; and through the bottom plate of the box, a little produced, there passes a fine skrew-pin Z, to be turned by the fingers; whose end, by working against the surfaces of the ruler below, gradually raises or depresses this end of the box, while it turns upon a small axis vx near the bottom of the other end of it.

Upon the ends of the ruler op two brass plates oq, pr, are fixed, whose planes are perpendicular to the length of the ruler; these plates, being equal in length, have their upper parts formed into circular hooks q, r, to be hung upon the cylindrical ends of the transverse axis of the telescope; the interval between the hooks being of a proper length to interpose them between the shoulders of the cylinders at the end of the axis and the brass notches they rest upon.

The frame $poqr$, being thus suspended upon the transverse axis, raise or depress the tube of the level by twisting the knob of the skrew Z, till you bring either end of the air-bubble to rest at any point a, towards the middle of the tube, and observe any mark upon the side of the tube that is opposite to it. Then take off the frame $poqr$, and, turning the ends of it contrary ways, hang it again upon the cylinders. And, if the air-bubble rests exactly at the same mark as before, the transverse axis is truly horizontal: if not, depress that end of the axis which lies on the same side of the mark as the bubble does, or raise the opposite end, till the bubble returns about halfway towards the mark. Then, having made a new mark where it rests, transpose the frame again, and repeat the same practice till the bubble rests exactly at the same point in both positions of the frame. Instead of making marks, over-against one end of the bubble, it is better to have a fine pointer, sliding upon a wire, along the top of the tube.

Let a plane passing through the axis qr, *fig.* 5, 6, and the mark a where the bubble resteth, cut the tube of the level in the curve abc; and let a line ac, drawn parallel to the axis qr, cut off the arch abc, and after the frame of the level has been transposed, the chord ac of the arch abc will still be situated somewhere in the same parallel to qr as before, suppose at $\alpha\gamma$. Now, since the ends of the chords ac, $\alpha\gamma$, are turned contrary ways in the same line, it is plain that the mark a, which was the highest point in the arch acb, being now transposed to α, is become the low point of the same arch in the situation $\alpha\beta\gamma$. Therefore the bubble cannot now remain at the mark α, but will ascend to the highest point of the arch $\alpha\beta\gamma$; which will be γ, if the arch be circular. For then the tangents ad, $\gamma\delta$ to the points a and γ will be parallel to each other; and, ad being horizontal, $\gamma\delta$ will be so too; and consequently γ will be the highest point. Let $b\beta$, drawn parallel to the axis or to $a\gamma$, touch the arch $\alpha\beta\gamma$ in β; and, it is evident, the point β will be lower than γ. Therefore by depressing that end of the axis qr, which lies on the same side of the mark α as the bubble does at γ, the point γ will also be depressed; and so the bubble will recede from γ towards the mark α till it comes to β, when β becomes the highest point; that is, when the tangent $b\beta$ and the axis qr are parallel to the horizon: and then, if the frame $qopr$ be transposed back again, the bubble will rest at the same point β as before.

Now, if the arches abc, $\alpha\beta\gamma$ be circular, b and β are exactly the middle points of the arches. But, if the arches be not circular, the points b and β will not be in the middle, yet, being at the greatest distance from the chords ac, $\alpha\gamma$, they will be the points where the bubble will rest, when the axis is horizontal.

It must be observed of these levels so suspended, that, if you gently turn the frame about the axis of suspension, the air-bubble will frequently change its place, though the supporters of the axis keep fixed; either because the plane of the curvity of the tube is not parallel to the axis, or because the cavity of it is not cylindrical, or upon both accounts. It is therefore necessary to reduce the plane of the frame as near to the same vertical position as possible, which may be done either by a plumbet hanging down by the side of a perpendicular ruler fixed to the horizontal one op, in *fig.* 4, or by another tube of a spirit level, fixed upon the ruler op at right-angles to it. But, if the frame $poqr$ vibrates freely upon the axis, this additional apparatus will be needless.

If the far end of the telescope be just made to preponderate the elevation of it, for observing the appulses of stars to the cross hairs, it may be gradually altered by a string, tied to its near end, and wound about a peg fixed below the telescope. The peg may be made to turn with a proper degree of stiffness between two semicircular notches pressed gently together by a skrew-pin passing through both the pieces. Or the same design may be executed several other ways.

If, after the telescope is turned upside down, and the contrary ends of the transverse axis are placed upon the same notches, you perceive that the same point of the object is covered by the intersection of the hairs in the focus of the telescope; it is certain that the line of sight is perpendicular to the transverse axis. But, if the intersection covers a different point of the object, the hairs must be moved by the key above-mentioned, till they appear to bisect the line that joined those two points of the object as near as you can judge; then, by reverting the telescope to its former position, you will find whether the hairs be exactly adjusted.

For let the line cd, *fig.* 7. be the transverse axis which the telescope turns about a, the intersection of the cross hairs; b the center of refractions in the object-glass, and ab the line of sight. Let ab, produced, meet a remote object in e; and the point e will appear in the telescope to be covered by the intersection a, because the image of it falls upon a. Imagine a line gh drawn through the center b to cut the axis cd at right-angles in f, the hair $a\alpha$ in g, and the object $e\epsilon$ in h; and when the ends of the axis cd are transposed by reverting the telescope, the perpendicular bg will keep its position, or be parallel to it; but ba will be transposed into the position $b\alpha$, equally inclined to the contrary side of the perpendicular bfg. Produce αb till it meets the remote object in ϵ, and the cross hairs at α will now appear to cover the point ϵ. But the perpendicular gbh bisects the interval $e\epsilon$ in h. Therefore by moving the intersection of the cross hairs from α towards g, till you perceive the middle point h is covered by it, it is manifest that the line of sight is now perpendicular to the transverse axis cd; and consequently upon reverting the telescope, the same point h will be covered as before. Hitherto I have supposed the telescope to be turned about an axis cd, lying in the same plane with the line of sight; but, if it turns about any other line parallel to cd, it is easy to understand that the motion of the line gbh will still describe a plane perpendicular to this transverse axis. It is scarce necessary to be observed that the perpendicularity of the line of sight to the transverse axis has no dependence upon its passing through the middle of the aperture of the object-glass, nor of being parallel to the sides of the tube; nor is it required to coincide with the axis of the object-glass. *Smith's Optics.*

MERIDIONAL *parts* (*Dict.*)— To find the Meridional parts to any spheroid, with the same exactness as in a sphere.

Let the semi-diameter of the equator be to the distance of the focus of the generating ellipse from the center, as m to 1. Let A represent the latitude for which the Meridional parts are required, s the sine of this latitude, the radius being unit; find the ark B, whose sine is $\frac{s}{m}$; take the logarithmic tangent of half the complement of B from the common tables; subtract this logarithmic tangent from 10.0000000, or the logarithmic tangent 45°; multiply the remainder by $\frac{7915.7044678978}{m}$ &c. and the product subtracted from the Meridional parts in the sphere, computed in the usual manner from the latitude A, will give the Meridional parts expressed in minutes for the same latitude in the spheroid, provided it be oblate.

Example: if $mm : 1 :: 1000 : 22$, then the greatest difference of the Meridional parts in the sphere and spheroid is 76.0929 minutes: in other cases, it is found by multiplying the remainder abovementioned by 1174.078.

When the spheroid is oblong, the difference of the Meridional parts in the sphere and spheroid, for the same latitude, is then determined by a circular ark. *Phil. Transf.* N°. 461.

MESENTERY (*Dict.*)— The disorders incident to the Mesentery deserve our most attentive consideration, since the superfluous humours of the veins are easily conveyed to it, and lay a foundation for very terrible disorders, such as a cholera, melancholy, fluxes, gripes, cachexies, atrophies, languors, slow and erratic fevers, together with other diseases, whose natures are not to be discovered without great difficulty. When the Mesentery is affected with a tumor without inflammation, the tumor is generally, at first, lax and soft, but, some time after, becomes intirely dry and indurated. This tumor, and the part in which it resides, are insensible of pain; for which reason the internal swelling, which lies pretty deep, is only to be discovered by a rough touch.

In this case, the part affected is distended, which lessens the diameters of the intestines, and, by that means, occasions costiveness; which effect is by no means produced by a tumor of the abdominal muscles, or prominent fat; for neither of these affect the intestines. The fat, also, when laid hold of by the hand, may be distinguished from the abdominal muscles. But, when the tumor is lodged in the abdominal muscles, it is always discoverable by the first touch, and is ever painful when pressed, and sometimes painful without any compression. Besides, a tumor of the abdominal muscles is prominent, when not pressed; perceptible upon the mildest touch, and of an oblong figure, like that of the musculus rectus. *Lommii Medic. Observat.*

Obstructions of the Mesentery proceed from the same causes with

with those of the liver and spleen, but happen more frequently and easily, by reason of the narrowness of the meseraic; and, especially, of the lacteal vessels, which convey the chyle to the organs allotted for the second digestion. And when the chyle, which is so often mixed with crude and gross humours, stagnate, and produce obstructions, in the lacteal veins, the meseraic veins are, also, obstructed by gross humours conveyed from the liver, spleen, and other parts, and lodged there for a considerable time. During the stay of these humours, they become gradually thicker, so, as at last, sometimes, to produce a scirrhous tumor. With these humours are, also, sometimes, mixed gross flatulences, which generally prove the causes of violent symptoms. To the obstruction, also, or rather the contraction, of these vessels, we refer the compression of the glands dispersed through the whole substance of the Mesentery; for these, increasing beyond measure, as happens in strumous persons, compress the meseraic veins, and hinder not only the due distribution of the chyle, but, also, the circulation of the blood.

The diagnostic signs of obstructions of the Mesentery are divided into three classes, which either indicate the species of the disease, the part affected, or the productive causes.

The signs which indicate the species of the disorder, that is, obstructions of the hypochondria, and their causes, are the same with those producing obstructions of the liver and spleen. But the signs which in a peculiar manner indicate, that the Mesentery is affected, are tension and resistance in the middle of the abdomen, under the stomach, and in the umbilical region, where there is, also, a sense of weight, sometimes an obtuse pain, and sometimes one of an highly acute kind, when flatulences are contained in these parts: a pain is, also, sometimes, perceived in the back, to which the Mesentery is affixed; rumblings and noises happen in the belly, eructations are excited, and vapours are raised to the head, by which means various symptoms are produced: in a word, all the symptoms which generally attend melancholy, indicate obstructions of the Mesentery, because that disorder is produced and cherished by obstructions of the same kind.

As for the prognostics: this disorder is not of itself very dangerous, because the Mesentery is capable of bearing great disturbances, without any immediate danger to life. Besides, generous remedies may be used for the cure of this disorder, which, when duly exhibited, generally produce the desired effect, unless the disorder causes hypochondriac melancholy, which, on account of the obstinate nature of the melancholic humour, is generally called the reproach of physicians. But, as the Mesentery is not furnished with an exquisite sensation, and as the obstructions of it are generally not very troublesome to the patient, they are often neglected, and lay a foundation for other highly dangerous disorders.

The cure of this disorder is to be performed in the same manner with that used for removing obstructions of the liver. *Riverius, Prax. Med.*

MI'LIUM, *millet*, the seed of a plant, which by consent of authors, both ancient and modern, is refrigerating and drying; it is of bad juice, difficult of digestion, binds the belly, and generates flatulences; it is, however, well known to be a very grateful food to many nations at present. In former times it served to make bread, under a dearth of better corn, as we are assured by Dioscorides, Pliny, Galen, and others of the ancients. Among the Italians, says C. Bauhine, loaves made of millet, which are yellow, are eaten hot by many, not out of necessity, but for their sweetness; but, when this bread is grown hard, it is quite black. Of the flour of millet and milk the Italians make fine cakes, which must be eaten as soon as dressed, or else they become glutinous, and ungrateful to the taste. In former times they made a sort of white puddings of millet, as Pliny tells us. And among the Cossacks and Tartars, their principal food is millet, the crude meal of which they mix with the milk of mares, or with blood drawn from the crural vein of their horses. A pudding, prepared of millet, boiled in milk, with an addition of butter, and sugar sprinkled over it, is much in request among the Germans at present; and these puddings have been long ago introduced into England, and are still in fashion.

The flower of millet was formerly used in fomentations for the gripes, and for pains of the head and nerves; it was applied externally in bags, because the use of it in cataplasms was difficult, on account of its friability. If the membrane of the brain happens to be wounded, it is excellently conglutinated says Archigenes, by infusing thereon the juice of calaminth, and sprinkling it with the dry flour of millet. A decoction of millet, with figs and raisins, is called by Heurnius a noble sudorific and diuretic. Or, take of a decoction of millet, boiled till it bursts, four ounces; white wine, two ounces. Let the patient take it hot. *Chesneau. Raii Hist. Plant.*

Millet is diuretic and astringent; the seeds are of extraordinary service in diseases of the lungs, and exulcerations of the kidneys; made into a cataplasm, they are anodyne and resolvent. *Hist. Plant. adscript. Boerh.*

Indian MI'LLET.—It delights in a fat and humid soil; for which reason some sow it in their fields to correct their luxuriance; it was brought from India into Spain, Italy, and other warm countries: they sow it in summer, and reap it in autumn.

The seed is like panic both in taste and temperament. The poorest sort of people in Italy, and the peasants in the Paduan, grind the seed, and make it into loaves, which are friable, and afford but little nutriment, being black, difficult of digestion, and binding. It is more usual to make puddings, or white pots, of the flour and milk. In Tuscany they sow it more for the sake of feeding their poultry, than to serve as aliment for men. They, also, give it to their cows, horses, and swine. Of the pith of the stalks is prepared an excellent remedy for the strumæ; the preparation of which see in the Bauhines and Matthiolus; which last author commends, also, the flowers, for uterine fluxes and the dysentery. *Raii Hist. Plant.*

MILLEFO'LIUM, *yarrow*, in botany, a genus of plants, whose characters are:

The leaves are very finely cut; the calyx is squamose, and almost cylindrical; and the flowers are very closely collected into umbella's.

Yarrow has a white creeping root, which spreads much on the surface of the ground. The leaves are long and narrow, having on each side several very finely divided pennæ. The stalk is firm and erect, a foot or two high, somewhat hairy, and beset alternately with smaller, and rather finer leaves. The flowers grow on the top of the branches in flat umbels, each flower being made of five little, white, roundish leaves, set about a thrum of the same colour, growing in a scaly calyx, in which is contained flattish white seed. It grows every-where in the fields, and flowers in June and July. The leaves are used.

Yarrow is cooling, drying, and binding; very serviceable in in all kinds of hæmorrhages, whether spitting or vomiting blood, bleeding at the nose, dysentery, or the too great flux of the menses, or violent flooding, cooling, and tempering its immoderate heat and sharpness. It, also, helps a gonorrhœa, strangury, heat of urine; and, applied outwardly, is of service against ruptures, and to staunch the bleeding in fresh wounds. *Miller's Bot. Off.*

This plant is a little acrid, bitter, aromatic, and gives a considerable tincture of red to blue paper. It seems to me, that the acid part of the natural salt of the earth, disengaging itself of the other principles through the texture of this plant, forms, with the terrestrial parts, an aluminous salt, united with a little essential aromatic oil.

By the chemical analysis are extracted from the yarrow several acid liquors, a great deal of earth, no volatile concrete salt, and a little urinous spirit.

Thus this plant is vulnerary, resolvent, and astringent. It is used in ptisans, and infusions, after the manner of tea. Some boil its leaves in broths, to stop all sorts of hæmorrhages, and especially the irregular flux of the piles and fluor albus. Its juice is prescribed from eight ounces to six; the powder, from a drachm to half an ounce: it is mixed, also, with paste, to make astringent biscuits. Tabernæmontanus says, the water of yarrow is good for the epilepsy; and that the wine of mead, made with this plant, stops all sorts of irregular fluxes. *Martyn's Tournefort.*

MINE (*Dict.*)—*Tracing of* MINES, a term used by our miners, to express the tracing up the mineral appearances on the surface of the earth to their head, or original place, and there discovering a Mine of the metal they contain.

This practice depends on the change wrought on the face of the earth by the deluge, of the effects of which these remains are a very great proof. The superficial, or upper part of veins, is always the poor, the richer ores lying deeper, the poor ones only serving to lead the way. These poor ores, or stones impregnated with the metallic matter of the Mine, and called by our workmen shoad-stones, were probably, at the creation of the earth, brought regularly up to the surface, and shewed the places of the metals below. But, at the time of the covering the earth by the waters of the deluge, they were, with the rest of the surface, washed off, and carried, with the descent of the water, down into the plains, or into the beds of rivers, and there carried many miles down the stream. This being an allowed truth, the art of training a Mine is easy; for, though this carrying the shoad-stones and poor ore was done so many ages ago, yet, all the way that some pieces were carried on, others would be deposited by the way, and, the heaviest and richest falling first, the lightest would always be carried farthest, and there would be always left a stream of this matter all the way from the place where it was first produced, that is, where the Mine now is; for the breaking of the surface of the earth, at this great catastrophe, was not so deep as to reach that; and this stream or train of matter will be found richer and richer as it approaches the Mine, and finally will stop at the place where it is.

Where there is supposed to be a Mine of any metal, the hills and countries all about are diligently searched; the situations, and descent of the lands, and the earth, stones, and other fossil bodies, are examined, particularly the colour and nature of the various sorts of earth and stones which are found on the hills where the Mine is suspected to lie, that they may be readily

dily known again, if any of them are found in the neighbouring valleys. The ftones which denote the loads, and are called fhoad-ftones, are found two, three, four, or even five miles from the hills, where they originally lay; but, if the fame fort of ftones are remembered on the hills, the train is to be made out.

After any great land-flood, in which it is fuppofed there are ufually fome new frets made in the banks of the rivers, thefe are carefully examined, to fee whether any metalline ftones may be found in their fides and bottoms, all being then fo clean, that the fmalleft fhoad-ftone may ufually be feen. If no ftones of this kind are found, it fometimes is of ufe, in order to farther refearches, to examine whether any pieces of earth, of a different colour and nature from that of the reft of the bank, be found; for, this being, if any fuch is found, wafhed alfo from the neighbouring hills, it proves a great direction which fide of the hill to fearch into.

If no fhoad-ftone or grewt of a different nature from the reft be found in thefe frets or newly worn banks, the miners leave the place for the prefent. For though the bed of the river afford many metalline ftones, they never regard them, the continual change of place they receives from the current of the water, rendering them only tokens that there is metal fomewhere in the country; but they confound and perplex rather than inftruct in the fearch after the places where it is.

If there be found indeed ftones of the fhoad-kind, full of protuberances, or having fharp angles, as if newly broken, it may be worth while to fee whether they are not wafhed out of fome part of the neighbouring banks by the late floods; as this fort of appearance is a token of their having been newly taken into the bed of the river. But, if they are rounded and fmooth, it may be concluded that they have been long fubject to the action of the water, and brought, perhaps, many miles from the places where they were originally lodged in the earth, where only they could have been of any ufe to the tracer of the Mine.

When the frets in the fides of rivers have been traced in vain, the fearcher after a Mine goes up to the fides of the hills moft fufpected to have Mines in them, and there feeks for a convenience of bringing a little ftream of water to run down. When this is found, he cuts a trench about two feet over, and as deep as the fhelf. The water is turned into this cut, and after two or three days running in it, all the filth will be wafhed away, and the loofer part of the earth cleared off; and if any fhoad-ftones are lodged within the whole courfe of this cut, they will be found. If any fuch are found, it is an unqueftionable proof that there is ore in the higher parts of the hill; this encourages the work, and there is always found a Mine, or at leaft a fquat, which will, without much danger, repay the expence and trouble. The fquats are flat parcels of the ore, lying in different and diftinct places of the hills, and not communicating with one another.

Sometimes a great deal of this labour is faved, and the fhoad-ftones are found on the furface of the ground, either turned up by the plough, or thrown up in fmall quantities in mole-hills, or raifed by fome other accident; for they are feldom found naturally lying on the very furface of the earth; for the putrid remains of vegetable and animal fubftances, and other adventitious matter, have raifed the furface of the earth in all places, fince the time of the flood, and made indeed a fort of new furface. Thefe ftones were certainly laid bare on the furface of the ground, at the time of their being carried down from the Mines; but this adventitious matter has buried them in this long tract of time, and they are generally found under about a foot of a fort of vegetable mould. If, by any of thefe fearches, a fhoad is found, the miners have nothing to do but to follow it to its head, and there make the opening; but if no fuch direction can be had, nor any fhoad found, and there is yet fufpicion that there is a Mine in the hill, the method is to make an effay-hatch, as it is called; this is funk near the foot or bottom of the hill, and is an opening of about fix feet long, and four feet broad, made in the fearch of a vein as deep as the fhelf; this is a caution that muft be always carefully obferved, for if they are made lefs deep than this, they may mifs of the vein, though there is one. And the finking thus deep is always attended with certainty, for if no fhoad is found on this, it may be concluded there is none there; except that fometimes it is found that the fhoad has been wafhed clean away, within two or three feet from the land: and then the load or vein is two feet farther, or thereabouts, up in the hill. If any fhoad is found in the effay-hatch, there is a certainty of a vein of ore; neither doth it add a little toward the making a conjecture how high up the hill, or how far off the vein ftring, or bonny, is, carefully to mark how deep from the furface of the earth the fhoad lies, for this is held an infallible rule, that the nearer the fhoad lies to the fhelf or faft ground, the nearer the vein itfelf is, and vice verfa.

When there is no fhoad or appearance of a Mine found in the firft effay-hatch, if the conjecture of a Mine being in the hill has any tolerable foundation, the tracing it does not end here; but they go ten or twelve fathoms up the hill, and there open a fecond effay-hatch, and if no ore or fhoad-ftone is found in this, they go as many fathoms on each hand at the fame height with the fecond hatch; and there open a third and a fourth hatch, of the fame depth and dimenfions with the firft; if in neither of thefe there is found any fhoad-ftone, they afcend proportionably with three more hatches, if the fpace of ground requires, at every ten or twelve fathoms, and in this manner open them three abreaft, at twelve fathoms diftance up to the top of the hill. If no fhoad is found in any of thefe, it is concluded then that there is no tracing a Mine there, and the hill is left.

If any fhoad is found in any of thefe hatches or openings, the afcending hatches from this are kept on in a direct line, and, the deeper the fhoad lies, the nearer the vein is. The fhoad grows gradually deeper from the furface, but nigher the fhelf as they approach the Mine: as, fuppofe it be but half a foot from the fhelf and feven feet deep from the furface, the vein is then concluded to be within a fathom or two; and on this the firft proportion of twelve fathoms between every hatch is leffened, to fix, four, two, one, or even lefs than that, as the vein is conjectured to be more and more near.

It often happens, for want of a good guefs in this matter, that the diggers over-fhoot the load; that is, they open their next hatch too high up the hill, or above the load or vein: this is a miftake eafily difcovered and eafily rectified. If a fhoad is found lying near the fhelf in one hatch, and in the hatch above there is no fhoad at all, it is a proof that the hatch is too high, and the remedy is only to fink a hatch at a middle diftance between the laft two, which will probably fall upon the very point of the load, and finifh the work of tracing.

Sometimes it happens that, in continuing the tracing of the firft fhoad, a fecond or new one is found; it is not uncommon for two fhoads to be thus found in one hatch, and this is eafily difcovered without any danger of miftake; for fuppofe in the laft hatch the fhoad which they trace lay at eight feet deep, and in this it lies at ten feet, and, befides this, there is a fhoad found at two feet depth; it is very certain, that the fhoad at ten feet deep is the fame they were before tracing, and this is a new one pointing to another vein or load, which is now firft difcovered fo near the furface of the earth. This has generally gravel or earth mixed with it, and is to be carefully examined; when the higher hatches are opened, this is continually found, as well as the old load; and when the firft is traced to the point of the vein, this fecond is to be continued in the fame manner, by other hatches opened at the fame diftances above: it often happens that in tracing this fecond fhoad, the hatches dug for it difcover another new one or a third fhoad; all thefe are to be traced one over the other by the fame hatches, and will all be found worth the feeking after. The old writers on minerology agree with us in this obfervation, and tell us, it is not uncommon in fome places to find as far as feven loads lying parallel to one another in the fame hill. In thefe cafes, however, there is ufually one mafter-load, or grand vein; the other fix, that is, three on each fide, being the leffer or concomitant veins. Five in the fame manner fometimes lie in this order, the grand load in the middle and two on each fide; but the more common method is three, a large one, and two fmaller.

Every load has a peculiar coloured earth or grewt about it, which is found alfo with the fhoad, and this always in a greater quantity, the nearer the fhoad lies to the load, and becomes leffened by degrees to the diftance of about a quarter of a mile, further than which that peculiar grewt is never found in any quantity with the fhoad; fo that this is a proof that the load or vein is near, when it is found in quantity.

A valley may chance to lie at the foot of three feveral hills, in fuch a manner, as to contain three feveral grewts, or that earth which was moved with the fhoad in the concuffion of the ftrata at the deluge, with as many different fhoads or trains of fhoad-ftones in the midft of each: in this cafe it will be very neceffary to know the caft of the country, and of each hill in refpect to its grewt, for the furer training of them one after another as they lie in order: according to the foregoing rules of effay-hatching, the uppermoft in this cafe always directs which hill to begin with firft.

It fometimes happens that, after having trained the fhoad found in a valley up to the upper parts of a hill, there is only a fquat, or bonny, found inftead of a right vein of ore, for thefe detached parcels of ore have their fhoads as well as the right veins. Thefe are ufually about two or three fathoms long, and a fathom broad; few of them are larger, moft lefs, and they never communicate with any other load or vein, nor ever fend forth any of their own. The extremities of thefe beds of ore terminate without fending out any ftrings, not lying within walls as the loads; but though they are in the fhelf or faft ground, not moved by the flood, their furface is equal every-where with that of the imaginary fhelfy one, and they go down five or fix fathoms deep and there terminate at once. The ore contained in thefe are rich, and they are always wrought out to the confiderable advantage of the owners.

Thefe are the general rules of tracing Mines, and though fomewhat tedious and expenfive, they are certain, and never liable to the error and difappointment the other fhorter ways, as they are called, are liable to. Thefe fhort ways are by the *virgula divinatoria* or the hazel-wand, whofe bending in cer-

 tain

tain places, without any external visible force, is to point out the place where the vein of ore lies: the waters thought to issue from the particular loads are also used by some as a short means of finding the veins; other of these ways are also by mineral steams and effluvia, by the barrenness of the soil, and the pitching of nocturnal lights on the supposed orifices of mines. But these methods are too extravagant or too uncertain to be used in cases of so much consequence. When the mine is found by more certain rules of tracing, the digging it is a matter of less difficulty.

English MI'NERALS.—Dr. Woodward has observed, that the English Minerals are much more valuable and numerous, than has been generally supposed. Fuller's earth, a thing so cheap as to be disregarded by many, he observes, is of almost as much value to our commerce, as any article of foreign production. The property this earth has of imbibing oil and grease, is not confined to the trifling service of taking out accidental stains in cloaths, but it is of so much use in cleansing the wool and the cloth made of it, that we could never have flourished in the cloth trade in the manner we have done, had we not this fossil among us so plentiful and cheap, and at the same time so excellently good. This earth is one instance of the pre-eminence of our soil above others. Another instance we have in our black lead or wadd, a mineral of great use and value in several branches of trade and arts; and which is found no where fine and good, except in England, and in our colonies; and that of the last place, though better than the black lead of other nations, is greatly inferior to our own.

The amber and jet of England are found in considerable quantities, and are equal to those of any other part of the world. Our canal coal comes very near the beauty of jet, and even our common coal for firing is greatly superior, in goodness, to that of any other part of the world, and is no where found in such vast plenty as with us. The English earths and gravel are well known to be superior to those of other countries, in none of which, such grass plats or such gravel walks are to be seen, as in the English gardens. We have stones, slates, flags, and the other necessary fossils for building, in sufficient plenty.

Vitriol and alum are found in greater plenty in England, than in any other country; and are so easily worked or procured from their ores, that we can sell them cheaper than any other people. *Woodw. Cat. Foss.*

Tin is another article, in which England has always had a great pre-eminence; the county of Cornwall alone produces more tin than all the world besides, and the tin of England is well known to excel that of other nations, as well in value as in quantity.

Lead ore is also richer in England than in any other country, and is found in greater quantities here than any where else; besides this, it runs more kindly in the fire, and requires less trouble and expence in the working, than any other lead; and is, when wrought, much finer and more ductile, than any other lead.

This does not arise from any peculiarity in the metal, for lead is the same in all countries, when equally purified; but the spar which lies about, and is mixed with our lead ore, is of such a nature and disposition, that it is easily wrought upon and readily parts from it, leaving the metal more pure than it can be procured by the common large operations in other countries; so that they are forced to send it away much less pure than ours is.

Copper and iron are also found in very great plenty, and several ores of these metals have of late been brought into use, which were not known before the modern improvements in chemistry.

MINERO'LOGY (*Dict.*) — The necessity of cleaving and opening rocks has always been accounted one of the most troublesome articles in the business of mining; they being often composed of such stone as tools can work but very slowly upon in the common ways. Fire and gun-powder have been the two things principally had recourse to on these occasions; and both successfully, but in different ways. The fire calcines stones, and they then easily become shattered to pieces, and give way to tools that would not touch them before; but in this case, besides the expence of wood, the hinderance of the labourers is an article to be considered, for the rocks are made so hot all about the place where the fire has been, that the people cannot get to work again for a day or two, and then the effect of fire reaches but a little way in the rock.

Gun-powder makes its way much farther, and at the same time is much cheaper and does not delay the work, but the labourers may go on immediately afterwards. There have been many ways contrived of using this, but one of the simplest and best seems to be that delivered by Mr. Beaumont, in the Philosophical Transactions. For this there are only three simple instruments required, a borier, a gun, and the quinet or wedge. These are the names the miners on Mendip-hills give the instruments. The borier is an iron instrument, steeled at the end; it is two feet two inches long, and is somewhat thicker at the steeled end than in any other part: the use of this is to make the hole in the rock deep enough to receive the powder. The gun is about six inches long, and an inch and quarter in diameter; and has a hole drilled through it, to receive the priming. The quinet is a wedge of iron of about six inches long, and so shaped, that its flat part on one side joins with a flat part in the gun made to receive it, and by that means the gun is fastened very firmly in its place. *Philos. Trans.* N°. 167.

The manner of using these instruments is this: one man holds the borier on the rock, turning it round, while another forces its point in by blows of a large hammer on the other end. When the hole is made somewhat deeper than the length of the gun, they dry it with a rag, and then put into it two or three ounces of powder; over this they lay a paper, and then they put the gun into the hole, and fasten it in by driving in the quinet or wedge against its flat part. When the powder and gun are thus fixed, they pass down a wire through the hole drilled in the gun, and with this they pierce a hole through the paper that covers the powder; they then prime the gun, and lay a train with a lighted match; but all go out of the mine before the gun-powder takes fire, and, as soon as it has gone off, they go down to work again, finding the rock split, and the instruments unhurt. The paper in this case is put over the powder only, that the tools may be safely employed in driving down the gun and the quinet, because, were not the powder covered, it might do mischief to the workmen by going off by some spark caused by striking either against those instruments, or against the rock itself.

MI'SSEL-*bird*, in zoology, the common English name of the larger species of thrush, called also the shrite, and by authors the turdus viscivorus major. It is much larger than any other of the thrush kind. Its legs and feet are yellow; its head of a brownish lead colour; and its back, tail, and rump, of the same colour, with an admixture of yellow; but, in the summer months, it a little changes its colour, and becomes more grey, or of the colour of unripe pickled olives; its throat, breast, and belly, are all variegated with black spots; the middle of its belly whitish, and the upper part of its breast, and part of its sides, and the under feathers of its tail yellowish. *Ray's Ornithology.*

MIST.—The bluish Mist, which we sometimes see on our fields and pastures in a morning though often innocent, yet has been in some places found to be the actual cause of murrain, and other fatal diseases among the horned cattle.

Dr. Winklar gives, in the Philosophical Transactions, an account of a murrain affecting the cattle in Italy and other places, which was evidently seen to spread itself over the countries in the form of a blue Mist. Wherever this was perceived, the cattle were sure to come home sick; they appeared dull and heavy, and refused their food; and many of them would die in four and twenty hours. Upon dissection there were found large and corrupted spleens, sphacelous and corroded tongues; and in some places those people who were not careful of themselves, in their management of the cattle, were infected and died as fast as themselves. The principal cause of this disease seemed to be the exhalation of some unwholesome steams from the earth; and it was observable, that there had been three earthquakes in Italy the year before it happened. The method of cure which succeeded best, was this: as soon as any beast appeared to be sick, they examined the tongue, and, if aphthæ, or little blisters, were found on it, they scraped it with a silver instrument made with sharp teeth at the sides, till it bled in all those parts where the apthæ were; the blood was then wiped away with a cloth, and the whole tongue washed several times with vinegar and salt. After this the following medicine was given internally: take of soot, brimstone, gun-powder, and salt, of each equal parts; mix these in as much water as will make them thin enough to be swallowed, and let a spoonful be given for a dose three or four times a day. The cattle which were in health had this medicine given them, as well as the sick; and the consequence was, that very few died in Switzerland, while almost all died in other places.

It was very remarkable that the contagion, on this occasion, seemed to travel slowly and regularly on: it came at the rate of about two German miles in twenty-four hours: this it kept regularly to, during the whole time of its raging, and never appeared in very distant places at the same time.

The whole surface of the earth emitting these effluvia, no cattle escaped them in the course of their way, but those which were kept within doors at rack and manger fell ill at the same time, and in the same manner with these in open fields. Dr. Slare was of opinion, that it was owing to certain insects which could not fly faster than at the rate of two German miles a day; and that they travelled regularly, and spread the mischief where they passed; but there wanted some judicious persons, versed in these observations, to have examined both the state of the air, and the beasts, on this occasion. *Philos. Trans.* N°. 145.

MITE, in natural history, the name of a small animal, very well known and found in old cheese, and many other bodies both recent and perishing.

To the naked eye the Mites in cheese appear like moving particles of dust, but the microscope discovers them to be perfect animals, having as regular a figure, and performing all the functions of life as perfectly as creatures that exceed them many times in bulk. See *Plate* XXXI. *fig.* 8.

They are crustaceous animals, and are usually transparent; the principal

principal parts of them are the head, the neck, and the body. The head is ſmall in proportion to the body, and has a ſharp ſnout, and a mouth that opens and ſhuts like a mole's. They have two ſmall eyes, and are extremely quick-ſighted; and, when you have once touched them with a pin, you will eaſily perceive how they avoid a ſecond touch.

They are of different ſorts; for ſome of them have ſix legs, and others have eight. Each leg has ſix joints ſurrounded with hairs, and two little claws at the extremity, with which it very nicely takes hold of any thing. The hinder part of the body is plump and bulky, and in an oval form, from which there iſſue out a few exceeding long hairs. Other parts of the body and head are alſo beſet with thin and long hairs.

The males and females are eaſily diſtinguiſhed in theſe little animals. The females are oviparous as the louſe and ſpider, and from their eggs the young ones are hatched in their proper form, without having any change to undergo afterwards. They are, however, when firſt hatched, extremely minute, and, in their growing to their full ſize, they caſt their ſkins ſeveral times.

Theſe little creatures may be kept alive for many months between two concave glaſſes, and applied to the microſcope at pleaſure. They are thus often ſeen in winter, conjoined tail to tail; and this is performed by an incredible ſwift motion. Their eggs, in warm weather, hatch in twelve or fourteen days; but, in winter, they are much longer. Theſe eggs are ſo ſmall, that a regular computation ſhews, that ninety millions of them are not ſo large as a common pigeon's egg. *Baker's Microſcope.*

MNE'ME-*cephalicum balſamum*, the name of a famous compound balſam, ſaid to have been purchaſed from a certain Engliſh phyſician by Charles Duke of Burgundy, at the price of ten thouſand florins. Some who have been very laviſh in its praiſes have affirmed, that it has a power of preſerving in the mind the remembrance of all things that are paſt; but this ſeems ſtretching the praiſe of it a little too far. It is prepared in the following manner: take of the juices of the leaves of baum and baſil, of the flowers of tamariſk lilies, primroſes, roſemary, lavender, borrage, and broom, of each two ounces; of lilies of the valley, roſes, and violets, each one ounce; of cubebs, cardamoms, grains of paradiſe, and yellow ſaunders, carpobalſamam, Florentina iris, ſaffron, ſavory, piony flowers, and thyme, of each half an ounce; of liquid ſtorax, ſtorax calamita, opoponax, bdellium, galbanum, gum ivy, and labdanum, of each ſix drachms; roots of long birthwort and piony, and oil of turpentine, ſpikenard, coſtus, juniper, bays, maſtich, ben, and ſpike, of each, five drachms. The dry ingredients are to be beaten to powder, then mixed with the reſt, and, a ſufficient quantity of water being added, the whole is to be diſtilled by an alembic, and the oil carefully ſeparated from the water. The method of uſing it is this: the firſt two months the paſſages of the ears and noſtrils are to be anointed with the bigneſs of a pea of it every day; then, for two months longer, the ſame is to be repeated every third day; after this, it is to be uſed once a week; then, once a fortnight, till a year is expired; and, after this, it is to be uſed once in two months for the ſucceeding years. This is the account of Sennertus. *Sennert. Praſt.*

MNI'UM, in natural hiſtory, the name of a genus of moſſes, the characters of which are theſe: it has heads of two different kinds, the one ſort naked and duſty, having no calyptra or other covering; the others are regular capſules, like thoſe of the hypnum and bryum, containing a fine powder, and covered with a calyptra or hood. This diverſity in the fructification diſtinguiſhes the Mnia from all the other moſſes; but theſe diverſely conſtructed heads are in ſome ſpecies found on the ſame plants; in others, on different ones of the ſame ſpecies, as the male and female flowers are in hemp, mercury, and many others of the larger plants. The ſtalks which ſupport the membranaceous heads are long and naked; thoſe which ſupport the naked heads, are in ſome naked, in others covered with leaves; but they are in all ſhorter than the others. *Dillen. Hiſt. Muſc.*

MI'XTURE, *mixtura ſimplex, ſimple mixture*, in pharmacy, the name of a form of medicine uſed in the preſcriptions of ſome modern phyſicians. It is made by mixing ten ounces of the ſpiritus theriacalis camphoratus of Bates, ſix ounces of ſpirit of tartar, and two ounces of ſpirit of vitriol; theſe are to be ſet in a glaſs hermetically ſealed for three weeks, that they may be perfectly mixed; the doſe is a drachm or thereabouts. Its virtues are, that it reſiſts putrefaction, promotes ſweat, and is of great ſervice in malignant fevers.

MO'AR-*boere*, in huſbandry, a term uſed to expreſs a peculiar diſtemperature of corn, generally comprehended under the common term of a blight. In this caſe the earth ſinks away from the roots of the corn, and leaves the plant ſtanding in great part above ground with naked roots; theſe being too weak to ſupport the ſtalks, the plants fall, and the ears become light. This a diſtemperature peculiar to corn, growing on light and looſe lands. *Tull's Horſehoing Huſbandry.*

The remedy is this: turn a ſhallow furrow againſt the rows, when they are ſtrong enough to bear it, and the mold is fine and dry; the motion of the ſtalks with the wind will draw in this looſe powder, and it will ſpread itſelf equally among all the plants in the row, though it be triple or quadruple. It is eaſy to ſee that this remedy is only practicable in the method of the horſehoeing-huſbandry; for, in the common way of ſowing, there is no means of relief in this caſe. And, in general, the horſehoeing-huſbandry prevents the falling of the wheat, the ſtalks never drooping ſo abſolutely in the drilled wheat, as they do in that ſown the common way.

MOCK-*Bird*, the name of an American bird of the merula kind, and very much approaching the blanvogel or cæruleus. It is of the ſize of the common lark: its beak is ſhort and ſtraight, its tail very long, and its whole body of a very fine deep blue. *Ray's Ornith.*

MOCK-*Lead*, in minerology, a name given by the Engliſh writers to a ſort of foſſil, called alſo blende and galena. It has very much the appearance of an ore of lead, being bright and gloſſy, of a bluiſh black colour, and plated; but, on trial, it is found to yield very little or none of that metal.

MODE (*Dict.*) — Some Modes cannot exiſt without the ſubject, as being only circumſtances thereof; as roundneſs, length, &c. but there are others which are likewiſe ſubſtances, as apparel, hair, nails, &c. which may ſubſiſt without the ſubject.

MODI'LIONS.—*Plate* IV. *fig.* 5, in the Dictionary, repreſents a Modilion of Vignola, and *fig.* 8. a Modilion of Scamozzi.

MO'FFAT-*Waters*, mineral waters of conſiderable efficacy at Moffat, in the county of Annandale. They ariſe from two ſprings on the declivity of a hill, which yield about 1360 gallons of water daily. Theſe waters have a ſulphureous taſte and ſmell, like the waſhings of a gun-barrel; their colour is milky or bluiſh. The ſeaſon for uſing them is between the middle of April and the end of September; but they may be drank all winter, and, if the rains be moderate, the ſtrength of the water is not found to be impaired. The water of the upper ſpring, being too foul for drinking, is made uſe of for bathing, and is, for this purpoſe, made ſomewhat warmer than tepid. The quantities of water, uſually drank, are pretty large, exceeding ſometimes a gallon. It is uſual to join purgatives, and that in great doſes, frequently repeated with the uſe of the waters; but this is thought unjuſtifiable by ſome. The water is alterant and diuretic. Its purging is owing to the large quantities drank, or to ſome ſingularity in the conſtitution, as a weak ſtate of the ſtomach and inteſtines. Few medicines are ſaid to be ſuperior to theſe waters in diſorders of the ſtomach and bowels. It has alſo proved uſeful in nephritic, nervous, and hyſteric cholics, melancholy, barrenneſs, female weakneſſes and diſorders, as alſo in old gleets, either natural, or cauſed by venereal diſorders. In rheumatic and ſcorbutic complaints it is advantageous, and in cutaneous eruptions. It is ſaid ſeldom to fail in ſcrophulous diſorders. This water gives but ſmall marks of a chalybeate nature with galls, nor any of acidity with tincture of roſes, or ſyrup of violets; neither does it produce any effervеſcence with oil of tartar per deliquium, or ſpirit of ſal ammoniac. It ſeems to contain a ſubtile volatile ſulphur, but in a ſmall quantity, ſince it ſoon loſes its remarkable ſmell and taſte, when expoſed to the air, and that acid liquors can neither ſeparate nor precipitate it. Upon evaporation, there is found a dirty ſalt mixed with earth. This ſalt ſeems not to be nitre, nor ſal ammoniac, but common ſalt, and, by a ſlow evaporation of a ſolution of ſea ſalt, cryſtals, not unlike thoſe of the ſalt of Moffat-water, have been obtained. A particular account of theſe waters may be ſeen in the firſt volume of the Edinburgh Eſſays phyſical and literary.

MOIRE, in conchyliology, the mohair ſhell, a name given by the French virtuoſi to a peculiar ſpecies of voluta, which ſeems of a cloſely and finely reticulated texture, and reſembles on the ſurface a piece of mohair, or a very cloſe ſilk-worm's web. See the article VOLUTA.

MO'LA, in zoology, a name of a fiſh commonly called in Engliſh the ſun fiſh. It is of a very ſingular figure. Its body is broad and ſhort, and its hinder extremity is terminated by a circular fin, which ſerves it for a tail; ſo that it looks like the head of a large fiſh ſevered from its body; it is frequently of two feet in length, and ſometimes very much exceeds that ſize, growing even to two hundred weight. It has no ſcales, but is covered with a hard, harſh, and rough ſkin. Its back is black, and its belly white; the ſides are of a middle colour between both. Its back and belly both terminate in a narrow edge. Its mouth is very ſmall for the ſize of the fiſh, and, when open, is round. Its jaws are hard, and edged like a knife within; externally they are rough, as if beſet with ſeveral rows of ſmall teeth. The head does not at all project from the reſt of the body. The eyes are very ſmall. It has only one pair of fins, which are ſituated near the gills, which are only two elliptic holes covered with their proper membranes. Its fleſh is very ſoft, and its bones are all griſly and tender. The ſkin ſticks very firmly to the fleſh, and is not eaſily taken off. It is caught in the Mediterranean, and ſometimes in the Britiſh ſeas. *Willughby's Hiſt. Piſc.*

MOLE-*hills.*—Theſe little hillocks of earth are a very great prejudice to the paſture lands, not only waſting ſo much of the land as they cover, but hindering the ſcythe in mowing. In the weſt of England, they uſe a peculiar inſtrument for the breaking up of theſe; it is a flat board, very thick, and of about eight inches in diameter, into which there is faſtened a perpendicular handle of three or four feet long. It has four broad

and

and sharp iron teeth at the front, which readily cut through the hill, and spread the earth it consists of; and, behind, there is a very large knob, proper for breaking the clods with, if there are any. Some use a spade, or other common instrument, in the place of this, but not so well. There is, however, a much better instrument even than this, for destroying these hills, where they are in very great numbers. This is a kind of horse machine; it has a sharp iron about three feet over, and with a strong back. It is about four or five inches broad, and has two long handles for a horse to be harnessed to, and a cross bar of iron to strengthen it at the bottom of the handles, reaching from one handle to the other. The middle of this cross bar is furnished with one, two, or more, sharp pieces of iron, like small plough-shares, to cut the Mole-hills into two, three, or more parts. The iron behind is of a semi-circular figure. A single horse is harnessed to this machine, and a boy must be employed to drive it, and a man to hold and guide it; the sharp irons or shares are the first thing that meets the hills; they run through it, break its texture, and cut it into several parts, and the circular iron, following immediately behind them, cuts up the whole by the roots, and leaves the land level. This instrument will destroy as many Mole-hills in one day as a common labourer can in eight, and would be of very great advantage to the kingdom, if brought into general use. *Mortimer's Husbandry.*

MOLO'SSES, the dross of sugar, or what remains after the sugar is extracted from the juice of the cane.

Artificial MOLOSSES. There has been found a method of making Molosses from apples, without the addition of sugar. The apple that succeeds best in this operation, is a summer sweeting of a middle size, pleasant to the taste, and so full of juice, that seven bushels will yield a barrel of cyder.

The manner of making it is this: the apples are to be ground and pressed, then the juice is to be boiled in a large copper, till three quarters of it be evaporated: this will be done with a moderate fire in about six hours, with the quantity of juice abovementioned; by this time it will be of the consistence and taste as well as of the colour of Molosses.

This new Molosses serves to all the purposes of the common kind, and is of great use in preserving cyder. Two quarts of it, put into a barrel of racked cyder, will preserve it, and give it an agreeable colour.

The invention of this kind of Molosses was owing to Mr. Chandler of Woodstock, in New England, who, living at a distance from the sea, and where the common Molosses was very dear and scarce, provided this for the supply of his own family, and soon made the practice general among the people of the neighbourhood. It is to be observed, that this sort of apple, the sweeting, is of great use in making cyder, one of the very best kind we know being made of it. The people in New England also feed their hogs with the fallings of their orchards of these apples: and the consequence of this is, that their pork is the finest in the world. *Philos. Trans.* N°. 374.

MOLOSSES *spirits*, a very clean and pure spirit, much used in England, and made from Molosses or common treacle dissolved in water, and fermented in the same manner, as malt for the common malt spirit. If some particular art is not used in the making of this, it will not prove so vinous as the malt spirit, but more flat and less pungent and acid, though otherwise much cleaner tasted, as its essential oil is of a less nauseous flavour. Whence, if good fresh wine-lees, abounding in tartar, be duly fermented in the solution made thin for that purpose, the spirit will by that means become much more vinous and brisk, and approach more to the nature of the foreign spirits.

After the first distilling of Molosses spirits from the wash into low wines, it is to be rectified, and in the succeeding rectifications proper additions are to be made. Alkaline salts, so common in the rectifying malt spirits, must be avoided in this case, as not at all suiting this spirit; and the neutral ones only must be used, such as sandiver, common decrepitated salt, sal enixum Paracelsi, and the like; but, upon the whole, nothing so considerable is to be expected from these salts, as from a careful rectification in balneo mariæ, without any other admixture; by this alone repeated two or three times with fresh water each time, the spirit will at once be made fit for the nicest uses.

Where the Molosses spirit is brought to the common proof strength, if it be found not to have enough of the vinosity, it will be very proper to add to it some good spiritus nitri dulcis; and, if the spirit be clean worked, it may by this addition alone be made to pass on ordinary judgments for French brandy.

When newly distilled, this spirit like all others is colourless, and limpid as water; but our distillers always give it the same sort of yellow tinge, which the foreign spirits are found to obtain from the casks they are sent over in. They have many ways of giving this colour extempore; but the two most in use are, either by an extract of oak-wood, or by burnt sugar.

Molosses spirit coming dearer than that of malt, it is frequently met with, basely adulterated with a mixture of that spirit, and indeed seldom is to be bought without some dash of it. Many have a way of mixing malt in the fermenting liquor; by this the yield of the whole is greatly increased, and the maker may assure the buyer that the spirit is pure as it ran from the worm.

England is the principal place where this spirit is made at this time; it was at one time prepared in great quantities in France, especially in the river Loire; but it is now forbid there, under a severe penalty. In Holland also they have it not, on account of the high duty laid upon treacle in favour of their own sugar-bakers.

We meet with very little of Molosses spirit reduced to the strength of alcohol or spirit of wine, though, when rectified to this state in a proper manner, it is very little inferior to the real alcohol of wine, the name of which is so well known among us, though the thing itself is perhaps never seen here; all that we call spirit of wine being no other than malt spirit reduced to an imperfect alcohol, or a spirit almost totally inflammable.

Great quantities of Molosses spirit are used in the adulterating of brandy, rum, and arrac; and great quantities are used alone in the making cherry brandy, and other drachms, by infusion, in all which many prefer it even to the foreign spirits.

In most of the nice cases in our compound distillery, the Molosses spirit supplies the place of a pure and clean malt spirit, which we have not yet the way of producing in the large way to advantage. Our cinnamon, citron, and other fine cordial waters, are made with it; for the malt spirit would give these a very disagreeable flavour.

There is also another use to which this spirit serves extremely well, and which even a foreign spirit which has any remarkable flower will not do so well in; this is the making the extemporaneous wine, which some people are so fond of. See the article *Extemporaneous* WINE.

It gives a yellow stain to the hands, or other substance dipped into it; and may therefore be of use in dying. It is possible also, that the vinegar-makers may find use for it in their way; but the most advantageous of all its uses is to the distiller himself; a quantity of it added to new treacle intended for fermentation will be of great use in the process, and increase very considerably the quantity of spirit; but the proportion in regard to the new matter must not be too great. *Shaw's Essay on Distillery.*

MOLU'CCA *Balm*, or *baum*, in botany, a genus of plants, whose characters are:

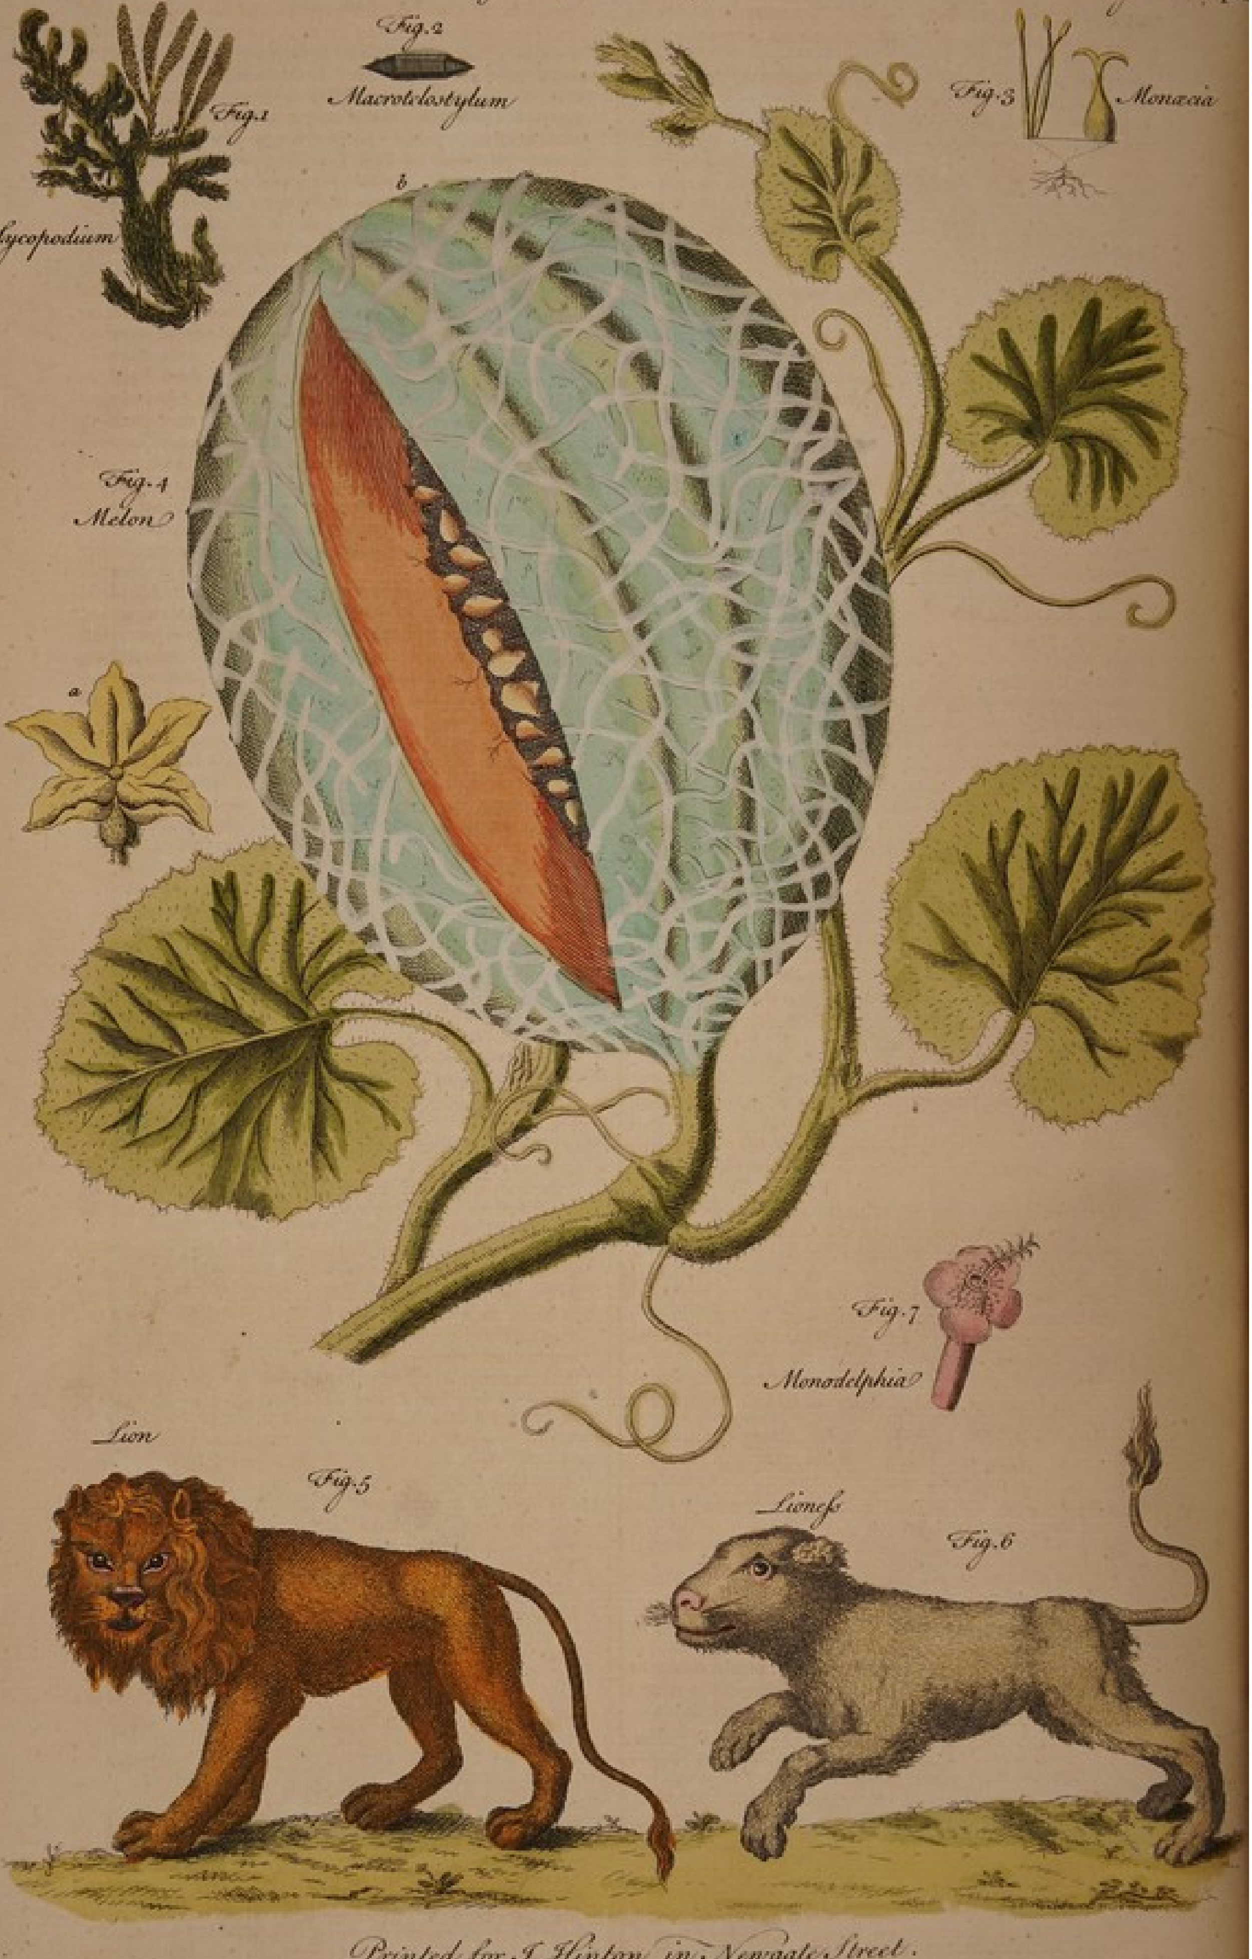
The calyx is expanded, large, bell-shaped, as it were membranaceous, and open. The galea is hollow, the beard tripartite, and the middle segment commonly bifid. The flower is very small, and concealed in the center of the calyx. The seeds are angulous, and hardly covered.

This plant takes its name from the Molucca islands, where it was discovered. It is a vulnerary, and very good in a phthisis, being used as tea. If the disease be attended with spitting of blood, the expressed juice is of service, on account of its astringent quality, which is adapted to an hæmoptoe. No plant is a better lithontriptic, the leaves being infused in wine, or spirit of wine. It has the virtues of baum, but smells somewhat stronger. Here it may be proper to observe, that the perfectly cerulean colour of all plants proceeds from the fatness of the soil in which they grow; this is universally true of them all, and particularly in the instance before us. *Hist. Plant. adscript. Boerhaave.*

MOLUCCA *beans*, a name given by Sir Robert Sibbald, in his Prodromus, and by Mr. Wallace, in his Description of the Orkney-islands, to a sort of fruit frequently cast on shore in the North-west islands of Scotland, especially, on the coasts most exposed to the waves of the occidental ocean.

Some call them Orkney-beans; though they are not the produce of that island, or indeed of any part of Europe, but of America.

How the product of Jamaica, or other parts of America, should be brought to the shores of Scotland and Ireland, seems not easy to determine on any certain foundation. It is easy to conceive that, when they grow by the sides of rivers, they may fall off from the trees into them, and be thence conveyed into the sea. It is likewise easy to see, that, when they are thus floating on the surface of the sea, they may be carried about by the winds and currents, and be carried a great way; but their journey this way must naturally be stopped by the main continent of America, and they must be forced through the gulf of Florida, or the canal of Bahama, going thence constantly east, and into the North American sea. This is easily conceived by a similar fact which happens every day: which is, that a kind of sea lentil, called sargossa, which grows very plentifully on the rocks about Jamaica, is washed off from thence, and carried by the winds and currents, which, for the most part go impetuously the same way, towards the coast of Florida, and thence into the North American ocean; and are there found floating on the surface. Thus far it is easy to trace our fruits from their native soil; but how, after this, they should make the rest of their voyage is a great mystery, and not to be accounted for by us, unless we suppose, that as ships, when they go south, expect a trade easterly wind, and, when they come north, expect, and generally find a westerly wind, for at least two parts in three of the year; so we are to suppose these fruits, being brought north by the current from the gulf of Florida, are put into these westerly winds way, and by them conveyed to the coasts of Scotland and Ireland. *Philosophical Transactions*, N°. 222.



Printed for J. Hinton in Newgate Street.

MOLYNEUX'S *parallactic teleſcope*, a curious teleſcope for finding the parallaxes of the heavenly bodies, invented by that ingenious gentleman.

The curious and uſeful teleſcope was ſuſpended in a vertical poſition, by two poliſhed cylinders, fixed near the top of the tube, ſo that their common axis, if produced through the tube, would paſs at right-angles to its axis, through a point near the center of the object glaſs. When the teleſcope was turned upon theſe cylinders, its axis of viſion moved like a pendulum in the plane of the meridian, and at the ſame time, a fine long wire, whoſe loop was put over one of the cylinders, hung down by the ſide of the tube, being gently ſtretched by a plumbet immerſed in a veſſel of water, deſigned to retard its vibrations. The lower end of this wire played gently againſt the ſmooth ſide of a ſlender braſs plate, fixed tranſverſely to the ſide of the tube, ſo as to point northwards and ſouthwards; and in the middle of this plate was punched a very fine round hole rather broader than the thickneſs of the wire. The teleſcope was gradually moved upon its axis of ſuſpenſion by the preſſure of a long ſkrew, in a parallel direction; the ſkrew worked in a hole of a plate, fixed to the wall of the houſe; and the tube was made to bear againſt the end of the ſkrew by a weight, fixed to the end of a ſtring, paſſing over a pulley, and having its other end tied to a hook, fixed in the ſide of the tube. The oppoſite end of the long ſkrew was fixed, like an axis, in the center of a braſs wheel, whoſe circumference was divided into a convenient number of equal parts, while an index, fixed to the board, pointed to the diviſions of the wheel.

Things being thus prepared, while the wheel was gently turned, the part of the wire, which played againſt the tranſverſe plate, was viewed through a double microſcope, until the little hole in this plate appeared to be biſected by the wire. The teleſcope being thus rectified immediately before the beginning of every obſervation of the tranſit of γ draconis (which paſſes very near the zenith of Kew) and the diviſion of the wheel over-againſt the index being then noted, the wheel was turned again, till the interſection of the wires in the focus was brought to touch the ſtar at the inſtant of its tranſit. Then, by the number of the revolutions of the wheel, and the parts of a revolution that had paſſed by the fixed index, the angular motion of the axis of the teleſcope was eaſily collected, from a proper table of minutes and ſeconds, anſwering to thoſe revolutions. Now, the differences of theſe angles, found at different obſervations, are the differences of the ſtar's declination. And, the inſtrument being rectified every time as above, it is eaſy to underſtand that theſe angular differences could not be altered by any warping, ſhrinking, or ſwelling of the materials of the inſtrument. *Smith's Optics.*

MO'NBIN, *the hog plum-tree*, in botany, a genus of trees, whoſe characters are:

It hath a roſe-ſhaped flower, conſiſting of ſeveral leaves, which are ranged in a circular order; from whoſe cups ariſes the pointal, which afterwards becomes an oval, fleſhy, ſoft fruit, incloſing an hard ſtone, in which are contained four kernels or ſeeds.

This tree is a native of the warmeſt parts of America, where it grows in the ſavanna's, and low marſhy places, in great plenty. It riſes to be forty or fifty feet high, and divides into a great many crooked branches, which are beſet with winged leaves, ſomewhat like thoſe of the aſh-tree. The flowers, which appear in the ſpring, are produced in large pyramidal bunches at the extremity of the branches, which are of a white colour, and are very ſweet. Theſe are ſucceeded by ſeveral yellow oval-ſhaped plums, growing in cluſters. The wood of this tree, being ſoft, is uſed, inſtead of cork to ſtop bottles in America. *Miller's Gard. Dict.*

MONOE'CIA †, in botany, a claſs of plants which have not the male and female parts, that is, the ſtamina and piſtillum in the ſame, but in different flowers; and thoſe on the ſame individual, or on the different ſtalks, growing from the ſame root; thoſe which contain the ſtamina are called the male flowers, thoſe which contain the piſtillum the female ones.

† The word is derived from the Greek μόνος, the ſame, and οἶκος, habitation.

The plants of this claſs are the alder, mulberry, amaranth, &c. See *Plate* XXXII. *fig.* 3.

MONODE'LPHIA †, in botany, a claſs of plants, whoſe ſtamina or male parts, by reaſon of their filaments running in among one another, are all formed into one body.

† The word is formed of the Greek μόνος, ſingle, and ἀδελφή, brotherhood or community; theſe coalitions of the ſtamina in flowers being underſtood in botany by that term.

Of this claſs are the crane's-bill, mallow, &c.

The general characters of this claſs of plants are theſe: there is always a perianthium to the flowers, no ſpecies of the whole claſs being without it. This is always permanent, and ſurrounds the baſe of the ſeed-veſſel, after the flower is fallen. The flower always conſiſts of five petals, which are cordated at the top. The ſtamina are a great number of filaments, which grow together in one body at the baſe, and are looſe at the top. The external ones are ſhorter than the others, and the antheræ are always incumbent. In the piſtils there is found a receptacle of the fructification, which is placed in the center of the flower. The germina are erect, and ſurround in a rotary manner the apex of the receptacle. The ſtyles are all found growing together, at the bottom, into one body, with the receptacle, and in their upper part they are divided into as many filaments as there are germina. The ſtigmata are ſlender and expanded. The fruit is a capſule, divided into as many cells as there were piſtils in the flower. This is of very various figures in the various genera and ſpecies; but the ſeeds in all are uniform, or ſhaped like kidneys. See *Plate* XXXII. *fig.* 7.

MONOPE'TALOUS, in botany, a name applied to the flowers repreſented in *Plate* XXXVI. *fig.* 1.

MONTRO'SE *waters.* Steel ſpaws are very numerous in the country about Montroſe in Scotland: the principal of theſe are at Aberbrothoc, Kincardin, and Peterhead. That of Aberbrothic is in greateſt eſteem.

The water of this Montroſe well is univerſally diuretic; being drank from two to three pints, purges; and half the quantity ſucceeds with ſome. It has been found very uſeful in ſtranguries and ſtoppage of urine, ſcorbutic diſorders, flatulences, ſpaſmodic cholic, and ſpitting of blood. In rheums and ſtrains it has been of good uſe by way of cold pump, where perſons could not bear ſuch uſe of ordinary cold water. *Med. Eſſ.*

MOON (*Dict.*)— We have obſervations and tables concerning the Moon's motion, by Mr. Richard Dunthorn, in the Philoſophical Tranſactions, N°. 482, where he gives an hundred obſerved longitudes of the Moon compared with the tables, viz. 25 eclipſes of the Moon, taken, except the firſt, from Flamſteed's Hiſtoria Cœleſtis, the Philoſophical Tranſactions, and the Memoirs of the Royal Academy of Sciences; the two great eclipſes of the ſun in 1706 and 1715; 25 ſelect places of the Moon, from Flamſteed's Hiſtoria Cœleſtis; and 48 of thoſe longitudes of the Moon, computed from Flamſteed's Obſervations by Dr. Halley, and printed in the firſt edition of of the Hiſtoria Cœleſtis.

In the Philoſophical Tranſactions, N°. 473, we have a new method of computing the appulſes of the Moon to the fixed ſtars and planets; as alſo of the eclipſes of the earth, commonly called eclipſes of the ſun, by Mr. Gerſten, profeſſor of the mathematics at Gieſſen.

The full Moon appears to the naked eye broader than a circular object, ſubtending an equal angle, ſeen by perfect viſion. In a Moon of three or four days old the illuminated part appears too broad, in proportion to the obſcure part, and likewiſe ſeems to extend more outwards, or to have a greater diameter than the obſcure part. Alſo, in an eclipſe of the ſun or Moon, the bright part appears too broad in proportion to the dark part, and the eclipſe appears leſs than it really is.

This obſervation was made by Horrox, and is accounted for by Dr. Jurin, in his Eſſay upon Diſtinct and Indiſtinct Viſion.

MOOR-*cock*, an Engliſh name for the red game, or our lagopus, more commonly called the gor-cock. It is a very delicate bird, larger than a partridge, and common on the hills in Derbyſhire and Yorkſhire. *Ray's Ornithol.* See the article GOR-*cock.*

MOOR-*hen*, *gallinula*, in zoology, the name of a genus of water birds, the characters of which are theſe: the head is ſmall, the body compreſſed, the beak ſhort and moderately crooked, the wings ſmall, and hollowed like thoſe of the common cock and hen kind; the tail very ſhort, the legs long, and the toes remarkably ſo.

The common Moor-hen, called gallinula chloropus by authors, is a very well known bird, ſomewhat like the coot in ſhape, but ſmaller, and very much flatted in the body. Its feet are greeniſh, and its breaſt a lead-coloured blue; its belly greyiſh. It is common about our rivers, and is a very well taſted bird. *Ray's Ornithol.*

MOOR-*land*, or MOORY *land*, in agriculture, is a black, light, and ſoft earth, very looſe, and without any admixture of ſtones, and with very little clay or ſand.

The uppermoſt ſtratum of the fen lands is uſually of this earth, and it uſually conſtitutes a moderately thick or deep bed. Intermixed with water, it cannot eaſily be worked up into a paſte; and, when with labour worked into ſomewhat of a firm maſs, its ſurface appears ſpongy and porous; and, as ſoon as dry, it eaſily moulders away to powder.

It is uſually ſoft to the touch, unleſs it be worked very cloſely between the fingers; then it ſhews a mixture of a ſmall quantity of ſand, both to the touch and to the eye.

It ſeems indeed to conſiſt almoſt intirely of pure vegetable matter, and this, lying in ſuch plenty on the ſurface of the fenlands, is the cauſe of their being ſo very fertile.

The great diſadvantage of the places which have this ſoil, is their being liable to be glutted with wet; and, to remedy the inconveniencies ariſing from thence, the farmers who rent theſe lands have a cuſtom of burning the ſoil at proper ſeaſons. It burns very freely and eaſily, the ſurface readily catching flame; and a ſubſtance ſomewhat bituminous, uſually contained among the ſoil, helps the burning. *Moreton's Northampt.*

MOOR-*ſtone*, the name of a very remarkable ſtone found in Cornwall,

Cornwall, and some other parts of England, and used in the coarser works of the present builders.

This is truly a white granate, and is a very valuable stone. It is a very coarse and rude, but beautiful congeries of variously constructed and differently figured particles, not diffused among, or running into one another, but each pure and distinct, though firmly cohering with whatever it comes in contact with. Its colours are principally black and white; the white are of a sort of marble texture, and opake, formed into large congeries, and emulating a sort of tabulated structure; among these, there are many of a pure crystalline splendor and transparence, and among these are lodged in different directions many small flaky masses of pure talcs of several colours; some are wholly pellucid, others of an opake white, others of the colour of brown crystal, and a vast number perfectly black. *Hill's Hist. of Foss.*

The people of Cornwall who have this stone in great plenty, use it in the tin works, and particularly in their tin kiln, on the good effect of which a great deal depends. This kiln is four-square, and at its top is placed a large block of Moorstone; the usual size of this block is six feet in length and four in breadth; in the middle of this block there is made a hole of about six inches in diameter. This stone serves as a head to cover another like stone placed beneath it; but this under one is not so long as the upper by six inches. The reason of this is, that it must not reach the innermost or back part of the wall, which is the open place through which the flame ascends from another place below that, where a very strong fire of furz is constantly kept up; and there is another little hole also on the outside. The forepart is like a common oven, and has such a sort of chimney.

The tin ore is roasted in this kiln, to burn away the mundic, in this manner: the ore is brought in powder, and poured out in heaps on the surface of the top stone; a man stands there, and thrusts it down through the hole in this stone into the kiln, that is, to the surface of the under stone; a person who stands below, spreads this as it falls with an iron rake, and gives notice to the person above, when there is enough down, that is, when the surface of the lower stone is covered three or four inches thick. When this is done, the hole at the top is covered with green turfs, that the flame may reverberate the stronger, and the heat that the Moor-stone acquires helps to roast the ore; while the flame that comes up from the ore is blue, there yet remains mundic among it; but when this is burnt off, the flame is yellow. *Phil. Transf.* N°. 69.

The miners in some parts of Cornwall use the name Moorstone for a sort of coarse free-stone, which lies very often over the tin ore; this is of a greyish colour, and is somewhat softer than that usually employed in building.

MOOSE *Deer*, a very large and beautiful species of deer, common in North America.

The stag or male of this kind has a palmed horn, not like that of our common or fallow deer, but the palm is much longer and more like to that of the German elk; but it differs from that in having a branched brow-antler between the burr and the palm, which the German elk hath not.

The large horns found fossile in Ireland, have, from their vast dimensions, been supposed to have originally belonged to the black Moose deer; but they, as likewise most other of the large horns found in this part of the world, appear to be the horns of the German elk, having no brow-antlers.

Mr. Ray mentions, in his Synopsis of animals, a pair of extremely large fossile horns, which he saw in a museum in Sussex; but he mentions no brow-antlers in these, and therefore probably they, as well as most others preserved in museums, were the horns of the German elk.

It is not agreed by authors what number of young the Moose brings forth at a time; Mr. Dudley says but two; but Josselyn, and from him Neal, say three; and these authors add, that they do not go so long with young as our does, by two months.

There is, beside the Moose, another animal of the deer-kind, very common in Virginia, and other of the Northern provinces of America. This creature has round horns, not spreading out as in the stag or red-deer, but meeting nearer together at the tips, and bending forwards over the creature's head; and the brow-antlers are not crooked and standing forward, but straight and upright. The skin of this deer is of a sandy colour, with some black hairs, and is spotted all over while young with white spots, as some of our fallow deer are, and it is about the bigness of our fallow deer when full grown.

The Dama Virginiana of Mr. Ray was different from this, if the description be exact, and the horns of the palmated kind. This Dama of Mr. Ray seems to be what Josselyn, in his Voyages, calls the Maurouse; but his description is too short to form any regular judgment from, he only says that the maurouse is like the Moose, but that its horns are small, and the creature about the bigness of a stag. *Phil. Transf.* N°. 444.

Josselyn mentions also the buck, the stag, and the rain-deer; but it is very much to be doubted whether they are the same with the Moose deer.

MO'RTAR (*Dict.*)—*Plate* XXXV. *fig.* 15, in the Dictionary, is a large Mortar; and *fig.* 22. represents the curve described by a bomb, shot from a Mortar.

MORTAR, among bricklayers, a kind of cement, composed of lime, sand, hair, &c. in which they lay the bricks, &c. in building.

The glass-makers in France are said to use a sort of Mortar, for plaistering over the inside of their furnaces, which is made of a sort of fuller's earth, which is procured at Beliere, near Forges, which is the only earth in France that has the property of not melting in this excessive heat; and also the pots which hold the melted metal, are made of this sort of earth, and will last a long time.

Mortar for sun-dials on walls, may be made of lime or sand tempered with linseed-oil, and, for want of linseed-oil, may be made of scummed milk; but oil is better: this spread upon the wall will harden to the hardness of a stone, and not decay in many years, and will endure the weather six times as long as the ordinary plaister, made of lime and hair with water.

MO'RUS, *the mulberry.*— The fruit of this tree, while unripe, is very astringent, but, when thoroughly ripe, it is of a contrary quality, rather purgative, cooling, very pleasant, and quenching thirst. Its syrup, which is very pleasant, is the only use made of it in the shops.

The more general cultivating mulberry-trees in England might be of greater use than is at present supposed in many respects. In Devonshire they have a way of mixing mulberry-juice with their cyder in the making, and thus make the very best of all English vinous liquors. And as to the great article of breeding silk-worms, though a recommendation from the crown could not bring about the planting these trees in sufficient number for it in James the First's time, yet the trees have been found to flourish every-where with us, when properly planted, and the worms feed very kindly and work very well with us. When this manufacture was first attempted, the people of many parts of England, nay, and in some parts of the dampest places in Ireland, tried it, and always with success. The only thing that stopped the progress of so valuable a thing, at that time, was the want of a sufficient quantity of mulberry-trees, and the scheme has been neglected ever since. *Phil. Transf.* N°. 133.

The tree was always esteemed by the ancients for its delicious fruit, before the use of its leaves was ever found out. The Romans, in the height of their luxury, preferred it before all the foreign fruits; and Columella and the other ancients are very express in the method of propagating it.

The common mulberry-tree is to be propagated either by sowing the seeds, or by laying down the tender branches, which in two years will be well rooted, and may be cut off from the tree, and transplanted into the places where they are to remain. But those plants which are propagated from seeds, are usually the most vigorous, and grow the most regularly, and with the straighter stems; but then there is a great disadvantage attending this propagation, which is, that the trees are frequently altogether male, producing only catkins, and no fruit; so that it is better to do it by layers from a tree, which is known to produce plenty of good fruit; the straightest shoots should be always chosen for layers; and, when they are transplanted, they should be tied up to stakes to keep them straight. This tree should not be often pruned, but only such branches are to be cut off, as cross and bruise one another.

The mulberry-tree thrives best in a light soil, which should not be too wet, nor over dry; and it should always have an open exposure; for, if planted too near trees or buildings, so as to be shaded thereby, the fruit seldom ripens well; though it will be to great advantage to have them defended from the west and south-west winds, by trees or buildings at a distance.

The soil under the mulberry-tree should always be well dug up every year, and manured, which proves of very great service to the fruit.

The white mulberry is cultivated in France and Italy for the sake of its leaves, as there is an opinion, that the silk-worms should be fed only with these; but it is affirmed by persons who seem to know best, that the Persians feed their worms only with the leaves of the black kind.

The trees, intended for feeding silk-worms, should not be suffered to grow tall, but kept in a sort of hedge; and instead of pulling off the leaves singly, they should be cut off with sheers, together with the young branches; this is not only much sooner and more easily done, but it is less injurious to the trees. The white sort is propagated either by seeds or layers, as the black, and is equally hardy. *Miller's Gard. Dict.*

MOSS.— These small plants, though neglected for many ages, have, by the industry and application of later botanists, been found a very numerous and very beautiful class of plants; and not without their use in medicine and mechanics, and to various purposes of human life. Dr. Dillenius, who has studied them with an uncommon care, and given a very valuable history of them, has described more than six hundred species; the greater part of which are found in our own country, though some peculiar to others; and, doubtless, there yet remain vast numbers unheeded and unknown in many countries. See *Plate* XXXVI. *fig.* 2.

Uses of MOSSES.— Were there no other use in these minute and beautiful objects than the admiring the wonderful works of the Creator,

Creator, this were enough to make the ſtudy of them worthy of attention; the almoſt endleſs variety of the figure and ſtructure of their leaves, the ſlenderneſs of the ſtalks that ſupport them, and regularity and nice order in which they are arranged; the minuteneſs of their roots, and the ſlenderneſs of the pedicles which bear the heads, each of which is often ſmaller than the fineſt hair; and the extreme exility of the veſſels through which juices are conveyed along theſe for the nouriſhment of the plant and ſeeds, can never enough be admired; and the various ſtructure of the heads or ſeed-veſſels with their coverings, by means of which the tender ſeeds and farinæ are defended, afford to the microſcopic obſerver an endleſs fund of admiration.

But theſe are not all the uſes they were intended for, many may yet remain unknown; but we at preſent well know that ſeveral of the uſnea's are great and valuable medicines, uſed as deſiccatives and aſtringents; that the common cup Moſs is one of the greateſt remedies in the convulſive coughs of children, called the chin-cough, is known to every one; and Dr. Mead has ennobled the grey ground lichen, by publiſhing its virtues in one of the moſt terrible of all diſeaſes, the bite of a mad dog. The common green liverworts are known medicines in diſorders of the breaſt, as are alſo all the ſpecies of polytricha. The ſeeds of our lycopodium are given with ſucceſs in nephritic caſes; and the Indians give one of their ſpecies in many diſtempers, and, as they ſay, with great benefit. The common white ground coralloides ſerves the rain deer of Lapland for food, when all other herbage is loſt; and the confervæ ſerve for food to many of the fiſhes both of the ſea and rivers, and to ſeveral water-fowl. And theſe, as well as the land Moſſes, afford ſhelter and habitation to many inſects, and their young. Many of the ſpecies of coralloides and lichenoides are found of great uſe in that profitable branch of commerce, the art of dying; and, doubtleſs, many others have alſo the ſame qualities, though not yet diſcovered; and we may be guided, in ſearches of this kind, by obſerving that many of them tinge the papers, between which they are dried, to very beautiful and laſting colours. The Moſſes which cover the trunks of trees, as they always are freſheſt and moſt vigorous on the ſide which points to the north, if not only produced on that, ſerve to preſerve the trunk of the tree from the ſeverity of the north winds, and direct the traveller in his way, by always plainly pointing out that part of the compaſs.

The ſoft marſh and bog Moſſes ſerve the poor in many places for ſtuffing their beds, and in the buſineſs of tranſporting plants from other countries, nothing is of ſo great uſe as the ſtalks and leaves of theſe little vegetables: the ſucculent plants coming over in great beauty and vigour, when rolled up in dry Moſs; and trees and ſhrubs, by having their roots covered with ſuch as is ſomewhat moiſt.

The great quality of the Moſſes, which makes them ſo ſerviceable in this caſe, is, that they do not heat and ferment on being moiſtened, as hay and ſtraw would.

Moss *on trees*, in gardening. The growth of large quantities of Moſs on any kind of tree is a diſtemper of very bad conſequence to its increaſe, and much damages the fruit of the trees of our orchards.

The preſent remedy is the ſcraping it off from the body and large branches, by means of a kind of wooden knife, that will not hurt the bark; or with a piece of rough hair-cloth, which does very well after a ſoaking rain. But the moſt effectual cure is, the taking away the cauſe. This is to be done by draining off all the ſuperfluous moiſture from about the roots of the trees, and may be greatly guarded againſt in the firſt planting of the trees, by not ſetting them too deep.

If trees ſtand too thick in a cold ground, they will always be covered with Moſs; and the beſt way to remedy the fault, is to thin them. When the young branches of trees are covered with a long and ſhaggy Moſs, it will utterly ruin them; and there is no way to prevent it, but to cut off the branches near the trunk, and even to take off the head of the tree, if neceſſary, for it will ſprout again; and if the cauſe be in the mean time removed by thinning the plantation, or draining the land, the young ſhoots will continue clear after this.

If the trees are covered with Moſs, in conſequence of the ground's being too dry, as this will happen from either extreme in the ſoil, then the proper remedy is, the laying mud from the bottom of a pond or river, pretty thick about the root, opening the ground to ſome diſtance and depth to let it in; this will not only cool it, and prevent its giving growth to any great quantity of Moſs, but it will alſo prevent the other great miſchief which fruit-trees are liable to in dry grounds, which is, the falling off of the fruit too early. *Mortimer's Husbandry.*

Silk Moss, in botany, a name given by Count Marſigli to a ſpecies of ſea Moſs, of a very remarkable fineneſs and ſoftneſs, much more reſembling ſilk than any other vegetable productions. It is wholly compoſed of a ſort of tuft or fine hairs or filaments, and is of a bluiſh green colour, and almoſt tranſparent. It grows on rocks, ſtones, ſhells, or any thing elſe that lies in its way, and is found, uſually, at ſmall depths; it is not ſo tough and flexible as many others of the ſea plants, but is eaſily rubbed to powder between the fingers. When examined by the microſcope, the ſingle filaments do not appear of the ſame equable ſurface and uniform texture; but they are ſeen to be jointed and made up as it were of a great number of pieces faſtened end by end to one another, in the manner of the beads of a lady's necklace. It is of a fine bluiſh green, and perfectly tranſparent before the microſcope, and reſembles a ſtring of gems, ſuch as the aqua marina, or ſome other like ſtone. *Marſigli, Hiſt. de la Mer.*

Moss is alſo a name given by ſome to the boggy ground in many parts of England, more uſually a fen and bog.

MOTHER-*wort*, *cardiaca*, in medicine, is only uſed in the ſhops as an ingredient in ſome of the compound waters, intended againſt hyſteric complaints; and the country people frequently make an infuſion of it in the manner of tea, for the ſame purpoſe. It is alſo ſaid to be good in flatulencies and cholics, to give great relief in epileptic caſes, and to deſtroy worms. It promotes urine and the menſes, but its power this way is greatly inferior to that of penny-royal.

MOUNTAIN (*Dict.*)—The difficulty of breathing at the tops of high mountains is a thing ſo plainly felt, that none who has ever been in the way of making the experiment, but is well convinced of the certainty of the fact. Acoſta deſcribes what he felt on the tops of the high Mountains of Pariacaca very judiciouſly.

The Mountains of Armenia, and particularly that on which Noah's ark is ſuppoſed to have reſted, have been alſo made famous by the like accounts; though the ſnows that lie on the tops of their Mountains make it impracticable to aſcend their tops, the people who climb as they can, always find that they breathe with more difficulty, and are compelled to fetch their breath oftener, than when on the plains; and, on travellers complaining of this, their guides always tell them, that it is a known thing, and is what every body ſuffers there.

The Mountains in Languedoc and the Pyreneans have the ſame effect. People of curioſity have ſometimes remained hours on the ſummit of theſe Mountains, and always found the ſame ſort of difficulty in breathing; but it is poſſible that this may be owing to the exhalations of certain ſteams from the earth in theſe places, leſs loaded with a weight of air than below; and this appears the more probable, as in going up the Mountain Teneriffe, if many people are in company, and aſcend different ways, ſome uſually bear it better than others; and the very complexions of ſome are turned yellow by the exhalations which are very plainly perceived by their ſmell and ſharpneſs, while others who aſcend to the ſame height by different tracts, eſcape.

The moſt remarkable Mountain in the world, in ſhape, is that called the needle Mountain, or the inacceſſible Mountain, in Dauphiny.

This is a vaſt hill, placed as it were bottom upwards, or ſet on its ſummit on the earth with its broad baſe elevated in the air; it is but about a thouſand paces in circumference at the bottom, and is above two thouſand at the top. On the center of the plain at the top there ſtands another ſmall and very narrow, but very high hill.

It obtained the name of the needle, as it got the other, by its being ſuppoſed impracticable to the aſcent of any one, by reaſon of its projecting ſo greatly outwards. Some hardy perſons, however, once ventured to climb it, and found at the top a number of the chamoiſe, animals by no means qualified for climbing, and which doubtleſs had never either aſcended or deſcended the Mountain, and which muſt be ſuppoſed to have bred there for many ages, though it be very difficult to account for their firſt getting to the place. *Hiſt. Acad. Par.*

MUFFLE, in metallurgy, is an arched cover, reſiſting the ſtrongeſt fire, and made to be placed over coppels and teſts in the operations of aſſaying, to preſerve them from the falling of coals or aſhes into them; though at the ſame time of ſuch a form, as not to hinder the action of the air and fire on the metal, nor prevent the inſpection of the aſſayer.

The Muffles may be made of any form, ſo they have theſe conditions; but thoſe uſed with coppels are commonly made ſemi-cylindrical, or, when greater veſſels are employed, in form of a hollow hemiſphere.

The Muffle muſt have apertures, that the aſſayer may look in; and the fore-part of it muſt be always quite open, that the air may act better in conjunction with the fire, and be inceſſantly renewed; for, without this, ſcarce any fumes are to be produced; and, without theſe, the vitrification of lead is ſcarce practicable; for, when the air is once filled with a certain quantity of vapours, it ſcarce admits any more afterwards; and for this reaſon a conſtant ſucceſſion of freſh air is neceſſary. The apertures in the Muffle ſerve alſo for the regimen of the fire; for the cold air ruſhing into the larger opening before, cools the bodies in the veſſel; but if ſome coals are put in it, and its aperture before be then ſhut with a door fitted to it, the fire will be increaſed to the higheſt degree, much more quickly than it can be by the breathing-holes of the furnace. Another uſe of theſe apertures is alſo, that the arſenical vapours of lead and antimony, paſſing through the holes in the back part of the Muffle, may not be offenſive to the aſſayer, who ſtands before it.

As to the height, length, and depth of the Muffles, theſe muſt be proportioned to the ſize and number of the veſſels they are intended to cover; and care muſt be taken in this, that all parts of the inner surface of those vessels must be in the reach of the assayer's eye. The most frequent size of the Muffle, however, is four inches high, six or eight inches long, and four or six inches broad. The segments cut off at the bases, for the lesser holes, must be of such a proportioned height, that the least vessels, put under it, may not be in the way of coals or ashes falling into them; for that always hinders the vitrification of lead, and the destruction of the other metals and semi-metals, and will sometimes intirely reduce them again, when already destroyed; and the scoriæ, softened by ashes, soften and retard the operation.

Wooden moulds, of a proper shape, are most convenient for the making these Muffles in, and the matter for making them is the same with that of the German clay tests; that is, either a pure native clay, of a condition to bear the fire, which will be known upon the trial; or such clay, hardened by a mixture of the powder of stones: and, in order to the forming of these, the mass must be made tolerably soft and pliant. Knead a sufficient quantity of this mass with your hands upon a flat stone; spread it out evenly into a thin cake or plate, somewhat longer and broader than you intend the Muffle to be made; and so thick, that two or more thin plates or laminæ, of about two lines thick each, may be cut off from it. This is easily done by rolling the mass on the stone with a rolling-pin, strewed over lightly with ashes, or powder of chalk.

When the cake is thus rolled out, with a thin, fine, and perfectly straight brass wire, cut off, from the cake, one thin plate; this must be done with great caution, lest it should break; take this up, and, rubbing it over with oil or fat, lay it over the mould; then cut out a semicircular piece from the mass, of the same thickness with the former, and with this cover the back plane, or farther end of the mould, joining the edges of this plate to those of the former, closely and perfectly, by wetting them well with water.

Next, cut off from the cake another thin plate, to be the bottom of the Muffle; this may be either left loose for the Muffle to be placed on it occasionally, or the bottom edges of the already formed Muffle may be joined to it all round, by means of water, as the back was before joined to the arched part of the Muffle. But, whether it be intended that the bottom shall be thus fixed on, or left loose, it must be half an inch broader every way than the bottom of the Muffle, that this may stand the more firm and sure upon its basis.

When the Muffle is thus made, wet your hands, and rub it carefully all over, that the small and perhaps invisible cracks, and the chinks in the plates, may be closely joined, and the whole matter of it applied perfectly close to the surface of the mould.

When the Muffle has been some time exposed to the air, and is somewhat dried and hardened on the mould, cut out two or three hemispherical pieces on each side, to make the holes before described, at the basis and back; and then draw away the mould from within it; for if the Muffle is suffered to dry perfectly on the mould, it always cracks. When the whole is perfectly dry, let it be baked in a potter's kiln, or in the assayer's oven; but, without great care in the latter method, and lighting the fire at top first, it is apt to crack, so that the potter's kiln, where at hand, is much the better way of baking it. *Plate* XXXI. *fig.* 9.

If there be adapted to the formerly described convex mould another concave one nearly fitting it, only leaving room for the thickness of the Muffle between, and the clay be placed between them, and formed by this means into its exact shape, by a strong and every way equal pressure, this will make Muffles not only with much less trouble, but they will be much stronger, less apt to crack, and more capable of resisting the fire, than those made by the hand in the other way.

The only caution, necessary for the making them, is, that the clay be a little drier than when it is to be worked by the hand; that the sides, both of the inner or convex mould, and of the outer concave one, be thoroughly oiled or greased, and the pressure on the surface of the outer or concave mould be as strong and as equal as may be. There is no clay better for the making these Muffles than the Windsor loam, an earth well known among the chemists and glass-men, and always to be sold in London; and the rubbing the insides of the mould with black, in fine powder, very well supplies the place of greasing them, to prevent the matter from sticking to them.

These are the Muffles ordinarily used in assaying; but, when very large tests are to be covered, they use large spheroidal Muffles, made of cast iron, or sometimes of the same clay, and wrought in the same manner, only made upon proportionably larger moulds. The clay is usually, for these large ones only, laid in a lump on the top of the mould, and with wet hands spread all over it to the bottom, and by this means a Muffle is made with little trouble. *Cramer's Art of Assay.*

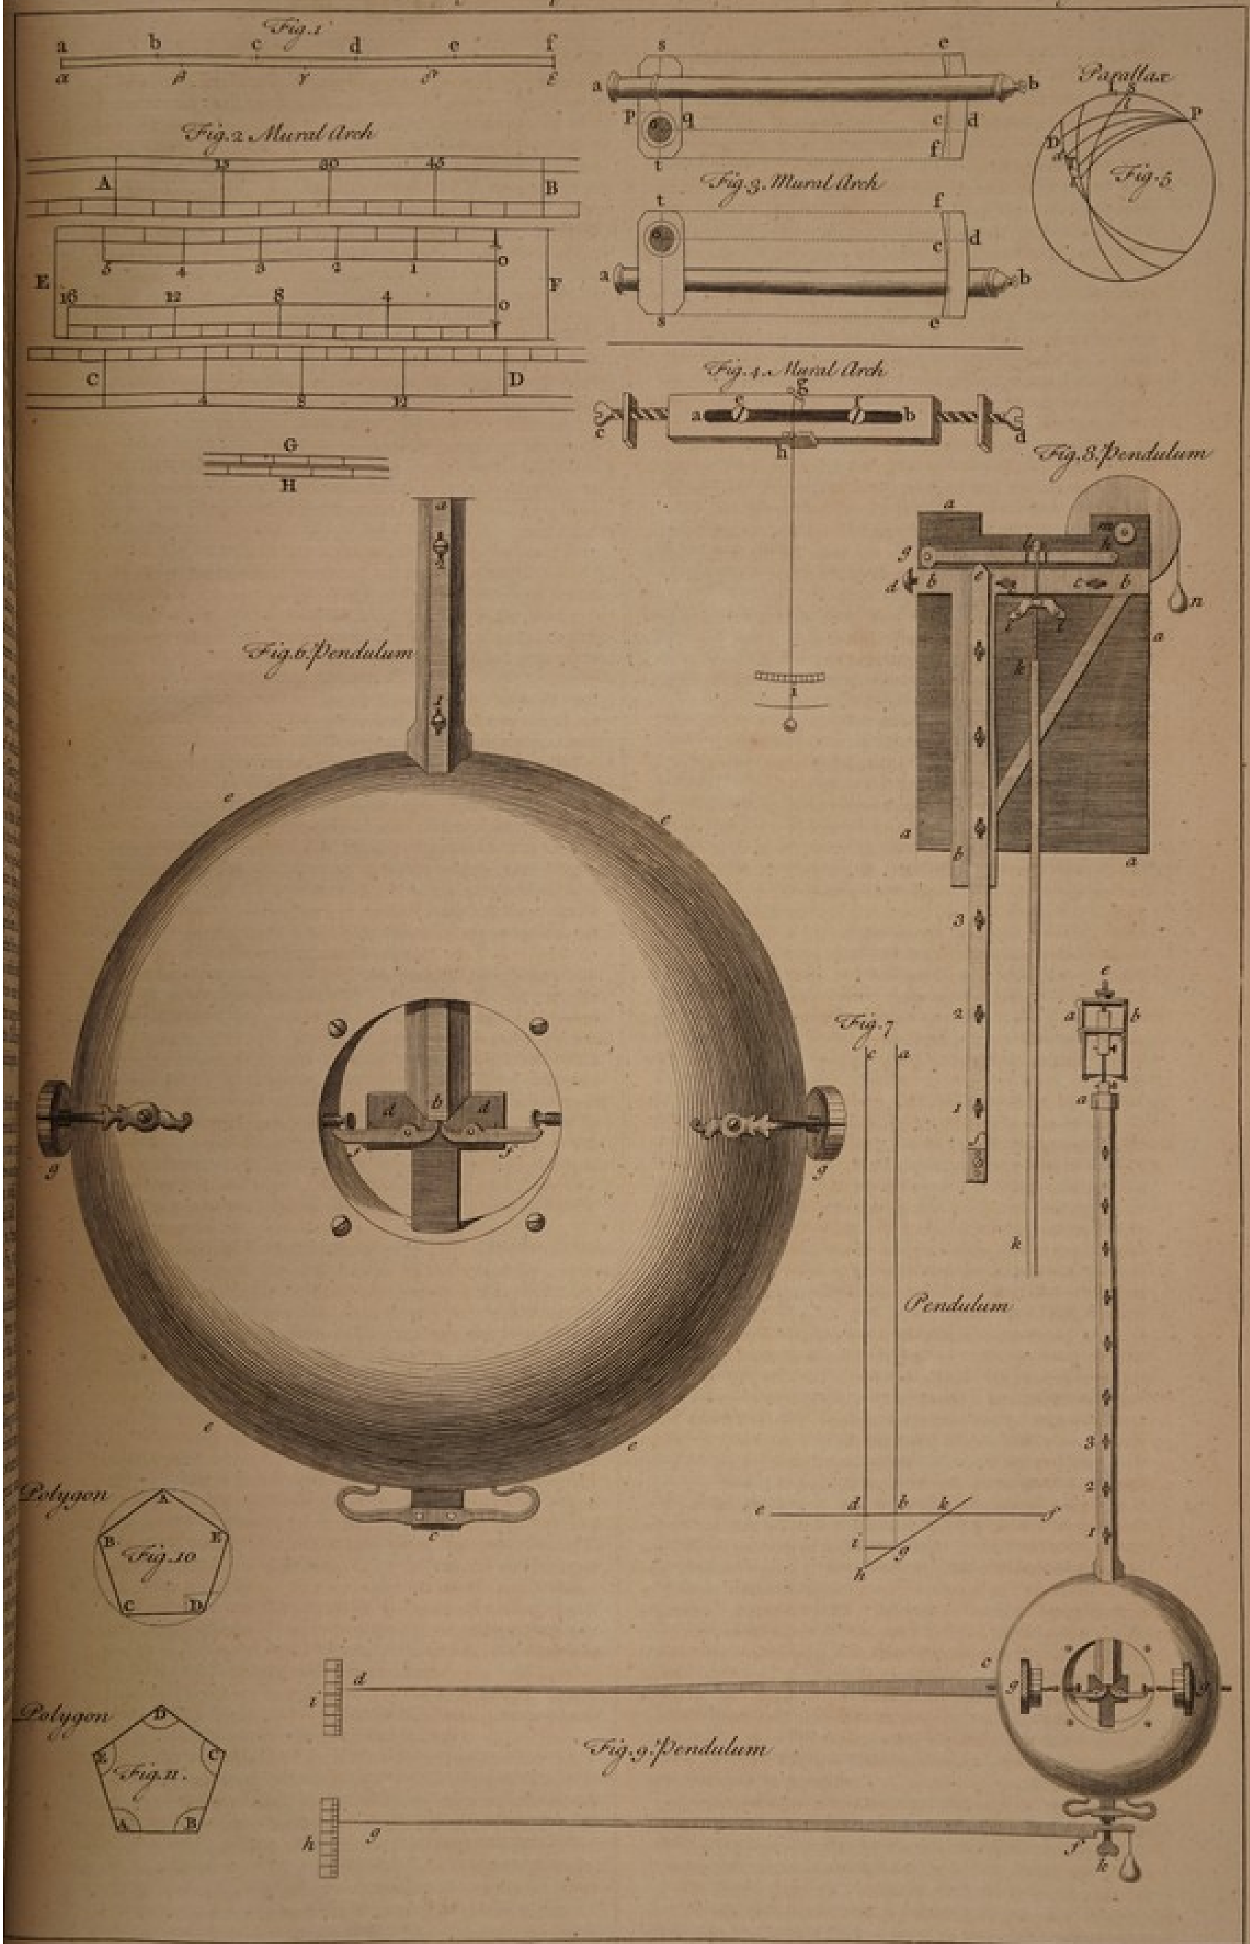
MU'MMY, among the gardeners, is the term used for a sort of waxy composition used in grafting. It is made of one pound of common black pitch, and a quarter of a pound of turpentine, put into an earthen pot with a cover fitted to it; this is to be set in the open air, and the cover being taken off, the matter is to be set on fire, and when it has burned a little while, it is to be quenched, by putting on the cover. This is to be repeated till the mixture is of a proper consistence, which is known by pouring a little of it on a pewter plate, on which, when it is enough, it will coagulate immediately. When it is of this consistence, it is to be poured into another pot, and a little yellow wax is to be added to it, and then, melting the whole together, is to be kept for use. *Miller's Gard. Dict.*

MU'RAL *Arch* (*Dict.*)—The following is a description of the Mural arch in the Royal Observatory at Greenwich.

Since the measure of time by pendulum-clocks, and consequently of the apparent diurnal motion of the heavens, has of late been brought to the utmost perfection, astronomers are agreed that a large quadrant, with a telescopic sight, fixed in the plane of the meridian to a free-stone wall, and thence called a Mural arch, is by far the most accurate, expeditious, and commodious instrument of all others for the chief purposes in astronomy. For, by observing the times by the clock of the appulses of any objects in the heavens to the plane of the meridian, we have their right ascensions; and, by their meridian altitudes observed at the same times, the latitude of the place being once determined, we have also their declinations, and, by consequence, their places in the heavens. Thus, by a good instrument of this kind, a catalogue of the places of the fixed stars may be made in less than a tenth part of the time, and with much greater certainty and exactness than by the best moveable quadrant or sextant, as might easily be shewn; not to mention the saving an immense labour in trigonometrical calculations. I think the noble Tycho Brahe was the first astronomer that used a Mural arch, for taking meridian altitudes; but he could not determine right ascensions so accurately as now, for want of the late improvements in pendulum-clocks. After him, Hevelius, Flamsteed, and others, made use of the like instruments, whose descriptions may be seen in their printed works; but I pass them all over, as being far inferior to this at Greenwich: the expence of which was defrayed by the bounty of his late Majesty King George the First; and the particular accuracy, whereby it excels all others, is owing to the extraordinary skill and contrivance of the late Mr. George Graham; who, besides the direction of the whole design, and inspection of the inferior workmen, was pleased to perform the divisions of the arch, and all the nicer parts of the work, with his own hands; and to him I am highly obliged for informing me in the methods he took to perform it. How far the tables of the moon's motion are corrected by an incredible number of observations made with this noble instrument by our royal astronomer Dr. Halley, and how near they are brought to sufficient exactness for finding the longitude at sea, are related under their proper articles in the Dictionary and Supplement At present I proceed to a description of the instrument.

Excepting the circular limb, the quadrant is chiefly composed of straight iron bars, joined together, as represented in *Plate* XXXI. *fig.* 10, 11. The breadth of every bar is two inches and nine-tenths, and its thickness, one-tenth and three-fourths, nearly. In speaking of the disposition of these bars, those, whose planes compose the plane of the quadrant, I shall call flat bars; and those, whose planes are perpendicular to the former, I shall call perpendicular bars. The lines in *fig.* 10, represent the disposition of all the flat bars, and those in *fig.* 11. represent the disposition of all the perpendicular bars, placed behind the flat ones; and are only to be seen on the back-side of the quadrant. The chief design, in this disposition of both sorts of bars, is to secure the figure and plane of the quadrant from any alterations that may be caused, either by the weight of the materials, or by their swelling or shrinking by the weather, or by the motion of the telescope about the center of the quadrant, or by any accident whatever: the whole fabric is farther strengthened by a great number of short iron plates or pieces of the like bars bent to a right-angle, and placed behind the quadrant in the angles made by the flat and perpendicular bars, and riveted to them both. Their number and places where they are riveted are represented in *fig.* 11. by the small parallelograms adjoining to the lines: and, to make more room for the rivets, the edge of each perpendicular bar does not divide the breadth of the flat bar in the middle, but in the ratio of 2 to 1; and the little plates are riveted on the broader side. The black thickenings of the lines at their intersections in the eleventh figure represent little plates of iron bent in right-angles, and riveted in the angles made by the intersections of the perpendicular bars. At the circumference of the quadrant there is also a perpendicular bar, bent circular, and fastened all along the middle of the breadth of the limb or flat arch of the quadrant, by a sufficient number of the little plates we have been speaking of.

The limb of the quadrant is composed of two quadrantal arches, of the same length, breadth, and thickness; one of iron, the other of brass laid over it. The breadth of each is three inches and four-tenths, and the common part of their breadths, where they lie doubled one over the other, and are riveted together, is two inches and two-tenths, the brass limb being remoter from the center than the iron one by an inch and two-tenths. The limb was reduced to a true plane, as follows: *a b d e*, *fig.* 12, represents the quadrant, placed very firm upon a level plane, with its brass limb lying upwards: and *l m* represents an axis made of iron, placed perpendicular to



Printed for J. Hinton in Newgate Street.

to the plane of the quadrant, and pointing to its center *e*; *m n* is an arm of iron, equal in length to the radius of the quadrant, and fixed at right angles to the bottom of the axis *l m*; to the end of this arm an iron ſcraper *n p* was fixed directly over the braſs limb; and, being firmly ſupported by the arm and its braces, was turned about the axis *l m*, till, by ſcraping the braſs, it reduced its ſurface to a perfect plane; care being taken that the edge of the ſcraper was exactly perpendicular to the axis of its motion.

There are two arches ſtruck upon the braſs limb; one with a radius of 8 feet, or more exactly of 96, 85 inches; and the other, with a radius of 95, 8 inches. This inner arch is divided into degrees, and 12th parts of a degree; and the outward arch into 96 equal parts, which are ſeverally ſubdivided into 16 equal parts. The beam of the compaſs which ſtruck theſe arches, was ſecured from bending by ſeveral braces faſtened to it; and, when an arch was ſtruck, 60 degrees of it were determined by placing one point of the compaſs at *a*, and by making a ſtroke at the other at *b*. This arch *a b* was biſected in *c* by drawing two ſmall arches upon the centers *a* and *b*, with ſuch a radius as to croſs the arch *a c b*, in two points as near together as poſſible without touching each other; then the ſmall interval between them was biſected at *c*, by eſtimation of the eye, aſſiſted by a magnifying glaſs. After this, the interval between the points *a* and *c*, or *c* and *b*, was taken with the beam compaſs, and was transferred from *b* to *d*, which determined the length of the quadrantal arch *a c b d*. Every one of the three arches being biſected in the ſame manner, the quadrant became divided into 6 equal parts, containing 15 degrees a-piece; and every one of theſe was divided into three equal parts as follows. To avoid making any falſe or ſuperfluous points in the quadrantal arch, with its radius unaltered, but upon any other center, there was ſtruck another faint arch, upon which the chord of 15 degrees, already found, was transferred from the quadrantal arch; and the third part of 15 degrees, being determined by trials upon the faint arch, was transferred back again upon the quadrantal arch; which then was divided into 18 equal parts, containing 5 degrees a-piece; and the 5th part of theſe was found by trials, as before, in dividing a ſeparate arch, drawn upon a new center for this purpoſe only. The ſubdiviſions of the degrees into 12 equal parts were made by biſections and triſections as before. Thus was the whole quadrant divided without any falſe or ſuperfluous points.

The outward quadrantal arch was divided into 96 equal parts, by no other method than that of biſection, till 60 degrees or two thirds of the quadrant became divided into 64, and the remaining third into 32, equal parts; which make 96 in the whole. And every one of theſe were alſo divided into 16 equal parts, by continual biſections. Theſe two ſorts of diviſions are a check upon each other, being in effect two different quadrants; and, the diviſions in one being reduced into the diviſions of the other, by a table made for that purpoſe, they are never found to differ above five or ſix ſeconds in any place of the limb: and, when they do, the preference ought to be given to the biſected diviſions, as being determined by a ſimple operation.

The diviſions hitherto mentioned being only very fine points in a fine arch *a b d*, ſcarce diſcernible by the naked eye; it was neceſſary, as uſual, to ſtrike lines perpendicular to the arch, through every one of them. But, ſince it is very difficult, and tedious too, to draw lines exactly through every point by the edge of a ruler, the following method was judged more accurate and expeditious. It was propoſed then to divide any other concentric arch, *f h t* (*fig.* 12.) by croſs ſtrokes, into a ſimilar parts to thoſe in the given arch *a e g e d b*. Take a ſmall beam compaſs, and, having once fixed its points at any convenient interval, upon the centers *e*, *g*, &c. being the given points of the divided arch, ſtrike the ſmall arches *f i*, *h k*, &c. cutting the undivided arch in *f*, *h*, &c. then will the intercepted arches, as *f h*, &c. be ſimilar to the arches *e g*, &c. that is, they will ſubtend the ſame angles at their common center *o*. For joining *e f*, *g h*, and alſo *o f*, *o h*, *o e*, *o g*, the triangles *e o f*, *g o h*, will be ſimilar and equal to each other; every ſide in one being reſpectively equal to every ſide in the other. Therefore by taking away the common angle *e o h*, from the equal angles, *e o f*, *g o h*, the angles *e o g*, *f o h*, that remain, will alſo be equal.

If the triangles *e f o*, *g h o*, &c. be right-angled at *f* and *h*; the dividing ſtroke *f i*, *h k*, &c. will cut the quadrantal arch *f h t*, at right angles alſo, at *f* and *h*, &c.

In the thirteenth figure *a b c d* repreſents a ſquare piece of braſs (with ſeveral ſteady pins in it) ſkrewed to the flat bars, at the center of the quadrant, the ſkrew-holes being ſo large as not to touch the ſkrews; and *k l m n* repreſents a thick circular plate of braſs, with a hollow pipe *f g* fixed perpendicular to the middle of it; this plate was turned exactly circular in a lathe, upon a braſs arbor *o i*, turned tapering and a little hollow in the middle, ſo as to fit the cavity of the pipe *f g*, and to bear againſt it chiefly at both ends. When the hollow pipe *f g* is put through the hole (exactly fit for it) in the middle of the ſquare *a b c d*, the braſs circle *k l m n* is fixed to the plane of the ſquare *a b c d*, with ſkrews and ſteady pins. The point *o*, in the pole of the arbor *o i*, is not only the center of the circular neck *k l m n*, about which the teleſcope muſt turn, but alſo the very center upon which the divided arches were ſtruck upon the limb of the quadrant. The end of the teleſcope that holds the object glaſs, lies croſs one end of an oblong plate of braſs *s t*, at right angles to its ſides, and is held to the plate, by a brace that may be widened and ſtreightened by a ſkrew. Towards the other end of the plate *s t*, there is a round hole, lined with a ſteel collar *p q r*, to be put over the braſs neck *k l m n*, and to turn round upon it. The ſection of this collar, made perpendicular to the plane of it, is repreſented at *z*; the broader of the two rings being under the plate *s t*, and contiguous to the ſquare plate *a b c d*. Over this neck and collar there is fixed a braſs ſpring repreſented at *v*, and ſkrewed to the neck *k l m n*, to keep the collar from ſlipping from it; and over all theſe is ſkrewed a cap repreſented at *x*, to cover the center work, and to keep off the duſt; which is alſo prevented from coming between the plates *a b c d* and *s t*, to the neck and collar, by means of a braſs hoop ſurrounding the broad rim or baſe of the collar *p r*, and ſkrewed to the back-ſide of the plate *s t*; which hoop is received into a circular grove 1, 2, 3, 4, made in the ſquare plate *a b c d*, without touching any part of it.

The chief excellency of the preſent center work conſiſts in preſerving the place of the central point of the quadrantal arch in the pole of the arbor *o i*. For, whenever the neck plate *k l m n* ſhall be worn ſo much as to cauſe an unſteady motion of the teleſcope about the center of the quadrant, a new neck plate and pipe may be caſt, well hammered and turned upon the poles of the ſame arbor *o i*, to fit the hole and collar; and then it will carry the teleſcope about the center of the limb, as exactly as when all was new.

The fourteenth figure gives a view of the quadrant fixed to the eaſtern ſide of a free-ſtone wall, built for that purpoſe in the plane of the meridian. The whole weight of the quadrant is ſupported by two ſtrong iron pins fixed to the wall (as hereafter deſcribed) and projecting through two holes made in two ſquare plates of iron riveted to the quadrant at *a* and *b*, in the tenth figure. The pin at *a*, which bears the greateſt part of the weight, is immoveably fixed in the wall; but the pin at *b* is moveable up or down by a ſtrong ſkrew, in order to bring one ſide of the quadrant to an horizontal, and the other to a vertical poſition.

The contrivance for the motion of the pin *b* is this: in the fifteenth figure *l m n o* repreſents an oblong plate of iron, let into the free-ſtone wall, and faſtened to it by bolts of iron, which paſs through the wall and through another plate let into the oppoſite ſide of it; the bottom of each plate being bent ſquare and bedded in the ſtone. And *e*, *f*, *g*, *h*, are the heads of 4 iron ſkrews, whoſe ſhanks going through 4 long ſlits, made in another iron plate, repreſented by the ſmaller parallellogram, are ſkrewed into the fixed plate *l m n o*. The moveable pin *b c* is fixed to this leſſer plate, which is raiſed, or depreſſed, by means of a long ſkrew *k i*, working againſt the bottom of the pin *b c* at *d*; being turned round in a ſtrong concave ſkrew, fixed to the bottom of the larger plate at *p q*. The key for turning the long ſkrew *k i* is a ſector of a circular plate repreſented at *r s t*; the ſquare hole in its center *t* being put upon the ſhank *k*. The radius of the key is juſt ſo big as to move in the ſpace between the wall and the bars of the quadrant; and a chiſſel *s* is inſerted into the teeth upon the arch of the key, to give power to the hand that moves it.

The weight of the quadrant being thus ſupported by the pins *a*, *b*, (*fig.* 14.) the plane of it is fixed to the wall and adjuſted in any poſition, by much the ſame number of hold-faſts as there are little ſquares round about the quadrant in the ſeventh figure. Each hold-faſt conſiſts of two ſeparate parts; one of them is fixed to the wall, and the other to the quadrant.

In *fig.* 15. *a b* repreſents the wall ſeen end-ways, and *c*, *c*, ſeveral hold-faſts fixed into it. Between the chaps of each hold-faſt, repreſented at *d*, *e*, there paſſes one end of a ſmall plate of braſs, whoſe plane is parallel to the plane of the quadrant, the other end being bent to a right angle and riveted to the perpendicular bars of the quadrant; and each plate is pinched by two oppoſite ſkrews *r*, *s*, that work through the chaps *d*, *e*, which are made pretty wide for adjuſting the poſition of the plane of the quadrant. The intent of the ſkrews in the chaps of the hold-faſt was alſo that, if the wall or quadrant ſhould ſwell or ſhrink, ſo as to alter their proportions, the braſs plates might ſlide without diſtending the inſtrument. The hold-faſts are not faſtened in the wall with lead, which is apt to yield, but with a compoſition made of ſtone-duſt, pitch, and brimſtone, or roſin; ſuch as ſtone-cutters uſe for cementing broken ſtones.

The continuance of the exactneſs of the quadrant depends, in a great meaſure, upon a free and eaſy motion of the teleſcope round the center of it; which will be obtained by counterpoiſing the weight of the teleſcope, and by eaſing the center of the quadrant of as much of thoſe weights as poſſible. For this purpoſe in *fig.* 14. *a b* repreſents an iron axis laid croſs the top of the wall; having two braſs plates fixed perpendicular to the ends of it, with notches or holes cut in them for this axis to turn in, which points to the center of the quadrant at right angles to its plane. To that end of this axis next the quadrant, an iron arm *c d* is fixed, having

having two brass plates *c e*, *d f*, almost perpendicular to it; to them are riveted two slender slips of fir, whose other ends meet at *g*, near the eye glass; being held together in a brass cap or socket. Through a small plate fixed to one side of a collar, embracing this lower end of the telescope, there passes a screw pin at *g* parallel to the telescope; which pin, being skrewed into the cap at the end of the slips, holds up the telescope tight against the center work. The slips are strengthened by 5 or 6 cross braces of the same wood, as represented in the figure. To the other end of the axis *a b* another arm *h i* is fixed parallel to the telescope, and in a contrary direction, carrying a weight *i* to counterpoise the weight of the telescope, and make it rest in any position. And, for the greater ease and freedom of its motion, two small brass rollers are fixed to each side of it, at *k* and *l*, which are held tight to the plane of the limb by a plate springing against its backside, which plate has also a roller at each end of it.

When the telescope is pretty nearly directed to an object whose altitude is to be taken, a plate *m n*, which is carried by the telescope along the limb, and lies cross it, may be fixed to it by a screw, not here represented. Then by twisting the head *o* of a long skrew *o p*, which is parallel to the limb, and which works through a female skrew, annexed to the plate *m n*, and whose neck at *p* turns round in a collar annexed to the telescope; a very gradual motion is given to the telescope for bringing the cross hairs exactly to cover the object.

To avoid the trouble of subdividing the quadrantal arch into smaller parts, the telescope carries a small brass plate, which slides upon the limb, and is called a nonius, from the name of its inventor. To understand the reason and use of this plate, it is convenient to premise the following theorem: If a line *a f*, (*plate* XXXIII. *fig.* 1.) be divided into any number of equal parts, *a b*, *b c*, *c d*, *d e*; and an equal line *α ε* be divided into other equal parts, *α β*, *β γ*, *γ δ*, *δ ε*, whose number is one less than the number of parts in *a f*; I say that *α β*, *α γ*, *α δ*, *α ε*, will exceed *a b*, *a c*, *a d*, *a e*, respectively, by one, two, three, or four parts of *a b*; whose denominator is the number of parts in *a e*, or in *α ε*. For let the lines *a f*, *α ε*, be coincident at both ends, and, since any equimultiples of two quantities *a b*, *α β*, are in the same ratio as the quantities themselves, it will be as *a b* : *α β* :: *a c* : *α γ* :: *a d* : *α δ* :: *a e* : *α ε*, or *a f*, and disjointly as *a b* : *b β* :: *a c* : *c γ* :: *a d* : *d δ* :: *a e* : *e ε*, or *e f*. The consequents, *b β*, *c γ*, *d δ*, *e ε*, are therefore in the same arithmetical progression as the antecedents *a b*, *a c*, *a d*, *a e*; and the first of the consequents *b β* is the same part of its antecedent *a b*, as the last consequent *e f* is of its antecedent *a e*, or as *α β* is of *α ε*, the number of parts in *a e* and *α ε* being equal by the first supposition: and it is manifest that any two equal and coincident arches of a circle have the same property.

The upper arch A B (*fig.* 2.) represents a degree divided into 12 equal parts, containing 5 minutes in each; and the end arch C D a 96th part of the quadrant, divided into 16 equal parts; and E F the nonius, or subdividing plate fixed to the telescope, and sliding with it in the space between the arches A B, C D. The degrees and minutes, and also those 96 parts of the quadrant, are numbered from the left hand to the right, beginning from the intersections of the vertical radius, in order to measure the distances of objects from the zenith; but the parts upon the nonius are numbered the contrary way, beginning from the line *o o*, called the index; which is drawn perpendicular to the sides of the nonius, at the end next the right-hand; and the line of sight through the telescope is so adjusted by the cross hairs in its focus, as to be parallel to the index *o o* produced through the center of the quadrant. In the scheme the nonius E F is so situated, that the upper end of the index *o o* is not opposite to any one stroke upon the adjoining arch, but to some unknown point of a 12th part of a degree, intercepted between 50 and 55 minutes. To find the overplus above 50, I observe by looking back from the index, that a stroke of the nonius, which lies between the numbers 3 and 4, is directly opposite to a stroke upon the adjoining arch, which shews that 3 minutes and a half are to be added to the 50 minutes aforesaid.

For since a degree is divided into 12 equal parts, containing 5 minutes in each, and since the length of the nonius is made equal to 11 of those parts, and is divided into 10 equal parts; it appears by the theorem, in counting back again from the coincident strokes to the index, that the first part of the nonius exceeds the first upon the limb by $\frac{1}{10}$ of this latter part, that is, by $\frac{1}{10}$ of 5 minutes, which is half a minute; and by consequence that 7 parts of the nonius, from the coincident strokes to the index, exceed the 7 corresponding parts of the arch, by 7 half minutes, or 3′ 30″.

When it happens that no one stroke upon the limb is directly opposite to a stroke upon the nonius, then look for that single part of the limb, which is so opposed to a single part upon the nonius, as to be exceeded by it at both ends, as represented in the parts G and H. Then, if by estimation of the eye, this part of the nonius exceeds the part of the limb equally at each end, allow 15″ more than if they had coincided at their ends next the index; and, as according as the excess next the index is judged to be one third, one half, double or treble of the other excess, allow 7½″, 10″, 20″, 22½″, respectively. For since the sum of the two excesses is always the same, and answers to 30″, (as is plain, when one of them is diminished to nothing;) the number of seconds to be added will always be to 30″, as the excess next the index is to the sum of the two excesses.

The lower arch of the nonius is divided into 16 equal parts, and is equal in length to 17 equal parts upon the opposite arch, and consequently will determine 16 parts of any one of them, by the theorem and method abovementioned. In the present scheme the opposite strokes of the nonius and the lower arch are supposed to coincide at the end off the 9th part upon the nonius, which shews that the index cuts off 9 sixteenths of the opposite part of the arch. And so the length of the arch, from the beginning of a 96th part of the quadrant, is thus denoted, 15, 9, the lower pointer being past the 15th stroke.

This way of subdividing by a nonius is preferable to the common method of drawing diagonals; both because the trouble of drawing so many diagonals is intirely avoided, and also because they cannot be drawn so exactly by the edge of a ruler, as the lines upon the nonius; and lastly because the intersection of these diagonals with the index or fiducial edge (as they call it) by reason of their great obliquity to each other, cannot be determined so exactly by the eye, as the coincidence of two strokes in the nonius and the arch, which stand directly opposite to one another.

The object glass being firmly and immutably fixed in the telescope, the nonius plate *c d* (*fig.* 3.) and the collar plate *s t*, were both skrewed fast to the telescope, when taken off from the quadrant; and the line of sight was brought to be parallel to the line *c o*, drawn through *o*, the center of the collar *p q*, to *c* the beginning of the divisions on the nonius, in this manner: the lines *s o t* and *e c f* being drawn upon these plates both perpendicular to *o c*, any distances *o t* and *c f* were taken equal to each other on one side of *o c*; and any other distances *o s* and *c e* (long enough to go beyond the telescope) were also taken equal to each other on the opposite side of *o c*. Through the four points *e*, *s*, *t*, *f*, the ends of the two plates were filled exactly parallel to *o c*. Then placing the points *t*, *f*, upon two points *m*, *n*, of an horizontal line drawn upon a firm plane, a point of a remote object covered by the cross hairs was marked. And the telescope being turned half round its axis *a b*, and the opposite points *e*, *s*, of the plates being placed upon the same points *m*, *n*, another point of a remote object now covered by the cross hairs was also marked; and, the telescope remaining fixed, the cross hairs were moved in its focus, till, after several repetitions of this practice, the same point of the object was covered by them in both positions of the telescope; and then the line of sight was exactly parallel to the line *o c*, supposing the object was very remote. But, because smaller marks upon a nearer object are better discerned, the hairs were so adjusted till in each position of the telescope they covered a separate mark, the interval of the marks being taken equal to the difference of the heights of the axis of the telescope, above the fixed line *m n*, as near as could be measured.

The object glass being well centered (*see the article* CENTERING) the line of sight was first of all made parallel to the plane of the quadrant, as near as it need be, by the measures of the brass work annexed to the telescope; and then the plane described by the line of sight, turned about the center of the quadrant, was brought into the plane of the meridian, by observing whether the fixed stars passed over the cross hairs at the same instant of time, as they passed over a meridian telescope, placed so near the quadrant, that the two observers could hear each other calling out at the times of the transits. And, by the coincidence of these observations upon stars at various altitudes, it appeared that the plane of the quadrant was wrought very true. For it is certain that the meridian plane described by the meridian telescope, as turning upon a transverse axis, must be truer than that described by the quadrantal telescope, as guided by the rollers upon the limb.

When the quadrant was thus reduced into the plane of the meridian by the hold-fast above described, that radius of it, which terminates 90 degrees, was placed exactly vertical (by the movement abovementioned) with a plumb line of very fine silver wire; playing exactly over the middle of the central point *a* (*plate* XXXI. *fig.* 13, 14.) (in the pole of the arbor *a i*) and also over the stroke at 90 degrees upon the limb below. This position of the quadrant being once found, another plumb line was suspended by the side of the quadrant, quite clear of the center work, so as to play exactly over the middle of a fine point made in the limb below, in order to examine afterwards whether the quadrant has kept its place. For this purpose, an oblong piece of brass *a b*, (*plate* XXXIII. *fig.* 4.) laid flat upon the square plate at the center of the quadrant, was gradually moved to the right or left, by two skrews *c*, *d*, working against the ends of it: a slit *a k* being cut lengthways through the plate to slide along two other skrew-pins *e*, *f*, fixed in the back plate. The wire of the plumbet was hung by a loop upon a pin *g*, and lay in a very fine angular nick, filed in the edges of a little plate *h*, which

projected

projected a little farther than the loop, for the wire to bear upon it. This plate *b*, and the pin *g*, were both fixed to the oblong plate *a b*; by whose gradual motions above described, the wire *b i* was brought to play exactly over the middle of the hole *i* in the limb; and then the plate *a b* was pressed to the quadrant by the screws *e, f*. *Smith's Optics*.

MU'REX, in natural history, the name of a genus of shell-fish, the characters of which are these:

It is an univalve shell, bent with sharp spines and tubercles, with a rough clavicle exerted near the summit in most species, but in some depressed. The mouth is always expanded, and sometimes as liquor, sometimes not; the lip is sometimes digitated, sometimes elated or folded, or jagged; and the columella is sometimes rough, sometimes smooth. See *Plate* XXXVI. *fig.* 3.

The antients were furnished with their finest purple dye, from a fish of the Murex kind, and therefore expressed the purple colour by the word Murex. We find, in Virgil,

——Tyrio ardebat murice lana.

Plumier tells us, that, in America, the Murex is called pisseur, from its readily ejecting the liquor, which gives the purple colour, when it is taken from the rocks. And Fabius Columna distinguishes the Murex from the purpura and buccinum, but in a very injudicious manner. He says the purpura affords the fine purple colour: the Murex is covered with spines and turbercles, and the buccinum is known by its smooth and long wreath. But he should have known that the affording the purple dye is common to the Murex and purpura, and even to some of the buccinum kind; and that there are Murexes with very few spines or tubercles, and buccina which are not smooth. The knowledge of the insufficiency of these characters would have engaged him in seeking others more essential; and a person of his great abilities would then perhaps have prevented half the confusion that has happened since in the world, on occasion of errors of this kind propagated from his writings, and those of two or three others of his time. See the article PURPLE.

MU'SA, *the plantain-tree*, in botany, a genus of plants, whose characters are:

The root sends forth shoots, while the stalk, after producing its fruit, decays. The stalk is like a reed, without branches, but running into very large leaves, which are first involved, as in the cannacorus, and afterwards expanded in the form of a circle at the top of the stalk. The flowers and fruit are disposed in clusters, and inclosed in sheaths, as in the palma, or date-tree; the flower is polypetalous, anomalous, and grows on the apex of the ovary. The ovary is like that of a cucumber, soft, tricapsular, esculent, full of seeds, and furnished with a long tube, which has a globular apex.

Musa is the Arabic name for this plant, which by Pliny, as we suppose, is called pala, from the word bala, which is the name by which it is known to the Malabarians at this day. Though all botanists reckon it among trees, it hardly deserves the name of a shrub, much less of a tree, since it has an annual stalk. By Oviedus, and others, it is called platanus; whence comes our English name, the plantain tree; unless we should rather think it was so called from its resemblance to plantain, in its ribbed and fibrous leaves.

The fruit is esteemed delicious food; and, they say, was never known to create any disorder, though eaten ever so freely. Linschooten says, that it has a sweet taste like flour and butter mixed together, and, therefore, may supply the place of bread and milk-meals, with a simple kind of diet, by which the human body may be supported without any other food.

As to its virtues, Alpinus speaks thus: the fruit is of a soft, viscid, fat, and sweet substance, extremely grateful to those who use to eat it, and very nourishing, but burthensome to the stomach, difficult of digestion, and generates a thick and viscid juice, which causes obstructions of the viscera, and especially of the liver; it is, however, beneficial in a cough, and an asthma proceeding from heat. The Egyptians use the decoction with good success in a cough, excited by a distillation of hot humours, and for inflammations of the pleura, lungs, and kidneys, and for a dysury; it is, also, said to stimulate to venery, eaten raw or boiled.

The authors of the Hortus Malabaricus tell us, that the root bruised, and taken in milk, cures the vertigo; that the water of it, mixed with sugar, is drank with good success, for a burning heat of the kidneys, and for pains excited by the urine; and relieves those whose bodies have been infected with quick-silver. The pith of the tree, or the whitish medullary substance, which bears the fruit, being bruised, and taken inwardly with honey, is good for the affections of the eyes, as is also butter, in which slices of the fruit have been fried.

It grows in all parts of the East and West-Indies, and also in Africa. The ficus Indica of Linschooten I take to be only a variety, not a species, of the Musa; for it appears to be the same with that described by the authors of the Hortus Malabaricus, both from the synonyma, and the place where it grows; for the Malabarians, he says, call it palan, and those of Bengal, quelli, which are names much like the bala of the Hortus Malabaricus and Keli. Among the species, also, or varieties, I find one, both in the Hortus Malabaricus, and in Linschooten, called cadalin.

The leaves, which are an ell long, and three spans broad, or, according to Lerius, six feet long and two broad, equal in dimensions to those of the lapathum aquaticum, supply the Indians at Goa, with much useful furniture for their houses, and the Turks make use of them instead of paper; a shoot is often loaded with a hundred plantains, clustered together like grapes; and the branches, from whence they hang, often grow to such a bigness, that, when lopped off with the fruit, they can hardly be carried upon a pole between two porters. The plant bears fruit all the year, and supplies the Indians with provision every day. *Raii, Hist. Plant.*

MUS'CLE (*Dict.*)—The learned Dr. Morton, in his Inquiry into the cause of voluntary muscular motion, proposes and solves the following problem:

A Muscle being given in its natural state, in a living animal body, it is asked how, or by what mechanical means, that Muscle contracts, and is again relaxed, at the command of the will?

Every Muscle of an animal body is observed to be an instrument composed of fibres or lesser muscles, which are joined together, every-where, by one common membrane or substance, called, from its appearance, cellular. This substance, when it arrives at the surface of the muscle, becomes uniform, and makes one intire sheath for the whole Muscle, or bundle of fibres, and renders it distinct from others.

The constituent fibres in many Muscles are observed to be partly fleshy, and partly tendinous; the one changing, or being continued, into the other, for the conveniency of insertion and motion. But the observation is universal, that the fleshy fibres alone contract in muscular motion, and that this contraction is always wave-like, or in alternate curls, from one extremity to the other of a given fibre.

We constantly observe, in every Muscle, numerous arteries, veins, and nerves. These are generally distributed together, or in the same course, by means of the connecting cellular substance, into every point of the fleshy fibres. Injections, and the knife of the anatomist, have followed them a great way, and reason completes the distribution, since you can nowhere wound the flesh of a Muscle, but it shall bleed, and witness a sense of pain.

Therefore there is a circulation of blood, throughout the whole fleshy substance of a Muscle, and further the Muscle feels in every part.

In a living animal, if you tie the artery and vein, which principally belong to a given Muscle, that Muscle is disabled from acting, at the command of the will. Steno, a Danish anatomist of the last century, performed this experiment upon the descending aorta, and thereby took away the use of all the lower limbs *(vide Bgererum, p.* 296) at once, and restored them at pleasure. Late anatomists have it tried upon lesser vessels, with the same constant success. (*Vide Albini Histor. Muscul. p.* 19.)

In a living animal, if you tie the nerve that supplies a given Muscle, that Muscle is disabled from acting at the command of the will. This experiment is distinctly mentioned by Galen in his treatise on the Muscles, and is approved by the trials of later anatomists. (*Alb. p.* 19.)

From these two experiments it is clear, and generally agreed upon, that, in order to the performance of voluntary muscular motion, besides the particular structure, there is required an absolute freedom of the blood-vessels and the nerves.

Muscular motion is observed to be voluntary and involuntary. Of the first kind are all the Muscles of an animal body; of the latter, the only complete instance is the heart. The first seems more complex than the latter, since, besides the motion, it implies an additional act of the will. Effects, that are less compounded, ought naturally to precede effects that are more; these receiving light from the former, where both are homogeneous. For this reason, I have placed here two lemma's relating to automatic, or involuntary motion.

Lemma I. The heart, in its natural state, in a living animal body, being given, its contraction proceeds solely from, or is mechanically caused by, the warm blood, flowing into and filling its fleshy substance in every part.

If this be denied, let the body of an animal be taken quickly after death, and let a warm mild fluid of any kind be injected gently into the heart, so as to fill it. When this is done, we shall see the heart quicken and contract, as in the life of the animal. This experiment was first distinctly mentioned by Peyer, a Switzer, (see a small treatise of his, printed anno 1682, at Amsterdam, and intitled, Miraculum anatomicum in cordibus suscitatis) and is now known to every anatomist. But, if this effect is thus constantly produced soon after death, how much more, when the animal is alive? And if, by the introduction of any common fluid, with the bare addition of a warmth cognisable by our senses, how much more by the introduction of the living blood, an inimitable and wonderful fluid, and the immediate subject of the vital warmth?

If therefore it is granted, that we ought not to admit more causes of natural things than are real (and present for the occasion) and sufficient for explaining the appearances, and we must grant a rule, whose use is so obvious in the Newtonian, which

which is the philosophy of nature; we shall, I say, also grant, that the contraction of the heart, in its natural state, in a living animal body, proceeds solely from, or is mechanically caused by, the warm blood, flowing into, and filling, its fleshy substance in every part. Which was to be proved.

Corollary. The subsequent relaxation admits no difficulty: for, if the blood is the immediate mechanical cause of the contraction, when the blood is removed, the effect ceases.

Lemma II. A Muscle of voluntary motion, in its natural state, in a living animal body, being given, it will contract, by the introduction of a warm mild fluid, into its fleshy substance in every part.

If this be denied, let the body of an animal be taken quickly after death, and the crural artery be pierced, and a warm mild fluid be injected into it: we shall then see the Muscles, to which the artery belongs, quicken and contract, as if the living animal moved them. This experiment was known to Mr. Cowper, and is confirmed by Albinus (see *Hist. Musc.*) But, if this effect is constantly produced soon after death, how much more when the animal is alive?

Therefore a Muscle of voluntary motion, in its natural state, in a living animal body, will contract, by the introduction of a warm mild fluid, into its fleshy substance, in every part: which was to be proved.

But here it may be objected, with some appearance of reason, that there is a warm fluid, the living blood, in every part of the fleshy substance of all the Muscles, during the life of the animals; and yet it is a fact, that no Muscle of voluntary motion contracts, but at the command of the will, morbid cases excepted. This objection comes close to the original question, and, however reasonable it may seem, will quickly vanish before some common observations concerning the objects of sense in general, and their manner of operating upon the different organs, so far as it universally agrees.

We must first beg leave to make an easy postulatum, viz. that the nerves are the immediate instruments of sensation, though they are differently organised for the different senses.

It is a certain fact, that, in the several senses, the proper objects being supposed present, the sensation is intirely relative; or, in other words, that the presence of a powerful object always obliterates the present sensation of a weak object; and that the constant habitual presence of any one object, in the same given degree, produces no sensation at all.

Thus we observe, that the light of the sun extinguishes the light of the stars; a stronger taste covers a weaker; the sound of a drum drowns an ordinary human voice; itching is banished by smart and pain; a weak scent, by one that is strong; cold, or a less degree of warmth, by heat, or a greater degree of warmth; and, universally, our daily experience demonstrates to us, that every organ of sense, made familiar to a given degree of its object, affords no manner of sensation of the object in the given degree.

Thus it fares with the warm blood, which has constantly flowed through the whole minute substance of every Muscle of voluntary motion in an animal body, from the time of their formation, or unfolding in the womb. And it is highly probable, that the quickening of the child in a woman is no other than the completion of that state, in which the blood begins freely to flow through, and to affect the instruments of voluntary motion; and, till it becomes familiar to them, produces those frequent shudders, or general muscular contractions in the whole frame of the fœtus, which for a fortnight or more are the constant signs, that it has now obtained an animal life.

And here arises an apparent difference, though it will be found the greatest uniformity, between the Muscles of voluntary and those of involuntary motion; and namely the heart; which, being appointed to protrude the vital fluids during the life of an animal, has a short alternate remission of its contracting cause; and is thereby rendered capable of admitting a constant and necessary supply of labour and stimulus together, without any force, or contradiction, to the natural order of the whole.

It follows undeniably from what has been said, that if we can prove, that a given Muscle of voluntary motion does really feel an increase of the familiar warmth of its contained blood, or an equivalent, to rise and fall instantly at the command of the will, we shall then duly account for the subsequent motion. Or, more particularly, if we can prove, that the will has a direct power of heightening, increasing, and rendering more acute, the sense of any nerve, distributed to a given Muscle, the same familiar positive degree of warmth in the contained blood will, to this more acute sense, appear to be proportionably heightened and increased, and the Muscle (by Lemma II.) will instantly contract, and continue in that state during the action of the will; allowing for a small feebleness, that will gradually arise from the gradual exclusion of the contracting cause, and from the blunting of this more acute, and, as it were, new sensation; which yet, as we see, may be proportionably compensated, by the will, for a time, even to the destruction of the nerve, the blood-vessels, and indeed the whole organ, by a mortification, which has been known to succeed a long muscular contraction.

We know from daily experience, that the will hath a power over all the organs of sense, to heighten, or render acute, and again to relax them, their proper objects, in a reasonable degree, being supposed present. And the same experience teaches us, that this power is greater or less, according to the more or less frequent use and exercise that is made of it. For it is obvious to every one, that any sound man is able to feel, to taste, to smell, to hear, and to see, more accurately when he pleases. And it is equally obvious and certain, that any one of these five senses, being exercised, with an uncommon degree of attention and industry, either from choice, or from necessity, arrives at an uncommon degree of accuracy and perfection. Indeed it is intirely from use and exercise, that a child learns to distinguish at all between the several objects of a given sense, or, which are the same, between the several degrees, or modes, of its proper object.

All these particulars being demonstrably true of every sense, that we can directly examine, the inference is very fair to the single sense (Lem. II.) that we cannot directly examine; and, in truth, the induction, in this case, is but one step below a complete experimental demonstration.

It appears therefore, that the will hath a direct power of heightening, increasing, and rendering more acute, the sense or feeling of a given nerve, dispersed throughout the whole contracting substance of a given muscle, with all its gradations of accuracy and perfection, by repeated use and exercise.

Solution, or answer to the problem. — It follows, therefore, that, a muscle being given, in its natural state, in a living animal body, the blood, which is present in every part of its contracting substance, and which, in effect, to the sense of the given Muscle (which is occasionally rendered more acute) puts on an increased heat, and again lays it down at the command of the will, is the immediate mechanical cause, by which the Muscle does instantly contract, and is again relaxed, at the command of the will.

Therefore, a full solution is given to the question proposed: which was to be done.

Corollary 1. Hence it appears, that muscular voluntary motion is performed merely as a sensation extremely acute, and under the nicest management of the will: which explains its velocity in a great measure.

Corol. 2. Hence it appears, that the Galenic distinction of nerves, into nerves of sensation and nerves of motion, which greatly puzzles physiology, has no real foundation in an animal body.

A short scholium. The solution, that is given to the problem, may be assumed in a philosophical synthesis, and the various appearances may thence be announced, as well in natural as in morbid cases; which again may be subjected to a strict examination. Some trial has been made of this, and a surprising agreement found: but the detail must be omitted. In the course of this inquiry, every foreign disquisition is industriously avoided, and such at this time would be a further question, why blood, in a certain, or apparent, degree of heat, contracts a muscular fibre?

The business of natural philosophy is, to observe and to note down facts that are constant; and, singling out those that are similar, to collect their proper universal, by a fair and regular induction; and to acquiesce in this, till a new collection of constant and similar facts affords an higher universal, and leads nearer the first cause. *Philosophical Transactions*, Vol. 47.

MUSCLE, in natural history; see the article MYTULUS.

MUSCLES *of vegetables*. — The Muscles of animal bodies have been the subject of numerous dissertations; but those in vegetables have been less regarded. Mr. Tournefort, however, has plainly proved, that many of the vessels of plants become in the drying fibres capable of tension; that in many plants there are great numbers of these fibres which have all the same direction, and always act all together, and can only shorten or contract themselves in one particular direction; wherefore the parts composedof these fibres are very properly compared to the Muscles of animals. By the word Muscle we understand a part composed of these fibres so determinately arranged, that by their contraction they can only move the part in some certain and determinate manner; and, in this which seems the received sense of the word, there are many instances in which it may be used to parts of plants, with the strictest justice.

All the pods of the leguminous plants, as pease, &c. are composed each of two valves, more or less convex on the outside; these are placed evenly upon one another, and fastened together by means of a great number of very fine vessels; they are fastened much more firmly together at the back, than at the fore-rim; and the large vessels which carry nourishment both to the valves and seeds, are lodged there, and send many ramifications both to one and the other of the valves of the pod.

Each valve is formed of two ranges of fibres; the exterior arrangement is formed into a sort of net-work, and the threads which compose it issue from the back of the pod, and are propagated longitudinally, and somewhat obliquely through the surface of the valves, and finally terminate at the edge or fore rim of the pod, after they have entered into the fleshy part, with

with the net-like plexus of vessels, of which they make frequent anastomoses.

The anterior plan or arrangement of fibres crosses the exterior, in the same manner as the interior intercostal Muscles in the human body cross the exterior; and these form the inner membrane of the pod: these fibres arise, like the others, from the back of the pod, and run obliquely to the edge. A necessary consequence of this structure is, that the arrangement of exterior fibres must become dry before the others, as must also the fleshy substance in which they lie; and the consequence of this is, that they must contract and draw the edge of the valve to which they belong at once upward and outward, and endeavour to separate it from the edge of the other valve, drawing with it the anterior arrangement of fibres; this therefore pulls open the pod, and the air which is very hot at the season when the seeds of these plants ripen, insinuating itself into the interstices of the internal arrangement of fibres which are exposed to it by the opening of the pod, soon acts upon them, and they begin to contract in their turn. These fibres were once the vessels which conveyed the nutritive juices to the pods and seeds; but when that use is no longer necessary for them, and when no more juices ascend, after the seeds have arrived at their destined size, they then shrink up, and no more perform the office of vessels, but become mere fibres. As these do not all dry up, and suffer this change together, but necessarily it happens, first to those which are situated at the greatest distance from the pedicle, and, consequently, those are the first of the anterior fibres which act by shortening themselves; this, therefore, begins at the extremity of the pod, and is continued up to the pedicle; and the effect is that, as these interior fibres are stronger and more numerous than the exterior, which are at this time as far shortened as they are capable of, they now draw backwards and inwards the lips of the edge of the pod towards the back. When the warm air acts upon these fibres to dry and contract them, it draws nearly equally at both their ends; and, therefore, if the two arrangements of fibres were regularly transverse, each valve of the pod must be drawn by this action into a sort of tube, or pipe; but as they are placed in an oblique direction, and parallel to one another, the natural effect of their contraction must be the drawing the valve into a spiral form, which we see is exactly the case. The lines which form the rim of each valve can make no resistance to this contraction, because they are so dried up by the warm air, and want of juices, that they may be crumbled to powder between the fingers, and easily break in any part with the smallest force. This class of plants gives numerous instances of this sort of Muscles in vegetables, and they are more obvious than most others, being not only common in the hedges, but cultivated in gardens for the uses of the kitchen, &c. The ingenious author of the system gives many other instances in other plants. *Mem. Acad. Par.* 1693.

MU'SHROOM (*Dict.*)— Mr. Miller says, that the true eatable Mushroom is distinguished from the poisonous and unpleasant kinds by these marks. When young, it appears of a roundish form like a button, the stalk as well as the button being white, and the fleshy part very white when broken, the gills within being livid. As they grow larger, they expand their head by degrees into a flat form, and the gills underneath at first are of a pale flesh colour, but, as they stand long, become blackish.

In order to propagate Mushrooms, the meadows and pastures should be searched for them in August and September; and, wherever they are found, the ground should be opened all about the roots, where there will be found abundance of small white knobs. These are to be taken up with lumps of earth about them. Then some new horse-dung is to be procured, and, the litter being shaken out, the dung must be laid together on a heap to ferment for eight days. A trench must then be dug, and the dung laid in it a foot thick, and covered over six or eight inches thick with light rich earth; and into this, on each side, should be put in the knobs of Mushroom spawn, as it is called, at six inches distance. After this, another layer of dung is to be made upon this earth, to six or eight inches thickness, or more, but observing to draw in the sides, so as not to cover the knobs of Mushrooms above half an inch; then another layer of earth is to be laid on this, and some more knobs of the Mushroom spawn placed on this at the sides, as in the former; then put on a third layer of dung, drawing it in still narrower, that it may not cover the second plantation; and cover this with another layer of earth, drawing this up into a ridge at top, and planting more of the Mushroom spawn in this, but still laying it in sideways as before. When all is thus finished, the whole bed is to be covered half a foot thick with dry litter, to prevent the earth from drying too fast. When the bed has been made a fortnight, it should be carefully looked over, drawing away the litter with the hands, to see whether any young Mushrooms appear; and they must be gathered as they grow large; for, if suffered to remain, they will rot upon the bed, and destroy all the young spawn that is about them. And, when they begin to produce, the bed must be searched every other day, all the year round, and every day in August and September, which is the time of their principal increase, to gather such as are fit for use. The manner of gathering them is, to pull them gently out of the ground, so that no part of their stalk may be left behind; but, if any part of the spawn is pulled up with the stalk, that must be carefully returned into the bed. As the cold or wet weather comes on, the covering of dry litter over the whole bed must be increased. A bed, thus managed, will remain good many months, and produce vast abundance of Mushrooms; and the spawn may be at times taken out from it to supply other new beds. At whatever time of the year this is taken up, it should be carefully laid up in a dry place till the month of July following, which is the proper time for planting it in new beds. *Miller's Gard. Dict.*

MUSQUETEE'RS, *mousquetaires*, in France, are troopers who fight sometimes on foot, sometimes on horse-back; they are gentlemen of good families, and are divided into two troops, the one called the grey Musqueteers, because of the colour of their horses; the other the black Musqueteers, for the same reason.

MU'STARD, *sinapi*, in botany. See SINAPI.

The common Mustard is cultivated in many places, both in gardens and fields, for its seeds. It is propagated by sowing the seeds in spring upon an open place, which has been well dug or plowed. When the young plants are come up, they must be cleared of weeds, and hoed up to about eight or ten inches asunder. They will then grow strong, and, when the seeds ripen, the whole plant is cut down, and the seeds thrashed out. But, besides this, there is another kind of Mustard, commonly known by the name of the white or garden Mustard, which is sown for a sallad herb in spring: the seeds of this are to be sown very thick in drills on a warm border, or a moderate hot-bed; they will be fit to cut for sallading in three weeks after the sowing. *Miller's Gard. Dict.*

MUTA'TIONES, among the Romans, postages, or places where the public couriers were supplied with fresh horses.

MUTEFE'RRIRA, a body of horse kept up in Egypt, in the service of the grand Signior; these, with the chaouses, were originally the guards of the Sultan of Egypt. This is a body of the greatest dignity, as is expressed by the word, which signifies a chosen people. *Pocock's Egypt.*

MYIA'GRUS *Deus*, in the heathen mythology, a name given sometimes to Jupiter, and sometimes to Hercules, on occasion of their being sacrificed to, for the driving away the vast numbers of flies which infested the sacrifices on certain public occasions. The word is generally spelt Myagrus; but this must be an error, as this word does not express the fly-destroyer, but the mouse-destroyer; and we have it sufficiently testified by the ancients, that flies were the only creatures against whom this deity was invoked.

MY'STRUM, among the ancients, a liquid measure, which was the fourth part of the cyathus.

MY'RTUS, *the myrtle*, in botany, the name of a genus of trees, the characters of which are these: the flower is of the rosaceous kind, and is composed of several petals, arranged in a circular form. The cup finally becomes a fruit or berry of the shape of an olive, coronated at the end, divided into three cells, and containing kidney-shaped seeds.

There are several species of this plant preserved in our gardens; they are all easily propagated from cuttings. The best season for this is July, and the straightest and youngest vigorous shoots are to be chosen. These should be cut off about eight inches long, and the leaves of the lower part stripped off to about two inches high, and that part of the stalk twisted which is to be placed in the ground; they are to be planted in pots of light rich earth, at about two inches distance from each other, observing to close the earth very well about them, and give them a gentle watering. They are then to be removed into a moderate hot-bed, and shaded and watered once in two or three days, till they have taken root. In about a month's time they will be rooted, and will begin to shoot, and must then be inured, by degrees, to the air; and in August they should be removed into the open air, but placed in a warm situation, and sheltered from the winds; they should stand here till October, and then be removed into a green-house, where they should be placed so as to have as much air as possible. In the March following, they should be removed into separate pots of rich earth, and in May set out to the open air in a warm and well defended place. They will require in the summer frequent waterings, and the dead leaves should be carefully picked off. As they advance in growth, they are to be shifted at times into pots of a larger size; and this should be done either in April or in August; and, towards the end of October, they should always be removed into the green-house. *Miller's Gard. Dict.*

MY'TULUS, *the muscle*, in natural history, the name of a genus of shell-fish, the characters of which are these: it is a bivalve shell, of an oblong form, ending in a point, and having its two extremities equal. It is sometimes smooth, sometimes rough. In some species flat; in others elate, and in some has the beak elate. The tellina and pinna marina, of each of which there are several species, are properly of this genus.

Muscles are well known to have a power of fastening themselves very firmly either to stones, or to one another's shells, in a very strong and firm manner; but the method of doing this was not well understood, till the observations of the accurate Mr. Reaumur explained it.

Every one who opens and examines a common muscle will find,

find, that in the middle of the fish there is placed a little blackish or brownish body resembling a tongue; this in a large muscle is near half an inch long, and a little more than a sixth of an inch in breadth, and is narrower at the origin than at the extremity; from the root of this tongue, or that part of it which is fastened to the body of the fish, there are produced a great number of threads, which, when fixed to any solid substance, hold the muscle firmly in its place: these threads are usually from an inch to two inches in length, and in thickness, from that of a hair to that of a hog's bristle. They issue out of the shell in that part where it naturally opens, and fix themselves to any thing that lies in their way, to stones, to fragments of shells, or, which is the most common case, to the shells of other muscles; whence it happens that there are usually such large parcels of muscles found together. These threads are expanded on every side, and are usually very numerous; an hundred and fifty have been found issuing from one shell; they serve the office of so many cables, and each pulling in its proper direction, they keep the muscle fixed against any force that can be offered from whatever part it comes. The filaments are well known to all who eat muscles, who ever carefully separate them under the name of the beard; and Mr. Reaumur has found, that while the animal is living in the sea, if they are all torn away by any accident, the creature has a power of substituting others in their room: he found that, if a quantity of muscles were detached from one another and put into a vessel of any kind, and in that plunged into the sea, they in a little time there fastened themselves both to the sides of the vessel and to one another's shells; the extremity of each thread seemed in this case to serve in the manner of a hand to seize upon any thing it would fix to, and the other part which was slenderer and smaller to do the office of an arm in conducting it.

To know the manner of the muscle's performing this operation, this diligent observer put some muscles into a vessel in his chamber, and covered them with sea water; he here saw that they soon began to open their shells; and each put forth that little body before described by its resemblance to a tongue, and at the root of which these threads grow; they extended and shortened this part several times, and thrust it out every way, often giving it not less than two inches in length, and trying before, behind, and on every side with it, what were the proper places to fix their threads at: at the end of these trials they let it remain fixed for some time on the spot which they chose for that purpose, and then, drawing it back into the shell with great quickness, it was easy to see that they were then fastened by one of these threads to the spot where it had before touched, and remained fixed for a few minutes; and, in repeating this workmanship, the threads are increased in number one at every time, and, being fixed at different places, they sustain the fish at rest against any common force.

The several threads were found to be very different from one another, the new formed ones being ever whiter, more glossy, and more transparent than the others; and it appeared, on a close examination, that it was not, as might have been most naturally supposed, the office of the tongue to convey the old threads one by one to the new places where they were now to be fixed, but that these in reality were now become useless; and that every thread we see now formed, is a new one made at this time; and, in fine, that nature has given to some sea fishes, as well as to many land insects, a power of spinning these threads for their necessary uses. And that muscles and the like fish are, under water, what caterpillars and spiders are at land. To be well assured of this, however, Mr. Reaumur cut off all the beard or old threads of a muscle as close as he could, without injuring the part, and the proof of the opinion of their spinning new ones at pleasure was now brought to this easy trial, whether these muscles so deprived of their old ones could fix themselves as soon as others which were possessed of theirs, and could throw out their threads to as considerable distances. The experiment proved the truth of the conjecture, for those whose beards or old threads were cut off, fixed themselves as soon as those in which they were left, and spread their threads to as great distance every way.

When the mechanism of this manufacture was thus far understood, it became a natural desire to enquire into the nature of the part by which it was performed: this has hitherto been mentioned under the name of the tongue, from its shape; but it is truly the arm of the fish, and, whenever it happens to be loosened from its company, or fixed in a wrong place, it serves the animal to drag its whole body, shell, and all along, and perform its several motions. It fixes itself to some solid body, and then, strongly contracting its length, the whole fish must necessarily follow it, and be pulled towards the place where it is fixed. This is an use, however, that this part is so rarely put to, that it is not properly to be esteemed a leg or an arm, for this; but, according to its more frequent employment, may much better be denominated the organ by which the threads are spun.

Though this body is flat in the manner of a tongue, for the greater part of its length, it is however rounded or cylindric about the base or insertion, and it is much smaller there than in any other part; there are several muscular ligaments fastened to it about the root or base, which hold it firmly against the middle of the back of the shell; of those ligaments there are four, which are particularly observable, and which serve to move the body in any direction. There runs all along this body a slit or crack, which pierces very deeply into its substance, and divides it as it were into two longitudinal sections; this is properly a canal, and along this is thrown the liquor which serves to form the threads; and it is in this canal or slit that these threads are moulded into their form. Externally, this appears only a small crack or slit, because the two fleshy sections of the parts almost meet and cover it; but it is rounded and deep within, and is surrounded with circular fibres. This canal is carried regularly on from the tip of the tongue, as it is called, to its base, where it becomes cylindric; the cylinder in this part being no other than a close tube or pipe, in which this open canal terminates. The cylindric tube contains a round oblong body, of the nature of the threads, except that it is much longer; and from the extremity of this all the threads are produced, this serving as a great cable to which all the other little cordages, dispersed towards different parts, are fixed. The tube or pipe in which this large thread is lodged, seems the reservoir of the liquor of which the other threads are formed; all its internal surface being furnished with glands for its secretion. *Mem. Acad. Par.* 1711.

N.

NA'BLUM, in Hebrew, nebel, an inftrument of mufic among the Hebrews. The feventy and the vulgate tranflate it fometimes by Nablum, and at other times by pfalterion, or lyra, or even cithara.

The Nablum was a ftringed inftrument, very near of the form of a Δ, which was played upon by both hands, and with a kind of bow. See Calmet's Differtation concerning the inftruments of mufic of the ancient Hebrews, prefixed to his fecond volume of his Commentary upon the Pfalms. *Calmet's Dict. Bibl.*

NAILS, in building (*Dict.*) — The feveral kinds of Nails are very numerous.— As back and bottom Nails, made with flat fhanks to hold faft, and not open the wood.— Clamp Nails, thofe proper to faften the clamps in buildings, &c. Clafp Nails, whofe heads, clafping and fticking into the wood, render the work fmooth, fo as to admit a plane over it: they are of two kinds, viz. long, proper for fine buildings of fir, &c. and ftrong, fit for oak, and other hard wood. — Clench Nails, thofe ufed by boat, barge, &c. builders; proper for boarded buildings, that are to be taken down, becaufe they will drive without fplitting, and draw without breaking.—Clout Nails, thofe ordinarily ufed for nailing on of clouts to axle-trees. — Deck Nails, thofe proper for faftening of decks in fhips, doubling of fhipping, and floors laid with planks.— Dog Nails, proper for faftening of hinges to doors, &c.—Flat points, are of two kinds, viz. longs, much ufed in fhipping, and proper where there is occafion to draw and hold faft, yet no neceffity of clenching. —Jobent Nails, thofe commonly ufed to nail thin plates of iron to wood. — Lead Nails, ufed to nail lead, leather, and canvas to hard wood. — Port Nails, commonly ufed to nail hinges to the ports of fhips.—Pound Nails, are four-fquare in the fhank; much ufed in Norfolk, Suffolk, and Effex, though fcarce elfewhere, except for paling. — Ribbing Nails, ufed to faften the ribbing, to keep the ribs of fhips in their place in building. — Rofe Nails, are drawn four-fquare in the fhank, and commonly in a round tool.—Rother Nails, chiefly ufed to faften rother-irons to fhips. — Round-head Nails, proper to faften on hinges, or other ufes, where a neat head is required. —Scupper Nails, much ufed to faften leather and canvas to wood.—Sharp Nails, much ufed, efpecially in the Weft-Indies, made with fharp points, and flat fhanks. — Sheathing Nails, ufed to faften fheathing-boards to fhips: the rule for their length, is to have them full three times as long as the board is thick. — Square Nails, of the fame fhape as fharp Nails; chiefly ufed for hard woods. —To which may be added tacks; the fmalleft, ferving to faften paper to wood; middling, for wool-cards and oars; larger, for upholfterers and pumps.

In lathing, 500 Nails are ordinarily allowed to a bundle of five-feet laths.—In flooring, 200, i. e. 240, are allowed for a fquare of flooring.

Nails are faid to be toughened, when too brittle, by heating them in a fire-fhovel, and putting fome tallow or greafe among them.

NA'RDUS, an Egyptian mufical inftrument, made like two plates of brafs, and of all fizes, from two inches to a foot in diameter; they hold them by ftrings faftened to their middles, and ftrike them together fo as to beat time. They are ufed in the Coptic churches, and the Mahometan proceffions. *Pocock's Egypt.*

NA'MUR-*marble*, a name given by our artificers to a fpecies of black marble, which is very hard, and capable of a good polifh, but has no variegations of any other colour. It is common in Italy, France, and Germany, and is the fpecies called the Lucullean marble by the Romans. *Hill's Hift. of Foffils.*

NA'PLES-*yellow*, the common name in the colour fhops of London, and among our painters, for the ocre called giallalino. See GIALLALINO.

NA'PUS, in natural hiftory, a name given to a fpecies of voluta, approaching to the nature of the famous admiral fhell, and more commonly known by the name of the falfe admiral, or baftard admiral.

NA'RES, *the noftrils.* — Among the various diforders incident to the noftrils, none are of greater importance than hæmorrhages, which arife from a copious conveyance of blood to the head; in confequence of which, the fmall arteries in the tunica pituitaria are preternaturally filled, and their extremities, being too much diftended, are at laft opened, and difcharge their contained blood.

Such is the fabric of the noftrils, that they are eafily fubject to eruptions of blood; for, in their internal parts, the blood veffels, divided, into highly minute parcels, are copioufly diftributed through that coat which covers the vomer, the offa fpongiofa, and the ethmoidal bones, and are, at the fame time, externally covered with a very flender membrane. Hence, when the blood is copioufly conveyed to the noftrils, it is with difficulty returned through their fmall veins, but eafily ftops in the minute arteries, diftends their extremities, burfts them, and produces an hæmorrhage. It, alfo, fometimes happens, that this blood elevates the extremities of thefe minute arteries into fmall aneurifms, which afterwards prove the occafion of a copious dropping of blood.

That, in hæmorrhages of the nofe, there is a copious and violent afflux of the blood and humours to the head and noftrils, is fufficiently obvious from the violent motion of the heart and arteries, the ftrong pulfe, efpecially in the neck and temples, the fenfe of the weight in the head, the rednefs of the face, the fwelling of the face and whole head, a drynefs and heat of the internal noftrils.

The principal caufe of this congeftion is the unequal progrefs of the blood, efpecially through the ducts of the internal parts, whether conveying arteries, or returning veins: by which means it happens, that the blood is too fcantily conveyed to fome parts, and too copioufly to others, where it breaks the veffels, and difcharges itfelf.

Whatever, therefore, contributes to produce fuch an unequal motion of the blood, in a proportionable degree, excites, hæmorrhages. Now, all hæmorrhages, and more efpecially that from the noftrils, are generally accompanied or preceded by a ftricture of the fkin and external parts, a detumefcence of the veffels, an horripilation, a refrigeration, coftivenefs, a retention of the flatulences, rumblings in the abdomen, laffitudes of the limbs, and pains of the belly. Hence, it is obvious, that the caufe of this unequal circulation of the blood is a certain ftricture of the fibres and moft minute veffels, efpecially in the extremities; for when, by means of this fpafmodic ftricture, the veffels, efpecially fuch as return the blood, lymph, or any other humours, as, alfo, the excretory ducts of the fkin, through which, according to the laws of nature, the ferous part of the blood ought to be eliminated, are compreffed, the blood regurgitates to the large internal veffels, by which means a greater and quicker contraction of the heart and arteries is produced, and the blood itfelf more powerfully conveyed to the weak parts, efpecially where its congeftion and difpofition lay a foundation for hæmorrhages, and other diforders.

The cure. — When a violent hæmorrhage threatens danger, and too much impairs the ftrength, the affiftance of the phyfician becomes neceffary. The principal intentions of cure are, after difcovering the genuine caufes, to remove them by proper meafures.

When, therefore, a redundance of the blood and humours, together with their expanfive force and turgefcence, hinders their free and equal paffage through the minute veffels, and produces enormous hæmorrhages, which principally happens to young perfons in the fpring, after violent exercife, or the ufe of fuch fpirituous things as throw the blood into preternatural commotions, befides venefection, which diverts the courfe of the blood from the head, preparations of nitre are, above all other things, efficacious for checking the orgafm of the humours, and relaxing the fpafmodic ftricture of the parts. Thus Paracelfus and Hildanus, in all hæmorrhages, ufed purified nitre with great fuccefs: and Riverius, in his Praxis and Obfervations, greatly extols this medicine for ftopping all hæmorrhages. Of fimilar, though fomewhat inferior efficacy, are acids, whether of the mild kind, obtained from the vegetable kingdom, fuch as the juices of lemons and barberries, the water and juice of wood forrel; or of the more ftrong and powerful kind, obtained from the mineral kingdom, fuch as the phlegm, or fpirit of vitriol diluted, or the tincture of rofes, and flowers of the daify, prepared with water of wood forrel and fpirit of vitriol, and drank with fpring water; the efficacy of which is, alfo, very great in checking the inteftine and elaftic force of the blood.

But, becaufe, in thefe dangerous hæmorrhages, there is generally a certain fpafmodic ftricture of the nervous parts, which is foon fucceeded by an unequal motion of the fluids, befides the preparation of nitre already recommended, we muft have recourfe to gentle anodynes, fuch as preparations of poppies, the water, for inftance, the extract, or the fyrup of wild pop-

pies,

pies, the fyrup of white poppies, and emulfions prepared of the four cold feeds, the feeds of white poppies, and the waters of the flowers of the Egyptian thorn, elder, the lime-tree, meadow-fweet, the common chamomile, and primrofes.

In fymptomatic hæmorrhages, and thofe accompanying exanthematous diforders, meafles, fmall-pox, fcorbutic purple fever, and petechiæ, it is not expedient to exhibit any other medicines, than fuch as, by moderating the intenfe heat, may gently promote perfpiration. For this purpofe,

Take, of the water of chamomile flowers, four ounces; diftilled vinegar, one ounce; of crabs eyes and diafcordium, each one drachm; of nitre, one fcruple; and, of the fyrup of wild poppies, a fufficient quantity; make into a mixture: of which, let the patient take two fpoonfuls every two hours, and keep himfelf moderately warm in bed; and, if the diforder is malignant, a powder, compofed of diaphoretic antimony, depurated nitre, and camphire, is to be exhibited.

Apolypus in the noftrils. — The internal parts of the nofe, as other parts of the body, are often fubject to flefhy excrefcences, called polypufes, though they feldom have more feet or roots than one. This diforder is, by fome, called farcoma; and, by others, hyperfarcoma. But thefe caruncles are of various fizes and confiftences; fometimes foft, and capable of elongation, when drawn; fometimes, though very feldom, hard, and, as it were, rigid; fometimes white, and fometimes of a pale red colour: at firft, they are, for the moft part, fmall; but, in procefs of time, they increafe, fome flower, fome fafter; fo that I have feen fome, in three or four days, hang out of the nofe: though they are generally free from pain, yet, fometimes, they are attended with pain and hardnefs, become livid, and incline to a cancer. Some are confined to the nofe, others hang down to the lips; fome fill, greatly expand, and enormoufly dilate the nofe; fome appear as one caruncle, with an equal furface; others like a clufter. Some, again, grow backwards, through the aperture, by which the breath defcends from the nofe to the fauces; and are vifible behind the uvula, and then occafion not only a great difficulty of fpeaking and fwallowing, but likewife of breathing, and almoft ftrangle the patient. Sometimes, they expand themfelves both through the nofe, and fauces, though both noftrils are feldom obftructed by them. The polypus, as we have already obferved, has generally but one root, and that flender; fometimes, indeed, it is thick, and furnifhed with large veins; however, as it appears now and then with many roots, the ancients feem to have derived the name from thence. This excrefcence often proceeds from the inferior or middle part of the nofe, and, fometimes, from the pofterior and upper part, and even from the finufes of the cranium and os ethmoides; but it is, in general, formed in and from the pituitary membrane, and, particularly, from an obftruction of one or more of its glands; which, being gradually increafed by noxious humours, fills the nofe, or hangs down below it; and, confequently, it feems nothing more, than a morbid expanfion and elongation of the glands, and that fpongy membrane. But, in my opinion, the farcoma nafi is of a very different nature; for a polypus is generally foft, and hangs like a fig, by a flender or thick root, as by a ftalk; whilft the farcoma is fometimes foft, fometimes hard, and fixed upon a large, firm, and immoveable bafis.

From the preceding account of the nature and difpofition of a polypus, we cannot be at a lofs for the diagnoftic and caufes of it. And, firft, a white, reddifh, foft polypus, without pain, is of a mild nature: on the contrary, that is dangerous, which is painful, hard, livid, or black, or difcharges a pus, or acrid and fœtid humours; for fuch tend to a cancer. The caufes are often latent and internal, though it is fometimes produced by external violence. By a latent caufe, we mean an infpiffation of corrupt and glutinous blood in the fmall veffels and glands of the pituitary membrane; for that foft and fpongy membrane may be eafily diftended by a congeftion of noxious humours. The external caufes may be violent falls or blows, too frequent an introduction of the finger into the nofe, an irritation of the pituitary membrane, and too ftrong fternutatory powders. Laftly, the manifeft internal caufes are frequent catarrhs, a defluxion, ulcers of the nofe, or too profufe hæmorrhages. A farcoma proceeds from much the fame caufes; and both are fometimes attended with a fpina ventofa, and caries of the bones of the nofe: inftances of which have fometimes occurred to me.

The cure is eafier, and the danger is lefs, when the polypus is of a favourable kind; as when it is not feated very far in the nofe, when it has a flender root, and hangs loofely, or when it is capable of elongation, and laftly, when the patient is of a good habit: on the contrary, when it is inacceffible, has a thick root, and is incapable of elongation, the removal is more difficult, efpecially if the patient is afflicted with a fcorbutic or venereal diforder at the fame time. The danger of the cure is likewife increafed, by the difficulty of fuppreffing the profufe hæmorrhage, which attends the extirpation or evulfion of a polypus, efpecially if it is fixed on a deep and large bafis. If it tends to a cancer, that is, if it becomes hard, livid, and painful, which is very common, it is fafeft to palliate the diforder by lenitives; for it is dangerous to irritate this, as other cancers. In the like manner, when the polypus is inacceffible, or arifes from a fpina ventofa, as I have feen a large one, it is hardly poffible, after a removal, to prevent its fprouting again, unlefs the fpina ventofa be firft cured. Further, if it extends to the fauces, fpeech, deglutition, and even refpiration, are fometimes hindered, as Celfus obferves, and the cure is extremely difficult. Laftly, when it fills both noftrils, the cure is very difficult, becaufe, generally, it proceeds from fome worfe diforder. Thefe obfervations are equally true, with regard to a farcoma, efpecially if the bones of the nofe are afflicted with a fpina ventofa.

The cure of a polypus cannot be reafonably expected from any thing but a total removal, which may be accomplifhed by cauftic medicines, or proper inftruments; and this, either all at once, or at different times. The firft may be applied when the excrefcence is foft and fmall, or fhort and large, with this caution, that the cauftic may not corrode the found parts of the nofe. Among the mild corrofive medicines proper for this purpofe, the moft celebrated is powder of favin, burnt alum, red precipitate, white vitriol, and hermodactyl root, either alone or mixed with honey, or fome digeftive ointment, laid on the polypus with a tent; or, if it is feated externally, without a tent, by which, flight ones are fometimes removed. Poterius fays, the powder of heliotropium, or fcorpionwort, introduced into the nofe with cotton, twice a day, will remove a polypus very readily, and with little pain; but we are left in the dark as to the particular fpecies of heliotropium, or fcorpionwort, proper for this ufe. Rulandus recommends a mercurial water, with which he affirms he has cured a polypus, by wetting it every morning and evening. To this clafs alfo belong unguentum Ægyptiacum, the unguentum fufcum of Wurtzen, the oil of tartar per deliquium, the effence of favin, and particularly an effence prepared of fublimate mercury and fpirit of wine, with which Wedelius informs us he cured a cetain polypus. According to Nuck, in Operat. Chirurg. Cap. de Polypo, great fervice is done in polypufes by lime-water, efpecially if, after mixing a grain or two of fublimate mercury with it, it is made into a phagedenic water. The fame end is, alfo, anfwered by precipitate mercury, upon which fome fpirit of wine has been deflagrated; by water faturated with fal ammoniac; and, if we may believe Mufitanus, by the acid fpirit of fal ammoniac. If thefe prove ineffectual, then ftronger remedies muft be applied, fuch as the lapis infernalis, fublimate mercury, the arcanum corallinum, and others of a like nature; but thefe fhould be mixed with honey, or bafilicon, and laid on with great care, that they may not corrode the found parts; and, if the polypus lies concealed in the nofe, a fmall portion of the medicine fhould be introduced by a quill, or fome other tube. Of equal virtue, in removing a mild polypus, are the fpirit or oil of vitriol, aqua fortis, and butter of antimony, when applied with a feather or pledget: whatever is ordered muft, at every dreffing, be removed by fciffars, or a pair of forceps. Thibaut followed this method: he laid two plaifters between the polypus and found part, for the prefervation of the latter; when he carefully applied to the former butter of antimony, with a tent or pledget; and next, to prevent too deep a penetration, he wafhed it off with warm water. By this method Garengeot affirms that he performed the operation in a moment; but this author does not tell us, whether he applied the cauftic more than once, though, I am perfuaded, it muft be frequently repeated; for a fingle application will hardly produce the defired effect.

But, in general, inftruments are preferable to cauftics; and this operation may be performed by various methods. Before the operation the patient fhould be prepared, and then feated oppofite to the light, an affiftant reclining his head backwards, and fecuring it with his hands. When this is done, the furgeon may chufe either of the following methods, which feems to him beft fuited to the circumftances of the cafe. We fhall begin firft with the method defcribed by Celfus: 'The polypus, fays he, fhould be feparated from the bone by a fharp inftrument, in the fhape of a fpatula, taking care not to wound the cartilage beneath it, which would be difficult to cure. After the feparation it muft be extracted with a fteel hook; then, to fupprefs the hæmorrhage, the cavities of the nofe fhould be filled with a pledget, or fome folded lint moiftened with a proper medicine: after the fuppreffion of the hæmorrhage, the ulcer muft be deterged with lint. When it is cleanfed, the cicatrix muft be formed by injecting proper medicines, till the cure is completed.' The method propofed by Ægineta is not very different from this. He orders the patient to be placed againft the light, the furgeon to open and dilate his nofe with his left hand, whilft, with his right, he extirpates the polypus circularly, with a fharp fpatula, made for that purpofe, in the fhape of a myrtle leaf; applying the edge of the inftrument to that part where it adheres to the nofe, then turning the inftrument, to extract it with the handle. To induce a cicatrix, he ufes leaden pipes. We difcover the whole polypus to be removed, firft by the fight, then by the voice, and freedom of refpiration through the nofe. Albucafis advifes to extract the polypus out of the nofe with a fteel hook or forceps, and then remove as much as can be reached by incifion; and this to be repeated till the whole is taken off. If the excrefcence cannot be totally removed, Paulus and Albucafis order a pretty thick piece of linen, like a cord, full of knots, at a finger's breadth, or lefs, from each other,

ther, to be tied to the remains, and tranfmitted from the nofe to the palate; then to be drawn out of the mouth, which may be done with a forceps. The two ends of this cord, one hanging from the nofe, the other from the mouth, fhould be drawn backwards and forwards, till the remains of the polypus are deftroyed: for which purpofe the cord fhould be dipped in unguentum Ægyptiacum. Fabricius ab Aquapendente rejects thefe methods, and endeavours to eftablifh one of his own, which is performed by a fharp forceps. Thefe he gently introduces into the nofe, to the root of the polypus; and, with them, both extirpates and extracts the whole, or as much as he can reach. This he juftly prefers to all others, and fays, if the whole cannot be removed at once, it may be repeated, till nothing remains. If the wound bleeds plentifully, which is not very common, he orders the hæmorrhage to be fuppreffed with red wine alone, or mixed with alum. Sennertus and Glandorp followed this practice, and I myfelf have known it to fucceed often.

NASTU'RTIUM, *garden-creffes*, in botany, a genus of plants, whofe characters are:

It refembles, in all refpects, the thlafpi, or mithridate muftard, with a lefs foliaceous margin, and multifid leaves, to diftinguifh it.

This crefs has a fmall white ftringy root, from which fpring many finely laciniated winged leaves, three or four inches long, of a pleafant, hot, biting tafte; the ftalks about a foot high, fmooth, and round; the leaves which grow on them are lefs cut in, and have larger and broader laciniæ. The flowers are fmall, of four white leaves, fet together in tufts on the top of the ftalk, and are fucceeded by little round feed-veffels, flat on one fide, containing red round feed. It is fown every year in gardens, and flowers in May. The leaves and feed are ufed.

The leaves are much ufed in fpring as a fallad herb, their warming quality being ufeful to correct the coldnefs of others mixed with them; they are good for the fcurvy and dropfy, as alfo for the palfy and lethargy. A cataplafm of the leaves, with hog's lard, cures fcald heads. The feed, likewife, helps the fcurvy and dropfy, and fwelling of the fpleen, and opens obftructions in the female fex. *Miller's Bott. Off.*

Another fpecies of the Nafturtium is, water-creffes, which are frequently eaten in the fpring as a fallad. The whole plant is of a very acrid tafte, and is a powerful attenuant and refolvent. It is recommended as a kind of fpecific in the fcurvy, and is eaten in great quantities by many with that intent. It is good againft all obftructions of the vifcera, and, confequently, in jaundices, and other chronic difeafes. It is alfo a powerful diuretic and promoter of the menfes. People have pretended to preferve the virtues of this plant in waters, fyrups, and conferves; but the beft way of taking it is, either to eat it as a fallad, or to drink its expreffed juice fingly, or mixed with that of the other antifcorbutic plants, as brooklime, &c. which is often done.

NA'TRON or NATRUM (*Dict.*)— There have been various opinions about the natrum of the ancients, and fome have been of opinion, that our falt-petre or nitre was the fame fubftance; but this has always been difcountenanced by the more judicious. Dr. Hill, who had met with a falt from the fame part of the world whence the ancients had their natrum, and which anfwered to all the characters they have given of it, defines it to be a falt fometimes pure, and fometimes fouled with earth, fermenting with acids, and forming flat oblong cryftallifations, with four unequal fides, and two truncated ends. Thefe were the characters of that falt, and thefe perfectly agree with the accounts we have of nitre in the earlieft ages, though we have none fufficiently accurate, to take them all in. And, whatever may have been the opinion of fome, that the natrum or nitre of the Hebrews was very early loft, a careful examination of the ancients proves the contrary, and that this very falt was the nitre both of the Greeks and Romans, the nitrum and aphronitrum of Diofcorides, and the nitrum of Pliny. It is found in broad and flat maffes of various fizes, but ufually fmall, and, when broken, are found to be compofed of fafciculi or bundles of fmall fibres, of an oblong and flatted figure, and laid but loofely together.

It is naturally of a dufky white, but is fometimes found of a brown colour, and fometimes of a fine deep red. This is its pureft ftate; but, befides this, it is frequently found in form of powder mixed with dirt, and rifing in little hillocks on the furface of the ground. It is of an acrimonious pungent tafte, and is more like the alkaline falts produced by burning vegetables, than any of the native falts. It diffolves in a very fmall quantity of water, and ferments violently with aqua-fortis, or any other weaker acid menftruum.

It is found in great plenty in Iindy, a province in the inner part of Afia, and in many other parts of the Eaft, and might be had in any quantities. Perhaps it would be worth confidering as a branch of commerce, as it would fupply the place of pot-afhes in the making foap and glafs, as the fame author has tried.

The characters recorded of the nitre of the ancients are, 1. That it would ferment with vinegar; and, 2. That it had an abfterfive quality. Thefe we have from the fcriptures: and the reft were, that it was of an acid tafte; that is was found native in the eaftern parts of the world; that it ferved in the place of foap, and that, with fand, it would make glafs. All thefe properties this falt has; and it may be added, that no other native falt has them. *Hill's Hift. Foff.*

NA'TURAL, in mufic, is applied to a fong, the notes whereof move eafily and gracefully, giving the performer as little trouble as poffible; as when it is not carried too high, or funk too low, whereby the voice or inftrument is in no wife forced or ftrained. *Vid. Broff. Muf. Dict. in voc.*

NAVE *of a wheel*, is that fhort thick piece in the center of the wheel, which receives the end of the axle-tree, and in which the ends of the fpokes are fixed; it is bound at each end with hoops of iron, called the Nave bands; it has likewife, in each end of the hole, through which the end of the axle-tree goes, a ring of iron called the wifher, which faves the hole of the Nave from wearing too big.

NAVIGA'TION (*Dict.*)— The principal articles, in the act of navigation, paffed in the twelfth year of Charles II, are the following:

1. That no goods or commodities fhall be imported or exported to or from any of the Englifh colonies in Afia, Africa, or America, but on veffels built within the dominions of England, or really belonging to Englifhmen; and whofe mafters, and at leaft three-fourths of the crew are Englifh *, on pain of forfeiture of the goods and veffel.

* Under the name Englifh, here, are comprehended all the king's fubjects of England, Ireland, and the Plantations; as was explained in a fubfequent act, 13 and 14 Car. II. c. 11.

2. That no perfon born out of the fubjection of England, or not naturalifed, fhall exercife any commerce in thofe colonies for himfelf, or others.

3. That no merchandizes of the growth of Afia, or America, fhall be imported into any of the dominions of England on any other than Englifh veffels.

4. That no goods of foreign growth or manufacture that fhall be brought into England, Wales, Ireland, iflands of Jerfey or Guernfey, or town of Berwick on Tweed, in Englifh built fhipping, or other fhipping belonging to the forefaid places, and navigated by Englifh mariners as aforefaid, fhall be fhipped or brought from any other place or country, but only from thofe of the growth or manufacture thereof.

5. That all kinds of dried and falted fea-fifh, train-oils, blubber, and whale-fins, not caught by Englifh veffels, imported into England, fhall pay double duties.

6. That the commerce from port to port in England and Ireland fhall be carried on wholly by Englifh veffels, and Englifh merchants: the crew to be always three-fourths Englifh.

7. That none but Englifh veffels fhall reap the benefit of the diminutions made, or abatements to be henceforth made, in the cuftoms.

8. All veffels are prohibited importing into England and Ireland any of the commodities of Mufcovy, or even any mafts, or other timber, foreign falt, pitch, rofin, hemp, raifins, prunes, oil of olive, any kind of corn, or grain, fugars, afhes, and foap, wine, vinegar, or brandy, except veffels, whereof Englifh are owners or part-owners, and where the mafter and three-fourths of the mariners are Englifh.— And that no currants, or other commodities, the growth or manufacture of the Turkifh empire, fhall be imported, but in veffels of Englifh build, and navigated as aforefaid; except only fuch veffels as are of the building of the country or place whereof fuch commodities are the growth or manufacture, or of fuch part where fuch goods are ufually fhipped for tranfportation, and unlefs the mafter and three-fourths of the crew be natives of the country where they are laden.

9. All timber, mafts, boards, falt, pitch, tar, rofin, hemp, flax, raifins, figs, prunes, olive oils, corn, or grain of any kind, fugar, pot-afhes, brandies, and wines, and all goods of the growth and manufacture of Mufcovy, all currants and Turkifh goods imported into England, &c. in other than fuch fhipping, and fo navigated, fhall be deemed aliens goods, and pay accordingly.

10. That, to prevent frauds in buying and difguifing foreign veffels, the proprietors fhall take an oath, that they really belong to them, and that no alien has any part in them.

11. That Englifh veffels, and navigated by Englifh, may import, into the dominions of England, any merchandizes of the Levant, though not taken up in the places where they grow, or are manufactured: provided it be in fome part of the Mediterranean beyond the ftreights of Gibraltar. And the fame is underftood of commodities brought from the Eaft-Indies, provided they be taken up in fome port beyond the cape of Good Hope: and thofe from the Canaries, and other colonies of Spain; and the Azores, and other colonies of Portugal, which are allowed to be fhipped, the one in Spanifh ports, the other in Portuguefe.

12. Thefe penalties, prohibitions, and confifcations, not to extend to goods taken by way of reprifal from the enemies of England, nor to fifh caught by the Scots, or their corn, and falt, which may be imported into England by the Scotch built fhips.

13. Five fhillings per ton duty is impofed on every French veffel arriving in any port of England, fo long, and even three

months longer, as 50 ſols per ton lies on the Engliſh veſſels in France.

Laſtly, That ſugars, tobacco, and other commodities of the growth of the Engliſh colonies, ſhall not be imported into any other part of Europe, but the dominions of England. And that veſſels, going out of the ports of the ſame crown for the Engliſh colonies, ſhall give 1000 l. ſecurity, if under one hundred tons, and 2000 l. if above, before they depart, that they will import their cargo into ſome port in the ſaid dominions; and the like, before they quit thoſe colonies, that they will land their whole cargo in England.

NAU'TILUS, in natural hiſtory, the name of a genus of ſhell-fiſh, the characters of which are theſe: it expreſſes, in general, in every ſpecies, the figure of a boat or veſſel, made for ſwimming on the water; but, in the different ſpecies, it is of very different figures, roundiſh, or oblong, thin, or thick, furrowed, or ſmooth, and ſometimes is auriculated, ſometimes not. Bonani obſerves that this genus of ſhell-fiſh is very well named from the Greek ναυτίλος, which ſignifies both a fiſh, and a ſailor, for that the ſhells of all the a Nautili carry the appearance of a boat, or ſhip, with a very high poop.

Different authors, among the ancients and moderns, have called the Nautilus by the name of pompilus, nauplius, nauticus, ovum polypi, polypus teſtaceus, and the French call it le voilier. It is ſuppoſed, that men firſt learned the method of ſailing in veſſels, by what they ſaw practiſed by this creature.

NEC'TARINE, a fruit greatly eſteemed for its delicious flavour, and ſuppoſed to have its name from the nectar of the gods, in heathen ſtories.

It differs in nothing from the peach, but in having a ſmoother ſkin, and a firmer pulp. See PEACH.

We have ten kinds of Nectarines cultivated by the curious in gardening.

1. Fairchild's early Nectarine; this is a ſmall fruit of a red colour, and very well taſted, and ripens in July, the earlieſt of all this kind.

2. The Elruge Nectarine; this is a larger fruit of a purple colour, on that ſide which was towards the ſun, and of a greeniſh yellow on the other parts. This is a very well flavoured Nectarine, of a ſoft, melting juice, and parts from the ſtone: it ripens towards the end of July.

3. The Newington Nectarine; this is a fair large fruit, of a fine red toward the ſun, and of a yellowiſh green towards the wall. It has a very rich juice, but the pulp adheres to the ſtone: this ripens in Auguſt.

4. The ſcarlet Nectarine; this is of a fine glowing red towards the ſun, and of a pale red towards the wall; it ripens in the end of July.

5. The Brugnon, or Italian Nectarine; this is a fair, large fruit, of a deep red next the ſun, but of a ſoft yellow next the wall. The pulp is firm, and of a rich flavour, but cloſely adheres to the ſtone, and is red in that part: this ripens in the middle of Auguſt.

6. The Roman red Nectarine; this is a very fair large fruit, of a deep purple towards the ſun, and of a greeniſh yellow next the wall. The pulp is very firm and well taſted, but it is red about the ſtone, and adheres firmly to it: this is ripe in the middle of Auguſt.

7. The murry Nectarine; this is a middle-ſized fruit, of a dirty red next the ſun, and of a greeniſh yellow next the wall. The pulp is tolerably well flavoured, and ripens in the middle of Auguſt.

8. The golden Nectarine; this is a fair handſome fruit, of a ſoft red next the ſun, but of a gold yellow next the wall; and its pulp is very yellow, but of a faint red about the ſtone to which it adheres: it is a very well flavoured kind, and ripens at the end of September.

9. Temple's Nectarine; this is a very fine kind; it is of a ſoft red towards the ſun, and of a yellowiſh green next the wall. It parts from the ſtone, and is of a very rich flavour; the pulp is white in other parts, but yellowiſh about the ſtone: this ripens in the middle of September.

10. The Peterborough Nectarine, called by ſome the late green Nectarine; this is a middle-ſized fruit, of a pale green colour towards the ſun, and of a whitiſh green toward the wall; the pulp is firm, and well flavoured: it ripens towards the end of September.

The pruning, planting, and whole culture of this plant are the ſame with that of the peach. *Miller's Gard. Dict.*

NEE'DLE (*Dict.*)— Needles make a very conſiderable article in commerce; and the conſumption thereof is almoſt incredible.— The ſizes are from N°. 1, the largeſt; to N°. 25, the ſmalleſt.

There is ſcarce any commodity cheaper than Needles; which will appear ſomething extraordinary to the reader, after he has been ſhewn the great number of operations they undergo before they are brought to perfection.

Manufacture of NEEDLES.— German and Hungary ſteel is of moſt repute for Needles. The firſt thing is to paſs it through a coal fire, and under a hammer, to bring it out of its ſquare figure into a cylindrical one. This done, it is drawn through a large hole of a wire-drawing iron; returned into the fire, and drawn through a ſecond hole of the iron, ſmaller than the firſt: and thus, ſucceſſively, from hole to hole, till it have acquired the degree of fineneſs required for that ſpecies of Needles; obſerving every time it is to be drawn, that it be greaſed over with lard, to render it the more manageable. See WIRE-DRAWING.

The ſteel, thus reduced into a fine wire, is cut in pieces of the length of the Needles intended. Theſe pieces are flatted at one end on the anvil, in order to form the head and eye. They are then put in the fire, to ſoften them farther, and thence taken out, and pierced at each extreme of the flat part, on the anvil, by force of a punchion of well tempered ſteel, and laid on a leaden block, to bring out, with another punchion, the little piece of ſteel remaining in the eye.

The corners are then filed off the ſquare of the heads, and a little cavity filed on each ſide the flat of the head. This done, the point is formed with a file, and the whole filed over.

They are then laid to heat red-hot, on a long, flat, narrow iron, crooked at one end, in a charcoal-fire; and, when taken out thence, are thrown into a baſon of cold water to harden. — On this operation, a good deal depends; too much heat burns them; and too little leaves them ſoft; the medium is only to be learnt by experience.

When hardened, they are laid in an iron-ſhovel, on a fire more or leſs briſk, in proportion to the thickneſs of the Needles; taking care to move them from time to time. This ſerves to temper them, and take off their brittleneſs; care here, too, muſt be taken of the degree of heat.

They are then ſtraightened one after another with the hammer; the coldneſs of the water uſed in hardening them having twiſted the greateſt part of them.

The next proceſs is the poliſhing.— To do this, they take twelve or fifteen thouſand Needles, and range them in little heaps againſt each other on a piece of new buckram, ſprinkled with emery duſt. The Needles thus diſpoſed, emery duſt is thrown over them, which is again ſprinkled with oil of olives. At laſt, the whole is made up into a roll, well bound at both ends.

This roll is then laid on a poliſhing table, and over it a thick plank loaden with ſtones, which two men work backwards and forwards a day and a half, or two days ſucceſſively. By which means, the roll thus continually agitated by the weight and motion of the plank over it, the Needles within ſide, being rubbed againſt each other with oil and emery, are inſenſibly poliſhed.

In Germany, inſtead of hands, they poliſh with water-mills. After poliſhing, they are taken out, and the filth waſhed off them with hot water and ſoap: then wiped in hot bran a little moiſtened, placed, with the Needles, in a round box ſuſpended in the air by a cord, which is kept ſtirring till the bran and the Needles be dry.

The Needles, thus wiped in two or three different brans, are taken out and put in wooden veſſels to have the good ſeparated from thoſe whoſe points or eyes have been broken either in poliſhing or wiping; the points are then all turned the ſame way, and ſmoothed with an emery-ſtone turned with a wheel.

This operation finiſhes them; and there remains nothing but to make them into packets of two hundred and fifty each.

NEEDLE-*makers*.— Their buſineſs is a branch of the ſmithery, and light eaſy work, therefore fit for ſlight-made lads; but they ought to have good eyes, the finer ſorts requiring much nicety.

This trade is more extenſive than moſt people apprehend, their goods being not only conſumed in families, but uſeful to a great many trades: ſome of them alſo make fiſh-hooks, &c. and keep ſhops; others travel the country, to ſupply dealers there, though theſe are chiefly furniſhed by the haberdaſhers with finer ſorts, and by the ironmongers with the very large ſizes, as pack-needles, &c. by both which ſhop-keepers they are principally taken off the maker's hands, who moſtly work privately, and will take an apprentice with five pounds, whoſe hours are from ſix to eight; in which time a journey-man can earn two ſhillings, or two ſhillings and ſix-pence; and fifty pounds will ſet him up, if he makes for the ſhops only; but, if he intends to deal for himſelf, or keep ſhop, not leſs than 200 l. will be ſufficient.

They were incorporated into a company in the year 1656, in the time of Oliver Cromwel: livery-fine 3 l. 6 s. 8 d. But have no hall, therefore meet in Guild-hall to tranſact their buſineſs.

NE'GATIVE *power*, in algebra, is uſed for thoſe powers of a quantity which have a Negative ſign. Thus a^{-m} is called a Negative power. Negative powers ariſe from the diviſion of any power of a quantity by a greater power of the ſame quantity. Thus, $\frac{a^4}{a^6} = a^{4-6} = a^{-2}$; and in general, $\frac{a^m}{a^{m+n}} = a^{-n} = \frac{1}{a^n}$ for $\frac{a^m}{a^{m+n}} = \frac{1}{a^n}$. See POWER.

NE'GRO (*Dict.*)— We have a diſſertation on the colour of Negroes by Dr. John Mitchell, of Virginia, in the Philoſophical Tranſ-

Tranſactions, N°. 476, where he advances theſe propoſitions, and enters into a learned detail to ſupport them.

1. The colour of white people proceeds from the colour which the epidermis tranſmits; that is, from the colour of the parts under the epidermis, rather than from any colour of its own.

2. The ſkins of Negroes are of a thicker ſubſtance, and denſer texture, than thoſe of white people, and tranſmit no colour through them.

3. The part of the ſkin which appears black in Negroes, is the corpus reticulare cutis, and external lamella of the epidermis: all other parts are of the ſame colour in them, with thoſe of other people, except the fibres which paſs between thoſe two parts.

4. The colour of Negroes does not proceed from any black humour, or fluid parts contained in their ſkins; there being none ſuch in any part of their bodies, more than in white people.

5. The epidermis, eſpecially its external lamella, is divided into two parts by its pores and ſcales, two hundred times leſs than the particles of bodies on which their colours depend. This is founded on Leuwenhoek's obſervation that a portion of the epidermis, no bigger than what can be diſcerned with the naked eye, is divided into 125000 pores, and theſe pores muſt divide ſuch a portion of the ſkin into as many particles. But the particles of bodies on which their colours depend, are, by Sir Iſaac Newton's Optics, Lib. 2, p. 3, Prop. 7, 600 times leſs than theſe which can be diſcerned by the naked eye. Therefore, the particles of the ſkin muſt be about 200 times leſs than theſe, ſince $\frac{125000}{600} = 208\frac{1}{3}$. It may alſo be obſerved, that ſuch a ſmall portion of the epidermis is diviſible into 250 ſcales, which muſt increaſe the number of its parts.

6. From theſe propoſitions, and from Sir Iſaac Newton's Theory of Light and Colours, the doctor thinks he may conclude, that the proximate cauſe of the colour of Negroes is threefold; viz. the opacity of their ſkin, proceeding from the thickneſs and denſity of its texture, which obſtructs the tranſmiſſion of the rays of light; from the red and white parts under the ſkin, together with its greater refractive power, which abſorbs theſe rays; and the ſmallneſs of the particles of this ſkin, which hinders it from reflecting any light.

7. The influence of the ſun, in hot countries, and the manner of life of their inhabitants, are the remote cauſes of the colour of the Negroes, Indians, &c. And the ways of living, in uſe amongſt moſt nations of white people, make their colours whiter than they were originally, or would be naturally.

In ſupport of this propoſition, the doctor obſerves, that the ſkin is deprived of its white colour, by the force and influence of the ſun, four ways. 1. By being rendered opaque, from a diſſipation of its more aqueous and pellucid juices. 2. By a concretion of its veſſels and glandules, from this diſſipation of their aqueous contents, which renders the ſkin both thicker and denſer, or more callous and rigid. 3. By a new accretion of many new membranes, which render it thick and opaque. 4. By increaſing thoſe parts or principles in this compoſition of the epidermis, which have the greateſt refractive power, as the terreſtrial and fixed ſaline; but eſpecially the tenacious ſulphureous, which refract and abſorb light more ſtrongly than any other ſubſtances; while the more tranſparent and pellucid principles, as the aqueous, ſpirituous, and volatile ſaline, are evaporated by the heat, which cauſes the other more fixed principles to be accumulated; and theſe particles, being likewiſe more comminuted by the ſun, will, on this account, be black; as happens to oil, when boiled. Theſe cauſes, with thoſe firſt-mentioned, may, the doctor thinks, by conſpiring, make the ſkin quite black; eſpecially if we add another effect of the ſun's power, a peculiar necroſis of the epidermis, occaſioned by the forcible vibrations, contractions, and exſiccations of its fibres by the ſun-beams, which cauſe it to turn black, as theſe, or other parts do, by the heat of an inflammation, or a fever, in gangrenes, black tongues, &c.

We cannot pretend to follow the author in all the detail of his obſervations on this ſubject, nor of his anſwer to a material objection already mentioned from Mr. Boyle, that the ſun cannot be the cauſe of the colour of Negroes, becauſe ſeveral nations, in the ſame latitude with thoſe Negroes, are not made black by it. He ſeems to think the heat of Africa greater than that of other parts of the world. Whether it be ſo, or not, is, we doubt, not eaſy to determine; but it would be a ſtrong confirmation of his doctrine, if we could ſee any people, originally white, become black and woolly by tranſplantation, or vice verſa.

NEIEM-*el-ſalib*, *Egyptian cock's-foot-graſs*. It is a ſlender ſort of graſs, with white, geniculated, and creeping roots. The branches are geniculated, and adorned with four ſpikes, which repreſent the perfect figures of a croſs; whence the Egyptians call it Neiem-el-ſalib, that is, gramen crucis, the graſs of the croſs, or croſs-graſs.

The ſeeds, which are very minute, and like thoſe of common graſs, are very much uſed by all thoſe who are afflicted with the ſtone in the kidneys, or bladder, being eſteemed a good lithontriptic for diſſolving ſtony concretions in the bladder, which is a diſtemper very familiar, and, in a manner, endemial in Egypt. The women make very great uſe of the root in decoctions for their children, when ſeized with the ſmall-pox, or meaſles; and, alſo, for themſelves, when labouring under a ſuppreſſion of the menſes. Some regard a decoction of the ſeeds, moderately bruiſed, as a great ſecret, and a choice remedy for promoting the exanthematous eruptions, which we call peticulæ or petechiæ, in peſtilential fevers. The whole herb, but eſpecially the root, are much employed, alſo, in the cure of wounds in ulcers. The root is ſaid to be cold and dry, and of very fine parts, though the decoction thereof is very commonly uſed to provoke ſweats. *Raii, Hiſt. Plant.*

NEPHRI'TIS (*Dict.*)— The ſimple Nephritis is carefully diſtinguiſhed from the calculoſe one; for the former may, for a long time, affect a patient without any thing of a ſtone being in the caſe; and, on the contrary, a ſtone may be long lodged in the kidneys, without its bringing on any ſuch complaint as the Nephritis.

In the ſimple Nephritis there is always a ſenſation of pain and heat about the loins, which is plainly perceived to lie deep within the fleſh, but is never very acute. On the contrary, in the calculoſe Nephritis, the pain is violently ſharp.

In the ſimple Nephritis, the urine, after it has ſtood ſome time, ſhoots to the ſides of the pot pellucid cryſtals of a rediſh colour. But, in the calculoſe, the heavy matter immediately precipitates itſelf to the bottom, and is ſabulous and gritty; and the ſimple Nephritis is always greatly relieved by a gentle motion of the body, as walking, or the like; whereas all motion of the body exaſperates the calculoſe Nephritis.

The Nephritis is diſtinguiſhed alſo from the iſchiatic pains, which ſometimes run up to the ſame parts, by its being evidently perceived to lie deep within the fleſh, whereas thoſe pains affect the external muſcles; yet there is ſuch a connection and conſent of parts in theſe caſes, that not unfrequently the one is taken for the other.

Signs of it. Theſe are a pain in the region of the loins, which does not uſually affect both, but only, or, at leaſt, principally, one ſide, uſually the left. The pain is at firſt tenſive and dull, but afterwards becomes more acute; in the beginning it is often attended with a chillneſs, and general trembling, which is ſucceeded by a heat, and acrid gnawing, ſcarce to be ſupported; and this is uſually attended with a want of appetite, and loſs of ſtrength, and a continual, though not violent, thirſt. The ſleep is unſound, and there uſually is either a dull pain in the head, or a vertiginous complaint, more or leſs violent; and very frequently nauſeas, and reachings to vomit, attend the fits, or prognoſticate the acceſs of them.

The pain never extends itſelf down the whole thigh, nor is that ever wholly numbed, or rendered torpid by it; and the diſorder does not ſeem continual, but attacks the patient at different times, and theſe, after conſiderably long intervals, if he live regularly.

The diſorder, when the inflammation is known to be preſent, by its peculiar ſigns is to be cured, firſt, by the general remedies appropriated to the cure of all inflammations; ſuch as veneſection, revulſion, and dilution. Secondly, by mild, emollient, and antiphlogiſtic decoctions, drank in large quantities: thus: Take of the recent leaves of chervil, brook-lime, and pellitory of the wall, each two handfuls; of the roots of wood-ſorrel, ſuccory, and burdoc, each two ounces; of red chiches, an ounce and an half; of the bruiſed ſeeds of white poppy and lady's thiſtle, each four drachms. Boil in three pints of water for half an hour, and let the patient take two ounces of the decoction every quarter of an hour.

Or take, of the roots of graſs, ſix ounces; of bruiſed melon-ſeeds, an ounce and an half; and, of liquorice, one ounce. Boil in three pints of water, and let the patient uſe the decoction in the ſame manner, and for the ſame purpoſes, with the former.

And, by this method alone, a Nephritis, ariſing from a ſtone impacted in the ureters or kidneys, may be ſafely cured.

The remedies, moſt conducive to the cure of this ſpecies of Nephritis, are agrimony, vervain-mallow, ladies-mantle, marſh-mallows, brook-lime, the leſſer daiſy, middle conſound, chervil, wild carrot, dandelion, fennel, liquorice, ſtrawberries, graſs, rupture-wort, lettuce, hart's-tongue, Engliſh mercury, moneywort, white lily, reſt-harrow, pellitory of the wall, arſe-ſmart, ſcabious, golden-rod, and nettles, Fernelius's ſyrup of marſh-mallows, ſyrup of maiden-hair, ſyrup of ſuccory with rhubarb, ſyrup of white poppies, ſyrup of wild poppies, and ſyrup of violets, ſal ammoniac, ſal-gemmæ, and ſea-ſalt.

If the cauſes of a Nephritis are ſo ſtrong and powerful, that the diſorder can neither be removed by reſolution, nor any other method, but is protracted beyond the ſeventh day, an abſceſs is to be dreaded, the formation of which may be known from a remiſſion of the pain, which is ſucceeded by a pulſation, a frequently returning horror, a weight and ſtupor of the part. That an abſceſs is already formed, is obvious, from the former ſigns having preceded, from the pulſation, heat, and tenſion in the part, and from the purulent, fœtid, and apparently ſaline and putrified urine. As ſoon as we are certain that the abſceſs is formed, we are firſt to uſe powerfully maturating and emollient medicines; then, when the urine appears purulent, we muſt exhibit diuretics, conſiſting of pure medicated

medicated waters, whey, and other liquors of a like nature, using, at the same time, balsamics.

But, if this suppuration should continue for a long time, the whole kidney, being consumed, forms a kind of bag, of no use; and, in this case, a tabes renalis is frequently present.

If a schirrhus is formed here, there arises an incurable palsy, or lameness of the subjacent leg. Hence, also, are frequently produced a slow consumption and a dropsy.

But, if a small quantity of the inflammatory matter remains coagulated in the minute follicule of the urine, it forms a kind of basis or ground-work, to which the sabulous matter of the urine gradually adhering, forms a stone in the kidnies, which is by degrees augmented.

A Nephritis, also, sometimes degenerates into a gangrene, as is obvious from the violence of the cause and symptoms; the want of relief by remedies; and the sudden remission of the pain, without any apparent cause, accompanied with a cold sweat, a weak and intermitting pulse, a hiccup, either no discharge of urine at all, or an evacuation of such as is livid, black, full of hairs, fœtid, and rendered unseemly by brown or black caruncles; and a sudden and considerable loss of strength. In this case no measures are of any service, either for the relief or safety of the patient.

From what has been said it is obvious, that there are almost an infinite number of various species of a Nephritis; that their different causes are as numerous; that one of these causes is the stone; and that, at the same time, all these different species are to be cured almost in the same manner. Hence we understand the crisis of a Nephritis, and why this disorder so often happens in fevers. Hence, also, we are enabled to know and cure an ischury, arising from a fault of the kidnies or ureters.

NEPHRO'TOMY, in surgery, the cutting into the kidnies, in case of the stone being lodged there, and taking it out in in the same way as from the bladder.

This is an operation which has been very little practised, and usually supposed to be attended with very great danger: few authors who have treated of these diseases have so much as mentioned this operation, and the few that have named it, have generally condemned it. Sinibaldus, fancying that it was an operation anciently practised, strove very earnestly, indeed, to have it revived. He has called in the opinion of Hippocrates to support his account of its having been done with safety, and advises the surgeons to try their hands on brutes first, and accustom themselves to the operation, and, then, not to fear it in regard to men.

It is certain that a stone in the kidney is so terrible a disease, that it is very much to be wished that some safe operation could be invented to cure it; but it is making too free with Hippocrates, to say, that he countenances or directs such an operation in general. His words seems to express only the making an incision near the kidney; but, even if they are to be understood as directing the cutting into it, it is under such restrictions, that opportunities will very seldom offer; and, when they do, a common surgeon would not scruple performing all that is directed, without either consulting Hippocrates, or trying his skill upon brutes. Hippocrates only advises it in case of a swelling and imposthumation, where there is matter formed, and the tumor manifests itself upon the surface. In this case every surgeon would know it was his business to make an incision. *Phil. Transf.* N°. 223.

Cases requiring this are frequent, and that even without a stone. An inflammation in a kidney degenerates into an abscess, and, when matter is formed, the surgeon opens the tumor, and the matter is discharged. Sometimes stones, bred in the kidnies, cause imposthumations; the surgeon opens these, and the stones are brought away together with the matter. Nay, nature herself has done the whole for some people, and the stones have made way through the kidnies, and through the integuments, &c.

Tulipus gives an account, from his own observation, of a man who had a stone in his kidney, which, after many years, discharged itself through the loins, and occasioned a fistula in the part, through which the urine was long voided, together with the matter. The attempts of many surgeons to heal this fistula were vain, and, at length, one succeeding so far as to stop up the mouth of the ulcer, the matter which was used to be discharged from it was thrown into the abdomen, and the man died of a fever. Tulipus gives the death of this person as an objection against the operation of Nephrotomy in general, as he supposes a similar fate might attend the wounds made in these parts by the surgeon.

From an impartial examination of the works of Hippocrates, it does not appear that the cutting for the stone in the kidnies was regularly practised in his time, nor, indeed, for many ages after; for Celsus makes no mention of it, although he is very particular upon the operation of cutting for the stone in the bladder. Galen is so copious a writer, that he never misses any thing practised either in his own time, or before it, in his account of diseases; yet, he mentions nothing of this operation, though he is very long upon the article of the diseases of the kidnies. Cardan, indeed, mentions this operation, as one of those of the ancients, which were practised in his time. His hasty reading the works of Hippocrates has led him into this error, and he lays the fault of its being now lost, in a great measure, on Galen's omitting to mention it. It is wrong to accuse Galen of this omission, since neither Celsus, nor Ruffus, who preceded him, nor Aretæus who was his contemporary, nor, indeed, any of the Greek or Latin physicians, have named it, though they, as well as the moderns, mention, occasionally, an abscess in the kidnies, and the manner of curing it.

The Arabians, indeed, mention the operation as practised and countenanced by some persons before their time; but they all join in condemning it as a bold and hazardous operation, from which very little good is to be expected, and which sets the life of the patient in the most imminent danger. Avicenna speaks of it as the act of a madman, and it seems, that it was sometimes practised in his time, but, by his manner of naming it, seems to have been only done by some mountebanks, who, having no reputation to lose, ventured boldly, and sometimes had success. The rest of the Arabians are silent about the operation, and it seems to have been only practised by a few people in the days of this author, and wholly discountenanced afterwards, from its bad success.

Among the moderns, the first who has named it is Rousset, in his treatise on the Cæsarian Section. In order to invite men to countenance the Cæsarian operation, he recommends several other desperate ones, and, among the rest, this of Nephrotomy: but he is not able to produce one instance of its having been practised, either in his own, or earlier times, but when there was an abscess and an external tumor. Cælius Rodiginus gives, indeed, a very remarkable instance of an operation of this kind being performed by chance, by a woman, who, in the agony of her pain from the stone in the kidney, scratched with her own nails, till she tore through the flesh so deep, that eighteen stones were discharged at the wound.

The general opinion of authors is thus against the operation; and the most famed among those who have treated of wounds of the kidnies, say, that any wound which enters into the pelvis is mortal. Yet, this opinion, though general, is not certain or determinate; and we have an account, in the Philosophical Transactions, of the operation of Nephrotomy being performed with success, by Marchetti of Padua, on Mr. Hobson, the English consul at Venice.

NE'RVE (*Dict.*)— *Wounds of the* NERVES.— Upon the division of Nerves, the limb to which that Nerve was extended becomes instantly rigid, void of sensation, and withers: so that it is no wonder that a man instantly expires, upon the division of those Nerves which are sent to the heart or diaphragm: a wound also is attended with great danger where the Nerve is only partially wounded, and not intirely divided; for the wounded fibres contract themselves, and those which remain undivided suffer too great extension, which will bring on most violent pain, spasms, convulsions, inflammations, and gangrenes, and sometimes death itself. *Heister's Surgery.*

NET.— The places for using fowling nets to most advantage, are the morning and evening haunts where the birds come to feed. The Sportsman is to be at the place at least two hours before the time of their coming, and the Net must immediately be spread flat and even upon the ground, and the two ends fastened down with stakes. At the lower part there is to be a long cord fixed to the upper edge of the Net, by means of which it may be immediately raised and pulled over. The sportsman is to hide himself behind some natural or artificial shelter, at the extremity of his line, and some cut grass must be strewed all over the Net as it lies on the ground, to hide it from the fowl: and some live bird, that has been taken before, should be staked down before the Net, by way of a stale to draw in the others.

As soon as a sufficient number of birds are within the compass of the Net, it is to be pulled swiftly over them, and the fowler, having taken those that are under it, may stake down two or three more live ones, and spread the Net, covering it with grass as before. This sort of sport may be continued from as soon as it is light in the morning, till an hour after sun-rise; but, after that time, the birds have done feeding ravenously, and the sport is over for that day.

NEWT, or EFT.— The land Newt, or, as naturalists often call it, the land salamander, has something very remarkable in its outer coat. Its skin often appears dry, like that of the lizard kind, but often, also, it appears wetted, and as if covered with a fine shining varnish: the change from one to the other of these states is usually performed in an instant, and is frequently wet all over on the touching it. It also contains, under the skin, a sort of milky liquor, which spurts out to a distance on pressing the body of the animal.

The passages for this milk are a vast number of pores or holes, many of which are plainly visible to the naked eye; and very probably the first-mentioned liquor, which covers the skin in manner of a varnish, may be the same with this, its white colour not being distinguishable, when it is spread so thin over the surface of the animal. This milk resembles very much the milky juice which the lithymals, and many other of the succulent plants, afford on being cut or broken. It is of an insupportably acrid and styptic taste; and, though the tongue receives no injury from touching it, yet the sensation is so violent,

lent, that one is apt to imagine there muſt be a wound made in it. This animal, when bruiſed, yields alſo a very diſagreeable ſmell.

It has generally been ſuppoſed, that this animal is of a poiſonous nature; and the famous ſalamander of the old writers ſeems to be of the ſame genus, if not the ſame animal. Mr. Maupertuis, determined to inform the world of the truth, in regard to theſe remarkable particulars, cauſed a large number of theſe animals to be brought to him, which the country people, who had caught them about the bottoms of old walls, brought to him with as much caution as if they had been vipers.

The firſt experiment he made, was that of the incombuſtible quality of theſe animals: to this purpoſe, he threw ſeveral of them into a common fire; moſt of them periſhed immediately, but a few made ſhift to crawl out; but theſe could not get away on a ſecond trial, but periſhed like the reſt. It was obſerved, however, that, the moment they were thrown into the fire, the whole quantity of milky juice they contained was driven out at all the pores, and drying in an inſtant, ſtood in round globules, like ſo many pearls, till wholly conſumed by the heat.

It is poſſible, that the obſerving this creature to have a power of throwing out theſe juices, and covering itſelf at pleaſure with wet, might give riſe to the imaginary property of its ſubſiſting by the ſame means unhurt in the fire.

This trial being made, the next was to be certainly determined whether the creature were poiſonous or not. This Mr. Maupertuis propoſed to try two ways; the firſt, by making the creature bite ſome animals; the other, by making ſome other creature eat the Newt. But theſe experiments were attended with more difficulties than might be imagined, for it was neither eaſy to make it bite any thing, nor to make any creature eat it. No provocation could make the Newt bite, and, when its jaws were opened by force, its teeth were found ſo ſmall, and ſo placed, that they ſeemed rather intended to ſaw, or cut things to pieces, than to bite with; and when a chicken was brought to be bit, and the feathers removed from the part, the jaws had no force to make the teeth penetrate, and, when preſſed together, the teeth rather broke, or were put out of their places, than entered the animal, ſo that it was neceſſary to take off the ſkin, and the chicken then received ſeveral wounds, by forcibly preſſing the jaws of the Newt, together with parts of the raw fleſh between: after this, the lips and tongue of a dog, and the tongue of a turkey, were bitten in the ſame manner by other Newts. The animals were let looſe, and not one of them received the leaſt injury from the bite.

The following trial was made, whether the fleſh of the creature, or its milky juice, were poiſonous, when received into the ſtomach. Several animals were kept hungry a conſiderable time, on purpoſe to make them eat the animal, but none of them would touch it; ſo well has nature defended this little creature by the acrid juice under its ſkin, of which other animals are warned, as by inſtinct, and refuſe to ſwallow ſo diſagreeable a repaſt. A dog was at length compelled to ſwallow a Newt cut into ſeveral pieces while alive, and a turkey was forced to ſwallow, in like manner, a ſmall one. The dog's mouth was tied up for half an hour, and, half an hour after it was untied, he vomited up the tail and the feet of the animal, and received no injury; nor did the turkey, which ſwallowed the young one. After this, pieces of bread were ſoaked in the milky juice alone, and chickens were made to ſwallow them, and wounds inflicted with weapons dipped in the ſame juice, but no harm ever enſued to the creatures from either.

From all theſe trials, it appears very evident, that the ſtories of this creature's being poiſonous are as idle, and groundleſs, as thoſe of its living in the fire.

One thing remarkable this gentleman obſerved in his diſſections of the animal, which was, that he found in ſeveral of the females, at once, cluſters of eggs and living young ones. The eggs formed cluſters reſembling thoſe of the ovaries of birds, and the young ones were contained in two tubes, or long pipes, the coats of which were perfectly tranſparent, and the young ones were eaſily diſtinguiſhed through them, and there were counted in one female fifty-four of theſe, all living and vigorous. *Mem. Acad. Par.* 1721.

NICETE'RIA *Athenæ*, in antiquity, an Athenian ſolemnity, in memory of Minerva's victory over Neptune, when they contended which of them ſhould have the honour of giving a name to the city afterwards called Athens. *Potter, Archæol.*

NI'COL, in natural hiſtory, a word uſed by the miners in Germany, to expreſs a greeniſh cruſt covering ſeveral of the ſpecies of marcaſites and cobalt; it emits fumes that ſmell of garlic in the calcination, and is very injurious to the workmen, cauſing contractions of their limbs, and other diſorders. It is ſometimes found in maſſes alone, but that more rarely.

NI'GHTINGALE, *philomela*, in zoology. See PHILOMELA.

Virginian NIGHTINGALE, in zoology, the common, but improper, name of a bird of the groſs-beaked kind, called by authors the coccothrauſtes Indica criſtata.

It is a little ſmaller than our blackbird; it has a black ring ſurrounding the eyes and noſtrils; the beak is very large and thick, but not altogether ſo large as in the common groſs-beak; and its head is ornamented with a very high and beautiful creſt, which it moves about very frequently. It is all over of a very fine and lively red, but paler on the head and tail than elſewhere. It is brought to us from Virginia, and is valued in England, for its beauty and delicate manner of ſinging. It is very fond of almonds, and the like fruits. *Ray's Ornithol.*

NI'GHTSHADE. See SOLANUM.

NINTH, in muſic, one of the diſſonant intervals in muſic. It is properly the ſecond doubled, but is differently uſed. When an upper part ſyncopates, the ſecond is accented and treated as a Ninth; i. e. it is reſolved by an eighth, and accompanied by a third or fifth, and often a ſyncopated ſeventh. But, when the lower part ſyncopates, the ſecond is not thus uſed, but is accompanied by the fourth and ſixth. In thorough baſs, the Ninth has always, or, at leaſt, commonly, an eighth placed after it, thus, 9 8; to ſhew that this is reſolved by deſcending to the octave. *Broſſ. Dict. Muſ.*

NI'PPERS, in the manege, are four teeth in the fore-part of a horſe's mouth, two in the upper, and two in the lower jaw. A horſe puts them forth between the ſecond and third year. See TEETH.

NIPPERS, is alſo an inſtrument in uſe among ſmiths and farriers, being a kind of pincers, wherewith, in ſhoeing a horſe, they cut the nails before they rivet them. It is alſo uſed in taking off a ſhoe.

NIPPERS, *in a ſhip*, are ſmall ropes, about a fathom or two long, with a little truck at one end, and ſometimes only a wale-knot. Their uſe is to help to hold off the cable from the main, or jeer capſtan, when the cable is ſo ſlimy, ſo wet, or ſo great, that they cannot ſtrain it to hold it off with their bare hands.

NI'TRE (*Dict.*)—This ſalt gives the greateſt of all proofs of the effects of ſynthetical or recompoſing chemiſtry. It is firſt ſeparated or analyſed, in the following manner: take two pounds of refined ſalt-petre in fine powder; pour upon it one third of its weight of oil of vitriol, and diſtil it in a glaſs retort, in a ſtrong ſand heat, there will be produced a ſtrong acid ſpirit of Nitre, which cannot, by any experiment, be found to participate at all of the nature of the oil of vitriol uſed in its preparation. Then take a pound of freſh Nitre, melt it in a crucible, and throw into it, at times, pieces of charcoal, till it will no longer keep in fuſion with the ſame degree of fire; then increaſe the fire, and melt it, and then pour it into a proper veſſel; leave it to cool itſelf. This is fixed nitre, and is an alkali: now diſſolve this fixed Nitre in water, and exactly ſaturate that water with the acid ſpirit of Nitre before diſtilled; this compound liquor will, by ſtanding, ſhoot into true and perfect cryſtals of nitre. And the experiment ſucceeds as well, if a ſolution of pot-aſhes, or any other fixed alkali, be uſed inſtead of that of fixed Nitre. *Shaw's Lectures.*

If there is any highly penetrating and corroſive liquor, which, inſinuating itſelf into all bodies, corrodes, diſſolves, deſtroys, and changes their craſis and mixture, it is certainly the highly acid and concentrated ſpirit of nitre, deprived of all its phlegm, rendered inflammable, and totally volatile, and by the application of which, excreſcences, warts, and preternatural tumors of the human body, may be commodiouſly deſtroyed and eradicated. Notwithſtanding theſe circumſtances, this ſpirit, by the addition of the volatile ſalt of ſal ammoniac, or ſalt of tartar, is, after its effervescence, totally deprived of its corroſive quality, ſince the mixture degenerates into a nitrous ſalt; which, when diſſolved in water, affords a powerful diuretic liquor, excellent for provoking urine, in ſerous and cachectic diſorders: beſides, the corroſive quality of this ſpirit is excellently corrected, by mixing eight parts of highly rectified ſpirit of wine with one part of it, and diſtilling from an alembic, by means of a ſand heat; by which means, there is yielded a ſpirit of a fragrant ſmell, an acrid penetrating taſte, entirely free from a corroſive quality, excellently adapted for diſcuſſing and reſolving viſcid humours, and, conſequently, carminative. This dulcified ſpirit, in conſequence of the vaporous ſulphur it contains, is, alſo, poſſeſſed of an anodyne and ſedative virtue, highly efficacious in pains and ſpaſms; for which reaſon it is of far more uſe in practice, than the common ſpiritus nitri dulcis.

The reaſon of the proceſs is this, that highly rectified ſpirit of wine is nothing but a very ſubtile oil, immediately mixed with phlegm; for which reaſon, it is united and intimately mixed with this corroſive ſpirit, and both of them, when united, form a mixture of a third nature; which, when diſſolved in the inflammable ſpirit, comes over the helm, and conſtitutes the dulcified ſpirit of Nitre. But it is to be obſerved, that, at leaſt, five, ſix, or eight parts of the rectified ſpirit of wine ought to be added to one part of this ſpirit; for, if only two or three of the former were uſed, a violent conflict would be produced, and the corroding acid quality of the latter not totally deſtroyed: but, in the preparation of this ſpirit, it is to be obſerved, that the ſpirit of wine is not to be poured into the corroſive ſpirit; otherwiſe a violent conflict is produced, accompanied with a thick red ſmoke, which is prejudicial to the health of the by-ſtanders, and ſometimes ſucceeded by the breaking

breaking of the glaſs. But when the corroſive ſpirit is in ſmall quantities, and gradually mixed with the ſpirit of wine, all theſe diſadvantages are prevented.

This dulcified ſpirit, when poured into a ſilver ſpoon, and ſet on flame, leaves behind it a greeniſh ſpot on the ſpoon, which is a proof of an acidulated ſubtile nitrous ſalt: in ſuch a caſe, it is, therefore, expedient to dulcify theſe ſpirits more, and augment its virtues, by pouring into it a proper quantity of the vinous ſpirit of ſal ammoniac: when the acid of this ſpirit is thus corrected, it no longer leaves any ſpot on the ſpoon, and its anodyne and ſedative virtues are at the ſame time rather augmented.

This dulcified ſpirit of Nitre differs from the common ſort ſold in the ſhops, ſince the former is of a far more penetrating taſte and ſmell, and conſequently more efficacious. They alſo differ with reſpect to the preparation, ſince that of the ſhops is prepared with aqua-fortis, and mine with a duly dephlegmated ſpirit, impregnated with a vitriolic and highly concentrated ſulphur: my ſpirit produces a violent conflict and effervescence, with highly rectified ſpirit of wine; but the common dulcified ſpirit of Nitre none at all: hence it alſo happens, that there is not an intimate union of the acid of Nitre with the oleous parts contained in the rectified ſpirit of wine, which happens in my highly concentrated ſpirit. In the preparation of my ſpirit, nothing remains in the cucurbit, but all the fluid aſcends; whereas, in the preparation of the common ſpiritus nitri dulcis, the acid and corroſive liquor of the Nitre remains after diſtillation.

My dulcified ſpirit of Nitre, by the addition of a proper quantity of ſalt of tartar, loſes almoſt all its acid acrimony, and may for this reaſon be commodiouſly mixed with common water, for drink in burning fevers: thus, if two drachms of it are mixed with about two pints of ſpring water, they make a drink which powerfully allays thirſt, provokes urine, and procures ſleep. In inflammations of the fauces, eſpecially ſuch as attend quinſies, nothing affords more immediate relief, than this ſpirit mixed with ſugar, and a ſmall quantity of the ſpirit of camphire, diluted in common water, and uſed as a gargariſm. Sugar itſelf, alſo, ſwallowed in a ſmall quantity, affords relief in inflammations of the fauces.

This dulcified ſpirit of Nitre, when mixed in a ſmall quantity with rectified volatile ſpirit of hartſhorn, acquires a bezoardic and diaphoretic virtue; for which reaſon it is highly beneficial in all malignant fevers, where ſweating is neceſſary. *Hoff. Obſ. Phyſ. Chym.*

NI'TRUM *calcarium*, in natural hiſtory, a name given by Dr. Liſter to a peculiar ſpecies of neutral ſalt, which he firſt publickly deſcribed in his book on the Medicinal Waters of England. He very improperly calls it nitre; becauſe it has none of the properties or qualities of nitre, but only a ſort of general reſemblance in its external form. He obſerves that this ſalt, though very little known, was abundantly the moſt copious of all the ſorts afforded by the mineral waters in general; and ſays, its cryſtals were long and ſlender, and conſiſted of four ſides, and were terminated by a point compoſed of two triangular planes. He adds, that this ſalt doubtleſs had its origin from a mixture of the acid of ſulphur and a calcarious earth of an alkaline nature.

This ſalt is found in almoſt all the mineral waters of Germany, and is very juſtly obſerved by Hoffman to be of the nature of Glauber's ſalt: that it is not nitre, is evident from this, that it is not inflammable, nor will yield aqua-fortis by diſtillation. It ſeems, indeed, true Glauber's ſalt, compoſed of the acid of vitriol or ſulphur, for this is in both the ſame, and of that alcaline earth which is the baſis of ſea ſalt: this is its origin, in the veſſels of the chemiſt, as well as in the bowels of the earth; and probably the figure of the cryſtals of that obſerved by Dr. Liſter was the ſame in the point, as well as in the body, both being quadrilateral columns, terminated by pyramids compoſed of a number of triangular planes. *Hoff. Opera.*

NITRUM *nitratum*, in chemiſtry, the name of a preparation of nitre, made by adding a ſufficient quantity of ſpirit of nitre to a lixivium of pure nitre, and afterwards evaporating it to a pellicle, and ſetting it by to ſhoot. The cryſtals formed by this liquor are perfectly nitrous in their figure, but they will be of an acid taſte.

We ſee, by this, that it is poſſible to alter a ſalt, and to reduce it into the appearance of a different body, by means of ſubſtances before ſeparated from itſelf; and, in this caſe, the alteration is made, in almoſt any degree, at pleaſure; the ſalt produced being more or leſs acid, as more or leſs of the acid ſpirit is uſed: but it is to be obſerved, that, the more acid there is uſed, the more difficultly the ſalt dries, and the more difficultly it is kept dry, it being always ſubject to run in the air. This preparation of nitre is a good medicine in burning fevers. *Boer. Chem.*

NOAH's *ark-ſhell*, in natural hiſtory, the name of a kind of ſea ſhell, which authors were always puzzled about referring to any genus, till a late French author has referred it to a new genus he has made under the title cordiformis taking in the bucardia and triangular heart-ſhells. The cabinet of the curious affords us three ſpecies of this ſhell; the common kind, a yellow and white kind, with broad irregular lines, and a variegated kind. *Hiſt. Nat. Eclair.*

NOCTA'MBULI, (*Dict.*)—This is a very ſtrange and remarkable diſtemperature of the imagination, and, in different perſons, differs greatly in degree. Thoſe who are but moderately affected with it, only repeat their actions of the day, and, getting out of the bed, go quietly to the places they frequent at other times; but thoſe who are afflicted with it in the moſt violent degree, go up to dangerous places, and do things that would terrify them to think of, when awake: theſe are by ſome called lunatic night-walkers, becauſe fits are obſerved to return with moſt frequency, and violence, at the changes of the moon.

Cauſes of it. The only material cauſe that can be aſſigned, in this caſe, is a plethora, or over-fulneſs of blood; but this is influenced by an immaterial one, that is, by the fancy, which is buſily employed in dreams about particular objects.

Method of cure. The primæ viæ are firſt to be cleared of all their foulneſſes by a ſtrong purge; after this it is proper to bleed in the foot, taking away eight or ten ounces; then powders compoſed of nitre, cinnabar, and crabs eyes, ſhould be taken three or four times a day, and particular regard ſhould be had to the changes of the moon. It will be proper to ſet a veſſel of water by the bed-ſide, in ſuch a manner that the perſon will naturally ſtep into it on getting out, and be awaked by that means; and, if theſe things fail, a perſon ſhould be ſet up to watch him, and beat him, every time it happens. *Junker's Conſp. Med.*

NOCTU'RNA. The Roman catholics beſtow this name on that part of the church office or prayers, which they alſo call matutina or mattins, which are commonly divided into three nocturns, ſo called, becauſe they were uſed to be ſung only by night; which is ſtill obſerved in ſome cathedral churches, where they ſing their mattins at midnight, in imitation of the primitive Chriſtians, who, by reaſon of the Heathen emperors perſecutions, were forced to meet at nights, which gave their adverſaries occaſion of loading them with moſt abominable calumnies. *F. Simon.*

NOMO'THETÆ, Νομοθέται, among the Athenians, were a thouſand in number, and choſen by lot out of ſuch as had been judges in the court Heliæa. Their office was not (as their name ſeems to imply) to enact new laws by their own authority, for that could not be done without the approbation of the ſenate, and the people's ratification; but to inſpect the old, and, if they found any of them uſeleſs, or prejudicial, as the ſtate of affairs then ſtood, or contradictory to others, they cauſed them to be abrogated by an act of the people. Beſide this, they were to take care that no man ſhould plough, or dig deep ditches, within the Pelaſgian wall; to apprehend the offenders, and ſend them to the archon. *Potter. Archæol. Græc.*

Fracture of the NOSE.—In the Noſe both bone and cartilage are ſubject to fractures, which happen ſometimes on either ſide, and ſometimes in the middle, from blows or falls; if either of the bones in the front of the Noſe are fractured, it produces a flatneſs in the Noſe, and the air meets with obſtructions in its paſſage through the noſtrils; and, if the bone on either ſide is fractured, the part becomes hollow. When the cartilage is diſturbed, the Noſe inclines too much on one ſide. Theſe fractures ſometimes happen without a wound, but more uſually they are attended with a wound of the common integuments. If the injury of the Noſe is very great, the fracture can never be ſo perfectly cured, but that ſome deformity will remain. The vicinity of this part to the brain alſo, which is frequently injured at the ſame time, renders caſes of this kind often dangerous. A caries alſo, or an ozæna, or polypus, are no uncommon attendants on this diſorder. In order to reſtore the bones of the Noſe to their proper ſituation, the patient is to be placed in a ſeat oppoſite to the light, and his head held back by an aſſiſtant. The ſurgeon is to raiſe the depreſſed parts with a ſpatula, a probe, or a quill, applying externally the thumb of one hand, and the fore-finger of the other. If the bones of the Noſe are fractured on both ſides, they are to be on each in this manner, and the cavity of the noſtrils is to be filled up with long doſſils, to prevent the bones from collapſing; covering the part alſo for this end with ſome plaiſter, and applying firſt the dreſſings common to recent wounds. If the bone is fractured into ſeveral ſplinters, they are to be reduced into their proper places by the fingers; but if a ſplinter is ſo entirely ſeparated from the bone, that it will not eaſily unite with it again, it is to be taken out with the forceps. The bones will unite, when properly replaced, in about fourteen days, if no caries or abſceſs intervene. If the bone ſhould require a ſtronger ſupport than what has hitherto been mentioned, one may be formed out of ſtrong paper, either ſingle, or double, and adapted to each ſide of the Noſe, and ſupported by bolſters, and the whole muſt be kept in its place by a four-headed bandage not tied too tight. *Heiſter, Surg.*

NOTA'RICON, the third part of the Jewiſh cabala. Rabbi Nathan, in his great Aruch, ſays, that Notaricon is when a ſingle letter is taken for the ſign of a thing, i. e. for a whole name.—He adds, that the word comes from the Latin notarius, a perſon who writes in notes, or ſhort-hand.—And Rabbi Elias Levita gives the ſame account in his Theſbites, except that, in lieu of one letter for a word, he mentions 2 or 3. But,

But, after all, neither the one nor the other ſeems alone ſufficient: for, as ſingle letters frequently make a word, ſo, in the Notaricon, a whole word ſometimes ſtands for a ſingle letter.

There are therefore two principal kinds of Notaricon: the firſt is, when by aphæreſis, or apocope, the firſt or laſt letter of ſeveral words are joined to make a ſingle word, or phraſe; which therefore is of two kinds, the one initial, the other final: and each is done ſeveral ways, viz. either by taking the letters the common way, or backwards: though there is alſo a third kind, made, as the Rabbins call it, by leaps, i. e. by ſkipping over ſome letters. The firſt of theſe kinds, which the rabbins call raſche theboth, appears very antient; and is ſuppoſed by ſome, well verſed in the Hebrew, to have taken its origin from the pſalms, and other places of ſcripture, proceeding alphabetically; i. e. the firſt verſe beginning with א, the firſt letter of the alphabet; the ſecond with ב, the ſecond letter, &c.

The ſecond kind is alſo very common, and called ſophe theboth, i. e. the end of words. For inſtance, by telling the laſt letters of the words, מ ה שמו מה לי Mihi quodnam nomen eſt. Quodnam? they find the name of God, Jehovah. This becomes ſtill more puerile, when they take the letters backwards.

The third kind is more modern, more groſs, and perplexed: here a letter gives a whole word, inſtead of a word's only giving a letter; ſo that a word ſhall furniſh a whole phraſe.

Thus, for an example, in the firſt word of Geneſis, בראשית bereſchit, is found, "he created the heaven and the earth, "the ſea, the abyſs," &c.

NOTES, in muſic, (*Dict.*)—Of the ſeven muſical Notes, ut, re, mi, fa, ſol, la, ſi; the firſt ſix are aſcribed to Aretine, who is ſaid to have invented them at Pompoſa, in the dutchy of Ferrara. The ſeventh, viz. ſi, was added, according to ſome, by Vander Putten; according to others, by de Muris. It ſerves very good purpoſes, in avoiding the difficulty of the diviſions remaining in Guido's ſcale.

Indeed Voſſius will not allow Guido the honour of inventing any of them, but ſhews the Egyptians had uſed them long before him; in which he is confirmed by the teſtimony of Halicarnaſſeus: however, common fame aſcribes to him not only the notes, but alſo the lines, letters, or cleffs, flats, and ſharps.

The Notes ut, re, mi, &c. he is ſaid to have taken from a hymn, in the veſpers of St. John Baptiſt, Ut queant laxis reſonare fibris, &c.

Hitherto, the Notes only ſerved to expreſs the degrees of tune: they were all of equal value as to time, till about the year 1330, when John de Meurs, or de Muris, a doctor of Paris, gave different figures to the ſeveral points, to expreſs the quantity of time each was to be dwelt upon.

There are three things to be conſidered in theſe Notes. 1ſt, The quantity, i. e. the ſize and figure of the head. 2dly, The quality, i. e. the colour of the head, whether it be white or black, full or open. 3dly, The properties, as the Italians expreſs themſelves; viz. whether the Note is accompanied with a virgula, or comma, or not. It muſt likewiſe be conſidered whether the Notes be ſeparate and diſtinct, or bound together.

The ſeveral muſical Notes are, the large, which contains 8 meaſures; though Merſennus and ſeveral others make it 12; the long, containing 4 meaſures; the breve, containing 2; the ſemibreve, containing 1; the minim, $\frac{1}{2}$; the crotchet, $\frac{1}{4}$; the quaver, $\frac{1}{8}$; the ſemiquaver, $\frac{1}{16}$; and the demiſemiquaver, $\frac{1}{32}$.

Uſually we only diſtinguiſh ſix principal Notes, repreſented by as many different characters; viz. the ſemibreve, equal to two minims; the minim, equal to two crotchets; the crotchet, equal to two quavers; the quaver, equal to two demiquavers; and the ſemiquaver, equal to two demiſemiquavers.

The mathematicians compute, that one may make 720 changes, or varieties, with ſix Notes, without ever repeating the ſame twice; and that of the Notes of each octave one may make 40320 different tunes or ſongs.

NOVE'MVIRI, (*Dict.*) — Theſe nine magiſtrates of Athens government laſted but for one year; the firſt of which number was called archon, or prince; the ſecond baſileus, or king; the third polemarchus, or general of the army; and the ſix others were called the ſmothetæ or legiſlators. They took an oath exactly to obſerve the laws, and, in caſe of failure, obliged themſelves to beſtow upon the commonwealth a golden ſtatue as big as themſelves. Thoſe who diſcharged their office with honour, were afterwards received into the number of the ſenators of the Areopagus. *Plutarchus in Solon. & Pericle.*

NOVENDIA'LE, (*Dict.*)—This ſacrifice the Romans continued for nine days to divert the miſchiefs wherewith they were threatened by prodigy, and to appeaſe the anger of the Gods, in caſe the ſenate ſent an order to the high prieſt or prætor of the city, for the obſervation of this ſolemnity. Tullus Hoſtilius, the fourth king of Rome, was the firſt inſtitutor of theſe ſacrifices, after he had been informed of the prodigious hail which fell upon mount Aban, in the country of Latium, the bigneſs and hardneſs whereof made them to be taken for ſtones. *Titus Livius.*

NOVE'NSILES, certain Gods thus called by the Romans, either becauſe they were of ſhort ſtanding, or nine in number, as Health, Fortune, Veſta, Hercules, Romulus, Æſculapius, Bacchus, Æneas, and Faith; or, that they thought they preſided over novelties and changes. Others will have it, that was a name given to the nine muſes. *Lib. Gyrald. de Syntagm. Deor.*

NUAY'HAS, *the ague-tree*, a name given by the Indians to a ſort of bamboe cane, the leaves of which, falling into the water, are ſaid to impregnate it with ſuch virtue, that the bathing in it afterwards will cure the ague.

They uſe alſo a decoction of the leaves to diſſolve coagulated blood, giving it internally, and, at the ſame time, rubbing the bruiſed part externally with it. It is ſaid that this plant bears its flowers only once in its life, that it lives ſixty years before theſe appear, but that, when they begin to ſhew themſelves, it dies away in about a month afterwards, that is, as ſoon as it has ripened the ſeed; and from theſe ſeed only the vegetable can be propagated.

NUDIPEDA'LIA, ſacrifices which the Jews ſolemniſed with their bare feet, to be delivered from ſome great incumbent affliction. After having continued their prayers for thirty days together, and abſtained from wine, they ſhaved their heads, and went bare-foot to the temple, and offered their ſacrifices. The Jews finding themſelves oppreſſed by Florus, governor of Judea, for the emperor Nero, celebrated this bare-foot ceremony with extraordinary ſolemnity; Berenice, king Agrippa's ſiſter, accompanying them therein, and appearing alſo bare-foot in behalf of the Jews, before the tribunal of Florus, but without ſucceſs. Joſeph de Bello Judaic. S. Hieron. adverſ. Jovinian. The Greeks, Romans, and other nations alſo obſerved the like ſolemnities, as Tertullian informs us in his Apologetic.

NUM'BER, (*Dict.*)—*Figurate* NUMBERS. Thoſe of the firſt order are 1, 1, 1, 1, &c. Thoſe of the ſecond order the ſucceſſive ſums of thoſe of the firſt order, viz. 1, 2, 3, 4, 5, &c. and form an arithmetical progreſſion. Thoſe of the third order are the ſucceſſive ſums of thoſe of the ſecond, viz. 1, 3, 6, 10, 15, and are the triangular Numbers. Thoſe of the fourth order are the ſucceſſive ſums of the third, viz. 1, 4, 10, 20, 35, and are the pyramidal numbers, and ſo on.

The figurate numbers of any order may be found without computing thoſe of the preceding orders, by taking the ſucceſſive products of as many of the numbers 1, 2, 3, 4, 5, &c. in their natural order, as there are units in the Number, which denominates the order of figurates required, and dividing thoſe products always by the firſt product. Thus the triangular numbers are found by dividing the products 1×2, 2×3, 3×4, 4×5, 5×6, &c. each by the firſt product 1×2. The pyramids alſo are found by dividing the products, $1 \times 2 \times 3$, $2 \times 3 \times 4$, $3 \times 4 \times 5$, $4 \times 5 \times 6$, &c. each by $1 \times 2 \times 3$. In general, the figurate numbers of any order denoted by M are found by ſubſtituting ſucceſſively 1, 2, 3, 4, 5, &c. in the place of x in the general expreſſion $\frac{x \,.\, x+1 \,.\, x+2 \,.\, x+3, \ \&c.}{1. \quad 2. \quad 3. \quad 4. \quad \&c.}$ where the factors in the numerator and denominator are ſuppoſed to be multiplied by each other, and to be continued, till the Number in each be equal to that which expreſſes the order of the figurates required, diminiſhed by unity. And, when a figurate Number of any order is divided by the correſponding figurate of any higher order, the numerator of the quotient is invariable, and x. is in its denominator of as many dimenſions as there are units in the difference of the numbers that denote thoſe orders.

NUME'RIA, a Heathen goddeſs preſiding over numbers and accounts. *Auguſtin. de Civit. Dei.*

NUMMULA'RIA, *moneywort*, in botany, a genus of plants whoſe characters are:

The leaves are orbicular and conjugated; the calyx is quinquefid, incloſing a ſeminal veſſel, and conſiſting of five long ſlender ſegments, which expand themſelves in form of a ſtar. The flower is monopetalous, rotated, quinquefid, being cut even to the nail, or unguis, and furniſhed with five ſtamina, which, ariſing from the circumference of the baſe of the flower, grow together into one, in proceeding from the wings of the leaves. The placenta is ſeated in the bottom of the calyx, and on it grows the ovary, which becomes a round veſſel cloſely lodged within the calyx, and ſhooting forth a long tube.

Its leaves are ſouriſh, ſtyptic, and give a deep red tincture to blue paper: the acid abounds in the moneywort, and produces with the earth an aluminous ſalt, involved in a little oil, ſo that it is very aſtringent and vulnerary. Camerarius affirms, that, being boiled with milk, it is good for the ſcurvy. Fragus adviſes to boil it with wine and honey, and to give the decoction to drink to thoſe that have an ulcer in the lungs. The ſame author commends it in the dyſentery, loſs of blood, and the whites. Fuchſius preſcribes the herb, applied as a cataplaſm, to dry up ulcers. Matthiolus ſays it is very good for ruptures in children. *Martyn's Tournefort.*

NUN, in zoology, the common Engliſh name for the parus cæruleus, or blue tit-mouſe, diſtinguiſhed from the common by by its having a blue head, ſurrounded by a white line. *Roy's Ornithol.*

Nun, is alſo the name of a peculiar ſpecies of pigeon, called by Moore the columba veſtalis. It is but a ſmall pigeon, but ſomething larger than the jacobine, and has a very particular plumage, from which it has taken its name, its head being as it were covered with a veil.

The body of this ſpecies is all white; the head, tail, and ſix of the flight feathers black, red, or yellow; the eyes are pearl coloured, and the hood white: this is a large tuft of feathers on the hinder part of the head, and, the more numerous they are, the more the bird is eſteemed.

This is a very beautiful ſpecies of pigeon, and is very much eſteemed. Some of its feathers, however, will vary ſometimes from their true colour. Theſe birds are called foul-feathered. But it is a mere accidental variety, the young of ſuch being often as perfect and beautiful as of any others. *Moore's Columbarium.*

NU'RSERY, in gardening (*Dict.*) — Of this ſort there are great numbers in the different parts of this kingdom, but particularly in the neighbourhood of London, which are occupied by the gardeners, whoſe buſineſs it is to raiſe trees, plants, and flowers for ſale; and in many of theſe there is at preſent a much greater variety of trees and plants cultivated than can be found in any other part of Europe. In France, their Nurſeries (which are but few, when compared with thoſe in England) are chiefly confined to the propagation of fruit-trees, from whence they have the appellation of pepinier. For there is ſcarce any of thoſe gardens, where a perſon can be ſupplied either with ever-greens, flowering ſhrubs, or foreſt-trees. And, in Holland, their Nurſeries are principally for flowers: ſome few of them indeed propagate tender exotic plants. But thoſe Nurſeries in the neighbourhood of London do, ſeveral of them, include all theſe; and from hence moſt of the curious perſons abroad are ſupplied with furniture for their gardens. But I do not propoſe, in this place, to treat of theſe extenſive Nurſeries, or to give a deſcription of them; therefore ſhall confine myſelf to treat of ſuch Nurſeries only as are abſolutely neceſſary for all lovers of planting to have upon the ſpot, where they deſign to make their plantation. For, if theſe are large, the expence of carrying a great number of trees, if the diſtance is great, will be no ſmall article, beſides the hazard of their growing; which, when plants have been trained up in good land, and removed to an indifferent one, is very great. Therefore it is of the utmoſt conſequence to every planter, to begin by making of a Nurſery. But in this article I muſt beg leave to obſerve, that a Nurſery ſhould not be fixed to any one particular ſpot: I mean by this, that it would be wrong to continue the raiſing of trees any number of years upon the ſame ſpot of ground; becauſe hereby the ground will be ſo much exhauſted by the trees, as to render it unfit for the ſame purpoſe. Therefore all good Nurſery-gardeners ſhift and change their land, from time to time; for, when they have drawn off the trees from a ſpot of ground, they either plant kitchen herbs, or other things, upon the ground for a year or two, by which time, as alſo by dunging and trenching of the land, it is recovered, and made fit to receive other trees. But this they are obliged to from neceſſity, being confined to the ſame land; which is not the caſe with thoſe gentlemen, who have a large extent of ground in the country. Therefore all ſuch perſons I would adviſe to make Nurſeries upon the ground which is intended for planting, where a ſufficient number of the trees may be left ſtanding, after the others have been drawn out, to plant in other places; which, for all large-growing trees, but particularly ſuch as are cultivated for timber, will be found by much the moſt advantageous method: for all thoſe trees which come up from the ſeed, or which are tranſplanted very young into the places where they are deſigned to remain, will make a much greater progreſs, and become larger trees, than any of thoſe which are tranſplanted at a greater age. Therefore the Nurſeries ſhould be thinned early, by removing all thoſe trees which are intended for other plantations, while they are young; becauſe hereby the expence and trouble of ſtaking, watering, &c. will be ſaved, and the tree will ſucceed much better. But in expoſed ſituations, where there are Nurſeries made, it will be neceſſary to permit the trees to ſtand much longer, that, by growing cloſe together, they may ſhelter each other, and draw themſelves up: and theſe ſhould be thinned gradually, as the trees advance; for, by taking away too many at firſt, the cold will check the growth of the remaining trees. But then thoſe trees which are taken out from theſe Nurſeries, after a certain age, ſhould not be depended on for planting; and it will be prudence rather to conſign them for fuel, than by attempting to remove them large, whereby, in endeavouring to get them up with good roots, the roots of the ſtanding trees will be often much injured.

What has been here propoſed, muſt be underſtood for all large plantations in parks, woods, &c. but thoſe Nurſeries which are only intended for the raiſing of ever-greens, flowering ſhrubs, or plants which are deſigned to embelliſh gardens, may be confined to one ſpot, becauſe a ſmall compaſs of ground will be ſufficient for this purpoſe. Two or three acres of land, employed this way, will be ſufficient for the moſt extenſive deſigns; and one acre will be full enough for thoſe of moderate extent. And ſuch a ſpot of ground may be always employed for ſowing the ſeeds of foreign trees and plants; as alſo, for raiſing many ſorts of biennial and perennial flowers, to tranſplant into the borders of the pleaſure garden; and for raiſing many kinds of bulbous-rooted flowers from ſeeds; whereby a variety of new ſorts may be obtained annually, which will recompenſe for the trouble and expence, and will moreover be an agreeable diverſion to all thoſe perſons who delight in the amuſements of gardening.

Such a Nurſery as this ſhould be conveniently ſituated for water: for, where that is wanting, there muſt be an expence attending the carriage of water in dry weather. It ſhould alſo be as near the houſe as it can with conveniency be admitted, in order to render it eaſy to viſit at all times of the year; becauſe it is abſolutely neceſſary, that it ſhould be under the inſpection of the maſter; for, unleſs he delights in it, there will be little hopes of ſucceſs. The ſoil of this Nurſery ſhould alſo be good, and not too heavy and ſtiff; for ſuch land will be very improper for ſowing moſt ſorts of ſeeds; becauſe, as this will detain the moiſture in the ſpring and winter, ſo the ſeeds of moſt tender things, eſpecially of flowers, will rot in the ground, if ſown early. Therefore, where perſons are confined to ſuch land, there ſhould be a good quantity of ſand, aſhes, and other light manures buried, in order to ſeparate the parts, and pulveriſe the ground; and, if it is thrown up in ridges, to receive the froſt in winter, it will be of great uſe to it; as will alſo the frequent forking or ſtirring of the ground, both before and after it is planted.

The many advantages which attend the having ſuch a Nurſery, are ſo obvious to every perſon who has turned his thoughts in the leaſt to this ſubject, that it is needleſs for me to mention them here: and, therefore, I ſhall only beg leave to repeat here what I have frequently recommended, which is, the carefully keeping the ground always clear from weeds: for, if theſe are permitted to grow, they will rob the young trees of their nouriſhment. Another principal buſineſs is, to dig the ground between the young plants at leaſt once a year, to looſen it for the roots to ſtrike out: but, if the ground is ſtiff, it will be better to be repeated twice a year, viz. in October and March; which will greatly promote the growth of the plants, and prepare their roots for tranſplanting.

The ground you intend for the flower Nurſery ſhould be well ſituated to the ſun, but defended from ſtrong winds by plantations of trees, or buildings; and the ſoil ſhould be light and dry, which muſt always be obſerved, eſpecially for bulbous-rooted flowers, which are deſigned to be planted therein.

In this Nurſery ſhould be planted the off-ſets of all your bulbous-rooted flowers, where they are to remain until they become blowing roots; when they ſhould be removed into the pleaſure garden, and planted either in beds or borders, according to the goodneſs of the flowers, or the management they require.

You may alſo, in this ground, raiſe the ſeveral ſorts of bulbous-rooted flowers from ſeeds, by which means new varieties may be obtained; but moſt people are diſcouraged from ſetting about this work, from the length of time before the ſeedlings will come to flower: however, after a perſon hath once begun, and conſtantly continued ſowing every year, after the parcel firſt ſown has flowered, the regular ſucceſſion of them, coming annually to flower, will not render this method ſo tedious as it at firſt appeared.

The ſeedling auricula's, polyanthus's, anemonies, carnations, &c. ſhould be raiſed in this Nurſery, where they ſhould be preſerved until they have flowered; when you ſhould mark all ſuch as are worthy of being tranſplanted into the flower garden; which ſhould be done in their proper ſeaſons: for it is not ſo well to have all theſe ſeedling flowers expoſed to public view in the flower garden; becauſe it always happens, that there are great numbers of ordinary flowers produced among them, which will make but an indifferent appearance in the pleaſure garden. *Miller's Gard. Dict.*

NYCTE'LIA, feaſts in honour of Bacchus, ſo called, becauſe they were celebrated in the night; from the Greek word νὺξ, which ſignifies night, and τελεῖν, to ſacrifice, or perform any religious ceremony. Theſe feaſts were celebrated every three years, in the beginning of the ſpring, by night, with flambeaux and drinking, and accompanied with the worſt of inſolences and impurities; wherefore, alſo, the Romans forbad the ſolemniſing of them, becauſe of the horrid diſorders committed at them. *S. Auguſt. de Civitate Dei. Dempſter Paralipom. in Roſin. Antiq.*

NYC'TEUS, the ſon of Neptune by Celene, daughter of Atlas. He had two daughters, Antiope and Nyctimene, by Amalthæa, a nymph of Crete; Nyctimene, by the help of an old nurſe, as the ſtory goes, lay with her own father: but, the thing coming to be known, the father would have ſlain his daughter, had not Minerva out of pity turned her into an owl. *Propert. Ovid.*

NY'MPHA (*Dict.*)—*Nymphs of flies*, in natural hiſtory, is that ſtate of the fly-claſs, which is between their living in the form of a worm, and their leaving that form for that of their parent fly.

In this ſtate, in many genera of the flies, the worm, or maggot,

got, makes a ſhell of its own ſkin, which hardens, and becomes brown, or reddiſh, while the whole of its body becomes detached from it; and, after having lain ſome time in the form of an oblong ball, without any viſible parts of the creature that is to be produced from it, acquires, by degrees, the form of the fly, and all its limbs, and appears an embryo fly wrapped up in an extremely thin and fine membrane. This is properly the nymph ſtate, and, in theſe flies, when the parts of this nymph are more confirmed, and hardened, it is, in reality, no other than the fly wrapped up in this bag, which is ſo very tranſparent that every lineament of the inſect it contains may be clearly diſcerned through it. The wings, however, in this ſtate, appear as if they were not yet perfectly formed, but the truth is, that they are only very nicely and regularly folded together. The creature, however, in this ſtate, though ever ſo perfect, ſeems quite inanimate. When all the parts, however, have acquired their due ſtrength, the creature puts itſelf into motion, and gets looſe from its covering, which is no ſmall difficulty; for, though the ſkin of this is very fine and thin, yet, as it ſerves as a nice caſe to every part of the animal, the effects by which it is to get rid of it muſt be ſomewhat difficult to the creature. A much greater difficulty, however, it will neceſſarily be imagined to be for the embryo fly to get out of the outer ſhell, or caſe, which is uſually firm, hard, and rigid; but nature has ſo ordered it, that no more force ſhall be required for this great work than the creature is able to exert. One of the two ſorts of ſhells of theſe inſects, the one in form of an egg, and the other of the worm itſelf, are the two ways for the fly's egreſs.

For the firſt of theſe, it is always from the ſame end of the ſhell, in form of an egg, that the embryo fly is ſeen to make its way out. This is always that end which is near the head of the fly, and which was, originally, the head of the worm.

The head of the fly, however, is provided with no inſtrument to make this great opening. The point of the trunk is yet very ſoft, and, even when at its utmoſt hardneſs, it could only make a very ſmall and, in a manner, imperceptible hole. Nature has furniſhed the creature with another means of freeing itſelf from this ſhell. The cap at the top of this is made, as it were, of two halves, and they ſo looſely attached both to one another, and to the other part of the ſhell, that they very readily ſeparate with a ſmall force, and fall off from it. But this is not all; for, in every one of theſe ſhells, towards the joining on of the cap to the head part, there are two ribs, or prominent lines, diametrically oppoſite to one another, and reaching to ſome diſtance in the ſhell. Theſe ſeem formed to ſtrengthen the ſhell, but are, in reality, intended to weaken it, and are the places at which it not only eaſieſt breaks, but even ſplits and opens with a ſmall force. This, with the falling off the cap, gives ſufficient room of egreſs to the fly, and may be eaſily diſcovered to be intended ſo to ſeparate by nature itſelf; ſince, in breaking any other parts of the ſhell, it cracks irregularly and indeterminately, but here it ſeparates only at theſe lines.

It is eaſy, indeed, for us by a ſlight force to ſeparate the two pieces of the cap of the ſhell in theſe caſes, and a ſmall force does it; but this, though ſmall to us, is great in proportion to the ſtrength and circumſtances of the nymph, incloſed as it is on all ſides.

The ſkull of the fly to be conſidered, however, is ſolid and cruſtaceous, and of a conſtant and regular figure, as in other larger animals; yet, the fly, in this ſtate, is able to inflate and contract its head alternately, and by that means effects much of the great buſineſs of its liberty. This, extending the bulk of the head, is aſſiſted by a ſort of bladder, which the creature, at each of theſe inflations, puſhes out to ſome diſtance from its head, and which, ſometimes, even equals the head itſelf in ſize.

The air is the only means by which the fly can, in this manner, inflate and ſwell its head; and, when neceſſary, it ſwells its whole body in the ſame manner. The inflation of the head, and the throwing out this ſort of bladder, which is an operation the fly is never able to do afterwards through its whole life, are evidently meant to diſlodge and throw off the cap, and open the ſide lines of the ſhell. *Reamur, Hiſt. Inſect.* Vol. IV.

NYMPHÆ'A, *the water-lily*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the roſaceous kind, conſiſting of ſeveral petals arranged in a circular form; the ſeed veſſel ariſes from the cup of the flower, and is, when ripe, of a globoſe or conic figure, multicapſular, and filled with oblong ſeeds.

The beſt method to propagate theſe plants is, to procure ſome of their ſeed veſſels, juſt as they are ripe, and ready to open: theſe ſhould be thrown into canals, or large ditches of ſtanding water, where the ſeeds will ſink to the bottom; and, the following ſpring, the plants will appear floating upon the ſurface of the water, and, in June and July, will produce their beautiful large flowers. When they are once fixed to the place, they will multiply exceedingly, ſo as to cover the whole ſurface of the water in a few years.

In ſome ſmall gardens, I have ſeen theſe plants cultivated in large troughs of water, where they have flouriſhed very well, and have annually produced great quantities of flowers; but as the expence of theſe troughs is pretty great (their inſides requiring to be lined with lead, to preſerve them) ſo there are few people who care to be at that charge. *Miller's Gard. Dict.*

The plant is of a nitrous, paregoric, aperitive, moiſtening, refrigerating, and ſomewhat narcotic quality. The juice is drank in inflammations of the kidney and bladder. Of the flowers is prepared an oil, which has the ſame virtue as oil of olives, or oil of roſes. The leaves, bruiſed, make an excellent cataplaſm for inflamed parts; and a decoction of the roots and flowers is beneficial in burning fevers, by refrigerating; and the more, if the ſame remedy be applied to the ſoles of the feet and the groins. Of the expreſſed juice of the ſtalks, leaves, and fruit, boiled, is prepared a ſyrup, which is a moſt efficacious remedy for a gonorrhœa, and not the leſs proper when the diſorder is attended with an immoderate heat; for it was always a celebrated medicine for heat of urine. This ſyrup partakes ſomewhat of a narcotic quality, and is, therefore, extolled as a ſpecific in want of ſleep; it, alſo, prevents nocturnal pollutions, and extinguiſhes thirſt. *Hiſt. Plant. adſcript. Boerhaave.*

NYMPHÆ'UM, the name given to a ſort of public baths in the city of Rome, of which there were twelve in number; they were places of pleaſure, adorned with pleaſant fountains, cool grotto's, and curious ſtatues of nymphs, which were very delightful. Hiſtory tells us of many places of this kind that were built in Rome and Conſtantinople, but are now ruined by length of time. Only there is a building ſtill to be ſeen of this kind between Naples and mount Veſuvius in Italy. It is all of marble, and of a ſquare figure, and hath only one gate of entrance, which by ſome ſteps leads down to a large grotto paved with marble of divers colours, and the walls are all covered with ſhell work, in a curious manner repreſenting the twelve months of the year, and the four cardinal virtues. The water of a curious fountain, at the entry of the grotto, fills a canal that ſurrounds the place; and the whole is adorned with the ſtatues and pictures of divers nymphs, and abundance of other pleaſant figures. *Roſin. Ant. Rom.*

NYMPHOI'DES, in botany, the name of a genus of plants, approaching to the nature of the water-lily, or nymphæa, in external appearance, and thence uſually eſteemed a ſpecies of that genus, but improperly.

The characters of this genus of plants are theſe: the flower conſiſts of one leaf, uſually of a rotated form, and divided into ſeveral ſegments at the edge. The piſtil ariſes from the cup, and perforates the bottom of the flower, and finally ripens into a ſoft fruit, or capſule, of an oblong, compreſſed figure, having only one cell, and containing many ſeeds wrapped up in a calyptra.

O.

OAK (*Dict.*)— The characters are:

All the sorts of Oaks are propagated from acorns, which should be sown as soon as possible after they are ripe; for, if they are kept too long out of the ground, they seldom grow.

The manner of sowing these acorns, if designed for a small plantation, or to be removed, is, to prepare some beds of fresh earth, neither too strong and heavy, nor too light and dry; in these beds you should place the acorns in rows one foot asunder, and about two inches distance in the rows, covering them about two inches thick with the same fresh earth; observing to leave none of them uncovered, to entice the vermin, which may, in a short time, destroy all the seeds.

In the spring, when the plants begin to appear, you must carefully clear them from weeds; and, if the season proves dry, you should refresh them now-and-then with a little water, which will greatly promote their growth. In these beds the plants should remain until the following autumn, observing constantly to keep them clear from weeds; at which time you should prepare a spot of good fresh earth, in size proportionable to the quantity of plants, which should be trenched and levelled: then, towards the middle or latter end of October, you should carefully take up the plants, so as not to injure their roots, and plant them out in rows three feet asunder, and eighteen inches distance plant from plant; observing never to suffer the plants to abide long out of the ground, because their roots would dry, and endanger the growth of the plants.

When they are planted, you should lay a little mulch upon the surface of the ground, near their roots, to prevent the earth from drying too fast; and, if the season should prove very dry, you should give them a little water, to settle the earth to their roots.

When the plants have taken root in this nursery, they will require little more care than to keep them clear from weeds, and dig the ground between the rows every spring; in doing of which, you should cut off such roots as extend very far from the trunk of the trees, which will render them better for transplanting again: you should also prune off such side-branches as extend themselves very far, and would retard the upright shoot: but you should by no means cut off all the small lateral branches, some of which are absolutely necessary to be left on, to detain the sap for the augmentation of the trunk; for I have often observed, where trees have been thus closely pruned, that their heads have overgrown their bodies, so that they have bent downward and become crooked.

When these trees have remained in the nursery three or four years, they will then be large enough to transplant to the places where they are to remain; for it is not proper to let them grow very large before they are planted out; because these are very hazardous trees to remove when old, or after they have taken deep root.

The season for this work is, as I said before, in the autumn; at which time, if they are carefully taken up, there will be little danger of their succeeding. When they are planted, the surface of the ground should be mulched about their roots, to prevent its drying too fast: and, if the season is very dry, they should be watered, to settle the earth to their roots, which may be repeated two or three times in very dry weather: but you must carefully avoid giving them too much water, which is very injurious to these trees, when newly removed.

You should also stake them to prevent their being shaken and disturbed by the winds, which would retard their rooting. In transplanting of these trees, you should by no means cut their heads, which is too much practised: all that should be done, must be only to cut off any bruised or ill-placed branches, which should be taken off close to the place where they are produced: but there can be no greater injury done to these trees, than to shorten their shoots; for, when the leading bud, which is absolutely necessary to draw and attract the nourishment, is taken off, the branch often decays intirely, or, at least, down to the next vigorous bud.

The trees, thus raised and managed, will, if planted in a proper soil, grow to a considerable magnitude, and are very proper for a wilderness in large gardens, or to plant in clumps in parks, &c. but, if they are designed for timber, it is much the better method to sow the acorns in the places where they are to remain; in order to which, you should provide yourself in autumn with a sufficient quantity of acorns, which should be always taken from straight, upright, vigorous-growing trees; these should be gathered from under the trees as soon as may be after they are fallen, and, if possible, in a dry time, laying them thin in some open room to dry; after which they may be put in dry sand, and preserved in a dry place until the end of November, when you should prepare the ground for planting them.

The directions here given are designed only for small plantations in a garden or park, which are only for pleasure: but, where these trees are cultivated with a view to profit, the acorns should be sown where the trees are designed to grow; for those which are transplanted will never grow to the size of those which stand where they are sown, nor will they last near so long sound. For, in some places, where these trees have been transplanted with the greatest care, and they have grown very fast for several years after, yet, they are now decaying, when those which remain in the place where they came up from the acorns, are still very thriving, and have not the least sign of decay. Therefore, whoever designs to cultivate these trees for timber, should never think of transplanting them, but sow the acorns on the same ground where they are to grow; for the timber of all those trees which are transplanted, is not near so valuable as that of the trees from acorns. I shall therefore add some plain directions for the sowing of acorns, and managing of the young trees, during their minority, until they are out of danger, and require no farther care.

The first thing to be done is that of fencing the ground very well, to keep out cattle, hares, and rabbits; for, if either of these can get into the ground, they will soon destroy all the young trees. Indeed, they will in a few years grow to be out of danger from the hares and rabbits; but it will be many years before they will be past injury from cattle, if they are permitted to get into the plantation; therefore, durable fences should be put round the ground. If, in the beginning, a pale fence is made about the land, which may be close at the bottom, and open above; and within the pale a quick-hedge planted; this will become a good fence, by the time the pale decays, against all sorts of cattle; and then the trees will have got above the reach of hares and rabbits, so that they cannot injure them; for the bark of the trees will be too hard for them to gnaw.

After the ground is well fenced, it should be prepared, by plowing of it three or four times, and, after each plowing, to harrow it well, to break the clods, and cleanse the ground from couch, and the roots of all bad weeds. Indeed, if the ground is green sward, it will be better to have one crop of beans, pease, or turneps, off the ground, before the acorns are sown, provided these crops are well hoed to stir the surface, and destroy the weeds: for, if this is observed, the crop will mend and improve the land for sowing; but, in this case, the ground should be plowed as soon as possible, when the crop is taken off, to prepare it for acorns; which should be sown as soon as may be after the acorns are ripe: for, although these may be preserved in sand for some time, yet they will be apt to sprout; and, if so, the shoots are in danger of being broken and spoiled: therefore, I should advise the sowing early, which is certainly the best method.

In making choice of the acorns, all those should be preferred, which are taken from the largest and most thriving trees: and those of pollard trees should always be rejected, though the latter are generally the most productive of acorns; but those of the large trees commonly produce the strongest and most thriving plants.

The season for the sowing of the acorns being come, and the ground having been plowed, and levelled smooth, the next work is to sow the acorns; which must be done by drawing of drills across the ground, at about four feet asunder, and two inches deep; into which the acorns should be scattered, at two inches distance. These drills may be drawn either with a drill plough, or by hand, with an hoe; but the former is the most expeditious method, therefore, in large plantations should be preferred. In the drawing of the drills, if the land has any slope to one side, these should be made the same way as the ground slopes, that there may be no stoppage of the wet by the rows of plants crossing the hanging of the land. This should be particularly observed in all wet ground, or where the wet is subject to lie in the winter. When the acorns

are

are ſown, the drills ſhould be carefully filled in, ſo as to cover the acorns ſecurely; for, if any of them are expoſed, they will entice the birds and mice; and, if either of theſe once attack them, they will make great havock with them.

The reaſon of my directing the drills to be made, at this diſtance, is for the more convenient ſtirring of the ground between the rows, to keep the young plants clean from weeds: for, if this is not carefully done, it cannot be expected, that the young plants ſhould make much progreſs; and yet this is generally neglected by many who pretend to be great planters, who are often at a large expence to plant, but ſeldom regard them after: ſo that the young plants have the difficulty to encounter the weeds, which frequently are four or five times the height of the plants, and not only ſhade and draw them, but alſo exhauſt all the goodneſs of the ground, and conſequently ſtarve the plants. Therefore, whoever hope to have ſucceſs in their plantations, ſhould determine to be at the expence of keeping them clean for eight or ten years after ſowing, by which time the plants will have obtained ſtrength enough to keep down the weeds: the neglecting of this has occaſioned ſo many young plantations to miſcarry, as are frequently met with in divers parts of England.

About the end of March, or beginning of April, the young plants will appear above ground; but, before this, if the ground ſhould produce many young weeds, it will be good huſbandry to ſcuffle the ſurface over with Dutch hoes, in a dry time, either the latter end of March, or the beginning of April, to deſtroy the weeds, whereby the ground will be kept clean, until all the plants are come up ſo as to be plainly diſcerned; by which time it may be proper to hoe the ground over again; for, by doing it early, while the weeds are ſmall, a man will perform more of this work in one day than he can in three or four, when the weeds are grown large: beſides, there will be great hazard of cutting off or injuring the young plants, when they are hid by the weeds; and ſmall weeds, being cut, are ſoon dried up by the ſun; but large weeds often take freſh root, and grow again, eſpecially if rain ſhould fall ſoon after, and then the weeds will grow the faſter for being ſtirred; therefore, it is not only the beſt method, but alſo the cheapeſt huſbandry, to begin cleaning early in the ſpring, and to repeat it as often as the weeds are produced.

The firſt ſummer, while the plants are young, it will be the beſt way to perform theſe hoeings by hand; but afterwards it may be done with the hoe-plough; for, as the rows are four feet aſunder, there will be room enough for this plough to work; and, as this will ſtir and looſen the ground, it will be of great ſervice to the plants: but there will require a little hand labour where the plough is uſed, in order to deſtroy the weeds, which will come up in the rows between the plants; for theſe will be out of the reach of the plough, and, if they are not deſtroyed, they will ſoon overgrow and tear down the young plants.

After the plants have grown two years, it will be proper to draw out ſome of them, where they grow too cloſe; but, in the doing of this, great care ſhould be had not to injure the roots of thoſe left; for, as the plants which are drawn out are only fit for plantations deſigned for pleaſure, ſo theſe ſhould not be ſo much regarded in their being removed, as to ſacrifice any of thoſe which are deſigned to remain. In the thinning of theſe plantations, the plants may, at the firſt time, be left about one foot aſunder, which will give them room enough to grow two or three years longer: by which time it may be eaſy to judge which are likely to make the beſt trees. Therefore theſe may be then fixed on, as ſtandards, to remain: though it will be proper to have a greater number at this time marked than can be permitted to grow, becauſe ſome of them may not anſwer the expectation: and, as it will be improper to thin theſe trees too much at one time, ſo the leaving double the number intended at the ſecond thinning will not be amiſs. Therefore, if they are then left at about four feet diſtance in the rows, they will have room enough to grow three or four years longer: by which time, if the plants have made good progreſs, their roots will have ſpread over the ground; therefore it will be proper to take up every other tree in the rows. But, by this, I do not mean to be exact in the removing, but to make choice of the beſt plants to ſtand, whichever rows they may be in, or if they ſhould not be exactly at the diſtance here aſſigned: all that is deſigned here, is, to lay down general rules, which ſhould be as nearly complied with as the plants will permit: therefore every perſon ſhould be guided by the growth of the trees in the performance of this work.

When the plants have been reduced to the diſtance of about eight feet, they will not require any more thinning. But, in two or three years time, thoſe which are not to remain will be fit to cut down, to make ſtools for underwood; and thoſe which are to remain, will have made ſuch progreſs as to become a ſhelter to each other; for this is what ſhould be principally attended to, whenever the trees are thinned: therefore, in all ſuch places which are much expoſed to the wind, the trees ſhould be thinned with great caution, and by ſlow degrees: for, if the air is let too much at once into the plantation, it will give a ſudden check to the trees, and greatly retard their growth; but, in ſheltered ſituations, there need not be ſo great caution uſed as in thoſe places; the plants will not be in ſo much danger of ſuffering.

The diſtance which I ſhould chuſe to allow to thoſe trees which are deſigned to remain for timber, is, from twenty-five to above thirty feet, which will not be too near, where the trees thrive well; in which caſe their heads will ſpread, ſo as to meet in about thirty or thirty-five years: nor will this diſtance be too great, ſo as to impede the upright growth of the trees. This diſtance is intended that the trees ſhould enjoy the whole benefit of the ſoil. Therefore, after one crop of the underwood, or, at the moſt, two crops are cut, I would adviſe the ſtubbing up the ſtools, that the ground may be intirely clear, for the advantage of the growing timber, which is what ſhould be principally regarded: but, in general, moſt people have more regard for the immediate profit of the underwood than the future good of the timber, and, frequently, by ſo doing, ſpoil both: for, if the underwood is left after the trees have ſpread ſo far as that their heads meet, the underwood will not be of much worth; and yet, by their ſtools being left, they will draw away a great ſhare of nouriſhment from the timber trees, and retard them in their progreſs.

The ſoil in which Oak makes the greateſt progreſs, is a deep rich loam, in which the trees grow to the largeſt ſize; and the timber of thoſe trees which grow upon this land, is generally more pliable than that which grows on a ſhallower or drier ground; but the wood of the latter is much more compact and hard. Indeed there are few ſoils in England in which the Oak will not grow, provided there is proper care taken in their cultivation; though this tree will not thrive equally in all ſoils: but yet it might be cultivated to a national advantage upon many large waſtes in many parts of England, as alſo to the great profit of the eſtates where theſe tracts of land now lie uncultivated, and produce nothing to the owner. And, ſhould the preſent temper of deſtroying the timber of England continue in practice ſome years longer, in the ſame degree which it has for ſome years paſt, and as little care be taken to raiſe a ſupply, this country, which has been ſo long eſteemed for its naval ſtrength, may be obliged to ſeek for timber abroad, or be content with ſuch a naval ſtrength as the poor remains of ſome frugal eſtates may have left growing: for, as to the large foreſts, from whence the navy has been ſo long ſupplied, a few years will put an end to the timber there: and how can it be otherwiſe, when the perſons to whoſe care theſe are committed, reap an advantage from the deſtruction of the timber? *Miller's Gard. Dict.*

OAK-*leaf galls.*— Theſe are of ſeveral kinds; the remarkable ſpecies, called the muſhroom gall, is never found on any other vegetable ſubſtance but theſe leaves; and, beſides this, there are a great number of other kinds.

The double gall of theſe leaves is very ſingular, in that, as the generality of productions of this kind affect only one ſide of a leaf, or branch, and grow all one way, this kind of gall extends itſelf both ways, and is ſeen on each ſide of the leaf, in form of two protuberances, oppoſite the one to the other. Theſe are of differently irregular ſhapes, but their natural figure ſeems that of two cones, with broad baſes, and very obtuſe points, though, ſometimes, they are round, or very nearly ſo. Theſe make their firſt appearance on the leaf in April, and remain on till June, or longer. They are at firſt green, but afterwards yellowiſh, and are ſofter to the touch than many other of the productions of this kind: they are uſually about the ſize of a large pea, but ſometimes they grow to the bigneſs of a nut. When opened, they are found to be of that kind which are inhabited each by one inſect only, and each contains one cavity. The cavity in this is, however, larger than in any other gall of the ſize, or even in many others of three times the ſize; the ſides of it being very little thicker than the ſubſtance of the leaf.

On opening theſe leaf galls, which are properly the habitation only of one animal, it is common to find two, the ſtronger preying upon the body of the other, and ſucking its juices, as it does thoſe of the leaf; often, it is found wholly employed in devouring its unoffending neighbour at once: this is probably the caſe when its time of eating is nearly over; and, in fine, when we find the gall inhabited by only one inſect, or containing only one chryſalis, as it ought in its natural ſtate to do, we are never certain that this is the proper inhabitant, as it may be one of theſe deſtroyers who has eaten up the other, and ſupplied its place. *Reaumur's Hiſt. Inſ.*

OAK *puceron*, a name given by naturaliſts to a very remarkable ſpecies of animal of the puceron kind. The generality of ſuch animals live on the ſurface of the branches and leaves of trees and plants; but theſe bury themſelves in the clefts of the Oak, and ſome other trees, and, getting into the crevices, where the bark is a little ſeparated from the wood, they there live at eaſe, and feed to their fill, without being expoſed to their common enemies.

Black OATS.— Theſe are commonly ſown upon an etch crop, or on a lay, which they plow up in January, when the earth is moiſt, taking care to turn the turf well, and to lay it even and flat. Oats are to be ſown earlier in the northern parts of England than in the ſouthern.

Oats are ſown with a broad caſt, at twice, as they do barley, harrowing it well in; but this muſt always be harrowed the

ſame

fame way that the furrows lie of a lay, or but very little crofs, for fear of raifing the turf, but upon an etch, as foon as the land is plowed on an edge, they fow and harrow it in once; then fow it a fecond time, the full quantity, and harrow it five or fix times over, obferving to harrow once or twice acrofs, which breaks the clods, and covers the feed better than harrowing all one way. They commonly fow them upon a broad ridge, which they give the land but one plowing for. The ufual time for fowing black Oats, is, in the beginning of February, or a very few weeks later, fometimes not till the beginning of March: they are a hardy grain, and will bear any thing of wet or cold. Four bufhels of feed is the quantity for an acre; but they grow beft on a moift land, though they will not mifs any where. The farmer knows that his Oats are ripe when the ftalks turn yellow, the grain feels hard, and the hufk begins to open, and fhew the feed. After they are cut, they fhould lie for the dew and the rain to plump them, and make them thrafh well; and, if weedy, to kill the weeds: but, if there happen much rain, they muft be got in again as foon as dry, otherwife the Oats will foon fall out of the hufks, and great part of the crop be loft.

Red OATS.— The red Oat is a kind of corn very common in Staffordfhire, and fome of the northern counties; it is a fort of naked Oat, and is very proper for making Oat-meal, becaufe the kernel thrafhes out of the hull, without carrying it to the mill, or drying of it. This Oat is cultivated in the fame manner as barley.

White OATS.— This kind of Oats is commonly fown upon an etch, after wheat, rye, or barley: they only give the land one plowing, and fow them, and harrow them, as they do the black Oats, except the land is fubject to weeds; in that cafe, it is good to plow up the wheat, or rye ftubble, in November, which will make it rot the better, and be a kind of winter fallowing. Only, if you have a very dry burning ground, which black Oats will not delight in, in that cafe, they often fow them upon a lay. March and April are the ufual time of fowing white Oats, and the drier the weather is when they are fown, the better; they grow beft upon a dry, gravelly, or fand, land, and they are the beft of all to be fowed upon a land very fubject to weeds, becaufe, being fowed late, they allow a very late plowing, and, growing very quick after this, they over-top the weeds fooner than any other plant. The reaping of white Oats is the fame with that of the black, and they generally yield about the fame quantity, that is, twenty bufhels, or there abouts, from an acre. *Mortimer's Hufbandry.*

Wild OAT, in hufbandry, a kind of Oat, or Oat-grafs, which comes up of itfelf, without fowing, and is much hated and dreaded by the farmers. This, in many counties of England, is the greateft of all hindrances of the good crops of barley, and often of other grain. It is a rough and hairy Oat, and ufually black. In the wetter years, and after much froft, this is found to be moft troublefome.

The beft remedy the farmer has againft this, is, to fow the land moft apt to produce it with beans, and, when they are come up to about three inches high, to turn in fheep upon the ground, about twenty fheep to an acre; thefe will eat up all the fhoots of the wild Oat, and not touch the beans, fo long as there is any of the Oat fhoots left. *Morton's Northampt.*

O'CCUPIERS *of walling*, a term in the falt works for the perfons who are fworn officers, that allot, in particular places, what quantity of falt is to be made, that the markets may not be overftocked, and fee that all is carried fairly and equally between the lord and tenant. Thefe perfons always appoint how many houfes fhall work at a time; and, when there is falt to be made, thefe appoint a cryer to proclaim it to all the workers, that they may put to their fires at the fame time; and a like proclaiming of the time when they fhall leave off; and thofe who continue to work, after this prohibition, are to have their falt fpoiled or deftroyed. *Ray's Englifh Words.*

O'CHRA *vitrioli*, in natural hiftory, a name given to that yellow earth or ochre, which is one of the principles or conftituent parts of all vitriol. This is feparated from it by folution in water, and falls to the bottom of the veffel; and the yellow fubftance that tinges the fides of fountains, and fprings of chalybeate waters, in many places, is the fame fubftance, and fhews that they are only folutions of vitriol; which, as fuch, muft needs depofit that earth, which, though retained imperceptibly in the vitriol, yet cannot be fuftained in water fo well as while that falt was folid. A great proof of the earth called Ochra vitrioli being contained in a large quantity in that falt is, that it requires no earth befides to be mixed with it in diftillation: whereas common falt, nitre, and the other falts, require a great quantity of common earth to be added to them, to prevent their fufion. Alum, and vitriol alone, require no fuch additions, the firft of thefe containing a very large quantity of an alcalious white earth, as the other does of an ochreous yellow one.

O'CHRE, in natural hiftory, the name of a large genus of earths, ufed principally by the painters. The moft common kinds are either yellow or red, though there are brown, blue, and green Ochres, and a number of diftinct fpecies of all thefe colours. Of the yellow Ochres, Dr. Hill, in his Hiftory of Foffils, defcribes eleven fpecies. Of the red, the fame number. Of the brown, two. Of the blue and green, one fpecies each; and, of the black, two.

The greater number of thefe are, or have been, at one time, or other, in ufe in painting, in different parts of the world. Some, however, there are, efpecially of the yellow and red kinds, which that author has, himfelf, difcovered in different parts of our own and other kingdoms, which are worthy the trials of the perfons concerned in that branch of trade, as they have already been proved, at his requeft, in fmall quantities, and found to anfwer very well. *Hill's Hift. of Foff.*

Dr. Lifter obferves, that ochreous earths are feparated, in greater or lefs quantities, from all the medicinal fprings in England, and it is to thefe and the nitrous and muriatic falts that they all owe their virtues. The Ochre they contain, is ufually of the nature of that which our painters, to diftinguifh it from the yellower kind, call brown Ochre. This is produced from the iron ores that are met with in the way of the current of thefe waters; and, among the reft, the pyrites afford a great deal of them. All kinds of the pyrites, and all the lime-ftones of England, when they are fubject to be much moiftened under ground, will, in time, fhoot out their falts, and part with their earths. *Lifter. de Font. Med. Angl.*

The earth of the pyrites is Ochre, and the falt of the limeftone is the calcarious nitre, an alkaline falt of the nature of the natrum of Egypt; and from thefe two fubftances, and a fmall portion of common falt, which the waters take up in their paffage through the earths that contain it, all the virtues of them are owing. The falt of the pyrites being green vitriol, it might be expected, that this fhould be found in the waters impregnated by that fubftance; but Dr. Lifter obferves, that, though there are many fprings in England which are well known to receive their virtues from this foffil, yet there is no fuch thing as vitriol to be obtained from any of them; and this is not wonderful, fince we know that the pyrites will not yield its vitriol, when newly taken out of the earth, but muft be expofed a confiderable time firft to the air; fo that the Ochre is the only fenfible thing that it receives from this fubftance, and, perhaps, with it fome faline matter which is the bafis of vitriol, and would be vitriol in time, on a due expofition to the air.

OCTA'NDRIA, in botany, a clafs of plants with hermaphrodite flowers, and eight ftamina, or male parts, in each. See *Plate* XXXVI. *fig.* 4.

* The word is formed of the Greek ὀκτὼ, eight, and ἀνὴρ, male.

The plants of this clafs are the maple-tree, heath, &c.

OCU'LUS *beli*, in natural hiftory, the name of one of the femipellucid gems of the genus of the hydrophanæ, and called by Dr. Hill hydrophanes albido-cinereus, flavo-variegatus, nucleo centrali nigerrimo, or the greyifh white hydrophanes, variegated with yellow, and with a black, central, nucleus. See *Plate* XXXVI. *fig.* 5.

It is a very elegant and beautiful gem. Its bafis, or ground, is a whitifh grey, variegated with yellow, and fometimes with red, and a little black, but that more rarely, and is found in fmall maffes from half an inch to an inch in diameter; of a rounded figure, and thickeft in the middle, tapering away gradually to the fides. The outer part of the ftone, or that toward the edges all round, is ever of a whitifh grey, more or lefs variegated with yellow, &c. and its central nucleus is always of a deep and fine black, furrounded by a broad circle, of a pale yellow, and reprefenting very beautifully the pupil and iris of the eye; thefe are inclofed in the matter of the ftone, and are often furrounded by other very fine concentric circles, of a pale flame colour; but more frequently there is only the black pupil, furrounded by the yellow iris, and that placed in the body of the ftone which reprefents the white of the eye: the fhape of the ftone alfo favours its refemblance of an eye, and the whole is very elegant. It is of the hardnefs of the agate, and takes a tolerable polifh; when thrown into water, it has, in a great meafure, the property of the oculus mundi, the whole ftone becomes greatly more bright and lucid, and the grey part becomes of a plainly yellowifh caft.

There are many things improperly called Oculus Beli by our jewellers, but the genuine fpecies is very rare. Nothing is more common than to find in the agates little circular veins of different colours round a central fpot; thefe the lapidaries frequently cut out, with a proper quantity of the ftone about them, and call them Oculus beli. They are not peculiar to the agate, but are common alfo in the cornelian, and ftand fometimes fingle, fometimes two or three together, and, according to the colours of the circles, reprefent the eyes of various animals.

OCULUS *mundi*, in natural hiftory, the name of one of the femipellucid gems of the genus of the hydrophanæ. It is of one plain and uniform colour, which is a whitifh grey, and has no veins, or other variegations. It is found in fmall maffes, of the fhape of our common flints and pebbles. It has but a very obfcure degree of tranfparence, and is not capable of a fine polifh. This ftone, however, though of little beauty, has this fingular property, that, when thrown into a bafon of water, in the fpace of half a minute, it begins to change its appearance, and, very foon, inftead of a pale grey, becomes of of a very bright, and confiderably pellucid, pale yellow, like that of amber, or the yellow cornelian; this it retains as long as it remains in the water, but as foon as taken out, and dried, it refumes its grey colour, and becomes as opake as before. It is found, fo far as is yet known, only in China; but the fhores of fome of our own rivers afford us ftones coming up to its qualities in fome degree, though not fo beautifully tranfparent in water as the oriental. *Hill's Hiftory of Foffils.*

OLDENLA'NDIA, in botany, a genus of plants, whofe characters are:

It hath a rofe-fhaped flower, confifting of one leaf, which is divided into four parts, almoft to the bottom, and refts on the empalement; which empalement, afterwards, becomes an almoft globular fruit, having two cells, which contain many fmall feeds.

This plant was difcovered in America by father Plumier, who gave this name to it, in honour to Henry Bernard Oldenland, a German, who was a difciple of Doctor Herman, at Leyden, and was a very curious botanift. *Miller's Gard. Dict.*

OEDE'MA (*Dict.*)—The immediate caufe of an Oedema is doubtlefs to be afcribed to the too great ferofity or vifcidity of the blood, which ftagnates in the minute veficles of the fat or tunica cellulofa, and diftends the fkin. This diforder of the blood proceeds either from a cold and phlegmatic habit, or old age; and it happens moft frequently in cold weather, when the inclemency of the air increafes the difeafe, by coagulating the ftagnating blood. It is not, therefore, furprifing, that the tumor prodigioufly increafes, though it may feem favourable and much diminifhed in the morning; which is certainly to be afcribed to the warmth of the bed. This diforder may, alfo, proceed from an irregularity in diet, from an excefs in eating and drinking, or from the ufe of cold, crude, and hard meats. Fevers, particularly thofe of the intermitting kind, frequently conduce to this difeafe, efpecially if the patient has indulged himfelf in intemperate drinking, while the heat and thirft are upon him. Another caufe may be a profufe difcharge of blood, either by wounds or vomiting, or from the nofe, lungs, hæmorrhoids, or uterus. It may, alfo, arife from obftructions of the menftrual difcharge in women, or from a compreffion of the vena cava by the fœtus or a fcirrhus in the abdomen, by which means the reflux of the blood from the lower extremities is greatly impeded. It may likewife be afcribed to a life too fedentary, or too great an indulgence of lying in bed and fleeping; or to a phthifis, and difficulty of breathing; or to any other difeafe or fatigue of the body, which weakens the natural vigour of the heart in propelling the blood.

Hence it may eafily appear, by what fymptoms an Oedema may be known; but it is neceffary to obferve, that the harder the tumor is, and the longer it retains the print of the finger, the ftagnating blood or humour is the thicker and more tenacious.

An Oedema upon the feet can fcarcely be cured without removing the diftemper whence it fprings. In pregnant women, efpecially thofe of a robuft conftitution, œdematous tumors are attended with little or no danger; for they generally difappear fpontaneoufly after delivery, the vena cava being then freed from its compreffion. In weakly women the danger is greater, if they continue after delivery; as they are frequently fucceeded by a dropfy, an afthma, and even a fuffocation. The longer the duration is of thefe phlegmatic tumors, the greater is the danger, and the cure more uncertain; but, when they are recent, and attended with no other difeafe, the cure may be readily effected. Thofe, alfo, which follow an intermitting fever are milder than thofe which proceed from a too copious difcharge of blood, or any other weaknefs. If they proceed from the obftruction of a natural evacuation, they are beft cured by removing that obftruction. This diforder of the feet is eafily remedied in young perfons, but in the aged it is often incurable. When the feet are violently tumefied, and remedies, efpecially external applications, have little effect upon them, the confequence is, generally, a difficulty of breathing, fuffocation, and, at laft, death.

The cure of oedematous tumors is different, according to the different difeafes whence they proceed; and, therefore, it is, in the firft place, neceffary to inquire into their caufe. When they appear to arife from an internal diforder, recourfe muft not only be had to outward application, but principally to internal medicines. With regard to external applications, 1. Ufe frequent frictions, with warm cloths every morning and evening, till the feet grow red, and glow with heat. 2. In order to defend them from the inclemency of the air, efpecially in winter, let the legs be wrapped in furs, or other thick coverings; and, at night, let warm ftones, or pieces of oak, be laid under the feet in bed, for attenuating the blood. 3. Let a proper bandage be applied, beginning with the foot, and proceeding gradually to the knee, which will greatly ftrengthen the relaxed limb, prevent any collections or ftagnations of the blood, and the fkin from being diftended by the infpiffated blood. 4. Digeftive and ftrengthening medicines fhould likewife outwardly be applied; thus let the affected leg be placed over burning rectified fpirit of wine, and fo covered with cloths, as to receive and retain the vapour: by this method the ftagnating blood will either be perfpired in fweat, or returned to the circulation; and the relaxed leg will be wonderfully ftrengthened. 5. A remedy, often ufed by the vulgar, is the greater celandine, bruifed and applied with cloths to the feet. Others ufe in the fame manner water-pepper, either alone, or mixed with celandine, and not without fuccefs; for they are both powerful refolvents. Others apply the fcrapings of horfe-radifh, or a warm cataplafm of dittander, boiled in wine. An excellent difcutient, for this purpofe, is a cataplafm of pigeons dung mixed with falt and vinegar, which muft be often applied warm. Of equal efficacy are the following fomentations, a lixivium prepared from the afhes of oak, and the water in which blackfmiths cool their hot iron, which may likewife be mixed with fome ounces of fpirit of wine and a fmall quantity of alum, and applied warm with compreffes; or the feet may be bathed twice a day in this liquor. Lime-water applied in the fame manner, either alone, or mixed with fpirit of wine and alum, is very beneficial in this cafe, as is the following mixture:

Take of fpirits of wine, and wine vinegar, each a pound; crude alum, an ounce and an half; vitriol, a drachm: mix them together.

It is neceffary to obferve, that, after the ufe of the friction and fomentations, the leg muft be carefully wrapped up with bandages, and warm ftockings, or coverings; and the patient muft not only be very moderate in eating and drinking, but muft alfo ufe frequent motion and exercife, and never neglect proper internal medicines, without which all the external applications will nothing avail. Sometimes the mineral waters are very efficacious, in this diforder, though they do not always fucceed. Dr. Harris fays, that he has frequently removed this difeafe, by exhibiting the aperitive crocus of iron, mixed with the Peruvian bark; others affert, that they have done it with the bark alone, though fome condemn thefe remedies. It is therefore, proper, in this point, to take the advice of a phyfician. *Heifter's Chirurg.*

OENA'NTHE, *water dropwort*, in botany, the name of a genus of umbelliferous plants, the characters of which are thefe: the flower is of the rofaceous kind, compofed of feveral heart-fhaped petals, which are irregular in fize, and are difpofed in a circular form, on a cup, which afterwards becomes a fruit compofed of two oblong gibbofe ftriated feeds, which are flatted and fmooth on their inner fide, and end in a fort of prickles, the middle one of which is longer and ftronger than the others.

One of the fpecies of this plant, diftinguifhed by its yellow juice, and by its growing near waters, is a very terrible poifon. Many accounts have been given of people dying by it, but none which fets its terrible effects in fo juft a light, as one which happened very lately to fome French prifoners with us, and which is recorded in the Philofophical Tranfactions. Eleven French prifoners had the liberty of walking in, and about, the town of Pembroke; three of them, being in the fields, a little before noon, found, and dug up, a large quantity of this fatal plant, with its roots, taking it to be wild celeri, in order to eat with their bread and butter, after dinner; and, when they had wafhed it, they all three tafted, or eat a fmall quantity of it, in the fields.

As they were entering the town, one of them, without any previous notice of ficknefs at the ftomach, or diforder in the head, was immediately feized with convulfions; the other two ran home, and fent a furgeon to him, who attempted to relieve him by bleeding, but in vain, for he died in a very little time. The other two prifoners, wholly ignorant of the caufe of their comrade's death, and of their own danger, gave the roots they had brought in to the other eight prifoners, who all eat more or lefs of them with their dinner. A little while after dinner, the two remaining perfons who had gathered the roots, were feized in the fame manner as the firft, and one of them died, but the other recovered, having been blooded, and a vomit having been, with great difficulty, forced down his throat, as his jaws were, in a manner, locked together. The other eight were all immediately bled and vomited, and all recovered.

It is obfervable, that none of thefe perfons had thofe comatofe fymptoms which are well known to attend thofe who have eaten the common cicuta, or hemloc.

This root is well known in all that part of England, under the name of the five-fingered root, and is in frequent ufe externally with the common people, for the felon, or worft fort of whitloe. The Frenchmen eat only the root, and none of the leaves or ftalk.

It is extremely neceffary that this dangerous plant fhould be well known, as it grows very plentifully with us all about the banks of the Thames; and Mr. Watfon has caufed a fine drawing, both of this, and another poifonous plant, which it is often confounded with, the cicuta aquatica, or water hemlock of Wepfer, to be prefixed to that number of the Tranfactions where this account is given: and, this feems the more neceffary, as the plant appears to have been miftaken, in a manner, by all the world, not only the common people, but the more verfed in plants, having miftaken it at times for feveral very different things. The fame gentleman informs us, from various authors, that eight lads in Ireland had been poifoned by it, miftaking it for the root of the water parfnip; two men died by miftaking it for the Macedonian parfley; and Wepfer, who wrote an exprefs treatife on the poifonous nature of the water hemlock, has confounded this plant with it, faying, that Lobel had defcribed the water hemlock, under the name of this Oenanthe, or dropwort; and the generally accurate Hoffman, when treating of the vegetable poifons, makes no mention of the difference between thefe two plants.

OESO'PHAGUS (*Dict.*)—Conftrictions, whether in the pharynx, or middle of the gullet, when neglected, not only become chronical, but, alfo, by hindering the deglutition of the aliments, readily bring on a confumption, they, therefore, deferve to be expeditioufly treated by proper and fuitable remedies: and thefe remedies are of two kinds; the one calculated for allaying the fpafms, and the other for removing the caufes contributing to their production.

The former of thefe intentions is obtained by antifpafmodics and anodynes, joined with difcutients, and ufed both internally and externally; but, the more violent the conftriction is, the more expedient it is to begin the cure with external applications, becaufe internal medicines can hardly be fwallowed without the greateft difficulty. Some of thefe external medicines, by drawing the afflux of the humours to the inferior parts, and rendering the circulation of the blood equal, breaks the force of the fpafms: of this kind are clyfters, and bathing the feet. The clyfters ought to be prepared of emollient fubftances, with an addition of corroboratives, and repeated twice or thrice. The baths for the feet are to be pretty warm, and the legs are to be immerfed pretty deeply in them. The topics to be applied to the part affected are generally paregoric and nervous linaments, which may be prepared of aqua Anhaltina, fpirit of fal ammoniac, the effences of faffron and nutmeg, caftor, and camphire, and the balfam of life; which, if mixed with the anodyne mineral liquor, is an excellent medicine, when the difeafe is at its greateft height. It alfo proves beneficial, when a few drops of it are poured upon fugar, kept in the mouth, and flowly fwallowed. This intention is, alfo, anfwered by a few grains of theriaca, kept under the tongue, and fpit out. An ox's bladder full of fome warm emollient decoction, and applied to the part affected, is, alfo, of confiderable fervice in relaxing the fpafms.

Among internal antifpafmodics, the moft valuable are the oils of fweet almonds, and of olives, mixed with fperma-ceti; antifpafmodic powders, prepared of cinnabar; the pulvis Marchionis, prepared amber, and the extracts of faffron and caftor, or the nitrous powders, with one or two grains of camphire; as, alfo, the anodyne liquor, either alone, or mixed with effence of caftor; the fpiritus befoardicus buffii, or the fuccinated fpirit of hartfhorn, or the fpiritus nitri dulcis, mixed with a few drops of the genuine oils of chamomile or mace: but, when the diforder becomes chronical, we may ufe alternately, every other day, with thefe, antifpafmodic pills, which I generally prepare of the extracts of yarrow, chamomile, and St. John's-wort, mithridate, the extracts of faffron and caftor, and the diftilled oils of mace or mint.

When the fpafms are alleviated, the phyfician who intends to remove the material caufes of the diforder, ought carefully to inquire, which of them contribute to its production; for, if the diforder is produced by acrid fubftances, poifons, draftic purgatives, or emetics, their force is, with all expedition, to be obtunded with mucilaginous and oleous fubftances, and with preparations of milk. This intention is anfwered by pretty pinguious broths, and draughts of warm water continued to a naufea, that, thus, a gentle vomiting being excited, the poifon may be again carried off.

Sometimes acids fubdue the force of poifon: and by thefe Hoechftetterus, in a cafe of this nature, affirms that he cured a conftriction of the gullet, produced by malmfey wine in which confound had been boiled. And Foreftus, in the part before-mentioned, informs us, that a conftriction of the gullet, produced by aqua-fortis, was happily cured by mucilage of quinces.

When violent anger, excited at meals, brings on fpafms of the gullet, there generally happens, at the fame time, an effufion of bile into the ftomach. In this cafe, befides the mitigation of the commotions, the bile is to be corrected, left it acquire a corrofive and virulent quality; after which, it is to be eliminated from the body by gentle emetics or cholagogues. The bile is corrected by abforbent or mucilaginous fubftances, fuch as decoctions of oats or barley. The bile, on the other hand, is moft commodioufly eliminated by preparations of manna, joined with thofe of rhubarb, or by vomit, when thefe preparations are heightened by one or two grains of emetic tartar or ipecacuanha. But we are to take care, that the emetic, or the purgative, be not exhibited immediately after the fit of anger.

But if the fpafms of the gullet are produced by a dyfcrafy of the whole mafs of humours, or, particularly, if acrid and vifcid fordes of the primæ viæ lay a foundation for a long-continued diforder of this kind; thefe fordes are to be corrected by inciding, refolvent, digeftive, and abforbent medicines; and evacuated by preparations of manna, rhubarb, and the pilulæ balfamicæ. But as the diforder frequently proves obftinate to this treatment, there will be no medicine found more efficacious, than medicinal waters; among which, the beft are thofe of Sedlitz drank for about four days, and then fucceeded by thofe of Egra. In hypochondriacal diforders, alfo, where the excretions of blood, whether by the uterus or hæmorrhoidal veins, are fuppreffed, befides venefection and exercife, the Caroline baths, duly ufed, are, of all other things, the moft beneficial.

Chronical fpafms of the Oefophagus, which depend on a weaknefs of the nervous fyftem, and often recur, are rather to be cured by dietetic preparations and aliments, than by ftrong medicines; for, in this cafe, we are, for ordinary drink, to chufe decoctions prepared of viper's-grafs, fuccory, and cinnamon. All malt liquors are to be abftained from, and the patient is to ufe generous wine moderately. The aliments are to be light, and fmall in quantity, but exercife is to be frequently ufed. For corroborating the ftomach, balfamic elixirs, prepared without a fpirituous menftruum, are to be ufed. The redundance of the blood is to be diminifhed by properly repeated venefections; and the generation of fordes in the primæ viæ is to be prevented by gentle laxatives. But, above all, the paffions of the mind, which fo greatly contribute to the production of fpafms, are to be carefully guarded againft; then the Caroline fprings, and afterwards the baths of Toeplitz, are to be ufed. *Frederic Hoffman.*

O'FFA *Helmontiana*, the name of a celebrated chemical medicine prepared in the following manner:

Take of the alcaline fpirit of fal ammoniac, fo ftrong as to leave much of its falts undiffolved at the bottom; put it into a cold and dry cylindrical glafs, with a narrow mouth, fo as to fill about one half thereof; pour to it, gradually, a quantity of pure cold alcohol, fo as to run gently down the fides of the veffel, till it be full; a white coagulation will be made upon the furface, where the lighter alcohol refts upon the alcaline fpirit. If the glafs be now inverted, there will inftantly appear a white opake coagulation, where the alcohol and alcaline fpirit mix; and, when they are both well fhaken together, the whole becomes a white opake confiftent mafs, concreted together like ftone, fo that not a drop will fall out of the glafs, while inverted. Stop the veffel clofe, and fet it by: thus the mixture will foon refolve into a fluid, that floats at top, and a denfe, faline concretion, that falls to the bottom; fo that, in a year's time, the falt will almoft become folid below, with a liquor floating above it. If the whole mafs, thus produced, be diftilled with a foft fire, an alcaline, balfamic, oily, folid falt will fublime. The colder the feafon, and the place, in which the experiment is made, the better it will fucceed.

Remarks.— This is one of the moft difficult experiments in chemiftry, as it requires both the liquors to be perfect, and the obfervance of feveral circumftances, any one of which, being wanting, will caufe it to mifcarry; but, if they all be obferved, it will fucceed. Here, then, we fee, that pure volatile alcaline falt will clofely attract to itfelf the moft fubtile oil that is known, that is, alcohol; whence the foap fo produced is the moft fubtile and penetrating of all foaps, confifting of an exceeding fubtile and volatile alcali and oil, wonderfully united together in an inftant. If this medicine be diluted with canary, and taken upon an empty ftomach, it paffes, perhaps, through all the veffels of the body, refolves concretions, open obftructions, excites the vital powers, and thus fuccefsfully cures many dangerous diftempers, proceeding from an obftructing matter, capable of being refolved by it. But its virtue vanifhes too foon, as being fo extremely volatile, and therefore becomes unequal to the more ftubborn diftempers. It is highly commended in the jaundice, unattended with an acute inflammation; it does not diffolve the ftone, or prevent the concretion or increafe thereof; it feems to agree with falt of tartar rendered volatile; it diffolves in a gentle heat, like ice, and returns to a folid form in the cold. If pure alcohol be thus mixed with one third of dry volatile alcali, it makes a much more folid foap, as being without water, which is always double the quantity in the ftrongeft alcaline fpirit, with refpect to the pure falt. Helmont needed not have apprehended the fudden generation of the ftone from hence; for this matter is not the ftone, but diffolves with heat, dilutes with water, and proves totally and fpontaneoufly volatile, fo that it has nothing in common, nor like to the ftone. Helmont was not the inventor of the experiment, though the production be called Offa helmontiana; but Raymond Lully, long before him, and the Englifh author upon the Alcaheft, fuppofed to be George Starkey, inconfiderately pretends, that this foap, brought to a liquor by repeated diftillation, will become the alcaheft of Helmont. *Boerhaave's Chemiftry.*

OIL (*Dict.*)— In the diftillation of Oils there is a confiderable difference, with refpect to the quantities yielded; for fome vegetables afford a large portion, others a moderate quantity, and others but very little. Among all the productions of the earth, I know no fimple, which, befides its turpentine, yields a larger quantity of Oil, than favine; fince one pound of it, in the alembic, yields almoft three ounces of Oil. Hence, from two pounds of it, if the diftillation is duly managed, at leaft five ounces of Oil may be obtained. Savine is fucceeded by nutmegs, a pound of which yields one ounce of oil, which,

by

by diſtillation from an alembic, is raiſed, whilſt, at the ſame time, there is left at the bottom a large quantity of Oil which does not paſs over the helm, but is generally expreſſed from the nutmegs. Hence, it is obvious, that theſe nuts abound with a large quantity of mild and fixed Oil, which is obtained by expreſſion, as, alſo, with a ſubtile Oil procured by diſtillation.

Among flowers, thoſe of the ſpike abound moſt in Oil. Hence, four pounds of thoſe flowers, when dried, afford full three ounces of Oil; but a ſmaller quantity is obtained from the flowers of lavender, ſince four pounds of them yield only one ounce of Oil; which, however, is of a far more grateful and fragrant ſmell, than that of ſpike. Four pounds of the leaves of mint, gently dried, yield an ounce and an half of Oil; whilſt, from an equal quantity of the leaves of marjoram, hardly one ounce can be obtained. From fifty pounds of calamus aromaticus I only obtained two ounces of Oil: there is but a very ſmall quantity of Oil in mother of thyme, neither is there a large quantity of Oil afforded by rue: and, though this plant is of an acrid taſte, and penetrating ſmell, yet ten pounds of it yield only half an ounce, or two or three drachms, of Oil. Hence it is certain, that, in this ſimple, the ſaline is ſuperior to the oleous principle.

The flowers of the common and Roman chamomile yield but a very ſmall quantity of Oil; for which reaſon it muſt, when genuine, be ſold at a pretty dear rate; for the Oils of that kind, as commonly ſold, are almoſt all adulterated: the calamus aromaticus, alſo, though of a pretty acrid taſte, affords but little Oil.

The four carminative ſeeds, which are, aniſe, dill, caraway, and fennel, yield a large quantity of Oil; but thoſe commonly ſold are generally adulterated.

We are, alſo, to advert to the ſpecific and diſtinguiſhing taſte and ſmell of ſome Oils. Thus, the Oils of thyme and ſavory are ſo acrid as to corrode the noſtrils. The Oil of wormwood, which is highly bitter, fills the head with a fœtid vapour; and it is to be obſerved, that this oil, when diſtilled from green wormwood, is green; but of a browniſh-yellow colour, when obtained from old wormwood. The Oil of chervil, in taſte, reſembles that of fennel; Oil of tanſey, in ſmell, greatly reſembles the herb from which it is obtained.

It is in a particular manner to be obſerved, that plants, and their various parts, whether ſeeds, flowers, or leaves, do not in all ſeaſons, and at every age, yield equal quantities of Oil; for, if mint, thyme, rue, balm, or marjoram, when recent, tender, and young, are ſubjected to diſtillation, they yield little or no Oil; but they muſt be arrived at a juſt degree of vigour and perfection; when, for inſtance, they begin to riſe into ſmall heads or flowers: and, as, in old animals, the ſtrength is much impaired and diminiſhed, ſo, alſo, old plants loſe a great deal of their virtues, and yield but little Oil. Hence, it is obvious, that the perfect ſtrength and maturity of plants conſiſts in the abundance of the Oil they contain, and which is either large or ſmall, according to the period of their age.

It is, alſo, to be obſerved, that the ſeaſons and conſtitutions of the year contribute greatly to the obtaining a larger or ſmaller quantity of Oil; for I have often obſerved, that, if the ſpring or ſummer are too moiſt or rainy, herbs, and their flowers, ſpike, for inſtance, or lavender, do not yield ſo large a quantity of Oil, as when the ſeaſons are moderately warm and dry: hence we learn, that a due temperature, purity, and drineſs of the air and weather, contribute greatly to bring vegetables to their due maturity and perfection.

Adulteration of diſtilled OILS.— It is a ſhameful, though true, aſſertion, that the true and genuine Oils of plants are rarely to be had in the ſhops; ſince, in order to increaſe their weight and price, it is cuſtomary, in diſtilling them, to mix with them ſome pinguious or other ſubſtances of little value. As for the dear aromatic Oils exported from Holland, it is certain from experience, that they are almoſt all adulterated, as is obvious in the Oils of cinnamon, cloves, nutmegs, and mace. But in theſe the fraud is eaſily detected, by pouring alcohol of wine, or highly rectified ſpirit of wine, upon them; for this liquor immediately reſolves and imbibes the particles of the purer Oil, leaving, in the bottom, a large quantity of expreſſed Oil, either of almonds, or ben-nuts. But the more ſkilful of the chemiſts have an artful method of concealing this piece of fraud; for they adulterate pure Oil of cinnamon, or cloves, by adding an equal quantity of highly rectified ſpirit of wine, which may be ſo prepared, that one part of the ſpirit may abſorb one part of the Oil, whilſt the taſte remains, and the ſmell continues ſufficiently ſtrong and penetrating, ſo that the impoſition is with difficultly diſcovered. But this piece of fraud is, alſo, quickly diſcovered, if theſe Oils are poured into common water; for, then, the water immediately becomes milky, which effect is not produced by pure oil, when put into cold water, and left to itſelf. There is ſtill another method of adulterating Oils of plants, by mixing Oil of turpentine, or pine, with the herbs to be diſtilled; and this piece of fraud is moſt commonly committed in preparing cephalic Oils from plants, which abound with a balſamic reſin, ſuch as mint, origanum, ſage, roſemary, marjoram, ſavory, thyme, mother of thyme, the flowers of ſpike and lavender, and baſilicon; from which, by the addition of theſe Oils, they obtain a large quantity of Oil, though of a bad kind, and inconſiderable virtues; but ſuch Oils, if the plants are recent, retain their ſpecific and diſtinguiſhing taſte and ſmell. But this piece of fraud is eaſily detected; for, if ſuch Oils are kept ſome time, they loſe their grateful ſmell, and the diſagreeable odour of the turpentine remains. But there is ſtill a more expeditious method of diſcovering this fraud; for, if a piece of cloth macerated in ſuch Oil is put into a warm place, or expoſed to an hot furnace, the ſubtile fragrance is immediately exhaled, and the ſmell of turpentine diſcovers itſelf.

Beſides, the cephalic Oils, adulterated with turpentine, or Oil of pines, are more limpid than the genuine Oils, which are of a deeper colour. There is, alſo, another method of detecting this fraud; which is, when the letters of the ſignature put upon the mouth of the glaſs become ſucceſſively pale, which does not happen with the genuine Oils; for the effluvia of the turpentine contain a ſubtile acid, which, in proceſs of time, deſtroys the colour of the ink. Some, in the diſtillation of theſe Oils, inſtead of turpentine, add ſeeds which contain a large quantity of pinguious juice, ſuch as thoſe of poppies; and, by this means, that thick Oil, which at other times is generally expreſſed, with difficulty paſſes the helm, is raiſed and diſtilled in conjunction with a portion of ſubtile and ethereal Oil: and this is the uſual method of adulterating the Oil of rue; for, though rue is of a ſtrong taſte, and penetrating ſmell, yet there is hardly any plant, which affords a ſmaller quantity of oil: but pure Oil of rue is eaſily diſtinguiſhed from that which is adulterated, ſince, when genuine, it does not become thick and coagulated, when expoſed to the cold; but is inſpiſſated, when it is adulterated with any expreſſed oil. The Oils of chamomile and the tops of yarrow, when pure and recent, are of a beautiful bluiſh colour, which is afterwards changed into that of brown; for, if this bluiſh colour of the Oil of chamomile flowers remain above a year, it is a ſure ſign that it is adulterated; for it is cuſtomary to mix with it Oil of turpentine, which is of a deep bluiſh colour, on account of the tincture it receives from the copper of the veſſel. It is of great importance to the phyſician to be able to diſtinguiſh genuine from adulterated Oils; for theſe balſamic and cephalic Oils not only loſe much of their efficacy, but, alſo, acquire a foreign quality, by being adulterated; and it is ſufficiently known, that all terebinthinaceous ſubſtances violently exagitate the maſs of blood and humours, and create an intenſe heat in the body.

OIL *of ſtone.* In the manufacture of the Chineſe porcelain, they uſe a liquid matter of a white colour, which they call by this name, on which the great myſtery of finiſhing their work depends; yet, this has been leſs enquired into by the imitators of that ware in Europe, than many other articles of leſs conſequence. The ſtone of which this Oil is made, is of the ſame degree of hardneſs with that which the petunſe is prepared of. They procure it from quarries, and chuſe ſuch as is of a good white colour, and has many dark green ſpots in it.

Theſe ſpots are of the colour of the leaves of cypreſs. Sometimes a ſtone is choſen which has a brown ground, variegated with ſpots and blotches of a reddiſh colour. They firſt carefully waſh this ſtone; then, laying it in a clean place, they break it to pieces with iron inſtruments, and afterwards grind theſe to a perfectly fine and impalpable powder, by rubbing them in large mortars, with peſtles of ſtone faced with iron, and turned either by the labourers, or by water. When the whole is thus reduced to a fine powder, they throw it into a veſſel of water, and ſtirring it briſkly about, they let the coarſer part ſubſide to the bottom, and there ſwims a fine thick matter like cream, for two or three inches depth, on the ſurface. This they carefully ſcum off, and putting it into another veſſel of clear water, they let it throw down any coarſe matter it may yet contain; and, finally, taking off the thick ſurface again, they mix this with ſome freſh water in another veſſel, and leave it to ſubſide; then pouring off the clear water, they take out the remainder at the bottom of the veſſel, which is perfectly fine, and reſembles a thick cream. To every hundred pounds of this they add one pound of a ſubſtance of the nature of which we are not yet perfectly informed. It is ſaid to be a mineral reſembling alum. They calcine this firſt, and then beat it to a fine powder, and this, being added to the cream, or oil, as it is called, ſerves to keep it always in the ſame liquid ſtate. This ſubſtance, when finiſhed in this manner, has very little title to the name of an Oil; it is rather a varniſh, and is always uſed in mixture with another varniſh, which is called at this time fern Oil, and uſed to be called lime Oil; it is prepared in the ſame manner with the other after burning. See FERN *Oil.*

Animal OIL, *oleum animale*, in medicine, the name of an eſſential Oil diſtilled by a retort from blood, and recommended as a powerful remedy in epilepſies, the gout, and other obſtinate diſeaſes.

OIL *of camphor*, a name given by the chemiſts to a ſolution of camphor in ſpirit of nitre. It is uſed to exfoliate carious bones, and on other the like occaſions. It is obſervable, that camphor, which is ſoluble in this acid, in the proportion of one half its quantity, is not at all ſoluble in ſpirit of vitriol, ſpirit of of alum, or distilled vinegar; and that it is the only known vegetable resin that is soluble in this menstruum.

Connecting OIL, in chemistry, a term used by Boerhaave, and his followers, to express a certain Oil, found in all vegetable substances, but wholly differing from, and independent of, their essential Oil. This is not possessed of any of their virtues, or qualities, but seems the same in all plants, and is the means of their consistence and solidity, giving tenacity to their earth, which, without it, falls to dust, and the plant exists no more.

Red OIL, in the porcelain manufacture, a name given to a peculiar colour used on the China ware, or to those pieces of the ware which are coloured with it. It is a very elegant ornament, and would be worth our attempting to imitate in England, on our better sorts of wares. They who have visited the Chinese works affirm that it is done in the following manner: they mix the red colour called tam-tan-hum, or the copperas red, with Oil of stone (see OIL *of stone*) and with another Oil, as they express it, of the same kind, made of a whitish sort of pebble, or agate, found on the shores of their rivers, and the place of which might probably be supplied, with us, by common crystal. The powder is to be thoroughly mixed with these liquors, and the vessel dipped carefully into the mixture, or some parts of it only covered with it in figures: after this, it is to be set by to dry, and, when thoroughly dried, it is to be baked in the common way. The general method is that of covering the vessel all over, both inside and out, with this red; and it comes out of the most bright and brilliant colour imaginable, but it will not ring when struck upon, as our common China ware does. We seldom see this in any degree of perfection, but it is very elegant when fine. *Observ. sur les Cout. de l'Asie.*

OIL *of earth, oleum terræ.*— This Oil is of two kinds, the red and the black; the red is brought from the East-Indies, and is of a pellucid red colour, and has a strong smell like petroleum, but more grateful, as Schroder says; but, as to what we know of this Oil, it is either the same with petroleum, or else is unknown in our shops.

The Indian Oil of earth, described by Neuhovius, is scarcely ever brought over to us, but ingrossed by the Asian potentates; but, whether it be a species of petroleum, or naphtha, I cannot certainly determine. What is brought to us from the Indies, and sold for Oil of earth, is prepared of expressed Oil of the cocoa nut, mixed with medicated earths, as I have been informed by a person very skilful in these matters, and therefore wholly belongs to the class of vegetables. *Boerhaave.*

These kinds of bitumen differ only in degree, as some think, so as that the more spirituous and subtile part of it is the naphtha, the next to it the petroleum, and the grosser and more feculent part asphaltum; just as we see in amber, from which, by distillation, there is obtained, first, a spirituous and limpid Oil, representing naphtha; soon after, comes off a yellow and thicker Oil, resembling petroleum; and, last of all, a black feculent matter, which might pass for asphaltum. *Dale.*

OLIGAE'DRA, in natural history, the name of a genus of crystals.

The word is derived from the Greek ὀλίγος, a few, and ἕδρα, a plane, or side; and expresses a crystal which is composed of only a few planes.

The bodies of this class are crystals of the imperfect kind, being composed of columns affixed irregularly to some solid body at one end, and, at the other, terminated by a pyramid, being both pentangular; the whole consists only of ten planes, not, as the common kind, of twelve.

OLIVE-*tree, olea,* in botany, a genus of trees, whose characters are:

The leaves are, for the most part, oblong and ever green: the flower consists of one leaf; the lower part of which is hollowed, but the upper part is divided into four segments: the ovary, which is fixed to the center of the flower-cup, becomes an oval, soft, pulpy fruit, abounding with a fat liquor, inclosing an hard rough stone.

There are five sorts of Olive-trees preserved in the gardens of the curious, where they are planted either in pots or cases, and removed into the green-house in the winters, with oranges, myrtles, &c. but they are most of them hardy enough to endure the cold of our ordinary winters in the open air, provided they are planted upon a dry soil, and in a warm situation, though in severe winters they are demolished, or at least lose their heads, or are killed to the surface; but this is what they are liable to in the south parts of France, in which country these trees abound; and yet in very sharp winters are most of them destroyed. There was a parcel of these trees growing in the gardens of Camden-house, near Kensington, a few years since, which were seven or eight feet high; and in some good seasons produced very good fruit: these were planted against a south wall, but were permitted to grow up rude without pruning, or fastening to the wall, (which they do by no means care for; and, during the time they were below the top of the wall, they throve very well; but, after their heads were gotten above the wall, the north winds usually greatly prejudiced them every winter; and I believe the hard winter, 1739, intirely demolished them.

These plants may be propagated by laying down of their tender branches (in the manner practised for other trees) which should remain undisturbed two years; in which time they will have taken root, and may be taken off from the old plants, and transplanted either into pots filled with fresh light earth, or into the open ground in a warm situation. The best season for transplanting them is the beginning of April, when you should, if possible, take the opportunity of a moist season; and those which are planted in pots, should be placed in a shady part of the green-house until they have taken root; but those planted in the ground should have mulch laid about their roots, to prevent the earth from drying too fast, and be now-and then refreshed with water; but you must by no means let them have too much moisture, which will rot the tender fibres of their roots, and destroy the trees.

When the plants have taken fresh root, those in the pots may be exposed to the open air, with other hardy exotics; with which they should be housed in winter, and treated as myrtles, and other less tender trees and shrubs; but those in the open air will require no farther care until the winter following, when you should mulch the ground about their roots, to prevent the frost from penetrating deep into them: and, if the frost should prove very severe, you should cover them with mats, which will defend them from being injured thereby; but you must be cautious not to let the mats continue over them after the frost is past, lest, by keeping them too close, their leaves and tender branches should prove mouldy for want of free air, which will be of as bad consequence to the trees, as if they had been exposed to the frost, and many times worse; for it seldom happens, if they have taken much of this mould, or have been long covered, so that it has entered the bark, that they are ever recoverable again; whereas it often happens, that the frost only destroys the tender shoots; but the body and larger branches, remaining unhurt, put out again the succeeding spring.

These trees are generally brought over from Italy every spring, by the persons who bring over the oranges, jasmines, &c. from whom they may be procured pretty reasonably; which is a better method than to raise them from layers in this country, that being too tedious; and those which are thus brought over, have many times very large stems, to which size young plants in this country would not arrive in ten or twelve years growth. When you first procure these stems, you should (after having soaked their roots twenty-four hours in water and cleaned them from the filth they have contracted in their passage) plant them in pots filled with fresh light sandy earth, and plunge them into a moderate hot-bed; observing to skreen them from the violence of the sun in the heat of the day, and also to refresh them with water, as you shall find the earth in the pots dry. In this situation they will begin to shoot in a month or six weeks after, when you should let them have air in proportion to the warmth of the season; and, after they have made pretty good shoots, you should inure them to the open air by degrees; into which they should be removed, placing them in a situation where they may be defended from strong winds: in this place they should remain till October following, when they must be removed into the green-house, as was before directed. Having thus managed these plants until they have acquired strong roots, and made tolerable good heads, you may draw them out of the pots, preserving the earth to their roots, and plant them in the open air in a warm situation, where you must manage them as was before directed for the young ones, and these will in two or three years produce fruit, provided they do well. The Lucca and box-leaved Olives are the hardiest, for which reason they should be preferred to plant in the open air; but the first sort will grow to be the largest trees.

OMBRO'METER *, a machine to measure the quantity of rain that falls.

* The word is formed from the Greek ὄμβρος, rain, and μέτρον, to measure.

The following Ombrometer is that lately used by Mr Pickering.

This machine consists of a tin funnel, whose surface is an inch square, a flat board and glass tube let into the middle of it in a groove (the length and breadth of both board and tube being ad libitum) and an index. My board is about three feet long, to answer the height of the rails that go round the top of my house, to one of which it is hung, clear of any obstacle to prevent the free fall of the rain, with four little staples that slide over as many tenter-hooks. The bore of my tube is about half an inch; which, at a medium, is the best size, a larger bore obliging you to make your graduations the more contracted, and, consequently, the less plain and accurate; and a lesser not permitting you to return the water out of the tube when full, without the adhesion of a great deal to its sides; which, when you have placed the tube in its perpendicular situation, subsides, and sometimes fills up $\frac{1}{10}$ of an inch; which, without care, must necessarily make great mistakes in the diary. The method of graduating the board is this:

I had

I had a veſſel of tin made, whoſe contents were exactly a cubic inch. With this veſſel, filled with water exactly to its ſurface, I frequently gauged the tube, till, by repeated trials, I had found the height to which a cubic inch of water would riſe in it. The ſpace anſwering to this on the board I had graduated into 32 equal parts, and took the ſame method with the reſt of the tube, till in the ſame manner I had graduated four ſuch inches. Now, the ſurface of the funnel being, as has been ſaid, exactly a ſquare inch, no rain can by it get into the tube, but ſuch as falls within the ſquare of one inch, which, as the ſhower is more or leſs, has its exact quantity ſhewn upon the board, on which a moveable index is placed. This machine has highly anſwered my expectation; its form being very ſimple, and eaſily repaired, if any accident happen; for, ſhould the tube be broke, it is only rubbing out the graduation, which is marked with a black-lead pencil upon the board painted white, and gauging you a new tube with the cubic meaſure for a new graduation, and your machine is again complete. In winter it will be neceſſary to let no depth of water remain in the tube; for, ſhould there be a froſt, the expanſion of the ice will certainly break it. The machine will equally ſerve for diſſolved hail and ſnow. Its figure may be ſeen *Plate* XXXI. *fig.* 17. where *a a* is the board, *b b* the tube, *d* the funnel fixed, *c* a larger view of the funnel. *Philoſophical Tranſ.* Nº. 473.

OMENTUM, (*Dict.*) — As the Omentum is a ſoft and pinguious part in conſequence of its laxity, highly ſubject to receive the humours conveyed to it from other parts, it is for this reaſon, as well as the Omentum and pancreas, ſubject to various diſorders; which, however, are not deſcribed by authors, becauſe they can hardly, if at all, be diſcovered in live perſons; and are only to be inveſtigated by laying open their carcaſes, as is obvious from the caſes recorded by various authors. Thus Veſalius informs us, that in a certain carcaſe, when laid open, he ſaw the Omentum ſo preternaturally tumid, that it weighed about five pounds; whereas, in its natural ſtate, it hardly exceeds half a pound. Rouſſet, in his treatiſe de Partu Cæſareo, tells us that, upon laying open a carcaſe at Paris, there was a very conſiderable abſceſs found on the Omentum. Riolanus, alſo, in his Anthropographia, informs us, that, upon laying the body of a young gentleman of nineteen years of age, he ſaw the Omentum full of a large number of glands, from which a conſiderable quantity of ſordid humours had been conveyed to it; whilſt, at the ſame time, the meſentery and pancreas were, by means of the abſceſs, putrified; and the ſpleen ſo greatly diminiſhed, as to be almoſt entirely conſumed. And I myſelf, upon laying open the body of a canon of Montpelier, ſaw the Omentum ſcirrhous, poſſeſſing the whole epigaſtric region, and about four fingers breadth in thickneſs. The colour of this tumor of the Omentum reſembled that of the ſpleen: ſo that it is highly probable that the melancholic humour was tranſlated from the ſpleen, and accumulated in that part, ſince the patient was of an highly melancholic conſtitution, and ſince, through the ſplenic ramifications, there is a ſufficiently potent conveyance from the ſpleen to the Omentum. According to Hippocrates, in a dropſy, the waters are alſo frequently conveyed from the ſpleen to the Omentum, from which they gradually drop into the cavity of the abdomen.

But as the tumors of the Omentum are not, by all the efforts of art, to be diſtinguiſhed from thoſe of the meſentery, ſo their diagnoſtic or diſtinguiſhing ſigns cannot poſſibly be aſcertained. It is true, indeed, tumors of the Omentum are more eaſily perceived by the firſt touch, becauſe that part lies immediately under the peritonæum, whereas the meſentery is ſituated deeper: but the larger tumors of the meſentery riſe to the peritonæum, and even the epigaſtric muſcles are, ſometimes, ſo united with it, that, a ſuppuration happening, theſe tumors diſcharge their ſordid contents through the navel, or ſome other part.

But this difficulty of aſcertaining the diagnoſtic ſigns of theſe diſorders, by no means produces any perplexity in the method of cure; ſince, in all tumors of the ſame ſpecies poſſeſſing the inferior parts of the abdomen, the ſame meaſures are to be taken; which, however, are not ſo ſucceſsful in the Omentum which is not furniſhed with ſo commodious outlets for the matter of theſe tumors, as the other parts are. *River. Prax. Med. Lib.* 13. *Cap.* 5.

ONION, *cepa*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the liliaceous kind, and compoſed of ſix leaves; in the center of it there ſtand a piſtil which finally becomes a roundiſh fruit, divided into three cells, and containing roundiſh ſeeds. To this it is to be added, that the flowers are placed in ſpherical heads, and that the leaves, as well as ſtalks, are tubular.

Onions are much eaten, and it would be well if they were yet more ſo; they attenuate tough humors, cleanſe the ſtomach, and excite appetite, and in ſome degree promote the menſes. but they are apt to breed flatulences, and, if eaten too largely, to affect the head and diſturb the ſleep afterwards. An Onion, boiled to perfect ſoftneſs, is recommended by many as a cataplaſm for ripening peſtilential buboes. A freſh cut Onion, rubbed on the part till it becomes red and itch, is ſaid to be a cure for baldneſs. A mixture of equal parts of juice of Onions and ſpirit of wine is eſteemed a cure for deafneſs, a few drops being put at times into the ears: an Onion cut in two, and macerated an hour in the ſame ſpirit, is a good application for the head ach. A cataplaſm of roaſted Onions and butter is an excellent application for the piles.

The three ſorts of Onions, propagated for the ſake of their roots for winter uſe, are the Straſburgh Onion, the red Spaniſh Onion, and the white. Theſe are to be propagated by ſowing their ſeeds in the latter end of February, in a dry and ſomewhat ſandy ſoil, yet rich; in about a month's time the plants will appear, and, in a fortnight after that, they will be forward enough for hoeing, which muſt be done with a very ſmall hoe, cutting up all the weeds, and leaving the Onions two inches aſunder; this ſhould be done in a dry ſeaſon, and the ground will then be clear from weeds for a month: at the end of this time, they muſt be hoed again, and cut to three inches a-part; and, a month after this, to four inches; at which diſtance they will thrive well, and grow very large. Toward the latter end of July, the Onions will have arrived at their full growth, which is known by their leaves hanging down and ſhrivelling; and they muſt at this time be pulled up, and ſpread on a dry place, and turned every day, to prevent their ſtriking freſh roots; in a fortnight's time they will be dry enough to houſe, and ſhould be wiped clean, and ſpread thin in an upper loſt, or garret.

The differences between theſe ſpecies are not eſſential, they often degenerating into one another; and even the large Portugal Onion, after a few years, with us, will loſe itſelf ſo far, that no one would imagine it came of that race. *Miller's Gard. Dict.*

Welſh ONIONS, a ſort of Onions propagated by gardeners, for the uſe of the table in ſpring; they never make any bulb, and are therefore only to be eaten green with ſallads. They are propagated by ſowing their ſeeds towards the end of July in beds of a dry but rich ſoil; and, in three weeks after ſowing, they will appear above ground: they muſt be kept carefully cleared from weeds. About October all their leaves die away which has occaſioned ſome to think all the plantation loſt, and to dig up the ground for ſome other uſe; but, if they are ſuffered to ſtand, they will ſhoot up again very ſtrong in January, and from that time will grow very vigorouſly, and reſiſt all weathers, and will be fit to draw for young Onions in March, and are extremely green and fine, and more valued at market at that ſeaſon than any other kind; but they are much ſtronger than any other Onions, and have very much of the taſte of garlic.

Counterfeit OPAL. To imitate this gem in natural cryſtal, uſe the following method: take yellow orpiment and white arſenic, of each two ounces; crude antimony and ſal armoniac, of each one ounce; powder all theſe, and mix them well together; put this powder into a large crucible, and lay upon it ſmall fragments of cryſtal, and, upon theſe, other larger pieces of cryſtal; fill up the crucible with theſe, and lute on to it another crucible inverted, with a hole at the bottom as big as a ſmall pea; when the lute is dry, ſet the veſſel in a quantity of charcoal in a large chimney, covering them up with coals, to the middle of the upper crucible; ſo long as the materials fume out at the hole, keep up a ſtrong fire; when that is over, let the fire go out of itſelf, and then unlute the crucible; the greateſt part of the cryſtal will be found tinged to the colours of various gems; not only the Opal, which will be very fair and beautiful, but the topaz and ruby colour will be ſeen in others. *Neri's Art of Glaſs.*

OOST, in huſbandry, a name given by the people who manure hops, for the kiln in which they dry them after they are picked from the ſtalks. This is a ſquare room, built up of brick, or ſtone, ten feet wide, more or leſs, and having a door on one ſide. In the midſt of this room is a fire-place, about thirteen inches wide, and as much high; and in length, reaching from the mouth ſo nearly to the back part of the kiln, that a man has juſt room to go round it. This fire place is called a herſe, and the fire is let out into the room by ſeveral holes in the ſides, in the ſame manner as in malt kilns. Five feet above this, is laid the floor on which the hops are to be laid to dry, and this muſt have a wall round it, at four feet high, to keep the hops from falling out. At one ſide of the upper bed muſt be made a window by which to puſh out the hops, as they are dried, into a room prepared for them. The beds muſt be made of laths an inch ſquare, placed at a quarter of an inch diſtance from one another, and ſupported by beams underneath. The hops are to be poured on this bed with a baſket, till the whole is covered half a yard thick with them; when this is done, lay them even with a rake, and let a fire be made in the fire-place below. Some recommend a wood fire, but experience ſhews nothing does ſo well as charcoal; let the fire be kept at the mouth of the furnace, for the air will be carried all the way through; and thus let the hops lie, never ſtirring them till they are thoroughly dry; when they rattle under the rake, and the inner ſtalks are brittle, they are ſufficiently dried, and are to be puſhed out, and a freſh parcel laid in the Ooſt in their place. Some people dry their hops in a common malt kiln, ſpreading them on a hair cloth about ſix inches thick, and now and then turning them till they are all thoroughly dried, then laying them in a heap, till they are to be put in the bags. But both these ways are liable to some inconveniencies; the Oost generally overdries the under ones, by the time that the upper ones are dry enough; and the hair cloth, and the turning in the other way, breaks and shatters them, and spills many of the seeds.

OPHIO'GLOSSUM, *adder's-tongue*, in botany, a genus of plants, no part of the fructification of which is visible, except the fruit. This is an oblong, double, or distichous capsule, divided by a great number of transverse articulations into many cells, each of which, when mature, opens transversly, and is found to contain a great number of small seeds of a subovate figure.

This is a spring plant, and is only to be found in April and May. It is not uncommon in wet meadows, and is easily distinguished among the other spring plants by its spike, or tongue.

It is esteemed one of the best vulnerary herbs this nation produces, but it is more in use among the common people than in the shops. They give its juice internally, and use the herb bruised, or an ointment prepared from it, with lard, or May butter, externally at the same time. *Dale's Pharmac.*

OPODE'LDOC, the name of a plaister said to be invented by Mindererus, though often mentioned by Paracelsus.

There is a famous popular ointment, which goes by the name of Opodeldoc, which is said to be thus prepared:

Take of the roots of marsh-mallows, comfrey, gentian, long-birthwort, angelica, of each one ounce and an half; of the herbs sanicle, ladies-mantle, mouse-ear, colts foot, snakewood, periwinkle, bruised, of each half an handful; of the leaves of rosemary, sage, and lavender, of each one handful and a half; flower of rosemary, sage, and lavender, of each one handful; juniper-berries, two ounces; cumin-seeds, one ounce; camphire and castor powdered, of each one ounce and an half; and, of spirit of wine, three pints and an half.

Put all into a glass cucurbit, well luted, and digest for ten hours in balneo mariæ, that is, in hot water, but not to boil; then strain; and, the spirit of wine being sufficiently impregnated with the ingredients, then add one pound of Castile soap shaved thin; then digest in the same manner as before, until the soap is dissolved.

In order to succeed in this process, the juncture must be carefully luted with two or three doubles of paper, daubed over with the whites of eggs, and tied about with thread; when the luting is dried, digest in balneo mariæ for ten hours, the matrass being fixed in the middle of the kettle, with a layer of straw under it to keep it at the distance of two inches from the bottom: for the first eight hours, the water must be kept so hot about it, that you can scarce hold your finger therein; and the two other hours augment the heat, but not so much as to make the water boil.

After the spirit of wine is thoroughly impregnated with the tincture of the roots, herbs, leaves, and powders, cool it gently; and, straining it through a linen cloth, pour it again into the matrass, with one pound of Castile soap shaved thin; then fit the vessel of rencounter to the matrass; lute the junctures, and digest as before, till the soap is intirely mixed with the spirit, and the whole reduced to an ointment; then take out the matrass, and suffer it to cool.

If the doses and other directions are duly observed, it will be the consistence of an unguent, neither too thick nor thin; and the method of trying, if it is truly prepared, is, to rub some of it on your hand, which it will immediately penetrate, leaving only a greenish stain; though the natural colour of the ointment is brown.

It is excellent in strains, relaxations of the sinews in horses, as well as human kind; also, in all pains, numbness, weakness in the joints, or other parts, being well rubbed in.

A succedaneum for this celebrated preparation may be made in the following manner:

Take, of Castile soap, two ounces; of rectified spirits of wine, four ounces; and, of camphire, two drachms: and mix them well together.

OPO'SSUM, or POSSUM, in zoology, the name of a very remarkable American animal, described by various authors, under the names of maritacaca, carigoi, ropoza, carigueya, jupatuma, tlaquatzin, sarigoi, and semivulpa.

It is a creature of the size of a large cat. Its head is shaped like that of the fox; its nose sharp, and its upper jaw longer than the under; its teeth are small, but like those of the fox, and it has two long ones, like the hare, in the front of the mouth; its eyes are very beautiful, small, round, and vivid; its ears long, smooth, and very soft, placed erect, like those of the fox, and very thin and transparent. It has black whiskers, like those of a cat; and has other hairs of the same kind on the other parts of its face, and over its eyes; its tail is round, and a foot long, and is of great service to it, as it uses it to twist round the branches of trees, hanging itself to them by that means. The tail is hairy near the insertion, but naked all the other parts, and is partly black, and partly of a brownish white; the hinder feet are considerably longer than the fore ones, and each has five toes; they much resemble hands, and the nails are white and crooked, the hinder one being, as in the monkey kind, the longest. Its head, and legs, as Hernandez observes, something resemble those of the badger. It has a broad, longitudinal black streak, on the face; it is of a blackish colour, with a mixture of a brown and grey on the back and sides, and has somewhat of a faint yellowish cast on the belly. *Ray's Syn. Quad.*

ORA'NGE-*dew*, a sort of dew which falls, in the spring time, from the leaves of Orange and lemon trees, and is extremely fine and subtile. Mr. De la Hire, observing this, placed some pieces of glass under the leaves to receive it, and, having thus procured some large drops of it, was desirous of finding out what it was. He soon found that it was not a merely aqueous fluid, because it did not evaporate in the air; and that it was not a resin, because it readily and perfectly mixed with water: it was natural here to suppose it a liquid gum, but neither did this, on examination, prove to be the case; for, being laid on paper, it did not dry as the other liquid gums do. Its answering to none of these characters, and its being of the consistence of honey, and of a sweet sugar-like-taste, gave a suspicion of its being a kind of manna; and whatever in the other trials had proved it not a resin, a gum, &c. all equally tends to prove that it is this substance.

O'RCHARD (*Dict.*) — In planting of an Orchard, great care should be had to the nature of the soil, that such trees as are adapted to grow upon the ground intended to be planted, may be chosen, otherwise there can be little hopes of their succeeding; and it is for want of rightly observing this method, that we see, in many countries, Orchards planted which never arrive to any tolerable degree of perfection, their trees starving; and their bodies either covered with moss, or the bark cracks and divides; both which are evident signs of the weakness of the trees; whereas, if instead of apples the Orchard had been planted with pears, cherries, or any other sort of fruit to which the soil had been adapted, the trees might have grown very well, and produced great quantities of fruit.

As to the position of the Orchard (if you are at full liberty to chuse) a rising ground, open to the south-east, is to be preferred; but I would by no means advise to plant upon the side of an hill, where the declivity is very great; for in such places the great rains commonly wash down the better part of the ground, whereby the trees would be deprived of proper nourishment: but, where the rise is gentle, it is of great advantage to the trees, by admitting the sun and air between them, better than it can upon an intire level; which is an exceeding benefit to the fruit, by dissipating fogs, and drying up the damps, which, when detained amongst the trees, mix with the air, and render it rancid: if it be defended from the west, north, and east-winds, it will also render this situation still more advantageous; for it is chiefly from these quarters that fruit-trees receive the greatest injury: therefore, if the place be not naturally defended from these by rising hills (which is always to be preferred) then you should plant large growing timber-trees at some distance from the Orchard, to answer this purpose.

You should also have a great regard to the distance of planting the trees, which is what few people have rightly considered; for, if you plant them too close, they will be liable to blights; and the air, being hereby pent in amongst them, will cause the fruit to be ill-tasted, having a great quantity of damp vapours from the perspiration of the trees, and the exhalations from the earth mixed with it, which will be imbibed by the fruit, and render their juices crude and unwholesome.

Wherefore, I cannot but recommend the method which has been lately practised by some particular gentlemen with very great success; and that is, to plant the trees fourscore feet asunder, but not in regular rows. The ground between the trees they plough and sow with wheat and other crops, in the same manner as if it were clear from trees; and they observe their crops to be full as good as those quite exposed, except just under each tree, when they are grown large, and afford a great shade; and, by thus ploughing and tilling the ground, the trees are rendered more vigorous and healthy, scarcely ever having any moss, or other marks of poverty, and will abide much longer, and produce better fruit.

If the ground in which you intend to plant an Orchard has been pasture for some years, then you should plough in the green sward the spring before you plant the trees: and, if you will permit it to lie a summer fallow, it will greatly mend it, provided you stir it two or three times, to rot the sward of grass, and prevent weeds growing thereon.

At Michaelmas you should plough it pretty deep, in order to make it loose for the roots of the trees, which should be planted thereon in October, provided the soil be dry; but, if it be moist, the beginning of March will be a better season.

When you have finished planting the trees, you should provide some stakes to support them, otherwise the wind will blow them out of the ground; which will do them much injury, especially if they have been planted some time; for, the ground at that season being warm, and for the most part moist, the trees will very soon push out a great number of young fibres; which, if broken off by their being displaced, will greatly retard the growth of them.

In the spring following, if the season should prove dry, you should cut a quantity of green turf, which must be laid upon the surface of the ground about their roots, turning the grass downward; which will prevent the sun and wind from drying the

the ground, whereby a great expence of watering will be faved: and, after the firft year, they will be out of danger, provided they have taken well.

Whenever you plough the ground between thefe trees, you muft be careful not to go too deep among their roots, left you fhould cut them off, which would greatly damage the trees: but, if you do it cautioufly, the ftirring of the furface of the ground will be of great benefit to them; though you fhould obferve never to fow too near the trees, nor fuffer any great rooting weeds to grow about them, which would exhauft the goodnefs of the foil, and ftarve them.

If, after the turf which was laid round the trees be rooted, you dig it in gently about the roots, it will greatly encourage them.

There are fome perfons who plant many forts of fruit together in the fame Orchard, mixing the trees alternately: but this is a method which fhould always be avoided; for hereby there will be a very great difference in the growth of the trees, which will not only render them unfightly, but alfo the fruit upon the lower trees ill tafted, by the tall ones overfhadowing them; fo that, if you are determined to plant feveral forts of fruit on the fame fpot, you fhould obferve to place the largeft-growing trees backwards, and fo proceed to thofe of lefs growth, continuing the fame method quite through the whole plantation; whereby it will appear at a diftance in a regular flope, and the fun and air will more equally pafs through the whole Orchard, that every tree may have an equal benefit therefrom.

The foil of your Orchard fhould alfo be mended once in two or three years with dung, or other manure, which will alfo be abfolutely neceffary for the crops fown between: fo that where perfons are not inclinable to help their Orchard, where the expence of manure is pretty great; yet, as there is a crop expected from the ground befides the fruit, they will the more readily be at the charge upon that account.

In making choice of trees for an Orchard, you fhould always obferve to procure them from a foil nearly a kin to that where they are to be planted, or rather poorer; for, if you have them from a very rich foil, and that wherein you plant them is but indifferent, they will not thrive well, efpecially for four or five years after planting; fo that it is a very wrong practice to make the nurfery, where young trees are raifed, very rich, when the trees are defigned for a middling or poor foil. The trees fhould alfo be young and thriving; for, whatever fome perfons may advife to the contrary, yet it has always been obferved, that though large trees may grow, and produce fruit, after being removed, they never make fo good trees, nor are fo long-lived, as thofe which are planted while young.

Thefe trees, after they are planted out, will require no other pruning but only to cut out dead branches, or fuch as crofs each other, fo as to render their heads confufed and unfightly: the too often pruning them, or fhortening their branches, is very injurious; efpecially to cherries and ftone fruit, which will gum prodigioufly, and decay in fuch places where they are cut: and the apples and pears, which are not of fo nice a nature, will produce a greater quantity of lateral branches, which will fill the heads of the trees with weak fhoots, whenever their branches are thus fhortened; and many times the fruit is hereby cut off, which, on many forts of fruit-trees, is firft produced at the extremity of their fhoot.

It may, perhaps, feem ftrange to fome perfons, that I fhould recommend the allowing fo much diftance to the trees in an Orchard, becaufe a fmall piece of ground will admit of very few trees, when planted in this method: but they will pleafe to obferve, that, when the trees are grown up, they will produce a great deal more fruit, than twice the number, when planted clofe, and will be vaftly better tafted; the trees, when placed at a large diftance, being never fo much in danger of blighting as in clofe plantations, as hath been obferved in Herefordfhire, the great county for Orchards, where they find, that when Orchards are fo planted or fituated, that the air is pent up amongft the trees, the vapours which arife from the damp of the ground, and the perfpiration of the trees, collect the heat of the fun, and reflect it in fteams fo as to caufe what they call a fire blaft, which is the moft hurtful to their fruit; and this is moft frequent where the Orchards are open to the fouth fun.

But, as Orchards fhould never be planted, unlefs where large quantities of fruit are defired, fo it will be the fame thing to allow twice or three times the quantity of ground; fince there may be a crop of grain of any fort upon the fame place (as was before faid) fo that there is no lofs of ground: and, for a family only, it is hardly worth while to plant an Orchard; fince a kitchen garden well planted with efpaliers will afford more fruit than can be eaten while good, efpecially if the kitchen garden be proportioned to the largenefs of the family: and, if cyder be required, there may be a large avenue of apple-trees extended crofs a neighbouring field, which will render it pleafant, and produce a great quantity of fruit; or there may be fome fingle rows of trees planted to furround the fields, &c. which will fully anfwer the fame purpofe, and be lefs liable to the fire blafts before-mentioned. *Miller's Gard. Dict.*

O'RCHIS, *male fatyrion.* — This Orchis which is the common fatyrion of the fhops, has two oval roots, about as big as a fmall olive, of a whitifh colour, full of a flimy juice, which, contrary to moft other plants, have feveral white fibres growing above them; from thefe fprings a fingle fucculent ftalk, encompaffed with three fhining, fmooth, lily-like leaves fpotted with black. The flowers grow on the tops of the ftalks in a long fpike or thyrfus, of a purple colour; each flower being of an irregular form, confifting of fix leaves, fomewhat refembling a galea, with a fmall piece of ear ftanding erect on each fide, and a broad labella fpotted with deeper fpots. The feeds are very fmall, included in a triangular long capfula; it grows in moift meadows, and flowers in April. The roots only are ufed.

They are accounted a provocative and a ftimulus to venery, and a ftrengthener of the genital parts, and help conception, and for thefe purpofes are a chief ingredient in the electuarium diafatyrium: outwardly applied in form of a cataplafm, they diffolve hard tumors and fwellings.

The only officinal preparation is the aforefaid electuary. *Miller's Bot. Off.*

ORCHIS, *female fatyrion.* — This is a lower and fomewhat leffer plant than the former, having no fpots on the leaves; the fpike of the flowers is lefs, and not fo beautiful, of a purplifh colour, having the labella ftriped with green ftripes; it grows in the like places with the former, and flowers fomewhat later. The root is much alike, and is fuppofed to have the fame virtues.

Though thefe plants are ufed in the fhops for the fatyrion, yet they are not the fatyrion of Diofcorides and the ancients; that being, as is plainly proved by Parkinfon, and other fkilful botanifts, our common tulip, which much better anfwers the defcription of Diofcorides, than any of the Orchifes. *Miller's Bot. Off.*

ORE (*Dict.*)—The Ores of the richer metals, as gold and filver, ufually contain a confiderable portion of fulphur, and Alonfo Barba tells us, that the moft expert mineralifts in Peru always efteem abundance of fulphur a fign of a rich Ore in the neighbourhood. Among the richeft Ores of the mountain of Potofi, there are fuch quantities of native brimftone, that the cavities in the mines are often filled with a blue flame, on only bringing a lighted candle into them fo as to touch their fides. It has been wondered at, that, where there is abundance of fulphur in thefe mines, there fhould be no vitriol found, that being only a metal diffolved by means of fulphur; but this objection ceafes, when we confider the denfe and compact nature of thefe two metals, which renders them not foluble by means of fulphur, as the others are. Wherever there is ftore of fulphur, or of pyrites, or other ftones which contain fulphur in the mines of copper and iron, great ftore of vitriols are always found there alfo, being formed by the corrofion of the Ores of thofe metals by fulphur, which renders them foluble in water, from which they again concrete in form of falts. Chemiftry is able to imitate the operations of nature on this occafion feveral ways; for copper, or iron, being formed in thin plates, and either rubbed over with the acid fpirit of fulphur, or calcined with powder of common fulphur, become foluble in water, and afford cryftals of true vitriol, wholly analogous to the natural ones; and either blue or green, as iron, or copper, are the metals employed; but, thefe proceffes not being able to produce cryftals of falt, or vitriol, from either filver, or gold, it is not wonderful that nature is not able to form them by the fame means.

The general formation of fulphur from the Ores of metals, yet lying in the bowels of the earth, is, probably, after this manner: an acid, faline, fulphureous, fteam, or vapour, fuch as common fulphur is eafily reduced to, by heat not greater than that within the bowels of the earth, infinuating itfelf either through the pores of ftones, or through their cracks, which are always frequent about the veins of metals, penetrates into the bed of Ore, fuppofe of copper. The vapour is continually fupplied with frefh quantities from below; and, as it blends itfelf with the metal, corrodes it, as the fume of brimftone will do the fame copper in plates. The metal, thus corroded, being foluble in water, as we find by experience, it is neceffary, that the Ore muft, under the fame management, be fo too; and, in this cafe, the water, which is continually pervading all the ftrata of the earth, wafhes off the diffolved metal; and wherever it happens to be ftayed in fmall quantities afterwards, whether within the vein of the metal, or at a diftance from it, it cryftallifes the falt it contains, and common blue vitriol is produced, if the metal in the vein be iron. The fame procefs is obferved, and the event is the fame in all refpects, when copper is the metal corroded, except that the vitriol, inftead of blue, is green; this plainly accounts for the obfervation of the workers in copper mines, that vitriol and brimftone are ufually found together, the one being a natural confequence of the other. Sulphur is, indeed, often found where there is no vitriol, but vitriol is very feldom found without fulphur; it being not a diftinct principle, but a genuine production of fulphur. *Philof. Tranf.* N°. 104.

OREOSELI'NUM, *mountain parfley*, in botany, a genus of plants, whofe characters are:

It hath a rofe-fhaped unbellated flower, confifting of feveral leaves, placed in a circular order, refting on the empalement, which afterwards becomes as fruit, compofed of two feeds, which are oval, plain, large-ftreaked and bordered, and fometimes caft off their cover: to thefe notes muft be added, that the leaves are like parfley.

Thefe

These plants are propagated by feeds, which fhould be fown in autumn, as foon as poffible after they are ripe; for, if they are kept out of the ground until the fpring, they feldom grow. Thefe feeds fhould be fown in the places where they are defigned to remain; for, as they have downright carroty roots, they do not well bear tranfplanting. They require a moift light foil, and they are beft in a fhady fituation. The beft method is, to fow the feeds in drills, which fhould be made about eighteen inches afunder, and about half an inch deep. In the fpring, when the plants come up, they fhould be carefully cleared of weeds; and, where the plants are too clofe, they fhould be thinned, leaving them about fix or feven inches a-part, that they may have room to grow.

In two years after the feeds are fown, the plants (if they have thriven well) will be ftrong enough to produce their flower ftems, when they will begin to fhoot up in April, and their flowers appear in June; but their feeds will not ripen till the end of Auguft or September. Thefe plants will continue fome years, and will annually produce feeds; fo that the ground fhould be carefully dug between the plants every fpring, and conftantly kept clean from weeds, which is all the culture the plants will require.

O'RGANO, in the Italian mufic, is ufed to fignify the thorough bafs. It is ufually fcored with figures over the notes, for the harpfichord, bafs viol, and lute.

O'RGUES (*Dict.*)—Orgues are preferable to herfes, or portcullifes, becaufe thefe may be either broke by a petard, or they may be ftopped in their falling down; but a petard is ufelefs againft an Orgue; for, if it break one or two of the pieces, they immediately fall down again, and fill up the vacancy; or, if they ftop one or two of the pieces from falling, it is no hindrance to the reft; for, being all feparate, they have no dependence upon one another.

ORI'GANUM, *wild marjoram*, in botany, a genus of plants, whofe characters are:

The calyx is long, fimple, tubulous, and clofely feated among foliaceous fcales; in this is fituated the flower, having an erect, roundifh, bifid galea, or creft, and a beard divided into three parts, the middle one being hollow like a fpoon. The flowers are collected into fquamous fpikes, refembling thofe of the mufcari; and fometimes form a fort of umbella, fhooting forth one on each fide of the fcales.

This Origanum, or wild marjoram, is a foot, or more, high, having many hairy, brown, brittle ftalks, with two broad, round-pointed leaves, bigger than marjoram, fet at a joint on very fhort foot-ftalks, and of a brownifh green colour. The flowers grow on the tops of the ftalks, being fmall, labiated, and galeated, of a purple colour, among long heads, compofed of a great number of green fcales. The roots are woody and fibrous. It grows in hedges and thickets, and flowers in July. The tops and leaves are ufed.

This Origanum, though not fo ftrong as the Origanum Creticum, yet is very good for obftructions of the breaft, liver, and womb; helps the jaundice, fhortnefs of breath, and ftoppage of the menfes; comforts the head and nerves. The diftilled oil helps the tooth-ach, being put upon lint into the aching tooth. *Miller's Bot. Off.*

The wild marjoram is acrid, aromatic, deterfive, and gives a very faint tincture of red to the blue paper; which makes us conjecture, that this plant is filled with a volatile, aromatic, and oily falt, not entirely deftitute of acid; whereas, in the artificial volatile falt, the acid of the fal ammoniac has been detained by the falt of tartar.

Befides, the wild marjoram contains abundance of terreftrial parts. It is diuretic, diaphoretic, good to make one fpit, and provoke the terms. A tea of it may be ufed in an afthma, violent coughs, indigeftion, and pleurify. It is ufed in the wafhings for the feet, and femicubiums for the vapours, green-ficknefs, and palfy. Take wild marjoram dried at the fire, and wrap it warm in a linen cloth, and cover the head well with it, for a rheum and rheumatifm in the neck, commonly called torticolis. *Martyn's Tournefort.*

ORNI'THIÆ, a name given by the ancients to certain winds, which ufually blow in fpring, at the time when the birds of paffage came over to them. Pliny fays, that thefe winds blew from the weft, and that, by fome, the Etefian winds are called by this name. Others fuppofe that they blew from the north, or north-weft.

ORNITHOGA'LUM, *ftar of Bethlehem*, in botany, a genus of plants, whofe characters are:

It hath a lily flower, compofed of fix petals, or leaves, ranged circularly, whofe center is poffeffed by the pointal, which afwards turns to a roundifh fruit, which is divided into three cells, and filled with roundifh feeds; to which muft be added, it hath a bulbous or tuberofe root, in which it differs from fpiderwort.

Thefe plants are propagated by off-fets, which their roots do commonly produce in great plenty. The beft time to tranfplant their roots is in July or Auguft, when their leaves are decayed; for, if they are removed late in autumn, their fibres will be fhot out, when they will be very apt to fuffer, if difturbed. They fhould have a light fandy foil; but it muft not be overdunged, which would caufe their roots to decay. They may be intermixed with other bulbous-rooted flowers in the borders of the pleafure garden, where they will afford an agreeable variety, and continue in flower a long time. Their roots need not be tranfplanted oftener than every other year; for, if they are taken up every year, they will not increafe fo faft; but, when they are fuffered to remain too long unremoved, they will have fo many off-fets about them as to weaken their blowing roots. Thefe may alfo be propagated from feeds, which fhould be fown and managed as moft other bulbous-rooted flowers, and will produce their flowers in three or four years after fowing.

ORNITHOPO'DIUM, *bird's foot*, in botany, a genus of plants, whofe characters are thefe:

The leaves are conjugated, in a feries of feveral pairs, and end in an odd one. The pod is hooked, jointed, and undulated, or waved; containing, within each joint, one round feed. The pods grow many together from the fame origin, in fuch a manner as to refemble a bird's-foot.

It grows in fandy and gravelly places, and flowers in fummer. The herb, which is of ufe in medicine, breaks and expels the ftone in the kidnies and bladder, and is effectual in an hernia.

OROBA'NCHE, *broom-rape*, in botany, a genus of plants, whofe characters are:

The root is fquamous, and the plant appears as if it were bare of leaves. The end of the pedicle opens into a multifid calyx; the flower is monopetalous, anomalous, bilabiated (the galea being hollow, and the beard trifid) collected into fpikes, and embracing an oblong ovary, furnifhed with a long tube unicapfular, bivalve, opening, when ripe, into two valves, and pregnant with very minute feeds.

It frequently grows to the roots of genifta, or broom; whence it is called rapum-geniftæ, or broom-rape; it is found alfo among corn. The herb preferved, or its fyrup, is of an excellent ufe in fplenetic and hypochondriac diforders; and an ointment prepared of the fame, with fwine's fat, is good for hard and fcirrhous tumors.

It grows in gravelly and dry places, and flowers in June and July. The herb, dried and pulverifed, is a prefent remedy for the cholic. *Dale.*

OROBOI'DES, a name given by Hippocrates, and other authors, to a furfuraceous fediment in the urine of perfons who have the jaundice: it is ufually of a reddifh brown colour; and is not peculiar to that difeafe, but is found in fome others.

ORO'BUS, *bitter vetch*, in botany, a genus of plants, whofe characters are:

It hath a papilionaceous flower, confifting of the ftandard, the keil, and the wings; out of whofe empalement rifes the pointal wrapped up in the membrane, which afterwards becomes a round pod, full of oval-fhaped feeds: to which muft be added, that two leaves joined together grow upon a rib that ends in a point.

OROBUS, is alfo the name of a plant, called wood peafe.

This plant grows in woody and bufhy places, flowers in April, and the feed is ripe in May. The tubera of the root tafte much like liquorice, and the Scottifh Highlanders make ufe of them in the fame diforders of the thorax, for which liquorice is proper. They call the plant karemyle, and ufe thofe tubera, tempered with water, to enable them to fupport hunger and thirf. the longer; for which purpofe, they find them very ferviceable, for, by their fweet and vifcid fubftance, they correct and mitigate, and even fix and reftrain, the acid and acrimonious humour in the ftomach; and, by that means, are a remedy againft hunger and thirft. If this plant, therefore, be not the fame with what Theophraftus calls fythica (which is generally thought by the learned to be liquorice) it is certainly very much like it, being leguminous, filiquous, and of the fame qualities. And it feems very probable, that the tubera of this plant were the food with which the Britons fuftained themfelves for fome days, when they were preffed by the enemy; as it is related by Dion, in the life of the emperor Severus. For this plant, fays Dr. Sibbald in his introduction to the Natural Hiftory of Scotland, has the virtues of liquorice; and its tubera by our Highlanders, who, to this very day, retain the manners, and way of living, of the ancient Scots, are ftill applied to the fame ufes; but, as for liquorice, I know not, that it grows any where in the whole Ifland without cultivation. *Raii Hift. Plant.*

ORPE'LLO, a preparation of brafs ufed in the glafs trade, and prepared in this manner: cut plates of brafs into fmall pieces, and place them in a luted crucible, in a ftrong fire, but not fo violent as to melt it. Let it ftand in this manner for four days, in which time it will be well calcined; when cold, powder and fift it, and finally grind it on a porphyry. This will be a black powder; fpread this on tiles, which place on burning coals in the leer, near the hole, for four days; take off the afhes that may fall into it, and finally powder and fift it fine for ufe. It is known to be nicely prepared, when, on mixing with the melted metal in the glafs furnace, it makes it fwell and boil.

The colour it gives is a very elegant fky colour, and a fea-green, or a mixed colour between them, according to the quantity and degree of calcination. *Neri's Art of Glafs.*

ORVIETA'NUM (*Dict.*) — The antidotum Orvietanum is thus prepared:

Take

Take of old theriaca, and dried vipers, with their hearts and livers, each four ounces; of the root of viper's-grass, carline-thistle, masterwort, angelica, bistort, the smaller birthwort, contrayerva, white dittany, galangals, gentian, costus, and the true acorus; of the seeds of Macedonian parsley, of the leaves of sage, rosemary, goats-rue, carduus benedictus, and dittany of Crete; of bay and juniper-berries, each one ounce; of cinnamon, cloves, and mace, each half an ounce; and, of the best honey despumated, eight pounds; make into an antidote.

Reduce all the ingredients into a common powder; despumate the honey, and boil it to the consistence of a thick syrup. Suffer it to become half-cold, and then, by means of a spatula, carefully mix with it the theriaca and the powder, in order to make an electuary, to be kept, for use, in a close-stopped vessel.

This electuary, or antidote, is highly esteemed, as good against the plague, the small-pox, and the bites of poisonous animals. It also corroborates the brain, the heart, and the stomach. The dose is, from one scruple, to a drachm and an half.

ORYCTO'GRAPHY, is that part of natural history wherein fossils are described. *Wolfm. Disc. Prælim. Logic.*

ORYCTO'LOGY, is that part of physics which treats of fossils, or it is the science of fossils. Under this head comes the doctrine of salts, sulphurs, stones, gems, and metals. *Wolfm. Disc. Prælim. Logic.*

ORY'ZA. See RICE in the Dictionary.

OS *aureum, the golden mouth*, in natural history, a name given to a species of cochleæ of the lunar kind, or of that genus which have a round mouth. This, in the Os aureum, is of a fine yellow.

Os *calcis*, in anatomy, a bone of the foot; see the article FOOT, in the Dictionary.

Os *calcis luxated*. It sometimes happens, that the Os calcis, and no other bone of the foot, is displaced or luxated by some external force; and this happens sometimes toward the external, sometimes toward the internal side of the foot. When this accident happens, it is easily discovered by the violent pain it occasions; and by the inequality of the part, that is, there is a cavity plainly observable in one part, and a tumor in the other, on the place. The reduction of this dislocation is very easy. The patient is to be placed on a bed, and, while two assistants extend the limb in the opposite directions, the surgeon replaces the dislocated bone with his fingers, and the pressure of the palm of his hand, and then there is no more than a proper bandage and rest required to the cure. *Heister's Surg.*

Os *humeri*, in anatomy, a bone of the arm. See ARM in the Dictionary.

Os *humeri fractured*. Fractures of the Os humeri are least dangerous when near its middle, and much worse when near its upper or lower head. It sometimes happens, that the fractured ends of these bones keep their places, but much more frequently they are found slipped one over another, by which means the fractured limb is made shorter than the sound one: sometimes also, though much more rarely, it happens, that the dividends of the bone recede from one another, by reason of the weight of the arm, and by that means the fractured limb becomes longer than the sound one. In fractures of this bone, where the ends of the divided bone have slipped one over another, as is usually the case, there is required both force and skill to reduce them, especially if the patient has tense nerves and larger muscles, as is usually the case in strong men. To extend the arm on this occasion, the patient must be seated on a high stool, and an assistant must lay hold of his arm firmly above the fracture, keeping his elbow gently bent; then the lower part of the arm, beneath the fracture, is in like manner to be taken hold of, and the arm is to be gently extended forward, by endeavouring to remove easily each part from the other, in a right line. The surgeon is then to take hold of the fractured part of the arm, and with both his hands reduce the fractured bones into their proper places, while the arm is kept in a proper state of extension by the assistants; and, when they are replaced, the limb is to be rolled up with the proper bandages. *Heister's Surg.*

Os *innominatum*. See INNOMINATA *Ossa*, in the Dictionary.

Os *innominatum fractured*. A fracture of this bone very seldom happens, but, when it does, it is readily discovered by the injury and symptoms in the neighbouring parts, and is the more particularly dangerous, when the patient discharges a brown bloody matter. In restoring this bone, the patient must lie down on his sound side; the bone must be replaced with the hands, covered with compresses, dipped in spirit of wine, and kept on by the spica bandage. Afterwards bleeding, with cooling and relaxing medicines, must be used and a thin diet observed. *Heister's Surg.*

Os *sacrum*. See SACRUM *Os*, in the Dictionary.

Os *sacrum fractured*. When this bone is found to be fractured, the fragments are to be reduced into their proper places with the fingers, and, if any part of it be depressed inwards, a finger dipped into oil or butter, and with the nail close cut off, must be introduced up the anus in order to thrust the depressed fragment into its proper place, to which it is to be directed externally by the other hand. This being performed, a sticking plaister is to be applied, and compresses dipped in spirit of wine over it, to be kept on by the T bandage; or the plaisters may be let alone, and only the compress and bandage applied. The patient must keep his bed a fortnight, lying on his sides; or, if he will needs sit up, it must be on a chair without a bottom, that the bones may not be displaced by touching the seat. *Heister's Surgery.*

OSMUNDA, *Osmund royal*, in botany, a genus of plants, whose characters are:

It produces no flowers, but bears its fruit in clusters.

This is the biggest of our English ferns, sending forth several large-branched leaves, whose long broad pinnulæ are not at all indented about the edges, like the other ferns; they are of a light colour; among these arise several stalks, which have the like leaves growing on them on their lower parts, but towards the tops they are full of round, slender, seed-bearing, curled heads, an inch or more long when ripe, of a brown colour, covered with small dusty seed. These appear in June, and ripen in July. The root consists of a great number of small, long, round parts, matted together, blackish on the outside, and green within, covered over with small fibres. It grows in marshy, boggy places, particularly in a bog, at the backside of Woolwich, near the Warren.

The roots, the only part used, are accounted good for obstructions of the liver and spleen, and particularly esteemed for the rickets in children, as, also, for ruptures, wounds, and bruises. *Miller's Bot. Off.*

OSTEO'LOGY (*Dict.*) — There are properly two kinds of Osteology, one of which is to be learned from bones dried and prepared by boiling, and the other from the bones of a dead subject, as they are naturally connected with each other. Both these methods are very necessary for the practice of physic, and for the exact knowledge of the human body. By examining dry bones, however, we can only learn their exterior forms, their situation, and the connection which they may have with one another; but, when we consider them as joined together in a dead body, we are in a condition to observe many other things, in regard to them, very useful in physic; because their connections with one another, by cartilages and ligaments, and by the diversity of articulation, are sometimes very different in the dry from what we see them in the fresh bones. There are, for instance, in dry bones, certain cavities which appear to be cotyloide; because they are divested of their cartilages; but, in fresh bones, they are found to be glenoide, their cavities being filled with cartilages. And, on the other hand, some cavities appear to be glenoide in the skeleton, which are cotyloide in the body, their cavities being augmented by cartilaginous supercilia.

The exterior form and qualities of bones are much better demonstrated also from fresh subjects, than from prepared bones; because they lose a great many things in boiling, such as the cartilaginous bodies, the periosteum, the mucilaginous substance found between them, and the marrow contained in their cavities; all which may be shewn in a fresh body, but cannot be seen in a skeleton. *Riolan. Enchiridion Anatomicum.*

OSTEOSPE'RMUM, *hard-seeded chrysanthemum*, in botany, a genus of plants whose characters are:

The flower hath an hemispherical empalement, which is single, and cut into many segments; the flower is composed of several hermaphrodite flowers in the disk, which are tubulous, and cut at the brim into five parts: these are surrounded by several female flowers, which are radiated, each having a long narrow tongue, which is quinquefid: the hemaphrodite flowers have each five slender short stamina; these are barren: the female flowers have each a globular pointal, which afterwards becomes one single hard seed.

These plants are propagated by cuttings, which may be planted in any of the summer months, upon a bed of light earth, and should be watered and shaded until they have taken root. These may remain in the beds till they have gotten very good roots, when they must be taken up, and planted in pots: for, if they are suffered to stand long, they will make strong vigorous shoots, and will be difficult to transplant afterwards; during the summer season the pots should be frequently removed, to prevent the plants from rooting through, the holes in the bottoms of the pots, into the ground, which they are very apt to do when they continue long undisturbed, and then they shoot very luxuriantly, and, on their being removed, these shoots, and sometimes the whole plants, will decay.

OS'TREA, *the oister*, in natural history, the name of a very large genus of shells, the characters of which are these:

It is a bivalve shell, of a coarse external structure, and dirty appearance; each shell being composed of a great number of laminæ not nicely closed down upon one another. It is in some species smooth, in others striated, tuberose, or prickly; usually flat, but sometimes globose, plicated, and wrinkled into sinuses; the lower shell being always deeper than the other. Aldrovand supposes this genus of shell fish obtained the name Ostreum, from the Greek ὀστέον, a bone, as they are of a bony hardness.

Most authors have confounded the two genera of oisters and chamæ together, though there is an obvious and an invariable distinction. The oister is rough, and has a sort of beak; and, notwithstanding the roughness of both shells, it always ſhuts very evenly and firmly: add to this, that one of its ſhells is flat, the other convex; and is thus abſolutely diſtinguiſhed from the chamæ. *Hiſt. Nat. Eclair.*

Oiſters, in their growth, become faſtened to every ſolid ſubſtance which they happen to come into contact with; and rocks, ſmall ſtones, wood, ſea-plants, and a thouſand other things are found at times with Oiſters adhereing to them, whoſe ſhells have fitted themſelves to the form of the thing itſelf, and left their natural ſhape. The people who fiſh for, and trade in Oiſters, pretend to diſtinguiſh two kinds; one of which is fecund and will breed; the other which is barren. They ſay, they diſtinguiſh theſe by a little black fringe, which always ſurrounds the good breeding Oiſters.

The way to make Oiſters green is, to put them into ſmall pits where the water is about three feet deep, and where the ſun has great power; in theſe they become green in three or four days.

OSY'RIS, *poets caſia*, in botany, a genus of plants whoſe characters are:

It is male and female in different plants: the empalement of the flower is of one leaf, which is divided into three acute ſegments; the flower hath no petals; but thoſe on the male plants, have three ſhort ſtamina; and thoſe on the female have a roundiſh pointal, which afterwards changes to a globular berry, having a ſingle ſeed.

OTHO'NNA, *African ragwort*, in botany, a genus of plants whoſe characters are:

It hath a compound flower, conſiſting of many florets and half florets, incloſed in one common empalement: the florets are hermaphrodite; theſe are tubulous, and indented at the brim; the half florets are female; theſe are ſtretched out on one ſide with a narrow ſegment, like a tongue, beyond the empalement: the hermaphrodite flowers have each five ſmall ſtamina: the female flowers have an oblong pointal, which afterward turns to a ſingle oblong ſeed covered with a down.

O'TTER, in zoology, the name of an amphibious animal, ſmaller than the beaver, and has a longer and more ſlender body. Its tail is alſo longer than that of the beaver, and is all over covered with hair, and its legs are very ſhort in proportion to the ſize of its body. The feet have all five toes each, which are naturally expanded, and are connected by a membrane like the toes of web-footed fowl; and are all ſo equally diſtant, that there is no diſtinction of any in the place of the great toe in other animals. The head and face exactly reſemble the beaver, and the ears are ſmall, and placed under the eyes, near the upper jaw, as in the beaver. The hair is ſhort, and of a cheſnut brown, but paler under the belly. The tail has ſhorter hair than that of the body, but longer than that of the legs. *Ray's Syn. Quad.*

OV'EN, or *Aſſaying* OVEN; ſee *Aſſaying* FURNACE.

O'VIS, *the ſheep*. See the article SHEEP.

OU'TLICKER, or OUTLIGGER, in a ſhip, a ſmall piece of timber, three or four yards long, as occaſion ſerves, made faſt to the top of the poop, and ſtanding right out a-ſtern: at the outmoſt end of it is a hole, into which the ſtanding part of the ſheet is received, and made faſt through the block of the ſheet; and then again received through another block, which is ſeized to this Outlicker, hard by the end of it. This is ſeldom uſed in men of war, or in great ſhips; and, whenever it is made uſe of, it is becauſe the mizen maſt is placed ſo far aft, that there is not room enough within board to hale the ſheet flat.

OWL *Pigeon*, the name of a peculiar ſpecies of pigeon, called, by Moore, the columba bubo nominata. It is a ſmall and ſhort-bodied pigeon. It has a ſhort round head, and has a ſeries of feathers that ſeparate and open two ways upon the breaſt: but its moſt remarkable character is its beak, the upper chop of which is bent, and hooked over like an Owl's: this is the occaſion of its name: it is of various colours, as white, blue, or black, but is always of only one colour, never pied.

OU'ZELL, or *brook* OUZELL, in zoology, an Engliſh name for the rollus aquaticus, more uſually called the water rail.

OUZELL, or *ring* OUZELL, an Engliſh name for a bird of the merula or blackbird kind, remarkable for a white ring about its neck, and thence called by authors merula torquata; it is more commonly called, in Engliſh, the ring amzell. *Ray's Ornithology.*

OX, *bos*, a well known, and a very ſerviceable animal, in many reſpects; but his nature depends wholly on that of the bull and cow, from which he is bred. Derbyſhire and Lancaſhire are ſaid to have the beſt Oxen in England. Wales, and the iſland of Angleſea, afford a kind that are very valuable to the farmers, as they will fatten upon middling land; and the Scotch Oxen are yet hardier than theſe. The long-legged ſhort-horned cow, of the Dutch breed, is the beſt for milk; but then this kind needs to be very carefully kept. This ſort of cow will often yield two gallons of milk at a time.

When theſe creatures are intended to breed, the better the land is, the larger ſort of beaſts are to be choſen, and the greater will be the profit. But, of whatever ſort the breed is, the bull ſhould always be of the ſame country with the cow, otherwiſe it never ſucceeds ſo well. The bull ſhould be choſen of a ſharp quick countenance, his forehead broad and curled, his eyes black and large, his horns long, his neck fleſhy, his belly long and large, and his hair ſmooth and like velvet; his breaſt ſhould be large, his back ſtraight and flat, his buttocks ſquare, his thighs round, his legs ſtraight, and his joints ſhort. This ſort of bull is the beſt for breed, and makes the beſt Oxen for draught as well as for fattening.

The cow ought to have a broad forehead, black eyes, great clean horns, the neck long and thin, the belly large and deep, the thighs thick, the legs round, and the joints ſhort; a white large and deep udder with four teats, and large feet. The ſize muſt be proportioned to the goodneſs of the land. The largeſt cows, in general, give the greateſt quantity of milk; and it is always a good rule to take the cattle from a worſe ground than that on which they are to be kept; for, if from a better, they are apt to degenerate. The beſt time of a cow's life, for breeding of calves, is from three years old till twelve: the black cows are uſually choſen to breed out of.

The largeſt Oxen are to be choſen for work, and for feeding, but then it muſt be where there is land rich enough to maintain them. When they are to draw, care muſt be taken to match them well, both for height and ſtrength; for, if one be ſtronger than the other, the weakeſt will ſoon be deſtroyed. They muſt never be driven beyond their natural pace, for the beating them throws them into ſurfeits, and many other diſeaſes.

The time of putting Oxen to work is at three years old; they muſt be worked gently the firſt year, eſpecially in hot weather, and fed with a large quantity of hay: this will enable them to bear their labour better than graſs; and they ſhould be always kept in a middle ſtate, neither too fat nor too lean. They may be worked till they are ten or twelve years old, and then ſold.

It is obſerved, that meat and fair treatment ſucceed much better with this animal than blows. The beſt way to break a young one to the yoke, is to put him to it with an old tame Ox of about his own height and ſtrength. If he prove unruly after this, he muſt be kept hungry, and made to feed out of the driver's hand. Oxen are much more profitable to keep than horſes, there being no loſs in them; an old wrought Ox fattening as well as a young one, and being as good meat. Their keeping alſo is cheaper, for they eat no oats: their harneſs and their ſhoes alſo are conſiderably cheaper, and they are not ſo ſubject to diſeaſes. They muſt always indeed have good graſs and good hay, and they are not ſo ſerviceable as horſes, when there is much working in carts, and where the ways are good; but for winter plowing, where the ground is heavy, an Ox will do as much work as a horſe.

Every farmer who can keep two teams, would do well to have one of them of horſes, and the other of oxen; it is much better to yoke them together by the necks and breaſts, than by the horns as ſome do; and, where a man keeps an Ox team, he ſhould raiſe two Oxen and two cow calves every year to keep up his ſtock; for it is better for a farmer, in all neceſſary things, to be a ſeller than a buyer. Chalky land ſpoils the feet of Oxen more than any other. *Mortimer's Huſbandry.*

OX-*eye*, in the ſea language, a name given by the ſeamen to thoſe dreadful ſtorms that are ſometimes met with on the coaſt of Guinea; for at firſt it appears in the form of an Ox's eye, and not much bigger; but it deſcends with ſuch celerity, that in a very little ſpace of time, and often before they can prepare themſelves for it, it ſeems to them to overſpread the whole hemiſphere, and at the ſame time forces the air with ſo much violence, that the ſhips are ſometimes ſcattered ſeveral ways, ſome directly contrary, and ſometimes are ſunk downright.

OX-*fly*, in natural hiſtory, a ſpecies of two-winged fly, bred from a fly-worm, hatched under the ſkin of Oxen, from the egg of the parent fly lodged there.

This fly, cloſely examined, appears to be of the ſecond claſs, and to have a mouth without teeth or lips, and its mouth very ſmall. The antennæ are very ſhort, rounded at their ends, and of a gloſſy hue. The reticular eyes are of a deep cheſnut colour.

The female, has, in the under and hinder part of his body, a cylindric tube, which ſhe can thruſt out at pleaſure, and which is the inſtrument with which ſhe pierces the ſkin of the animal, to depoſit her egg. *Reaumur, Hiſt. Inſ.*

OX-*gang*, or OXENGATE, (*Dict.*)—In Scotland this term ſignifies a portion of arable land, containing 13 acres.

O'XYS, *wood ſorrel*, in botany, a genus of plants, whoſe characters are:

It hath a bell-ſhaped flower, conſiſting of one leaf, having its brim wide expanded, and cut into ſeveral diviſions: the pointal, which riſes from the flower cup, becomes an oblong, membranaceous fruit, divided into five ſeminal cells, opening outward from the baſe to the top, and incloſing ſeeds which ſtart from their lodges, by reaſon of the elaſtic force of the membrane which involves them.

OY'STER. See OSTREA.

OYSTER-*worm*, in natural hiſtory, a name given by writers to a kind of ſmall worm found in Oyſters, which ſhines in the dark, in the manner of the glow-worm; but with an univerſal light, and not in a peculiar part only, like this animal.

P.

P.

PACHODECARHO'MBIS *, in natural hiſtory, the name of a genus of foſſils, of the claſs of the ſelenitæ.

* The word is derived from the Greek παχὺς, thick, δέκα, ten, and ῥόμβος, a rhombus, and expreſſes a thick rhomboidal body, compoſed of ten planes.

The characters of this genus are, that the ſelenitæ of it conſiſt of ten planes; but as the top and bottom in the leptodecarhombes, or moſt common kind of the ſelenitæ, are broader and larger planes than any of the reſt, the great thickneſs of this genus, on the contrary, makes it four longer in all the bodies of it, meeting in an obtuſe angle from its ſides, its largeſt planes. *Hill's Hiſt. of Foſſ.*

PA'DDLE, in glaſs-making, the name of an inſtrument with which the workman ſtirs about the ſand and aſhes in the calcar. *Neri's Art of Glaſs.*

PÆDARTHRO'CACES, in ſurgery, is a diſeaſe of the bones, raiſing them into tumors near the joints, and differing from the ſpina ventoſa, in that it is not attended either with violent pains, or eroſions of the bone and adjacent parts. The word is derived from the Greek παῖς, a child, ἄρθρον a joint, and κακὸν, an evil, ſignifying, that it is a diſorder of the joints, to which children are principally ſubject; which is the caſe, becauſe the bones of children, being ſofter than thoſe of adults, are therefore the more eaſily diſtended by humours, and more frequently raiſed into tumors: theſe are hard in this caſe, and the adjacent ſoft parts are not inflated, and are free from redneſs, inflammation, and pain. It is, however, to be obſerved, that this diſorder, though at firſt very different from the ſpina ventoſa, is ſometimes known to degenerate into that diſorder. *Heiſter's Surgery.*

PÆO'NIA, *the peony*, in botany, the name of a genus of plants, whoſe characters are:

It hath a flower compoſed of ſeveral leaves, which are placed orbicularly, and expand in form of a roſe; out of whoſe empalement riſes the pointal, which afterwards becomes a fruit, in which ſeveral little horns, bent downward, are gathered, as it were, into a little head, covered with down, opening lengthwiſe, containing many globulous ſeeds.

They are propagated by parting their roots, which multiply very faſt. The beſt ſeaſon for tranſplanting them, is, towards the latter end of Auguſt, or the beginning of September; for, if they are removed after their roots have ſhot out new fibres, they ſeldom flower ſtrong the ſucceeding ſummer.

In parting of theſe roots, you ſhould always obſerve to preſerve a bud upon the crown of each off-ſet, otherwiſe they will come to nothing; nor ſhould you divide the roots too ſmall, eſpecially if you have regard to their blowing the following year; for, when their off-ſets are weak, they many times do not flower the ſucceeding ſummer, or, at leaſt, produce but one flower upon each root: but, where you would multiply them in quantities, you may divide them as ſmall as you pleaſe, provided there be a bud to each off-ſet; but then they ſhould be planted in a nurſery bed, for a ſeaſon or two, to get ſtrength, before they are placed in the flower garden.

The ſingle ſorts may be propagated from ſeeds, which they generally produce in large quantities, where the flowers are permitted to remain; which ſhould be ſown in the middle of Auguſt upon a bed of light freſh earth, covering them over about half an inch thick with the ſame light earth; the ſpring following the plants will come up, when they ſhould be carefully cleared from weeds, and, in very dry weather, refreſhed with water, which will greatly forward their growth. In this bed they ſhould remain two years before they are tranſplanted, obſerving in autumn, when the leaves are decayed, to ſpread ſome freſh rich earth over the beds about an inch thick, and conſtantly to keep them clear from weeds. *Miller's Gard. Dict.*

The roots, flowers, and ſeeds, are cephalic, and counted good againſt the epilepſy, apoplexy, and all kinds of convulſions, and nervous affections, both in young and old; as alſo in hyſteric caſes, the obſtructions of the menſes, and the retention of the lochia. The root and ſeed are hung about children's necks, to prevent convulſions in breeding their teeth. *Miller's Bot. Off.*

PAI'NTING *in oil.*— The art of Painting in oil was unknown to the ancients; and it was a Flemiſh Painter, one John van Eyck, or John de Bruges, who firſt diſcovered, and put it in practice, in the beginning of the fourteenth century: till him, all painters wrought in freſco, or in water-colours.

This was an invention of the utmoſt advantage to the art; ſince, by means hereof, the colours of a Painting are preſerved much longer and better, and receive a luſtre and ſweetneſs which the antients could never attain to, what varniſh ſoever they made uſe of to cover their pieces.

The whole ſecret only conſiſts in grinding the colours with nut-oil or linſeed-oil: but it muſt be owned, the manner of working is very different from that in freſco, or in water; by reaſon the oil does not dry near ſo faſt; which gives the painter an opportunity of touching and retouching all the parts of his figures, as often as he pleaſes: which, in the other kinds, is a thing impracticable.

The figures too are here capable of more force and boldneſs, inaſmuch as the black becomes blacker, when ground with oil than with water; beſides that, all the colours, mixing better together, make the colouring ſweeter, more delicate and agreeable, and give an union and tenderneſs to the whole work, inimitable in any of the other manners.

Painting in oil is performed on walls, on wood, canvas, ſtones, and all ſorts of metals.

To paint on a wall.— When well dry, they give it two or three waſhes with boiling oil, till the plaiſter remain quite greaſy, and will imbibe no more. Over this they apply deficcative or drying colours, viz. white chalk, red oker, or other chalks beaten pretty ſtiff. This layer being well dry, they ſketch out, and deſign their ſubject; and at laſt paint it over; mixing a little varniſh with their colours, to ſave the varniſhing afterwards.

Others, to fortify their wall better againſt moiſture, cover it with a plaiſter of lime, marble-duſt, or a cement made of beaten tiles ſoaked with linſeed-oil; and at laſt prepare a compoſition of Greek pitch, maſtich, and thick varniſh boiled together, which they apply hot over the former plaiſter: when dry, they lay on the colours as before.

Others, in fine, make their plaiſter with lime-mortar, tile-cement, and ſand; and, this dry, apply another of lime, cement, and iron ſcum; which, being well beaten and incorporated with whites of eggs and linſeed oil, makes an excellent plaiſter. When dry, the colours are applied as before.

To paint on wood.— They uſually give their ground a layer of white tempered with ſize, or they apply the oil abovementioned; the reſt as in Painting on walls.

To paint on cloth, or canvas.—The canvas being ſtretched on a frame, they give it a layer of ſize, or paſte-water. When dry, they go over it with a pumice-ſtone, to ſmooth off the knots. By means of the ſize the little threads and hairs are all laid cloſe on the cloth, and the little holes ſtopped up, ſo as no colour can paſs through.

When the cloth is dry, they lay on oker, which is a natural earth, and bears a body; ſometimes mixing with it a little white lead, to make it dry the ſooner. When dry, they go over it with the pumice-ſtone, to make it ſmooth.

After this, they ſometimes add a ſecond layer compoſed of white lead, and a little charcoal black, to render the ground of an aſh-colour; obſerving in each manner to lay on as little colour as poſſible; that the cloth may not break, and that the colours, when they come to be painted over, may preſerve the better.

In ſome Paintings of Titian and Paolo Veroneſe, we find they made their ground with water, and painted over it with oil; which contributed much to the vivacity and freſhneſs of their works: for the water ground, by imbibing the oil of the colours, leaves them the more beautiful; the oil itſelf taking away a deal of their vivacity.

As little oil therefore is to be uſed as poſſible, if it be deſired to have the colours keep freſh: for this reaſon ſome mix them with oil of aſpic, which evaporates immediately, yet ſerves to make them manageable with the pencil.

To paint on ſtones or metals, it is not neceſſary to apply ſize, as on cloth; it ſuffices to add a ſlight layer of colours, before you draw your deſign; nor even is this done, on ſtones, where it is deſired the ground ſhould appear, as on certain marbles of extraordinary colours.

PA'LATE (*Dict.*)— The Palate is that arch and cavity of the mouth ſurrounded anteriorly by the alveolary edge and teeth of of the upper jaw, and reaching from thence to the great opening of the pharynx. This arch is partly solid and immoveable, and partly soft and moveable. The solid portion is that which is bounded by the teeth, being formed by the two ossa maxillaria, and two ossa palati. The soft portion lies behind the other, and runs backward like a veil fixed to the edge of the ossa palati, being formed partly by the common membrane of the whole arch, and partly by several muscular fasciculi, &c.

The membrane that covers all this cavity, is like that which lines the superior and middle portions of the pharynx. It is very thick set with small glands, the orifices of which are not so sensible as in the pharynx, and especially in the rugæ of the superior portion thereof, where Heister observed a considerable orifice, and a canal proportioned to that orifice, which he could easily inflate with air. This is certainly the best way of beginning these kinds of inquiries, especially if the pipe be held at first only very near the part, without endeavouring to force it in. To immerge the parts in clear water, is likewise a very good way to discover small orifices by the help of a microscope. Small ducts, of the same kind with what I have now mentioned, may be supposed to lie along the middle line, or raphe, of the arch of the Palate, and along the alveolary edge, because of some small tubercles, or points, which appear there.

This membrane, together with that of the posterior nares, forms, by an uninterrupted continuation, the anterior and posterior surfaces of the soft portion, or septum palati; so that the muscular fasciculi of this portion lie in the duplicature of a glandulous membrane. The muscles composed of these fasciculi shall be presently described.

The septum, which may likewise be called velum, or valvula palati, terminates below by a loose floating edge, representing an arch, situated transversly above the basis or root of the tongue. The highest portion, or top of this arch, sustains a small, soft, and irregularly conical glandulous body, fixed by its basis to the arch, and its apex hanging down without adhering to any thing, which is called uvula.

On each side of the uvula, there are two muscular half arches, called columnæ septi palati. They are all joined to the uvula by their upper extremities, and disposed in such a manner, as that the lower extremities of the two, which lie on the same side, are at a little distance from each other, and so, as that one half arch is anterior, the other posterior, an oblong triangular space being left between them, the apex of which is turned toward the basis of the uvula.

The two half arches on one side, by joining the like half arches on the other side, form the entire arch of the edge of the septum. The posterior half arches run by their upper extremities, more directly towards the uvula than the anterior. The anterior half arches have a continuation with the sides of the basis of the tongue, and the posterior with the sides of the pharynx. At the lower part of the space left between the lateral half arches on the same side, two glands are situated, termed amygdalæ.

The half arches are principally made up of several flat fleshy portions, almost in the same manner with the body of the septum. The membrane which covers them is thinner than the other parts of it towards the Palate, pharynx, and tongue. Each portion is a distinct muscle, the greatest part of which terminates in one extremity, in the substance of the septum, and of the half arches; and, by the other extremity, in parts different from these.

Ulcers of the PALATE.— These ulcers are of so malignant a nature, that, sometimes, they not only consume the soft parts, but corrode the bones, and extend themselves even to the nose. The voice of the patient becomes not only altered and broken, but whatever he drinks is immediately discharged by the nose with very great uneasiness. These ulcers proceed from a scorbutic acrimony, or a venereal infection in the blood; and, if the cause is not speedily removed, not only the Palate, but, likewise, the nose, will be in a miserable manner destroyed.

The first intention of cure, therefore, must be either to alleviate, or entirely remove, the acrimony of the blood, or the venereal malignity, by proper internal medicines. If the Palate is not yet perforated or consumed by the caries, let it be cleansed with frequent gargarisms, ointments, and injections. For this purpose, first, make a decoction of agrimony, St. John's-wort, ladies-mantle, and the like vulnerary herbs; then mix it with honey of roses, or, if more powerful detergents are necessary, with ungentum Ægyptiacum, or fuscum. The honey that swims a-top of the Ægyptiacum, and, also, Fallopius's alum-water, are excellent detergents, even when the caries has affected the bones. As often as the ulcer is thus cleansed, it will not be improper, soon after, to apply to the ulcerated part with lint, or a pencil, honey of roses, oil of myrrh, per deliquium, elixir proprietatis, or Peruvian balsam.

If the caries has already seized the bones, the morbid part may be separated from the sound, by the remedies already recommended, especially if the part be carefully anointed with the oil of cloves, or with honey of roses acidulated with spirit of vitriol, the internal medicines being constantly continued. But, when these do not succeed, the actual cautery ought to be gently applied to the morbid bone, after having carefully cleansed the ulcer with dry lint, and secured the tongue from injury, by covering it with wet linen cloths, and applying the speculum oris. After the cauterization is completed, continue the application of balsamic remedies, till the bone is again covered with flesh, and the ulcer entirely cured. But those perforations, which penetrate through the Palate to the nose, can never again be naturally closed.

PALE, in heraldry (*Dict.*)—*Plate* XLIV. *fig.* 8, in the Dictionary, represents one of the honourable ordinaries called Pale.

PALLISADOES, or PALISADOES, in fortification.—*Plate* XXXI. *fig.* 11, in the Dictionary, represents a row of Pallisadoes. See PALISADE, in the Dictionary.

PALIU'RUS, *Christ's thorn*, in botany, a genus of plants, whose characters are:

It has long and very sharp spines, disposed in regular order. The calyx is monophyllous and pentaphylloidal; the flower rosaceous, pentapetalous, and furnished with five stamina. The ovary in the bottom of the calyx becomes a fruit, resembling a bonnet, or target, and surrounding another almost globular and tricapsular fruit, containing, in each capsula or cell, one round seed.

The leaves and root of the Paliurus are astringent, stop a looseness, and digest and cure tubercles; and the fruit is so powerfully inciding, as to diminish the stone in the bladder, and promote excretions from the breast and lungs. The seeds bruised are commended against the cough, and the physicians of Montpelier prescribe their use in disorders from sand and gravel. *Raii, Hist. Plant.*

PA'LMA, the *palm-tree*, in botany, a genus of plants, whose characters are:

It hath a single unbranched stalk: the leaves are disposed in a circular form on the top, which, when they wither, or fall off with age, new ones always arise out of the middle of the remaining ones; among which, certain sheaths or plain twigs break forth, opening from the bottom to the top, very full of flowers, and clusters of embryo's.

These plants may be easily produced from the seeds, provided they are fresh; which should be sown in pots filled with light rich earth, and plunged into an hot-bed of tanner's bark; which should be kept in a moderate temper, and the earth frequently refreshed with water.

When the plants are come up, they should be each planted into a separate small pot filled with the same light rich earth, and plunged into an hot bed again, observing to refresh them with water, as also to let them have air in proportion to the warmth of the season, and the bed in which they are placed. During the summer time they should remain in the same hot bed; but in August you should let them have a great share of air to harden them against the approach of winter; for, if they are too much forced, they will be so tender as not to be preserved through the winter without much difficulty, especially if you have not the conveniency of a bark stove to keep them in.

The beginning of October you must remove the plants into the stove, placing them where they may have a great share of heat, these being somewhat tenderer, while young, than after they have acquired some strength: though indeed they may be sometimes preserved alive in a cooler situation, yet their progress would be so much retarded, as not to recover their vigour the succeeding summer. Nor is it worth the trouble of raising these plants from seeds, where a person has not the conveniency of a good stove to forward their growth; for, where this is wanting, they will not grow to any tolerable size in eight or ten years.

Whenever these plants are removed, which should be done once a year, you must be very careful not to cut or injure their large roots, which is very hurtful to them; but you should clear off all the small fibres which are inclinable to mouldiness; for, if these are left on, they will in time decay, and hinder the fresh fibres from coming out, which will greatly retard the growth of the plants.

The soil in which these plants should be placed, must be composed in the following manner, viz. a third part of light fresh earth taken from a pasture ground; a third part sea sand; and the other part rotten dung, or tanner's bark: these should be carefully mixed, and laid in an heap three or four months at least before it is used; but should be often turned over, to prevent the growth of weeds, and to sweeten the earth.

You should also observe to allow them pots proportionable to the sizes of the plants; but you must never let them be too large, which is of worse consequence than if they are too small. During the summer season they should be frequently refreshed with water; but you must be careful not to give it in too great quantities; and in winter they must be now and then refreshed, especially if they are placed in a warm stove; otherwise they will require very little water at that season.

These plants are most of them very slow growers, even in their native countries, notwithstanding they arrive to a great magnitude; for it has been often observed by several of the old inhabitants of those countries, that the plants of some of these kinds have not advanced two feet in height in twenty years; so that, when they are brought into these countries, it cannot

cannot be expected they should advance very fast, especially where there is not due care taken to preserve them warm in winter: but, however slow of growth these plants are in their native countries, yet they may be with us greatly forwarded, by placing the pots into an hot-bed of tanner's bark; which should be renewed as often as necessary, and the plants always preserved therein both winter and summer, observing to shift them into larger pots as they advance in growth, as also to supply them with water: in which management I have had several of them come on very fast; for I observe the roots of these plants are very apt to root into the bark, if these pots remain a considerable time without shifting, where they meet with a gentle warmth; and the moisture arising from the fermentation of the bark doth preserve their fibres plump and vigorous. *Miller's Gard. Dict.*

PA'NCREAS (*Dict.*)— The Pancreas, by means of its glandular structure, secretes from the cœliac arteries an humour into one common duct, which terminates in the duodenum, into which it discharges all the quantity of lymph secreted.

This pancreatic juice is almost insipid, or but gently saline, limpid, continually secreted in large quantities, by the motion, pressure, warmth, and contiguity of the heart; but it is most copiously discharged, when, during digestion, the stomach is turgid. It is neither acid nor alcaline, but bears a great resemblance to the saliva, not only with respect to its origin, but also with respect to its qualities, and the vessels subservient to its generation. In those who are alive, this juice is mixed and incorporated with the bile; and, being lodged in the same common duct, produces no marks of any intestine motion, but is equally mixed with it, or is discharged alone, and by itself, into the empty intestines. Hence, the uses of the pancreatic juice, when mixed and incorporated with the chyle, the fæces, the bile, and the mucus, are to dilute the thick parts of the fluids, to produce a due mixture of them, to render the chyle capable of mixing with the blood, to fit it for its passage through the lacteals, to correct the acrimonious parts of the fluids, to correct the viscidity and bitterness, and to change the colour of the bile, and to mix it intimately with the blood to serve as a proper menstruum or vehicle, so to change the tastes, smells, and qualities of aliments, as that they assume nearly the same nature; and, lastly, to go and return, and consequently answer all these ends, with the utmost expedition. *Boerhaav. Instit.*

Practical authors furnish us with some instances of abscesses in the Pancreas, which, however, were not discovered till after the death of the patients: but such abscesses may be, in a great measure, guessed at, from the symptoms of the patients, some of which are the same with those accompanying a scirrhus of the Pancreas; but to these signs may be added a slow fever, the almost inseparable concomitant of internal abscesses, long-protracted watchings, short sleeps, and, after them, weariness, faintings, and cold sweats.

If the patient has a tumor under the region of the stomach, that is indolent, and it is attended with an obstinate costiveness, we may be sure there is a scirrhus of the Pancreas; especially if any of the causes of a scirrhus have preceded.

The pancreatic juice dilutes the fæces, and perhaps stimulates the intestines, in some measure, to an expulsion of their contents; therefore, when there is a defect of this, the patient must be costive.

When a person has a cancer in the Pancreas, when fasting, he will feel a great weight under the stomach; after eating he is in extreme pain, but more so, if he vomits; he will have a diarrhœa, and then fall into an atrophy, and die.

A copious use of cherries, perfectly ripe, is very much recommended in a scirrhus of the Pancreas; and they are preferable to currants, which, have something acrimonious in them, and are prejudicial to hysterical women.

PANGO'NIA †, in natural history, the name of a genus of crystal.

† The word is derived from the Greek πᾶς, numerous, and γωνία, an angle or bending, and expresses a crystal, composed of many angles.

The bodies of this genus are single-pointed, or imperfect crystals, composed of dodecangular or twelve planed columns, terminated by twelve planed pyramids, and the whole body, therefore, made up of twenty-four planes.

PANIO'NIA, Πανιώνια, in antiquity, a festival in honour of Neptune, celebrated by a concourse of people from all the cities of Ionia.

One thing is remarkable in this festival, that if the bull offered in sacrifice happened to bellow, it was accounted an omen of the divine favour; because that sound was thought to be acceptable to Neptune. *Potter, Archæol. Græc.*

PA'RALLAX (*Dict.*)— PARALLAX *of declination*, is an arch of a circle of declination S I, *Plate* XXXIII. *fig.* 5, whereby the Parallax of altitude increases or diminishes the declination of a star.

PARALLAX *of right ascension and declension*, is an arch of the equator D *d*, *Plate* XXXIII. *fig.* 5, whereby the Parallax of altitude increases the ascension, and diminishes the descension.

PARALLAX *of longitude*, is an arch of the ecliptic T *t*, *Plate* XXXIII. *fig.* 5, whereby the Parallax of altitude increases or diminishes the longitude.

PARALLAX *of latitude*, is an arch of a circle of latitude S *l*, *Plate* XXXIII. *fig.* 5, whereby the Parallax of altitude increases or diminishes the latitude.

PARIETA'RIA, *pellitory of the wall*, in botany, a genus of plants, whose characters are:

The flower is male, tetrapetaloidal, stellated, furnished with four stamina, and with testiculi, having a small apex in the center, without an ovary. The flower is female, consisting of a foliaceous, trifoliated calyx, in whose center is a conoidal ovary, furnished with a fimbriated tube in another place of the plant. The floscules and ovaries are closely collected in thick nodes to the stalks.

It is cooling, opening, and cleansing, abounding in nitro-sulphureous salt, and is accounted very good for the stone, gravel, stoppage and heat of urine; and for these purposes the juice, or decoction, is given in draughts, or in clysters; some commend the same for coughs. *Miller's Bot. Off.*

By the chemical analysis, pellitory yields a great deal of oil, a great deal of fixed salt and earth, and several liquors, of which some are acrid, and the rest acid: as for the volatile salt, one obtains none that is concrete from this plant, but it yields an urinous spirit.

PARKINSO'NIA, in botany, a genus of plants, whose characters are:

It hath a polypetalous, anomalous flower, consisting of five dissimilar leaves, from whose cup arises the pointal, which afterwards becomes a rough-jointed point; each knot or joint containing one kidney-shaped seed.

This plant was discovered by father Plumier, in America, who gave it this name, in honour to the name of Mr. John Parkinson, who published an Universal History of Plants, in England, in the year 1640.

It is very common in the Spanish West-Indies; but, of late years, it has been introduced into the English settlements in America, for the beauty and sweetness of its flowers. This, in the countries where it grows, naturally rises to be a tree of twenty feet high, or more; and bears long slender branches of yellow flowers, which hang down after the same manner as the laburnum. *Miller's Gard. Dict.*

PARNA'SSIA, *grass of Parnassus*, in botany, a genus of plants, whose characters are:

The leaves are roundish, and disposed in a circle; the calyx pentaphylloidal; the flower rosaceous, one on a stalk, consisting of greater and smaller fimbriated petals. The ovary becomes a small conoidal fruit, opening into three or four keel-shaped cells, full of minute seeds.

It grows in putrid and marshy places, and flowers in August: the parts used in medicine are the root, herb, and seed.

The juice of the leaves, and decoction of the root, are most approved medicines for the eyes. The seed is a powerful provocative of urine, and stops a looseness and vomiting. Dioscorides. It strengthens the liver, and frees it from obstructions. Chab. It is vulnerary and astringent, and is said to be effectual in stopping hæmorrhages. *Hist. Plant. adscript. Boerhaav.*

PA'RROT, the English name for a well known genus of birds.

PA'RSNEP, *pastinacha*, in botany, the name of a well known root.

The Parsnep is to be propagated by sowing their seeds in February or March, in a rich mellow soil, which must be deep dug, that the roots may be able to run deep without hindrance.

It is a common practice to sow carrots, at the same time, upon the same ground with the Parsneps; and, if the carrots are designed to be drawn young, there is no harm in it. The Parsneps, when they are grown up a little, must be thinned to a foot distance, and carefully kept clear of weeds. They are finest tasted, just at the season when the leaves are decayed; and such as are desirous to eat them in spring should have them taken up in autumn, and preserved in sand. When the seeds are to be saved, some very strong and fine plants should be left for it at four feet distance; and towards the end of August, or in the beginning of September, the seeds will be ripe: they must then be carefully gathered, and dried on a coarse cloth. They should always be sown the spring following, for they do not keep well. *Miller's Gard. Dict.*

The common wild Parsnep is frequent by road sides, and in dry pastures; it flowers in autumn, and ripens its seed soon after. The seeds deserve to be brought into use in medicine, much more than they are at present. They are warm and carminative, though not so violently hot as the caraway seeds and others which we commonly use on these occasions. They dispel flatuses, and are in great esteem among the country people, for curing the cholic. They also are diuretic and aperient, and gently promote the menses.

PARTI'TION, in husbandry. The Partitions in land sown with wheat by the drill, for the horse-hoeing husbandry, are different, according as the wheat is sown, in double, treble, or quadruple rows. The double row has but one Partition, and this is best to be used in cases where the land is suspected to be full of the seed of weeds, which must be taken out with the hand-hoe. This Partition should be twelve or fourteen inches wide. Whole fields drilled in these rows may be hand-hoed at the expence of four shillings an acre; and, when there is but one foot in fix, the price of that work ought to be proportionable.

The common width of the two Partitions, when the wheat is fown in treble rows, is fix or eight inches. Care is to be taken in this particular; for, if they are planted clofer, they will ftarve one another before the intervals are hoed to give them a frefh fupply of nourifhment; and, if they are planted too far afunder, the two outer rows will thrive well, but the middle row will be ftarved, and look worfe and weaker, becaufe of its being alfo a greater diftance from the hoed intervals. In quadruple rows the Partitions are beft to be feven inches wide each; at this diftance the plants will thrive fufficiently, and, if they are fet nearer, the whole will be worfe; and, if farther off, the outer rows will thrive, but the two inner ones will be ftarved, by reafon of their diftance from their plowed intervals.

PA'RTRIDGE, *perdix*, in ornithology.— The Partridge is a timorous and fimple bird, and is fo valuable at the table, that there are a great many ways of taking it invented by the fportfmen, all of which fucceed from the folly and fear of the animal.

The places that Partridges moft delight in, are corn fields, efpecially while the corn grows; for that is a fafe retreat, where they remain undifturbed, and under which they ufually breed. They frequent the fame fields after the corn is cut down, and that with another intent; for they then feed on the corn that has fallen from the ears, and find a fufficient fhelter for them under covert of the ftalks, efpecially thofe of wheat ftubble. When the wheat ftubble is much trodden by men or beafts, they retire to the barley ftubble, and will there hide themfelves in coveys of twenty or thirty. When the winter comes on, and the ftubble fields are trodden down or plowed up, they then retire to the upland meadows, where they lodge in the high grafs, and among the rufhes; fometimes they refort to the low coppice woods, efpecially if there be corn lands near them.

Red-legged PARTRIDGE, a very delicate and valuable bird, called cutumo by the Italians.

It is diftinguifhed from the common Partridge by the rednefs of its beak and legs. It is of a greyifh afh-colour on the back; its throat is white near the head, but has a fmall black fpot on each fide at the angle of the bill, and this white fpace is furrounded by a black line; its breaft is of a yellowifh brown, and its wings are variegated with black, yellowifh, and white. It is not found in England, but is fometimes fhot in the iflands of Guernfey and Jerfey. *Ray's Ornithology.*

PA'RTY-*china*, a name given by the Englifh merchants and others to a fort of porcelain or China ware, which is elegantly painted on the outfide with fome bright colour, and blotted or variegated with round or fquare fpots of a different tinge. The manner in which the Chinefe do this is a very fimple and eafy one, and may be imitated in our own potteries with great eafe. They prepare as many pieces of paper as they intend to have fpots on the veffel, and cut them exactly into the fhape of thofe fpots: they wet thefe, and then fpread them fmoothly on the places where the fpots are to be. When this is done, they cover the veffel with the brown and gold, or any other varnifh, and then take off the papers: in the places which they covered no varnifh has come, fo that they are fo many regular white fpaces. Thefe they cover with fome other colour, laying it on carefully with a pencil: when this is done, they varnifh over the whole veffel with the common varnifh, and bake it. In fome veffels they lay on only plain blue, or plain black, in the fpaces defigned for fpots; and, after the firft baking, they cover thefe with gold, and make them fo many figures of fquares, triangles, or globes in pure gold. *Obferv. fur les Coutumes de l'Afie.*

PA'SSION (*Dict.*)— Dr. Cheyne confiders the Paffions as either fpiritual or animal:— fpiritual Paffions he defines to be thofe fentiments produced in the foul by external objects, either fpiritual ones immediately, or material ones by the meditation of the organs of the body.

Animal Paffions he defines to be thofe effects produced by fpirits or bodies, immediately on the body.

Hence, as outward objects may be confidered either as goods or evils; the moft natural divifion of the Paffions, whether fpiritual or animal, as they regard thofe objects, is into pleafurable and painful.

And, in this fenfe, all the Paffions may be reduced to love and hatred; of which joy and forrow, hope and fear, are only fo many modifications or complexions, according to the various appearances, pofitions, &c. of the object.

In effect, all the Paffions may not only be reduced to two, viz. love and hatred; but, perhaps, to one, love; and even that may be all refolved into felf-love; and this into a principle of felf-prefervation, or neceffary invincible defire of pleafure, or happinefs.— The reft are only rivulets from this fource, or fpecial applications of this principle to particular occafions. Thus, the defire of any thing, under the appearance of its goodnefs, fuitablenefs, or neceffity to our happinefs, conftitutes the Paffion of love: the defire of efchewing or avoiding any thing, apprehended to be mifchievous, hurtful, or deftructive, conftitutes hatred or averfion: the defire of a good, which appears at the fame time probable, and in our power, conftitutes hope; but, if the good appear improbable, difficult, or impoffible, it conftitutes fear or defpair: the unexpected gratification of defire is joy: the defire of happinefs to another under pain, or fuffering, is compaffion; and the defire of another's punifhment, revenge, or malice, &c.

The fingle defire of happinefs, then, is the fpring or motive of all our Paffions; as thofe are of all our actions. Some wife and reafonable motive, or end of action, fays Dr. Morgan, is certainly neceffary to all wife and reafonable action; to act without a motive would be the fame thing as not to act at all, that is, fuch an action could anfwer no farther or better end than not acting; and confequently the action, as well as the agent, would be fo far infignificant and ufelefs. He who fhould have no object at all of his love or averfion, hope or fear, joy or grief, muft be fimply and purely indifferent to all action; and confequently muft either be in a ftate of perfect reft and inaction, or in a ftate equivalent thereto; wherein the action of fuch a being could be of no more fignificancy, than the uncertain fluctuation of an atom, or the quivering of a feather in the air.

The natural, or occafional caufe of all the Paffions, Malebranche makes to be the motion of the animal fpirits, which are diffufed through the body to produce and preferve a difpofition therein fuitable to the object perceived; to the end, that the body and mind may mutually affift each other on this occafion; it being the order of the Creator, that our wills be followed by motions of the body proper to execute them; and that the motions of the body mechanically excited in us by the view of external objects, be accompanied with a Paffion of the foul which inclines to will or nill what appears ferviceable or noxious to the body.

It is a continual impreffion of the will of the Creator, that unites us thus intimately to a piece of matter, and occafions this reciprocation of motions and fenfations; were this impreffion of the Creator's will fufpended a moment, we fhould be delivered from all dependence, all Paffions, &c. For what people ufually imagine of a neceffary connection between the motions of the fpirits and blood, and the emotions of the foul, is inconceivable.

Certain little parts of the bile, fay they, move with fome violence among the fibres of the brain: therefore the foul muft neceffarily be agitated with fome Paffion, and this Paffion muft be anger, rather than love. What relation can we conceive between the faults of an enemy, a Paffion of contempt or hatred, and a bodily motion of the parts of the blood ftriking againft certain parts of the brain? How can the union or alliance of two things fo different as fpirit and matter be effected, but by the omnipotent will of the author of nature?

It is a point, about which, the divines and philofophers can never agree, whether this relation and connection of thoughts of the mind and motions of the body be the gift of nature, or the punifhment of the firft fin; and whether the Paffions be the inftitution of nature, or the corruption thereof? Indeed, confidering the good and wife purpofes the Paffions ferve, and that abfolute neceffity they are of, it is furprifing it fhould ever be doubted, that they are effential to human nature.

PASTES, in the glafs-trade, a fort of compofitions of the glafs kind, made from calcined cryftal, lead, and metallic preparations, to imitate the feveral natural gems. Thefe are no way inferior to the native ftones, when carefully made and well polifhed, in brightnefs or tranfparency, but want their hardnefs.

The general rules to be obferved in the making them are thefe: 1. That all the veffels in which they are made are firmly luted, and the lute left to dry before they are put into the fire. 2. That fuch veffels are chofen for the work as will bear the fire well. 3. That the powders be prepared on the porphyry ftone, not in a metal mortar, which would communicate a tinge to them. 4. That the juft proportion in the quantities of the feveral ingredients be nicely obferved. 5. That the materials be well mixed; and, if not fufficiently baked the firft time, to be committed to the fire again, without breaking the pot; for, if this be not obferved, they will be full of blifters and air bladders. 6. That a fmall vacuity be always left at the top of the pot, to give room to the fwelling of the ingredients. *Neri's Art of Glafs.*

To make a Pafte of extreme hardnefs, and capable of all the colours of the gems, with great luftre and beauty, take, of prepared cryftal, ten pounds; falt of polverine, fix pounds; fulphur of lead, two pounds; mix all thefe well together into a fine powder, make the whole, with common water, into a hard Pafte, and make of this Pafte fmall cakes, of about three ounces weight each, within them, in their middle; dry thefe in the fun, and afterwards calcine them in the ftraighteft part of a potter's furnace; after this, powder them, and levigate them to a perfect finenefs on a porphyry, and fet this powder in pots in a glafs furnace to purify for three days; then caft the whole into water, and afterwards return it into the furnace, where let it ftand fifteen days; in which time all foulnefs and blifters will difappear, and the Pafte will greatly refemble the natural jewels. To give this the colour of the emerald, add to it brafs, thrice calcined: for a fea green, brafs brass simply calcined to a redness: for a sapphire, add zaffer, with manganese: and, for a topaz, manganese and tartar. All the gems are thus imitated in this, by the same way of working as the making the coloured glasses; and this is so hard, that they very much approach to the natural gems. *Neri's Art of Glass.*

The colours, in all the counterfeit gems made of the several Pastes, may be made deeper or lighter, according to the works for which the stones are designed; and it is a necessary general rule, that small stones for rings, &c. require a deeper colour, and large ones a paler. Besides the colours made from manganese, verdigrease, and zaffer, which are the ingredients commonly used, there are other very fine ones, which care and skill may prepare: very fine red may be made from gold, and not much inferior to that from iron; a very fine green from brass or copper, and a sky colour from silver; and a much finer one from the common small garnets of Bohemia, which are of little value. The gems also afford glorious colours, like their own. *Neri's Art of Glass.*

The fine blue from silver is, probably, only from the small quantity of copper used in the alloy.

A very singular and excellent way of making the Paste to imitate the coloured gems, is this: take a quantity of saccharum saturni, or sugar of lead, made with vinegar, in the common way; set it in sand, in a glass body well luted from the neck downwards; leave the mouth of the glass open, and continue the fire twenty-four hours; then take out the salt, and, if it be not red, but yellowish, powder it fine and return it into the vessel, and keep it in the sand-heat twenty-four hours more, till it becomes as red as cinnabar. The fire must not be made so strong as to melt it, for, then, all the process is spoiled. Pour distilled vinegar on this calcined salt, and separate the solution from the dregs; let the decanted liquor stand six days in an earthen vessel, to give time to the finer sediment to subside; filtre this liquor, and evaporate it in a glass body, and there will remain a most pure salt of lead; dry this well, then dissolve it in fair water; let the solution stand six days in a glazed pan; let it subside; then filtre the clear solution, and evaporate to a yet more pure white and sweet salt; repeat this operation three times; put the now perfectly pure salt into a glass vessel, set it in a sand heat for several days, and it will be calcined to a fine impalpable powder, of a lively red. This is called the sulphur of lead. *Neri's Art of Glass.*

Take all the ingredients as in the common composition of the Pastes of the several colours, only, instead of red-lead, use this powder, and the produce will well reward the trouble of the operation, as experience has often proved.

PASTURE.—Pasture ground is of two sorts: the one is low meadow land, which is often overflowed; and the other is upland, which lies high and dry. The first of these will produce a much greater quantity of hay than the latter, and will not require manuring or dressing so often: but then the hay produced on the upland is much preferable to the other; as is also the meat which is fed in the upland more valued than that which is fatted in rich meadows: though the latter will make the fatter and larger cattle, as is seen by those which are brought from the low rich lands in Lincolnshire. But where people are nice in their meat, they will give a much larger price for such as hath been fed on the downs, or in short upland Pasture, than for the other, which is much larger. Besides this, dry Pastures have an advantage over the meadows, that they may be fed all the winter, and are not so subject to poach in wet weather; nor will there be so many bad weeds produced; which are great advantages, and do, in a great measure, recompense for the smallness of the crop.

I have already mentioned the advantages of meadow land, or such as is capable of being overflowed with water, and given directions for draining and improving low Pasture land, under the article LAND; therefore shall not repeat that here, but just mention some methods for improving of upland Pasture.

The first improvement of upland Pasture is, by fencing it, and dividing it into small fields of four, five, six, eight, or ten acres each, planting timber trees in the hedge-rows, which will screen the grass from the drying pinching winds of March, which prevent the grass from growing in large open lands; so that, if April proves a dry month, the land produces very little hay; whereas in the sheltered fields the grass will begin to grow early in March, and will cover the ground, and prevent the sun from parching the roots of the grass, whereby it will keep growing, so as to afford a tolerable crop, if the spring should prove dry. But, in fencing of land, it must be observed, as was before directed, not to make the inclosures too small, especially where the hedge-rows are planted with trees; because, when the trees are advanced to a considerable height, they will spread over the land; and, where they are close, will render the grass sour; so that, instead of being an advantage, it will greatly injure the Pasture.

The next improvement of upland Pasture is, to make the turf good, where, either from the badness of the soil, or for want of proper care, the grass hath been destroyed by rushes, bushes, or mole-hills. Where the surface of the land is clayey and cold, it may be improved by paring it off, and burning it in the manner before directed: but, if it is an hot sandy land, then chalk, lime, marl, or clay, are very proper manures to lay upon it: but this should be laid in pretty good quantities otherwise it will be of little service to the land.

If the ground is over-run with bushes or rushes, it will be a great advantage to the land to grub them up towards the latter part of the summer; and after they are dried, to burn them, and spread the ashes over the ground just before the autumnal rains; at which time the surface of the land should be levelled, and sown with grass seed, which will come up in a short time, and make good grass the following spring. So, also, when the land is full of mole-hills, these should be pared off, and either burnt for the ashes, or spread immediately on the ground, when they are pared off, observing to sow the bare patches with grass seed, just as the autumnal rains begin.

Where the land has been thus managed, it will be of great service to roll the turf, in the months of February and March, with an heavy wood roller; always observing to do it in moist weather, that the roll may make an impression: this will render the surface level, and make it much easier to mow the grass, than when the ground lies in hills; and will also cause the turf to thicken, so as to have what the people usually term a good bottom. The grass, likewise, will be the sweeter for this husbandry, and it will be a great help to destroy bad weeds.

Another improvement of upland Pastures is, the feeding of them: for, where this is not practised, the land must be manured at least every third year; and where a farmer hath much arable land in his possession, he will not care to part with his manure to the Pasture. Therefore every farmer should endeavour to proportion his Pasture to his arable land, especially where manure is scarce, otherwise he will soon find his error; for the Pasture is the foundation of all the profit which may arise from the arable land.

Whenever the upland Pastures are mended by manure, there should be a regard had to the nature of the soil, and a proper sort of manure applied: as, for instance, all hot sandy land should have a cold manure; neat's dung and swine's dung are very proper for such lands; but, for cold lands, horse dung, ashes, and other warm manures, are proper. And, when these are applied, it should be done in autumn, before the rains have soaked the ground, and rendered it too soft to cart on; and it should be carefully spread, breaking all the clods as small as possible, and then harrowed with bushes, to let it down to the roots of the grass. When the manure is laid on at this season, the rains in winter will wash down the salts, so that the following spring the grass will receive the advantage of it.

There should also be great care had to the destroying of weeds in the Pasture every spring and autumn: for, where this is not practised, the weeds will ripen their seeds, which will spread over the ground, and thereby fill it with such a crop of weeds as will soon overbear the grass, and destroy it; and it will be very difficult to root them out, after they have gotten such possession; especially ragwort, and such other weeds as have down adhering to their seeds.

These upland Pastures seldom degenerate the grass which is sown on them, if the land is tolerably good: whereas the low meadows, which are overflowed in winter, in a few years turn to an harsh rushy grass, though the upland will continue a fine sweet grass for many years without renewing.

There is no part of husbandry, of which the farmers are in general more ignorant than that of the Pasture: most of them suppose, that when old Pasture is plowed up, it can never be brought to have a good sward again: so, their common method of managing their land, after plowing, is, to sow, with their crop of barley, some grass seeds, as they call them; that is, either the red clover, which they intend to stand two years after the corn is taken off the ground, or rye grass, mixed with trefoil: but as all these are, at most, but biennial plants, whose roots decay soon after their seeds are perfected; so, the ground, having no crop upon it, is again plowed for corn: and this is the constant round which the lands are employed in, by the better sort of farmers; for I never have met with one of them, who had the least notion of laying down their land to grass for any longer continuance; therefore, the seeds which they usually sow, are the best adapted for this purpose.

But, whatever may have been the practice of these people, I hope to prove, that it is possible to lay down land, which has been in tillage, with grass, in such a manner, as that the sward shall be as good, if not better, than any natural grass, and of as long duration. But this is never to be expected, in the common method of sowing a crop of corn with the grass seeds: for, wherever this has been practised, if the corn has succeeded well, the grass has been very poor and weak; so that, if the land has not been very good, the grass has scarcely been worth saving: for the following year it has produced but little hay, and the year after the crop is worth little, either to mow or feed. Nor can it be expected to be otherwise; for the ground cannot nourish two crops: and, if there were no deficiency in the land, yet the corn, being the first, and most vigorous of growth, will keep the grass from making any considerable progress; so that the plants will be extremely weak, and but very thin, many of them, which came up in the spring, being destroyed by the corn; for, wherever there are roots of corn,

it

it cannot be expected there should be any grass. Therefore, the grass must be thin, and, if the land is not in good heart, to supply the grass with nourishment, that the roots may branch out after the corn is gone, there cannot be any considerable crop of clover: and, as their roots are biennial, many of the strongest plants will perish soon after they are cut; and the weak plants, which had made but little progress before, will be the principal part of the crop for the succeeding year: which is many times not worth standing.

Therefore, when ground is laid down for grass, there should be no crop of any kind sown with the feeds; and the land should be well plowed, and cleaned from weeds; otherwise the weeds will come up the first, and grow so strong, as to overbear the grass, and, if they are not pulled up, will intirely spoil it. The best season to sow the grass feeds upon dry land is, about the middle of September, or sooner, if there is an appearance of rain: for, the ground being then warm, if there happen some good showers of rain after the feed is sown, the grass will soon make its appearance, and get sufficient rooting in the ground before winter; so will not be in danger of having the roots turned out of the ground by the frost, especially if the ground is well rolled before the frost comes on, which will press it down, and fix the earth close to the roots. Where this hath not been practised, the frost has often loosened the ground so much, as to let in the air to the roots of the grass, and done it great damage; and this has been brought as an objection to the autumnal sowing of grass: but it will be found to have no weight, if the above direction is practised: nor is there any hazard of sowing the grass at this season, but that of dry weather, after the feeds are sown; for, if the grass comes up well, and the ground is well rolled in the end of October, or the beginning of November, and repeated again the beginning of March, the sward will be closely joined at bottom, and a good crop of hay may be expected the same summer. But, where the ground cannot be prepared for sowing at that season, it may be performed the middle or latter end of March, according to the season's being early or late; for, in backward springs, and in cold land, I have often sowed the grass in the middle of April, with success: but there is danger, in sowing late, of dry weather, and especially if the land is light and dry; for I have seen, many times, the whole surface of the ground removed by strong winds at that season; so that the feeds have been driven in heaps to one side of the field. Therefore, whenever the feeds are sown late in the spring, it will be proper to roll the ground well soon after the feeds are sown, to settle the surface, and prevent its being removed.

The sorts of feeds which are the best for this purpose, are, the best sort of upland hay feeds, taken from the cleanest Pastures, where there are no bad weeds: if this feed is sifted to clean it from rubbish, three bushels will be sufficient to sow an acre of land. The other sort is the trifolium pratense album, which is commonly known by the names of white Dutch clover, or white honey-suckle grass. Eight pounds of this feed will be enough for one acre of land. The grass feed should be sown first, and then the Dutch clover feed may be afterwards sown: but they should not be mixed together; because the clover feeds, being the heaviest, will fall to the bottom, and consequently the ground will be unequally sown.

When the feeds are come up, if the land should produce many weeds, these should be drawn out before they grow so tall as to overbear the grass: for, where this has been neglected, the weeds have taken such possession of the ground, as to keep down the grass, and starve it; and, when these weeds have been suffered to remain until they have shed their feeds, the land has been so plentifully stocked with them, as intirely to destroy the grass: therefore it is one of the principal parts of husbandry, never to suffer weeds to grow on the land.

If the ground is rolled two or three times, at proper distances after the grass is up, it will press down the grass, and cause it to make a thicker bottom: for, as the Dutch clover will put out roots from every joint of the branches which are near the ground, so, by pressing down of the stalks, the roots will mat so closely together, as to form a sward so thick as to cover the whole surface of the ground, and form a green carpet; and will better resist the drought. For, if we do but examine the common Pastures in summer, in most of which there are patches of this white honey-suckle grass growing naturally, we shall find these patches to be the only verdure remaining in the fields. And this, the farmers in general acknowledge, is the sweetest feed for all sorts of cattle; yet never had any notion of propagating it by feeds: nor has this been long practised in England; for, till within a few years, that some curious persons imported the feed from Brabant, where it had been long cultivated, there was not any of the feeds saved in England; though now there are several persons who save the feeds here, which succeed full as well as any of the foreign feeds which are imported.

As the white clover is an abiding plant, so it is certainly the very best sort to sow, where Pastures are laid down to remain: for as the hay feeds which are taken from the best Pastures, will be composed of various sorts of grass; some of which may be but annual, and others biennial; so, when those go off, there will be many and large patches of ground left bare and naked, if there is not a sufficient quantity of the white clover, to spread over and cover the land. Therefore, a good sward can never be expected, where this is not sown: for, in most of the natural Pastures, we find this plant makes no small share of the sward; and it is equally good for wet and dry land, growing naturally upon gravel and clay, in most parts of England: which is a plain indication how easily this plant may be cultivated, to great advantage, in most sorts of land throughout this kingdom.

Therefore, the true cause why the land which has been in tillage, is not brought to a good turf again, in the usual method of husbandry, is, from the farmers not distinguishing which grasses are annual from those which are perennial: for, if annual or biennial grasses are sown, these will of course soon decay; so that, unless where some of their feeds may have ripened and fallen, nothing can be expected on the land but what will naturally come up. Therefore this, with the covetous method of laying down the ground with a crop of corn, has occasioned the general failure of increasing the Pasture in many parts of England, where it is now much more valuable than any arable land.

After the ground has been sown in the manner before directed, and brought to a good sward, the way to preserve it good is, by constantly rolling the ground with an heavy roller, every spring and autumn, as hath been before directed. This piece of husbandry is rarely practised by farmers: but those who do, find their account in it; for it is of great benefit to the grass. Another thing should also be carefully performed; which is, to cut up docks, dandelion, knapweed, and all such bad weeds, by their roots every spring and autumn: this will increase the quantity of good grass, and preserve the Pastures in beauty. Dressing of these Pastures every third year is also a good piece of husbandry; for otherwise it cannot be expected the ground should continue to produce good crops. Besides this, it will be necessary to change the seasons of mowing, and not to mow the same ground every year; but to mow one season, and feed the next: for, where the ground is every year mown, it must be constantly dressed, as are most of the grass grounds near London, otherwise the ground will be soon exhausted. *Miller's Gard. Dict.*

Pasture *of plants.* See the article FOOD *of plants.*

PATE'LLA *(Dict.)—Fracture of the* Patella. The Patella, or knee pan, is much more subject to a transverse fracture than to one in any other direction. The longitudinal fracture of this bone happens more rarely, but, when it does, is much more easily cured; because the fragments of the bone, in this case, generally keep in their right places, but, when the bone is broken, not only transversly, but into several pieces, the case is yet more difficult and dangerous. The cure of this fracture must be attempted in this manner: in a longitudinal or perpendicular fracture, the patient must be laid upon his back, and, extending the foot, the surgeon must replace the fragments on both sides with the pressure of his hands, binding them up carefully with the uniting bandage; which must be applied in this case in the same manner with that used in large wounds in the belly or forehead. But when the Patella is broken transversely, or into several pieces, the patient being laid in the same posture, and extending his foot as before, the surgeon is with great care to endeavour, with the palms of both hands, assisted by his fingers and thumbs, to bring together and replace the fragments in their natural situation; and, when that is done, they must be retained firmly together, by means of a plaister made in form of a half-moon, or properly perforated, and then the foot and leg are to be bound up, and placed so that they cannot be easily moved: but, to prevent the bone from being displaced again, the patient must not use his leg, till after the ninth or tenth week. *Heister's Surgery.*

Patella *luxated.* The Patella is most usually luxated either on the internal or external side of the joint, though physicians give accounts of its being sometimes luxated both above and below it. Whenever the knee itself is perfectly luxated, the Patella can scarce avoid being displaced at the same time, because of its strong connection to the thigh and to the tibia.

The reduction of a luxated Patella is usually no great difficulty.

The patient is to be laid flat on his back on a table or bed, or upon an even floor, so that his leg may be pulled out straight by an assistant; when this is sufficiently extended, the surgeon must grasp the Patella with his fingers, and afterwards, by the assistance of his hand, press it strongly into its proper place. This may be also possibly affected, while the patient stands upright: when this is done, there remains nothing but carefully to bind up the part, and let the patient rest for some days; sometimes gently bending and extending his leg in the mean while, that it may not become stiff. *Heister's Surgery.*

Patella, *the limpit,* in natural history, the name of a genus of shell-fish, the characters of which are these: it is an univalve shell, of a gibbose shape, always fixed in its natural state to a rock or to some other hard body, and having its apex or summit sometimes sharp-pointed, sometimes obtuse, sometimes straight, sometimes crooked, sometimes whole, and sometimes perforated. There are several species of each of these kinds.

PATELLA, in the hiſtory of inſects, a name given by Liſter, and ſome others, to a certain little huſk or ſhell found on the bark of the cherry, plum, and roſe-trees, and ſome others, containing an animal within, and uſeful in colouring. Theſe Patella are of a globular form, except when they adhere to the tree, and are of a ſhining cheſnut colour in moſt kinds. The huſk itſelf ſtrikes a very fine crimſon colour on paper, and within it is found a white maggot of no value: this, in time, hatches into a very ſmall but beautiful bee. The whole ſize of this bee is not more than that of half the body of an ant. They have the ſting of bees, and the three ſpots placed in a triangle on the forehead, which are ſuppoſed to be eyes. They are black, and have a large round whitiſh or pale yellow ſpot upon the back. The upper pair of wings are ſhaded and ſpotted, but the under pair are clear.

The ſhells or huſks deſerve a trial, to find whether the colour they yield might not be brought to uſe; it is to be obſerved, that the deepeſt-coloured huſks afford the fineſt and deepeſt purple: they muſt be alſo uſed, while the creature contained in them is in the maggot form; for, when it is changed into the bee ſtate, the ſhell is dry and colourleſs. Dr. Liſter, who firſt obſerved theſe Patella, went ſo far on the comparing them with the common kermes, as to declare that they were of the ſame nature with that production; but his hiſtory of their being the workmanſhip of a bee, to preſerve her young maggot in, is not agreeable to the true hiſtory of the kermes; for that is an inſect of a very peculiar kind. This author has been too juſtly cenſured for his precipitancy in judging of things, and perhaps has fallen into an error by means of it here.

It is very poſſible that theſe Patella may be the ſame ſort of animal with the kermes, but then it produces its young within this ſhell or huſk, which is no other than the ſkin of the body of the mother animal; but as there are many flies, whoſe worms or maggots are lodged in the bodies of other animals, it may be, that this little bee here deſcribed may love to lay its egg in the body of the proper inſect here deſcribed, and the maggot hatched from that egg may eat up the proper progeny, and, undergoing its own natural changes there, iſſue at length in form of the bee. This may have been the caſe in ſome few which Dr. Liſter examined, and he may have been miſled by this to ſuppoſe it the natural change of the inſect. *Philoſ. Tranſact.* N°. 72.

PATER *patratus*, among the Romans, the firſt and principal perſon of the college of heralds, which formed a kind of board or council to examine the differences that aroſe between neighbouring ſtates, and endeavour amicably to accommodate the ſame. *Danet in voc.*

PAVIA, *the ſcarlet-flowering horſe-cheſnut*, in botany, a genus of plants, whoſe characters are:

The leaves are like thoſe of the horſe-cheſnut, and conjugated; but ſo diſpoſed, as to have every conſequent order croſs the preceding. The end of the pedicle becomes a long tubulous red calyx, of the ſame colour with the flower, with a margin divided into ſix ſegments. Within the calyx grows an anomalous pentapetalous flower, ſo diſpoſed, as, with its five petals, to reſemble a monopetalous bilabiated flower; for the two upper petals, in conjunction, form a kind of galea; the two lateral ones, the jaws, and the under one, the beard. The flower incloſes eight ſtamina, each furniſhed with its apex, and the flowers are diſpoſed in ſpikes. The ovary in the bottom of the calyx, ſhooting forth a long, cylindrical, red tube, becomes a tricapſular, tricoccous fruit, containing globular ſeed.

PEACH, *perſica*, in botany, the name of a genus of trees, the characters of which are theſe: the flower is of the roſaceous kind, being compoſed of many petals, arranged in a circular form. The piſtil ariſes from the cup, and finally becomes a fleſhy fruit of a roundiſh figure, ſulcated lengthwiſe, and containing a ſtone rough and full of irregular holes, containing an oblong kernel.

The curious in fruits account twenty-eight ſorts of Peaches, but many of them ſeem very trifling diſtinctions. The fineneſs of this fruit, in general, depends on the firmneſs of the pulp, the delicacy of the flavour, and the thinneſs of the ſkin. A fine Peach ſhould be of a fine deep red next the ſun, and of a pale whitiſh hue next the wall; and the pulp ſhould be of a yellowiſh caſt, and very juicy; and the ſtone ſhould be ſmall, though the fruit in general be large.

The varieties of the Peach are produced, like thoſe of the fine flowers, by ſowing the ſeeds; and, though many raiſed this way will be of little value, as is alſo the caſe in flowers, yet probably among a parcel of ſtones, ſaved from the finer kinds of Peaches, there would be ſome new kinds produced; which, as they were raiſed here, would be eaſily kept up in their perfection; which is not to be expected of thoſe brought from other countries.

The beſt method of ſaving the ſtones is, to let ſome of the fineſt Peaches of the beſt kinds hang till they drop of themſelves from the tree, and, then, the ſtones ſhould be immediately planted on a bed of light rich earth, planting them four inches deep in the earth, and at about ſix inches aſunder. The beds ſhould be covered, to preſerve them in winter; and in ſpring, when the trees come up, they muſt be cleared of weeds, and well watered. The next ſpring they ſhould be carefully taken up, and planted in the nurſery at greater diſtances; and, after two or three years ſtanding here, they may be removed to the places where they are to remain; or they may at that time, when the condition of their fruit is known, be grafted on other ſtocks, which is the common way now uſed to propagate theſe trees.

The common method of propagating the Peach is, by grafting. In order to this, ſome good ſtocks ſhould be provided, which ſhould be of the muſcle, or a white pear plum. When theſe ſtocks are two or three years old, they will be ſtrong enough to bud; and the common ſeaſon for doing this is about Midſummer. The buds ſhoulds be choſen from a healthy tree, which produces a great deal of fruit: they muſt be taken from the trees either in a cloudy day, or elſe in the morning or evening, when the ſun has not much power: they ſhould then be inoculated on the ſtalks as ſoon as poſſible, and the ſtalks treated with the uſual care afterwards. See INOCULATION.

When theſe are to be tranſplanted where they are to remain, the moſt proper ſoil for them is a light rich paſture land, taken up with the turf, and rotted together, before it is to be uſed; and the borders to be made with this cannot be too wide, and ought to be raiſed five or ſix inches above the level of the ground; or, if the ſoil be moiſt, more than that. They muſt be tranſplanted in autumn, as ſoon as the leaves are fallen off; and ſhould never be ſet at leſs than fourteen feet diſtance from one another. The heads of the trees are then to be raiſed up againſt the walls, to keep the roots from being moved by the winds; and they ſhould be watered at times, with a noſe on the watering pot, and the water ſprinkled all over them. In the middle of May the new ſhoots are to be nailed to the wall, training them horizontally; and the foreright ſhoots are to be rubbed off: in October, the new branches ſhould be pruned, ſhortening them according to the ſtrength of the tree; if ſtrong, they may be left eight inches long; if weak, they ſhould only be left five; and the ſame care is to be taken of them for the ſucceeding years.

There are two general rules always to be obſerved in the pruning of Peach and nectarine trees, which are, 1. Always to have enough bearing wood. 2. Not to lay in the branches too cloſe to one another. All Peach-trees produce their fruit from the young wood, either of the ſame, or, at the moſt, of the former year's ſhoot; for this reaſon the branches are to be ſo pruned, as to encourage them to throw out new ſhoots in every part of the tree: and this is to be done in May, when, by pinching, or ſtopping the ſtrong ſhoots, there may be new wood forced out in any part of the tree. This is the method of the ſummer pruning; the winter pruning is uſually done in February or March, but is much better done at Michaelmas, as ſoon as their leaves begin to fall; and the wounds will then have time to heal before the ſevere froſts come on.

In pruning of theſe trees it muſt always be obſerved alſo, that it is beſt done under a wood bud, not a bloſſom bud; which may be diſtinguiſhed by the wood buds being leſs turgid, and longer, and narrower than the bloſſom bud; for, if the ſhoot have not a leading bud where it is cut, it will commonly die down to the leading bud. In nailing the ſhoots to the wall, they ſhould be placed at as equal diſtances as poſſible, and ſo far apart that the leaves may have room; and they muſt always be trained as horizontally as poſſible, that the lower part of the tree may be well wooded, which it will not be, if the branches are ſuffered to run upright. *Miller's Gard. Dict.*

PEACH-*colour*, the pale red colour of the bloſſoms of the Peach-tree.

To give this beautiful colour to glaſs, add, at different times, and in ſmall quantities, the powder of prepared manganeſe to the maſs, for the making of lattimo, or milk-white glaſs, while in fuſion. This alone gives the Peach colour; but the metal muſt be immediately worked when of a right tinge, for the colour is very apt to go off. *Neri's Art of Glaſs.* See the article LATTIMO.

PEAR, *pyrus*, in botany. All the ſorts of Pears, propagated in gardens, are produced by budding, or grafting them upon ſtocks of their own kind, which are commonly called tree-ſtocks, or elſe upon the quince or white-thorn ſtocks; but the laſt are now generally diſuſed, the fruit produced this way being apt to be dry and mealy. The quince ſtocks are, however, in great eſteem for the trees deſigned for dwarfs or for walls; becauſe they do not let the ſhoots grow ſo faſt and luxuriant. But there are objections againſt even theſe, which are of ſome conſequence; for there are many kinds of Pear which will not do upon them, but will die, or become weak and good for nothing after three or four years; and the hard-breaking Pears are rendered very unpleaſant by being grafted on theſe ſtocks, while the buttery or melting ones are meliorated by them. And it is to be added, that no ſort of Pear will thrive upon a quince ſtock in a poor or gravelly ſoil.

PEAR-*trees* planted either againſt walls, or in eſpaliers, muſt not be placed nearer to one another than twenty feet. Pear-trees commonly produce their bloſſom buds firſt, at the extremity of their laſt year's ſhoots; the common way of pruning is very prejudicial, therefore, as it takes off the part which ſhould bear the fruit, and occaſions new ſhoots from the ſame branch, which will over-fill the tree with wood, the trees should always be carefully looked over in summer, and all the foreright shoots taken off, by which means the fruit will not be overshaded, and the trees will need but little winter pruning. The several sorts of summer Pears all ripen best in espaliers, but the winter Pears require a south-east or south-west, or else an east wall. *Miller's Gard. Dict.*

It is said that crabs and wild Pears, such as grow in the wildest and most barren clefts, and on hills, may make the richest, strongest, most pleasant and lasting wines that England yields. See *Phil. Trans.* N°. 477.

PEARCH. See PERCA.

PEARCH-*glue*, in mechanics, the name of a kind of glue, of a remarkable strength and purity, for the manufacture of which we are beholden to the Laplanders, from whom Scheffer has described it. They take a number of large Pearches, and, slitting them open, they carefully pick away the flesh with a knife, so as to leave the skin pure. They put a number of these skins into a vessel of warm water, which they expose to the sun, and by that means keep it in a continual moderate heat for several days; when the scales become loose by this maceration, they take out the skins and rub them clean off. The soft and clean skin remains then alone, and feels as soft as a wetted bladder. These clean skins they throw into a small quantity of fresh water, and boil them gently over the fire, stirring the whole together, and towards the end beating it forcibly with little sticks. The skins by this means at length wholly dissolve in the water, and the whole becomes a thick transparent liquor; which, when boiled as long as the thickness of it will permit, without burning, they pour it out on a flat stone, and, as it cools, they cut it into cakes exactly resembling our glue, but that they want the coarse reddish colour it has, and have no disagreeable smell. When they would use this, they dissolve it in more water, exactly as we do our glue. The bows of this people give us a very great proof of the strength of this sort of glue; they are made of two pieces fastened together with it, and though put to the most forcible trials, as these people are very strong, and use them in shooting bears, rain-deer, &c. yet the glue part is never known to start. *Scheff. Hist. Lap.*

PEARL *colour*, in glass. This beautiful colour is given to glass in the following manner: put tartar calcined to a whiteness into putrified crystal, while in fusion, at several times, in small quantities, mixing it well every time, till the glass is become of the desired colour, and, when it is, work it quick as can be, for it is a colour that is quickly gone. *Neri's Art of Glass.*

PEASE, *pisa*, in botany.—We have several sorts of Pease cultivated for use in the gardens about London and elsewhere; and, as many people are desirous of having them very early, it is a common practice to raise them on hot-beds. The method of doing this is, to sow the Pease under warm hedges or walls. In the middle of October, when the plants are come up, their stalks are to be kept earthed up, and thus they are to remain till the beginning of January, or even till February, covering them against the severe frosts with Pease haulm, or other light covering. In January or February, there must be made a moderate hot-bed; the dung must be laid about two feet thick, and carefully beat down, and covered about six inches deep with light fresh earth; and, when the frames have been set on about four days, the plants must be planted in the earth, at a about a foot distance, in rows, and placed in each row at about two inches one from another. They must be watered and shaded till they have taken root, and then they must have as much air as may be; and, when they begin to fruit, they should be watered more frequently than before, which will occasion their producing a larger quantity of fruit.

The common dwarf-Pea is the sort always used on this occasion, as all the rest ramble too much in their stalks.

The first sort of Pea to be sown to succeed those on the hot-beds is the hot spur; of which the gardeners reckon three or four sorts, which differ very little from each other; but that called the master's hot-spur is usually preferred to the rest. These are to be sown in October, as those intended for the hot-bed, and treated every way in the same manner; but in spring these are subject to be destroyed by slugs and other vermin; the best method of destroying which is, to slake a little lime, and throw over the earth among the plants. For fear of this crop miscarrying by the severity of the weather, it is always proper to sow two others after this, at the distance of a fortnight each; and after this there should be no others sowed till the end of January; and after these there should be others at the beginning and end of February. To succeed these, which will supply the table with early Pease, the Spanish morotto, which is a large Pea, and a very plentiful bearer, should be sowed in rows on a clear plat of ground; the rows should be two feet and a half distant, and the Pease dropped at an inch or two asunder: these must be all very carefully covered two inches deep with earth, and the rooks, mice, &c. prevented from getting at them. A fortnight after this another spot should be sowed with this or some other large Pea, and this continued every fortnight till the latter end of May. *Miller's Gard. Dict.*

Field PEASE. The common white Pea succeeds best in a light land, somewhat rich: the time of sowing them is in the middle of April. Three bushels are the common allowance for an acre; and they kill the weeds the land is subject to, better than any other crop. In Staffordshire they sow the garden rouncivals in fields, and they grow and yield very well, though they are left trailing upon the ground without any support of sticks.

The white and rouncival Pease are only to be sown with a broad cast, and harrowed in; but the common grey Pea, which is more frequently sown in fields than either of them, must be sown under furrow, and delights most in a cold wet clay. These are to be sown in February; and the common quantity of seed is two bushels to an acre. The blue Pea is the best kind for light sandy land, and is to be early sown; all Pease love land manured with lime or with marle. In Suffolk they plow up their lays in the beginning of March, and, turning the turf well, they have a cross stick set with iron pegs, which they strike down with their feet: these pegs make holes at equal distance; into which they have boys and girls following to put the Pease singly, till all the land is set. As soon as this crop is cut, they plow the land across, and, harrowing it well, they plow it again, and sow it about Michaelmas with wheat, and the next year with barley, then with oats; after which the land requires new improvement. *Mortimer's Husbandry.*

PEBBLES, *calculi*, in natural history, the name of a genus of fossils, distinguished from the flints and homochroa, by their having a variety of colours.

In all the strata of pebbles there are constantly found some which are broken, and whose pieces lie very near one another; but, as bodies of such hardness could not be broken without some considerable violence, their present situation seems to imply, that they have suffered that great violence in or near the places where they now lie. Besides these, there are others also found which have as plainly had pieces broken off from them, though those pieces are no where to be found; whence it seems equally plain, that, whatever has been the cause of their fracture, they have been brought broken, as we find them, from some other place, or else that the pieces broken from them must, at some time or other, have been carried from this place to some other distant one.

Several of these broken Pebbles have their edges and corners so sharp and even, that it seems evident they never can have been tossed about or removed since the breaking; and others have their sides and corners so rounded, blunted, and worn away, that they seem to have been roughly moved and rolled about among other hard bodies, and that too either with great violence, or for a very long continuance; since such hard bodies could not have been reduced to the condition we now see them in without long friction.

It may be supposed by some, that these stones never were broken, but have been naturally formed of this shape; but it will be easily seen by any one who accurately surveys their veins or coats that surround the nucleus, like the annual circles of a tree, that they must have been originally intire; and this will be the more plain, if they are compared with a stone broken by art. Such pebbles as are found in strata, that lie near the surface of the earth, are much more brittle than those which lie in deeper strata.

The more clear and transparent the sand is, which is found among Pebbles, the more beautiful the Pebbles are generally observed to be.

The use of these stones, and their disposition in the earth, is a subject of great admiration; and may serve as one of the numerous proofs of an over-ruling providence in the disposal of all natural bodies. The surface of the earth is composed of vegetable mould, made up of different earth mixed with the putrid remains of animal and vegetable bodies; and is of the proper texture and compages for conducting the moisture to the roots of trees and plants: and under this are laid the sands and Pebbles which are a sort of drain to carry off the redundant moisture deeper into the earth, where it may be ready to supply the place of what is constantly rising in exhalations; and lest the strata of sand should be too thick, it is common to find thin ones of clay between, which serve to put some stop to the descent of the moisture, and keep it from passing off too soon; and lest these thin strata of clay should yield and give way, and by their softness, when wetted, give leave to the particles of sand to blend themselves with, and even force their way through them, there are found in many places thin coats of a poor iron ore placed regularly above and below the clay; and by that means, no tonly strengthening and supporting the clay, but effectually keeping the sand from making its way into it. *Phil. Trans.* N°. 483.

PECTEN, in natural history, the name of a genus of shell-fish, the characters of which are these:

It is a bivalve shell, shutting close in all parts, of a flatted shape, striated in the manner of a comb, and often auriculated, sometimes only semi-auriculated, and in some species not auriculated at all. There are also some few species which are elate, not flat as the others.

This shell-fish is one of the spinners of the sea, having a power of of spinning or forming threads like the muscle; but they are much shorter and coarser, even than those of that fish: so that they can never be wrought into any sort of work, in the manner of the longer and finer threads of the pinna marina. The use of these threads which the Pecten or scallop spins, is to fix the creature to any other body that is near, whether it be a stone a piece of coral, or another shell. All these threads proceed, as in the muscle, from one common trunk; they make their way out of the shells in those Pectens which have only one ear, a little below that ear; in the others probably they issue out on both sides. It is an evident proof, that the fish has a power of fixing itself at pleasure to any solid body, by means of these threads, that after storms the scallops are often found tossed upon rocks, where there were none the day before; and yet these are fixed by their threads, as well as those which had remained ever so long in their place. They form their threads in the very same manner with the muscle, only their organ which serves for spinning is shorter, and has a wider hollow, whence the threads are necessarily thicker and shorter.

PEDILU'VIUM.—This word signifies no more than a bath for the feet, which may be prepared of the same ingredients with other baths; and, as it requires a less apparatus, is for that reason frequently used as a succedaneum to them; for a bath for the feet may either consist of pure light water alone, or, in order to correct the qualities of heavy and hard waters, a lixivium, or bran of wheat, or chamomile-flowers, may be added; or such waters may be mixed with milk. But, though baths for the feet are only immediately applied to the inferior parts and extremities of the body, yet their virtues and efficacy diffuse themselves further, and alleviate violent disorders in remote and distant parts of the body; for, whilst the feet are cherished with such a warm liquor, the nervous, tendinous, and muscular fibres, by the intertexture of which they are formed, are relaxed and unbended; the pores and ducts, before constricted, are enlarged; the blood has access to the parts; and the return of the humours from them is rendered free and uninterrupted. By this means, the impetus of the blood on other parts is diverted; and, to the surprising relief of the patient, derived to the inferior parts. Besides, baths for the feet, by their temperate heat, act upon the blood and humours, which, during their use, pass through the vessels of the feet, render them more thin and diluted, and by that means qualify them for passing more expeditiously through all the various ducts and parts of the body. Hence it is, that, if pretty hot baths for the feet are used, they increase the pulse, and excite a sweat over all the body. Besides, the consent of the feet, as being nervous and tendinous parts of an exquisite sensation, is so great with all the other nervous parts of the body, especially those of the abdomen, that, if the feet are only rendered thoroughly cold, a cholic is forthwith produced, the patient becomes costive, the skin is rendered rough, perspiration is intercepted, and the salutary evacuations from the uterus, and hæmorrhoidal veins, stopped. For this reason, it is not to be doubted, but when the feet are fomented, and their spasmodic stricture removed by means of a tepid bath, the salutary effect must, also, be propagated to those remote parts of the body, with which they have so near and immediate a consent.

Baths for the feet are certainly highly expedient for the purposes of derivation, in those diseases which arise from congestions of the humours to the head and breast, produced by spasms of the inferior parts, and especially of the hypochondria. Among this kind, besides lethargic diseases, we may reckon almost all disorders of the head, such as madness, melancholy cephalæas, hemicranias, the clavus hystericus, vertigos, tooth-achs, pains of the ears, a gutta rosacea, inflammations, and defluxions of saline humours on the eyes, immoderate hæmorrhages from the nose, and long watchings. Of this kind are, also, some disorders which affect the breast, such as convulsive asthmas, dyspnœas arising from a plethora, palpitations of the heart, dry coughs, and spittings of blood. Besides, baths for the feet, in consequence of their singular efficacy in relaxing spasms, are highly beneficial in spasmodic and convulsive disorders, in pains, cardialgias, cholics, especially of the hæmorrhoidal kind; gripes produced by the stone, and inflations of the stomach, accompanied with an uneasiness of the præcordia. Besides, baths for the feet promote the salutary excretions by perspiration, urine and stool, together with those made from the uterus, and hæmorrhoidal veins, by procuring a free circulation of the blood, attenuating the humours, and solliciting them to the emunctories of the body. Baths for the feet, also, remove and prevent very terrible disorders of the head and breast especially those which return at certain periods; and I myself, says Hoffman, have known the daily use of these baths for the feet remove the most terrible and obstinate cephalalgias. Some, also, in intermittent fevers, advise the use of these baths, though not on the days of remission. And this piece of practice is productive of very salutary effects, as is obvious from Obs. 144. Decad. 2. An. 6. Miscell. Nat. Curios. where we have an account of a quartan fever cured by means of foot-baths. And *Kozak de Salib. Sect.* 12. *cap.* 10.

But it is to be observed, that baths for the feet produce far more happy effects, if, before they are used, the quantity of blood is lessened by venesection in the feet; if they are used about bed-time, and the feet not exposed to the cold after them, but kept duly warm, till the patient gets to bed; by which means the perspiration, all over the body, is increased. But baths for the feet must not be used about the time the menses are about to flow, or already present, because, by diverting the course of the blood from the uterus and solliciting it to the inferior parts, this salutary discharge is either stopped or prevented. On the contrary, baths for the feet, used some days before the stated period for the menstrual discharge, excellently promote it, especially if, at the same time the pilulæ Becheri, or temperate emmenagogues, are used. We must, also, carefully abstain from astringent, aluminous, and sulphureous baths, in order to prevent a sweating of the feet, discuss oedematous tumors, cure ulcers, or remove arthritic pains, since, by means of such astringent, aluminous, and sulphureous baths, the virulent matter is repelled to the internal and more noble parts. And because the common hot spring in the Caroline baths, commonly called Der Prudel, is possessed of an highly repellent quality; so bathing in it ought to be very cautiously used in all disorders affecting the surface of the body, and more especially in gouty and arthritic pains. *Hoffman.*

PE'LICAN, in the Linnæan system of zoology, makes a distinct genus of birds of the order of the anseres, or goose kind; the characteristic of which is to have a beak of a depressed form, with a hooked point, and furnished with a large bag or purse beneath. *Linnæi System. Nat.*

PE'LLACK, the name of a young spout whale, often found in Zealand; where they run into creeks, and so entangle themselves among the rocks, that they are cast on shore, or easily taken. *Phil. Transf.* N°. 473.

PEN'DULUM (*Dict.*)—Soon after the invention of Pendulum-clocks (justly ascribed to the celebrated Mr. Huygens) it was found, that they were liable to considerable inequalities in their motion; which were imagined to arise from the Pendulum, in its vibrations, describing an arc of a circle; and, consequently, that the larger vibrations must be slower than the shorter ones. In order to remedy this imperfection, the same Mr. Huygens wrote a treatise, called Horologium oscillatorium (a piece of geometry, which does honour to the last century) in which he demonstrates, from the properties of the cycloid, that the vibrations of a Pendulum, moving in a cycloid, would be performed in equal times, even though the vibrations were unequal. Pendulums therefore were made to vibrate in a cycloid; but great inequalities were still observed in the motion of clocks.

We do not read of any attempts, after this, to regulate the motion of clocks, till the year 1726, when Mr. George Graham delivered into the Royal Society a paper, which is published in the Phil. Transf. N°. 392, in which he says, that, it having been apprehended, that the inequalities in the motion of clocks arose from a change of length in the Pendulum, by the influences of heat and cold, he, about the year 1715, made several trials, in order to discover, whether there was any considerable difference of expansion between brass, steel, iron, silver, &c. when exposed to the same degrees of heat; conceiving, that it would not be very difficult, by making use of two sorts of metals differing considerably in their degrees of expansion and contraction, to remedy, in great measure, the irregularities, to which common Pendulums are subject. He says also, that, from the experiments he then made, he found their differences so small, as gave him no hopes of succeeding that way, which made him leave off prosecuting this affair any more at that time: that, some time after, having observed an extraordinary degree of expansion, by heat, in quicksilver, he thought of a proper manner of applying a column of it to the Pendulum of a clock, in order to prevent the inequalities arising from its different lengths by the effects of heat and cold; which succeeded accordingly, and is what is now called Mr. Graham's quicksilver Pendulum. Mr. Graham, in the same paper, takes notice, that, though the Pendulum of a clock was to remain invariable, yet there would still be some irregularities in the motion of the clock, arising from the friction of the different parts of the clock-work, and from the different degrees of foulness.

In the year 1725, Mr. John Harrison, of Barrow, in Lincolnshire, made several experiments upon wires of different metals, in order to find their different degrees of expansion and contraction: for he thought, that, by a proper combination of wires of two different metals, differing considerably in their expansion and contraction, he might be enabled to keep the center of oscillation of a Pendulum always at the same distance from the point of suspension. In consequence of these experiments, he made a Pendulum, consisting of one steel wire, at the end of which is the bob or weight, and, on each side of this wire, four wires alternately brass and steel, so disposed and contrived, as to raise the Pendulum the same quantity as it is lengthened by heat, and to let down the Pendulum in the same proportion as it is raised by cold. He made also a drawing of a clock, in which the wheels are disposed in in a different manner from those then in use; which drawing I have seen, signed by himself in the year 1725. Two of these clocks with Pendulums, as described above, were finished in the year 1726. In these clocks Mr. Harrison has made a particular sort of pallets, so as to be almost intirely free from friction; for, though he had thus happily succeeded in his contrivance to prevent the inequalities in the motion of the clock, arising from the different lengths of the Pendulum by the effects of heat and cold, yet he found there were considerable errors still remaining, occasioned by the friction of the pallets, as in the common way. He has also suspended the Pendulum upon the wall of the house, intirely independent of the clock and clock-case: for he had observed considerable alterations in the going of the clock, when the Pendulum is suspended as in the common manner. His Pendulum vibrates in an arc of about 15 degrees, with a bob of about three pounds, between cycloidal checks, which he himself found were necessary, though he had never heard of M. Huygens's book, till after he had made them. He has also disposed the force of his Pendulum-wheel upon the Pendulum, by his sort of pallets, in such a manner, that the vibrations of the Pendulum will not be affected by the different resistance of the air. Upon the whole, this clock is made in such a manner, as to be almost intirely free from friction; in consequence of which he uses no oil, and therefore there is no necessity ever to clean the clock. When he settled in London, he sent for one of these clocks from the country, and set it up in his house in Orange-street, in the year 1739, where it has stood ever since, and in all that time has never varied above one minute from the truth. He can depend upon it to a second in a month.

About the year 1729, Mr. Harrison made his first machine for measuring time at sea, in which he has likewise applied this combination of wires of brass and steel, to prevent any alterations by heat and cold. In the year 1726, he went on board one of his majesty's ships of war with this machine to Lisbon, and returned, where this machine was seen by every curious and ingenious person, who were pleased to go to his house. Since that time, he has made two more of these machines or clocks for keeping time at sea, in both which he has likewise this provision, to prevent the effects of heat and cold.

Mr. John Shelton, who was the principal person employed by Mr. Graham in the making of astronomical clocks, informs me, that Mr. Graham, in the year 1737, made a Pendulum consisting of three bars, viz. one of steel, between two of brass; and that the steel bar acted upon a lever, so as to raise the Pendulum, when lengthened by heat, and to let it down, when shortened by cold. This lever, which is very strong, rests upon a roller; which roller is made moveable, so as to adjust the arms of the lever to their true proportion. The whole was made to be as free from friction, as possible, in such a construction. Mr. Graham made observations, by transits of the fixed stars, of the motion of the clock with this sort of Pendulum, and from the experience of several years (during which the clock was kept constantly going) he found, that the clock was liable to sudden starts and jerks in its motion. Of this he informed Dr. Bradley, Mr. Bliss, and several other gentlemen.

I have been informed, that one Mr. Frotheringham, a quaker, of Lincolnshire, caused a Pendulum to be made, consisting of two bars, one of brass, and the other of steel, fastened together by screws, with levers to raise or let down the bob; and that these levers were placed above the bob.

In the History of the Royal Academy of Sciences at Paris, for the year 1741, there is a memoir of M. Cassini, in which he describes several sorts of Pendulums for clocks, compounded of bars of brass and steel, and applies a lever to raise or let down the bob of the Pendulum, by the expansion or contraction of the bar of brass. He has also given us, in the same memoir, a problem for finding the proportion, which the two arms of the lever should have, to answer the intended purpose; and also a demonstration of it.

In June, 1752, Mr. John Ellicott gave in to the Royal Society a paper, containing the description of a Pendulum, consisting of two bars, one of brass, and the other of iron, fastened together by screws, with two levers in the bob of the Pendulum, so contrived, as to raise and let down the bob, by the expansion and contraction of the brass bar; and also to adjust the arms of the levers to their true proportion. He says, that he first thought of these methods of applying bars of brass and iron to prevent the irregularities of a clock, arising from the different lengths of the Pendulum, by the effects of heat and cold, in the year 1732; and that he put this his thought in execution in the year 1738.

He has also given us in the same paper another construction of a Pendulum to prevent the effects of heat and cold, consisting of two bars, one of brass, and the other of iron; the brass bar acting upon a lever, at the end of which is fastened the Pendulum; the whole so constructed and contrived, as to raise the Pendulum, when it is lengthened by heat, and to let it down, when shortened by cold. *Short, in the Philos. Trans. Vol.* 47.

Mr. Ellicott's contrivances for remedying these defects in clocks are given us by that ingenious gentleman himself in the following manner:

About the year 1732, an experiment, which I made, in order to satisfy some gentlemen, that the rod of a Pendulum was liable to be considerably influenced by moderate degrees of heat and cold, led me to consider, that, as metals differ from each other in their density, it was highly probable they might likewise differ from each other in their expansion; and that this difference of the expansions of two metals might be so applied, as in a great measure to remove those irregularities in the motion of a clock, which arise from the effect of heat and cold upon the length of a Pendulum. With this view, not long afterwards I contrived the Pendulum now described by *plate* XXXIII. *fig.* 6.

In which *a b* represents a bar of brass, made quite fast at the upper part by pins, and held contiguous, at several equal distances, by the screws 1, 2, &c. to the rod of the Pendulum, which is a bar of iron; and, so far as the brass bar reaches, is filed of the same size and shape, and consequently does not appear in the figure; but, a little below the end of the brass bar, the iron is left broader, as at *d d*, for the conveniency of fixing the work to it, and is made of a sufficient length to pass quite thro' the ball of the Pendulum to *c*. The holes, 1, 2, &c. in the brass, through which the shanks of the screws pass into the iron rod of the Pendulum, are filed, as in the drawing, of a length sufficient to suffer the brass to contract and dilate freely by heat and cold under the heads of the screws. *e e e e* Represents the ball of the Pendulum: *f f*, two strong pieces of steel, or levers, whose inner centers, or pivots, turn in two holes drilled in the broad part of the Pendulum-rod, and their outer ones in a strong bridge, or cock, screwed upon the same part of the rod, but omitted in the draught; because, when put on, it covers this mechanism. *g g*, are two screws entering at the edge, and reaching into the cavity near the center of the ball. The ends of these screws next the center are turned into the form represented in the drawing, which, pressing with the weight of the ball against the longer arms of the levers, cause the shorter arms to press against the end of the brass bar at 6. Things being in this situation, let us suppose, that the rod of the Pendulum, and the brass annexed to it, grow longer by heat; and that the brass lengthens more than the iron of the same length: then the brass, by its excess of dilatation, will press the short ends of the levers downwards at *b*, and at the same time necessarily lift up the ball, which rests upon the long ends of the same levers at *f f*, to any proportion necessary: and, provided the ends of the screws do press upon the levers at a proper distance from the centers, the said ball will be always kept at the point of suspension, notwithstanding any alteration the rod of the Pendulum may be liable to from heat or cold. What this distance ought to be, may very nearly be determined, if the difference of the expansion between the brass and iron bars is known; for the proportion the shorter arms of the levers ought to bear to the longer ones will always be, as the excess of the expansion of the brass is to the whole expansion of the iron, as may be thus easily demonstrated. *Fig.* 7. Let the line *a b*, drawn perpendicular to the line *e f*, represent a bar of iron; the line *c d* a bar of brass; the pricked line *b g*, the expansion of the iron bar, and *d b* the expansion of the brass bar by the same degree of heat: let the line *g i* be parallel to *e f*, then will *i b* represent the difference of the expansion of the two metals: through the points *b*, *g*, draw a right line cutting the line *e f*, as in *k*; to represent one of the levers turning upon its center at *g*, *b* the point where the brass bar acts upon the shorter end of the lever, and *k* the point where the screw acts upon the longer end of the lever, which being the place where it intersects the line *e f*, it is evident the ball of the Pendulum will be as much raised by the lever, as it would have been depressed by the expansion of the iron; but the triangle *i b g* is similar to the triangle *b g k*; and therefore, as *i b*, the excess of the expansion of the brass, is to *b g*, the whole expansion of the iron, so will *b g*, the shorter arm of the lever, be to *g k*, the longer arm of the lever. *Q. e d.*

At *c*, *fig.* 6. is placed a strong double spring, whose ends, pressing against the under edge of the ball, hinder it from bending the brass bar by its forcible action thereon at the point *b*, which, when the ball is of a considerable weight, it might otherwise be very liable to do.

The description here given is exactly agreeable to the original contrivance; and the only alteration I have since made in it, consists in placing the screws *g g* within the ball of the Pendulum, as represented in *fig.* 9.

But, as the success of this contrivance depended intirely upon the supposition, that metals were expanded differently by the same degree of heat, before I attempted to put it in execution, I thought proper to inquire what experiments had already been made upon this subject, when Mr. John Eames put into my hands Mr. Graham's account of his quicksilver Pendulum (as it is now commonly called) published in the Philosophical Transactions, N°. 392, which account I found to be introduced by the following paragraph:

'Whereas several, who have been curious in measuring of time, have taken notice, that the vibrations of a Pendulum are slower in summer than in winter; and have very justly supposed this alteration has proceeded from a change of length in the Pendulum itself, by the influences of heat and cold upon it, in the different seasons of the year; with a view therefore of correcting, in some degree, this defect of the Pendulum, I made several trials, about the year 1715, to discover whether there

there was any considerable difference of expansion between brass, steel, iron, copper, silver, &c. when exposed to the same degrees of heat, as nearly as I could determine; conceiving it would not be very difficult, by making use of two sort of metals differing considerably in their degrees of expansion and contraction, to remedy, in great measure, the irregularities, to which common Pendulums are subject. But although it is easily discoverable, that all these metals suffer a sensible alteration of their dimensions by heat and cold; yet I found their differences in quantity, from one another, were so small, as gave me no hopes of succeeding this way, and made me leave off prosecuting this affair any farther at that time.'

The reading this paragraph proved at that time sufficient to make me lay aside all thoughts of succeeding in a contrivance founded upon principles, which a gentleman of so great abilities, and known accuracy in making experiments, had, after trial, judged to be insufficient. And it was not till about the latter end of the year 1734, that I again resumed them on the following occasion. A gentleman, desirous to make some experiments concerning the expansion of metals, employed me to make him an instrument like one invented by Mr. Muschenbroek for that purpose, which he calls a pyrometer. Upon looking over Mr. Muschenbroek's experiments, I not only found the difference between the expansion of some of the metals much greater than I expected, but, as I thought (if they were to be depended upon) sufficient to answer my former purpose. This led me to consider the structure of the instrument, which Mr. Muschenbroek made use of in his trials, and, upon examination, I thought it liable to some objections, which I imagined would make the result of experiments made by his instrument very uncertain. I therefore endeavoured to contrive one of a different construction, that might be more to be depended upon. See PYROMETER. Having made a great variety of experiments with this instrument upon bars of different metals, as nearly of the same dimensions as possible, I found, upon a medium, their several expansions by the same degree of heat to be as follows:

Gold	silver	brass	copper	iron	steel	lead
73	103	95	89	60	56	149.

And, as I found so great a difference between the expansion of brass and iron, I immediately determined to make a Pendulum after the manner above described, composed of those two metals, and likewise ordered a clock to be made, with the utmost care and exactness; and, as I then apprehended, with some considerable improvements, with which I intended to make the experiments. These were both finished in the beginning of the year 1738; and, having no reason to doubt of success, I shewed the Pendulum to the late Mr. Machin, and gave him a drawing and description of it, in order to its being communicated to the Royal Society; but objections were made to it, of which the only one, that appeared to have any weight, was, that it had been found by experiment, that two bars of different metals, screwed together, so as to be in contact with each other, would not expand regularly and smoothly, but by jerks. In order to examine into the force of this objection, I directed two bars of equal dimensions to be made, one of brass, the other of iron, of about two feet in length, fastened together after the same manner, as the two rods of the Pendulum, which I intended to place so, that, by acting very near the center of an index of a considerable length, even the smallest alteration in the bars would be made sensible, and by the motion of the index I should be able to form a judgment, whether the rods moved regularly and freely, or not: but, before this was put into execution, I contrived, by fastening the two bars to the back plate of a clock, not only to make them answer the end above proposed, but, at the same time, to lengthen or shorten a Pendulum of a common construction, in such a manner, as sufficiently to correct the irregularities arising from the influence of cold or heat upon it. The manner of applying them is described by *fig.* 8.

In which, *a a a a* represents the back plate of the clock, *b b b*, a triangular piece of brass, screwed by two screws, through the slits *c c*, to the plate, yet so that it may be drawn backwards or forwards by means of the screw at *d*. *e f* Is a brass bar, about two feet in length, made fast at the bottom, by a screw and two pins at *f*, to an iron one of equal dimensions, to which it is likewise screwed by the screws 1, 2, 3, &c. after the same manner as the rod of the Pendulum already described. The iron bar is fastened at the upper end to the triangular piece of brass, nearly under that part of the brass bar marked *e*. *g h* Is a strong brass or iron lever, moveable upon a center at *g*, and supported by the upper end of the brass bar; *i i* is the cock, on which, in a common clock, the Pendulum is hung; *k k*, part of the rod of the Pendulum, whose spring, passing through a fine slit in the cock *i i*, is fastened to a stud riveted into the lever at *l*. The slit in the cock must be made so close, as to prevent the spring from having any lateral motion in it.

From this description it is evident, that, if the brass bar expands more than the iron one, it will raise up the lever, and, consequently, the Pendulum, which is fastened to it; and, as the length of the Pendulum is only from the center of oscillation to the under part of the slit, through which the spring passes, the Pendulum will be thereby shortened; and, by making the point of the brass bar to act upon a proper part of the lever (to which it is capable of being adjusted by means of the screw *d*) the Pendulum may be shortened to whatever degree shall be necessary.

To prevent the Pendulum from bending the bars, which it would be liable to do, if the ball of the Pendulum was of any considerable weight, the end of the lever, farthest from its center of motion, is hooked to the end of a chain, which is wound about and fastened to a small pulley at *m*. Upon the same arbor, to which this pulley is fixed, is fastened another pulley, of a much larger diameter, to which is hung, by a silk line, the weight or counterpoise *n*. By means of this counterpoise, any part of the weight of the Pendulum, that shall be desired, may be taken off from pressing against the brass bar. And if, upon the end of the arbor, to which the pullies are fixed, an index be placed, so as to point to a graduated circle, the least motion of the lever will not only be easily perceived, but also whether that motion is uniform and regular, or not. And, upon having, some time after, made a clock with this contrivance added to it, I had the pleasure to find the index not only to move very sensibly, but very regularly, and never, that I could perceive, by jerks. And I doubt not, but, when the point of bearing of the brass bar upon the lever is once well adjusted, it will be found to lengthen or shorten the Pendulum to as great a degree of exactness, as any other method whatsoever. But, as I have not as yet thought of any other method of adjusting it, except from actual trial in different seasons of the year, I must prefer the Pendulum to this method, which, from the great ease, as well as exactness, with which it is capable of being adjusted, will, I think, appear to have much the advantage over any other contrivance yet made use of for this purpose.

The method I take for adjusting the longer arms of the levers of the Pendulum to the shorter ones is described in *fig.* 9. To a strong post, fixed to the wall, is fastened a small shelf, supported by two brackets *a b*. In the middle of this shelf is fastened a wire, by the screw *e*; to the end of which the Pendulum is to be hung. Below this shelf, at the distance of about forty inches, is placed the index *c d*, turning freely upon a center: the length of the index is fifty inches. At the distance of half an inch, upon a part of the index produced beyond the center, is placed a steel pin; and in the back of the Pendulum, as near the center of oscillation as may be, is drilled an hole to receive this pin; when the Pendulum is hung upon the wire against the post, and the wire is screwed higher or lower by the screw *e*, till the pin resting against the upper part of the hole (which is filed into a proper shape for that purpose) keeps the index nearly in an horizontal position. Below the bottom of the Pendulum is placed a second index *f g*, exactly like the former, except that it is kept in an horizontal position, by the screw *k* bearing against the end of the iron rod. When the experiment is to be made, the Pendulum is first put into a box, and gradually heated by a large fire, to a considerable degree, being often turned, that every part may be equally exposed to the fire. And having continued shut up in the box for some time after it is removed from the fire, that the two rods may be heated as uniformly to the same degree as possible, the Pendulum is hung upon the wire, and the two indexes made to stand nearly in an horizontal position. The two graduated plates *h i* are then slid upon a wire, till the divisions in each marked *o* are pointed to by the indexes. As the Pendulum cools, the lower index will be seen gradually to descend; but, if the ends of the two screws, in the ball of the Pendulum, act upon proper parts of the levers, the upper index will continue in the same place. If the ends of the screws are either too far off, or too near the centers of the levers, the index will either rise or descend; and, by comparing the number of divisions it has varied, with those which the lower index has varied, a near estimate may be made, how much the screws require to be altered; and, in a very few trials, they may be easily adjusted to a very great exactness. In order to make an actual trial, how far this contrivance of the Pendulum will answer the end proposed, it is necessary, that the clock, to which the Pendulum is fitted, be made with great exactness, and intirely to be depended on: for otherwise the experiments will be very uncertain, as I found in the clock I first made use of.

I have already observed, that, in order to render this clock as perfect as possible, I made it, in several respects, different from the common ones, in hopes of removing some imperfections I apprehended they were liable to. But as, in this attempt, I fell into an error, which it was a considerable time before I discovered, my making the trial was thereby greatly retarded. And, in order to prevent others from falling into the like mistake, I shall beg leave to give some short account of it.

In a common clock the Pendulum is usually hung by a spring to a cock on the back plate of the clock, whilst the wheel and pallets, by which the Pendulum is kept in motion, are placed in the middle of the frame; and the Pendulum is moved by a piece of steel (called the crutch) riveted to one end of the arbor, to which the pallets are fastened. This disposition of the pieces I apprehended liable to some considerable objections: to remedy which, I contrived to fix the pallets to the upper part of the Pendulum itself, above the center of motion; and, in order to make the Pendulum vibrate as freely as possible, it

was

was made to turn upon two fteel points, and was hung in the middle of the frame, exactly under the fwing-wheel, and fo as to vibrate in the fame plane with it. By this means I was in hopes, that it would have moved with much greater freedom and regularity, than when hung after the common method; and, upon trial, it was found to move with fo great freedom, that a Pendulum of above twenty pounds weight, when hung in its place without the clockwork, and made to vibrate thro' an arch of two degrees, was found to make above 1200 vibrations, before it had loft half a degree, and was obferved to have a fenfible motion above twenty hours afterwards; and the clock, when firft put together, was kept going, for feveral days, by a weight of only eleven ounces, hung to the end of a fingle line. But it was not long, before I difcovered, that this great freedom made it liable to be confiderably affected by the leaft motion.

A remarkable inftance of this was publifhed in the Philofophical Tranfactions, N°. 453. But the greateft objection to this method was, the points being fubject to wear; and I found, that the leaft alteration in them would occafion the clock to vary much more, than (without having made the trial) I could have imagined. To remedy this inconvenience, I made the Pendulum to move upon edges, like thofe, on which the beam of a pair of fcales turns (a method I had good reafon to believe had been made ufe of with fuccefs;) but I found thefe likewife liable to wear, though not in fo fhort a time as the points; fo that, after much time fpent in making feveral experiments, in order to remedy this inconvenience, I found myfelf obliged to lay this method wholly afide, and to hang the Pendulum upon a fpring, as ufual.

In making this alteration, I obferved one circumftance, which I think deferves to be taken notice of. Before I made any alteration in the work, I took particular notice to what height the Pendulum required to be raifed, before the pallets would efcape from the wheel. I next obferved the number of degrees of each vibration of the Pendulum, when moved by the clockwork; and then, the clockwork being removed, the Pendulum was made to defcribe an arch of two degrees; and particular notice was likewife taken, in what fpace of time it had loft half a degree each vibration. Having then made the neceffary alterations for hanging the Pendulum by a fpring, and particular care being taken that the pallets fhould efcape off from the wheel exactly at the fame angle as before, the Pendulum being hung by its fpring, and made to vibrate through an arch of two degrees, it was obferved to lofe half a degree in about half the time it did when turning upon edges. But, upon being fet a-going by the clock-work, the Pendulum was found to defcribe an arch of near two degrees more than before: for, when it turned upon the edges, it defcribed an arch of only three degrees; whereas, now it was hung by the fpring, it vibrated near five degrees; which was very different from what I expected. This alteration being made, I foon found, that the clock went very regular; and, after a fufficient trial, was fully fatisfied the Pendulum would anfwer my expectations. *Philof. Tranf.* Vol. 47.

Mr. Poleni feems to think, that, if a long Pendulum were made to fwing in the place of the meridian, and another of equal length in a plane perpendicular to the meridian, fome difference might be found in their vibrations from the centrifugal force arifing from the earth's rotation about its axis. See *Philof. Tranf.* N°. 468.

PENE'LOPE, in zoology, the name ufed by the authors for the bird commonly known in England by the name of the widgeon; alfo, called in fome places the whewer; and by the Germans the fchmey.

PE'NGUIN, in zoology, a name given by failors of different nations to two different fpecies of water fowl, both web-footed, and both wanting the hinder toe.

The Penguin of the Englifh is the bird more commonly known by the name of the goifugel.

It grows to the fize of a common tame goofe, and is black on its back, or upper part, and white on the belly. Its wings are very fmall, and by no means fit for flying. Its beak is fomewhat broad and long, compreffed on the fides and back, and has towards the extremity feveral furrows, feven or eight on the upper fide, and about ten on the under; and the lower chap fwells into a protuberance downwards. Its head has two white lines reaching from the beak to the eyes. Its tail is very fhort, and it has no hinder toe.

PE'NNY-*earth*, in agriculture, a term ufed by the farmers for a hard loamy, or fandy earth, with a very large quantity of fea fhells intermixed in it; fome of which being round and flat, and in fome meafure refembling pieces of money, have occafioned the earth's being called by this name. It is an earth not eafily dug, but is ufually undermined with pickaxes, and then falls in large lumps; which, with the frofts, break to pieces, and leave the fhells loofe. It is prepared by breaking and mixing well with water, and then makes very defireable floors. The Jerfey combers comb-pots are alfo made of it, and the fides and roofs of ovens are plaiftered with it; and, being rightly managed, it combines into a flower almoft as ftrong as plaifter of Paris. *Moreton's Northamptonfhire.*

PEN'NYROYAL, *pulegium*, in botany, &c. See PULEGIUM.

The feveral forts of Pennyroyal all propagate themfelves very faft by their trailing branches, which take root at every joint; fo that no more is required in their culture and propagation than to cut off and plant out thefe rooted branches: they fhould be planted at a foot diftance every way, that they may have room to grow. The beft feafon for this is in September, that the plants may be rooted before winter. They love a moift foil, and generally grow very faft. *Miller's Gard. Dict.*

PENTAEDRO'STYLA *, in natural hiftory, the name of a genus of fpars.

* The word is derived from the Greek, *πέντε*, five, *ἕδρα*, a fide, and *στῦλος*, a column.

The bodies of this genus are fpars, in form of pentangular columns, terminated by pentangular pyramids at one end, and irregularly affixed at the other to fome folid body.

PENTAPHYLLO'PDES, *wild tanfey*, in botany, a low plant, which never arifes up to the ftalk, but creeps upon the ground, emitting fibres from the joints, by which it roots in the earth, and fpreads very much; the leaves are made up of feveral pinnæ fet oppofite; each being about an inch long, and not half fo broad, ferrated about the edges, and having feveral fmall pieces among them, like agrimony, covered over with a fhining filver-coloured down: the flowers grow at the joints on long foot-ftalks, of five yellow leaves like cinquefoil. The root is flender, with many fibres of a dark-brown colour. It grows in moift barren places, and where water has ftood, all the winter, flowering in May.

The leaves only are ufed, and are accounted reftringent and vulnerary; good to ftop all kinds of fluxes, and preternatural evacuations; to diffolve coagulated blood, to help thofe who are bruifed by falls: outwardly, it is ufed as a cofmetic, to take off freckles, fun-burn, morphew, as, alfo, in reftringent gargarifms. *Miller's Bot. Off.*

PE'PO, *the pompion, or pumpkin*, the name of a genus of plants, allied to the melon and cucumber kinds: the characters of the genus are thefe:

The flowers confift of one leaf each, fhaped like a bell, wide open at the mouth, and divided into feveral fegments at the end. Of thefe flowers fome are male, or fteril, having no embryo; others are female, or fruitful, having an embryo, which ripens into a large fruit, with fometimes a fmooth, fometimes a rough bark. The figure is fometimes oval, fometimes round, and the bark often very hard, tuberous, and hollow: it is divided into three cells within, and contains flat feeds, furrounded with a fort of ring, and fixed to a fpongy placenta.

All the kinds of pompions are cooling, moiftening, allay fharp humours, and quench thirft.

They are hard to be digefted, weaken the ftomach, and caufe wind and cholic.

Pompions contain much phlegm, a middle quantity of effential, falt and a little oil.

They agree in hot weather with young bilious people; but perfons of a cold and phlegmatic conftitution ought to abftain from them.

They ufually mix the pompions with fome aromatic herbs, fuch as parfley, onions, muftard, pepper, and feveral other fharp and volatile things, fit to attenuate the vifcous phlegm of this fruit in the ftomach.

They preferve pompions with fugar, in order to make them more pleafing to the tafte and more wholefome. In fhort, they rarify their grofs fubftance by boiling them well; and befides, the fugar, wherewith they are mixed, gives them a little fort of pricking quality, that makes them lefs infipid to the tafte, and more eafy of digeftion. Preferved pompions may be ufed in diftempers of the breaft, in order to allay the fharpneffes that are there.

Pompions contain a great many feeds, which are flat, oblong, covered with an hard rind, that is a little woody, whitifh, or greyifh. Under this there is a fmall, fweet, and very pleafant kernel, which contains a great deal of oil, that may be eafily preffed out of it; and is proper to foften the fkin, and make it more fmooth. *Lemery on foods.*

PE'PPER-*water*, a liquor prepared by the curious for examination by the microfcope, as always affording a great number of fmall animals.

The method of preparing it is this: put common black Pepper, grofly powdered, into an open veffel fo as to cover the bottom of it half an inch thick, and put to it rain or river water, till it covers it an inch; fhake or ftir the whole well together at the firft mixture, but never difturb it afterwards: let the veffel be expofed to the air uncovered; and in a few days there will be feen a pellicle or thin fkin fwimming on the furface of the liquor, looking of feveral colours.

PE'RCA, *the pearch.*— The name Perca is of Greek origin, and is derived from the word *περκος*, which fignifies variegated with black or dufky fpots; a character common to moft of the fpecies of this fifh.

The common pearch affords good fport for the angler. The beft time for their biting is, when the fpring is over, and before the heats of fummer come on. At this time they are very greedy, and the angler, with good management, may take, at one ftanding, all that are in the hole, be they ever fo many.

The proper baits are a minow or young frog; but the worm called the brandling, well fcowered, is alfo excellent at all times of the year. When the pearch bites, he should always have a great deal of time allowed him to swallow the bait. The pearch will bite all day long, if the weather be cloudy; but the best time is from eight to ten in the morning, and from three till six in the afternoon. The pearch is very abstemious in winter, and will seldom bite in this season of the year; if he does at all, it is in the middle of the day, at which time indeed all fish bite best at that season.

If the bait be a minow, which is the bait that affords the most diversion to the angler, it must be fastened to the hook alive, by putting the hook through the upper lip, or the back fin; it must be kept at about mid-water, and the float must be a quill and a cork, that the minow alone may not be able to sink it. The line must be of silk, and strong; and the hook armed with a small and fine wire, that, if a pike should take the bait, as is not unfrequently the case, he may be taken. The way to carry the minows or small gudgeons alive for baits, is this: a tin pot is to be provided with holes in the lid, and filled with water, and the fish put into this; the water is to be changed once in a quarter of an hour by the holes, without taking off the lid at any time, except when the bait is to be taken out.

A small casting net, made for these little fish, should be taken out with the pearch tackle, and one or two casts of this will take baits enough for the day, without any farther trouble. When the bait is a frog, the hook is to be fastened to the upper part of the leg. The best place for the fishing of pearch is, in the turn of the water near some gravelly scour. A place of this kind being pitched upon, it should be baited over night with lob-worms chopped to pieces; and in the morning, on going to it, the depth is to be regularly plumbed, and then the hook is to be baited with the worm, or other bait; and, as it drags along, the pearch will soon seize upon it.

PE'RCEPIER, *parsley-piert*, in botany, a genus of plants, whose characters are:

The calyx is quadrifid; the flower is produced in the alæ of the leaves; the seeds are produced single in each seed vessel, which is formed by the calyx.

This is a small low plant, lying generally upon the ground, whose round hairy branches are seldom an hand's-breadth long; they are full of small leaves, set alternately at the joints, a little hairy, narrow at the stalk, and broadest at the ends, cut into three round sections; the flowers are small, and stamineous, growing in clusters at the joints, among the leaves; they consist of four leaves, and are succeeded by small round seeds. The root is full of fibres. It grows in dry places, and in fallow fields, as, also, among corn.

Parsley-piert is not an officinal plant, and is seldom prescribed by physicians; but the vulgar have a great opinion of it as a breaker or bringer away of the stone and gravel, and a provoker of urine; and is given by them for that purpose either in powder, or a decoction of it in white-wine. *Miller's Bot. Off.*

PERETE'RION, a name given by chirurgical writers to the perforating part of the trepan.

PE'RFECT, *perfecti*, in church history, a designation which the followers of Valentius assumed to themselves. *Hoffm. Lex. in voc.*

PERFOLIA'TA, *thorow-wax*, a medicinal plant having a small sticky root, from which spring smooth, and frequently reddish stalks. The leaves are of a bluish-green colour, of an oval shape; smooth, and not indented about the edges; full of nerves, which run obliquely from the center to the circumference of the leaf: they are perforated by the stalk, which runs through them, and is divided towards the top into several branches, at the ends of which grow small umbels of yellow flowers, usually five together upon one stalk, with as many small leaves under each umbel; the three outermost being the largest: each flower is succeeded by two oblong striated seeds. It grows only among the corn, and flowers in June and July. The whole plant is used.

Thorow-wax is reckoned among the vulnerary plants, and is especially serviceable in green-wounds, bruises, ruptures, contusions, as, also, for old ulcers and sores, either given in powder, or the decoction. *Miller's Bot. Off.*

PERI'GRAPHE, a word usually understood to express a careless or inaccurate delineation of any thing: but in Vesalius it is used to express the white-lines or impressions that appear in the musculus rectus of the abdomen.

Fistula of the PE'RINÆUM. — Sometimes, after the operation of lithotomy, or after a puncture of the Perinæum or bladder, or from an abscess in the Perinæum near the urethra, or from a scirrhus in the glandula prostata, or when, by the bad habit of the patient, a wound or ulcer can by no means be healed, but its lips become callous, a fistula is formed, through which the urine is preternaturally discharged with great uneasiness to the patient. These fistulas are sometimes generated in the Perinæum by malignant abscesses, which spread amongst the fat under the skin, to the intestinum rectum and scrotum, the urethra remaining entire; but these cannot be called urinary fistulas, because no urine is discharged by them. The urinary fistulas are often occasioned by the use of tents, or pipes, which have been too long retained in the wound after extracting the stone; or when the Perinæum has been greatly distended, lacerated, or burst, by a large rough stone; or when, by the obstruction of a stone in the urethra, the acrimony of the urine corrodes the adjacent parts, and at last the skin, especially if the patient be of an ill habit of body.

The cure of this fistula varies according to the habit of the patient, and the degree of this disorder. When the fistula is large, and has consumed a great part of the urethra, and the patient is of an ill habit and weak, a cure is not without great difficulty, and very seldom, obtained; and, the more callous, or inveterate, the fistula is grown, the harder is the task to remove it. On the other hand, if the fistula is small, and not much indurated, if the patient is young, and of a good habit, the cure may proceed with ease and expedition. But, if a scirrhus is produced in the prostate glands, before a cure can be effected, the scirrhus must first be removed, which I have learned by experience to be a most difficult task.

There are four methods of treating these fistulas: First, the tent-pipe, or whatever is contained in the wound, which occasioned the fistula, must be immediately removed. Then, the patient must be laid upon the bed, or a seat, in the same position as is required for performing the operation of lithotomy; and the indurated sides of the fistula must be extirpated with great dexterity. After the application of a vulnerary balsam, or powder, the lips of the wound must be brought into contact by an adhering plaister; and over it should be laid a narrow compress on each side of the wound, and the whole must be secured with a tight bandage. After the operation, the patient should be confined to his bed, with his knees tied together, and strictly injoined to abstain from motion, that the lips of the wound may more easily coalesce. For a few days a very little drink must be allowed him, that he may not often be excited to make water. The dressings ought not to be renewed till the second or third day, or as long as the patient can contain his urine. The wound being, by these means, almost conglutinated, the patient may be treated in the same manner, as if he had been cut for the stone; and, if he has youth in his favour, he may begin to walk about gently, and by degrees. Thus, if the fistula is not malignant, he may be restored to his former health. Secondly, another method of cure is, by consuming the indurated or callous lips of the fistula with corrosive medicines; and, after removing the escar with basilicon, or digestive ointment, the wound may be conglutinated by a vulnerary balsam, and adhesive plaister, as before. The most proper corrosives in this case are, the troches of red lead, the lapis causticus, or infernalis, or white precipitate mixed with Arcæus's balsam; or, in a recent fistula, a piece of blistering-plaister, according to Cheselden's method, as we are told by Douglas, in the Appendix to his History of the lateral operation.

It is to be observed, that the cure of these fistulas sometimes advances slowly, especially if the orifice be wide; if the callous parts are not totally extirpated or consumed; and if the patient cannot sufficiently refrain from motion, or observe a proper diet. If from these, or the like causes, the fistula is not removed, but begins to renew its callosity, the operation must be repeated, till the parts appear sound. Thirdly, sometimes these fistulas may be cured, by bringing the lips of the bleeding wound, after the callous part is cut off, into contact with a proper suture of two or more stitches. The dressings may be those before directed; and, as the lips of the wound appear to conglutinate, the threads may be cut and extracted. Fourthly, it may be sometimes necessary, during the cure, to keep a catheter in the bladder and urethra, by which the urine may be discharged, and its course turned from the wound, the conglutination of which it would greatly obstruct. If the orifice of the fistula be too small to admit of those methods, it may be dilated with a sponge-tent, or enlarged by incision.

I shall only mention another way of treating these fistulas, which is called the palliative method. For this purpose is the instrument described by Nuck and Solingen, and proposed by Winslow, which, while the fistula is compressed, and closed by it, prevents the efflux of the urine that way; and thus the disorder, when a perfect cure cannot be obtained, may at least be mitigated. But experience informs us, that this is not to be depended upon, as the urine easily escapes through it, and it is troublesome to the patient. *Heister. Chirurg.*

PERISTERI'TES, *the pigeon stone*, in natural history, a name given by some whimsical people to an odd conformation of a pebble, which they suppose to represent very exactly a pigeon without its wings. It seems to have been a mere lusus naturæ, in the formation of a common pebble.

PERITE'RE, in architecture, a place encompassed round with columns, and with a kind of wings about it. Here the pillars stand without, whereas in the peristyle they stand within.

PE'RIWINKLE, in natural history, the English name of a species of shells, called by authors buccina. See BUCCINUM.

PEROQUE'TTE, in zoology, the name of a small species of the psittacus or parrot kind, with a long tail.

PE'RSIAN *Wheel* (*Dict.*)—A machine better adapted to the use of raising water for the use of lands than that called the Persian wheel given in the Dictionary, under the article WATER *Works*, and will be farther in the Supplement. See WATER *Works*, Dictionary and Supplement.

PE'RSICA, *the peach-tree*. See the article PEACH.

PERSICA *terra*, in natural history, an earth of the ochre kind, known

known in the colour ſhops of London by the name of Indian red.

It is a very fine purple ochre, of a conſiderably compact texture, and great weight; while in the earth it is of a pure blood colour, and it is not to be cut with the ſpade, but is dug with iron crows, and falls in irregular maſſes. It is of a rough duſty ſurface, and full of conſiderably large glittering particles: theſe are white, and of a fine luſtre. It adheres firmly to the tongue, is rough and harſh to the touch, ſtains the hands very deeply, and is of a rough aſtringent taſte, and makes a very violent effervescence with acid menſtruums.

PERSICA'RIA, *ſpotted arſmart*, in botany, a genus of plants, whoſe characters are:

The flowers are diſpoſed in ſpikes, at the top of the ſtalks and branches: the calyx is quadrifid, though ſome take it for a tetrapetaloidal flower: the ſtamina are ſix in number: the ovary, in the center of the calyx, is compreſſed, of an oval or orbicular form, and furniſhed with a bifid fimbriated tube: the ſeed is flat, and ovally acuminated. A membrane ſurrounds the ſtalk, at the riſe of the leaves, and ſmall branches, oppoſite to the leaves.

PERSICARIA *urens*, lake-weed, arſmart, or water-pepper. — This ſpecies of arſmart grows not ſo much branched as the Perſicaria mitis maculoſa; the leaves are long, and proportionably narrower, and more like the leaves of the peach-tree, whence it takes its name Perſicaria; but they are not ſerrated about the edges, and they want the ſpot that is in the leaves of the mild arſmart, and they have a very hot biting taſte, burning the tongue like pepper. The flowers grow in long ſlender looſe ſpikes, of a paler colour than the Perſicaria mitis maculoſa, but containing like ſeed: it grows in like places with that, and flowers about the ſame time.

This has been accounted an extraordinary plant againſt the ſtone, Mr. Boyle having, in his book of the Uſefulneſs of experimental Philoſophy, given to the diſtilled water of this plant a mighty character for its virtues againſt that diſtemper. It is commended, alſo, as very cleanſing, and good for old ſtubborn ulcers.

PE'TIOLE, *petiolum*, among botaniſts, expreſſes that ſtalk which ſupports the leaves of a plant, as the peduncle does the fructifications.

Some uſe the word petiolum to denote the whole middle rib of a leaf of any plant, which is the ſtrongeſt part of it, and runs from the ſtalk by which the leaf adheres to the tree or plant to its extremity, and from which the lateral fibres, or nerves, as they are uſually called, commonly ariſe.

PETASI'TES, *butter-bur*, in botany, a genus of plants, whoſe characters are:

The root is large and perennial; the leaves are grey, large, and orbicular. The calyx is cylindrical, multifid, ſquamous, and contains many floſcules collected into a flower. The flowers are diſpoſed in a thyrſus, and appear before the leaves; and the ovaries are furniſhed with a tube, which has a clavated bifid apex.

The roots of butter-bur are ſudorific, alexipharmic, and good for all kinds of fevers, and malignant, infectious, and peſtilential diſtempers; they are cordial, preventing fainting and ſhortneſs of breath; they likewiſe provoke urine, and are accounted good to deſtroy joint-worms. They are outwardly applied, in the form of a cataplaſm, to peſtilential buboes and plague-trees; a great quantity of them are put into the aqua theriacalis. *Miller's Bot. Off.*

PE'TROL (*Dict.*) — In Broſely, Bently, Pitchford, and other places adjacent in Shropſhire, there lies over moſt of the coal-pits, or mines, a ſtratum or layer, of a blackiſh rock, or ſtone, of ſome thickneſs, which is porous, and contains great quantities of bituminous matter.

This ſtone, being brought to the workhouſe, is ground ſmall by horſe-mills, ſuch as are uſed for grinding flints, to make glaſs of; the powder is thrown into great coppers of water, where, by boiling, the bituminous matter is ſeparated from the ſtony, or gritty, this laſt ſticking to the bottom, the other ſwimming at the top.

This bituminous ſubſtance, being gathered together and evaporated, comes to the conſiſtence of pitch, and with the help of an oil diſtilled from the ſame ſtone, and mixed with the pitch, comes to be thinner, or like tar; the uſes of both which materials, either for ſhipping, or otherwiſe, theſe ſubſtances are ſaid to ſupply, or even to excel. This has been tried on ſeveral boats, and it does not crack, like the ordinary pitch or tar, but always keeps black or ſoft; and therefore is propoſed to hinder the worms from getting into the ſhips pitched with it.

There is, likewiſe, diſtilled from this ſtone an oil, which may be uſed for oil of petre, or turpentine, and has been tried in aches and pains. *Philoſophical Tranſactions.*

PE'TUNTSE, as it is uſually called PETUNSE, one of the two earths, or foſſil ſubſtances, of which the porcelain ware of China is made. The other is named kaolin. See KAOLIN. The Petuntſe is ſprinkled all over with bright glittering particles. It is beat into powder, and afterwards made up into a ſort of bricks, and in that form it is ſent to the places where it is to be wrought. It is of a hard texture, and of a ſomewhat greeniſh colour. Mr. Reaumur, of the Academy of Sciences of Paris, who was extremely induſtrious in ſearching into the nature of porcelain, obtained ſome ſpecimens of the Petuntſe, both in its native ſtate, and in form of the brick, which is given it after it is powdered and reduced to a paſte.

Mr. Reaumur found that the Petuntſe was ſo far from being an earth, as uſually ſuppoſed, that it was truly of the nature of the European flint or pebble, as he eſtabliſhes the character of that body: but, to underſtand this rightly, it is to be obſerved, that this author makes the flints and pebbles a very large claſs of bodies, ſome of which are more, ſome leſs tranſparent; and that this Petuntſe is of the nature of the coarſer, or leſs tranſparent kind, the ſurface of which, when broken, is not ſo ſmooth and poliſhed as that of the ordinary flint. The great character of theſe ſtones for the porcelain manufactures is, however, that they are very eaſily vitrified, without the aſſiſtance of any ſalt, and without the immediate contact of the fire, the operation ſucceeding in a crucible; which is not at all the caſe in regard to the European flint, they very differently melting alone in a crucible, and then only into a whitiſh opake glaſs.

It being certain from hence, that one of the two ingredients of the China ware is eaſily vitrifiable, it follows, from the experiment of the whole mixture, or China ware not being reducible into glaſs in a large fire, that it is a compoſition of a vitrifiable and a not vitrifiable (or at leaſt not eaſily vitrifiable) ſubſtance; and conſequently, that the kaolin is a ſcarce vitrifiable body, and that the reſult of the action of fire, on a mixture of theſe two, is a ſemivitrification; which is what we call the China ware.

If we, therefore, could, in Europe, provide the materials of China, or ſuch as were like them, we might reaſonably hope to ſucceed; and this appears far from improbable. The Petuntſe is eaſily ſupplied by many of our own earths, ſtones, and ſands, as nothing is required in it more than a property of running eaſily into a white glaſs. The kaolin ſeems moſt to be reſembled by our European talcs. *Mem. Acad. Par.* 1727.

PEUCEDA'NUM, *hog's-fennel*, in botany, a genus of plants, whoſe characters are:

The root is perennial, deeply ſunk, and hairy. The leaves are winged, narrow, graſſy, and divided into three parts. The ſeed is flat, almoſt oval, ſlightly ſtriated and marginated.

Hog-fennel is accounted good to clear the lungs of tough viſcid phlegm, and thereby to help old coughs and ſhortneſs of breath; it likewiſe opens obſtructions of the liver and ſpleen, and helps the jaundice; it likewiſe provokes the menſes, and gives eaſe in labour-pains; the juice, ſnuffed up the head, is commended by the ancients, againſt the lethargy, apoplexy, epilepſy, and other diſorders of the head and nerves. *Miller's Bot. Off.*

PE'WIT, in zoology, the Engliſh name of a common bird of the larus, or ſea gull kind, called by ſome authors larus cinereus, and by others cepphus, and, in ſome of the counties of England, the black cap and ſea crow.

It is about the ſize of a pigeon. Its beak is red, its head and throat of a greyiſh black, and its neck, tail, breaſt, and belly white; the middle of its back grey. It has its Engliſh name from its note, which ſeems to expreſs the word Pewit. It is affirmed by many, that the head of this bird is only black at a certain ſeaſon of the year. *Ray's Ornithol.*

PHAGEDE'NIC *Water* (*Dict.*) — This lime-water, to every pint of which twenty or thirty grains of ſublimate have been added, is a great deterger of foul wounds, ulcers, and other ſtuborn diſorders.

PHALA'NGOSIS, in ſurgery, the name of a tumor and relaxation of the eye-lids, which is often ſo great as to deform the eye, and very much impede viſion. Sometimes, the relaxed eye-lid ſubſides or ſinks down, occaſioned either by a palſy of the muſcles which ſuſtain and elevate the eye-lid, or elſe from a relaxation of the cutis above, from various cauſes. Sometimes, alſo, an œdematous or aqueous tumor is formed on the eye-lids, ſo as almoſt entirely to exclude viſion; but this laſt caſe ſhould be well diſtinguiſhed from the other, and may be remedied without much difficulty, by the uſe of internal and topical medicines; ſuch as purges and diuretics, given inwardly, and a compreſs dipped in warm ſpirit of wine and lime-water.

But, in the paralytic or relaxed caſe, the uſe of cordial and nervous medicines muſt be propoſed internally, and outwardly balſam of Peru and Hungary-water are to be employed. If all theſe fail, the remaining method is to extirpate a ſufficient quantity of the relaxed cutis; and then, after healing up the wound, the remainder will be ſufficiently ſhortened. *Heiſter's Surgery.*

PHALE'NÆ, in natural hiſtory, the name by which authors diſtinguiſh thoſe butter-flies which fly by night, and which the French thence call papilions nocturnes, and we vulgarly moths.

All the creatures of this claſs are quiet by day, remaining fixed to the ſtalks or leaves of plants, except only ſome of the males, which are now and then found fluttering about in the woods in ſearch of the females; but, as ſoon as night approaches, they all fly about. This diſpoſition is very remarkably implanted in their nature; for, when kept ſhut up in boxes, they always remain quiet without changing place all day, but as ſoon as the ſun is about ſetting, they always begin to flutter about, and fly

as

as much as their prison will permit them. The species of these are more numerous even than those of the day butterflies. The day kinds all have trunks fitted for sucking the juices of flowers for their nourishment, but many of the Phalenæ wholly want them: these, however, have always the beards which serve to defend the trunk from injuries in the day flies, and sometimes, in the place of the trunk within these, there is found a small white protuberance or two. It is certain, therefore, that many of the Phalenæ have no organs of eating, nor take in any food during their whole lives in that winged state. *Reaumur Hist. of Inf.*

PHARMACOCHE'MIA, a term used to express that part of the chemical art which treats of the preparation of medicines. It is thus called by way of distinction from that chemistry which is wholly employed about the transmutation of metals by means of the philosopher's stone; this being called spagiricochemia.

PHEA'SANT, in ornithology, a bird so nearly allied to our common poultry, that it would naturally appear a very easy thing to breed them up from young; but the proper food of them is not sufficiently enquired into. Though they eat corn when full grown and in health, yet they have recourse in their young state, and when sick, to another sort of food, preying on several insects, and that in a very voracious manner.

The young Pheasants and partridges prey upon ants; and they will never succeed with us, if they have not a proper quantity of ants to have recourse to, as soon as they leave their roost in a morning. When musty corn, or want of due care in cleaning their houses, has made them sick, a repast of ants will often recover them. When that fails, they may be offered millepedes or earwigs, or both together, which will always do much better than either singly. To this medicine must be added a proper care that their common food of corn be very sweet, their habitation kept nicely clean, and their water shifted twice a day. They must not be let out of the house in a morning till the dew is off the ground; and after sun-set they must be immediately taken in again: in the heat of the day they must be allowed to bask in the sun in a dry sandy place. With these regulations the birds of this kind will succeed much better than they usually do. The Pheasant is a bird of a sullen disposition, and, when the coupling time is over, there are seldom found more than one in a place. *Philos. Trans.* N°. 23.

PHILADE'LPHIA-*stones*, a name given by some authors to what are called by others Christians bones, found in the walls of that city. It is a common error, that these walls are built of bones, and the tradition of the country is, that, when the Turks took the place, they fortified it for themselves, and built their walls of the bones of the Christians whom they killed there. Dr. Smyth, in one of his epistles, mentions this wall as an instance of the Turkish barbarity; but this is an idle opinion, what passes for bone being only a loose and porous stone of the sparry kind, found in an old aquæduct which is still in the wall. Sir Paul Rycaut brought home pieces of these stones, which he also supposed to have been bones; but on examination they proved to be no other than various bodies, chiefly vegetable, incrusted over and preserved in a spar of the nature of that which forms incrustations in Knaresborough spring, and other places with us. These bodies are often cemented together in great numbers by this matter, and their true shape lost in the congeries, till a diligent and judicious eye traces them regularly. *Woodw. Cat. of Foss.* N°. 2.

PHILOME'LA, *the nightingale*, in zoology, the name of a small bird, famous for his singing.

The nightingale has from all antiquity been allowed the first rank among song birds. He is somewhat less, though longer than a sparrow; far from a beautiful bird, and weighs hardly an ounce. His bill is long and flexible, of a darkish colour; and, when opened, discovers a wide orange-coloured throat. The eyes are full and lively; the feathers of the head, neck, and back fallow; the wings, and especially the tail, somewhat brighter; the throat, breast, and belly of a light ash colour; the legs long, and the claws slender. The hen much resembles the cock, but is a little more upon the ash colour, as are also the young ones. This bird affects solitude, is wild and timorous, and it seems the effect of this natural fearfulness that he often jerks his tail. The most celebrated authors on birds mention no more than one species of nightingales, but the fanciers tell us of no less than three; First, the mountain nightingale, being the smallest of all. Secondly, the middle-sized field nightingale. Thirdly, the water nightingale, which frequents the banks of rivers, and is the biggest, stoutest, and best songster; for that will sing eight months in the year, whereas the others sing no more than three at most. However, the best connoisseurs hold that there is but one species of nightingale, in which there is a variety of size, shape, and colour, as in the gold-finch, and more especially in the canary-bird.

The ordinary resort of the nightingale is the side of some hill, or brook, especially if near an echo: there he most delights to sing, and interrupts his warblings by short pauses, as, if listening and making responses to the echo of his own voice. Hence, few circumstances of place can suit this songster, and, when he quits these, you may be sure he leaves off his singing at the same time; and, when he visits them again, it is as certain that you will again hear him. I have observed, that of these favourite places he prefers that which has the advantage of an echo, and best favours his ambition of being heard by his hen, and every rural animal, as well as mankind; and, in case he repairs to any other, it is only to avoid the wind that then blows, especially a northern one, which is most disagreeable to him. Whilst the hen is laying her eggs, and more especially when she sits, then it is that the male utters his most beautiful notes, and night and day redoubles the energy of his song, to divert and comfort his female for the pains of laying, and the fatigue of sitting. Accordingly, it is remarkable that he then chuses some convenient place in the neighbourhood of the nest. Sometimes he pitches upon a place fit to answer all his several intentions, of hearing his echo, attending upon his female, and keeping an eye upon passengers, and then you will hear him incessantly in his song.

The nightingale usually builds his nest near the ground among briars, in box or yew-trees, at the foot of an hedge or bush; and for this reason many layters of eggs come to ruin, being devoured by dogs, foxes, polecats, weasles, &c. The nest is pretty long and deep, consisting chiefly of dry oak leaves, and holds very well together, provided it be not moved, for it will fall asunder upon a touch. It is assured that the nightingale will in hot countries produce four layters of eggs a year; in this country but three at most, and the third seldom comes to good, on account of the cold beginning to set in. They commonly lay four or five eggs, which look as if they were bronzed over, and from whence are generally hatched more cocks than hens. In order to find a nest, it will be proper to go in the morning at sun-rise, or in the evening towards sun-set, near the place where the cock has been heard to sing, which most commonly is not a great way from the nest; there you are to remain still, and without making the least noise, and in a short time you will perceive whereabouts the nest is, by the coming and going of the cock and hen, and by the chirping of the young ones.

The right time for catching nightingales is the whole month of April, and, the sooner they are caught after their arrival, the longer they continue in song. Those taken in May, being already paired, must be caged a long while before they can be brought to sing, and then their music is short and trifling. From sun-rising to ten in the morning are the best hours for catching them, for after fasting the night they are eager for food, and greedily seize a meal-worm. In a wood it is easy to make choice of that nightingale which has the finest song; for, if the wood be of such extent as to feed four nightingales and their families, these four place themselves at the four corners of the wood, and seldom and never invade each other's bounds. The evening before you set your trap, you must go to the wood they frequent, and mark the places where you hear them; then take a twig, about a foot long, sharpened at one end, a slit at the other, so as to hold a couple of meal-worms spitted upon a pin: stick it up in the ground, about twenty or thirty paces from the place you hear the bird sing, so that he may easily espy it, and turn up the earth round it; and this do wherever you hear a nightingale. Next morning repair to the place where you planted your twigs, and, if you find that the baits have been eaten, you need not doubt but the nightingale will soon return, in expectation of a fresh supply. You are therefore to set your trap near the twig, in as private a place as possible, but so as to leave him a full view of the meal-worms, and turn up the fresh mould, which will invite the nightingale, in hopes of meeting with worms, ants, or other insects, his ordinary food If he should espy you placing the trap, you may depend upon his coming to it soon after you are retired; and, if he should be gone to some other of his favourite places, you need only find him out by his song, and throw a stone at him, which will infallibly send him to his former station. When he is caught in the trap, you must seize him cautiously by his legs, and disengage him from the net, slipping him immediately into a little silk purse, at least six inches long, and two wide, taking all possible care not to rumple his wings or tail, which would considerably retard his singing. I know a fancier, who, to avoid the inconveniency of a net, in which the bird attempting to escape is apt to entangle himself, makes use of a piece of thin green silk, of which he is no more shy than of a net; and thus the feathers are secured from the least damage. On your return home, you are to fix a cage on the outside of your window, which is to remain there the nightingale's whole singing season, wherein you must place his meat and drink, as will be hereafter described. The wires of the cage must be quite covered with a piece of green serge, or cloth, so as to exclude the light. It is absolutely necessary that this cage should be exposed to the east, as much as possible. The heat of the south fatigues the bird, and hinders his singing, and, besides, so dries him up, that he will be apt to turn blind in a few months.

The cage, placed as above directed, must be sheltered from the rain, and the heat of the sun, by an umbrella, or boarded shed. Some set it upon a small table within the window, but then the casement must be left open night and day, and nobody must come into the room, but the person that is to take care of the bird, who must give him his meat and drink as softly as possible, and without jarring his cage. Under such management, a nightingale, newly taken, will sometimes begin to sing in three

three days, but never exceeds eight, provided he was caught before May. In the cage must be placed two small cups, one with water, in which you must put three or four meal-worms, which the nightingale will soon find out; in the other you must put between twenty and thirty meal-worms for his food at first. In caging the nightingale, you must open that end of the purse next the head, and slide him out gently, and, when he is halfway out, you must make him swallow a few drops of water to refresh him, by dipping his beak again and again into the water; when you may let him slip out of the purse into his cage, presently closing the door. The bird will continue sullen for some time under his new confinement, but the meal-worms will soon revive his spirits, and make him forget his loss of liberty. About four hours after caging the bird, it will be proper to visit him, and, softly opening the door of the cage, take out the meal-worm cup to put in twenty fresh worms, and at the same time the bottom of the cup should be covered with a little of the paste I shall hereafter describe, which is to be his constant food. About seven in the evening, visit him again, and give him twenty-five more worms, some of which should be cut in two, that the paste may cling to them, which the nightingale swallowing, will be insensibly brought to like it. The next day give him twenty-five more at eight in the morning, as many at noon, and also at seven in the evening, all cut in two, and mixed with a little of the paste. Be very careful not to stir the cage, which will make the bird wild, nor must you ever suffer him to see you. Do the like the third day, only now cut the worms in three or four pieces, to mix the better with the paste. So you are to go on for three weeks, when you may lessen gradually the number of the meal-worms, and increase the quantity of the paste, and this as you find he relishes it; for some will take to it sooner than others, and it is no small advantage to have a nightingale soon reconcileable to this sort of meat, for it makes him very stout, and continues him long in his song. If you can easily procure meal-worms, it will be proper to give your bird ten or fifteen three times a day, the whole singing season. But you must remember not to put them at first into a transparent glass cup, by which misconduct many have lost their birds in three days, without knowing that the bird, seeing the worms through the sides of the cup, endeavours in vain to seize them, and so is starved to death. It may seem surprising that to make a nightingale sing you must darken him up on all sides, whereas all other birds are quite mute under this circumstance; but experience has shewn that this little creature is so extremely timorous, that every thing he sees is a new object of terror, which sets him a fluttering till he kills or maims himself against the wires of the cage; but, when kept without light, he consoles himself very well with eating and drinking.

The trap, commonly used in England, Mr. Ward describes to consist of a board about the bigness of a round trencher, a spring and a wire as round as the trencher, with a green silk net fastened to it; there is a little cork that comes through with a string, and keeps up the trap; on the cork is pinned a meal-worm, and, when the bird pulls the worm, the trap falls.

Of breeding nightingales. — Towards the end of the spring, which is the time of their last laying, catch a pair of old birds. To which purpose find a nest, as was before directed; then set two traps baited with meal-worms, very near the nest, thus you will soon have both cock and hen; when you have brought them home along with the nest and young ones, you are to put them altogether in a dark closet where not the least light can penetrate. Their meat and drink must be placed near them in two china cups, and in a third about fifty meal-worms; and, every day at the same hours, you must do as has been prescribed for nightingales newly taken: and thus you will soon have the satisfaction of seeing the cock and hen fetch the meat and meal-worms to feed their young; their meat should be one half bread, the other bruised hempseed, and minced boiled beef, with a little parsley, and now and then some yolk of egg boiled hard; or the paste which I shall hereafter describe, mixed with equal parts of raw sheep's heart, or beef finely minced, first, clearing away very carefully all the skin, fat, and sinews. The affection these creatures have for their young ones causes them, without a moment's regret of their lost liberty, immediately to set about nursing them up in their prison. As soon as they can feed themselves, you may put the cock and hen in two separate cages, where they are to be kept the whole winter till the next spring. But, in case the eggs should not be hatched when you take the old ones, you must be content with the birds only, which you are to keep separate, as I have said, but in the same dark closet where you purpose they shall lay eggs the next spring, that so they may be used to the place, for which end you may sometimes suffer them to get out of their cages; and thus you will have a pair of nightingales prepared in every respect for home breeding at the proper season.

The next year about the beginning of April, open the cages for the whole season, and about the closet scatter dry oak leaves, picked dog's grass, and deer's hair, with one or two old nightingale's nests. In the corner of the closet near the window, stick fast two or three branches of slender dry twigs, tied slightly together, letting the lower end rest on the floor. Then take some handfuls of the oak leaves and stuff them among the twigs, leaving open the passage where your hand went in, for an entrance to the nightingales; you must likewise place near at hand a small wooden tray full of ordinary garden mould, and a small shallow earthen pan of water for them to bathe themselves in, which should be renewed every day. This pan however must be taken away when the hen sits. The situation of the closet should be towards the south, so as to be exposed as much as may be to the sun-shine, and skreened from the north-wind. I have known persons of curious taste inclose a pair of nightingales in a grand aviary, or cage built on purpose, in a proper corner of a garden, and surrounded with little yew-trees, maples, and liliacs, where they built their nest and brought up their young as well as in the open country.

With the above precautions you will find the œconomy of our nightingales very diverting. And, if the closet looks into a garden, you may safely venture to take out a pane of the window glass, and leave the old ones at liberty to go out and return, which they will not fail to do, whilst their young ones are incapable of feeding themselves. At first, it will be best not to trust them both out together, but the cock by himself, and then the hen by herself, and at last both together; observe too, that the hole they pass through should be as near the nest as may be. By this management, you will have the pleasure of hearing the cock sing almost continually day and night in your garden, whilst the hen is sitting; and they will have the opportunity of procuring a thousand little insects, after the eggs are hatched, wherewith to feed their young. You must be cautious of visiting the closet too often, especially whilst you allow them the liberty of the garden, and it should be the business of only one person to look after them, which will make them the more familiar. But it is necessary, above all, that neither dog, cat, mouse, or rat, should ever disturb them, for any of these would infalliably drive them away so as never to return again.

How to bring up your nightingales without the cock or hen. You must get a nest of the first layter, as being ever the most stout and vigorous birds, and consequently the best singers, and the least liable to fail in their moulting. The nest should not be taken till the birds are pretty strong, and, when taken, should be carried home in a dark basket, with only a few breathing-holes. To feed them properly is a delicate point, to give them too much or too little is equally dangerous. Their gaping wide is no indication that they want meat, for this they will do whenever you come nigh them, or touch their nest; provided you understood well their language, their cry would be the most significant token; but, if you do not, it will be best to observe the following directions. About half an hour after sun-rising, give them their first feed, the second an hour after, and so on by the hour till sun-set; the last feed should be somewhat more plentiful than the rest. They should be fed with a skewer flatted at the end; give them but four mouthfuls at a time, though they would take more, even to bursting; be sure likewise not to mistake one for another, else some may be starved and others over-crammed. At a month's end, or sooner, if they are of the first layter, they will be able to feed themselves, which you may know by presenting a small meal-worm to them; you may then separate them in different cages. The young ones being so far brought up, you may, for perfecting their song, carry them into the country to hear the old nightingales sing, otherwise they will scarce answer the trouble which has been taken about them; at least, you must wait a long while before they will be able to entertain you to your liking. I know a fancier who has been these twenty years bringing up nightingales from the feeding stick, of which he always has a large stock by him; some of them he had twelve years, and may be called tolerably good, but no ways equal to those bred in the country. This is however an easier way for such as are already provided with old nightingales taken with the trap, and kept a whole year or more. Take a nest of young ones, and place them in the same chamber with an old nightingale. Begin feeding the young ones with the stick, and leave the old one's cage open day and night, taking care to place a small pot of the young ones meat, that is, the paste mixed with minced beef or mutton, close to his own feeding trough. This done, if you suffer the young ones to cry a little while before you proceed to feed them, you will soon perceive the old bird to go out of his cage, chirp to the young ones, fill his bill with their paste, and feed them. When, therefore, at your morning visit, you find that he has been distributing meat to the young ones, you may trust that business to him entirely, for he will feed them till they can feed themselves: or you may afterwards have the pleasure of seeing them eat with him at the same pot, and follow him into his cage. Put them into separate cages. If you pursue this method, as I have done, with success, and may be practised on various other birds, as sparrows and gold-finches, you may spare yourself the pains of attending your young nightingales, which requires a deal of time and fatigue. The old bird will take as good or better care of them than you can, and, besides, will teach them their song.

I will add, that, if you chuse this way of bringing them up, it will be best to provide yourself with a hen, and keep her a whole

whole year in a cage, in order to be a nurfe, under which management fhe never fails to prove one; whereas a cock often fails in this point of duty, nor does he ever fing as long as he is engaged in it.

Of the time and manner of teaching young nightingales tunes by whiftling, or the flageolet.

When you perceive, by the chirping of a young one, that he is a cock, put him into a cage covered with green ferge; and let him hang in a chamber quite out of the hearing of nightingales, as well as of all other birds. For the firft week let him be kept near the window, or the lighteft part of the room; then remove him by degrees backward to the darkeft part, where he muft remain all the time of his learning, nor muft he be annoyed or diverted by any kind of noife whatever, nor difturbed by people's coming near him. His tune fhould not be whiftled or piped to him too often; half a dozen leffons a day will be fully fufficient, two in the morning, two at noon, and as many in the evening. Two feveral tunes are enough for one bird. The flageolet fhould be of the fofteft and mellowelt tone, and not of too high a pitch. I muft again infift upon the neceffity of keeping a young nightingale apart, as foon as he is able to feed, if your intention be to learn him a tune. And another thing I am to admonifh the reader of, that notwithftanding he has kept conftantly whiftling or piping to his bird, even to his moulting time, without having any thing from him in return, more than a little chirping, yet this fhould not difcourage him. The bird's voice is feldom formed before the enfuing fpring, and therefore his leffons fhould be continued without intermiffion. When that feafon arrives, you will find to your equal furprize and delight, that your fcholar has not forgotten his inftructions. I have known it happen, that when the piping has been neglected at the autumn and winter, out of mere defpair, the nightingale has notwithftanding of his own accord ftruck into his tune, and gone through a great part of it at the beginning of the fpring.

How to have finging nightingales all the year.

About the beginning of December put an old cock into the blind cage, then fhut him up in a clofet, which you muft darken by degrees, fo that not a ray of light can enter, till June, when you may gradually let in the light. In this month, as others ceafe, he will begin to fing. Then you are to put another old cock in a light cage, and keep him in the dark till December, and as much as poffible from hearing the finging of the other, and comfort him with a little wood fire in the chimney of the room during the cold of the winter, all which feafon he will likewife fing.

But if you would bring a nightingale to an almoft conftant fong, by blinding him, you muft proceed thus: keep him in the blind cage a whole year, then take the bird in your hand, and clofe up his eyelids thus: break off the bole of a tobacco-pipe, and, having heated the thick end of the ftem red-hot, bring it near the bird's eye, and blow through it, which will caufe him to fhut it, and a glutinous tear will iffue, which will perfectly clofe it up, without any farther inconvenience to your bird; a dexterous operator will eafily do this without at all fcorching of the eye-ball, for, though the anguifh would not kill him, yet he would be a good while in recovering, befides being disfigured; whereas, if proper care be taken, you may reftore his fight by feparating the eye-lids with the fine point of a pen-knife.

As foon as the bird is blinded, make him fwallow a drop of water, then put him in his cage in the fame dark room, keep him till the forenefs of his eyes be gone off, which ufually is in a week or ten days; then let in the light upon him by degrees.

How to make nightingales refort to places unfrequented by them.

In the month of May find a neft of the firft layter, but do not take it till the young ones are at leaft a week old; then go early in the morning, and fet two traps, baited with meal-worms, near the neft, fo you will eafily get the father and mother in your poffeffion in lefs than an hour; as foon as you have caught them, put them in feparate filk bags, and fo bring them to the place where you defign to fix them. Take alfo with you two fmall fquare cages covered with thick green ferge, without wires or perches. In taking the neft, do not feparate it from the branches that fupport it, but cut them off, and bring away the neft and them together; and it will be beft to remove the whole tree, if it be a fmall one; when you have brought it to your intended place, plant it in the fame afpect as before; the neft fhould be covered with wool or cotton in the tranfporting, to keep the young ones from getting out or taking cold. Having fixed the neft, place the two cages with an old one in each, fo that the neft may be between them at twenty or thirty paces diftance, and let the doors of the cages be turned towards the neft. To each door muft be faftened a thread forty or fifty yards long, whofe ends you muft hold together in your hands, and, concealing yourfelf behind fome tree or hedge, pull open the doors and fuffer the old ones to efcape from their cages with the following precautions. Let the young ones grow hungry and chirp for their food before you let the old ones efcape, who then will readily find them: releafe the hen firft, and, fome little while after, the cock; then carry off the cages as quietly as you can, and come no more there that day. Thus from your window you may entertain yourfelf with the pleafure of feeing the old ones bring up their young, which will, themfelves, be fure to breed upon the fame fpot the next year.

Of the tokens of health and ficknefs in nightingales, and how to cure them.

A nightingale may be looked upon to be in a good ftate of health: 1. If he fings much. 2. If he often feathers himfelf. 3. If he be brifk and alert, and jerks his wings much. 4. If he roofts on one leg only, and is greedy of meal-worms. On the contrary, when a nightingale fleeps on his belly in the bottom of the cage, it is a fign he is either fick or fullen, provided his feet are not baked up and difabled with his dung, in which cafe a little warm water in a faucer, placed in his cage, foon relieves him. Sometimes a little impofthume forms on the bird's rump, which fhould be fnipped with the point of a pair of fciffars, and the matter fqueefed out, giving him a few meal-worms to cherifh him, or a fpider or two, which never fhould be omitted at the beginning of March, be he fick or well. If he grows lean through much finging, mix poppy feeds in his meat. When his fong and moulting are over, he is apt to grow too fat, therefore the poppy feeds muft then be left out. If he be very lean, feed him with raw fheep's heart well cleared of all its fkin and fat, minced very fmall and mixed with an equal quantity of the pafte hereafter defcribed. If he is bound up, give him four or five meal-worms, and, if he dungs too loofe and often, fheep's heart and poppy feeds will bring him to rights. The cramp often afflicts him, which, if it once attacks a young one, it is fure to kill him; in old ones, it generally arifes from too much expofure to the cold, and a warmer place is the remedy. There is an odd diforder to which this bird is very liable, it may be called the falling ficknefs. After a few precipitate motions he fhall drop from his perch on his back at once, with his legs ftretched upwards, and his eyes diftorted, when, without fpeedy relief, he foon breathes his laft. The only method is to take him, and, with a pair of fciffars, cut off the hind claws fo near the heel as to draw a drop or two of blood; then wafh his feet in white wine, of which if he does not foon revive, make him fwallow a drop worm, and he will be quite reftored in an hour or two. To conclude, if you would fecure a nightingale in a healthy conftitution, do not fail in the month of March to purge him with half a dozen black fpiders, one every day.

Of the proper food for nightingales.

There is not perhaps a bird eafier to feed than a nightingale; all meat agrees with him, provided it be mixed with flefh, without which he will not be nourifhed. He is naturally carnivorous, and lives on fpiders, wood-lice, ants eggs, flies, and feveral forts of worms, all of them animal fubftances, which agree with his conftitution; the knowledge whereof has put many upon preparing compofitions proper to be fubftituted in the room of his natural food. The moft common of this fort in France is equal parts of bruifed hempfeed, crumbed bread, and minced boiled beef, well mixed together; this does very well for them, but it is troublefome to the feeder, as it muft be made frefh every day in fummer. I fhall therefore give the compofition of a pafte, which will keep good a long time, and what I have ufed many years with great fuccefs.

Take two pounds of lean beef ftakes, Spanifh or chick peafe hufked, millet feeds, poppy feeds, fweet almonds, of each half a pound: wheat flour two ounces; virgin honey, a pound; faffron in powder, a drachm and an half; the yolks of twelve new laid eggs; frefh butter, the quantity of a hen's egg.

Firft let the peafe and millet feeds be powdered and fifted. The poppy feeds muft be only well bruifed, becaufe their oilinefs will not admit of fifting. The beef muft be either finely minced or pounded in a marble mortar, and cleared of all fat and fkin; the almonds muft be likewife pounded after blanching in hot water, and they muft be wrought to a perfect pafte, otherwife the birds cannot digeft them. Then break the eggs and feparate the yolks into a broad earthen difh, and add the honey and the faffron. When thefe three are well mixed, incorporate therewith fucceffively the beef, almonds, meals, and flour, ftirring the whole with a wooden fpatula, till no clots remain; then turn the mixture into another glazed earthen difh, whofe infide has been rubbed over with butter. Set it on a gentle fire, ftirring it continually, efpecially the bottom, to keep it from burning; continue it on the fire till the pafte will no longer ftick to your fingers, and has acquired the ftiffnefs of a new kneaded bifcuit. This done, remove it from the fire, and let it cool in the difh. Afterwards put it into a tin box clofe covered, and keep it in a dry place for ufe.

It is not eafy to fucceed in the preparation at the firft trial; it depends on a degree of drying to be found out only by experience; when it is over dry, it lofes its fubftance, and fheep's heart muft be often mixed up with it, elfe the birds will lofe their flefh; on the other hand, if it be under dried, it will turn mouldy in keeping, if you have not a good number of birds to feed: for it is calculated at the rate of a fix months provifion for one bird. For the want of the Spanifh peafe, maize, or Turkifh corn, will do as well.

Laftly, notwithftanding I have experienced that this pafte is of itfelf fufficient to keep nightingales full in flefh, yet I am convinced that, when I mixed with it an equal quantity of fheep's heart for regaling them upon certain occafions, their fong would be ftronger and more lafting. I would therefore recommend fuch addition during the finging feafon.

PHILO'NIUM *Londinenfe*, the name by which the medicine commonly called Philonium Romanum, is called in the late London Difpenfatory. The compofition is alfo much altered, as well as the name, and is now ordered to be made thus: take white pepper, ginger, carraway-feeds, of each two ounces; opium, fix drachms; fyrup of diacodium boiled to the confiftence of honey, three times the weight of all the reft. The opium is to be diffolved in a little wine, and then mixed with the fyrup; after which the powders are to be ftirred in, and the whole made into an electuary. *Pemberton's London Difpenfatory.*

PHILOSO'PHIC *Chemiftry*, an art of dividing or refolving all the bodies in our power by means of all the inftruments that can be procured, and that as well into integrant as into conftituent parts, and joining thefe parts together again, fo as to difcover the principles, relations, and changes of bodies, make various mixtures and compofitions, find out the phyfical caufes of phyfical effects, and hence improve the ftate of natural knowledge, and the arts depending on it. *Shaw's Lectures.*

PHILO'SOPHY (*Dict.*)—Philofophy may be divided into three parts, intellectual, moral, and phyfical. The intellectual part comprifes logic and metaphyfics. The moral part contains the laws of nature and nations, ethics and politics. And, laftly, the phyfical part comprehends the doctrine of bodies, animate or inanimate. Thefe, with their various fubdivifions, will take in the whole of Philofophy.

Wolfius makes the three parts of Philofophy to be the doctrine of God, the human foul, and of bodies. However, when he fubdivides, and comes to treat the feveral branches feparately, his divifions readily come under the three heads intellectual, moral, and phyfical, before-mentioned. The doctrine of God and the human foul may be ranged under the fame head metaphyfics, the notion of the divine nature being formed from that of the human foul, excluding limitations and imperfections.

PHILOSOPHY *of the Afiatics.* All the inhabitants of Afia are either Mahometans, Pagans, or Chriftians. The Mahometan fect is the moft numerous; one part of the people which inhabit this part of the world have preferved the worfhip of idols; what few Chriftians are found among them, are fchifmatics, and only the remains of fome ancient fects, efpecially that of Neftorius. What will appear at firft moft furprifing, is yet true, that the latter are the moft ignorant, and perhaps the moft fuperftitious people in all Afia. As to the Mahometans, they are divided into two fects, that of Abubeker and that of Ali: thefe two fects mutually hate each other, though the difference between them confifts rather in ceremonies and fome private opinions than in fundamental doctrines. Some among the Mahometans have preferved certain opinions of the ancient philofophic fects, particularly thofe of the old Oriental philofophy. The information which the famous M. Bernier gives us, who lived a long time among them, and was himfelf well fkilled in philofophy, has put this matter paft all doubt. 'He tells us the Perfian magi, whom he calls cabalifts, affert that God or the almighty being whom they term Achar, immoveable, immutable, not only produced fouls out of his own proper fubftance, but every material and corporeal being of the univerfe alfo; and that this production is not performed fimply in the manner of efficient caufes, but in the fame manner as a fpider, who fpins a thread from her navel firft, and fpreads it when fhe will. The creation, therefore, according to this doctrine, is an extraction and extenfion, which God makes of his own proper fubftance, of thefe nets, which he draws as it were out of his entrails; and deftruction, therefore, is nothing but a refumption which the almighty being makes of his own divine fubftance within himfelf; fo that the laft day, which they call maperle or pralia, at which they believe all things fhall be deftroyed, will be nothing but a general refumption of all thefe filaments, which God had in this manner drawn out of himfelf. Therefore, fay they, there is nothing of reality, in all we imagine of feeing, hearing, fmelling, tafting, and feeling: the univerfe is nothing but a dream and an illufion; the multiplicity and variety of objects that ftrike us, are only one and the fame thing, which is God alone, as all the different numbers we know, ten, twenty, &c. are nothing more than the fame unit repeated feveral times.' But if you afk them fome reafon for their opinion, or to explain how this extraction and refumption of fubftance is performed, this extenfion and apparent diverfity; or how it is poffible that God, not being corporeal but fimple, as they acknowledge, and incorruptible, can neverthelefs be divided into fo many portions of fouls and bodies; they only reply by allegories, and never anfwer directly: God, fay they, is like an immenfe ocean, in which feveral phials full of water moved; that thefe phials, which way foever they went, were yet in the fame ocean, and that, if any of them broke, the water, contained in them, was at the fame time united to its whole, to this ocean of which they were parts. Or they will tell you that God, like light, is the fame through the whole univerfe, and yet, like that, appears in a hundred different forms, according to the diverfity of objects on which it falls, or according to the different colours and figures of glaffes through which it is tranfmitted: thus they avoid anfwering objections by recurring to allegories, and throw duft in the eyes of an ignorant people. The laft recourfe of the magi themfelves is to reveries, and the aurea carmina of their Goult-hen-raz.

This is the doctrine of the Pendets, heathens of the Indies; and the cabala of the magi and the generality of the Perfian literati is of a piece with it, and which is fet forth in moft lofty and fublime verfes in their Goult-hen-raz, or Flower bed of Myfteries: this was the doctrine of Fludd, whom the famous Gaffendi has fo learnedly refuted; and from the little we know of the doctrines of Zoroafter, and the Oriental philofophy, it feems highly probable the philofophy we have now fpoken of proceeded from them.

After the Perfians come the Tartars, whofe empire is the moft extenfive in all Afia, for they poffefs all that vaft tract of land which lies between mount Caucafus and China. What accounts travellers have given us of this people are fo uncertain, that it is difficult to determine, whether they ever had any tincture of philofophy. We only know that they have funk into the groffeft fuperftition, and are either Mahometans, or idolaters. But, as there are numerous orders of priefts among them called lamas, it may be worth enquiring whether they had not more learning than the people committed to their care; but no great infight can be got from what authors have publifhed on this fubject.

The worfhip which thefe lamas pay to idols proceeds on the belief that the idols are images of the divine emanations, and that fouls which are alfo emanations from God dwell in them. All thefe lamas have a high-prieft over them called the grand lama, whofe common refidence is on the top of a mountain. One can fcarce imagine the profound veneration the idolatrous Tartars have for him; they look on him as immortal, and the inferior priefts keep up the cheat by their tricks. All travellers in fhort agree, that the Tartars are the moft rude, fuperftitious, and ignorant people of all Afia. The law of nature is almoft totally extinguifhed among them; we muft not therefore be furprifed at their having made no greater progrefs in philofophy.

If we go out of Tartary into India, we fhall not meet with lefs ignorance and fuperftition, and thefe to fo great a degree that fome authors have been of opinion that the Indians had no knowledge of a God: but this opinion feems not well grounded. Abraham Rogers in fhort tells us that the Bramins acknowledge one fole and fupreme God whom they call Viftnou; that the firft and moft ancient production of this God was an inferior deity called Brama, which he formed out of a flower that floated on the great abyfs before the creation of the world. The virtue, fidelity, and gratitude of Brama were fo eminent, they tell us, that Viftnou gave Brama power to create the univerfe. The particulars of their doctrine are related by different authors with a variety fo very perplexing, that it is extremely difficult to diftinguifh the truth: this variety proceeds in fome meafure from the great refervednefs of the Bramins to all ftrangers, but principally from this, that thofe travellers who have taken upon them to tranfmit their opinions to us, have been very little fkilled in their language. But all modern accounts concur in this, that the Indians acknowledge one or feveral Deities.

We cannot in this place omit fpeaking of Budda or Xekia, fo much celebrated among the Indians, for having taught them the worfhip of the Deity; thefe people look upon him as the greateft philofopher that ever exifted, but the hiftory of him is fo full of fables and contradictions, that it is impoffible to reconcile them: all we can conclude from the diverfity of fentiments which authors have delivered upon this fubject, is that Xekia made his firft appearance in the fouthern part of India; that he at firft taught the inhabitants dwelling on the fea-coafts, and that from thence he fent his difciples forth who fpread his doctrine throughout all India.

The Indians and Chinefe both unanimoufly bear witnefs, that this impoftor had two forts of doctrine; one public calculated for the people, the other kept as a fecret and revealed only to fome of his difciples. Le Comte, La Loubere, Bernier, and efpecially Kempfer, have fufficiently explained the former to us, which they call the exoteric; and thefe are its principal tenets.

1ft. There is a real difference between good and evil.

2d. The fouls of men and brutes are immortal, and only differ in proportion to the fubjects they inform.

3d. The fouls of men, feparated from their bodies, receive either recompenfe of their good actions in a place of delights, or the punifhment of their crimes in a place of torments.

4th. The retreat of the bleffed is a place where they fhall tafte happinefs without end, and this place they call Gokurakf.

5th. The gods differ from each other according to their nature, and the fouls of men according to their merits; confequently the degree of happinefs they fhall enjoy in thefe Elyfian ſian fields ſhall be in proportion to their deſerts: notwithſtanding the proportion of happineſs that each of theſe ſhall enjoy will be ſo great, that they ſhall not deſire any thing beyond it.

6. Amida is the governor of theſe bleſſed retreats and protector of human ſouls, eſpecially of thoſe deſtined to enjoy eternal happineſs. He is the ſole mediator who can obtain the remiſſion of ſins for men, and life eternal. Note. Many Indians and Chineſe aſcribe this to Xekia himſelf.

7th. Amida will not grant this happineſs but to ſuch as follow the law of Xekia, and lead a virtuous life.

8. Now the law of Xekia contains five general precepts, on the practice of which depends eternal ſalvation. The firſt forbids killing any thing that hath life: the ſecond forbids theft: the third inceſt: the fourth lying: the fifth and great commandment forbids the uſe of ſtrong liquors.

Theſe five precepts are held in great reverence, throughout all ſouthern and eaſtern Aſia. Several of their learned men have wrote comments on them, and conſequently rendered them obſcure, for they have divided them into ten counſels, to enable them to acquire the perfection of virtue, every counſel is ſubdivided into five go frakkai, or private admonitions, which have rendered the doctrine of Xekia extremely ſubtile.

9. All men, both lay and eccleſiaſtic, who ſhall have rendered themſelves unworthy of eternal happineſs, by the iniquity of their lives, ſhall be ſent after death into a place of horror, called Dſegokſ, where they ſhall ſuffer torments which ſhall not be eternal, but endure a certain undetermined time; theſe torments ſhall be in proportion to their crimes, and inflicted more ſeverely in proportion to the neglect of occaſions offered for the practice of virtue.

10. Jemma O is the governor and judge of theſe dreadful priſons; he will examine all the actions of men, and puniſh them with different torments.

11. The ſouls of the damned may receive ſome alleviation of their woe from the virtue of their relations and friends, and nothing can be more ſerviceable to them, than prayers and ſacrifices made for the dead, by the prieſts, and addreſſed to Amida the great father of all mercies.

12. The interceſſion of Amida prevails on the inexorable judge of hell to mitigate the rigour of his decrees, and render the puniſhments of the damned more ſupportable, without offending his juſtice, by ſending them back again into the world as ſoon as poſſible.

13. After ſouls have been thus purified, they are ſent into the world again to animate bodies, not of men, but of unclean beaſts, whoſe nature correſponds to the vices which had infected the damned during their lives.

14. Souls ſhall paſs by ſucceſſion from baſer into more noble ſubtile bodies, till they again deſerve to animate the human frame, in which they may, by a virtuous life, merit eternal happineſs. But if on the contrary they again commit ſin, they muſt undergo the ſame puniſhments and tranſmigrations.

This is the doctrine Xekia taught the Indians, and which he wrote with his own hand on the leaves of trees. But his exoteric and eſoteric doctrine differed greatly: Indian authors tell us that, when Xekia drew near his end, he called his diſciples to him, and diſcovered to them thoſe dogmas which he had kept ſecret during his life-time. Thoſe which follow have been extracted from the books of his ſucceſſors.

1. The void, vacuum, is the beginning and end of all things.

2. From that all men proceeded and to that they ſhall return after death.

3. All that exiſts comes from this principle, and returns to it again after death; this principle conſtitutes our ſouls and all the elements, conſequently all things which think and have a being, however different they ſeem to be, differ not really in themſelves, and have no diſtinct eſſence.

4. This principle is univerſal, wonderful pure, limpid, ſubtile, infinite, can neither be born, die, nor be diſſolved.

5. This principle has neither virtue, nor intelligence, nor power, nor any ſuch-like attribute.

6. Its eſſence is to do nothing, think of nothing, deſire nothing.

7. He that deſires to lead an innocent and happy life muſt uſe all his endeavours to become like his principle, that is to ſay, he ought to conquer or rather extinguiſh all his paſſions, that he may not be troubled or diſquieted by any thing whatever.

8. He who obtains this point of perfection, ſhall be abſorbed in ſublime contemplations, without any uſe of his intellectual faculties, and will enjoy a divine repoſe which is the completion of all happineſs.

9. When we have arrived at the knowledge of this ſublime doctrine, we muſt leave the exoteric doctrine to the people, and countenance it.— It is probable this ſyſtem gave birth to a famous ſect among the Japaneſe, which teaches, that there is only one principle of all things; that this principle is clear, luminous, incapable of increaſe or decreaſe, without figure, powerfully perfect, wiſe, but deſtitute of reaſon or intelligence, being in an abſolute inaction, and perfectly tranquil, like a man whoſe attention is fixed intenſely on one object without thinking on any other: they tell you farther, that this principle is in all and every being, and communicates its eſſence to them, in ſuch a manner, that they are the ſame thing with it, and reſolve themſelves into it, upon their diſſolution.

This opinion is different from Spinoſiſm, becauſe it ſuppoſes the world to have been formerly in a very different ſituation from what it is at preſent. A follower of Conſucius has refuted the abſurdities of this ſect by the common maxim, Ex nihilo nihil fit; from whence it appears they taught, that nothing was the firſt principle of all things, and conſequently that the world had a beginning, without matter or cauſe efficient; but it is more probable that they meant, by the word void, only ſome thing which has not the ſenſible properties of matter, perhaps the ſame as the moderns call ſpace, which is a being very diſtinct from body, the extenſion of which is indiviſible, impalpable, penetrable, immoveable, and infinite. It is very evident ſuch a being could not be the firſt principle, if it was incapable of acting as Xekia aſſerted. Spinoſa has not carried the abſurdity ſo far; the abſtract idea which he gives of the firſt principle, is, properly ſpeaking, nothing but the idea of ſpace to which he has attributed motion, in order to join to it all the properties of matter afterwards.

The modern Jews are not unacquainted with the doctrine of Xekia; their cabaliſts account for the origin of things by emanations from a firſt cauſe, which muſt neceſſarily have been pre-exiſtent, though perhaps under another form. They ſpeak alſo of a return of all things into the firſt ſtate, as if they were of opinion, that their enſoph or firſt infinite being contained all things, and that the ſame quantity of beings ſubſiſted before, as after creation. When the being is in its uncreated ſtate, God is ſimply all things; but when the being comes into the world, it does not therefore increaſe in quantity, but God opens and expands himſelf by emanations. Therefore, they often ſpeak of great and ſmall veſſels deſtined to receive theſe emanations of rays which proceed from God, and of canals by which theſe rays are tranſmitted; in a word, when God withdraws theſe rays, the external world periſhes, and all things become God again.

What we have ſaid concerning the doctrine of Xekia may help us to trace out its true original. It ſeems probable that India was not his native country, not only becauſe his doctrine appeared new, when he carried it thither, but farther becauſe there is no Indian nation that boaſts of having given him birth, and Croza's authority, who relates that all the Indians agreed in ſaying Xekia was born of an Indian king, is not ſufficient to make us alter our opinion: for Kempfer has very well obſerved that all the nations ſituated on the eaſt of Aſia give the name of India to all the ſouthern parts of that vaſt country. This unanimous concurrence of the Indians only proves therefore that Xekia was born in ſome ſouthern climate. Kempfer conjectures he was an African, that he had been inſtructed in the Philoſophy and myſteries of the Egyptians, that a war which laid all Egypt waſte, drove him thence, whereupon he, with ſome companions, took refuge among the Indians, who received him as another Hermes and a new legiſlator; he taught them not only the hieroglyphic doctrine of the Egyptians but their myſteries alſo: Kempfer offers theſe arguments in ſupport of his opinion.

1. The religion which the Indians received from this legiſlator has a very evident connection with that of the ancient Egyptians: for all theſe nations repreſented their gods under the ſhape of animals and men of monſtrous figures.

2. The two principal dogmas of the religion of the Egyptians were the tranſmigration of ſouls, and the worſhip of Serapis under the figure of an ox or cow. Now the ſame doctrines are evidently the grounds of the religion of the Aſiatic nations. Every one knows, the blind reverence theſe people have for all animals, even the moſt noxious, from a perſuaſion that human ſouls inhabit their bodies; they pay ſuperſtitious honours to the cow, and her image is placed in their temples. It is remarkable theſe notions prevail more among all theſe barbarous people, as they come nearer to Egypt.

3. The people of Aſia, on the Eaſt, have the Egyptian deities, and worſhip them, though under different names.

4. This conjecture is confirmed by a paſſage in hiſtory. Cambyſes king of Perſia, 536 years before Chriſt, made an invaſion into Egypt, ſlew Apis, which was the palladium of this kingdom, and drove all the prieſts out of the country. Now, if we compare the eccleſiaſtical epocha of the Siameſe, which begins from the death of Xekia, with the time of the expedition of Cambyſes, we ſhall find them coincide exactly.

5. Laſtly, the image of Xekia repreſents him with an Ethiopian viſage and woolly hair, which are particular to the people of Africa. All theſe arguments, well weighed, ſeem to leave no room to doubt but that Xekia was an African, and taught the Indians thoſe doctrines he had learned in Egypt.

PHLEBOTOMY (*Dict.*)— In bleeding it ſometimes happens, that an artery is opened either inſtead of, or together with, the vein: an accident of this kind is attended with the utmoſt danger. An artery is known to be wounded when the blood ſpins out very forcibly from the orifice, and that, by ſtarts or leaps, not in an even ſtream, and extends itſelf in a greater arch from the orifice to the baſon. The colour of the blood from an artery is alſo much more florid than from a vein; to which add, that, on preſſing the finger on the veſſel below the orifice,

the

the blood starts out more violently than before, and stops, or at least abates, on pressing above the orifice; quite the contrary of what happens on the opening a vein.

In an accident of this kind, the surgeon should have presence of mind not to betray the case by his fears to the patient, or attendants: he should observe whether the blood flows freely from the orifice, or whether it insinuates itself in any considerable quantity between the integuments. If the first is the case, he must take a large quantity of blood away, even till the patient faints, persuading the attendants that the heat of the blood requires it; and, while the patient is in his fainting fits, as the flux then ceases, he may commodiously dress and bind up the wound, and by this precaution hinder a fresh hæmorrhage or an aneurism. The surgeon must place some small piece of money between the folds of the first compress, and on this place two, three, or more compresses, each larger than the other: and then, binding the cubitus, apply two bandages in this manner, as after bleeding in the vein, only a little tighter; and lay a thick, long, and narrow compress over the artery, from the cubitus to the axilla: and the patient must be warned to wear his arm in a sling, pinned to his cloaths, for a fortnight, and refrain from all use of it.

If the blood from the wounded artery be found to insinuate itself between the integuments, the orifice must be immediately compressed, and tied up as before directed; and the arm often inspected, to see whether a bleeding within the integuments does not yet continue. The patient must be frequently bled in the other arm, and if a large quantity of blood should be lodged from the wounded artery under the integuments, it will be necessary to open the integuments to discharge it.

It is too common an accident to find a nerve or a tendon punctured in bleeding, and this is generally known to be the case by the patient's making a severe outcry at the time; and especially if he complains afterwards of acute pains, and the limb begins to swell and be inflamed, convulsed, stiff, and extended as in the cramp; which symptoms, if not timely relieved, threaten convulsions of the whole body, a gangrene of the part, and even death in a short time.

The best method to be taken in this accident, is, to first bathe the part with a mixture of oil of turpentine and spirit of wine, and then invest the whole arm with the diachalciteos plaister, melted down in oil of vinegar and roses, retaining it on by the expulsive bandage; which, beginning upon the hand, ends gradually by spiral turns to the top of the shoulder; by which means the impulse of the blood on the part is not only much abated, but also the pain and inflammation much diminished: and, lastly, the following cataplasm should be applied to the arm, to complete the cure: take flour of barley and bitter vetch, of each two ounces; chamomile flowers and melilot flowers, of each two handfuls, fresh butter, an ounce and an half: boil these into a cataplasm with soap suds, and apply them to the arm, till the pain and other bad symptoms are removed. *Heister's Surgery.*

PHO'CA, *the sea calf*, in the Linnæan system of zoology, a distinct genus of animals, the characters of which are, that they have two paps placed near the navel, feet adapted to swimming, and have no ears.

There are two kinds of this animal: the common one, called the sea calf, which has its canine, or dog-teeth, inclosed, like the others, in its mouth; and the other, which some improperly call the hippopotamus, or sea horse, which has these teeth exerted or thrust out. *Linnæi System. Natur.*

We have a draught of this animal in the Philosophical Transactions, N°. 469, by Dr. Parsons, who observes, that Aldrovandus, Johnston, Rondeletius, and Gesner, have made several mistakes in the figure of this creature, so as to convey no just idea of it.

This animal is viviparous, and suckles its young by the mamillæ, like quadrupeds; and its flesh is carneous and muscular. That dissected by Dr. Parsons was seven feet and an half long, though very young, having scarce any teeth, and having four holes regularly placed about the navel, which in time become papillæ.

PHO'LAS, in natural history, the name of a genus of shells, the characters of which are these: it is an oblong multivalve shell, composed of five shells, though in some improperly accounted species of this genus, only of two. It is smooth in some species, in others rough, and in some reticulated; in some species it shuts close and even, in others it gapes always open.

PHO'LIS *, in natural history, the name of a genus of fossils of the class of the gypsums or plaister-stones, the distinguishing characters of which are, that the bodies of it are considerably hard, composed of somewhat broad particles, and of a bright crystalline lustre.

* The word is derived from the Greek φολὶς, a scale, or small flake, from these bodies being composed of particles of that form.

PHO'SCAS, in zoology, the name of a fresh water fowl of the duck kind, and of the size of the common widgeon. Its body is remarkably flat; its beak and legs are blue; its head and neck are of a brownish colour, variegated all over with numerous triangular black spots; and on the top of the head these spots are larger than elsewhere, and are of a somewhat greenish hue; the back, wings, and tail are of a dusky brown, but the edges of the feathers are pale or whitish; the wings are variegated by two long white streaks; the breast and sides are of the same colour with the back, but paler; and the belly of a fine white, but with a few dusky spots under the tail. *Ray's Ornithol.*

Antimonial PHO'SPHORUS, in chemistry, the name of a substance, having the qualities of the Phosphorus discovered by Mr. Geoffroy in his experiments on antimony. This gentleman had prepared a soap from pot-ashes, quick-lime, and oil, with which he made several experiments on antimony; among others, he was desirous, by means of this, to reduce some diaphoretice antimony, which he had before made from two parts of the regulus antimony, and three parts of nitre; but, instead of the reduction which he was labouring after, his operations afforded him a much more singular phænomenon: the result of them being a Phosphorus, which he had never thought of; a matter, which, after having remained perfectly quiet, while closely stopped down, took fire, as soon as ever it was exposed to the air; and that with a violent detonation, and darting every way a shower of fire.

It is easy to see, that there are in the preparation all the requisites for such an effect; nitre, charcoal furnished by the burnt soap, and sulphur both from the soap and from the regulus of antimony; and, to all these, a sort of calx, either from the soap, or from some earthy parts of the antimony. It is easy to conceive, that all these substances, coming to a mixture together, should be ready to catch fire, and blaze upon a proper application; but it is not less difficult to account for this effect's being produced merely by the air, after the whole had been for a long time in a state of rest.

The method of preparing this new species of Phosphorus is this: Mr. Geoffroy mixed two ounces of his soap with one ounce of this diaphoretic antimony; this mixture, being put by little and little into a red-hot crucible, took fire, and swelled very much. After it had done flaming, the mass subsided, and became a red or fire-coloured substance, of an even surface, but still throwing up a vast quantity of bluish green luminous vapours; and all this regularly happens on every fresh throwing in of the matter, without the least variety. When the whole quantity was thrown in, and had ceased to give any flame or luminous vapour, it remained in the crucible in the form of an inverted mushroom, being hollow, very porous, and of a black colour. When the crucible was taken out of the fire, the edges of this substance were beaten down into the middle, and the whole covered with an ounce of fresh soap. When this last soap was burnt, and a small bluish flame appeared upon the surface of the mass, the crucible was covered with a lid, and a large quantity of charcoal laid upon it, and the fire blowed up very briskly, by an hundred blasts of the bellows, or thereabouts; but, notwithstanding the fierceness of the fire, there were no fluid scoriæ formed, but the whole mass remained spongy and porous. The fire was then suffered to go out, and the crucible placed in a corner of the elaboratory to rest for five hours. In the evening, when the crucible was perfecty cold, Mr. Geoffroy went to examine the matter, and a servant went to uncover the mass, by removing its surface with an iron instrument; but, the moment the air was admitted, the whole mass took fire, burning with a very considerable noise, and darting its flames to a very great distance.

Mr. Geoffroy repeated the process several times, and always with the same success, whether his own diaphoretic antimony, or that made in the common manner. The great caution, to insure the success, seems to be the taking care of not carrying the fire too far before the addition of the last quantity of soap. *Mem. Acad. Scienc. Par.* 1736.

PHOSPHORUS *of sulphur*, the name given by the French academians to a new-discovered species of the Phosphorus, which readily takes fire on being exposed to the open air.

The invention was M. le Fevre's, and the process is this: the ingredients are two drachms of common sulphur, half an ounce of steel filings, ten grains of colophony, and six drachms of common water. These things being all weighed and set apart, powder about half a drachm of the sulphur in a small mortar, then add the colophony, and afterwards the remainder of the sulphur. When this is all reduced to a fine powder, put in the steel-filings, and rub the whole together till it is so thoroughly mixed, that the steel does not appear, but the colour of the whole looks every-where uniform and regular: then add about twenty drops of the water, and, after beating the whole together, add as much more, and continue to do so till the mass is of the substance of a paste, but not too moist. Put this paste into a small matrass that will contain about three ounces, and pour on it more of the water till it swim above the surface of the paste near a quarter of an inch. The matter of the paste will then break, and appear in form of a granulated powder under the water; put the matrass on a sand furnace, but give it no greater heat than that the hand can lie upon the matrass. When it begins to heat, the mixture will ferment and swell, and become black; it is then to be stirred with an iron rod, and a little more water must be added every

quarter

quarter of an hour, till the whole is used. The matter will then be very black and liquid, and it is to be then taken from the fire, and set by for the whole night. This is the first and most essential part of the operation, and, in this, great care is to be taken that the fire be not too violent; for if the sulphur be burnt, the operation will be spoiled, and the matter would ferment so high as to run over at the mouth of the vessel.

To finish the operation, a little water must be added to the matter, so as to swim over it, and the vessel must be again set in the sand, and a stronger fire given than before; this is known to be strong enough, when there is any humid vapour observed to arise out of the mouth of the vessel. This fire is to be continued about two hours, that the greater part of the humidity may be evaporated; which is known by the iron rod finding some resistance when put into the vessel, and the matter it brings up being granulated and solid, or no longer moist; it must then be immediately taken from the fire, and the whole is then finished. It is necessary to be very exact in this last critical minute, for a very little longer standing on the fire will burn the sulphur, and render all the former care of no effect. The black matter remaining in the matrass is to be taken out, and the sides scraped clean with an iron rod; any piece of this that happens to fall on a paper takes fire in a very little time, and burns away like the other Phosphorus. The process is a very nice one, but, by observing all the rules here laid down, several persons have succeeded in making the Phosphorus to perfection: the whole intent of the operation seems to be to join together the minute particles of steel and sulphur; which, when thus joined, cannot fail to be very inflammable, and to take fire on receiving the smallest humidity from the air to make them ferment.

It cannot but be observed, that this Phosphorus is founded on Lemery's experiments of steel and sulphur taking fire together; but this is a greatly more nice and accurate operation, and a fine improvement on the original plan, which was only, by mixing large quantities of steel filings and sulphur together into a paste with water, and burying this in the earth, to make it take fire of itself, and thus represent the natural phænomena of vulcanos, thunder, lightning, &c. *Mem. Acad. Par.* 1728.

PHRY'GIAN *stone, phrygius lapis*, in natural history, the name of a stone described by the ancients, and used in their time in dying; probably from some vitriolic or aluminous salt contained in it, which served to enliven or fix the colours used by the dyers.

It was a light spongy mass, resembling a pumice, and the whitest and lightest were esteemed the best. Pliny gives us an account of their preparing it for use for dying, which was by moistening it with urine, and then heating it red-hot, and suffering it to cool again; this calcination was repeated three times, and the stone was then fit for use; and Dioscorides recommends it in medicine after burning ;he says it was drying and astringent.

PHYLLERE'A, *phyllerey*, in botany, the name of a genus of plants, the characters of which are these: the flower consists only of one leaf, and is of a bell-like shape, and divided into four segments at the edges. The pistil arises from the cup, and is fixed in the manner of a nail to the hinder part of the flower. This finally becomes a fruit of a roundish figure, containing roundish seeds.

PHYLLI'TIS *marina, sea hart's tongue*, in natural history, a name given by some authors to a species of sea plant, the leaves of which, in some degree, resemble those of the common hart's tongue. It grows on the rocks at great depths, and is seldom seen, unless when taken up by the coral-fishers. Its leaves are sometimes single, sometimes they divide into two: they are of a dusky green colour, and are about two inches in length: they have each a nerve or rib running along their middle; they are very thin and transparent, and are of a sort of cartilaginous structure; and each has several rows of small points on each side of the middle rib, which not unaptly resemble the seed spots on the leaves of some of the capillary plants; but not on those of the Phyllitis, or hart's tongue, in particular, because they are in that plant not round but oblong, and stand only in a single row on each side the rib.

When this plant is viewed by the microscope, it appears, in all parts of the leaf, full of little holes; and those which are so plain to the naked eye, are no other way different from the imperceptible ones, but in that they are larger. The plant has no root, and therefore takes in its nourishment by these numerous holes in its surface. *Marsigli, Hist. de Mer.*

PHYLLOBO'LIA, φυλλοβολια, in antiquity, a custom, that prevailed among the ancients, to strew flowers and leaves on the tombs of the dead. The Romans adopted this custom from the Greeks, and added likewise wool.

The Phyllobolia was also used on occasion of a victory obtained at any of the public games, when not only the victors, but likewise their parents, were strewed with flowers and leaves. *Hoffm. Lex. Univ. in voc.*

PIANI'SSIMO, in the Italian music, is used to signify that the part to which it is added should be played very softly, and so as that the sound may seem at a great distance, and almost lost in air.

PIA'NO, in the Italian music, signifies soft and sweet, by way of an echo.

PIANO PIANO, in the Italian music, is nearly the same with pianissimo, or rather a degree between it and Piano.

Piu PIANO, in the Italian music, signifies more slow or more soft, and is much the same with Piano Piano.

PI'CA, *the pye, or magpye*, in the Linnæan system of zoology, the name of one whole order of the bird kind; the character of which is, that they have a convex beak, flatted above. The birds of this order are, the bird of paradise, the magpye, the crow, the cuckow, the wood-pecker, the sitta, the creeper, the hoopoe, and the ispida. *Linnæi. Syst. Nat.*

PICA *marina*, in ornithology, the name of a bird called in English the sea pye, and, by Bellonius and some others, the hæmatopus. It is of the size of the common magpye; its beak is three fingers breadth long, straight, and of a reddish or a blackish colour, and ending in a point, and seeming well fitted for its business of rooting up the limpets from the rocks, the bodies of this fish being its common food; its legs are red; it has no hinder toe, and has its other toes so far connected by a membrane, as to seem almost of a middle nature between the web-footed and other birds; its head, neck, back, throat, and half its breast are black, as is also its rump; its tail is half black and half white, as are also its wings. It is common on the western shores of England, and on the shores of Wales. *Ray's Ornithology.*

PICK, among miners, is a tool with which they use to cut down the clifts and rocks of stone to make passages in the earth. *Houghton's Complete Miner in the Explanation of the Terms.*

PICK-*ax*, in the military art, a tool carried by the pioniers to dig up ground that is too hard for the spade; they are of great use for mending ways, and in fortification.

PI'CKER, or *horse* PICKER, in the manege, an iron instrument five or six inches long, bent or crooked on one side, and flat and pointed on the other. It is used by the grooms to cleanse the inside of the horses feet, and to pick out the earth, sand, or small stones that get into them.

PI'CKEREL, in ichthyology, an English name used by some authors for the jack or pike.

PICTAVIE'NSIS *colica*, the name of a kind of very terrible nervous cholic, more usually called colica Pictonum; and by the natives in the West-Indies, where it rages, the dry belly ach. It is so popular a disease in the Leeward islands, that it may be very justly reckoned endemic among them, most of the people there having been at one time or other subject to it in all its fury.

PIE'RRE *d'Automne*, a French name translated from the Chinese. It is the name of a medicinal stone, famous throughout the East for curing all disorders of the lungs.

It is a tedious preparation of human urine, and made as follows: they put thirty pints of the urine of a strong and healthy young man into a large iron pot, and set it over a gentle fire; and when it begins to boil, they add to it, drop by drop, about a large tea cup full of rape oil: it is then left on the fire till the whole is evaporated to a thick substance resembling black mud; they then take it out of the pot, and laying it on a flat iron, they dry it so that it may be powdered very fine. This powder they moisten with fresh oil, and put the mass into a double crucible, surrounded with coals, where it stands till thoroughly dried again. They finally powder this again, and, putting it into a china vessel covered with silk, cloth, and a double paper, they pour on boiling water, which makes its way, drop by drop, through these coverings, till so much is got in, as is sufficient to reduce it to a paste. This paste is well mixed together in the vessel it is kept in, and this is put into a vessel of water, and the whole set over the fire. The matter thus becomes again dried in balneo mariæ, and is then finished. *Observ. sur les Cout. de l'Asie.*

PIE'RIDES, among the ancients, an epithet given to the muses, upon account of their having been born in that part of the country of Macedon which was called Pieria. *Pitisc. in voc.*

PIGA'YA, in natural history, a word used by the natives of Brazil as a name for the famous ipecacuanha-root.

PI'GUS, in zoology, the name of a species of leather-mouthed fish, very much approaching to the nature of the carp.

It is of the same shape and size with the common carp, and its eyes, fins, and fleshy palate wholly the same. From the gills to the tail there runs a crooked dotted line: its back and sides are bluish, and its belly reddish: it is covered with large scales, from the middle of every one of which there rises a fine, pellucid, and very sharp prickle.

It is a finer fish than the carp for the table, and is in season in the months of March and April. It is caught in lakes in some parts of Italy, and is mentioned by Pliny, though without a name.

PIKE, in ichthyology, a name given by us to the fish called by authors the lucius and esox, and by the old Greek writers oxyrynchus.

This fish is the tyrant of the fresh waters, and is at once the most voracious and the longest-lived of all fish, according to the generality of naturalists.

The very large Pike are esteemed as a pompous fish at the tables of great people; but they are coarse, and the middling ones are in reality much the best.

The Pike never swims in shoals, as most other fish do, but always lies alone, and is so bold and ravenous, that he will seize upon almost any thing less than himself. This fish breeds but once in a year, which is in March. It is found in almost all fresh waters, but is very different in goodness, according to the nature of the places where it lives. The finest Pike are those which feed in clear rivers; those in ponds and mires are inferior to these, and the worst of all are those of the fen ditches. They are very plentiful in these last places, where the water is foul and coloured, and their food, such as frogs, and the like, very plentiful, but very coarse; so that they grow large, but are yellowish and high-bellied, and differ greatly from those which live in the clearer waters.

The fishermen have two principal ways of catching the Pike; by the ledger, and by the walking bait.

The ledger bait is fixed in one certain place, and may continue while the angler is absent: this must be a live bait, a fish or frog; and, among fish, the dace, roach, and gudgeon, are the best; of frogs, the only caution is to chuse the largest and yellowest that can be met with. If the bait be a fish, the hook is to be stuck through the upper lip, and the line must be fourteen yards at least in length: the other end of this is to be tied to a bough of a tree, or to a stick driven into the ground near the Pike's haunt, and all the line wound round a forked stick, except about half a yard. The bait will by this means keep playing so much under water, that the Pike will soon lay hold of it.

If the bait be a frog, then the arming wire of the hook should be put into the mouth, and out of the side; and with a needle and some strong silk the hinder leg of one side is to be fastened by one stitch to the wire-arming of the hook. The Pike will soon seize this, and must have line enough to give him leave to get his haunt and poach the bait.

The trolling for Pike is a pleasant method also of taking them: in this a dead bait serves, and none is so proper as a gudgeon. This is to be pulled about in the water till the Pike seizes it, and then it is to have line enough, and time to swallow it: the hook is small for this sport, and has a smooth piece of lead fixed at its end, to sink the bait; and the line is very long, and runs through a ring at the end of the rod, which must not be too slender at top.

The art of feeding Pike, so as to make them very fat, is, the giving them eels, and, without it, it is not to be done under a very long time; otherwise pearch, while small, and their prickly tender fins, are the best food for them. Bream put into a Pike pond are very proper food: they will breed freely, and their young ones make excellent food for the Pike, who will take care that they shall not increase over much. The numerous shoals of roaches and ruds, which are continually changing place, and often in floods get into the Pike's quarters, are food for them a long time.

Pike, when used to be fed by hand, will come up to the very shore, and take the food that is given them out of the finger of the feeder. It is wonderful to see with what courage they will do this, after a while practising; and it is a very diverting sight, when there are several of them nearly of the same size, to see what striving and fighting there will be for the best bits, when they are thrown in. The most convenient place is near the mouth of the pond, and where there is about half a yard depth of water; for, by that means, the offal of the feedings will all lie in one place, and the deep water will serve for a place to retire into and rest in, and will be always clean and in order.

Carp will be fed in the same manner as Pike; and though by nature a fish as remarkably shy and timorous as the Pike is bold and fearless, yet, by custom, they will come up to take their food out of the person's hand, and will, like the Pike, quarrel among one another for the nicest bits. See the article FEEDING *of fish*.

Half PIKE, in the military art, is the weapon carried by an officer of foot. It differs from a Pike, because it is but eight or nine feet long, and the spear is smaller and narrower.

PIKE, is also the name of an Egyptian measure, of which there are two kinds, the large and the small.

The larger Pike, called also the Pike of Constantinople, is 27 $\frac{200}{1000}$ English inches. They measure all foreign goods with this, excepting only such as are made of flax and cotton: for then they use the small Pike, called Pike belledy, or the Pike of the country; because they measure with it all the manufactures of the country. This Pike consists of about 25 $\frac{576}{1000}$ English inches. *Pocock's Egypt.*

PILATRO, or PILATRO *di Levante*, a salt used in the glass trade, in some particular cases. It is extracted from the froth of the sea, coagulated by heat in the hot countries. *Merret's Notes on Neri.*

PILCHARDUS, *the common pilchard*, in zoology, a fish much approaching to the nature of the common herring, but smaller and differing in several other particulars.

It is generally found swimming in vast shoals, and is caught on many parts of the English shores. Its flesh is better tasted than that of the herring.

PILE-*worms*, are a kind of worms found in the Piles of the sea dykes in Holland. These worms are of various sizes, some of the young ones are not above an inch or two in length; but others have been found of thirteen or fourteen inches long. The heads of these creatures were covered with two hard shells, or hemicrania; which together form a figure resembling an augre, and with which they bore the wood. The best remedy against them is, to perforate the Pile with many small holes, about an inch asunder; then it must be done over with a varnish in the hottest sun, and, while the varnish is hot, brick dust must be strewed over it; and this being several times repeated, the pile will be covered with a strong crust, impenetrable to all insects. See a farther account of these creatures in the *Phil. Trans.* N°. 455.

PILES, the popular name for the hæmorrhoids. See the article HÆMORRHOIDES, *in the Dictionary*.

PILE (*Dict.*)—As we are often obliged to set inclined Piles, in order to give more strength to works intended to support a swell of water or projection of earth, the description of a machine to drive them may not be disagreeable, as it is quite a modern invention, and never published in English that we know of.

Plate XXXIV. *fig.* 1, 2, and 3, exhibit this machine fully; *fig.* 3, which is the plan of it, is composed of four shafts, on one of which A B are raised the uprights C D, E F, marked with the same letters in *fig.* 1, 2, which shew the elevation and profile of the machine, and, consequently, the inclination these parts have to their base; the two in the middle seen in the reverse, as well as the others, serve for guides to the ram G, the ears of which H H are fastened with keys; these uprights exceed the height of the cross-piece I to support the pulley K on which the rope passes that makes the ram play. The two pieces, in form of a buttress, support the fore part of the machine, and the axis N, common to both wheels, made like a drum; on each of which is twisted a cord, but contrariwise, so that one may wind off as the other winds on, and reciprocally, while a third, corresponding to the axis, winds off or on as the ram ascends or descends. As, for example, to raise it, draw the rope T which winds off above the great drum P; then the second V winds on the little drum O, and the third rope Y which communicates with the ram G winds up on the axis N, and, when the ram is come to the top of the guide, draw the rope of the counterpoise Z, and the ram falls.

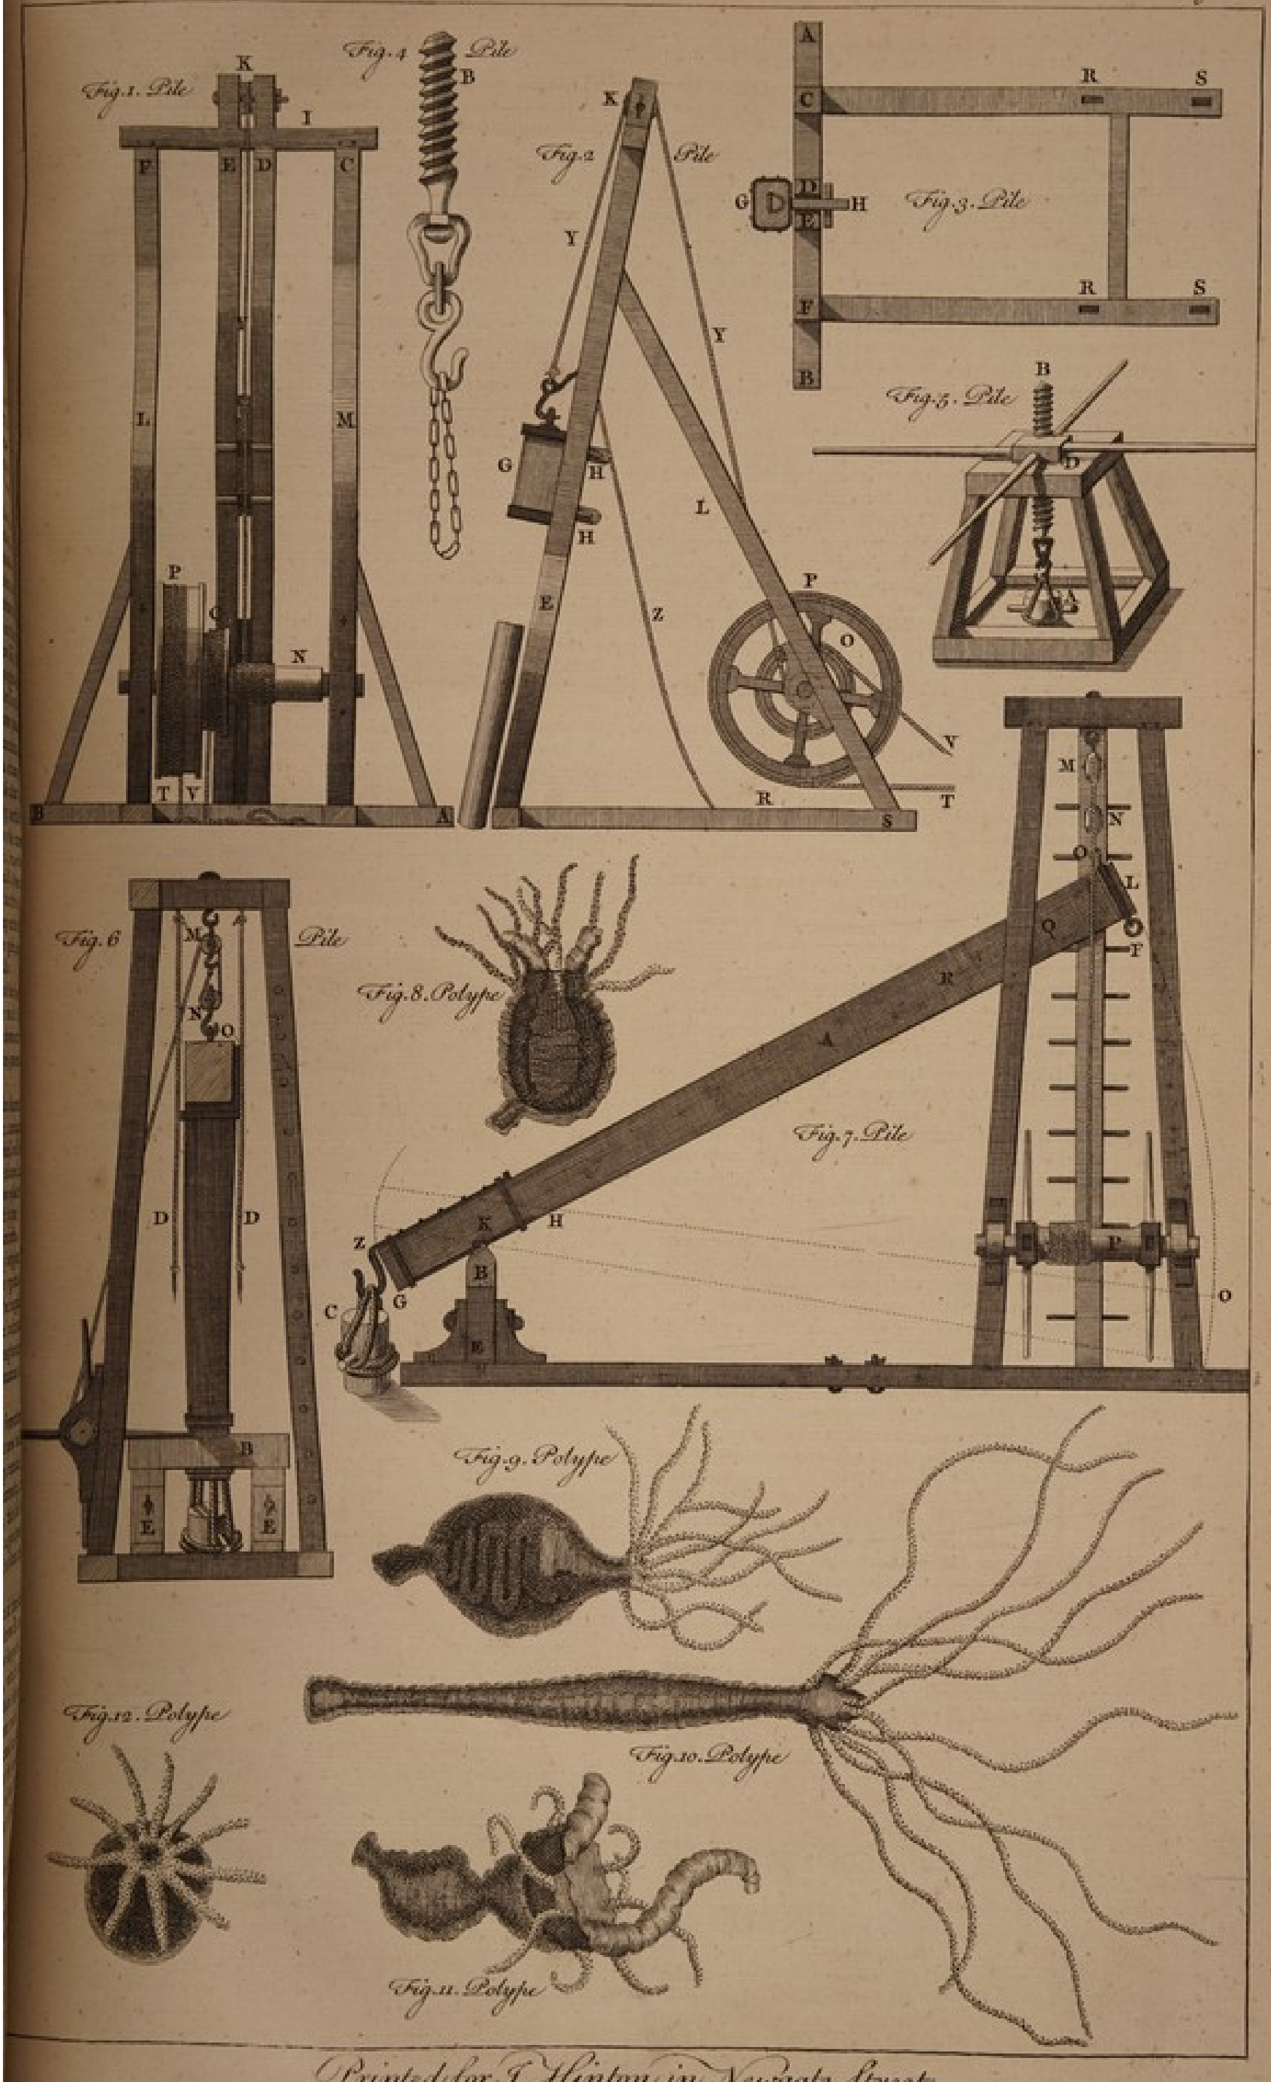
To repeat the operation, draw the rope V of the small wheel, then the rope T winds on as the former winds off, which also causes the third rope Y to be drawn downwards by the counterpoise which is hooked to the ram; then proceed as before.

The great wheel P is supposed to be six feet in diameter, the little wheel O three feet, and the axis N one; consequently the power T, communicating with the great wheel, will be as one to six, to the weight of the ram; therefore six men can easily raise a ram of 900 pounds, estimating the power of each man at no more than 25 pounds, which is the lowest it can be rated at in a work of this kind; because, as the ram rests on an inclined plane, the rope Y does not absolutely support the whole weight; but I do not mention this as any great abatement, because the friction of the machine may be supposed to compensate for it. It is easy to see that the inclination of the guide may be increased or diminished by lengthening or shortening the buttresses L M, according to the situation of the Pile, and the design of direction in driving it.

A description of a machine to draw PILES.—It is sometimes necessary to draw Piles when we intend to erect new buildings, in places where the vestigia of old buildings remain; or to make use of Piles, which have been driven formerly, and are of no service where they stand at present; this last was the case, when, on the demolition of Dunkirk, a great part of the Piles were drawn, and timbers made use of to form the sluice of Mardyke.

Plate XXXIV. *fig.* 4, 5, represent a machine of this kind; *fig.* 5. exhibits a wooden frame, supporting a screw B and nut D placed over the Pile A, the head of which is supposed to have been bored, in order to receive an iron pin, which takes firm hold on the Pile, by the help of a rope or chain suspended to a hook, represented *fig.* 4. By turning the nut with levers as you do a capstan, the screw is forced to ascend and draws the Pile with it. The principal difficulty is to fix the machine on a foundation solid enough to resist the power of the screw; if it should happen that the Pile is under water, a flying scaffold placed on boats may be made use of.

Fig. 6. and 7. represent another machine of the same kind, which are intelligible enough by the draught without any long explanation; its design is to lift, at the extremity L, a beam G L placed on a fulcrum B, to make the counterpoise, because there is a notch at K to prevent it from slipping; we will suppose the length of the beam being divided into nine equal parts, G K to be one, consequently the remaining part K L will be equal to eight. This beam must likewise be furnished at its extremities with proper irons to draw the Pile C. We are to suppose it at first in a state of rest, represented by the dotted lines; that a rope is fastened at its extremity O, which after having passed on pullies, comes out opposite to the roll of the machine; which, being put in motion, raises L, the



Printed for T. Hinton in Newgate Street.

the extremity of the beam into the position we see it, to hook the rope which goes round the Pile at the lower extremity G; then the roll is let loose, to leave the beam to its own proper weight; which, assisted by the advantage that the arm of a lever gives it, acts very forcibly on the Pile, as may be judged from the following calculation.

To calculate the action of this beam, we will suppose it eighteen feet in length and twelve inches square; then G K will be two feet, and K L sixteen feet in length: now, a solid foot of dry oak weighs about sixty pounds, we will call it so in the present calculation: to be exact, we must take K H, equal to G K, in order to look on both parts of the weight of the beam, as in equilibrium to each other; then imagine the remainder of its gravity to be reunited in A, the center of gravity of the part H L, which acts on the Pile, is equal to a power of 840 pounds, which is the weight of fourteen cubical feet of oak timber, equal to the arm of the lever K A of nine feet, while the other K G acts in proportion to its length two feet; thus, in a state of equilibrium, the power A equal to 840 pounds will be to its action on the Pile as K G to K A, or 2 to 9, which is equal to 3780 pounds; this may be increased in proportion to a power applied at the extremity R L; let us suppose, for example, 600 pounds applied at the extremity of the lever K Q the sextuple of K G, their effort on the Pile will be 3600 pounds; which, added to 3780 pounds, make 7380 pounds, for the force acting upon the Pile. This machine was experienced by Marshal Belleisle, in 1749, to be of the greatest use in drawing Piles, when he had a mind to destroy the two bridges he had thrown over the Var; these stood on a forest of Piles, but they were easily extracted by these engines; those driven into a strong soil fourteen or fifteen feet could not resist them above four or five minutes.

The force of this machine may be surprisingly increased, by making use of a roller to draw down the extremity of the beam L, notwithstanding the resistance of the Pile C. Put the beam in the position G L, *fig.* 7; unhook the pulley M N, the beam will keep its place; then hook the pulley M by an S to the ring F, fasten the other end of the pulley N in like manner to the foot of the machine, in order to obtain a fulcrum, and you may draw the beam down easily by a power applied to the lever of the roller. It might still be made to produce a greater effect, if the impulse of a ram were applied at the extremity of the beam, and this might easily be contrived in one machine.

A description of a saw to cut off PILES *under water.*— The saw contrived for this purpose is in the form of a triangular prism, and represented in *Plate* XXXV. *fig.* 1, 2, 3; twenty-eight men may be employed in working it, though a less number may suffice; these men are placed upon a float to work the machine; the use of the saw is to cut the Piles and stakes in the platform of the pier down level; the manner of its working is shewn *fig.* 1, K is the blade, which weighs about 250 pounds, is four inches broad and seven lines thick on the fore part, which declines gradually to four or five lines on the back, F, F, F, F, the frame, A, A, A, A, the plat-form of piles.

At the same time that the men are employed in pushing and drawing the saw perpendicularly to the side of the Piles, being set to the arm which are at the top L, *fig.* 2, 3, the extremities of the blade are drawn parallel to the same sides by weights suspended at the extremity of the ropes R R, *fig.* 1, which go on pullies fastened at the head of the compass of the frame of the periphery of the Pile.

PILL, *Aromatic* PILLS, *pilulæ aromaticæ*, a form of medicine in the New London Dispensatory, intended to stand in the place of the pilulæ diambræ of the former, and the pilulæ alephanginæ, or aloephanginæ, of that, and some other dispensatories.

The composition is this: take socotrine aloes, an ounce and an half; gum guaiacum, an ounce; the aromatic species and balsam of Peru, of each half an ounce; let the aloes and gum guaiacum be powdered separately, and afterwards mixed with the rest, and formed into a mass with syrup of orange peel. *Pemberton's Lond. Disp.*

PILLS *of colocynth with aloes*, *pilulæ colocynthide cum aloe*, a name given, in the New London Pharmacopœia, to the purging pill, commonly known by the name of pilulæ cociæ minores.

As this is originally a prescription of Galen's, and the manner of proportioning the ingredients has been altered for the worse, since his time, by enlarging the quantity of that nauseous ingredient the colocynth; the college have reduced it to its former proportions, and ordered it to be made in this manner: take socotrine aloes and scammony, of each two ounces; pith of coloquintida, one ounce; oil of cloves, two drachms; let the dry species be reduced to powder separately, the oil mixed among them, and the whole formed into a mass, with syrup of buckthorn. *Pemberton's Lond. Disp.*

Mercurial PILLS, *pilulæ mercuriales*, a form of medicine prescribed in the late London Pharmacopœia, and containing crude mercury mixed for internal use.

The composition is to be made as follows: take of pure quicksilver, five drachms; of Strasburg turpentine, two drachms; of the cathartic extract, four scruples; rhubarb powder, one drachm; grind the quicksilver with the turpentine till it makes one uniform mass, and then add the other ingredients, and beat up the whole into Pills. If the turpentine be too hard, it must be softened with a little oil of olives. *Pemberton's Lond. Disp.*

Soap PILLS, *pilulæ saponaceæ*, a form of medicine prescribed in the late London Dispensatory, and ordered to be made in the following manner: take almond soap, four ounces; strained opium, half an ounce; essence of lemons, a drachm; soften the opium a little with wine, and beat that and the soap with the essence, till it be reduced to the form of a Pill.

This is intended to stand in the place of the Pill, commonly called Mathews's Pill, and is very happily corrected, in regard to the taste of the soap, by the addition of the essence of lemons. *Pemberton's Lond. Disp.*

Ward's PILL. See WARD's *Pill.*

PI'LLOW *of a plough*, a term used by the farmers to express that part of a plough which serves to raise or sink the beam, and with it the share, as the land is to be plowed shallower or deeper.

This Pillow is a cross piece of wood, reaching from one of the crow-staves or uprights to the other; and, as they are bored with two rows of holes, this Pillow can be slipped up or down to any height, and kept there by pegs or cords in the holes. *Tull's Husb.* See PLOUGH.

PILULA'RIA, *pepper-grass*, the name of a very remarkable little plant, of which Mr. Bernard de Jussieu has given a very accurate account in the Memoirs of the Academy of Sciences of Paris.

PI'MPERNEL, *pimpernella*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of one petal, which is of a rotated form, and is deeply divided into four segments, and contains a vast number of stamina, or a fimbriated style. The cup finally becomes a fruit usually of a quadrangular figure, and pointed at each end: this is sometimes divided into two cells, sometimes it consists only of one; and it contains numerous seeds, usually of a longish figure.

The seeds of this plant are warm, carminative, and discutient: they are given with success in cholics and flatulencies, and in suppressions of urine. The leaves and roots also possess the same virtues; and when the diuretic property only is expected from it, the root alone, fresh taken up, cut small, and boiled in water, is the best. The decoction is to be drank in large draughts, and often repeated.

PI'MPLE, in medicine, a small pustule arising on the face.

By mixing equal quantities of the juice of houseleek, sedum minus, passed through paper, and of spirit of wine rectified by itself, a white coagulum of a very volatile nature is formed, which Dr. Burghart commends for curing Pimples of the face; and says, that the thin liquor separated from it, with sugar-candy, is an excellent remedy for thick viscid phlegm in the breast. *Satyr. Silesiac. Spec.* 4. *Ob.* 2.

PIN (*Dict.*)— The perfection of Pins consists in the stiffness of the wire, and its blanching, in the heads being well-turned, and the points filed. The London pointing and blanching are in most repute; because after forming the points on the stone, our Pin-makers smooth them again on the polisher; and in blanching, use fine tin well calcined, and sometimes silver leaves prepared by the gold-beaters; whereas, in other parts, they use a mixture of tin, lead, and quick-silver, which not only blanches worse than the former, but is also dangerous, by reason of the ill quality of that mineral, which renders a puncture with a Pin thus blanched very difficult to cure.

The consumption of Pins, and the number of artificers employed in the manufacture thereof, are incredible. In Paris alone there were anciently above 1000 people employed in it, at present there are none; yet there is every year sold above 50,000 crowns worth of the Pin-wire, to the Pin-makers of the neighbouring places, all brought thither from Stockholm.— In the little town of Rugle in Normandy, there are computed at least 500 workmen employed in the Pin manufacture; the whole town being peopled therewith.

Notwithstanding that there is scarce any commodity cheaper than Pins, there is none that passes through more hands before they come to be sold.— They reckon twenty-five workmen successively employed on each Pin, between the drawing of the brass-wire and the sticking of the Pin in the paper.

Pins are distinguished by numero's; the smaller called from N° 3, 4, 5, thence to the 14th, when they are only accounted by two to two, viz. N°. 16, 18, and 20, which is the largest size.

Besides the white Pins, there are also black ones made for mourning from N°. 4, to N°. 10.—These are usually of iron-wire.

Lastly, there are Pins with double heads, of several numero's, used by the ladies to fix the buckles of their hair for the night, without danger of being disturbed by their pricking, &c.

PINE-*tree*, *pinus*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the amentaceous kind, being composed of a great number of stamina, but it is barren: the embryo fruit appear in other parts of the tree, and finally become a sort of cone, between the several scales of which, each having two hollows, there are found two seeds contained in a stony husk, which is frequently elated. To

this

this it is to be added, that the leaves grow more than one out of the same theca.

Pitch, tar, resin, and turpentine, are all made from these trees by a very familiar process. In the spring time, when the sap is most free in running, they pare off the bark of the Pine-tree, to make the sap run down into a hole which they cut at the bottom to receive it: in the way, as it runs down, it leaves a white matter like cream, but a little thicker: this is very different from all the kinds of resin and turpentine in use, and it is generally sold to be used in the making of flambeaux, instead of white bee's wax. The matter that is received in the hole at the bottom, is taken up with ladles, and put in a large basket; a great part of this immediately runs through, and this is the common turpentine. This is received into stone or earthen pots, and is ready for sale. The thicker matter, which remains in the basket, they put into a common alembic, adding a large quantity of water; they distil this as long as any oil is seen swimming upon the water; this oil they separate from the surface in large quantities, and this is the common oil or spirit of turpentine: the remaining matter, at the bottom of the still, is common yellow resin. When they have thus obtained all that they can from the sap of the tree, they cut it down, and, hewing the wood into billets, they fill a pit dug in the earth with these billets, and, setting them on fire, there runs from them, while they are burning, a black thick matter: this naturally falls to the bottom of the pit, and this is the tar. The top of the pit is covered with tiles, to keep in the heat; and there is at the bottom a little hole, out at which the tar runs like oil: if this hole be made too large, it sets the whole quantity of the tar on fire; but, if small enough, it runs quietly out.

The tar, being thus made, is put up in barrels, and, if it be to be made into pitch, they put it into large boiling vessels, without adding any thing to it: it is then suffered to boil a while, and, being then let out, is found, when cold, to be what we call pitch. *Phil. Transf.* N°. 243.

PINE-*apple*. See ANANAS, Dictionary and Supplement.

PINE-*apple*, in metallurgy, a word used to express a sort of mould, used in the refining silver. It has this name from its shape, resembling the fruit of that name.

When the refiners have taken the mixture of the silver and mercury together out of the cauldron, and strained it through two coarse wet cloths, to make it the thicker, they then beat it with a sort of battledoors, to drive out yet more of the quicksilver; and, straining it again after this, they take out the remaining amalgame, and, forming it into little pellets, they put these carefully into the moulds called Pine-apples, pressing them down. The amalgame, when put into this vessel or mould, is usually so rich as to be about one fifth silver. The manner of divesting this of the quicksilver afterwards is by means of fire; in which the quicksilver rises in vapour, and the silver is left pure behind: but the carelessness of the workmen in doing this, and particularly the using bad vessels, or the not luting them close, causes a waste of this mineral greater than could be conceived. Alonso tells us, that in the city of Potosi alone, at the time of his writing, when the trading in metals ran but low, above thirty-thousand pieces of eight were wasted in quicksilver that was lost one year with another. To prevent this, they then principally studied the means of keeping the silver as dry of quicksilver as they could, in the Pine-apple; but, it then holding four fifths of the whole mass in quicksilver, the great waste was in the separating it afterwards. *Alonso Barba de Metal.*

PINE-*salt*, a name given to a preparation of the bark of the Pine-tree, used as a sort of seasoning to food in the manner in which we use salt.

Scotch PINE, generally called the Scotch fir, is the most profitable of all the sorts, to cultivate in large plantations; and will grow in almost any soil or situation; for in the most barren sand, where little else but fern and heath would grow, I have seen plantations of these trees thrive much beyond expectation; and upon chalky hills, where there have been scarce three inches of earth, there are many noble plantations of this sort. I have also observed, where they have been planted in a strong clay, and also in a moist peaty soil, that they have grown to admiration; so that there is no part of England, in which these trees might not be propagated to a great advantage.

But where these trees are designed to be planted in large quantities, it will be much the better way to make a nursery on the spot where the seeds should be sown, and the plants raised until they are three years old, which is a proper age to plant them out for good; for, the younger they are planted, the better they will thrive, provided they are kept clear from weeds; and, if the situation where they are intended to stand is much exposed to winds, the plants should be planted closer together, that they may be a shelter to each other, and draw themselves upward; and, as the trees advance, they may be thinned by degrees; and the thinnings of these plantations have, in many places, paid the expence of planting; for these are very serviceable for scaffolding, and many other useful businesses.

It is the wood of this tree which is the red or yellow deals, and is more valuable than that of any other sort of pine or fir: this is a native of Denmark, Sweden, and many other northern countries: and in the High-lands of Scotland there are several large woods of this tree now growing; and the seeds being brought from thence into England, has occasioned the name of Scotch Fir being generally applied to it here, but in Norway it is called grana.

PINK, a well known flower in our gardens, being a species of the genus of the carnation. See CARNATION.

The damask Pink, white shock, scarlet, pheasant's-eyed Pink, of which there are great varieties, both with single and double flowers, the old man's head, and the painted lady pinks, with several others. These may be propagated by layers, as the carnations, and many of them by cuttings planted in July, or from seeds, by which method new varieties may be obtained. The manner of sowing these seeds being the same with the carnations, I shall refer back to that, to avoid repetition, and shall proceed to the China Pink, which is a flower of later date amongst us than any of the former; which, although it hath no scent, yet, for the great diversity of beautiful colours which are in these flowers, with their long continuance in flower, merits a place in every good garden.

The double China-PINK. — There is a great variety of different colours in these flowers, which vary annually as they are produced from seeds, so that, in a large bed of these flowers, scarcely two of them are exactly alike, and their colours in some are exceeding rich and beautiful; we should therefore be careful to save the seeds from such flowers only as are beautiful; for they are very subject to degenerate from seeds.

And the seeds of the double sort will produce many double flowers again, but the seeds of the single will scarcely ever produce a double flower.

These flowers are only propagated by seeds, which should be sown towards the end of March, in a pot or box of good light earth, and set under a glass to forward its vegetating; giving it water as often as you shall see necessary, and in about a month's time your plants will come up and be of some bigness; you must therefore expose them to the open air, and in a short time after prepare some beds of good fresh earth, not too stiff, in which you may prick out these plants, about three inches square, observing to water and shade them, as the season may require.

In those beds they may remain until the middle of June, at which time you may remove and plant them in the borders of the pleasure garden, being careful to preserve as much earth to their roots as possible; and in a month's time after they will begin to flower, and continue until the frost prevent them. About the middle or latter end of August their seeds will begin to ripen, at which time you should look over them once a week, gathering off the pods that are changed brown, and spread them on papers to dry, when you may rub out the seed, and put it up for use. Though these plants are usually termed annuals, and sown every year, yet their roots will abide two years, if suffered to remain, and will endure the greatest cold of our winters, if planted in a dry soil, and without any shelter; as I experienced anno 1728, at which time I had a large bed of these flowers, which was raised a foot above the level of the ground; and, although its situation was such, that the sun never shone upon it from October to March, yet I had not one root destroyed in the whole bed, although it stood open, and without any care taken of it. *Miller's Gard. Dict.*

PIN'NA, *a fin*, in natural history, the name of that part of a fish which distinguishes it from other aquatic creatures, no animal but a fish having fins and wanting legs.

The fin is properly a part standing out, or hanging from the body of the fish, and consisting of a membrane supported by several rays or oblong bones; which are in some hard and firm, and in others cartilaginous.

PINNA *marina*, in natural history, the name of a shell fish, by the latest writers on these subjects referred to the genus of muscles.

PINTA'DO, *or Afra avis*, in natural history, a name given by the antient Roman authors to the Guinea hen.

Varro, Columella, and Pliny, with many others, make the meleagris the same species of bird; but Suetonius, Scaliger, and some others are of opinion, that the antients meant two very different birds by these names; and the latter of these authors endeavours to bring Varro over to his side, by altering the pointing in the passage of that author which relates to it.

The bird is of late become very common in England, and breeds with us in great plenty. The hen lays her eggs and sits upon them in the same manner with the common hen; but the eggs are smaller and not so white as the hen's eggs, but have a tinge of flesh colour and some black spots. They are not so tame and domestic as our own fowls, and particularly they will not lay in houses, but get into the hedges and among bushes, where they lay and hatch; but this is the occasion of great loss among them, the wild vermin destroying a great part of the young brood. The female also is less careful about the great business of hatching and taking care of them, than any other bird we are acquainted with. She will often leave her nest when the eggs are near hatching, and never return to it again; and often will desert the young as soon as hatched, if she remains at her nest till that time. The best

best method, therefore, is to set other fowls upon the eggs of this kind. The young fowls of this kind are very beautiful, they look like so many partridges. Their beaks and legs are red, and their whole plumage is at that time of the colour of the partridge. See *Tab. of birds*, N°. 21.

The hen, if her nest is found, and the eggs at times taken away, but so as always to have one there, will continue to lay till she has deposited an hundred, or sometimes an hundred and fifty eggs, which are very well tasted. This is a very active and sprightly bird, and of an unquiet and troublesome disposition to the owner. It runs very swiftly, in the manner of the quail and partridge; but its wings are short, and it is not made for flying; yet at night it will not roost among other fowl, but gets upon a house or tree, or any other high and safe place. The cry of the bird is sharp and disagreeable to many ears, and it is almost continually making it. It is of a quarrelsome disposition, and will be mistress of the yard: its agility, and the sharpness of its beak, generally obtaining it the victory with whatever bird it fights.

PIPE, in mining, is where the ore runs forwards end-ways in a hole, and doth not sink downwards or in a vein. *Houghton's Compl. Miner, in the explan. of the terms.*

PIQUET, or *picket*, a celebrated game at cards, much in use throughout the polite world.

It is played between two persons, with only thirty-two cards; all the duces, threes, fours, fives, and sixes, being set aside. In reckoning at this game every card goes for the number it bears, as a ten for a ten; only all court-cards go for ten, and the ace for eleven: and the usual game is one hundred up.—In playing, the ace wins the king, the king the queen, and so down. Twelve cards are dealt around, usually by two and two; which done, the remainder are laid in the middle: if one of the gamesters finds he has not a court in his hand, he is to declare he has carte-blanche, and tell how many cards he will lay out, and desire the other to discard, that he may shew his game, and satisfy his antagonist, that the carte-blanche is real; for which he reckons ten.

Each person discards, i. e. lays aside a certain number of his cards, and takes in a like number from the stock. The first, of the eight cards, may take three, four, or five; the dealer all the remainder, if he pleases.

After discarding, the eldest hand examines what suit he has most cards of, and reckoning how many points he has in that suit: if the other have not so many in that, or any other suit, he tells one for every ten of that suit.—He who thus reckons most is said to win the point.

The point being over, each examines what sequences he has of the same suit, viz. how many tierces, or sequences of three, quartes or fours, quintes or fives, sixiemes or sixes, &c. For a tierce they reckon three points, for a quarte four, for a quinte fifteen, and for a sixieme sixteen, &c. And the several sequences are distinguished in dignity by the cards they begin from: thus ace, king, and queen are called tierce major; king, queen, and knave, tierce to a king; knave, ten, and nine, tierce to a knave, &c. and the best tierce, quarte, or quinte, i. e. that which takes its descent from the best card, prevails; so as to make all the others in that hand good, and destroy all those in the other hand.—In like manner a quarte in one hand sets aside a tierce in the other.

The sequences over, they proceed to examine how many aces, kings, queens, knaves, and tens each holds; reckoning, for every three of any sort, three: but here too, as in sequences, he that, with the same number of threes, has one that is higher than any the other has, for example, three aces, has all his others made good hereby, and his adversary's all set aside.—But four of any sort, which is called a quatorze, always sets aside three.

All the game in hand being thus reckoned, the eldest proceeds to play, reckoning one for every card he plays above a nine, and the other follows him in the suit; and the highest card of the suit wins the trick.—Note, unless a trick be won with a card above a nine (except the last trick) nothing is reckoned for it; though the trick serves afterwards towards winning the cards; and that he who plays last does not reckon for his cards, unless he wins the trick.

The cards being played out, he that has most tricks reckons ten for winning the cards.—If they have tricks alike, neither reckons any thing.—The deal being finished, and each having marked up his game, they proceed to deal again as before, cutting afresh each time for the deal.

If both parties be within a few points of being up, the carte-blanche is the first thing that reckons, then the point, then the sequences, then the quatorzes or threes, then the tenth cards. He that can reckon thirty in hand by carte-blanche, points, quintes, &c. without playing, before the other has reckoned any thing, reckons ninety for them;—and this is called a repique;—if he reckons above thirty, he reckons so many above ninety.—If he can make up thirty, part in hand, and part play, before the other has told any thing, he reckons for them sixty. — And this is called a pique. Whence the name of the game.

He that wins all the tricks, instead of ten, which is his right for winning the cards, reckons forty,—and this is called a capot.

This game has in some cases been the object of mathematical computations.

Thus Mr. de Moivre has proposed and solved the following problems.

1°. To find at Piquet the probability which the dealer has for taking one ace or more in three cards, he having none in his hands. He concludes from his computation, that it is 29 to 28, that the dealer takes one ace or more.

2°. To find at Piquet the probability which the eldest has of taking an ace or more in five cards, having no ace in his hands. Answer, 232 to 91, or 5 to 2 nearly.

3°. To find at Piquet the probability which the eldest has of taking both an ace and a king in five cards, he having none in his hand. Answer, the odds against the eldest hand taking an ace and a king are 331 to 335, or 21 to 20 nearly.

4°. To find at Piquet the probability of having twelve cards dealt to, without king, queen, or knave; which case is commonly called cartes-blanches. Answer, the odds against cartes-blanches are 323 to 578,956, or 1791 to 1 nearly.

5°. To find how many different sets, essentially different from one another, one may have at Piquet before taking in. Answer, 28,967,278. This number falls short of the sum of all the distinct combinations, whereby 12 cards may be taken out of 32, this number being 225,792,840; but it ought to be considered, that, in that number, several sets of the same import, but differing in suit, might be taken, which would not introduce an essential difference among the sets.

Mr. de Moivre also gives some observations on this game, which he had from an experienced player. See *Doctrine of Chances, pag.* 151 to 159.

Monf. de Monmort has also treated of Piquet in his Analyse des Jeux de Hazard.

PISSASPHALTUM, in natural history, the name of a genus of fossils, the characters of which are these: they are fluid mineral bodies, of a somewhat thick consistence, dusky, and opake, of a strong smell, and readily inflammable, but leaving a residuum of greyish ashes after burning.

Brine PITS, the name given, by the people of Worcestershire and Cheshire, to the wells or Pits affording the salt water, out of which they extract the salt.

These waters, though they all contain salt, yet have other things also in them, and these not in small quantity. They all contain a very large proportion of stony matter; this is common to the whole set, but particular substances besides this are found in the particular Pits. At Northwich in Cheshire, there are four Pits, the water of all which stinks very strongly of sulphur, and contains so much vitriol, that it will turn black like ink, with a decoction of galls; yet this is boiled into a very fine and pure kind of salt, common at our tables under the name of basket salt, and having no such properties.

There is a vast quantity of stony matter precipitated from these pans of brine in the boiling them to salt; this is partly saved in small pans set at the side of the boiler, and partly precipitates to the bottom of the pan, where it forms a crust like that at the bottoms and sides of our tea-kettles, which the workmen find it necessary to remove every week; but there is no vitriol or sulphur separated. *Phil. Transf.* N°. 150.

In the country near where these brine Pits are, the instruments used in boring bring up fine and hard salt; so that they give proofs of there being rocks of salt in many places. All along the river Weever, on each side, the earth affords brine wherever it is opened; but all these are not fit for boiling, many of the Pits affording a brine too weak to be worked to any advantage. The very strongest Pits sometimes also become at once too weak; it is owing to the irruptions of fresh openings into them, and sometimes the river itself makes its way into them, and overflows them with such a quantity of fresh water, that they are utterly spoiled. The brine-Pits at Weston, near Stafford, afford a brine that stinks like rotten eggs; this turns instantly to ink with galls, and purges and vomits violently, if taken even in a small quantity. This in boiling deposits a white flaky sand, or stony matter, without smell or taste, and the salt is pure and fine.

The Pit at Droitwich, in Worcestershire, affords no sand in the boiling, nor any the least sediment of the stony matter at the bottom of the pan, and the salt is the purest of all the others; and by the people of the country is esteemed the most wholesome, because of its being without the sand. This and the other Pits hereabout all have the smell of rotten eggs, especially after a little rest, as on the Monday morning after the Sunday's rest. If meat be put to pickle in the brine of these Pits, instead of being preserved it will stink in twenty-four hours, sometimes in twelve, yet they yield the best salt of any inland Pits in the world.

The sulphur spaws of Yorkshire, which are very numerous in different parts of the county, all stink violently of rotten eggs; but, if well drawn and worked, they would prove as inoffensive as the rest, and only so many weaker or stronger brine-Pits; and the smell is no other than that of the Cheshire and Staffordshire brine, when it has been left some time at rest. It is remarkable, that, though the stony matter is deposited in such vast plenty by the waters of all our salt springs, it is not found

found in any abundance in those places where salt is made out of the sea-sand, as in Lancashire and some other places; so that it is much more than the natural quantity of spar contained in water that is thus deposited; and indeed it appears from trial, that the brine of our salt-springs, in general, contains more than twenty times the quantity of spar that common water does.

This stony matter separates itself from the water before the salt does, and thus it appears to do in many other waters impregnated with mineral particles. The vitriolic waters all contain ochre and salt, and in all these the ochre separates itself first in the boiling, and then the vitriol, and the stony matter precipitated from common salt springs affords, on an analysis, the salt called nitrum calcarium, in considerable abundance. *Phil. Transf.* N°. 156.

PITH (*Dict.*)—As the substance of the trunk in trees becomes more woody, the Pith is compressed and strained to such a degree, that it wholly disappears.

The Pith of trees is continued farther into their minute parts than is generally conceived; the smallest branches and pedicles of the leaves and flowers have their share of it, according to the nature of the trees they belong to; and even the middle ribs of the leaves, when examined by the microscope, are not without it: a transverse section of one of these ribs of the leaf of a pithy tree shews a very beautiful arrangement of vessels, or little bladders, containing a quantity of clear liquor, and resembling in all respects those of which the Pith in the branches is composed. The Pith in these is not round, however, as in the others, but flat, and runs from one end of the pedicle to the other, in form of a thin white rib, gradually lessening to a point.

The Pith of plants, in fine, seems what the marrow is in animals, a congeries of an infinite number of vesicles, which seem destined to separate a finer juice than is necessary for the nourishment of the coarser parts of the tree. It is observed of plants which have a larger than ordinary share of Pith, that they produce larger quantities of flowers than others; instances of this are seen in the rose, the iliac, and the common elder: and, in the ferulaceous plants, the quantity of flowers is not only profusely large, according to the great quantity of Pith in their stalks, but the Pith seems carried up the stalks all the way to the seeds themselves; the long seeds of the sweet myrrhis, and other the like plants, while not ripe, being only Pith. *Mem. Acad. Scien.* 1709.

PLANE *tree*, *platanus*, in botany, the name of a genus of trees, the characters of which are these: the flower is of the amentaceous kind, and is of a glomerated shape, and composed of a great number of stamina with their apices. These flowers are barren, and the embryo fruits are found on other parts of the plant; these finally become larger, and contain several seeds winged with down.

PLANET (*Dict.*) — *Plate* VII. *fig.* 2, 3, 4, 5, 6, 7, and 8, exhibit the proportion that the several Planets bear to each other.

PLANS *of bridges*, the representations of these structures laid down on a plane, such as they appear on the ground.

PLANTA'GO, *plantain*, in botany, a genus of plants whose characters are:

The calyx is monophyllous, quadrifid, tubulous, and very tender. The flower in it is monopetalous, shaped somewhat like a bason, quadripartite, and expanded in form of a star: the ovary is guarded by four long stamina; whence some take the flower to be apetalous. The fruit is a shell, almost of an oval or conic form, when ripe, opening transversly into two parts (one of which rests upon the other;) and is divided by an intercloſure into two capsules, full of oblong seeds.

Plantain is cold, dry, and binding, and useful in all kinds of fluxes and hæmorrhages, as spitting and vomiting of blood, bleeding at the nose, the excess of the catamenia, or lochia, as also, for the involuntary making of urine, its heat and sharpness, and the gonorrhœa. It is likewise good to stop the bleeding of wounds, and to consolidate their lips.

The only officinal preparation is the simple distilled water. *Miller's Bot. Off.*

Its leaves are bitter, astringent, and give a faint red colour to the blue paper; the roots give it a deeper, and are only astringent; which shews, that, in the leaves, the sal ammoniac, and the terrestrial parts of this plant, are clogged with a great deal of sulphur; thus the Plantain is vulnerary, resolving, and febrifugous. Tragus commends it very much for the phthisic. In the country they drink the juice, from two ounces to four, at the first access of the paroxysm of intermitting fevers; two drachms of the extract of this plant, or a drachm of its seed reduced to powder, cure a looseness, and all sorts of hæmorrhages. The ptisan and water of Plantain have the same virtues. They are prescribed in the dysentery, spitting of blood, in the immoderate flux of the piles, or terms, for the whites, and losses of blood. In fine, the Plantain is used in all vulnerary and detersive potions. In the inflammation of the eyes, Camerarius made a collyrium with the juice and leaves of this plant mixed with rose-water and sugar. Simon Pauli used the extract of Plantain, and the decoction of sarsaparilla, to cure a young man that made bloody urine, after a gonorrhœa. The gargarism of Plantain is excellent for the diseases of the throat; this plant is an ingredient in the powder which Julian Paulmier has prescribed to cure madness. *Martyn's Tournefort.*

PLA'SHING, a term used by our farmers to express an operation performed at certain times upon the quick-set hedges, in order to assist their growth and continuance. This operation is performed sometimes in October, but more usually in February; and this is by much the better season for it. Suppose a hedge to be of twenty or thirty years growth, and full of old stubs, as well as young shoots, this is the kind of hedge that requires Plashing most of all.

The old stubs must be cut off within two or three inches of the ground, and the best and longest of the middle-sized shoots must be left to lay down. Some of the strongest of these must also be left to answer the purpose of stakes. These are to be cut off to the height at which the hedge is intended to be left, and they are to stand at ten feet distance one from another: when there are not proper shoots for these at due distances, their places must be supplied with common stakes of dead wood. The hedge is to be first thinned, by cutting away all but those shoots which are intended to be used either as stakes, or the other work of the Plashing: the ditch is to be cleaned out with the spade, with sloping sides each way; and when there is any cavity on the bank on which the hedge grows, or the earth has been washed away from the roots of the shrubs, it is to be made good by facing it, as they express it, with the mould dug from the upper part of the ditch; all the rest of the earth dug out of the ditch is to be laid upon the top of the bank, and the owner should look carefully into it, that this be done; for the workmen, to spare themselves trouble, are apt to throw as much as they can upon the face of the bank; which, being by this means overloaded, is soon washed off into the ditch again, and a very great part of the work undone again, whereas what is laid on the top of the bank always remains there, and makes a good fence of an indifferent hedge.

In the Plashing the quick, two extremes are to be avoided; these are, the laying it too low, and the laying it too thick: this makes the sap run all into the shoots, and leaves the Plashes without sufficient nourishment; which, with the thickness of the hedge, finally kills them. The other extreme of laying them too high is equally to be avoided; for this carries up all the nourishment into the Plashes, and so makes the shoots small and weak at the bottom, and, consequently, the hedge thin. This is a common error in the north of England. The best hedges, made any where in England, are those of Hertfordshire; and they are plashed in a middle way between the two extremes, and the cattle are by that prevented both from cropping the young shoots, and from going through; and a new and vigorous hedge soon forms itself.

When the shoot is bent down that is intended to be plashed, it must be cut half-way through with the bill: the cut must be given sloping, somewhat downwards, and then it is to be wound about the stakes, and, after this, its superfluous branches are to be cut off, as they stand out at the sides of the hedge. If, for the first year or two, the field where a new hedge is made can be plowed, it will thrive the better for it; but, if the stubs are very old, it is best to cut them quite down, and to secure them with good dead hedges on both sides, till the shoots are grown up from them strong enough to plash; and, wherever void spaces are seen, new sets are to be planted to fill them up. A new hedge, raised from sets in the common way, generally requires Plashing about eight or nine years after. *Mortimer's Husbandry.*

PLA'STERING. The modern taste runs greatly into Plastering, and it were much to be wished that this art could be again brought to its ancient perfection. In our best buildings, the plastered walls and ceilings crack and fly, and in a little time grow damp, or moulder to decay. The Romans had an art of rendering their works of this kind much more firm and durable, and there is no reason to despair of reviving this art by proper trials.

The ancient Plastering of these people, preserved to this time, where it has not met with violent blows or injuries from accidents, is still found as firm and solid, as free from cracks and crevices, and as smooth and polished on the surface, as if made of marble. The bottoms and sides of the Roman aqueducts were made of this Plastering, and endured many ages without hurt, unless by accidents; witness that, whereof some yards are still to be found on the top of the Ponte de Gards, near Nismes, for the support of which that famous bridge was built to carry water to the said town. The roofs of houses and the floors of rooms at Venice are covered with a sort of plaster, made of later date, and yet strong enough to endure the sun and weather for several ages, without cracking or spoiling, and without much injury from people's feet.

The secret of preparing this Venetian plaster is not among us; but it would be worth while to try whether such a substance might not be made by boiling the powder of gypsum dry over the fire, for it will boil in the manner of water; and, when this boiling or recalcining was over, the mixing with it rosin, or pitch, or both together, with common sulphur, and the powder of sea shells. If these were all mixed together, and the water added to it hot, and the matter all kept hot upon the fire till

till the inſtant of its being uſed, ſo that it might be laid on hot, it is poſſible this ſecret might be hit upon.

Wax and oil of turpentine may be alſo tried as additions : theſe being the common ingredients in ſuch cements as we have accounts of as the firmeſt. Strong ale-wort is by ſome directed to be uſed, inſtead of water, to make mortar of lime-ſtone be of more than ordinary ſtrength. It is poſſible, that the uſe of this tenacious liquor to the powdered ingredients of this propoſed plaſter might greatly add to their ſolidity and firmneſs. *Philoſ. Tranſ.* N°. 93.

PLATES, in gunnery.—The prize Plates are two Plates of iron on the cheeks of a gun carriage, from the cape ſquare to the center, through which the prize bolts go, and on which the hand-ſpike reſts where it poiſes up the breach of the piece. Breaſt Plates are the two Plates on the face of the carriage, one on each cheek. Train Plates are the two Plates on the cheeks at the train of the carriage. Dulidge Plates are the ſix Plates on the wheel of a gun carriage, where the fellows are joined together, and ſerve to ſtrengthen the dulidges.

PLA'TFORM (*Dict.*) — All practitioners are agreed, that no ſhot can be depended on, unleſs the piece be placed on a ſolid Platform ; for, if the Platform ſhakes with the firſt impulſe of the powder, it is impoſſible but the piece muſt likewiſe ſhake ; which will alter its direction, and render its ſhot uncertain. To prevent this accident, the Platform is uſually made extremely firm to a conſiderable depth backwards, ſo that the piece is not only well ſupported in the beginning of its motion, but likewiſe through a great part of its recoil. However, it is ſufficiently obvious, that, when the bullet is ſeparated from the piece, it can be no longer affected by the trembling of the piece or Platform ; and by a very eaſy computation it will be found, that, in a piece ten feet in length, carrying a bullet of twenty-four pounds, and charged with ſixteen pounds of powder, the bullet will be out of the piece before it has recoiled half an inch ; whence, if the Platform be ſufficiently ſolid at the beginning of the recoil, the remaining part of it may be much ſlighter, ſince its unſteadineſs beyond the firſt half inch will have no influence on the direction of the ſhot : and hence a more compendious method of conſtructing Platforms may be found out. *New Princip. of Gunn.*

PLA'TONISM (*Dict.*)—In after-times, about the firſt ages of the Chriſtian church, the followers of Plato quitted the title of Academiſts, and took that of Platoniſts.

It is ſuppoſed to have been at Alexandria in Egypt, that they firſt aſſumed the new title, after having reſtored the ancient academy, and re-eſtabliſhed Plato's ſentiments ; which in proceſs of time had many of them been laid aſide.

Porphyry, Plotin, Iamblichus, Proclus, and Plutarch, are thoſe who acquired the greateſt reputation among the Greek Platoniſts : and, among the Latins, Apuleius and Chalcidius. — Among the Hebrews, Philo Judæus.—The modern Platoniſts own Plotin the founder, at leaſt the reformer of their ſect.

The Platonic philoſophy appears very conſiſtent with the Moſaic ; and a great party of the primitive fathers follow the opinions of that philoſopher, as being favourable to Chriſtianity. —Juſtin is of opinion, Plato could not learn many things he has ſaid in his works, from mere natural reaſon ; but thinks he might have learnt them from the books of Moſes, which he read when in Egypt.

Hence Numenius, the Pythagorean, expreſſly calls Plato the Attic Moſes ; and upbraids him with plagiariſm, in that he ſtole his doctrine about the world and God, from the books of Moſes. Theodoret ſays expreſsly, that he has nothing good and commendable about the Deity, and his worſhip, but what he ſtole from the Hebrew theology ; and Clemens Alexandrinus calls him the Hebrew philoſopher.

Gale is very particular in his proof of the point, that Plato borrowed his philoſophy from the ſcriptures, either immediately, or by means of tradition; and, beſides the authority of ancient writers, brings ſome arguments from the thing itſelf.— As, for inſtance, Plato's confeſſion that the Greeks borrowed their knowledge of the one infinite God, from an ancient people, better and nearer to God than they ; by which people, our author makes no doubt, he meant the Jews : from his account of the ſtate of innocence ; as, that man was born of the earth, that he was naked, that he enjoyed a truly happy ſtate, that he converſed with brutes, &c.—In effect, from an examen of all the parts of Plato's philoſophy, phyſical, metaphyſical, and ethical, this author finds, in every one, evident characters of its ſacred original.

As to the manner of the creation, Plato teaches that the world was made according to a certain exemplar, or idea, in the divine architect's mind. And all things in the univerſe, in like manner, he ſhews, do depend on the efficacy of eternal ideas.

This ideal world is thus explained by Didymus : ' Plato ſuppoſes certain patterns or exemplars of all ſenſible things, which he calls ideas ; and, as there may be various impreſſions taken off from the ſame ſeal, ſo is there a vaſt number of natures exiſting from each idea.' This idea he ſuppoſes to be an eternal eſſence, and to occaſion the ſeveral beings in nature to be ſuch as itſelf is : and that moſt beautiful and perfect idea, which comprehends all the reſt, of whatever kind, he maintains to be the world.

Further, Plato teaches that the univerſe is an intelligent animal, conſiſting of a body and a ſoul.

The firſt matter whereof this body was formed, he obſerves, was a rude indigeſted heap, or chaos : now, adds he, the creation was a mixed production ; and the world is the reſult of a combination of neceſſity and underſtanding, i. e. of matter, which he calls neceſſity, and the divine wiſdom.

The principles, or elements, which Plato lays down, are fire, air, water, and earth.

He ſuppoſes two heavens ; the empyrean, which he takes to be of a fiery nature, and to be inhabited by angels, &c. and the ſtarry heaven, which he teaches is not adamantine or ſolid, but liquid and ſpirable.

His phyſics, or doctrine de corpore, is chiefly laid down in his Timæus ; where he argues on the properties of body, in a geometrical manner ; which Ariſtotle takes occaſion to reprehend in him.—His doctrine de mente is delivered in his tenth book of Laws, and his Parmenides.

St. Auguſtine commends the Platonic philoſophy ; and even ſays, that the Platoniſts were not far from Chriſtianity : he adds, that the generality of the new Platoniſts of his time embraced the faith.

Juſtin Martyr profeſſes, that Plato's doctrine was of the utmoſt advantage to him, in helping him to believe the myſteries of the Chriſtian faith.—To which it may be added, that it was in good meaſure by Plato's help that Origen confuted Celſus.

Indeed, the late author of Platoniſme devoilé carries things to an extravagant length, when he contends, that the dogmata of of our religion are only the opinions of Plato ; that the fathers give us nothing of the myſteries thereof, but what they learnt from him ; and that Chriſtianity is only Platoniſm veiled, or covered over. To which opinion, however, M. le Clerc ſeems a little inclined.

Among the multiplicity of things to be done, and to be avoided, for the preſervation of animal life, &c. how ſhould we have diſtinguiſhed between the one and the other, but for the ſenſations of pleaſure and pain ? Theſe are not only ſpurs, to urge us on, but alſo guides, to direct us whither we are to go. Where-ever nature has fixed pleaſure, we may take it for granted, ſhe there injoins a duty ; and ſomething is to be there done, either for the individual, or the ſpecies.

Hence, it is that our pleaſures vary at different ſtages of life ; the pleaſures, for inſtance, of a child, a youth, a grown man, an old man, &c. all tending to thoſe particular things required by nature in that particular ſtate of life, either for the preſervation, ſimply, or for that and propagation, &c.

Hence, from the different conſtitutions of the body, at different ages, it were very eaſy to account for all the particular taſtes and pleaſures thereof : not by deducing the pleaſures mechanically from the diſpoſition of the organs in that ſtate ; but by conſidering what is neceſſary for the perfection and well-being of the individual in that ſtate, and what it is to contribute to that of the ſpecies.—In a child, mere preſervation in the preſent ſtate is not enough ; it muſt likewiſe grow : to bring this to paſs, nature has made the returns of hunger, &c. more frequent, as well as more acute ; and the pleaſures of feeding more exquiſite. And, that the exceſs of aliment in proportion to the bulk of the body may be diſpenſed withal, ſhe has made one of the great pleaſures of that ſtate to conſiſt in a ſeries of ſportive exerciſes, by means whereof the parts of the body come to be opened and expanded, and arrive at maturity. This done, the pleaſures that conduced thereto diſappear ; and others, ſuited to the new ſtate, ſucceed.

PLEURONE'CTES, in ichthyology, the name of a genus of fiſhes of the malacopterygious kind, the characters of which are theſe : the branchioſtege membrane, on each ſide, contains ſix bones of a cylindric figure ; and in the middle between theſe, but lower down, there are two others joined together at the end, but theſe are ſcarce conſpicuous. Both the eyes are placed in one ſide of the head ; in ſome they are in the right ſide, and in others in the left. The eyes are covered with a ſkin. One ſide of the fiſh is always white, the other is ſpotted or obſcure.

PLO'MO, in metallurgy, a name given by the Spaniards, who have the care of the ſilver mines, to the ore of that metal when it is found adhering to the ſurface of ſtones, and incruſting their cracks and cavities in the form of ſmall and looſe grains of gunpowder. Though theſe grains be but few in number, and the reſt of the ſtone have no ſilver in it, yet, they are always very happy in meeting with it, as it is a certain token that there is a very rich vein ſomewhere in the neighbourhood. And, if, in digging forwards, they ſtill meet with theſe grains, or the Plomo, in greater quantity, it is a certain ſign that they are getting nearer the good vein.

PLO'VER, *pluvialis*, in zoology, a bird of paſſage well known among ſportſmen.

The Plovers are very eaſily taken at the time of their firſt coming over, when they have not got any other birds mixed among them ; but, when they afterwards pick up the teal and other ſhy birds among them, it becomes more difficult. The beſt ſeaſon for taking them is in October, eſpecially in the beginning of that month : after this they grow timorous, and are not eaſily taken again till March, which is the time of their coupling. The ſevereſt froſts are not the beſt ſeaſon for taking them in nets, but variable weather does better. The north-weſt wind is found diſadvantageous to the taking of them ;

 and,

and, in general, great regard is to be paid to the courſe of the wind in ſetting of the nets. All ſea fowl fly againſt the wind when the land lies that way; and the nets for the taking them are therefore to be placed in a proper direction accordingly.

PLOUGH (*Dict.*)— The advantage of digging with the ſpade, or ſuch other inſtrument, very naturally led men to the invention of the Plough, a greatly more expeditious way of doing the ſame thing; that is, cutting and breaking the earth into ſmall pieces; but in this the ſpade has the advantage of the common Plough, as it goes deeper, and divides the earth more minutely; but the improvement of the common Plough into the four-coultered one, ſhews that it is eaſy to make the Plough perform this office as much better, as it uſually does it worſe than the ſpade.

The Plough deſcribed by Virgil had no coulter; and at this time, the Ploughs of Italy and the ſouth of France, have none; and the Ploughs in Greece, and in the eaſtern nations in general, are of the ſame kind. Neither is it indeed poſſible to uſe a coulter in ſuch a Plough; becauſe the ſhare does not cut the bottom of the furrow horizontally, but obliquely: in going one way it turns off the furrow to the right-hand, but in coming back it turns it off to the left; therefore if it had a coulter, it muſt be on the wrong ſide every other furrow.

It is a great miſtake in thoſe who ſay that Virgil's Plough had two earth-boards, for it had really none at all; but the ſhare itſelf, always going obliquely, ſerved inſtead of an earth board; and two ears, which were the corners of a piece of wood lying under the ſhares, did the office of ground-wriſts. This faſhion of the Plough continues to this day in thoſe countries; and in Languedoc this ſort of Plough performs tolerably well when the ground is fine, and makes a ſhift to break up light land. This is the ſort of land that is common in the Eaſt, and the arable lands about Rome, being never ſuffered to be fallow ſo long as to come to turf: this Plough ſucceeds very well in ſuch places, but it would be wholly impoſſible to turn up what in England we call ſtrong land, with it.

The Engliſh Ploughs are therefore different from theſe, as the ſoil is different. Our Ploughs, where well made, cut off the furrow at the bottom horizontally; and therefore, it being as thick on the land ſide as on the furrow ſide, the Ploughs cannot break it off from the whole land at ſuch a thickneſs, being ſix times greater than what the eaſtern Ploughs have to break off, and for this purpoſe it muſt have, of neceſſity, a coulter to cut it off: by this means the furrow is turned perfectly whole, and no part of the turf of it is broken; and if it lie long without new turning, the graſs from the edges will ſpread, and form a new turf on the other ſide, which was the bottom of the furrow before the turning; but is now become the ſurface of the earth, and will ſoon become greener with graſs than it was before plowing.

If whole, ſtrong, turfy furrows are plowed croſs-ways, as is too commonly practiſed, the coulter cannot eaſily cut them; becauſe, being looſe underneath, they do not make a proper reſiſtance or preſſure againſt its edge, but are apt to be drawn on heaps, and turned in all directions, but without cutting.

Some of our Ploughs have heavy drags, with long iron tines in them; and though theſe broken pieces of furrows, being now looſer than before, require keener edges to cut them, theſe tines have no edges at all. Thus the clods of earth are toſſed into heaps again, and the ſurface left bare between them, and great labour and expence is uſed to very little purpoſe: all this is owing to the one coulter.

If the ſoil be ſhallow, it may be broken up with a narrow furrow, which will the ſooner be brought into tilth; but if it be a deep ſoil, the furrows muſt be proportionably enlarged, or elſe a great part of the good mould will be left unmoved, and ſo be loſt. The deeper the land is, the worſe it is broke by one coulter; that is, it is broke into larger furrows, and it requires ſuch repeated labour to conquer this, that, often, the beſt land will ſcarce pay the tillage.

This gives an opportunity to ſervants to cheat their maſters. They plow ſuch deep land with a ſmall furrow, and ſhallow, to the end, that the turf and furrows may be broken the ſooner, and the ſuperficial part made fine. They pretend the Plough will go deeper the next time; but this is never the caſe,

This ſort of land muſt not be plowed the ſecond time in wet weather; for this will cauſe the weeds to multiply, and the earth will be formed into thick and heavy clods where trodden: and in dry weather, the reſiſtance of the untouched earth below, and the ſlight preſſure of the Plough above, will always be reaſons why the Plough will enter no deeper the ſecond time than it did the firſt.

Another way to conquer a ſtrong turf, is to plow it up firſt with a breaſt Plough, very thin; and when the ſwerd is rotten, then it is to be plowed to the proper depth: but this method is liable to great objections; it is very troubleſome and expenſive, and if the turf be pared off in the winter, or early in ſpring, it is a chance but the rains come on, and ſet it to growing faſter than before: if, on the other hand, it be pared later in the year, though the turf be thoroughly killed by the ſucceeding dry weather, yet the time is loſt, and the farmer loſes the ſowing ſeaſon for wheat, which is the proper corn for ſuch ſtrong land.

The four-coultered Plough is the proper inſtrument for the farmer to have recourſe to on this and many other the like occaſions. This is an improvement on the common Plough, that makes it cut the pieces of earth into four; that is, it thus divides the earth four times as ſmall as the common Plough.

The common two-wheeled Plough has of late years become univerſally uſed in many countries, and is found greatly preferable to the Ploughs they uſed before; there is an objection to it, indeed, in regard to ſome ſtiff and miry lands, in which the wheels become clogged up, and cannot turn. This, however, is eaſily remedied by twiſting thumb ropes of ſtraw about the iron circle and ſpokes of the wheels; theſe ſpreading as they turn, and, as the circle twiſt bears upon the ground, throw off the dirt, and never clog. The two principal parts of this Plough are the head and the tail: the Plough-head contains the two wheels and their axis, or ſpindle, paſſing through a box, and turning round both in it and in the wheels. There are fixed perpendicularly in this box two crow-ſtaves, as they are called, which are flat and narrow boards, each having on it two rows of holes, whereby to raiſe or ſink the beam of the Plough, by pinning up or down the pillow, to increaſe or diminiſh the depth of the furrow. Behind are a pair of gallows, through which the crow-ſtaves paſs at the top by mortiſes, into which they are pinned; and to theſe are faſtened what are called the wilds, which are rings and crooks of iron, by which the whole Plough is drawn in the working. From the box to the center of the beam there is carried an iron-chain, conſiſting of four, five, or more long links, and called the tow-chain: this faſtens the Plough-tail to the Plough-head. It is fixed to an iron collar, faſtened in the beam at one end, and at the other paſſes through a hole in the middle of the box, and is pinned in with a wooden pin.

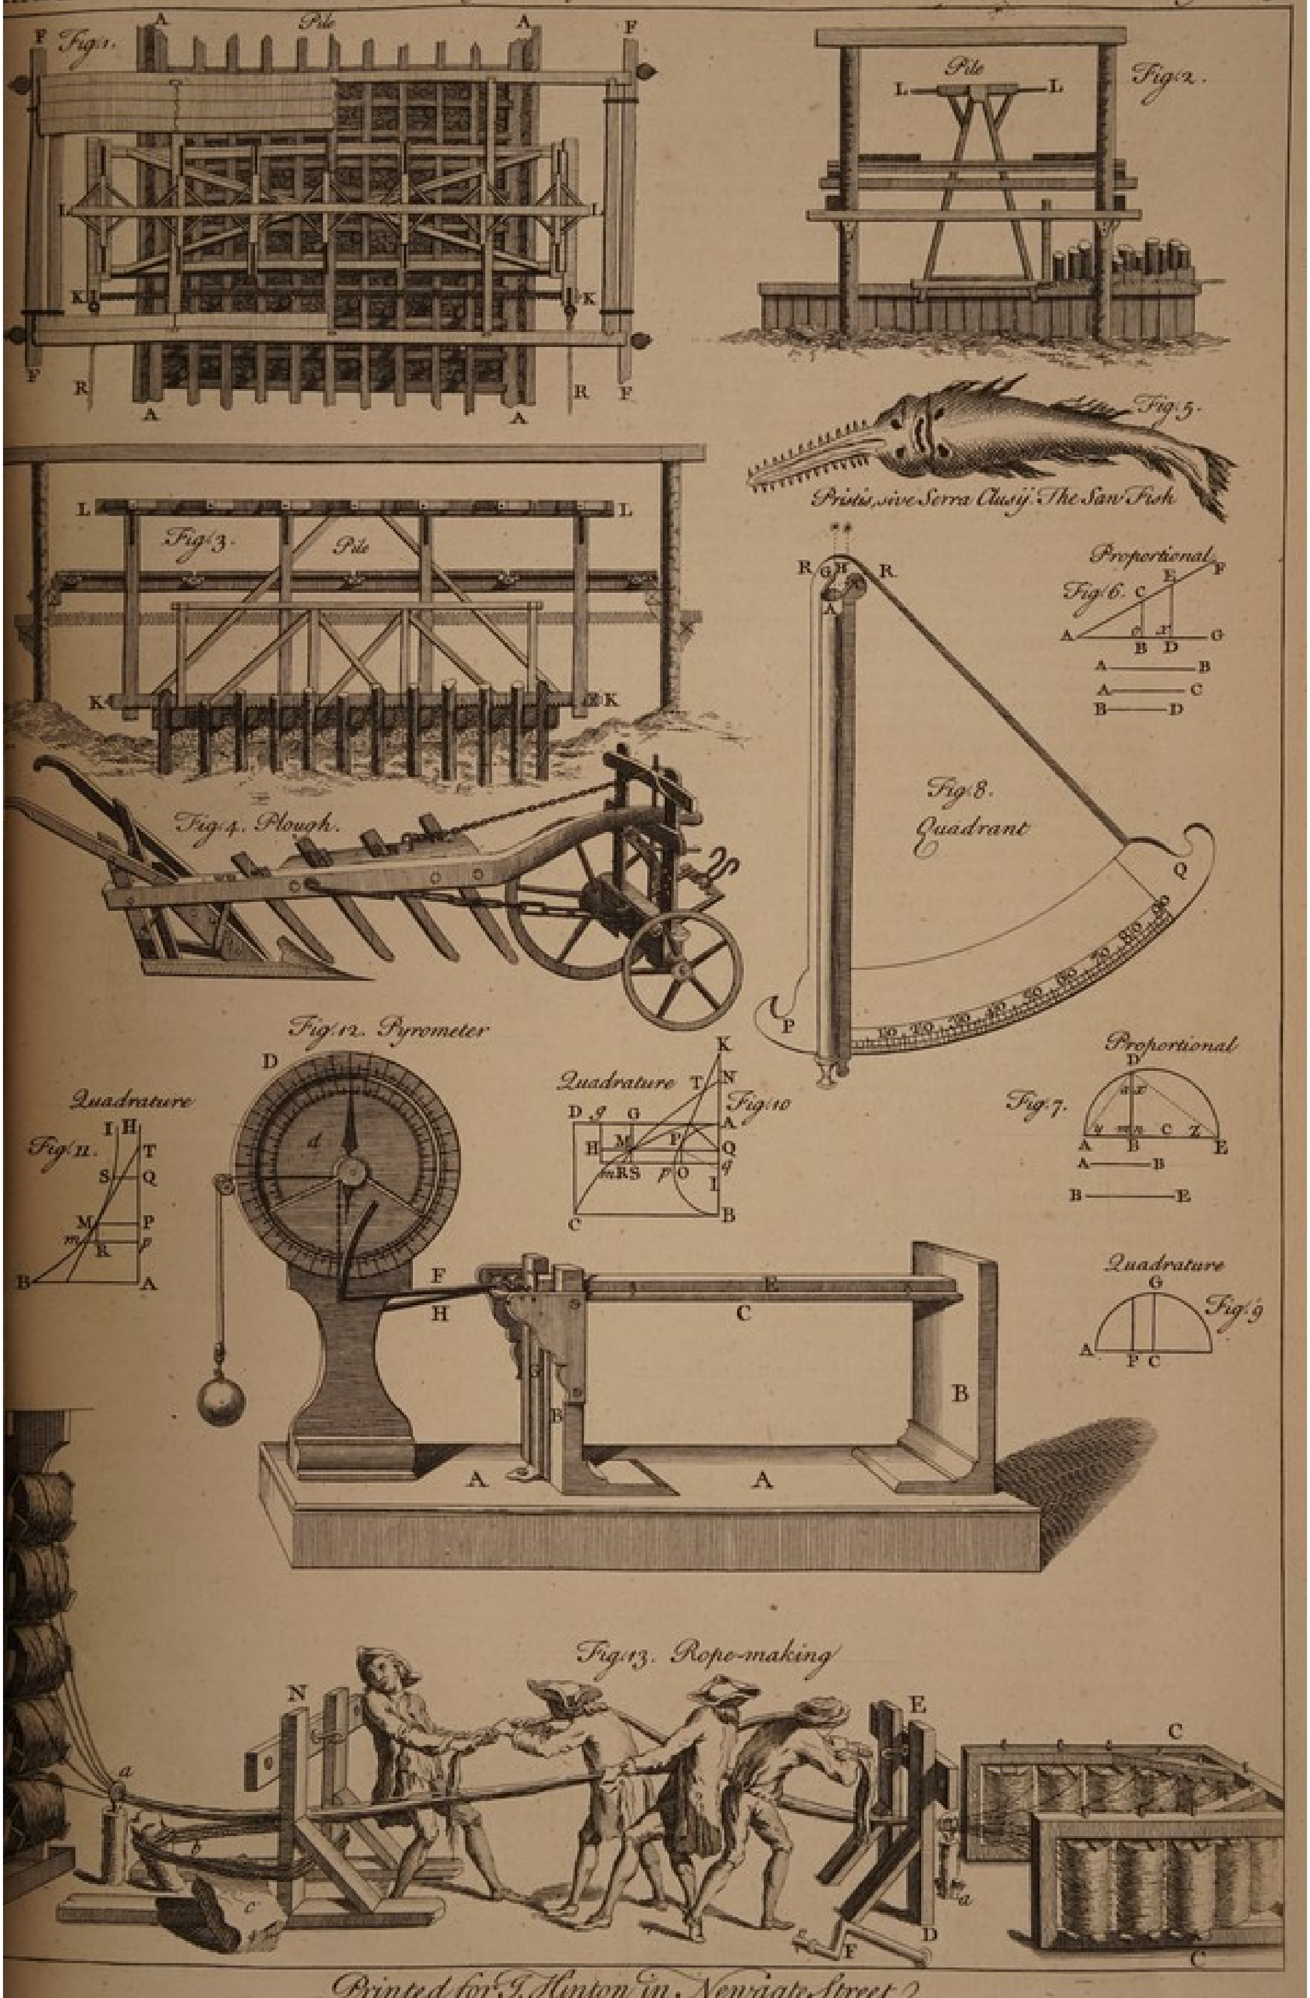
From the ſame iron-collar to which the tow-chain is fixed, there is alſo another chain faſtened, called the bridle-chain: this runs above the beam, as the tow-chain does below it, and is compoſed of ſmaller and more numerous links. At the upper end, as the tow-chain enters the box of the Plough, this bridle-chain is fixed to the top of what is called the ſtake of the Plough: this is a perpendicular ſtick, carried up parallel with the left crow-ſtaff, and pretty near it, and faſtened to it by a wyth or rope, or by the end of the bridle-chain itſelf, when that is long enough. This ſtake is alſo faſtened in its lower part, under the gallows, to the ſame crow-ſtaff, by another wyth or piece of rope.

Theſe are the parts of which the head-part of the Plough is compoſed. The Plough-tail conſiſts of the beam carried from the head to the very extremity, and ſerving as the ſupport and baſe of all the reſt. A little below the collar to which the tow-chain and bridle-chain are faſtened, this beam is pierced with a large hole, which lets through the coulter: this is a long and narrow piece, terminating in an edge, and reaching juſt to the ſhare; and it is fixed immoveably in its place by means of a wedge which is driven into the hole of the beam with it: the office of this coulter is to cut the earth as it is thrown up by the ſhare. Behind theſe, the ſame beam is pierced with two more holes, one very near its end: theſe give paſſage to two oblong pieces, called the fore-ſheat and hinder-ſheat, by which the Plough-ſhare is ſupported in its place. To the top of the hinder-ſheat there is faſtened a ſhort handle by a wooden pin. Parallel to the hinder-ſheat there runs up a piece of wood of much the ſame form, called the drock; and to this is faſtened another horizontal piece, called the ground-wriſt: theſe are all on the right-hand ſide of the Plough, and parallel with the fore-ſheat. There runs another piece of much the ſame form with it, on the right-hand; and the bottom of this is the earth-board. The long handle of this, which reaches as far that of the ſheat, is faſtened to the drock by a pin, the other end of which goes into the beam. Near the lower end of the fore-ſheat, there are two flat pieces of iron, which paſs from the two ſides of it up to the beam; and being let through it, are faſtened to the upper part by ſcrews and pins. Theſe keep the ſheat in its place.

The ſtructure of the four-coultered Plough is different, in ſome reſpects from this, though in general founded on it. Its beam is ten feet long, whereas that of the common Plough is but eight. The beam is ſtraight in the common Plough, but in this it is arched in one fourth part of its length, near the Plough-head. At the diſtance of three feet two inches from the end of the beam at the Plough-tail, the firſt coulter, or that next the ſhare, is let through; and at thirteen inches from this, a ſecond coulter is let through: a third at the ſame diſtance from that; and, finally, the fourth at the ſame diſtance from the third, that is, thirteen inches.

The crookedneſs of the upper part of the beam in this Plough is contrived to avoid the too great length of the three foremoſt coulters, which would be too much, if the beam was ſtraight all the way; and they would be apt to bend and be diſplaced, unleſs they were vaſtly heavy and clumſy. Aſh is the beſt wood to make the beam of, it being ſufficiently ſtrong, and yet light.

The ſheat in this Plough is to be ſeven inches broad. The fixing



Printed for J. Hinton in Newgate Street

ing of the ſhare in this, as well as in the common Plough, is the niceſt part, and requires the utmoſt art of the maker; for the well going of the Plough wholly depends upon the placing of this. Suppoſing the axis of the beam, and the left ſide of the ſhare, to be both horizontal, they muſt never be ſet parallel to each other; for, if they are, the tail of the ſhare, bearing againſt the trench as much as the point, would cauſe the point to incline to the right-hand, and it would be carried out of the ground into the furrow. If the point of the ſhare ſhould be ſet ſo, that its ſide ſhould make an angle on the right ſide of the axis of the beam, this inconvenience would be much greater; and if its points ſhould incline much to the left, and make too large an angle on that ſide with the axis of the beam, the Plough would run quite to the left-hand; and, if the holder, to prevent its running quite out of the ground, turns the upper part of his Plough toward the left-hand, the pin of the ſhare will riſe up, and cut the furrow diagonally, leaving it half unplowed. To avoid this and ſeveral other inconveniences, the ſtraight ſide of the ſhare muſt make an angle upon the left ſide of the beam; but that muſt be ſo very acute a one, that the tail of the ſhare may only preſs leſs againſt the ſide of the trench than the point does.

The great thing to be taken care of, is the placing the four coulters; for on this the ſucceſs of the whole depends. Theſe muſt be ſo ſet, that the four imaginary planes deſcribed by their four edges, as the Plough moves forward, may be all parallel to each other, or very nearly ſo; for if any one of them ſhould be very much inclined to, or ſhould recede much from either of the other, then they would not enter the ground together. In order to the placing them thus, the beam muſt be carefully pierced in a proper manner. The ſecond coulter-hole muſt be two inches and an half more on the right-hand than the firſt: the third muſt be as much more to the right of the ſecond, and the fourth the ſame meaſure to the right-hand of the third: and this two inches and an half muſt be carefully meaſured from the center of one hole to the center of the other. Each of theſe holes is a mortiſe of an inch and a quarter wide, and is three inches and an half long at the top, and three inches at the bottom. The two oppoſite ſides of this hole are parallel to the top and bottom, but the back is oblique, and determines the obliquity of the ſtanding of the coulter, which is wedged tight up to the poll. A perſpective view of this curious Plough the reader will find in *Plate* XXXV. *fig.* 4.

The coulter is two feet eight inches long, before it is worn; the handle takes up ſixteen inches of this length, and is allowed thus long, that the coulter may be driven down as the point wears away. *Tull's Horſe-hoeing Huſbandry.* See COULTER.

PLUM-*tree*, *prunus*, in botany, the name of a large and well known genus of fruit-trees.

All the ſpecies of Plums have within their fruit a hard ſtone, within which there is contained a ſoft and tender kernel: this kernel contains the ſeminal plant, from which would be produced another tree of the ſame kind, if it were ſet in the ground; and it is very natural to ſuppoſe, that the only uſe of the thick ſtone or huſk of this was only to preſerve its tender ſubſtance from rotting too ſoon in the earth, and to give it a proper time for developing its parts, to preſerve its natural oilineſs during that time, and to furniſh from its own ſubſtance a proper nouriſhment to the growing plant; for obſervation ſhews, that it finally breaks into a very fine powder.

There has not been found any ſpecies of Plum which had not its kernel contained in a ſtony coat of this kind, from whatever grafts they have been propagated; nor is there any art known by which the kernel of this ſort of fruit can, while growing, be deprived of its coat.

Mr. Marchand, however, in the year 1735, ſhewed, before the Academy of Sciences at Paris, certain Plums, whoſe kernels had no ſtone or ſhell round them; and found that they grew upon a tree which never had produced any others, and which had been known to produce ſuch for twenty years. The kernel in theſe was covered with a reddiſh ſkin, which was rough to the touch; and, within that, with another which was thinner and white. The kernel had nothing particular in it, except that it carried on one ſide of its outer ſurface, and that always in the ſame place, a little ſtony prominence, more or leſs dented on its convex part: this is uſually a twelfth of an inch broad, and two thirds of an inch long, and has no other appearance but that of a diſtempered part of the kernel, only that all the kernels have it.

The thick wrinkled ſkin which ſurrounds the kernel, ſeems in this caſe to ſupply the place of the ſtone or hard ſhell; and in this alſo it reſembles it, that the pulp of the fruit parts eaſily and readily from it: and the hard oblong body, which is placed on one ſide of the kernel, is by no means proper for this purpoſe. *Mem. Acad. Scienc. Par.* 1735.

All the ſorts of Plums are propagated by budding, or grafting them upon ſtocks of the muſcle-Plum, the white pear Plum, the St. Julian, or the bonum magnum.

Budding is much properer than grafting for theſe trees, as they are apt to throw out a great deal of gum from the wound: and the trees ſhould be no more than one year's growth from the bud, when they are tranſplanted; for, if they are more, they ſeldom ſucceed well, being very ſubject to canker; and, if they eſcape that, they uſually produce only two or three luxuriant branches. The whole management of planting and pruning them is the ſame with that of peaches.

If the walls againſt which they are planted are low, they ſhould be ſet eighteen feet aſunder; if they are higher, then fourteen or ſixteen.

Plums ſhould have a middling ſoil, for they ſeldom ſucceed well in too moiſt or too dry a one; and, when planted againſt walls, ſhould have an eaſt or a ſouth-eaſt proſpect. If they have one at full ſouth, they are apt to ſhrivel up, and become mealy.

Plums in general ſucceed very well with proper care on eſpaliers; they will alſo bear very well as ſtandards, but the fruit will be not ſo well taſted. Plums do not only produce their fruit on the laſt year's wood, but alſo on ſpurs that come out of the wood at two or three years old. It is a common error to be too free with the knife in the winter pruning, cutting off the extremities of all the branches; the conſequence of which is, that there is an over quantity of young ſhoots produced, and the fruit is ſmall and poor. *Miller's Gard Dict.*.

PLUMBA'GO, *lead-wort*, in botany, a genus of plants, whoſe characters are:

The root is fibrous, thick, fleſhy, hot, and perennial; the leaves are alternate and entire. The end of the ſhort pedicle unfolds itſelf into a monophyllous, quinquefid, and very hairy calyx, ſhaped like a tube, in whoſe center is ſeated the ovary furniſhed with its proper tube. On the apex of the ovary, grows a monopetalous flower, conſiſting of a long tube, which has its upper part expanded into a circle, ſo as to reſemble the flower of jeſſamin; theſe flowers are diſpoſed in ſpikes. The ſeed is oblong and acuminated.

This is a plant ſeldom or never uſed. It is of an hot and even a cauſtic nature, like pellitory of Spain; and has been made uſe of, like that, for the tooth-ach; it is ſaid, that, even held in the hand, it will cure the pain of the teeth. *Miller's Bot. Off.*

PLUMIE'RIA, in botany, a genus of plants, whoſe characters are:

It has the appearance of the apocynum, and abounds with a lacteous juice. The end of the pedicle paſſes into a little ſhort monophyllous calyx, out of which grows the flower, as in the nerium, but wants the petaloid crown. The ovary, which grows in the bottom of the calyx, becomes a long ſiliquous, double fruit, when opening, likewiſe, and pregnant with a multitude of ſeeds, placed as in the apocynum, but foliated.

This name was given to this beautiful ſpecies of plants, by Dr. Tournefort, in honour to father Plumier, who was botaniſt to the late king of France, and a long time in America, ſearching after new plants; and who has publiſhed a catalogue of the plants, with the new genuſes he conſtituted; and two volumes in folio, with figures and deſcriptions of many of the plants.

Theſe plants grow wild in the Spaniſh Weſt-Indies, from whence ſome of the moſt beautiful kinds were brought into the Engliſh ſettlements in America, and are cultivated in their gardens for ornament. The firſt ſort here mentioned is the moſt common kind, which is preſerved in the gardens of the inhabitants of Jamaica and Barbadoes. The flowers of this kind nearly reſemble thoſe of the red oleander, but are larger, and have an agreeable odour. Theſe are produced in ſmall bunches, at the extremity of the ſhoots, and generally appear in July and Auguſt in this climate, but in the Weſt-Indies they flower a great part of the year.

The milky juice of theſe plants is very cauſtic, and reckoned very poiſonous: in cutting off any of the branches of the plants, if the knife be not immediately cleaned, the juice will corrode it, and turn the blade almoſt black in a very little time, ſo as not to be cleaned off again; and, if dropped on linen, will cauſe it to waſh in holes, equal to aqua fortis.

PLU'MMING, among miners, a term uſed to expreſs the uſing a mine-dial, in order to know the exact place of the work where to ſink down an air-ſhaft, or to bring an adit to the work, or know which way the load inclines, when any flexure happens in it.

It is performed in this manner: a ſkilful perſon with an aſſiſtant, and with pen, ink, and paper, and a long line and a ſun-dial, after his gueſs of the place above ground, deſcends into the adit or work, and there faſtens one end of the line to ſome fixed thing in it; then the incited needle is let to reſt, and the exact point where it reſts is marked with a pen: he then goes farther in, the line ſtill faſtened, and at the next flexure of the adit he makes a mark on the line by a knot or otherwiſe; and then, letting down the dial again, he there likewiſe notes down that point at which the needle ſtands in this ſecond poſition. In this manner he proceeds from turning to turning, marking down the points, and marking the line till he comes to the intended place; this done, he aſcends and begins to work, on the ſurface of the earth, what he did in the adit, bringing the firſt knot in the line to ſuch a place where the mark of the place of the needle will again anſwer its pointing, and continues this till he comes to the deſired place above ground, which is certain to be perpendicularly

POL

larly over the part of the mine into which the air-ſhaft is to be ſunk.

PLUMO'SE *Antennæ*, in natural hiſtory, a term uſed to expreſs the antennæ, or horns of certain moths and butter-flies which are formed in the manner of feathers, being compoſed of a ſtem and fibres, iſſuing on each ſide from it: theſe are jointed and moveable any way, and even the ſmall fibres, at their ſides, are jointed at their bottoms and are moveable, but they move all together. *Reaumur's Hiſt. of Inſects.*

PLY'MOUTH-*marble*, among our artificers, a term uſed for a ſort of marble dug in great plenty about Plymouth and other parts of Devonſhire, where it lies in very thick ſtrata, and whence it is brought in large quantities to us; and, when wrought, looks little leſs beautiful than ſome of the Italian marbles.

It is very hard and firm, and of a beautiful texture; its ground is a bluiſh white, and its variegations are principally a pale red, and in ſmaller quantities brown and yellow: theſe lie in very orderly beds, and often there is a very agreeable glow of a faint red diffuſed through the whole ſubſtance. It is remarkably even in its whole ſtructure, and is therefore capable of a more than ordinarily elegant poliſh.

PO'CKET, in the wool trade, a word uſed to expreſs a large ſort of bag, in which wool is packed up to be ſent from one part of the kingdom to another.

The Pocket contains uſually twenty-five hundred weight of wool.

POD, among botaniſts, a ſpecies of pericarpium, conſiſting of two valves which open from the baſe to the point, and are ſeparated by a membranaceous partition, from which the ſeeds hang by a kind of funiculus umbilicalis.

PODE'RIS, in antiquity, a robe hanging down to the feet; but is chiefly uſed to expreſs a linen garment, a ſurplice, a ſhirt. The Jewiſh prieſts were covered with this kind of long ſurplices, during the time of their attendance in the temple; and this was the proper habit of their order. *Calmet, Dict. Bibl.*

PO'GGE, *or cataphractus*, in zoology, the name of a ſmall ſea-fiſh, caught in the Engliſh and ſome other ſeas.

POINT *of contrary flexure*, (*Dict.*) — The points of contrary flexure and reflexion of curves are uſually determined by ſuppoſing the ſecond fluxion of the ordinate to be nothing or infinite, that is, $\ddot{y} = o$, or *o o*, or $d\,d\,y = o$, or *o o*. See *L'Hopital Analyſe des Inf. petits.*

But this rule is liable to ſeveral exceptions, as is ſhewn very fully and clearly by Mr. Mac Laurin, in his Treatiſe of Fluxions.

The ordinate *y* paſſes through a point of contrary flexure, when, the curve being continued on both ſides of the ordinate, $\dot{y}$ is a maximum, or minimum. But this does not always happen when $\ddot{y} = o$, or *o o*. Mr. Mac Laurin obſerves in general, that if $\ddot{y}$, $\dddot{y}$, $\ddddot{y}$, &c. vaniſh, the number of theſe fluxions being odd, and the fluxion of the next order to them having a real and infinite value; then *y* paſſes through a point of contrary flexure; but, if the number of fluxions that vaniſh be even, it cannot be ſaid to paſs through ſuch a point, unleſs it ſhould be allowed that a double infinitely ſmall flexure can be formed at one point. *Lib. cit.*

The curve being ſuppoſed to be continued from the ordinate *y*, on both ſides, if $\dot{y}$ be infinite, the extremity of the ordinate is not therefore always a point of contrary flexure, as $\dot{y}$ is not always, in this caſe, a maximum, or minimum, and the curve may have its concavity turned the ſame way on both ſides of the ordinate. But theſe caſes may be diſtinguiſhed by comparing the ſigns of $\ddot{y}$ on the different ſides of the ordinate; for, when theſe ſigns are different, the extremity of *y* meeting the curve is a point of contrary flexure.

The ſuppoſitions $\dot{y} = o$, or *o o*, and of $\ddot{y} = o$, or *o o*, ſerve to direct us where we are to ſearch for the maxima and minima, and for points of contrary flexure; but we are not always ſure of finding them. For though an ordinate or fluxion that is poſitive, never becomes negative at once, but increaſing or decreaſing gradually; yet, after it has decreaſed till it vaniſh, it may thereafter increaſe, continuing ſtill poſitive, or, after increaſing till it becomes infinite, it may thereafter decreaſe without changing its ſign.

POINT *of reflexion*, in geometry, is commonly uſed inſtead of Point of retrogradation, or retrogreſſion.

Hop-POLES, the upright pieces of wood that ſerve for the Hops to twiſt round and grow upon.

The number, length, and bigneſs of the Poles are to be regulated according to the bigneſs of the hills, and their diſtance, and the nature of the ground and ſtrength of the plants. If the hills are wide, there muſt be the more Poles, ſometimes four or five to a hill, or more than that; but, if they ſtand near, two may ſerve for every hill. In hot, dry, and hungry ground, the Poles ſhould ſtand nearer than in rich mellow land, where they are more ſubject to grow groſs and heavy.

If the plants are ſtrong, and the ground rich, the Poles muſt be both large and long, or elſe the crop will ſuffer greatly: if the crop be poor, it is beſt to have but few, and thoſe ſmall and ſhort Poles, otherwiſe the hop will eaſily run itſelf out of heart, and the root will be impoveriſhed.

The Poles ſhould never be made over long the firſt year. The propereſt wood for hop-Poles is the aſh or the alder, and, if they have a ſort of fork at the top, they will keep up the hop the better. The Poles are to be diſpoſed between the hills, to be in readineſs; but they muſt not be ſet up till the plants begin to appear, that it may be known where they ought to be placed. This may be continued till the plants are a yard high, but it ought to be finiſhed at that time, becauſe the plants will be ſtinted or injured in their growth, if they have not ſomething to ſupport them, when arrived at that height.

The Poles muſt be placed not in the hill, but near that part of it out of which each plant to be ſupported grows. They muſt be driven far enough into the ground, ſo that they may rather break than be torn up. Their depth is to be judged by the nature of the ground, their own height, and their expoſure to the wind. Let all the Poles lean outward one from another, that they may ſeem to ſtand at an equal diſtance at the top, to prevent the choaking up the plants below: and they ſhould always lean towards the ſouth, that the ſun may the better ſhine in among them. A ſloping Pole is always more ready to bear a quantity of hops than an upright one, and the ſun ſhines on more of the plants at once by means of it. It is always neceſſary to keep ſome ſpare Poles, by way of reſerve, to be ready in caſe of the others breaking; for, in this caſe, the hops are ſoon ſpoiled with lying on the ground. If a Pole be over-burthened with hops, they may be unwound, and wrapped round a ſtronger Pole put in the place of the other.

The largeſt ſort of hop-Poles ſhould be twenty feet long, and nine inches in circumference, for hops at full growth; and they ſhould be polled about fourteen days after the dreſſing in of rich land. An acre of hop ground generally requires about three thouſand poles.

When the hops are grown to three feet high, they are to be conducted to ſuch of the Poles as are neareſt, or have feweſt hops on them; and they are to be wound about theſe Poles according to the courſe of the ſun, and tied to them looſely with ſome ruſhes, or with ſoft yarn: two or three ſtrings are ſufficient to each Pole, and great care is to be taken that the young ſhoots are not broken in the doing this: they are much more brittle in the morning than the heat of the day. During the months of April and May the plants are to be carefully attended, and kept turned round the Poles; and, when out of reach, a fork, ſtick, or ladder are to be uſed to this purpoſe.

About Midſummer they uſually leave running at length, and begin to branch; ſuch as do not, ſhould have the end broke off, to incline them to it, it being much to the advantage of the owner that they ſhould branch out. From the middle of May to the end of ſummer, the ground between the Poles ſhould be dug or turned up with a plough, to kill the weeds; and the earth about the hills raiſed higher, to keep them moiſt. *Mortimer's Huſb.*

POLAEDRA'STYLA, in natural hiſtory, the name of a genus of cryſtals. The word is derived from the Greek πολὺς, many, ἕδρα, ſides, the privative particle α, not, and στῦλος, a column; and expreſſes a cryſtal compoſed of many planes and having no column.

The bodies of this genus are cryſtals compoſed of two octangular pyramids, joined baſe to baſe, and conſequently the whole body conſiſting of ſixteen planes. Of this genus there are only two known ſpecies: 1. A brown kind with ſhort pyramids, found in conſiderable plenty in Virginia, on the ſides of hills; and, 2. A colourleſs one, with longer pyramids. This has yet been found only in one place, which is the great mine, at Goſſelaer, in Saxony, and there uſually lies at great depths. *Hill's Hiſt. of Foſſ.*

PO'LISHING *of ſhells*. This is an art of no long ſtanding in the world, in its preſent perfection; and as the love of ſea-ſhells is become ſo common among us, it may not be diſagreeable to the reader to find ſome inſtructions in executing ſo pleaſing a method of adding to their natural beauty, and the rules for which are at preſent ſo little known, though the effect of them be ſo much eſteemed.

Among the immenſe variety of ſhells which we are acquainted with, ſome are taken up out of the ſea, or found on its ſhores, in all their perfection and beauty; their colours being all ſpread by nature upon the ſurface, and their natural poliſh ſuperior to any thing art could give. Where nature is in herſelf thus perfect, it were madneſs to attempt to add any thing to her charms; but in others, where the beauties are latent, and covered with a coarſer outer ſkin, art is to be called in, and, the outer veil being taken off, all the internal beauties appear.

Among the ſhells which are found naturally poliſhed are the porcelanes, the caſſanders, the dolia, or conchæ globoſæ, the buccinums, the cornets, and the cylinders, or, as they are generally, though improperly called, the rhombi; excepting only two or three, as the tiara, the plume, and the butter-tub rhombus; where there is an unpromiſing film on the ſurface, hiding a very great ſhare of beauty within.

Though the generality of the ſhells of theſe genera are taken out

out of the sea in all their beauty, and in their utmost natural polish, there are several other genera in which all or most of the species are taken up naturally rough and foul, and covered with an epidermis, or coarse outer skin, which is in many rough and downy or hairy. The tellinæ, the muscles, the cochleæ, and many others are of this kind. The more nice collectors, as naturalists, insist upon having all their shells in their native and genuine appearance, as they are found, when living, at sea; but the ladies who make collections, hate the disagreeable outsides, and will have all such polished: it would be very advisable, however, for both kinds of collectors to have the same shells in different specimens, both rough and polished; the naturalist would by this means, besides knowing the outside of the shell, be better acquainted with its internal characters than he otherwise could be, and the lady would have a pleasure in comparing the beauties of the shell, in its wrought state, to its coarse appearance as nature gives it. How many elegances in this part of the creation must be wholly lost to us, if it were not for the assistance of an art of this kind! many shells in their native state are like rough diamonds, and we can form no just idea of their beauties till they have been polished and wrought into form.

Though the art of Polishing shells is a very valuable one, yet it is very dangerous to the shells; for, without the utmost care, the means used to polish and beautify a shell will often wholly destroy it. When a shell is to be polished, the first thing to be examined is, whether it have naturally a smooth surface, or be covered with tubercles or prominences.

A shell which has a smooth surface, and a natural dull polish, need only be rubbed with the hand, or with a piece of chamoy leather, with some tripoli or fine rotten-stone, and it will become of a perfectly bright and fine polish. Emery is not to be used on this occasion, because it wears away too much of the shell. This operation requires the hand of an experienced person, that knows how superficial the work must be, and where he is to stop; for, in many of the shells, the lines are only on the surface, and the wearing away ever so little of the shell defaces them. A shell that is rough, foul, and crusty, or covered with a tartarous coat, must be left a whole day steeping in hot water: when it has imbibed a large quantity of this, it is to be rubbed with rough emery on a stick, or with the blade of a knife, in order to get off the coat. After this, it may be dipped in diluted aquafortis, spirit of salt, or any other acid; and, after remaining a few moments in it, be again plunged into common water. This will greatly add to the speed of the work. After this it is to be well rubbed with linen cloths, impregnated with common soap; and, when by these several means it is made perfectly clean, the polishing is to be finished with fine emery and a hair brush. If after this the shell, when dry, appears not to have so good a polish as was desired, it must be rubbed over with a solution of gum-arabic; and this will add greatly to its gloss, without doing it any sort of injury. The gum-water must not be too thick, and then it gives no sensible coat, only heightening the colours. The white of an egg answers this purpose also very well; but it is subject to turn yellow. If the shell has an epidermis which will by no means admit the Polishing of it, it is to be dipped several times in diluted aquafortis, that this may be eaten off; and then the shell is to be polished in the usual way with putty, fine emery, or tripoli, on the hair of a fine brush. When it is only a pellicle that hides the colours, the shells must be steeped in hot water, and after that the skin worked off by degrees with an old file. This is the case with several of the cylinders, which have not the natural polish of the rest.

When a shell is covered with a thick and fatty epidermis, as is the case with several of the muscles and tellinæ: in this case aqua-fortis will do no service, as it will not touch the skin; then a rough brush and coarse emery are to be used; and, if this does not succeed, seal skin, or as the workmen call it fish-skin and pumice-stone, are to be taken in to assist.

When a shell has a thick crust, which will not give way to any of these means, the only way left is to plunge it several times into strong aqua-fortis, till the stubborn crust is wholly eroded. The limpets, auris marina, the helmet-shells, and several other species are of this kind, and must have this sort of management; but as the design is to shew the hidden beauties under the crust, and not to destroy the natural beauty and polish of the inside of the shell; the method of using the aquafortis must be this: a long piece of wax must be provided, and one end of it made perfectly to cover the whole mouth of the shell; the other end will then serve as a handle, and, the mouth being stopped by the wax, the liquor cannot get in to the inside to spoil it; then there must be placed on a table a vessel full of aqua-fortis, and another full of common water.

The shell is to be plunged into the aqua-fortis, and, after remaining a few minutes in it, is to be taken out and plunged into the common water. The progress the aqua-fortis makes in eroding the surface is thus to be carefully observed every time it is taken out: the point of the shell, and any other tender parts, are to be covered with wax, to prevent the aquafortis from eating of them away; and, if there be any worm holes, they also must be stopped up with wax, otherwise the aqua-fortis would soon eat through in those places. When the repeated dippings into the aqua-fortis shew that the coat is sufficiently eaten away, then the shell is to be wrought carefully with fine emery and a brush; and, when it is polished as high as can be by this means, it must be wiped clean and rubbed over with gum-water, or the white of an egg. In this sort of work the operator must always have the caution to wear gloves, otherwise the least touch of the aqua-fortis will burn the fingers, and turn them yellow; and often, if it be not regarded, will eat the skin and the nails.

These are the methods to be used with shells, which require but a moderate quantity of the surface to be taken off; but there are others which require to have a larger quantity taken off, and to be uncovered deeper; this is called entirely scaling a shell. This is done by means of an horizontal wheel of lead or tin, impregnated with rough emery; and the shell is wrought down in the same manner in which stones are wrought by the lapidary. Nothing is more difficult, however, than the performing this work with nicety: very often shells are cut down too far by it, and wholly spoiled; and, to avoid this, a coarse vein must be often left standing in some place, and taken down afterwards with the file, when the cutting it down at the wheel would have spoiled the adjacent parts.

After the shell is thus cut down to a proper degree, it is to be polished with fine emery, tripoli, or rotten stone, with a wooden wheel turned by the same machine as the leaden one, or by the common method of working with the hand with the same ingredients, when a shell is full of tubercles, or protuberances, which must be preserved. It is then impossible to use the wheel; and, if the common way of dipping into aqua-fortis be attempted, the tubercles, being harder than the rest of the shell, will be eat through before the rest is sufficiently scaled, and the shell will be spoiled: in this case, industry and patience are the only means of effecting a polish. A camel's hair pencil must be dipped in aqua-fortis, and with this the intermediate parts of the shell must be wetted, leaving the protuberances dry: this is to be often repeated, and, after a few moments, the shell is always to be plunged into water to stop the erosion of the acid, which would otherwise eat too deep, and destroy the beauty of the shell. When this has sufficiently taken off the foulness of the shell, it is to be polished with emery of the finest kind, or with tripoli, by means of a small stick; or the common Polishing-stone used by the gold-smiths may be used.

This is a very tedious and troublesome thing, especially when the echinated oysters and murexes, and some other such shells, are to be wrought; and what is worst of all is, that, when all this pains has been taken, the business is not well done; for there still remain several places which could not be reached by any instrument; so that the shell must necessarily be rubbed over with gum-water, or the white of an egg afterwards, in order to bring out the colours and give a gloss; in some cases it is even necessary to give a coat of varnish.

These are the means used by artists to brighten the colours, and add to the beauty of shells; and the changes produced by Polishing in this manner are so great, that the shell is often not to be known afterwards for the same it was; and hence we hear of new shells in the cabinets of collectors, which have no real existence as separate species, but are the polished appearance of others well known. To caution the reader against errors of this kind, it may be proper to add the most remarkable species thus usually altered.

The onyx-shell, which in its natural state is of a simple pale brown, when it is wrought slightly, or polished with just the superficies taken off, is of a fine bright yellow; and when it is eat away deeper, it appears of a fine milk-white with the lower part bluish: it is in this state that it is called the onyx-shell; and it is preserved in many cabinets in its rough state, and in its yellow appearance, as different species of shells. The violet shell, so common among the curious, is a species of porcelane, which does not appear in that elegance till it has been polished; and the common auris marina shews itself in two or three different forms, as it is more or less deeply wrought. In its rough state it is dusky and coarse, of a pale brown on the outside and pearly within; when it is eaten down a little way below the surface, it shews variegations of black and green, and, when still farther eroded, it appears of a fine pearly hue within and without. The nautilus, when it is polished down, appears all over of a fine pearly colour; but, when it is eaten away but to a small depth, it appears of a fine yellowish colour with dusky hairs. The burgau, when entirely cleared of its coat, is of the most beautiful pearl-colour; but, when only slightly eroded, it appears of a variegated mixture of green and red; whence it has been called the parroquet-shell. The common helmet-shell, when wrought, is of the colour of the finest agate: and the muscles in general, though very plain shells, in their common appearance, become very beautiful when polished, and shew large veins of the most elegant colours. The Persian shell in its natural state is all over white, and covered with tubercles; but when it has been ground down on a wheel, and polished, it appears of a very grey-colour with spots, and veins of a very bright and highly polished white. The limpets in general become very different when polished, most of them shewing very elegant colours; amongst these the tortoise-shell-limpet is the principal; it does not appear at all of that colour or transparency till it has been wrought.

The elegant species of shell called the junquil-chama, which has

has deceived so many judges of these things into an opinion of its being a new species, is only a white chama with a reticulated surface; but, when this is polished, it loses at once its reticular work and its colour, and becomes perfectly smooth, and of a fine bright yellow: and the violet-coloured chama of New England, when worked down and polished, is of a fine milk-white, with a great number of blue veins disposed like the variegations in agates.

The asses-ear-shell, when polished, after working it down with the file, becomes extremely glossy, and obtains a fine rose-colour all about the mouth. These are some of the most frequent among an endless variety of changes wrought on shells by Polishing; and we find there are many of the very greatest beauties of this part of the creation which must have been lost, but for this method of searching deep in the substance of the shell for them.

The Dutch are very fond of shells, and are very nice in their manner of working them: they are under no restraint, however, in their works, but use the most violent methods, so as often to destroy all the beauty of the shell. They file them down on all sides, and often take them to the wheel, when it must destroy the very characters of the species; nor do they stop at this, but, determined to have beauty at any rate, they are for improving upon nature, and frequently add some lines and colours with a pencil, afterwards covering them with a fine coat of varnish; so that they seem the natural lineations of the shell: the Dutch cabinets are by this means made very beautiful, but they are by no means to be regarded as instructors in natural history. There are some artificers of this nation who have a way of colouring shells all over with a different tinge from that which nature gives them; and the curious are often deceived by these tricks into the purchasing them as new species.

There is another kind of work bestowed on certain species of shells, particularly the nautilus; this is the engraving on it lines and circles, and figures of stars, and other things: this is too obvious a work of art to suffer any one to suppose it natural. Bonani has figured several of these wrought shells at the end of his work, but it is miserably throwing away labour to do them; the shells are spoiled as objects of natural history by it, and the engravings seldom worth any thing. They are principally done in the East-Indies.

Shells are subject to several imperfections; some of these are natural, and others accidental: the natural ones are the effect of age, or sickness in the fish. The greatest mischief happens to shells by the fish dying in them. The curious in these things pretend to be always able to distinguish a shell taken up with the fish alive, from one found on the shores: they call the first a living, the second a dead shell, and say that the colours are always much the faintest in the dead shells. When the shells have lain long dead on the shores, they are subject to many injuries, of which the being eaten by sea worms is not the least: age renders the finest shells livid or dead in their colours.

The finest shells are those which are fished up at sea, not found on the shores. The other natural defects of shells are their having morbid cavities, or protuberances, in parts where their should be none. When the shell is valuable, these faults may be hid, and much added to the beauty of the specimen, without at all injuring it as an object of natural history, which should always be the great end of collecting these things. The cavities may be filled up with mastic, dissolved in spirit of wine, or with isinglass; these substances must be either coloured to the tinge of the shell, or else a pencil dipped in water-colours must finish them up to the resemblance of the rest, and then, the whole shell being rubbed over with gum-water, or with the white of an egg, scarce any eye can perceive the artifice: the same substances may also be used to prepare the battered edge of a shell, provided the pieces chipped off be not too large. And, when the excrescences of a shell are faulty, they are to be taken down with a fine file. If the lip of a shell be so battered that it will not admit of repairing by any cement, the whole must be filed down to an evenness, or ground on the wheel.

POLLI'CIPES, *the toe-shell*, in natural history, the name of a genus of shells, the characters of which are these: they are multivalve flat shells, of a triangular figure, each being composed of several laminæ, which end in a sharp point. They stand upon pedicles, and are furnished with a great number of hairs. We have only one known species of this genus, and this always found in large clusters.

PO'LVERINE, the calcined ashes of a plant; a substance of the nature of our pot-ashes, or pearl-ashes.

It is brought from the Levant and Syria; but in the glass trade, though it be of the nature of the other ashes they use, it is always to be preferred to any other. The barillia, or pot-ashes of Spain, yield more pure salt than the Polverine of the Levant, but the glass made with it has always some tinge of bluishness: that made with the Polverine is ever perfectly white, and this is the substance that ought always to be used for the finest crystal.

The method of procuring the pure salt from these ashes, is to sift them and throw them in a proper quantity into a large copper of boiling water, continuing the boiling till all the salt of the ashes be dissolved by the water, and adding to the water, before the Polverine is put in, about ten pounds of tartar calcined to a blackness. The lee or water, thus impregnated with the salt, must stand a considerable time to settle; and, when perfectly clear, must be evaporated till it thicken, and begin to shew a white dry salt about its edges: then the fire must be kept very slow, and, a skimmer full of holes being sunk into the bottom of the copper, the salt will gather and harden upon it; and this must be taken out every now and then, and the salt taken off and dried for use. Three hundred pounds of Polverine thus yield eighty or ninety pounds of clear salt. When this is dried, it must be slightly calcined in the glass furnace, and then powdered and sifted through a coarse sieve, and kept dry. *Neri's Art of Glass.*

POLYADE'LPHIA *, in botany, a class of plants, whose stamina are formed into three or more separate bodies.

* The word is derived from the Greek πολὺς, many, and ἀδελφὸς, communiter. Among the plants of this class are orange-trees, St. John's wort, &c.

POLYA'NDRIA *, in botany, a class of plants, with hermaphrodite flowers, and a large number of stamina, or male parts, in each.

* The word is derived from the Greek πολὺς, many, and ἀνὴρ, male. The hermaphrodite flowers of this class have a large number of stamina on each, always more than twelve, and those growing to the receptacle of the future seeds.

Of this class are the water-lily, poppy, celandine, &c.

POLYA'NTHUS (*Dict.*) — A great number of plants, called Polyanthus, are found in our gardens; they are all species of a genus called primula. See PRIMULA.

The several varieties of Polyanthus's are produced by sowing of seeds, which should be saved from such flowers as have large upright stems, producing many flowers upon a stalk, the flowers large, beautifully striped, and that open flat: from the seeds of such flowers, there is room to hope for a great variety of good sorts.

These seeds should be sown in boxes filled with light earth, in December, being very careful not to bury the seed too deep; for, if it be only covered with light earth, it will be sufficient: these boxes should be placed where they may receive the benefit of the morning-sun until ten of the clock; but must by no means be exposed to the heat of the day, especially when the plants begin to appear; for at that time one whole day's sun will intirely destroy them: in the spring, if the season should prove dry, you must often refresh them with water; and, as the heat increases, you should remove the boxes more in the shade; for the heat is very injurious to them.

In May, these plants will be strong enough to plant out; at which time you should prepare some shady borders, which should be made rich; upon which you must set the plants about four inches asunder, observing to water them until they have taken root; after which they will require no farther care but to keep them clean from weeds, until the latter end of August following; when you should prepare some borders, which are exposed to the east, with a good light rich earth, into which you must transplant your Polyanthus's, placing them six inches asunder equally in rows, observing, if the season proves dry, to water them until they have taken root. In these borders your plants will flower the succeeding spring; at which time you must observe to mark such of them as are fine, to preserve; and the rest may be transplanted into wildernesses, and other shady places in the garden; where, though they are not very valuable flowers, they will afford an agreeable variety.

Those which you intend to preserve, may be removed soon after they have done flowering (provided you do not intend to save seeds from them) and may be then parted and transplanted into a fresh border of the like rich earth, allowing them the same distance as before; observing also to water them until they have taken root, after which they will require no farther care, but only to keep them clean from weeds; and the following spring they will produce strong flowers; and, if the kinds are good, will be little inferior to a shew of auricula's.

These roots should be constantly removed and parted every year, and the earth of the border changed, otherwise they will degenerate, and lose the greatest part of their beauty.

If you intend to save seeds, which is the method to obtain great variety, you must mark such of them, which, as I said before, have good properties: these should be, if possible, separated from all ordinary flowers; for, if they stand surrounded with plain-coloured flowers, they will impregnate each other; whereby the seeds of the valuable flowers will not be near so good, as if the plants had been in a separate border where no ordinary flowers grew; therefore, the best way is to take out the roots of such as you do not esteem, as soon as the flowers open, and plant them in another place, that there may be none left in the border, but such as you would chuse for seeds.

The flowers of these should not be gathered, except such as are produced singly upon pedicles, leaving all such as grow in large bunches; and, if the season should prove dry, you must now and then refresh them with water, which will cause their seeds to be larger, and in greater quantity, than if they were intirely neglected.

Towards the latter-end of May, the seed will be ripe, which may be easily known by the pods changing brown, and opening; so that you should at that time look over it three times a week, gathering each time such of it as is ripe, which should

ſhould be laid upon a paper to dry, and may then be put up until the ſeaſon of ſowing. *Miller's Gard. Dict.*

POLYCRO'TA, in the naval architecture of the ancients, a word uſed to expreſs ſuch of their gallies as had three, four, five, or more tires of rowers, ſeated out different heights; they were diſtinguiſhed by this term from the monocrota, or thoſe which had only ſingle rows of oars.

POLYGA'LA, *milkwort*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the perſonated kind, conſiſting of one leaf, not perforated behind, and divided before into two lips; the upper lip is bifid, and the lower one elegantly fimbriated. The piſtil ariſes from the lower part of the flower, and ripens at length into a fruit or capſule of a compreſſed figure, divided into two cells, and full of oblong ſeeds. The fruit is uſually found ſurrounded with the cup of the flower, which conſiſts of five leaves, two large and three ſmall ones, which claſp round the ſeed veſſel in the manner of ſo many wings.

Dr. Tennent gives his rattle-ſnake-root, or Virginian Polygala, in the doſe of thirty-five grains in ſubſtance, or in three or four ounces of a ſtrong infuſion, or in a yet ſtronger, in a proportionably ſmaller doſe. The effects of this root being found very great, it was ſuppoſed that its place might poſſibly be ſupplied by this ſpecies of our own growth. It is very certain, that the place of growth may, in ſome plants, make a very great alteration in their virtues; and that the different ſpecies of the ſame genus may, in other inſtances, produce different effects in the human body, ſome ſpecies of plants agreeing in their external forms and generical characters, while they differ in their virtues and qualities.

There appeared on trial a conſiderable difference to the taſte between the American and the European Polygala roots, that of Virginia being very aromatic, acrid, and bitter, and the European only ſlightly acrid, with a very feeble bitterneſs. Another thing that gave great ſuſpicion as to the parallel virtues of the roots of theſe two ſpecies was, that Geſner was found, in his account of virtues of the European Polygala, to call it a very briſk cathartic; a quality which might render its uſe very improper in many of the diſeaſes in which Mr. Lemery and Juſſieu found the Virginian kind to prove a ſerviceable medicine. This laſt was found always very ſpeedily to allay fevers of the pleuritic kind, without increaſing in any great degree the diſcharges by ſtool.

The roots of the European Polygama, being very ſmall and ſlender, gave alſo ſome trouble as to the procuring them in ſufficient quantity; and in hopes it might become a general medicine, it was determined to try the effects of the whole plant, root, leaf, and branch, in the diſeaſe in which the Virginian kind had been given with the greateſt ſucceſs, that is, in pleuriſies; and this was accordingly fairly tried.

The principal inſtances of their trials were two; the firſt to a woman of twenty-two years old, who had a violent fever, with a ſizy blood, and pain in the ſide. She was twice blooded, and had immediate, but not laſting relief from it, and was ordered the common ptiſans given on theſe occaſions. The malady increaſed, and the expectoration was but ſmall, and that of a thick yellow matter: a third bleeding finally was judged neceſſary, but was of no more ſervice than the others; and after this ſhe had the ſame ptiſan continued, but with the addition of a large quantity of the common European Polygala, ſtalk, root, and leaf. This took place in two or three hours, the expectoration became vaſtly plentiful, and the matter thin and white, from being thick and yellow. The woman, in fine, was cured, and the medicine was not obſerved to occaſion any nauſea, nor did it prove, as ſuppoſed, a violent purge.

The ſecond inſtance was in a man of a ſtout robuſt habit, and of twenty-five years of age. He was violently attacked with a pleuriſy; he was bled ſeven times, and was brought into one of the hoſpitals delirious, and ſeemingly very near death: he was there blooded in the foot, which reſtored his ſenſes; and he took a large quantity of the decoction of the Polygala, which cauſed him to expectorate in great abundance. The matter was firſt blackiſh, then reddiſh, and finally white, and the patient was perfectly cured. *Mem. Acad. Scienc. Par.* 1739.

Theſe are ſuch remarkable inſtances of the good effect of an herb to be had every-where in our own country, that they ſeemed very worthy to be recorded. The plant grows with us on dry grounds and heaths, and is about four inches long, not erect, but trailing upon the ground: the leaves are long and narrow, of a pale green, and the flowers are large and look beautiful: they ſtand in ſpikes, and are uſually blue; but very often white, and ſometimes red. The herb ſhould be pulled up root and all for drying.

POLYGLO'TTA *avis*, in zoology, the name of a bird deſcribed by Nieremberg, and which, he ſays, he ſaw and heard with admiration, ſinging in all tones. It is of the ſize of our ſtarling.

Its back is brown, and its breaſt and belly white; and near the neck and tail it is variegated with ſpots and ſtreaks of white. Its head has a ſtreak of white, which repreſents a ſort of crown of ſilver. It is mightily eſteemed, and kept in cages by the Spaniards, as infinitely ſuperior to all other birds in melody. It feeds on almoſt any thing that is given it, and is moſt fond of the warmer climates; but endures the more temperate ones without harm. *Ray's Ornithology.*

POLYGA'MIA *, in botany, a claſs of plants, which have a diverſity of combinations of male and female parts of their flowers, and many ways of fructification in the ſame ſpecies; ſome having male flowers, others female, each diſtinct and perfect in its kind; and others mixed, or hermaphrodite, with both male and female organs of fructification in each. See *Plate* XXXVI. *fig.* 6.

* The word is derived from the Greek πολὺς, many, and γάμος, marriage.

Among the plants of this claſs are the orach, pellitory of the wall, the aſh, &c.

POLYGON, *in fortification* (*Dict.*)—In order to ſhew the method of fortifying regular Polygons, it will be neceſſary to give a table ſhewing the meaſures of the principal lines and angles, in all regular works of this kind from four to twelve ſides incluſive.

A table of Polygons, ſhewing the meaſure of their lines, angles, &c.

Dodecagon	Undecagon	Decagon	Nonagon	Octagon	Heptagon	Hexagon	Pentagon	Square	Names of the Polygons.
360	360	360	360	360	360	360	360	360	The exterior ſide in yards.
695,46	638,78	582,50	526,28	470,36	414,82	360,00	306,24	254,56	Radius of exterior ſide in yards.
300,20	292,60	288,52	285,86	280,06	272,44	261,26	247,90	231,00	Interior ſide in yards.
572,14	519,36	466,90	417,86	365,96	313,96	261,26	210,00	163,34	Radius of interior ſide in yards.
123,32	119,42	115,60	108,42	104,40	100,06	98,68	95,34	91,22	Capital in yards.
86	82	78	72	68	64	60	54	45	Normal in yards.

98 56	98 16	97 08	96 24	93 36	89 26	83 08	74 36	61 56	Angle of baſtion, or flanked angle.
25 32	24 30	23 26	21 48	20 42	19 34	18 26	16 42	14 02	Diminiſhed angle.
128 56	131 00	133 08	136 24	138 36	140 52	143 08	146 36	151 56	Exterior flanked angle.
46 yds.	44 yds.	42 yds.	40 yds.	40 yds.	40 yds.	36 yds.	33 yds.	30 yds.	Breadth of the foſs, in yards.

By the help of this table, every thing relative to the maſter line of any of theſe fortreſſes are readily conſtructed.

1. To deſcribe any of the Polygons in the table.

Firſt. To conſtruct a Polygon in a circle. *Plate* XXXIII. *fig.* 10.

1. With the exterior radius of the given Polygon deſcribe a circle.

2. Apply the exterior ſide equal to 360 yards within the circumference of that circle, from A to B, B to C, C to D, &c. as many times as the propoſed Polygon has ſides.

3. Draw the lines AB, BC, CD, &c. and the Polygon will be conſtructed.

Secondly. To conſtruct a Polygon upon the exterior ſide. *Plate* XXXIII. *fig.* 11.

1. Draw the exterior ſide AB equal to 360 yards.

2. At the ends A, B, make angles equal to the angle of the Polygon, and in that position draw the lines A E, B C, each of the length of A B.

3. At the points E, C, make angles as before, and in those positions draw the lines E D, C D, each of the same length as A B.

And thus proceed until the Polygon is constructed.

Note, The two last lines may be found by describing intersecting arcs D, with the radius A B, from the centers E and C.

2. To fortify any regular Polygon in the table.

Or, To draw the master line of a regular fortress.

First. From the exterior side. *Plate* VI. *fig.* 13.

1. Make the exterior side A B equal to 360 yards, and find its middle C.

2. Draw C D at right angles to A B, and make C D equal to the normal.

3. Through D draw the lines of defence A D H, B D G.

4. Make the faces A E, B F, each of their proper lengths.

5. Transfer the distance F E from F to G, and from E to H.

6. Draw the curtin G H, and the flanks E G, F H.

This work being done for every front or side, the master line of the fortress will be described.

This method is most fit, when the master line is to be laid down on a place where there were no works before.

Secondly. To fortify from the curtin.

1. Make the curtin G H of its proper length, for the given Polygon.

2. Make the angles of the curtin H G E, G H F, as per table.

3. In the lines G E, H F, take the flanks G E, H F, of their proper length.

4. Make the angles of the shoulders G E A, H F B, as per table.

5. Make the faces F B, E A, of their proper lengths.

This method is proper to be used when a piece of an old fortification is to serve for a curtin, to save expence.

Thirdly. To fortify from the interior side.

1. Make the interior side I K of the length given in the table for the proposed Polygon.

2. From each end set off its proper demigorge K H and G I.

3. On K and I as centers, with the extent of the capital, as per table, describe arcs at B and A.

4. On H and G as centers, with the length of the line of defence, as per table, cut the former arcs in A and B.

5. Draw the lines A H, B G; in which take the faces A E, B F, and draw the flanks E G, F H.

This method is useful when modern ramparts and bastions are to be annexed to simple walls surrounding a place.

In either of the above methods, the work here described for one front is to be applied to every front of the Polygon; and it is recommended to the learner, that he applies the precepts given for one front to a complete Polygon; and, should a frequent repetition of these operations to a whole Polygon become disagreeable, they may be done only on two fronts, which may be thus drawn.

Draw a capital line A L; make the angles L A B, L A A, each equal to half the angle of the Polygon; and make the sides A B, A A, each equal to 360 yards.

POLYGONA'TUM, *Solomon's seal*, in botany, a genus of plants, whose characters are:

The flower consists of one leaf, is tubulous, and expands at the top in shape of a bell, and is divided into several segments: the ovary, which is situated in the center of the flower, becomes a soft globular fruit, containing roundish seeds.

These plants are easily propagated by parting of their roots in the spring, before they begin to shoot, observing always to preserve a bud to each off-set: they should be planted in a fresh light earth, where they will thrive exceedingly; but, if it be over rich, it will destroy their roots.

POLY'GONUM, *common knot-grass*, in botany, a genus of plants, whose characters are:

The root is creeping, and very fibrous; the stalks and branches are very full of joints; the calyx is deeply cut into five segments, which in their lower part, are herbaceous; but, above, of a flosculous colour; when ripe, the calyx becomes a capsule of seed. The flowers are produced at the wings of the leaves, and are concealed in their first rise under a very thin membrane; the seed is exactly triangular.

Knot-grass is cooling, drying, and binding, a good vulnerary, and helpful against all kinds of bleedings either external or internal, as against fluxes; and outwardly applied, is good for blood-shot inflamed eyes. *Miller's Bot. Off.*

This plant has an herby glutinous taste, and a little acid; it gives a deep tincture of red to the blue paper; it is likely, that the salt of knot-grass resembles alum, but is mixed in this plant with a little sal ammoniac and a great deal of sulphur.

For, by the chemical analysis, it yields a great deal of acid, earth, and oil, a little volatile, concrete, and very lixivial fixed salt.

Knot-grass is very vulnerary and astringent; the juice ptisan, or infusion of it in wine, is given to drink for the dysentery, piles, spitting of blood, and all sorts of hæmorrhages; the extract has the same virtues; the leaves, bruised, cure wounds. *Mart. Tournefort.*

PO'LYPE, or POLYPUS, in zoology, a small fresh water insect, which, when cut into a number of separate pieces, becomes in a day or two so many distinct and separate animals; each piece having the surprising property of producing a head and tail, and the other organs necessary for life, and all the animal functions. See *Plate* XXXIV. *fig.* 8, 9, 10, 11, 12.

The first discovery of this animal was owing to Mr. Leuwenhoek, who, in the year 1703, presented to the royal society of London a description of it, and an account of its uncommon way of producing its young: but the discovery of its amazing property of reproducing the several organs from its various pieces, was not made till the year 1739, by Mr. Trembley, at the Hague.

The production of its young is, indeed, different from the common course of nature in other animals; for the young one issues out from the side of its parent, in form of a small pimple or protuberance, which lengthening and enlarging every hour, becomes, in about two days, a perfect animal, and drops from off its parent to shift for itself: but before it does this, it has often another growing from its side; and sometimes a third from it, even before the first is separated from its parent. They breed quicker in hot than in cold weather; and what is very extraordinary is, that there never has yet been discovered among them any distinction of sex, or appearance of copulation; every individual of the whole species being prolific, and that as much if kept separate, as if suffered to live among others.

If the method of this little animal's producing its young be very amazing, its production of the several parts, when cut off, is much more so. The discovery of this was perfectly accidental; for Mr. Trembley, who had often met with the creature in the water, and from its fixed residence in one place, and some other observations, not being able to determine whether it were an animal or a vegetable, made the trial by cutting it asunder, when, to his amazement, he found, that in a few days each of these pieces was become a perfect animal, the head part having shot forth a tail, and the tail a head. A thousand other trials, by cutting the animal in different manners, first by Mr. Trembley, and afterwards, at his request, by Monf. Reaumur at Paris, and Mr. Folkes, Mr. Baker, and the other naturalists in England, were the result of this; and all succeeded in the same manner, by whoever they were tried.

It is not easy to say what is the size of this creature; for it can contract or extend its body at pleasure from the length of an inch or more, and the thickness of a hog's bristle, to the shortness of a single line, with a proportionable increase of thickness. Its body is round and tubular, at one end of which is the head, surrounded with six, eight, ten, or more arms, with which it catches its prey; and at the other, the anus and tail, by which it fixes itself to any thing it pleases.

There have been many different species of it discovered, the most elegant of which, the Polype a pannache, or plumed Polype, of Mr. Trembley, seems much to resemble the wheel-animal, so called from having the appearance of two wheels in its head, which Mr. Leuwenhoek discovered living in a sheath or case, and affixed to the roots of duckweed.

All the species are found in clear and slowly running waters, adhering by the tail to sticks, stones, and water-plants, and live on small insects. They are easily kept alive a long time in glasses, often changing the water, keeping the glasses clean, and feeding them with a small red worm, common in the mud of the Thames, or with other small insects.

The creature has its name from the Greek πολὺς, many, and πȣ̃ς, a foot, signifying an animal with many feet; but a more apposite one might easily have been invented, since it has in reality no feet at all. What were originally taken for feet, are what have since been called its horns, and of late more properly its arms, their office being to catch its prey.

The several strange properties recorded of this animal, though very surprising, are, however, none of them peculiar to it alone. The Surinam toad is well known to produce its young not in the ordinary way, but in cells upon its back. Mr. Sherwood has very lately discovered the small eels in sour paste to be each, without exception, full of living young ones. And as to the most amazing of all its properties, the reproduction of its parts, we know the crab and lobster, if a leg be broken off, always produce a new one: and Mr. Bonet, Mr. Lyonet, Monf. de Reaumur, and Mr. Folkes, have all found on experiment, that several earth and water worms have the same property, some of them even when cut into thirty pieces. The *urtica marina*, or sea-nettle, has been also found to have the same: and the sea star-fish, of which the Polype is truly a species, though it had long escaped the searches of the naturalists, was always well known by the fishermen to have it also.

Cluster POLYPE, the name of a species of small insect of the Polype kind, called by the French naturalists Polype a bouquet.

There is found on several of the water-plants, and on other substances, as sticks, boards, and the like, accidentally fallen into

into the water, a whitish substance that at first sight appears to be only a sort of mouldiness; but if the bodies on which this is found, be put into a vessel of clear water, and the matter examined with a magnifying glass, it is soon seen that this whitish substance is really a vast number of small animals, which are almost continually in motion. When this is brought before the microscope, the form and structure of the creatures is very evidently distinguished, and they are found to be minute roundish creatures, severally affixed to the end of a sort of stem or tail; and many of the stems are so interwoven and united together, that they form clusters, which have occasioned the name of the cluster-Polype to be given to the animal, though in itself it is really and properly single from the beginning. There are several species of Polype of this minute kind, that cluster themselves in this manner together; and according to these and other circumstances, the clusters are found larger or smaller, and more or less complex. *Phil. Transf.* N°. 474.

The smaller clusters should always be chosen for observation, as in the larger the bodies of the several animals that compose them are apt to hide and obscure one another; but the most beautiful and accurate of all observations is to be formed when they are single, as they are sometimes found; and this is the only opportunity of seeing distinctly in what manner the clusters are formed.

One of these single animals is not in length above the 240th part of an inch, and is of a shape nearly resembling that of a bell: the anterior part of this generally appears open when it presents itself properly; and the posterior part is fixed to the stem or pedicle, by the other extremity of which the creature fastens itself to any solid body that it meets with. The body is of a brownish colour, except at the smaller end, which, as well as the tail, is whitish and transparent; and, when the anterior part is open, there may always be perceived about its edges a very lively motion; and, when the creature presents itself in a better manner, there may be seen, on either side of the edges of the anterior part, somewhat resembling the wheels of a mill, continually moving with great velocity.

These creatures are able to contract their bodies, and often do it very suddenly, especially if any thing disturb the substance on which they are fixed: when they are thus contracted, the edges of their anterior parts are drawn just into their bodies; and, when the fright is over, it is a very agreeable sight to behold these edges turning out again, and putting themselves in motion as before. If the edges of the anterior parts of the bodies of these animals be strictly observed while in motion, the water about them will be found to be full of extremely minute round bodies, which are brought together by means of that motion, and serve the creature for its food: these may be often seen going down into the cavities of the body of the Polype, and that very suddenly, as if forcibly driven down; and, when swallowed too voraciously, are often thrown up again. These observations are best made when a small cluster of the Polypes are examined together.

If these Polypes are kept some time in the rain-water, they by degrees lose their brown colour, and become white and transparent throughout, except that a few spots of a dusky colour remain in their bodies; but if after this they are removed into other water of the same kind with the first, but newly taken out of the ditch, they in a little time recover their brown colour. When they become white, they plainly appear to be in a sickly condition, and cease to multiply; but, when they have fresh water and recover their colour, they immediately begin to multiply again.

These creatures are not absolutely and immoveably fixed to the bodies on which they are placed, but they can at pleasure quit them and swim about: in this swimming state they are always found single, and not in clusters; and they do not then appear in the same form as when they are fixed and open at their anterior ends. When they have swam about as long as they please, they either return to their clusters from which they separated themselves, or affix each singly to any thing they meet with: and this is a circumstance that merits to be carefully watched, because it is by means of this that we see in what manner the creature multiplies itself, and the clusters are formed.

As soon as a single animal of this kind is fixed to a stick, a stone, or any other substance, it begins to lengthen its stem or tail, which, though very short while swimming, and when first fixed, very soon becomes of its pristine length while in the cluster; and after this the creature begins immediately to multiply by the most amazing means in the world; that is, by splitting itself to pieces lengthways. The first motion towards this operation is the drawing in the lips or edges; this is soon done, and the body then loses its bell-like shape, and becomes round; the motion which was before perceived at the edges ceases, and there is only a slight tremulation to be seen within the body; after this the anterior part of the body becomes flat and broad, and the whole body shortens in proportion; and soon after this the whole body gradually splits itself regularly into two, from the center of the anterior part to the center of the hinder end, where it joins the tail or pedicle, and there soon appear two round and perfect bodies joined to that pedicle which before supported only one. The anterior parts of the two bodies soon begin to open, and gradually shew their edges, which perform the same motion the single one did before. The motion is at first very slow, but it grows quicker by degrees as they open; and, when they are perfectly expanded, it is as quick as it was in the original single body: it is at this time that the two bodies may be esteemed quite perfect. They are at first indeed less than the original Polype, from which they were formed, but they grow to the same size in a very little time: the whole operation of dividing itself takes up the creature about an hour; but, to form a true idea of the manner in which it is performed, there must be many observations made, and the creatures must be examined in all views and lights while about it.

The lips of these Polypes, when closely examined, appear to be composed of four or five transparent bands, all which have an undulatory motion. And, when the newly divided Polype is but slow in its motions, it is easy to discover that what afterwards appear to be like the wheels of a mill, are, in reality, only four or five oblong bodies, resembling a sort of fingers which alternately bend down, and extend themselves every instant. These are fastened to the band of the lips on each side of the mouth; and, when they are put into swift motion in the time of the full growth and vigour of the animal, they are not to be distinguished, as to form, nor can their motion be otherwise discovered than by its swiftness, which makes it resemble the quick turning of a wheel.

When the separation of the body of a single Polype of this kind is complete, one sees two regular and perfect bodies adhering side by side to the same pedicle, but soon after each of the new formed bodies begins to shew a pedicle of its own; these grow in a day's time to a moderate length, and unite at their bottoms to the end of what was the original single pedicle of the body while but one; they grow to this in the manner of the branches growing to the trunk of a tree. Twenty-four hours after the separation of the original body into two, these two begin to separate themselves in the same manner, each into two again; and these after a like time again separate: each of these separated animals has its own tail formed in a like period of time with the first; and the consequence is, that the first separation producing two, the second gives four, the third eight, and so the sixth sixty-four, the seventh 128, and so on; by which means a single animal, in a very few days, forms out of itself an immense cluster; each animal of which is perfect in itself, and independent of all the rest, and can, when it pleases, swim away and form a new cluster. They will multiply as fast in glass jars, as in their native free state in the waters; and clusters of them, begun near one another, will often join in such a manner as to form one complex cluster of an inch diameter: from these several clusters there detach themselves single Polypes from time to time, which go off, and fastening themselves to other bodies, become the authors of new progenies. *Phil. Transf.* N°. 474.

The original branch or stem of the first Polype remains always in the center of the cluster; but it is of no use, never afterwards having any body fixed to it.

There are, besides this species here described, four other known kinds of Polype, which divide themselves in the same manner by splitting into two lengthwise: those which come nearest to the first are slenderer, and their stems are more transparent. They are of a bluish colour, when many of them are seen together, and their stems or tails very aptly resemble spun glass. When this species is perfectly formed, the motion of its lips is less distinct than in the other; but it may be discovered in the same manner while they are newly separated and are but growing toward perfection, when it gradually becomes less and less distinct.

Another species of these Polypes is smaller than the last, but more open at the mouth, and deeper hollowed; and these are particularly distinguished from all the others, by having a motion in their stems and branches, which all the others want. The stems draw themselves up, and shorten all at once into the appearance of a spiral screw, and in a moment can dart themselves straight out to their full length again. All these multiply very speedily, but they have all enemies that destroy them in a very terrible manner, whole clusters making but single mouthfuls. The funnel Polypes are nearly allied to these creatures. *Phil. Transf.* N°. 474.

Funnel POLYPE, a name given by naturalists to a small water insect, in some respects approaching to the nature of the cluster Polype.

The funnel Polype nearly resembles a funnel, from which it has its name. It is long and hollow, and very wide at the anterior end. These little animals are of three species, a green, a blue, and a white one: they are all too minute for the observation of the naked eye, and must be viewed with great caution, and in several different directions and attitudes, before their true form can be discovered; and their anterior end, particularly, when carefully observed, is of a much more compound structure than might at first be imagined; there may be always be observed, round the edges of this part, a sensible motion, resembling that of an indented wheel, or rather that of a screw turned nimbly about. These, though they approach to the shape of the cluster Polypes, and resemble them in their having this

this motion about their mouths, yet never have any tendency to form clusters, but are ever found loose and single. There are always a number of little round bodies, which seem to be animals of a very minute size swimming about in the water in which these Polypes live, and these are continually drawn into the mouths of the Polypes, and serve them for food.

The manner of these creatures propagating themselves is very amazing; they do it by dividing their own body into two; but this is not done longitudinally, as in the cluster Polypes, nor transversly, but diagonally from the edge of the head to the opposite edge of the tail; so that, of the two thus formed out of one, the one has a head and no tail, the other a tail and no head; but these deficiencies are soon made up, and the head soon grows out of one, and the tail out of the other. Mr. Trembley, in his account of this insect, calls that of the two which has the old head, the superior Polype; that which has the old tail the inferior. The first particulars observable in a funnel Polype that is going to divide, are the lips of the inferior Polype, or those transparent edges that are so very conspicuous in the creature when perfectly formed. These new lips first discover themselves upon the Polype that is going to divide, from a little below the old lips to about two thirds of the length of the Polype, reckoning from the head: but these new lips are not disposed in a straight line, according to the length of the Polype, but run sloping near half-way round about. These lips are distinguished by their motion; but it is to be observed, that this motion is at first very slow, and requires an attentive eye and good glasses to discover it. *Phil. Transf.* N°. 474.

POLYTRI'CHUM, in botany, the name of a genus of mosses, the characters of which are these: the stalks are not much branched, and the capsules have calyptræ to cover them till mature. This calyptra is always hairy, and in many of the species is composed merely of long hairs, ranged lengthwise together, without any membrane; the others have membranaceous calyptræ, but covered with erect hairs. The leaves of those kinds are rigid, and have a membranaceous appendage, by which they touch the stalks and surround them; those of the others are softer, and have not this appendage. The basis of the pedicle which supports the head, is also in these surrounded by a sort of tube, round which there stand a number of membranaceous leaves; this is more visible in the larger than in the smaller species. The capsules in some of these mosses are square, in others they are roundish; and the square ones have usually an apophysis, by which they are joined to the pedicle, which the round ones never have, or at least very seldom.

POMGRA'NATE (*Dict.*)—These plants may be easily propagated by laying down their branches in the spring, which in one year's time will take good root; and may then be transplanted where they are designed to remain. The best season for transplanting of these trees is in the spring, just before they begin to shoot: they should have a strong rich soil, in which they flower much better, and produce more fruit, than if planted on a dry poor earth: but, in order to obtain these in plenty, there should be care taken in the pruning of the trees; for want of which, we often see these trees very full of small shoots, but do not find many flowers produced upon them; therefore, I shall set down directions for pruning of these trees, so as to obtain a great quantity of flowers and fruit.

The flowers of this tree always proceed from the extremity of the branches which were produced the same year: this therefore directs, that all weak branches of the former year should be cut out, and that the stronger should be shortened in proportion to their strength, in order to obtain new shoots, in every part of the tree: these branches may be laid in against the wall about four or five inches asunder; for, as their leaves are small, there is not a necessity of allowing them a greater distance. The best time for this work is about Michaelmas, or a little later, according to the mildness of the season: but, if they are left until spring before they are pruned, they seldom put out their shoots so early; and, the earlier they come out, the sooner will the flowers appear, which is of great consequence where fruit is desired. In summer, they will require no other dressing, but to cut off very vigorous shoots, which grow from the wall, and never produce flowers (for they are the middling shoots only which are fruitful;) and, when the fruit is formed, the branches on which they grow should be fastened to the wall to support them, otherwise the weight of the fruit, when grown large, will be apt to break them down. See (*plate* XXXVI. *fig.* 7.) where *a* is the flower, *b* the fruit, and *c* the fruit open.

Though, as I said before, the fruit of this tree seldom arrives to any perfection in this country, so as to render it valuable; yet, for the beauty of its scarlet-coloured flowers, together with the variety of its fruit, there should be one tree planted in every good garden, since the culture is not great which they require: the chief care is, to plant them upon a rich strong soil, and in a warm situation. Upon some trees which had these advantages, I have obtained a great quantity of fruit which have arrived to their full magnitude; but I cannot say they were well flavoured; however, they made a very handsome appearance upon the trees. *Miller's Gard. Dict.*

PO'MUM, *the apple.* See APPLE.

POPE (*Dict.*)—The spiritual monarchy of Rome sprung up soon after the declension of the Roman empire; and one great, though remote, instrument in promoting the increase of this monarchy, so pernicious to the supreme civil power, was the barbarity and ignorance, which from that time spread itself over the western parts.

Rome was chosen for the place of residence of the ecclesiastical monarchy, because this city had the particular prerogative of being the capital city of the Roman empire, where the Christian religion had its first rise and increase. For what is related concerning St. Peter's chair, is nothing but a vain pretence. So that here are no footsteps of divine institution to be found, the Papal power being purely human, and an usurpation upon the rights of other sees.

The bishops of Rome did not extend their power over the western parts all at once; but it was introduced from time to time, by degrees, by various artifices, and under various pretences. What chiefly contributed to its growth, was, first, the emperors chusing other places of residence besides Rome; for by their constant presence there they might easily have kept under the ambitious designs of the bishops. In the next place, the western empire was divided into several new kingdoms, erected by the several barbarous and pagan nations; and these, having been converted to the Christian faith by the direction of the Romish church, thought themselves obliged to pay her the profoundest respect.

The spiritual monarchy of Rome could not have been established, had its bishops continued dependent on any temporal prince; and therefore the Popes took their opportunity to exempt themselves from the jurisdiction of the Greek emperors, whose authority was greatly decayed in Italy.

The Pope, having freed himself from the authority of the emperors of Constantinople, and being in danger from the Lombards, who endeavoured to make themselves masters of Italy, had recourse for protection to the kings of France. Pepin, and afterwards Charles the Great, having entirely subdued the Lombards, these princes gave to the papal chair all that tract of land, which had been formerly subject to the Greek emperors. When the Romans mutinied against Leo III, he was forced to seek for assistance from Charles the Great, who restored the Pope. On the other hand, the Pope and people of Rome proclaimed Charles emperor; whereby he was put in possession of the sovereignty of that part of Italy, which formerly belonged to the governors of Ravenna, and the other remnants of the western empire; so that the Popes afterwards enjoyed these countries under the sovereign jurisdiction of the emperor, who therefore used to be called the patron and defender of the church, till the reign of the emperor Henry IV.

The Popes at length began to grow weary of the imperial protection, because the emperors consent was required in the election of a Pope, and, if they were mutinous, the emperors used to check them, and sometimes turn them out of the chair. The Popes, therefore, for a long time employed various artifices, to exempt themselves from the power of the emperors; which being at length effected, the Pope, not satisfied with this degree of grandeur, quickly set on foot a pretension of far greater consequence. For now he pretended to an authority over princes themselves, to command a truce among such as were at war together, to take cognizance of their differences, to put their kingdoms under an interdict, and, if they refused submission to the see of Rome, to absolve their subjects from their allegiance, and to deprive them of their crowns. This has been attempted against many crowned heads, and put in execution against some of them. And for this abominable pretension they plead their fictitious decretals, which grant to the Popes an unlimited power over all Christians whatever. Pope Boniface VIII. gave the world clearly to understand his meaning, at the jubilee kept in the year 1300, when he appeared sometimes in the habit of an emperor, and sometimes in that of a Pope, and had two swords carried before him, as the ensigns of the ecclesiastical and civil power.

But the Popes could not long enjoy this intolerable usurpation in quiet: for it was often called in question, till they were obliged to desist in part from their pretensions.

But, when the ecclesiastical monarchy seemed to be come to the pinnacle of its grandeur, when all the western parts were either in communion with, or in obedience to the church of Rome; there happened a revolt from the papal chair, which, though first started from a trifling occasion, came to such a head, that a great part of Europe withdrew itself from the obedience to the Pope, who was thereby put in danger of losing all. We mean the defection of Luther, which gave rise to the protestants.

The popish sovereignty, however, has pretty much recovered itself since this grand defection. As to those things, which Luther upbraided the church of Rome with, they are either quite abolished, or at least are transacted in a more decent manner: 'Si non caste, tamen caute.' Nor do the Popes now-a-days insult with so much haughtiness over princes; neither has the papal chair, of late years, been filled with such debauchees as Alexander VI, or such martial popes as Julius II.

In point of power, the Pope is able to send 50,000 men into the field, in case of necessity, besides his naval strength in gallies. We read how Paul III. sent Charles III. 12,000 foot and 500 horse; Pius V. sent a greater aid to Charles IX. and for riches, besides

PLATE XXXVI. *Engraved for the Supplement.* *Facing* Pomgranate

Printed for J. Hinton in Newgate Street.

besides his temporal dominions, which are extended above 300 miles in length, and 200 in breadth, he has the datary or dispatching of bulls. The triennial subsidies, annates, and other ecclesiastic rights, amount to an unknown sum; and it is a common saying at Rome, that, whilst the Pope can finger a penny, he can want no pence.

Policy exacts all her arts, and sets every spring she has in motion at the election of a Pope; nor do they always wait for the death of the present chief or head of the church, to begin those cabals and intrigues which are proper for advancing him, whom they esteem a fit person to fill the pontifical throne: And although the college unanimously invoke the assistance and aid of the Holy Ghost, to direct them in the choice of a vicar of Jesus Christ, yet their eminencies use all the artful precautions imaginable, one would think, to prevent him from being any way concerned in the election. There are several ways of electing a Pope, viz. by scrutiny, access, adoration, inspiration, and compromise. The election by scrutiny is the only way that has been used for a long while, and contains all the formality that appears most essential for the making the election of a Pope canonical. And yet the scrutiny is no more than a mere ceremony, since the several factions of the cardinals must unite before-hand in the choice of the person. This harmony and agreement is brought about by the most refined and delicate strokes of policy, and for the most part comes on after their eminencies have found out, by several scrutinies, the disposition of the sacred college. Then, if the votes for any of the candidates come near the number required, it is a very common practice for the other factions to fall off, and swim down the stream, and thereby contribute to the Pope's election, fearing to draw on them his hatred by a fruitless and unseasonable opposition. These are the policies which the common people ascribe to the Holy Ghost, at the election by scrutiny.

Each cardinal writes the name of him, whom he votes for, in a scroll of five pages. On the first is written (by one of his servants, that the cardinal may not be discovered by his hand) 'Ego eligo in summum pontificem reverendum dominum meum cardinalem.'— On this fold two others are doubled down, and sealed with a private seal. On the fourth the cardinal writes his own name, and covers it with the fifth folding. Then sitting in order on benches in the chapel, with their scrolls in their hands, they go up to the altar by turns, and, after a short prayer on their knees, throw the scroll into a chalice upon the table, the first cardinal bishop sitting on the right hand, and the first cardinal deacon on the left. The cardinals being returned to their places, the cardinal bishop turns out the scrolls into a plate, which he holds in his left hand, and gives them one by one to the cardinal deacon, who reads them with an audible voice, while the cardinals note down how many voices each person has; and then the master of the ceremonies burns the scrolls in a chafing-dish, that it may not be known for whom any one gives his voice. If two thirds of the number present agree, the election is finished, and he, on whom the two thirds fall, is declared Pope.

If the votes do not rise to a sufficient number, billets are taken in order to chuse the pope by way of accessus: and indeed there scarcely ever is a scrutiny without this accessus; it being scarce known that the holy father should be chosen by the former way alone. The accessus therefore is to correct the scrutiny. In this they give their votes by other billets, on which is written Accedo domino, &c. when they join their first vote to another's; or Accedo nemini, when they keep to their first vote. This practice is derived from the ancient method of debating in the Roman senate; when one senator was of another's opinion, he rose up and went over to his collegue, which was called pedibus ire in sententiam: when they kept their places, they said Accedo ad sententiam. The Pope is elected by compromise, when the cardinals, disagreeing in their choice, engage by mutual compromise to refer it to some particular cardinals of probity, and to acknowledge him whom they shall nominate, as duly elected. The election by way of inspiration is in some measure riotous and tumultuary. A select number of cardinals of different factions, who have determined to put every thing to the last push, begin to cry out, Such a one is Pope, as it were, by inspiration. They make their attempt this way, when they think they are strong enough to carry it. Adoration is the same as inspiration, which is, when two thirds of the conclave, being agreed in the person, go in a body, and adore and acknowledge the Pope they approve of, as head of the church. The elections by way of compromise, and inspiration, but seldom happen. The scrutiny and access are the methods generally observed.

When one of the cardinals is chosen Pope, the master of the ceremonies comes to his cell, to acquaint him with the news of his promotion. Whereupon he is conducted to the chapel, and clad in the pontifical habit, and there receives the adoration, or the respects paid by the cardinals to the Popes. Then, all the gates of the conclave being opened, the new Pope shews himself to the people, and blesses them, the first cardinal-deacon proclaiming aloud these words: 'Annuntio vobis gaudium magnum, papam habemus. Reverendissimus dominus cardinalis—electus est in summum pontificem, & elegit sibi nomen.' —After this, he is carried to St. Peter's church, and placed upon the altar of the holy apostles, where the cardinals come a second time to the adoration. Some days after is performed the ceremony of his coronation, before the door of St. Peter's church, where is erected a throne, upon which the new Pope ascends, has his mitre taken off, and a crown put upon his head, in the presence of all the people. Afterwards is a grand cavalcade from St. Peter's church to St. John's de Lateran, where the archbishop of that church presents the new Pope with two keys, one of gold, the other of silver; one of which is a sign of the power he has of giving absolution, and opening the gates of heaven to all believers; and the other of excommunicating sinners, and dooming them to purgatory. The first coronation, which is mentioned in the history of the Popes, was that of Damascus II. in 1048. In former times the Pope was crowned before the basilica of St. Peter. The reader may see all the ceremonies of the Pope's coronation particularly described in the Relig. Cerem. Vol. I. of which the above account is an abstract.

It is a general maxim, in the choice of a Pope, to elect an Italian; which is done, not only because they chuse rather to bestow this dignity on a native of Italy, than on a foreigner, but also because the security and preservation of the papal chair depends in a great measure on the balance which is to be kept between France and Spain; but this is not to be expected from a French or Spanish Pope, who would quickly turn the scale, and, by granting too great privileges to his countrymen, endeavour to exclude others from the papal chair. It is also a sort of maxim to chuse a Pope who is pretty far advanced in years, that there may be the quicker succession, and that it may not be in the power of a Pope, during a long reign, to alter their customs, or, by making his family too powerful, to entail, as it were, the papal chair upon his house. They also take care that he be not too near a kin to the deceased Pope, that the vacant church benefices may not be engrossed by one family. It often happens, that one is chosen Pope, of whom no body thought before; and this comes to pass, when the cardinals are tired out by so many intrigues, and are glad to get out of the conclave.

Ever since the time of Pope Sixtus IV, that is, since the year 1471, the Popes have made it their business to enrich their families out of the church revenues, of which there are very remarkable instances: for it is related, that Sixtus V, during a reign of five years, bestowed upon his family above three millions of ducats. The house of the Barbarini's, at the death of Urban VIII, was possessed of 227 offices and church-benefices, whereby they amassed thirty millions of scbudi's.

Sergius III or IV, who was before called os porci, i. e. swine's face, is said to have been the first Pope, who changed his name upon his exaltation to the pontificate. This example has been followed by all the Popes since his time, and they assume the names of Innocent, Benedict, Clement, &c.

When a Pope is elected, they put on him a cassock of white wool, shoes of red cloth, on which is embroidered a gold cross, a mantle of red velvet, the rochet, the white linnen albe, and a stole set with pearls. At home, his habit is a white silk cassock, rochet, and scarlet mantle.

The Pope's tiara, or crown, is a kind of conic cap, with three coronets, rising one above the other, and adorned with jewels. Paul II. was the first who added the ornament of precious stones to this crown. The jewels of Clement VIII's crown were said to be valued at 500,000 pieces of gold.

The Pope has two seals; one is called the fisherman's ring, and is the impression of St. Peter holding a line with a bait to it in the water: it is used for those briefs that are sealed with red wax. The other seal is used for the bulls, which are sealed with lead, and bears the figures of St. Peter and St. Paul, with a cross on one side, and a bust, with the name of the reigning Pope, on the other. Upon the decease of a Pope, these seals are defaced and broken by the cardinal Camerlengo, in the presence of three cardinals.

The custom of kissing the Pope's feet is very ancient; to justify which practice, it is alledged, that the Pope's slipper has the figure of the cross upon the upper-leather; so that it is not the Pope's foot, but the cross of Christ, which is thus saluted.

There are but few instances of the papal power, in England, before the Norman conquest: but the Pope, having been favoured and supported by William I, in his invasion of this kingdom, made that a handle for enlarging his incroachments, and, in that king's reign, began to send legates hither. Afterwards, he prevailed with king Henry I. to part with the right of nominating to bishoprics; and, in the reign of king Stephen, gained the prerogative of appeals. In the reign of Henry II, he exempted all clerks from the secular power. This king, at first, strenuously opposed this innovation: but, after the death of Becket, who, for having violently opposed the king, was slain by some of his servants, the Pope got such an advantage over the king, that he was never able to execute the laws he made. Not long after this, by a general excommunication of the king and people, for several years, king John was reduced to such streights, that he surrendered his kingdoms to the Pope, to receive them again, and hold them of him under a rent of a thousand marks. In the following reign of Henry III, partly ly from the profits of our best church benefices, and partly from the taxes imposed by the Pope, there went yearly out of the kingdom seventy thousand pounds sterling. But, in the reign of Edward I, it was declared by the parliament, that the Pope's taking upon him to dispose of English benefices to foreigners was an incroachment not to be endured; and this was followed by the statute of provisors against popish bulls, and disturbing any patron, in presenting to a benefice.

But the Pope's power received a mortal blow, in England, by the reformation in religion, begun in the reign of Henry VIII; since which time, to maintain the Pope's authority here, by writing, preaching, &c. is made a premunire upon the first conviction, and high-treason upon the second.

PO'PLAR, *populus*, in botany, the name of a genus of trees, the characters of which are these: the flower is of the amentaceous kind, being composed of a number of small leaves, furnished with a great quantity of apices; but these are barren. The embryo fruits are produced on those trees which produce none of these flowers; these are spiked, and consist of many leaves, under which there lies a sort of bell, which contains the embryo seed vessel, which finally becomes a membranaceous pod of a compressed figure. These are disposed in a spiked form, and open into two parts, containing seeds winged with down. To this it is to be added, that the Poplar has a peculiar and appropriated general appearance, by which it is obviously distinguished from the willow.

The species of Poplar, enumerated by M. Tournefort, are these: First, the common white Poplar, with large leaves. Secondly, the common white Poplar, with smaller leaves. Thirdly, the common black Poplar. And, fourthly, the Poplar with trembling leaves, called the aspen-tree. *Tourn. Inst.*

The Poplar, whether black or white, may be easily propagated, either by layers, cuttings, or suckers, of which the white kind always produces a great many from the root. The best season for the transplanting these suckers is in October, when the leaves begin to decay; and they should be removed into a nursery for two or three years, at the end of which time they will have got strength enough to be transplanted into the places where they are to remain.

When they are to be propagated by cuttings, it is best to do that in February, cutting off large truncheons of eight or ten feet long; which, being thrust down a foot deep in the ground, will take root very quickly, and, if the soil be moist, will grow to a considerable size in a few years.

The black Poplar is not so easily raised from these large truncheons, but should be planted in cuttings, of about a foot and a half long, planting them a foot deep in the ground. This will grow on almost any soil, but does much better on a moist one than on any other. They are the fittest of all trees for raising a shade quickly, as they will grow fourteen feet in height sometimes in one season, and in four or five years will be large trees.

A considerable advantage may be obtained by planting these trees upon moist boggy soils, where few other trees will thrive: many such places there are in England, which do not, at present, bring in much money to their owners; whereas, if they were planted with these trees, they would, in a very few years, over-purchase the ground, clear of all expence: but there are many persons in England, who think nothing, except corn, worth cultivating: or, if they plant timber, it must be oak, ash, or elm; and, if their land be not proper for either of these, it is deemed little worth; whereas, if the nature of the soil was examined, and proper sorts of plants adapted to it, there might be very great advantage made of several large tracts of lands, which at this time lie neglected.

The wood of these trees, especially of the white, is very good to lay for floors, where it will last many years; and, for its exceeding whiteness, is, by many persons, preferred to oak; but, being of a soft contexture, is very subject to take the impression of nails, &c. which renders it less proper for this purpose: it is also very proper for wainscotting of rooms, being less subject to swell or shrink, than most other sorts of wood: but, for turnery ware, there is no wood equal to this for its exceeding whiteness, so that trays, bowls, and many other utensils, are made of it; and the bellows-makers prefer it for their use; as do also the shoe-makers, not only for heels, but also for the soles of shoes: it is also very good to make light carts; the poles are very proper to support vines, hops, &c. and the lopping will afford good fuel, which, in many countries, is much wanted.—For the method of making the ointment from the buds of the Poplar, see POPULEUM in the Dictionary.

POPLAR-*Galls*. The black Poplar is famous among naturalists for producing a sort of galls, or protuberances, of various shapes and sizes, on its leaves and branches, which have been usually mistaken for the lodgment of worms hatched from the eggs of an ichneumon fly; but they are in reality produced by the operation of a viviparous insect, called the puceron, for the bringing up of its off-spring. See PUCERON.

PO'PPY (*Dict.*)—We have many species of this plant cultivated in gardens for the beauty of the flowers. They are all easily propagated by sowing the seeds in autumn. When the young plants come up, they are to be cleared from weeds, and thinned to a proper distance by pulling some up, where they stand too thick; for they never thrive well, if they are to be transplanted. They are to be left, according to their sizes, at six, eight, or ten inches distance.

They are very showy flowers, and make a splendid appearance in gardens; but they are but of a short duration, and are of an offensive smell, which makes them less valued at present than they have been.

Some sow these plants in spring, but it is not so well; because they then have not time to get strength before autumn, when they are to flower; and, for that reason, those sown in spring usually flower weakly. *Miller's Gard. Dict.*

Red POPPY.— The common wild red Poppy is one of the most mischievous weeds the farmers are plagued with among their corn, and it is the most difficult to thoroughly destroy of almost any other. Its seed will lie a long time in land unploughed, without ever shooting; but they will be sure to grow with every crop of corn. Mr. Tull gives an instance of the seeds of this plant being buried four and twenty years in a field of saint-foin, and at the end of that time, the land being ploughed for wheat, they all grew up among the corn, though, they had lain dormant so long before. *Tull's Horse-hoeing Husbandry.*

Yellow POPPY.— The yellow horned Poppy, called by authors papaver corniculatum luteum, is one of those vegetable poisons of our own growth, which may be very mischievous by their not being generally known, or suspected to be so. We have an account of the effects of this plant in the Philosophical Transactions, in an instance of a family in Cornwall, who eat of a pye made of the roots of this instead of eryngo, or sea holly, which it is the custom of the poorer people there to make into a coarse sort of pye for their food.

The man of the house, on eating of this pye while hot, was seized immediately with a violent delirium, one effect of which was his thinking every thing he saw was of a yellow colour, and taking every utensil of the house to be made of gold. The man and maid-servant eat after their master, and were soon after as mad as he, coming into the room where his friends were attending him, stripped naked and danced together. These people also took every thing they saw to be gold; and a child in the cradle, to whom a small piece of the pye had been given, was thrown into a drowsy disorder, and convulsed about the mouth; but, after a few days, it recovered.

The grown people were all seized with most violent purgings, and by that means escaped, after being miserably worn down by this complaint.

The symptom of supposing every thing gold, which ran thro' the whole family, and went even so far as to the supposing their stools gold, and ordering them to be saved, may possibly be in some measure owing to the idea they had of the plant whose roots they had been poisoned by; its flowers being as large as a rose, and of a fine yellow, and the juice of the whole plant being also yellow. *Philos. Trans.* N°. 242.

POPULA'GO, *marsh marigold*, in botany, a genus of plants, whose characters are:

The flower consists of several leaves, which are placed circularly, and expand in form of a rose; in the middle of which rises the pointal, which afterwards becomes a membranaceous fruit; in which there are several cells, which are, for the most part, bent downwards, collected into little heads, and are full of oblong seeds.

This plant is said to be of a refrigerating quality, like the nymphæa; but it is really, of a very caustic nature, so that cattle avoid it, though in the greatest want of grass; but, if they happen to eat it, they are first seized with an inflammation of the fauces, œsophagus, and stomach, and at last die. Hence, it appears to be a very acrimonious herb, and of the nature of hellebore. *Hist. Plant. adscript. Boerhaave.*

PO'RCELAIN (*Dict.*)—The most just and regular idea we can form of the Porcelain or China ware is, that it is an half vitrified substance or manufacture, in the middle state between the common baked earthen-ware of our vulgar manufactures and true glass. This is the essential and distinctive character of Porcelain, and it is only by considering it in this light, that we are to hope to arrive at the perfect art of imitating it in Europe.

This attempt is to be made on these principles in two different manners: the one by finding some appropriated matter on which fire acts with more than ordinary strength in the time of its passing from the common baked state of earthen-ware into that of glass. The other is, to compose a paste of two substances reduced to powder; the one of which shall be of force to resist a violent fire, so as not to become vitrified in it; and the other a matter very easily vitrifiable. In the first case, the matter is to be taken out of the fire at the time when it is imperfectly vitrified; and, in the other, the compound mass is to remain in the furnace till the one substance, which is the more easily vitrifiable, is truly vitrified; and being then taken out, the whole will be what Porcelain is, a substance in part vitrified, but not wholly so.

The first method is that by which the European Porcelain has generally been made, and, though that of St. Cloud, and some other places, has been very beautiful, yet it is always easy to distinguish even the finest of it from the China ware, and the nature of the two substances appears evidently different: these owing

Printed for J. Hinton in Newgate Street.

owing all their beauty to their near approach to vitrification, are made to endure a long and violent fire, and are taken from it at a time when a very little longer continuance would have made them perfect glaſs; on the contrary, the China ware being made of paſte, part of which is made of a ſubſtance in itſelf ſcarce poſſible to be vitrified, bears the fire in a yet much more intenſe degree than ours, and is in no danger of running wholly into glaſs from it.

The two ſubſtances uſed by the Chineſe are well known by the names of petuntſe and kaolin, and on examining theſe it appears very evident, that we have in Europe the very ſubſtances, or at leaſt ſubſtances of the very ſame nature, and capable of being wrought into a Porcelain equally beautiful and fine. *Mem. Acad. Scienc. Par.* 1739. See the articles KAOLIN and PETUNTSE.

Theſe are the two different ſemi-vitrifications, on one or other of which all the European manufactures, by which of the two proceſſes it is eaſy from the knowledge of theſe principles to determine, on breaking a piece of china of our manufactures, by which of the two proceſſes it is made. If it is made by ſeizing the half vitrified maſs of a ſubſtance which would ſoon after have been wholly vitrified, then the putting it in a crucible, into an equal degree of fire, will ſoon turn it wholly into glaſs. This is the caſe of moſt of our European Porcelain; but, if it be made of two ingredients, the one of which is not vitrifiable, or at leaſt not by ſuch fires, then the matter will melt, but will not vitrify: this is the caſe with the Chineſe Porcelain, which, if kept in fuſion a long time, yet when cold is China-ware ſtill; ſo that this is evidently made of two ſuch different ingredients.

Beſides theſe methods, there is yet another, of late invention, which makes a very beautiful china; and which, if it does not afford veſſels equal to thoſe of china, yet will afford them nearly approaching to theſe, and at a conſiderably ſmaller price. This method conſiſts in reducing glaſs to china. See the article GLASS *Porcelain.*

The fine deep blue of the old Porcelain ware of China is much valued by the curious; and it is much lamented, that the ſame colour is not uſed at this time. The art ſeems at preſent to be loſt; but perhaps it might be recovered by trials. It is certain, that the Chineſe have cobalt among them, and very probably they uſed a blue colour prepared from this before they had any commerce with us: notwithſtanding all the conjectures about their materials for colouring, this ſeems the moſt probable ſubſtance; and there is a way of preparing a colour from this, much ſuperior to that now in uſe, which we call ſmalt.

Cobalt is a mineral containing arſenic and a blue vitrifiable earth. The common way of preparing ſmalt is, by roaſting the cobalt in a reverberatory fire. This diſpoſes it to vitrify, and drives off the arſenic it contains in fumes, which collecting at the top, form true flowers of arſenic. It is very certain, however, from experiments, that, if this arſenic could be preſerved in the cobalt, the ſmalt would be of a much finer colour; for there are ſome kinds of cobalt which yield ſmalt without previous roaſting; and as the arſenic is in a great meaſure contained in theſe, the ſmalt are much finer coloured. Arſenic added to ſmalt, while in fuſion, greatly exalts its colour alſo; and there is a way of procuring ſmalt from cobalt, without fire, only by diſſolving it in an acid, and precipitating that ſolution with oil of tartar. The ſmalt, thus precipitated to the bottom, is of a much finer colour than any prepared by fire; but it is much more expenſive, and prepared in leſs quantity. It is very poſſible, that the Chineſe might have the art of making this kind of ſmalt before they knew us, and that to this was owing the fine blue of their Porcelain ware: but, when we traded with them, and they purchaſed ſmalt ſo much cheaper of us than they could make it themſelves, they naturally diſcontinued the manufacture of their own finer kind, without conſidering how greatly inferior the colour was which the other yielded. If this be the caſe, it will be eaſy to revive this art, and the adding the true old china blue to an European manufactures, in imitation of Porcelain, may give them a value which they have not at preſent.

The Chineſe had once a method of painting the figures of fiſhes and other things on the inſides of their veſſels, in ſuch a manner that they did not appear till the veſſels were filled with water, or ſome other clear liquor. This ſort of China-ware was called kiatſim, that is the concealed blue china. The art is now in a great meaſure loſt; but there may be ſome gueſs made as to the manner in which it might be done at this time. The veſſels which are to be made, muſt be very thin: the colours muſt be laid on in form of the fiſh, or other animals or figures, on the inſide, after the veſſel has been once baked. After this colour has had time to dry, the inſide of the veſſel muſt have a ſecond coat of the ſame earth, or ſtone ware, of which the veſſel is made; and over this a varniſh of the common kind. The conſequence of this will be, that the figures of the fiſh, in a very ſtrong colour, will be buried between two coats of the ware, which together form a complete veſſel. The outſide is then to be ground down almoſt to the figures, and, when they begin to appear, a new coat of the varniſh is to be laid over this. The figures will then be obſcured, and ſcarce, if at all perceivable; but, on filling the veſſel with water, the tranſparence of the ſides will be taken off, and the liquor will make a ſort of foil behind, which will throw out the figures of the fiſh. This might be done in any ware tolerably clear and tranſparent. The Porcelain of china would ſucceed beſt with it; but the pains and nicety required are too great, and all the attempts lately made by them have miſcarried. See the article STAINING *of Porcelain.*

The Chineſe make a great variety of figures on the ſurfaces of the vaſes of white China ware, and there is one kind of this greatly in eſteem among them, in which there are flowers and other figures; yet, the ſurface is quite ſmooth, and the ſubſtance extremely thin. The manner of making it is this: they firſt form the veſſel of the fineſt materials, as thin as they can; then, when they have poliſhed it inſide and out at the wheel, they put into it a ſtamp of its own ſhape, but cut with all theſe figures: they preſs this down ſo firmly on the yet moiſt veſſel, that the impreſſion is received in a very perfect manner; and, if the ſhape of the veſſel be at all hurt, they take it to the wheel again to reſtore it. They then finiſh it with the knife and ſciſſars; and, when they have made it as perfect as can be, they cover it with the fine white varniſh within and without. This fills up all the cavities of the impreſſion, and gives a perfectly ſmooth and even ſurface; yet the thickneſs of this varniſh in the traces of the figures gives it a different white, and the whole figures are as finely and accurately ſeen, as if painted on the outſide. This is an artifice that might eaſily be brought to bear among us, and ſeveral of our finer wares would make a pretty figure with it.

There is a current opinion among the Chineſe themſelves, that the Porcelain ware of former times was greatly ſuperior to that which they make at preſent; and that the burying china in the earth, for a long time, adds to its beauty; but all this is founded on error. The truth is, that our merchants beat down the price of the ware, and thereby compel them to make a worſe kind in general; but they are as able to do as fine things now as ever. What gave birth to the opinion, that burying Porcelain made it good, was, that finer pieces than ordinary are ſometimes found buried. Theſe are all precious vaſes, which the poſſeſſors buried, by way of ſecurity, in the times of civil war; and it is no wonder, that there are none but of the fineſt kind found buried on theſe occaſions. *Obſerv. ſur les Coutum. de l'Aſie.*

PORCELLA'NA, in natural hiſtory, the porcelain ſhell, or concha venerea, the name of a genus of ſhell-fiſh, the characters of which are theſe: they are of the univalve kind, and have for their mouth a long narrow ſlit, dentated on each ſide, and are of a conglobated, oblong, gibboſe, or umbonated form.

PO'RCUPINE, *hyſtrix*, in zoology, a creature of the ſize of the larger monkies, and is covered all over, except its noſe, the lower part of its legs, and the extremity of the tail, with ſpines of two or three inches long, and has no other hair but theſe. Theſe are yellowiſh for that half next the body, whence they are of a deep blackiſh brown, and at the very extremity they are white: they are hollow in the manner of quills; and Hernandez affirms, that the creature has a power of throwing them from its body to a conſiderable diſtance. The body is about a foot long, the tail ſomewhat longer than that, and its farther half covered thinly with hairs much reſembling hog's briſtles. The ears are ſmall, and are hid by the ſpines which cover the head. It has two long teeth in each jaw before; the noſtrils are very wide, the eyes round, prominent, and very bright and ſparkling, the feet are like thoſe of the monkey kind, and divided into four toes.

It climbs trees, but ſlowly and with difficulty, for want of a heel or hinder toe. It uſually twiſts its tail about a bough, to keep it ſafe from falling. It makes a grunting like that of a hog. It feeds on poultry, and its fleſh is very well taſted. *Ray's Syn. Quad.*

PORE'LLA, in botany, the name of a genus of moſſes, the characters of which are theſe:

The capſules contain a powder like thoſe of the other moſſes; and they have neither operculum, calyptra, nor pedicle; and their manner of ſhedding their powder is not by ſeparating into two parts, like thoſe of the ſelago and lycopodium, but by opening into ſeveral holes on all ſides.—It is not uſed at all in medicine.

POR'PESSE, an Engliſh name given indiſcriminately to two different fiſhes, the phocæna and the dolphin.

Artedi, who has been very careful in bringing together the ſynonyma of authors, tells us, that this is properly the Engliſh name only of that ſpecies of the dolphin, the character of which, according to this ſyſtem, is, that the body is almoſt of a conic form, the back broad, and the body ſubacute. This ſpecies is the phocæna of Ariſtotle, and the turſio or turſio of Pliny and Rondeletius. Schoneveldt calls it the ſmall northern or oriental dolphin, and the Swedes the marſuin. See the article DELPHINUS.

POR'PHYRY-*ſhell*, in natural hiſtory, a name given by authors to a ſpecies of ſea-ſhell of the purpura kind, with a ſhort clavicle and beak.

PO'RTABLE *Laboratory*.—Dr. Shaw, who has taken great pains to bring the ſtudy of chemiſtry more into uſe in England than it has hitherto been, has explained the eaſineſs of its operation in general, and attempted a means of making its

 practice

practice less expensive, by introducing, in the place of that vast number of furnaces, and other contrivances, figured and described by the generality of authors on that subject, a Portable laboratory, by means of which alone all the chemical operations may be commodiously performed. This laboratory, fitted for its several purposes, is figured on *Plate* XXXVII. *fig.* 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12.

Its contrivance is such, that not only complete courses of chemical experiments and operations may be commodiously performed by its means, but all the medicines may be prepared, in such quantities, as to supply not only the demands of a family, but of an apothecary's shop, in moderate business. The first person who planned out this sort of furnace was Becher, and the scheme executed by Dr. Shaw is an improvement on that attempt.

The furnace has four principal parts: 1. The cover. 2. The ring. 3. The body, and 4. The foot. The general office and use of the cover is to check, suppress, and throw back the heat and flame, that the fuel may not waste itself too fast, as it otherwise would do to very little purpose in in many of the operations; for, the action of the fire being not momentary but successive, the more it is kept in, and directed upon the subject, the more it is able to perform its effect, and that with the less expence or destruction of it. In order to increase the draught to the fire, and squeese the air more forcibly through the body of the fuel, there is a moveable funnel or chimney, which may occasionally be fixed to the orifice, in the top of the cover left for that and many other uses. See the *Figure*, *ubi supra*.

The ring is the place or seat of many operations. The body to be worked upon by the fire is frequently lodged in it; and, in other cases, it helps to enlarge the furnace, and renders it capable of operations it could not otherwise perform. The body of the furnace serves to contain the fuel, and is the common seat of the operations by the fire, in the running metals from their ores; and, in these and many other the like cases, it performs the office of crucible as well as fire-place, and contains the subject mixed along with the fuel, as is practised at the smelting-houses. To this body there belong three several grates, which may be placed at different heights therein, according to the nature of operation, and the distance required between the subject and the fire. Lastly, the foot is of two kinds, and is not only of use in supporting the rest of the parts, but it receives the ashes of the fuel, and the melted matter that may, in any of the operations, run down from the ores of the metals, or on other the like occasions, when the fire liquates any thing above. The more immediate appurtenances of this furnace are fuel and bellows. The general fuel is to be charcoal; or, as there is a contrivance for a vent or flue in the body of the furnace, common sea-coal may be employed, and the smoak directed up the chimney of the room, in which the furnace is to stand. The structure of this furnace is also very well fitted for a lamp, which is a sort of heat, highly convenient for some curious digestions and calcinations; and by this means these operations, which would otherwise require an athanor, may be conveniently performed, and that in the most accurate manner.

The number of chemical processes that may be performed by this furnace is not easily reckoned up; but it may not be improper to add an account of the several states, into which it is to be put for the performing them.

The most simple state of the furnace is a combination of its two lower parts, the body and the foot. When these are put together, it is fit for fusion by the naked fire, where the matter to be melted is to be mixed among the fuel; as, for instance, in the running the ores of lead, tin, or iron, which may thus, in the quantity of many pounds at a time, be separated from their dross, and purged for use, as exactly as at the mine works, or smelting-houses, either with the assistance of the bellows, or without, as the nature of the ore requires. By barely placing a grate in the middle of the body, the instrument becomes a melting furnace for a crucible, wherein all the operations that require a fire of fusion, animated either by the air, or bellows, are performable with such advantages as cannot be had in the common wind or blast furnaces made for this purpose. When only the body of the furnace with its middle grate is set upon the foot, it answers all the purposes of a shop furnace used by the apothecaries for decoction, inspissation, extraction, and the like purposes, where a naked fire only is required, and certain distillations and sublimations may also be performed conveniently by it.

It may in this state also be conveniently made to serve the purposes of a balneum mariæ, an ash heat, a sand heat, or a still stronger one for digestion and sublimation, by only setting on it in this state a vessel of water, or one filled with ashes, sand, or iron-filings; and thus several operations requiring the same kind of heat may be carried on at the same time. If instead of a common pan or vessel to hold water, sand, &c. the ring or third part of the furnace, be set on furnished with its set of pots, the whole is then a furnace fitted for that sort of distillation called distillation in capella vacua, where the retorts are contained in the cavity of the pots, and locked down therein without any visible medium between. By this means many operations may be performed in the distillation and separation of bodies, that could not be worked upon to so much advantage by any other method. Particularly the rectification of the strongest acid spirits is very easily and conveniently performed, this way, at very little expence.

If an iron pan be placed in the room of the ring just mentioned, the instrument is then a calcining furnace, where ores of metals may be roasted, and lead, antimony, and the like bodies may be conveniently reduced to ashes.

If the lowest grate be used instead of the middle one, then either a cold still, or, as it is generally called, a hot one, may be put into the body, and worked in the common manner with its head and refrigeratory. Thus all the cordial waters may be made, spirits may be rectified, and the essential oils distilled by the same means, as well as by the common fixed stills.

The last part, or cover of the furnace, may sometimes be applied to the ring, sometimes only to the body of the furnace without the ring. The instrument in this case becomes a proper reverberatory furnace, and is useful for cementation, cupellation, and the essaying of ores, and for distilling with a fire of suppression, that is, where the fire is placed above as well as below the subject, and the vessel that contains it.

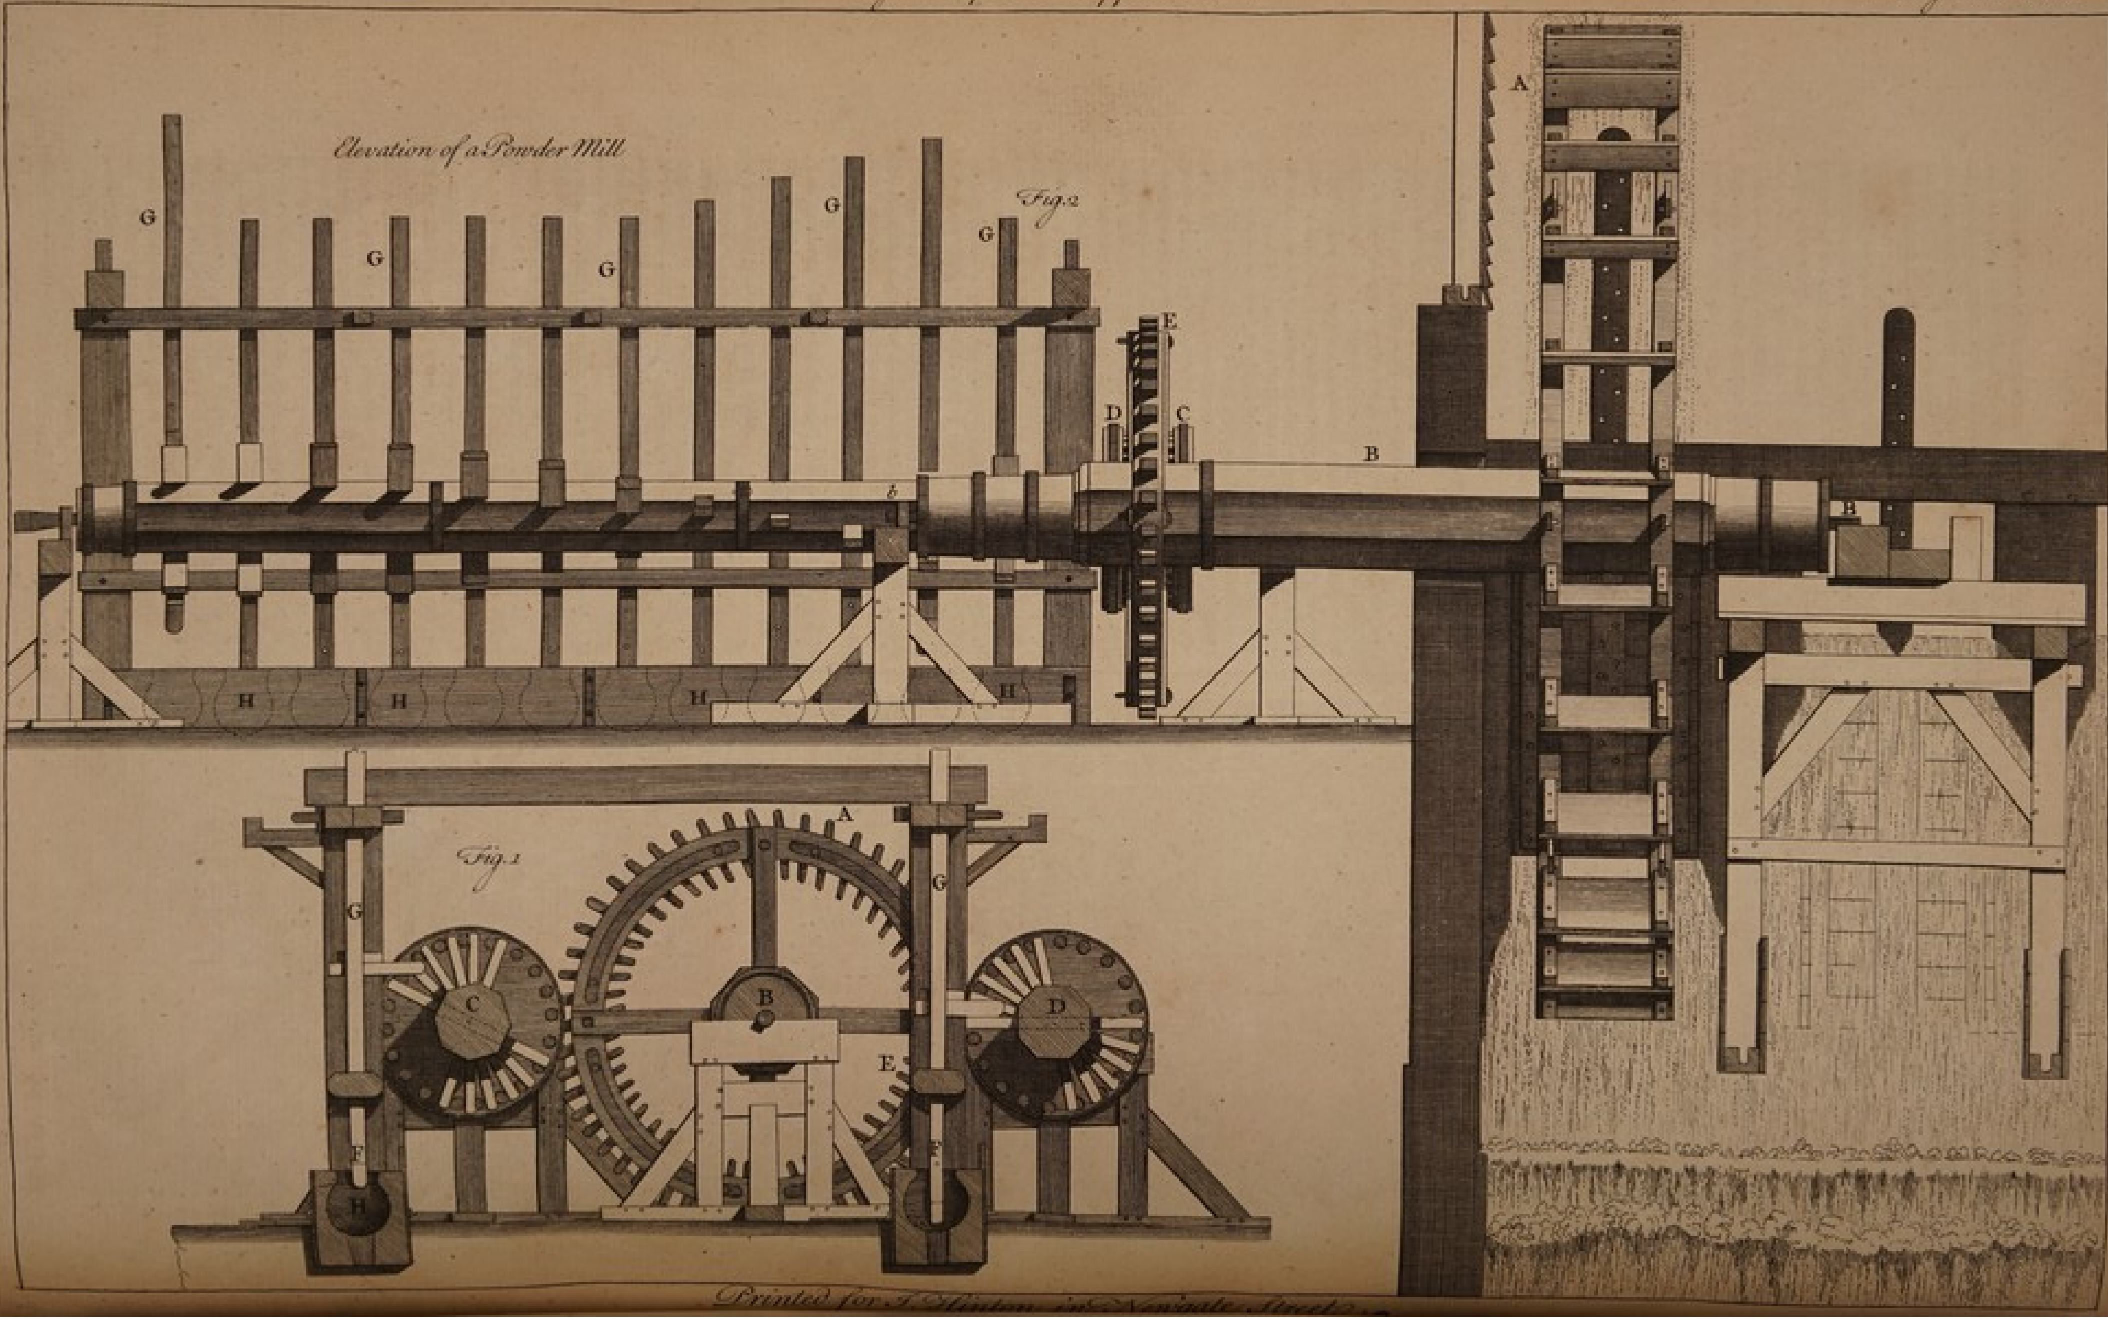
A furnace of this nature has numerous advantages, not only over all the chemical furnaces in common use, but even over those of the most celebrated structure and contrivance, described by authors on particular occasions, not excepting those of Glauber and Vigani. Those nicely contrived furnaces are generally adapted to some few particular purposes, and yet this easy kind answers in experiment those very purposes better; and at the same time is of general use on all the other occasions of chemistry. Experience has shewn, that it is better for the various uses of Glauber's philosophical furnaces, than those very furnaces themselves, though made for these very purposes; and for the higher operations as they are called of metallurgical chemistry. For example, to obtain a pure spirit of salt in plenty, Glauber orders the salt to be thrown upon the fire, and has contrivances to catch the rising vapour; but this is a tedious way, and turns to very little account in practice; nor is the matter much improved by quenching the coals in a brine of sea-salt, and afterwards burning them for their fume; but all that can be expected from these aukward contrivances, may be had commodiously from the furnace here described, where the fire, being animated by bellows, causes the fire to burn more free, and the fuel to yield the spirit it was impregnated with, much more quickly and easily than in the furnace contrived by that author for the purpose, while the fuel is supplied by the door without any disturbance to the operation. *Shaw's Ess. on a Portable Laboratory.*

There are many other curious philosophical experiments, which can be no way so well done as with this kind of furnace, and many scarce at all without it; it is excellently fitted also for enamelling, making of pastes, staining of glass, and making the artificial gems. And, besides these and a number of other curious uses, it is extremely well fitted for all the common purposes of fires. Any artizan who requires fire in whatever manner in his business, may contrive to apply it in this manner as he will; the offices of a common stove in a kitchen may also be very well supplied by it, and the warming a room, or vault, is as well done by it as by any of the common contrivances of stoves, ovens, and other things, made purposely for that use.

The outer case of the furnace is to be made of good plate iron of a considerable thickness, formed in separate pieces of the figures expressed in the plate, and its size may be such as the operator chuses; observing only a due proportion in its several parts. The inner sides of all the parts must be lined at least an inch thick with a proper luting, which must be carefully laid on and gently dried, the cracks, which happen in the drying, being filled up with more of the same luting. Windsor loam alone may be used to this purpose, but the author himself recommends the following mixture: take a bushel of Windsor loam, four quarts of brick-dust, two quarts of powdered green glass, two quarts of iron filings, four handfuls of cow hair, and eight handfuls of horse dung; these are all to be beat together, and a sufficient quantity of bullocks blood added, to make the whole into a stiff and uniform paste, which is to be carefully spread over every part of the furnace that the fire can touch.

PO'RUS *cervinus*, in natural history, a name given by authors to a species of sea plant, found among the rocks in the coral fisheries, and in other places. It grows at different depths, and seems to adhere to the rocks by a simple base, having no root, nor any thing in the place of one. It is branched in such a manner, that, with the help of a little imagination, it has been forced into the resemblance of a stag's horn. Its height is about an inch an half, often less when newly taken out of the sea; it is of a fine snow white colour, but, when it has lain some time to dry, it becomes of a dusky yellow. It is very thin, perfectly transparent, and seems composed of several fine membranes. When examined by the microscope, an admirable structure is discovered in it; the whole being composed of a membranous matter, in which are an infinite number of holes, and all these arranged into regular lines.

PLATE XXXVIII. *Engraved for the Supplement.* *Facing* Powder *Mill.*



Printed for J. Hinton in Newgate Street.

POSIDIUM, Ποσειδεών, in chronology, the seventh month of the Athenian year. It consisted of thirty days, and answered to the latter part of our December and the beginning of January.

POT-ASH (*Dict.*)—The art of reducing vegetables to this state is a very valuable one; the soap-maker, fuller, scowerer, dyer, and glassman, as well as the chemist and apothecary, depending greatly on it in many particulars.

The authors who are farther to be consulted in this case, are Glauber, in his Prosperity of Germany; but the chemical foundation of the whole appears in Boerhaave's Chemistry, and the papers of Stahl on this subject.

This salt has been made in New England in considerable quantities from rotten wood. What gave the occasion of knowing it, was, that a white oak in that province decayed, and a third part of its substance became rotten. This rotten part was tried to burn, and was found to turn almost wholly into a fine alkali salt, or Pot-ash, much stronger than that which is made in the usual way. What was most observable in the making of this salt was, that, while the wood was burning, it would melt of itself, and run down into hard lumps of salt; and this none of the wood of the same tree, which was found, would do, but only the rotten part: and what was most rotten of all, yielded the greatest quantity of salt, and that the most readily; whereas all the common alkali salts of wood, made by incineration, are blackish at first; and the lixivium made of them, although often filtred, will still be of a brown colour, occasioned by some of the charcoal of the wood so closely united to the salt as not to be easily separated from it. This alkali made from rotten wood was very white, even before solution; and the lixivium made with it was not at all tinged with brown, but clean like pure water, only a very small quantity of ashes subsided to the bottom. The lixivium was easily decanted from this, without the trouble of filtration, and, when evaporated to a driness, left the salt perfectly fine and pure. In the making this salt, as the fire grows more intense, the wood is seen to run together into great lumps, and bubble with a hissing noise.

The weight of the Pot-ash prepared in the common way is very considerable, in proportion to the wood used; but, in this, the salt nearly equals the whole weight of the wood. In the common way of making the Pot-ash, the salt is never distinguished by the eye among the ashes, nor even causes them to run into lumps; but in this case the salt always runs into large lumps, and is as easily distinguished from the rest of the ashes, though white, as salt of tartar of the purest kind would be.

It is very certain, that rotten wood in many places has been found, on trial, to yield much less salt than found wood; but the found wood of this tree, being tried, was found to yield no more salt than other wood, and consequently much less than the rotten part of it. On examining this tree on the spot, it was thought by good judges, that it had been at some distance of time struck with lightning, it being evidently torn from the top to the bottom: on that side where the decayed part separated from the found, there had been a channel of about five inches wide all the way down; but this was closed over by succeeding bark, and shewed no trace of the accident till on examining underneath, where the tree was found black for such a space, and the bark not of a piece with the rest.

From this it may be conjectured, that the wood, having been for so long a time, as till the growth of this bark, exposed to the wind and weather, naturally became rotten from the wet it received; and that the lightning, having penetrated the wood, had so altered and disposed the parts and pores of it, that they attracted and retained the nitrous salts of the air in great abundance, even as salt of tartar, and other the like salts, do; which, as Glauber observes, will be reduced, in continuance of time, to an absolutely nitrous salt, and the quantity also considerably increased,

The parts of this rotten wood were of a very different structure from those of ordinary wood in this condition; and, though the lightning had not calcined it into a salt, yet it had, as appears, sufficiently altered it to give that tendency to imbibe, and a power to retain the nitrous particles from the air, as well as the alkalies of vegetables perfectly calcined will do. If it should be objected, that nitre alone will not calcine into an alkali, it is easily answered, that nitre with charcoal will; and the remaining wood might very well serve as charcoal in this process. *Phil. Transf.* N°. 366.

POTATOE. The most advantageous way of propagating Potatoes is, the planting them at large distances, and digging or horse-hoeing the ground several times between them.

Mr. Tull gives an example of this, in which the hoeing succeeded much better than dung, and without the expence of it. A piece of ground was planted with Potatoes, the greater part of it in the common way; but in one part, worse than the rest, they had been set at a yard distance every way. The rest of the ground was dunged; this poor part had no dung, but was ploughed deep at several times four different ways, so that the ground was stirred and broken thoroughly every-where about the Potatoes. The consequence was, that though no dung was used here, and though the plants appeared much weaker than in the dung part, yet the crop was greatly better than that of the other part of the field. The roots here were all large, and in the other parts of the field, where the dung had been used without ploughing, they were so small, that the crop was scarce worth taking up.

This is one of many instances of the no great use in dunging land, without properly stirring it up, and serves to prove, what the crops of corn and every thing else confirm upon trial, that the stirring the earth sufficiently, without any farther trouble, will answer better without any other manure, than all the manure in the world without it. *Tull's Horse-hoeing Husbandry.*

POWDER-*flasks*, in artillery, are most commonly made of horn, of any convenient size and figure, to carry powder for priming of cannon: this is their chief use in armies.

Sometimes they are so made as to have a measure for the charge of the piece at top, but this is of more use to gentlemen in fowling, &c. than to soldiers, who have the charges of their piece put into cartridges, which they bite off, and first prime, and then load.

POWDER-*room*, in a ship, that part of the hold wherein the Powder is stowed.

POWDER-*mill*, a mill for pounding, mixing, &c. the ingredients of which gunpowder is composed.

Gunpowder is composed of salt-petre, sulphur, and charcoal. The sulphur must be well purified. Salt-petre is a salt extracted by different liminations from several sorts of broken stones, pieces of old and dry plaister, or rubbish of old buildings, especially cellars, and generally all earths which have been long in sheep-folds, stables, pigeon-houses, and other places where are gathered, either by a regular course or transpiration, the drainings of dunghills, manufactures, urines, and all salts proceeding from animals. These three matters, pulverised separately, are incorporated afterwards into one mass of a fixed weight, whereof the salt-petre makes three quarters, the sulphur half a quarter, and the charcoal the other half quarter. The sulphur serves to inflame the whole. The charcoal hinders its too sudden extinction. The salt-petre makes its strength, by the great dilatation it receives from the fire, and hardness of the parts it shoots. What we can discover in the terrible action of gun-powder is extremely confined, though we have learned by several Experiments to make it and manage it. See the article GUNPOWDER, in the Dictionary. The ingredients, which enter its composition, are harmless, while they remain separate; and it could be wished, for the repose of sailors, and those who have gun-powder in their neighbourhood, that all those matters could be exported, or kept separate, till a present occasion should require to join them together. This would be an important service to society: I ask it of them who want nothing else for the formation of the world but matter and motion. But, till they be pleased to favour us with it, we will continue to make the incorporation of the three matters gun-powder is composed of, in the mortars of the mill, with the assistance of the pestles and sprinkling. The mortar is a piece of wood made to receive twenty pounds of paste of the composition abovementioned.

There are twenty-four mortars in each mill; where are made at once, and in one day, four hundred and eighty pounds of gun-powder, by sprinkling each mortar with two pounds of water, taking care to repeat the sprinkling, from time to time, lest the matter should take fire. The paste having been pounded during three hours successively, it passes from one mortar into another. The mortar is pierced at bottom, and stopped with a cork or piece of wood in the form of a cone, to receive the strokes of the pestles, and reserve the mortar. The pestle is a piece of wood ten feet high, and four inches and a half broad, armed at bottom with a round piece of metal. The pestle weighs sixty-five pounds. The inspection of the pieces will make us conceive the effect thereof.

Plate XXXVIII. *fig.* 1. The profile of the wheel and cog-wheel.

A. The wheel.

B *b*. The arbor of the great wheel. It places one trunnion in *b*, and the other in B. See *fig.* 2.

C. The arbor of the trundle-head C seen beyond the cog-wheel.

E. The cog-wheel, from before which the trundle-head D has been taken off here.

F. The pestles.

G. The tails of the pestles; which are two pieces of wood, pierced with as many holes as there are pestles, to keep them even in the same row, while they go up and down.

H. The outside of the mortars.

Fig. 2. The plan of the whole machine.

A. The wheel.

B. The arbor.

C D. The two trundle-heads, each with its proper arbor, called here canting-wheel. The axis which makes the trundle-head turn is called canting-wheel, being environed with twelve small pieces of wood jutting out; these pieces are called lifts, because they are designed to raise the pestles; they catch them by the meeting of another piece of wood fastened laterally to each pestle. These fastenings are called stays.

E. The cog-wheel.

G. The tails of the pestles.

H. The bottom of the mortars.

If water be given to the wheel, the cog-wheel muſt march and drive contrary ways the two trundle-heads and their canting-wheels. Each, lift turning with the canting-wheel, meets at its return with the ſtay of a peſtle, and lets it fall into its mortar. Theſe twelve lifts are diſpoſed in ſuch a manner that there are always four of them up, and four peſtles unequally ready to fall. There is but one of them that falls at a time. From that diſpoſition of the peſtles depends the equality of the trituration of the peſtle. Which ſucceeds ſtill better, by making it paſs through the twenty-four mortars at regular times.

POWER (*Dict.*) — We find in ourſelves a Power to begin or forbear, continue or end, ſeveral actions of our minds, and motions of our bodies, barely by a thought or preference of the mind. This Power which the mind has thus to order the conſideration of any idea, or the forbearing to conſider it, or to prefer the motion of any part of the body to its reſt, and vice verſa, in any particular inſtance, is what we call the will.—And the actual exerciſe of that Power, is that which we call volition, or willing.

The forbearance or performance of that action, conſequent to ſuch order or command of the mind, is called voluntary: and whatſoever action is performed without ſuch a thought of the mind is called involuntary.

The Power of perception is what we call the underſtanding. Perception, which we make the act of the underſtanding, is of three ſorts: the perception of ideas in our minds; the perception of the ſignification of ſigns; and the perception of the agreement or diſagreement of any diſtinct ideas.

Theſe Powers of the mind, viz. of perceiving and preferring, are uſually called by another name; and the ordinary way of ſpeaking is, that the underſtanding and will are two faculties or powers of the mind. A word proper enough, if uſed ſo as not to breed any confuſion in men's thoughts, by being ſuppoſed (as there is room to ſuſpect it has been) for ſome real beings in the ſoul, that perform thoſe actions of underſtanding and volition. From the conſideration of the extent of the Power of the mind over the actions of the man, which every one finds in himſelf, ariſe the ideas of liberty and neceſſity.

So far a man has a Power to think, or not to think; to move or not to move, according to the preference or direction of his own mind; ſo far is a man free.

Wherever any performance or forbearance are not equally in a man's Power; wherever doing or not doing will not equally follow upon the preference of his mind; there he is not free, though perhaps the action may be voluntary.

So that the idea of liberty is the idea of a Power in any agent to do or forbear any action, according to the determination or thought of the mind, whereby either of them is preferred to the other: where either of them is not in the Power of the agent to be produced by him according to his volition, there he is not at liberty: that agent is under neceſſity. So that liberty cannot be where there is no thought, no volition, no will: but there may be thought, there may be will, there may be volition, where there is no liberty. Thus a tennis-ball, whether in motion by the ſtroke of a racket, or lying ſtill at reſt, is not by any one taken to be a free agent; becauſe we conceive not a tennis-ball to think, and conſequently not to have any volition, or preference of motion to reſt, or vice verſa. So a man ſtriking himſelf or his friend by a convulſive motion of his arm, which is not in his Power by volition, or the direction of his mind, to ſtop or forbear; nobody thinks, he has liberty in this; every one pities him, as acting by neceſſity and conſtraint. Again, ſuppoſe a man be carried, whilſt faſt aſleep, into a room, where there is a perſon he longs to ſee, and be there locked faſt in, beyond his Power to get out; he awakes, and is glad to ſee himſelf in ſo deſirable company, which he ſtays willingly in; that is, he prefers his ſtaying to going away: is not this ſtay voluntary? Nobody will doubt it; and yet, being locked faſt in, he is not at liberty to ſtay, he has not freedom to be gone.

Liberty, therefore, is not an idea belonging to volition, or preferring; but to the perſon having the Power of doing, or forbearing to do, according as the mind ſhall chuſe or direct. As it is in the motions of the body, ſo it is in the thoughts of our minds, where any one is ſuch, that we have Power to take it up, or lay it by, according to the preference of the mind, there we are at liberty.

A waking man is not at liberty to think, or not to think, no more than he is at liberty, whether his body ſhall touch any other or no: but whether he will remove his contemplation from one idea to another, is many times in his choice; and then he is, in reſpect of his ideas, as much at liberty, as he is in reſpect of bodies he reſts on. He can at pleaſure remove himſelf from one to another.

Yet ſome ideas to the mind, like ſome motions to the body, are ſuch, as in certain circumſtances it cannot avoid, nor obtain their abſence, by the utmoſt effort it can uſe: thus a man on the rack is not at liberty to lay by the idea of pain, and entertain other contemplations.

Wherever thought is wholly wanting, or the Power to act or forbear according to the direction of thought, there neceſſity takes place. This, in an agent capable of volition, when the beginning or continuation of any action is contrary to the preference of his mind, is called compulſion; when the hindering or ſtopping any action is contrary to his volition, it is called reſtraint. Agents that have no thought, no volition at all, are in every thing neceſſary agents.

POWER, in algebra.— If any Power of a quantity be divided by a greater power of the ſame quantity, the quotient muſt be negative. For the rule for dividing any Power of a quantity by another Power of the ſame, is to ſubtract the exponent of the diviſor from the exponent of the dividend, and make the difference the exponent of the quotient.

For inſtance, $\frac{a^6}{a^4} = a^{6-4} = a^2$ and $\frac{a^m}{a^p} = a^{m-p}$. Hence if p be greater than m, the exponent $m-p$ muſt be negative.

Thus if $p = m + n$, then $\frac{a^m}{a^p} = \frac{a^m}{a^{m+n}} = a^{-n}$.

It is obvious that $\frac{a}{a} = a^{1-1} = a^0$. But $\frac{a}{a} = 1$; and therefore $a^0 = 1$. In like manner $\frac{1}{a} = \frac{a^0}{a^1} = a^{-1}$; $\frac{1}{aa} = \frac{a^0}{a^2} = a^{0-2} = a^{-2}$; $\frac{1}{aaa} = a^{0-3} = a^{-3}$, ſo that the quantities a, 1, $\frac{1}{a}$, $\frac{1}{a^2}$, $\frac{1}{a^3}$, $\frac{1}{a^4}$, &c. may be expreſſed thus, a^1, a^0, a^{-1}, a^{-2}, a^{-3}, a^{-4}, &c.

This change of expreſſion is often of great uſe in the computation of fluxions and infinite ſeries.

When the quantity to be raiſed to any power is poſitive, all its powers muſt be poſitive. And, when the radical quantity is negative, yet all its Powers, whoſe exponents are even numbers, muſt be poſitive. For $- \times -$ gives $+$.

The Power then can only be negative, when the exponent is an odd number. Thus the Powers of $-a$ are $-a$, $+a^2$, $-a^3$, $+a^4$, $-a^5$, &c. Thoſe whoſe exponents are 2, 4, 6, &c. are poſitive, but thoſe whoſe exponents are 1, 3, 5, 7, &c. are negative. *Mac Laur. Algebr.*

Hence, if a Power have a negative ſign, no root of it, denominated by an even number, can be aſſigned; ſince no quantity multiplied into itſelf an even number of times can give a negative product. Thus the ſquare root of $-aa$ or $\sqrt{-aa}$ cannot be aſſigned, and is what mathematicians call an impoſſible, or imaginary quantity or root. See ROOT.

Obſerve, that every Power has as many roots, real and imaginary, as there are units in the exponent of the Power. This holds true of unity itſelf. *Mac Laur. Algebr.*

Imperfect POWER, in algebra, is uſed for a Power that has a fractional experiment; thus $a^{\frac{1}{2}}$ $a^{\frac{1}{3}}$ $a^{\frac{2}{3}}$ $a^{\frac{1}{5}}$, &c. are imperfect Powers. *Mac Laur. Algebr.*

Theſe are otherwiſe expreſſed by placing the given Power within the radical ſign $\sqrt{}$, and placing above the radical ſign the number that denominates what kind of root is required.

Thus, $a^{\frac{1}{2}} = \sqrt[2]{a^1}$; $a^{\frac{5}{3}} = \sqrt[3]{a^5}$; $a^{\frac{m}{n}} = \sqrt[n]{a^m}$.

Theſe imperfect Powers are alſo called ſurds.

POW'TER, *or Engliſh Powter*, the name of a peculiar ſpecies of pigeon, called, by Moore, the columba gutturoſa Anglica. It was firſt bred in England, and is a mixed breed, between what is called the horſeman and the cropper. It is a very beautiful ſpecies, and is valued for its length of legs and body, neatneſs of crop, and ſlenderneſs in girth, added to the beauty of its feathers. This ſpecies is often eighteen, ſometimes twenty inches long from the end of the bill to the extremity of the tail. Its legs, from the upper joint of the thigh to the toe nail, is ſometimes ſeven inches; the crop is large and round, eſpecially towards the beak, filling alſo behind, and making almoſt a perfectly orbicular figure. They are either blue-pied, black-pied, red-pied, or yellow-pied; the laſt colour is moſt valued. *Moore's Columbarium.*

Pariſian POWTER, a ſpecies of pigeon called, by Moore, columba gutturoſa Pariſiorum.

It was firſt bred at Paris, and thence ſent to Bruſſels, whence it was afterwards brought into England. It reſembles the Engliſh Powter, but is ſhort-bodied, ſhort-legged, thick in the girth, and long-cropped. It is admired for the beauty of its feathers, which is peculiar to itſelf; it reſembles in this a fine piece of that ſort of needle-work which the ladies call the Iriſh ſtich, being chequered with various colours in every feather, except the flight, which is white. It has generally a good deal of red intermixed with other colours, and, the more it has of this, the more it is eſteemed.

Horſeman POW'TING, a name given to a mixed breed of pigeons, produced between thoſe two kinds known by the names of the cropper and the horſeman, according to the number of times that the young are bred over from the cropper. They are diſtinguiſhed by the names of the firſt, ſecond, or third breed.

Small POX. See SMALL *Pox, Dictionary and Supplement.*

PRA'MNION, in natural hiſtory, the name of one of the ſemipellucid impellucid gems, so distinct from all the others as to make properly a peculiar genus of fossils. It is called by many of the antients morio, or morion, and by our lapidaries the black agate.

It is a stone of a very great concealed beauty. Our lapidaries, who know it by the name of the black agate, are very indeterminate in the application of that name, calling by it not only this, but every black stone capable of a good polish by the same name, and never looking for its great character, its hidden colour. It is found in the shape of our common flints and pebbles, but seldom larger than an egg; it appears, on a slight inspection, to be of a fine deep black, but held up against the sun, or the light of a candle, it discovers itself to be of a fine strong red, without the least admixture of any other colour. It is most frequently of a purplish tinge, like the amethyst, but is at times found of all the degrees of red, from the pale flower colour of the hyacinth to the deep red of the carbuncle. It is of great hardness, and capable of an elegant polish.

It is produced only in the East-Indies; and we sometimes have it thence among other stones, but it is not much regarded with us. The Romans were fond of it for engraving on, as we find by Pliny, and by a much more undeniable proof, many of the valuable antiques being cut on it. *Hill's Hist. of Foss.*

PRA'SIUS, in natural history, the name of a gem, much approaching to the nature of the emerald, but of a coarser green, and wanting its hardness, and having in its green a cast of yellow.

It is the stone which the antients called prasites; and, when of a greater than ordinary admixture of yellow, the chrysoprasus, and of which the gem, distinguished by later authors under the name of the smaragdoprasius, is only one of the varieties.

The Prasius, even in its most perfect state, is much less beautiful than most of the other gems: it is found of various sizes, and not unfrequently considerably large: it is seldom met with smaller than a pea; from that to the size of a horse bean is its most usual standard, from this to the size of a nutmeg it is more rarely found; and the larger specimens are coarser and less frequent than these.

PRA'YER, (*Dict.*)—We shall not here amuse the reader with a critical enquiry into the origin of words that express that duty which men have in all ages thought themselves indispensably bound to pay unto the deity, of what nature soever he be. It is almost needless too bserve that to adore and adorare are derived from ad and orare; as if we should say, ad os referre manum, to pray with the hand before the lips. We shall only observe, that men have extremely multiplied the terms designed to express a religious act, imagining, perhaps, that the same idea expressed in their prayers in different terms, attended with certain ceremonies which they thought most acceptable to God, might prove more successful, and in a more effectual manner secure the divine assistance. The Greeks and Romans thought there was a sort of magic charm in some particular words and superstitious forms, which they made use of in their Prayers, and were even persuaded, that, by the prevailing power of them, they could compel the deity to be favourable to them. As all mankind in general have the same favours to beg of God, it is no wonder that their forms of Prayer should be almost the same, or at least alike in many respects. They all tend to the same end, and their necessities are the same; but as man by degrees began to lose the true idea of the divine being, and took upon him to attribute corporeal qualities, or human frailties, to him, he likewise lost the true spirit of Prayer. He added superstition to his worship, served God under corporeal notions, and, being no longer capable of contemplating him in spirit, was pleased to represent him by images, statues, &c. Hence arose so many extraordinary ceremonies, such extravagant acts of devotions, and such an infinite number of forms used in Prayer; such, among the antients, was the Io Pæan, which made a part of their pompous addresses to Apollo, &c.

With regard to Prayers, Jesus Christ forbids his disciples to lengthen them by vain and impertinent repetitions. Doubtless a repetition of the same thing in Prayer proceeds neither from zeal nor respect. It is very probable, that the Prayers of idolaters might be very tedious; but it is surprising that Christians should have fallen into the same error. Surely, to repeat the same Prayer to God fifty times, in the space of an hour, is as impertinent as to present fifty copies of the same petitions one after another to a prince. Among the Turks there are a sort of bigots who affect to repeat the name of God with an irreverent volubility, which rather resembles madness than devotion. The antients were very fond of using the number 3 in their Prayers; for instance, Tibullus says, Ter cane, ter dictis respice carminibus; and Ovid, Ter tollit in æthera palmas, &c. They imagined also that the gods delighted in a long train of titles of pompous appellations, to express their supremacy and power; and lest they should unhappily distinguish thereby any nature that might give offence, they took peculiar care to mention those attributes with a salvo, or some modest restriction, such as, Sive deus, sive dea es; not presuming to ascertain the sex of the deity whom they worshipped.

When they prayed aloud, a minister of the gods rehearsed the Prayer to the people, who repeated it in the very same terms; and the same thing is now practised among the Roman Catholics and Protestants, as well as among the Turks.

The piety of the ancient Greeks, and the honourable opinion they entertained of their deities, is in nothing more manifest than in the continual Prayers and supplications they made to them; for no man of the least prudence would undertake any thing of moment, without first asking the advice and assistance of the gods: and we are told by Plato, that, 'at the rising both of the sun and moon, one might every-where behold the Greeks, as well those in prosperity, as those in afflictions and distresses, prostrating themselves, and hear their supplications'.

The Lacedæmonians had a peculiar form of Prayer; for they never used, either in their public or private devotions, to make any other request, than that the gods would grant what was honourable and good for them.

There were several ceremonies attending the manner of their supplicating the gods. The petitioners were usually crowned with garlands, and carried boughs of laurel or olive in their hands; laurel being an emblem of success or victory, and olive of peace and good-will. With these boughs they touched the knees, or head of the statue, to which they addressed themselves. Sometimes they prostrated themselves at the entrance of the temples, and kissed the sacred threshold.

The postures they used were different; sometimes they prayed standing, sometimes sitting, but most commonly kneeling, that being expressive of the greatest humility. The poets furnish us with innumerable examples of prostration before the images, altars, and thresholds of the temples. They turned their faces to the east, when they prayed to the gods; and to the west, when they addressed themselves to the heroes or demi-gods.

It was also an usual gesture, in praying, to lift up their hands, and is sometimes therefore used to signify praying; as in Horace:

Cœlo supinas si tuleris manus.

When they lay prostrate, or kneeled upon the earth, it was customary to beat it with their hands.

It was a common opinion, that their Prayers were more prevalent and successful when offered up in a barbarous and unknown language. The reason assigned for this was, that the first and native languages of mankind, though barbarous and uncouth, yet consisted of words and names more agreeable to nature. If they obtained their request, and it was a matter of consequence, they presented to the god some rich gift, or offered a sacrifice. Sometimes the favour received was registered in the temple, as a memorial of the goodness of the god.

Under the article of Prayer may be included that of imprecations. These were extremely terrible, being thought so powerful, when duly pronounced, as to occasion the destruction, not only of single persons, but of whole families and cities.

The most terrible imprecations were those pronounced by parents, priests, kings, or other sacred persons.

Among the Hebrews, it is certain, that Prayers were daily put up, together with their offerings. For this purpose they had liturgies, or prescribed forms, which may be proved to be used in the very infancy of the Hebrew nation. The forms of Prayer that belonged to the worship of the synagogue were very few at first; but they are since increased to a large number, which makes the service very long and tedious.

The most solemn part of the Jewish Prayers is that which they call the eighteen Prayers, composed, as they say, by Ezra, with the assistance of the great synagogue. To these eighteen another was added, a little before the destruction of Jerusalem, in the time of rabbi Gamaliel. It was designed against the Christians, who are meant in it under the names of heretics and apostates.

These nineteen Prayers are, in the Jewish liturgies, no other than as the Lord's Prayer in ours, being but the fundamental and principal part; for, besides these, they have many others, some going before, others intermixed with them, and others following after: but these alone, on account of their great excellency, are at this day used, without any the least difference, by the Jews in all parts of the world; and that, not only in their synagogue, but also in their private houses.

The Jews, anciently, when they went to pray, covered their head and face with a veil, as a mark of humility and confusion, when they appeared before the divine presence. The postures they used were, either standing, according to the example of holy men recorded in scripture, or bowing, or kneeling, or prostrating; which three last were used upon the great day of expiation, and other solemnities of confession and humiliation. They always turned their faces towards the temple, if they dwelt at Jerusalem; and towards the holy land, if they lived elsewhere. They were obliged to appear clean and neat in their cloaths, when they came to public worship, and not to eat, drink, or sleep, in their synagogues, in which every thing was to be done with decency and order.

The duty of Prayer is constantly and strongly enforced in the Koran of Mahommed. The mussulmans are directed to 'remember God (that is, to pray to him) standing, sitting, and lying on their sides'; viz. at all times, and in all postures.

The Turks perform their devotions, in their mosques, five times every day. When they come to the mosques, they pull off their shoes, and go in bare-footed; then they kneel down, laying their shoes before them, and resting their back-parts on their heels. At the conclusion of their Prayers they take out their beads, which are ninety-nine in number. After this, they lift up their hands at a little distance from their faces, and repeat a certain Prayer to themselves; then they smooth down their faces with their hands, take up their shoes, and go out of the mosque. These public prayers last but about a quarter of an hour.

PRE'BEND (*Dict.*)—The term Prebend is usually confounded with canonicate, or canonica; yet there is a real difference. A Prebend is properly a right which an ecclesiastic has in a cathedral, or collegiate church where he officiates, to receive certain ecclesiastical revenues, and to enjoy certain dues, either in money or in kind; (so called à præbendo, q. d. afforded or allowed him; not à præbendo auxilium or consilium episcopo) whereas canonica is a mere title, or spiritual quality, which a person enjoys independent of any præstation, or any temporal revenue: so that the Prebend may subsist without the canonicate; but the canonicate is inseparable from the Prebend.

For it is not to the Prebend that the right of suffrage and other spiritual rights are annexed, but to the canonicate; and, when the Prebend is joined to the canonicate, it becomes spiritual by virtue of the canonicate because it is absolutely attached to it.

Anciently the pope created canons with a right of having place in the choir, a deliberative voice in the chapter, and an expectation of the first Prebend that should become vacant; but this was prohibited by the council of Trent: yet the pope still confers the canonicate without any Prebend, when he would confer a dignity in a church, for the obtaining whereof, it is required the candidate be a canon.

This they call a canonicate ad effectum, and sometimes jus ventosum, which is no more than an empty title, conferred purely to qualify a man for a dignity restrained to the capacity of canon.

In some churches there are double Prebends, and in others semi-Prebends.

Originally the Prebend was only a livery, or portion of things necessary to life, given daily; at present the rents and profits of the church are divided into fixed portions, called Prebends, which are enjoyed independently. The nomination to Prebends is in the king. In France it is one of the honorary rights of the king, on his joyful accession to the crown, to nominate to the first Prebends vacant by death in the cathedral and collegiate churches.

Prebends are either simple, or with dignity.—The latter are such as, besides their Prebends, have some jurisdiction annexed to them.

Theological, or *divinity* PREBEND, is a Prebend appropriated to a doctor in divinity, in each cathedral and collegiate church throughout France, for preaching on Sundays, and making a public lecture thrice a week.

Preceptorial PREBEND, is that Prebend whose revenues are destined for the support of a preceptor or master, who is obliged to instruct the youth of the place gratis.

The canonicate is not here necessary to the Prebend.

Panorm. observes, that in the cathedral church of Chartres there are Prebends appropriated to laymen, and for the subsistence of some persons of birth and distinction.

PREDETERMINA'TION (*Dict.*)—*Physical Predetermination, or promotion*, if there be any such thing, is that action of God, whereby he excites a second cause to act; or by which, antecedently to all operation of the creature, or before it could operate in consequence either of the order of nature or reason, he really and effectually moves and occasions it to produce all its actions: that is, whatever the creature does or acts, is really done and acted by the agency of God on the creature, who is all the time passive. So that, without such Predetermination of God, all creatures must remain in an eternal state of inactivity; and, with such Predetermination, it is impossible but they should do what they are thus put upon doing.

It is strongly controverted, whether or no such a physical Predetermination be necessary to the action of natural causes? The Scotists maintain the negative; urging, that all natural causes are, of their own nature, determined to a certain action; whence it should seem needless to call in a new Predetermination of God, e. gr. to fire, to make it warm the hand. For if an object be, by the course of divine providence, applied to fire; what need a second application of the fire, to make it warm the object applied thereto, since beings are not to be multiplied unnecessarily?

And such Predetermination some philosophers hold still less requisite to produce the acts of the will: at least, say they, the human mind must be allowed the common power and privilege of a second cause, and therefore be intitled to produce its own acts, as well as other strictly natural agents.

The Thomists, on the other hand, stand up strenuously for the physical Predetermination: one of their principal arguments is drawn from the subordination of second causes to the first. Where there are several subordinate agents, say they, the lower agents do not act, unless first moved and determined thereto by the first; this being the very essence of subordination.

Again, the like they argue from the dominion of God over all his creatures: it is of the essence of dominion, say they, to apply and direct things subject thereto to its own operations; and this, if the dominion be only moral, morally; but if it be also physical, physically. And that this is the case in respect of God, and his creatures, is confessed.

PREMONSTRATE'NSES (*Lat.*) in French Premontrés; a religious order, founded by St. Norbet, descended from a noble family in the diocese of Cologn, who embraced the rule of St. Austin, and retired with thirteen companions to a place called Premonstratum, in the diocese of Leon, in Picardy, where he began his order, about the year 1119. The place was called Premonstratum, because it was pretended the blessed virgin herself pointed out (premonstravit) this place for the principal house of the order, and at the same time commanded them to wear a white habit.

The religious of this order were, at first, so poor, that they had nothing they could call their own, but one poor ass, which served them to carry wood, which they cut down every morning, and sent to Leon, where it was sold to purchase bread: but, in a short time, they received so many donations, and built so many monasteries, that, thirty years after the foundation of this order, they had above an hundred abbeys in France and Germany.

The popes and kings of France have granted many privileges, and been very liberal to the Premonstratenses. Besides a great number of saints, who have been canonized, this order has had several persons of distinguished birth, who have been contented with the humble condition of lay-brother, as Guy, earl of Brienne; Godfrey, earl of Namur, &c. It has likewise given the church a great number of archbishops and bishops.

The order of Premonstratenses increased so greatly, that it had monasteries in all parts of Christendom, amounting to a thousand abbeys, three hundred provostships, a vast number of priories, and five hundred nunneries. These were divided into thirty cyrcaries or provinces. But this number of houses is greatly diminished; for, of sixty-five abbeys it had in Italy, there is not one remaining at present; not to mention the loss of all their monasteries in Sweden, Norway, Denmark, England, Scotland, and Ireland.

These monks, vulgarly called white canons, came first into England in the year 1146, where their first monastery, called New-house, was built in Lincolnshire, by Peter de Saulia, and dedicated to St. Martialis. In the reign of Edward I, when that king granted his protection to the monasteries, the Premonstratenses had twenty-seven houses in this kingdom.

PRESBYTE'RIANS (*Dict.*)—The Presbyterians, as to doctrine, agree with the church of England: their chief difference lies in the point of discipline, viz. who shall appoint the governors of the church, and what subordination there shall or shall not be between them.

The Presbyterians allow of no hierarchy, no subordination in the persons of their ministers; bishops and priests, they maintain, in the times of the apostles, were the same; and therefore, though they allow episcopacy as now settled in the church of England to be very ancient, yet they deny it to be jure divino.

In lieu of a series of ministers one over another, in quality of priests, bishops, and archbishops, their polity consists in a series of assemblies, or synods: thus every minister is to be obedient to the classis under which he lives; and that class to a synod, provincial, classical, or œcumenical.

The power of ordination, with them, resides in a classis; and none are admitted to administer the sacrament, but those ordained by the imposition of hands of other ministers.

They make use of elders or lay-men to take care of their poor; and likewise in the government of the church, whence their name, from the Greek, πρεσβύτερος, signifying senior, elder.

This is now the reigning discipline in the church of Scotland; as it was, during the interregnum, in England.

Elders take care of the collections made on Sundays for the poor; each elder in a parish has a distinct district which he superintends, as is were, and acquaints the kirk session of any irregularities that are committed therein, as fornication, drunkenness, &c. and he recommends any person who is an object of charity, for a weekly allowance, &c. from the session, out of the said weekly collections.

PRESENTA'TION (*Dict.*)—PRESENTATION *of the virgin* is a feast of the Romish church held on the twenty-first of November, in memory of the holy virgin's being presented by her parents in the temple, to be there educated.

It is pretended, that there were young women brought up in the temple of Jerusalem; which some endeavour to prove from the second book of Maccabees, Sed & virgines quæ conclusæ erant, procurrebant ad Oniam; which is the sentiment of Eutochius on this passage. And Lyranus adds, that other more ancient authors observe, that young women were educated till marriage, either in the temple, or at least, in buildings contiguous thereto.

Emanuel Comnenus, who began to reign in 1143, makes mention of this feast in his constitution. Some even imagine it to have been eſtabliſhed in the eleventh century, among the Greeks; and think they ſee evident proofs of it in ſome homilies of George of Nicomedia, who lived in the time of Photius: ſo that it ſeems a miſtake in ſome modern critics to refer its inſtitution to Gregory XI. in 1372.

Some take it to have been inſtituted in memory of the ceremony practiſed among the Jews for their new-born females, correſponding to the circumciſion on the eighth day for males.

PRESENTATION *of our lady* alſo gives the title to three orders of nuns.

The firſt, projected in 1618, by a maid named Joan of Cambray. The habit of the nuns, according to the viſion ſhe pretended to have, was to be a grey gown of natural wool, &c. but this project was never accompliſhed.

The ſecond was eſtabliſhed in France about the year 1627, by Nic. Sanguin, biſhop of Senlis. It was approved by Urban VIII. This order never made any great progreſs.

The third was eſtabliſhed in 1664, when Fred. Borromeo, being apoſtolical viſitor in the Valteline, was intreated by ſome devout maids at Morbegnobourg to allow them to live in community in a retired place; which he granted, and erected them into a congregation, under the title of congregation of our lady. They live under the rule of St. Auguſtin.

PRETOR (*Dict.*)—For the better underſtanding the dignity of the Pretors, it will be proper fully to examine the reaſon of their name, inſtitution, number, dignity, and what their power and charge was. The word Pretor was peculiarly applied to this new magiſtrate, for before it belonged to the conſuls, and all perſons in authority, whether in civil or ſacred things; hence it is that we read, in ſome ancient epitaphs, Prætor ſacrorum, Prætor juventutis, &c.

The ancients not only called thoſe Pretors who commanded the armies, but alſo ſuch as had the charge either of ſacred or civil things. The occaſion of creating this magiſtrate, was a multiplicity of buſineſs upon the conſul's hands, and this was anno 388, and the neceſſity the republic found itſelf under of granting to the people a conſul of their own order; for the ſenate did not allow it, but upon condition that a new magiſtrate ſhould be created, that is, the Pretor, who was taken out of the patrician order: but, in the year 416, Q. Philo, a plebeian, got himſelf advanced to the office of Pretor, notwithſtanding the oppoſition made by the conſul Sulpicius againſt him.

There was no more than one of them from the year 388, till 510, according to Lipſius; but buſineſs coming to increaſe ſo much by reaſon of the great number of citizens and ſtrangers that came to live in Rome, and one being not enough, they thought it proper to conſtitute another, and their buſineſs was diſtinct; for one adminiſtered juſtice to the citizens of Rome, and for that reaſon was called Pretor urbanus; and the other took cognizance of the ſuits that happened between the citizens and ſtrangers, and he was called Prætor peregrinus: the firſt was more honourable than the other, and ſo he was intitled Prætor honoratus, and his edict named jus honorarium, as the lawyers ſay. But towards the year 520, they appointed two new Pretors: Livy informs us, they made ſix Pretors for one year. Tiberius afterwards named twelve Pretors, the number eſtabliſhed by Auguſtus, and as the ſenate preſſed him to increaſe them, he ſwore he would not do it: however he increaſed them to fifteen, in the year 786, according to Dion. The emperor Claudius enlarged the number to eighteen; but upon the declenſion of the empire, they were reduced to three only, as we may ſee by the laws of the emperors Valentinian and Macrinus, ſet forth, *L.* II. *C. de Off. Præt.*

The pretorſhip was the ſecond office for dignity in Rome, ſince it was conferred by the ſame auſpices as the conſulſhip, and that the Pretors were in hiſtory called collegæ conſulum, as Livy obſerves, L. I. Decad 1. The exterior enſigns of this office were the robe called prætexta, the curule chair, and ſix lictors. This office was annual, and he who diſcharged the ſame with honour, and without any diſgrace, had a right for all his life-time to wear the prætexta and white trabea; but ſuch as were guilty of male-adminiſtration were forced to lay it down. All their buſineſs in general conſiſted in three things, viz. to adminiſter juſtice to citizens and ſtrangers, to preſide over games, and to take care of the ſacrifices: they took care of the ſacrifices offered to the goddeſs called Bona Dea, as Plutarch ſays in Cæſar's life, and Cicero, L. I. Ep. 10. *ad Atticum.*

PRICKLE-*back*, in natural hiſtory, a ſmall fiſh ſo called from the Prickles on its ſides and back. Vaſt numbers of theſe little fiſh are to be found in almoſt all freſh waters, wherever it is poſſible for fiſh to live, as Mr. Arderon informs us, Philoſophical Tranſactions N°. 482, who gives us ſome account of theſe creatures. They are very deſtructive to the ſpawn of all ſorts of fiſh; and they themſelves are tormented to death by a kind of louſe of an oval figure, with eight legs and a very tranſparent body. This louſe has little fins always in motion, whether it be ſwimming about or fixed on the fiſh.

PRIDE *of the Iſis*, a name given by Dr. Plot to the common lampern, from its being found very plentifully and very delicate in that river.

PRIEST (*Dict.*)—Religious worſhip being once confined to temples, the appointment of miniſters for the deities became neceſſary: God himſelf inſtituted thoſe whom he deſigned for the ſervice of the true religion, and mankind eſtabliſhed thoſe who propagated that which was the falſe. Both the one and the other, from the mercenary views of worldly intereſt, have been multiplied to an infinite number. The Prieſts found means to hinder men from action, till they had been firſt conſulted. They ſet all the ſprings of the paſſions in motion, were at the head of all intrigues, and made themſelves maſters of the courts of princes; ſo great has the authority of Prieſts ever been in all religions. We know the power of the augurs, ſoothſayers, and Prieſts, among the Greeks and Romans; of the Magi among the Perſians; of the Druids among the Gauls, &c. The Mufti, and other doctors of the Mahometan law, are too often the grand engines in the moſt important debates of the Divan. Among the Germans, the Prieſts gave ſentence of life and death upon criminals. Many nations formerly choſe their Prieſts for kings. In the Eaſt and Weſt-Indies, China, Japan, &c. the Prieſts and monks have an unlimited power. Men are ſo formed by nature that there is an abſolute neceſſity that Prieſts ſhould have reſpect paid them, in order to maintain the dignity of religion; but the main point is, to ſet ſeaſonable bounds to that reſpect, ſo as not to fall into the exceſſes of thoſe, who give themſelves up blindly to the paſſions of Prieſts.

Among the ancient Greeks, the dignity of prieſthood was eſteemed ſo great, that, in moſt of their cities, and eſpecially at Athens, it was joined with that of the civil magiſtrate. In Egypt, the kings were all Prieſts; and, if any one, who was not of the royal family, uſurped the kingdom, he was obliged to be conſecrated to the prieſthood, before he could mount the throne.

But, beſides theſe royal Prieſts, there were others, taken from the body of the people, and conſecrated to the ſervice of religion. Theſe all were accounted the miniſters of the gods, and by them commiſſioned to diſpenſe their favours to mankind.

The Prieſts were differently appointed to their office; ſome obtained the prieſthood by inheritance, others by lot, others by the deſignation of princes, and others by popular elections. Whoever was admitted to this office, it was neceſſary he ſhould be found and perfect in all his members, it being thought a diſhonour to the gods to be ſerved by any one that is maimed, or any other way imperfect: and therefore, at Athens, before their conſecration, they were examined, whether they were ἀφελεῖς, perfect, having neither defect, nor any thing ſuperfluous. They were likewiſe obliged to be upright in mind, as well as perfect in body; to live chaſtely and temperately, abſtaining from thoſe pleaſures, which were allowed to other men: ſome were ſuch rigid obſervers of chaſtity, that they diſmembered themſelves. But, though moſt of them were obliged to ſtrict chaſtity and temperance, yet there are inſtances of married Prieſts among the Greeks.

It is not eaſy to give an exact account of the different orders of Prieſts among the Greeks; for not only every god had ſeveral ſorts of Prieſts conſecrated to him, but even the Prieſts of the ſame God were different, according to the diverſity of places and circumſtances.

What has been ſaid concerning the Grecian Prieſts is applicable likewiſe to thoſe of the Romans.

Among the Hebrews, the prieſthood was not annexed to a certain family, till after the promulgation of the law of Moſes. Before that time, the firſt-born of every family, the fathers, the princes, and the kings, were Prieſts. Cain and Abel, Noah, Abraham, and Job, Abimelech, and Laban, Iſaac and Jacob themſelves, offered their own ſacrifices. But, after the giving of the law, the prieſthood was annexed to the family of Aaron, of the tribe of Levi. However, we find the judges and kings of the Hebrews, on ſeveral occaſions, offering ſacrifices to the Lord, eſpecially before a conſtant place of worſhip was fixed at Jeruſalem.

The high-Prieſt was at the head of all religious affairs, and was the ordinary judge of all matters concerning the juſtice and judgment of the Jewiſh nation.

It was required, as neceſſary qualifications for the high-Prieſt, that he ſhould be born of one of his own tribe, that his father had married a virgin, and that he ſhould be exempt from all corporal defects and infirmities. When he was inveſted with that high dignity, and clad in pontifical ornaments, he was conſidered as the oracle of truth, and gave anſwers to the queſtions propoſed to him.

The high-Prieſt was forbidden to mourn for any of his relations, even for his father or mother; or to enter into any place where a dead body lay, that he might not contract any uncleanneſs. The habit of the high-Prieſt was much more magnificent than that of the other Prieſts. He wore a long robe of an azure-colour, at the bottom of which was a border adorned with little golden bells and pomegranates, and made of wool of different colours, and ranged alternately to equal diſtances. This robe was girded about with the ephod. Upon his breaſt he wore a pectoral, or breaſt-plate, and upon his head a tiara or bonnet, from whence hung down a plate of gold, on which were engraven these words, Holiness to the Lord. The ordinary or inferior Priests served immediately at the altar, offered the sacrifices, killed and flead them, and poured their blood at the foot of the altar.

The common habit of the Priests was, a kind of surplice, or linen tunic, without seam, with a sash of several colours, hollow, like the skin of a serpent. It went twice round the body, was tied before, and the ends hung down to the feet. When they were in the act of sacrificing, they threw this girdle over the left shoulder, that they might perform their office with the greater freedom. The Rabbins made this sash to be two and thirty cubits long. They wore a cap, or bonnet, of fine linen, folded several times round the head.

The age at which they entered upon the sacred ministry, was fixed by Moses to twenty-five or thirty years, and they were to end it at fifty. But, in David's time, the rule was changed; and they were permitted to attend the service of the temple at twenty years of age, and to dedicate themselves to the priesthood, during life.

The Lord had given no lands of inheritance to the tribe of Levi, in the distribution of the land of promise; but they were to be supported by tythes, first-fruits, and offerings. In the peace-offerings they burnt upon the altar the fat that covers the bowels, the liver, and kidney; the rest belonging to the Priest. The skin or fleece of every sacrifice was the Priest's; and this article alone was no inconsiderable allowance. When an Israelite killed any animal for his own use, he was to give the Priest the shoulder, the stomach, and the jaws. He had also a share in the wool, when the sheep were shorn. All the first-born, both of man and beast, belonged to the Lord, that is, to the Priests. The men were redeemed for five shekels. The first-fruits of trees likewise belonged to the Priests, as also of the land, and of animals. God also provided houses for the Priests, by appointing them forty-eight cities for their habitation.

Next to the service of the temple, the Priests were employed in instructing the people, deciding controversies, and distinguishing the several sorts of leprosy, the causes of divorce, vows, and all causes relating to the law. They publicly blessed the people in the name of the Lord. In the time of war, their business was to carry the ark of the covenant, to consult the Lord, to sound the holy trumpets, and encourage the people.

The consecration of Aaron and his sons to the priesthood was performed by Moses, in the wilderness, with great solemnity. Whether the same ceremonies were repeated at the consecration of every new high-Priest, is uncertain; and as to the inferior Priests, it does not appear that any particular ceremony was used for their consecration; but they seem to have been admitted to the priesthood only by performing the functions of the order.

PRI'MULA *veris, the primrose*, in botany, a genus of plants, whose characters are:

The root is perennial, the leaves are oblong and wrinkled, the calyx is quinquefid, pentagonal, and soft: in this calyx is seated a monopetalous flower, shaped somewhat like a salver, with its margin divided into five heart-shaped, bifid, segments; this flower is furnished with five stamina, which arise from the inside of its tubulous part. The seminal vessel is an oblong shell, concealed in a calyx, furnished with a long tuble, and gaping at its apex; the seeds are roundish.

The flowers are commended by some, as good against disorders arising from melancholy, and phlegmatic humours; the juice of the root is sometimes used as an errhine to purge the head of the tough slimy phlegm. *Miller's Bot. Off.*

PRI'NCES *Feather*, in botany, a name given to the amaranth. See AMARANTH.

PRINCES *Metal.*—Copper, though one of the less precious metals, yet has been found of so great use in the common affairs of life, that scarce any other has been subject to so many trials for its improvement, or the rendering it either more beautiful or more fit for certain purposes.

One of the first discoveries in these attempts was the making it into brass, by means of an addition of lapis calaminaris; and, though it was not at that time known to be a stone which contained any metal, yet the brass was always found to weigh one third more than the copper which had been used in the process. This yellow metal gave many people hopes of making copper approach yet nearer to gold, and, without knowing that zink was the separated metalline part of lapis calaminaris, the experimenters soon found, by happy accident or repeated chance mixtures, that it would give copper a yet finer and purer yellow; but it was also found, that this mixed metal was much more brittle than brass made in the common way. This, however, did not prevent the world from still valuing it for such works as were to be finished by casting, and did not require the hammer: and we, who first had it in perfection, called it Princes metal, from Prince Rupert, whom some suppose to have been the inventor of it; but the greatest perfection this metal was ever brought to, was by two Frenchmen, Mr. La Croix, and Mr. Le Blanc. Their methods of making the composition, though both beautiful, were very different. Mr. Le Blanc's was the brightest, and of the most elegant and lively colour; but Mr. La Croix's was greatly superior to that in ductility and softness, so that it was very easily malleable.

Mr. La Croix invented a sort of varnish or lacquer for his metal, which added a somewhat deeper tinge to it, as it was naturally rather too pale; and had this farther advantage, that, while it remained on the metal, it preserved it from rust or decay. This is a very material point in regard to a metal of which copper is the basis, since that is, of all other metals, most subject to be injured by the air, or by the contact of liquids of almost any kind. Mr. Le Blanc's metal is of a deeper, yet lively colour, and remarkably bright; and is of such a temper as to be admirably fit for working. The whole history of these metals is certainly, that they are composed of zink and copper in different proportions the one to the other; but it is not easy, without the help of numerous experiments, to determine what is to be the true proportion for either.

The microscope, however, shews a manifest difference, which may lead somewhat towards it; for the metal of La Croix is seen to be composed merely of a number of irregular striæ, while the other is discovered to consist of always two regular beds of them, which meet in the center of the piece; hence it is that this is always brittle, and will not well polish. The fabric of these metals was long kept a secret; but it was always to be discovered by melting it in a crucible in a strong fire, when it always sent up plain flowers of zink, and the remaining metal appeared no other than copper altered by calamine; that is, common brass. *Mem. Acad. Par.* 1732.

PRI'NCIPLE, in chemistry (*Dict.*)—*Fire considered as a* PRINCIPLE.—We reckon elementary fire the first Principle of bodies, as being that, from whence all the rest receive their activity. It is a simple and most subtile body, in a continual swift motion, filling, and easily permeating, the pores of all other bodies. Its immense subtility is evident from this, that it penetrates all bodies whatsoever; and its swift motion, from that rapidity which it is capable of communicating to them. Its force is in proportion to the quantity of it any where collected. In the sun, which may be looked upon as a vast congeries of this substance, its motion is most violent. In culinary fires, the quantity and motion of it are not so great, but still greater, than in spirituous and volatile liquors, where it is hardly to be perceived, except when they are set on fire. Not only all motion, but, also, heat proceeds from it, which, as it exists in bodies, is nothing but the excessive motion of their parts. It is, also, too subtile and active ever to be collected pure in chemical analyses; wherever it is found, it is always united with water and earth, in salts and sulphurs; and is sometimes concentered with bodies in so great quantities, as considerably to increase their weight, as is evident in calcined antimony, in which there is an addition made of almost a fifth part.

Water considered as a PRINCIPLE.— Elementary water is a simple, liquid, insipid, inodorous, pellucid substance. Its fluidity is owing entirely to the action of fire, and when that action is very great, its parts are actually divided, and the whole turned to vapour; but, when it is very small, they cohere strongly, and turn to ice. This element the chymists call phlegm, and it may be conceived to consist of small, smooth particles, of an oblong or oval figure, and perfectly rigid or inflexible. From the minuteness of its particles, it easily penetrates the pores of almost all bodies. An oval figure seems more agreeable to the fluidity and motion of the water, than a spherical, and, likewise, to the solidity we observe in ice; the points of contact being too few, in spherical bodies, to form so strong a cohesion. Were its particles angular and flexible, they would be too weak to penetrate and dissolve salts, and would, likewise, be too much resisted; but, as their surface is smooth, they can easily enter the pores of salt, and afterwards they easily separate their parts, that is, dissolve them by their rigidity and oval figure. The want of taste or smell in water seems to proceed from the smoothness, obtuseness, and smallness of its particles, which cannot vellicate the nerves of the tongue and nostrils. The fluidity of water arises from the smallness, smoothness, and figure of its particles, and from the easy motion thereof by the fire contained in their interstices. Without the action of fire separating these particles, and keeping them in continual motion, their fluidity would presently be lost, how much soever their structure may dispose them to it, and they would become one solid mass. On the other hand, if the action of fire upon them be very great, they are farther separated from one another, and fly off in vapour and smoke. In fine, water is transparent, because its pores are so disposed, as readily to transmit the rays of light.

Earth considered as a PRINCIPLE.—Elementary earth is the same with the terra damnata, or caput mortuum of the chymists; being a simple, friable, porous substance, without smell or taste, consisting of particles of no regular figure, and altogether unfit for motion. The porosity of earth seems to arise from the irregular figure of its particles; and as these particles often touch one another only by their angles, the whole mass must necessarily be friable. The want of taste and smell seems to be owing to their inaptitude for motion.

In the analyses of bodies, the last thing is always this Principle of earth; and, in their composition, it seems to serve as a basis or foundation for the other parts of the mixture; and to it the dryness, solidity, and hardness of bodies, are in a great measure, to be ascribed.

Salt,

Salt, as has been said, is a mixed body; but I chuse to introduce it immediately after the Principles, because, in all the common analyses of bodies, it is obtained entire, and a great deal of pains and accuracy is required to decompose it, or reduce it to its principles. It is, also, the sole origin of the taste, smell, and many other properties of bodies. It may be defined to be a mixed body, formed by the concretion of fire, water, and earth, into a solid rigid substance, soluble in water, and fusible by fire. As its particles may be conceived to cohere by large surfaces only, salt cannot be friable like earth; but requires a considerable force to separate its parts, which fly off from one another, like those of glass, with a sensible noise. It becomes the cause of taste and smell, because its particles terminate in strong points, which vellicate the nervous membranes of the tongue and nose.

Salt is of three kinds, acid, acrid, or alcaline, and a third, compounded of the other two, called, in Latin, sal salsus.

Acid salt is a congeries of inflexible solid parts, of an oblong figure, and pointed at both ends. That its particles are rigid and hard, appears from the force, with which it divides and dissolves solid bodies; and its sharpness and pungency are evident from the effect it has on the tongue, different from the corrosion of acrid salts. Acid salt is easily dissolved by water, and after this solution, its particles are equally dispersed through that fluid, and have the same motion with it. Hence it appears, that the particles of both substances have nearly the same specific gravity; and, likewise, that the motion of the aqueous parts is great enough to overcome the cohesion of the parts of salt.

Concerning the manner, in which the particles of acid salt are compounded of fire, water, and earth; nothing can with certainty be determined. It may be conjectured however, that several particles of water, being collected into one little mass, are cemented together by some particles of fire and earth, lodged in the interstices left between them; and that all these, taken together, are disposed in an oval form, or that of two cones joined by their basis. This configuration, however, is not the same in all acid salts; but the differences may all be reduced to three; the nitrous acid, the muriatic, and the vitriolic.

The word alcali is derived from cali, the Arabic name of a plant, from the ashes of which a salt is obtained, proper for making glass: and thence it came to be used for all salts got from the ashes of plants, and afterwards for all salts, and other substances whatever, that ferment with acids.

Acrid or alcaline salt seems to be a congeries of spherical particles, with rough, prickly surfaces, because of their great disposition to motion, and their corrosive burning taste, the points of the surfaces acting on the nervous papillæ of the tongue, like so many files, whereas acid salt is only pungent. But then, by these points, a larger surface is exposed to the action of fire, than could otherwise; and thus the particles of alcaline salt are very volatile, and easily raised by a gentle heat. The origin of this salt is probably from a certain connection of acid points and terrestrial particles; because, in many operations of chymistry, such salts arise from the mixture of acid salts and earth; as we see particularly in the preparation of fixed nitre, and fermentation of urine. Nitre, being distilled, leaves a compound fixed salt behind, of the same nature with the sea-salt, out of which, by a nicer distillation, an acid liquor may be extracted, without any volatile salt, or, at least, but a very small quantity; but if the same fixed salt be previously fermented, and then distilled, it yields a large quantity of volatile salt, and very little fixed salt, or acid; because, by fermentation or calcination, the acid and terrestrial particles are intimately mixed, the acid spicula entering the pores of the earth, and so forming new molecules, which are dense and close towards the center, and prickly on the surface, by the acid points sticking out. Such are the particles of volatile alcalies, of which, if a great number be joined together, they must cohere very strongly, by means of their points, and form molecules of irregular figures, in the pores of which watery, earthy, sulphureous, or acid particles may be received and absorbed. Hence it is that acid salts are seldom pure; and, as they are very often filled with particles of earth, they resist the most violent degree of fire, and will sooner melt than be raised by it. This is the true nature of fixed alcaline salt, such as salt of tartar, or the salts got from the ashes of plants called lixivial salts. If they be impregnated with sulphureous particles, they continue very volatile, and are raised by a small degree of fire; as we see in salt of urine, hartshorn, and others got from animals. Acrid salts easily melt, when exposed to a moist air, because the particles of water contained in it readily enter their pores. When thus melted, they become properly lixivia, and are commonly termed oils, as oil of tartar per deliquium. Volatile alcaline salts, diluted with water, are called volatile urinous spirits; such as the volatile spirit of urine, of hartshorn, blood, and others.

The sal salsus, or third kind, is compounded of acid and alcaline molecules united together; and the figure of its particles is principally produced by the kind of acid that enters its composition. The impression these particles make on the tongue is more dull and languid, than that made by acid or acrid parts alone; because the molecules formed by the union of these are larger in bulk, and consequently less disposed for motion; and, therefore, though there is a greater quantity of alcali, or points, in one of these molecules than in the former, yet their bulk makes them less capable of entering the pores of the skin, and vellicating the nervous papillæ, than when they are in a disjointed state. The taste of these salts is termed saline, and varies according to the thickness of the spicula, their number, and the other parts that may be mixed with them. That this is the true original of this kind of salts, is evident, both from the artificial composition thereof, from acid and acrid particles blended together, and from the resolution of them into the same. Thus, by pouring spirit of nitre, of sea-salt, or of vitriol, on salt of tartar, new salts are produced exactly of the same appearance with nitre, sea-salt, or vitriol; and, by analysing these three salts, the essential salts of plants, sal ammoniac, and others, an acid and alcaline salt may be obtained, in some fixed, in others volatile.

What the chymists call oil, or sulphur, is not a simple substance, but a body compounded of fire, water, earth, and salt; but we chuse to introduce it here, as it is most commonly separated in the operations of chymistry, and is not resolved without difficulty into its component Principles. It may be defined to be a fluid, viscid, inflammable, transparent body, without taste or smell, though by mixing it differently with salts these sensible qualities are produced, compounded of fire, water, earth, and salt; and it may be conceived to consist of many flakes or flocculi, each of which is again made up of very small flexible filaments, formed of the four Principles before-mentioned, by fermentation, as well in the bowels of the earth, as in the bodies of vegetables and animals: thus, an aromatic plant, growing in water, will, by distillation, yield an oil, which could never have been obtained from the water, in which it stood; and all oils may by art be resolved into water, earth, and salt. From these filaments variously concreted arise the flakes already mentioned, which are of different thicknesses; and in the pores thereof is lodged the element of fire, which, also, runs in rivulets through their interstices. Upon these depend the specific levity, inflammability, and fluidity of oil; but, as, notwithstanding the intestine motion caused by the element of fire, the small flakes still adhere, in some measure, together, this fluid must be more viscid than any other.

From what has been said concerning the nature of alcaline salts, and the figure and structure of the oily flocculi, it is easy to conceive, why all alcalies dissolve sulphurs; for, since the alcaline particles are spherical and prickly, they cannot enter the interstices of the flakes, without carrying away some of them from the rest; and thus, by degrees, thoroughly dissolving them. But the dense, rigid, and pointed molecules of acids, being forced into these interstices, increase the density, and strengthen the texture of the flocculi; and from the diversity of these, and of the acid spicula mixed with them, arise the different kinds of sulphurs. Sulphurs formed in the earth by fire, acid salt, water, and a very fine earth, are termed bitumens. Thus bitumens dissolved in a large quantity of water form the mineral oils, or petrolea. But, if they are mixed with earth and salt, the solid bitumens are produced, differing from one another in degrees of purity, according to the quantity or grossness of the earth, or different degrees of mixture. Thus fossil coals, jet, amber, and the common bitumens, and bituminous earths, are produced. If there be but a small quantity of earth, and much acid salt, the common mineral sulphur of brimstone is formed. If the mineral original bitumen is joined to a fusible earth, capable of vitrification, it communicates to it a metallic form; that is, the sound, brightness, softness, ductility, malleability, and all the other sensible qualities of metals.

This origin of mineral bitumens may be confirmed by many experiments: if a mixture of equal parts of oil of vitriol and oil of turpentine be digested together, for a considerable time, in a very gentle heat, and afterwards distilled in a retort, there will come over first a yellowish liquor, resembling petroleum, both in smell and consistence. What remains in the retort, is, at first, a soft bitumen, and afterwards turns into an hard black mass, easily inflammable, and, when burnt, smelling exactly like a fossil coal. But, if the distillation be continued, a white acid liquor will next be obtained, which, by standing, lets fall a grey powder, which is true common brimstone, a yellow substance of the like nature adhering likewise to the neck of the retort; what is left behind being a black, shining, light substance, disposed in thin disgregated strata, like talc, in which, by the help of the load-stone, iron may be discovered. Thus, therefore, all these bitumens may be artificially produced; and the analysis of the natural ones further confirms the manner of their formation. Thus the chymists have shewn, that metals are nothing but bituminous substances, which have undergone a long digestion; for, by depriving of them of their sulphur, they are reduced to ashes, and then to glass. This is easily seen in the imperfect metals; for, if any of them are exposed to a long heat, and especially to the rays of the sun, collected by a large burning-glass, the sulphureous principle flies off, and only a calx or ashes will be left behind, which, in a more vehement degree of fire, are presently vitrified;

fied; and, by restoring the sulphur, this glass may be again reduced to metal.

The inflammable substances in animals and vegetables consist of a different combination of the Principle of sulphur and acid salt; for the oil, or sulphur, in these, is formed by a small portion of earth joined to the elementary fire, acid salt, and water: this oil, when joined to an acrid salt, produces gums; when joined to a fine acid, and a new accession of fiery particles, it produces essential oils and inflammable spirits; but, if the acids are more gross, by reason of a larger quantity of earth joined to them, it forms resins, as we learn from the artificial composition of all these substances. By mixing spirit of wine with volatile spirit of urine, we obtain a mucilaginous concretion, or thin gum. Oil of olives and salt of tartar, melted together, make a kind of soap, or thick gum; and if spirit of wine be digested for a long time with oil of vitriol, and then distilled, an inflammable oil is obtained, resembling, in smell, and other qualities, the essential oils of plants, a true resin being left behind in the retort.

In animals this same oleaginous Principle forms the fat, and other glutinous or gelatinous substances; these last being composed of an acrid volatile salt and oil, as appears from their analysis: but fat is made of the same oil and acid salt; for, if oil of olives and spirit of nitre be mixed together and digested, a substance will be found in every thing resembling the fat of animals.

Sulphureous substances found in bodies are either fixed or volatile. The fixed sulphurs are either solid, such as fat, resin, and the bitumens; or fluid, as oils. Volatile sulphurs are such as fly off with a small degree of fire, and have an appearance compounded of that of oil and water. Such are inflammable spirits obtained from the flowers and fruits of plants.

All bodies consist of the five Principles above-mentioned; and the diversity of bodies arises entirely from the different combination of them. These combinations, or mixtures, of the five Principles are produced by motion, and that motion entirely by the element of fire. This motion is sometimes slow and insensible, as in the growth and maturation of fruits; more lively and quick, as in the fermentation of must; or very vehement, as in the deflagration of bodies. All these motions go by the general name of fermentation; and, if they tend to the destruction or dissolution of bodies, they are termed corruption.

The most simple, or least compounded, mixture of Principles is seen in the fermentation of salts, which consists principally of water and earth; next of sulphur, made up of water, earth, and salt; then of the acrid salts, both fixed and volatile, with the essential salts of plants, and sulphureous bodies, whether solid or liquid. The manner how these mixtures are brought about, and the changes arising from thence, will best be understood by examples.

The fruit of the vine, just beginning to put on the form of grapes, is insipid, or, at least, tastes only like grass. As it grows, a certain acidity is discovered in it, which at first produces an austere taste; then an acerb one, in which state the juice is termed omphacium, which, in distillation, yields a great quantity of water, some acid liquor, and a small portion of oil, a large proportion of earth being left behind. In this juice, therefore, the austere and acerb tastes are owing to the acid spicula, just breaking out through the earthy parts, but not wholly disengaged from them. When the grapes come to be fully ripe, the austere taste is changed to a sweet one, because the juice, being more thoroughly penetrated by the element of fire, is rarefied, and put in a more violent motion, by which the salts throw off their earthy involucra entirely, and by a new combination of these salts, water, and earth, are formed sulphurs, or oils. But, if any of the acid salts remain after the composition of the sulphurs, they continue still entangled by the filaments thereof; and their sharp points, vellicating the nervous papillæ of the tongue, create that agreeable taste which is perceived in must. The must in distillation affords a quantity of phlegm, next a pretty large portion of an acid water, some acrid or volatile urinous salt, and a quantity of thick oil, much beyond what was gained by the former distillation. Lastly, from the mass that remains in the retort, an acrid fixed salt may be obtained by the common method. However, even in this juice of ripe grapes, or must, the salts and oils are not carried to the greatest degree of fineness, and part of them remain still involved in the earthy involucra. But, if a large quantity of it be set to ferment, the igneous particles begin to act again, and by them this intestine commotion is is continued, till all the gross parts are either attenuated, or thrown out from the liquor, and the salts and sulphurs perfectly set free from the earthy parts, and intimately mixed with one another. The liquor in this state is wine, and the gross parts, that fall to the bottom of the vessel, are termed lees. The briskness and penetrating quality of the wine seems to be owing to the large proportion of the element of fire, which harbours among the filaments of the sulphureous flocculi; and, this liquor being distilled, we obtain, first, a great quantity of inflammable spirit, then a copious phlegm, next an acid liquor with some portion of an oily spirit, a thick oil, and, lastly, a small quantity of caput mortuum, which will yield a little fixed salt.

In this distillation a far less quantity of acid liquor is obtained than from must, which, on the other hand, yields no inflammable spirit. If the lees of wine be well dried, and then distilled, they yield a very large quantity of volatile urinous salt, the acid salts, combined with the sulphureous and earthy particles, being, by fermentation and heat, converted into alcaline salts.

In the same manner, if green peas or beans be distilled, they yield a great deal of acid liquor and phlegm, with a small proportion of oil. If they are first fermented with common water, an inflammable spirit is got from them in the same manner as from wine; and, if they are kept for some months in a dry place, they yield a volatile alcaline spirit, without any acid liquor, or, at least, but very little. Whence it is evident that acid salt, by its union with other particles, is changed into sulphur; and, by its union with earthy and sulphureous particles, becomes an alcaline volatile salt; and by being driven into earthy particles, becomes an alcaline volatile salt; as, by being driven into earthy particles, alone, by the force of fire in calcination, it is changed into a fixed alcali.

It may be proper, upon this occasion, to observe, that the salts of all plants are not entirely alike, but differ from one another, not only as the quantity of sulphur, water, or earth, which is joined to the acid, is greater or less; but, also, according to the original nature of the acid which enters their composition. Acid salts, as we have already said, are of three kinds, muriatic, nitrous, and vitriolic. Muriatic salts, such as sea-salts and sal-gemmæ, being crystallised, put on a cubic figure, the particles thereof appearing to be formed of two quadrilateral pyramids, joined together by their bases. Nitrous crystals represent prisms with six sides formed by the juxta-positions of two triangular pyramids; and crystals of vitriol seem to consist of two hexagonal pyramids, as far as can be judged by the particles thereof, when carefully separated from all metals. These original salts, combined with others, form compound salts, of almost all kinds. Thus, in the vegetable kingdom, the different sorts of vinegars are nothing but some original acid salt dissolved in phlegm. The essential salts of plants, obtained without fire, consist of some acid joined with particles of earth, or of the other Principles. Sal ammoniac arises from the union of acid and volatile alcaline salts. Fixed alcalies are only the acid spicula struck into earthy molecules; and volatile alcalies consist of the same acid joined to very fine particles of earth and sulphur, so as to form prickly globules. Moreover, the same varieties of acid salts are to be met with in vegetables, that are found in minerals. Thus, the essential salts of pellitory of the wall, borage, wild cucumber, and the like, are nitrous; and, when thrown upon burning charcoal, they fulminate like nitre. The fixed salts of carduus benedictus, glass-wort, and spurge, are like sea-salt, their particles having the same cubic figure; and, when thrown upon burning charcoal, they decrepitate. The crystals of tartar are like those of vitriol; and that they are formed by a vitriolic acid, appears from the sulphureous smell of tartar, when artfully calcined.

Besides the saline compounds already mentioned, other mixtures are formed in plants, such as gums, resins, honies, and the like. Gums are something between acid and oil, being an acid salt, so fixed in the earth, as that the greatest part of it is changed to an alcali, the other into oil; so that the mixture arising from thence is an oily salt, resembling the saponaceous concretes of the chymists, made of oil of olives, and a lixivium of tartar, or the mucilaginous bodies formed of spirit of wine and the volatile spirit of urine. And thus we see, that all seeds which are oily, when ripe, are in the beginning only a mucilage, or imperfect oil. Resins consist of oil and acid, and accordingly are artificially produced by mixing spirit of vitriol with spirit of wine, or of turpentine. They are either solid, or liquid; but these differ from one another only in the proportion of earth, that enters their composition. Melleous juices, which either exude spontaneously from plants, such as manna, or are obtained by art, as sugar, are essential salts, consisting of a mixture of acid and alcali, with a large proportion of oil.

The mineral kingdom furnishes us with a great variety of instances of the way how the Principles of bodies may be combined together. The lime-stone and parget are so framed, that, by being calcined, a vast number of cells are opened by the fire, into which water easily enters, with an hissing or collision of the included igneous particles. If the water remains long in these little receptacles, nitrous parts are formed, as we see in old walls, built with these materials, from which nitre may always be obtained. The greatest part of this nitre, by distillation, is changed into an acid spirit; but, by calcination, turns to an alcaline salt. And it may be, that the nitre of the ancients, or that alcaline mineral salt, which was dug out of the earth in Egypt, and other countries, and is obtainable by art from mineral waters, was nothing but nitre calcined by the heat of the earth, and so converted into a fixed alcaline salt. The vitriolic acid, joined with different metallic substances, produces all the kinds of vitriol; with an astringent earth, it forms alums; and, with the Principle of fire, common brimstone, which, by deflagration, may again be converted into oil of vitriol, the other Principles flying off. Brimstone may, likewise, be artificially produced by uniting the Principle of fire to any vitriolic acid.

The like mixture of the Principles of bodies may be observed in the animal kingdom. Chyle and milk contain a latent acid; which easily discovers itself by putrefaction, but this acid salt, having undergone a due fermentation, or some other action analogous to that in the animal body, is changed into a volatile alcali, obtainable in great plenty from the blood, serum, bile, urine, and other juices

In a healthful body, however, these volatile alcalies are never perfectly formed, the animal salts being more of the nature of sal ammoniac, with a mixture of earthy and oily parts, to which mixture the glutinous quality of the blood and serum is owing. By putrefaction, or calcination, all animal liquors are changed, so as to afford perfect volatile alcalies, has has been evidently shewn by experiment. *Geoffroy.*

Original PRINCIPLE, *principium originale*, a name, given by Tachenius and some other authors, to salt, without considering it as acid, alcali, or of any other particular kind, or any mode of existence: the salt of wood, or vegetables, not being alcali till after burning, and so on; but salt, that is the base of these, being evidently existent in the bodies, and, in regard to wood, seeming indeed to constitute its character as such, since the evaporation of it causes the wood to lose all its strength and to decay; for we find that in rotten wood there is no alcali at all; and the Venetians, who sink their timber for ship-building into water, while it is green, prevent, by that means, the evaporation of those salts, and leave the wood little less durable than stone. On these and the like principles, Tachenius supposes salt to be the true original Principle of bodies; but many others allow this name only to water, or at least that water is, in almost all natural bodies, the most copious, the most active, and the most influencing part; yet even this is found to agree much better with some bodies than with others. The birch and elder feed more kindly on a thin uliginous moisture; the elm, the pine, the fir, and cedar, chuse a stronger liquor; yet these and many more, the most widely different that can be from one another, are often seen to draw their whole substance and bulk, whether annual or perennial, from the same piece of ground, impregnated, so far as is possible to be judged of, with the same sort of juices, and from the ambient air and dews, when as yet by our best diligence we cannot distinguish the liquors or salts approaching closely to their several roots; and, if we wholly take away and exchange all the earth from the roots of trees whose barks, sap, and fruit, have very much differing salts, and are of very different kinds, yet we shall find each tree to prosper better by the exchange, instead of being injured by it.

Hence, we may suspect, that the very contextures of the bodies of plants, from the first germination of the seed, and as they form gradually from the invisible Principles of their seeds, are, however and imperceptibly, the natural alembics, where the common water and air are changed into the different juices, gums, resins, &c. as the animal organisation in the body of the cow changes the juices of every sort of grass and esculent vegetable into one and the same milk.

The sea plants growing on shells, or affixed to yet harder stones, taking no nourishment from the thing they grow on, but being as it were all root, and taking the whole from the ambient water; yet, that water giving to different species of them, though itself the same to all, the different textures of herbaceous to some; tough and horny to others; and to some absolutely stony; as the corals, many of which have been esteemed, by the generality of authors, absolute stones.

Trees of several different kinds are found in America growing out of the same dry and hard rock, and the various kinds of succulent plants; the poisonous ones and their opposites, or remedies, as the euphorbium and the antieuphorbium; the most acid pungent, and the most soft and emollient, out of the same barren lands of Arabia, where it could not be expected that any plants could grow at all. Hence, it is easy to apprehend, how the seeds in their time, and after them the roots, stems, and leaves of trees, may be the proper strainers to separate and prepare the several saps and juices, and to ferment the liquors into their several particular salts. See the articles VEGETATION and SALT.

PRISMA'TIC *Antennæ*, in natural history, a term used to express the horns or antennæ of a peculiar genus of butterflies. As these of the common kind are slender and buttoned at the end, those become very thick a little way from their origin, and continue of that diameter through their whole length, till just at the extremity they turn a little and terminate in a sharp point. The anterior part of these is rounded, as in the other kinds; but behind they are made up of two planes meeting in an angle, and each of these has a row of hairs on it: these meeting at their summits, form an angular vacant space or alley below. *Reaumur's Hist. Inf.*

PRI'STIS, *the saw-fish*, a fish of a very large size, and armed with a very remarkable weapon like a saw, at his nose, from whence he has his name. See *plate* XXXV. *fig.* 5.

This fish, from its large size, is generally reckoned a kind of whale, but erroneously; for it is truly of the same genus with the galei or hound fishes. It is ash-coloured on the back, and white on the belly; its head is of a heart-like shape, and flatter; its mouth is placed far below the end of the snout, and in the under part of the head, as in the zygæna; its lips are rough and sharp, like a file, but it has no other teeth; its head is terminated by a long and flat bony substance, furnished on each side with jags or points like deep teeth of a saw. There are from twenty to thirty of these teeth on each side. The body is round, and grows small towards the tail. The sword of this fish is sometimes five feet long. It is found in the Western Ocean.

PRI'VET-*fly*, in natural history, the name of a species of fly, very common on the shrub from whence it has its name. It is called the erinopterus, and is remarkable for having its wings deeply divided into segments, so that they seem composed of feathers like birds wings. The creature, as it sits, looks like a small feather.

PROBABI'LITY (*Dict.*)— In the doctrine of Probability, one important observation may be made, viz. that, if one premiss only of an argument be probable, the conclusion is necessarily probable. But, if two or more premisses be probable, the conclusion will not be necessarily probable. Thus, for instance, supposing the Probability of each premiss expressed by $\frac{9}{10}$, the Probability of the conclusion will be but $\frac{81}{100}$, which shews it to be improbable. For we may call any thing improbable, if the measure of the chance for its happening is less than $\frac{1}{2}$. If there had been three premisses, and the Probability of each equal to $\frac{9}{10}$, the Probability of the conclusion would be $\frac{729}{1000}$, which is considerably improbable. Again, supposing the Probability of the truth of each premiss be 2 to 1, or expressed by $\frac{2}{3}$, the Probability of the conclusion, in the case of the two premisses, would be $\frac{4}{9}$. Where three premisses are assumed to infer a conclusion, this would be $\frac{8}{27}$; and, in case of four premisses, the Probability of the conclusion would be but $\frac{16}{81}$, which is less than $\frac{1}{5}$; so that one might with advantage lay four to one against the truth of a conclusion founded upon four probable premisses, for the truth of which, separately taken, two to one might be laid. It is to be observed, in all these cases, that the premisses are supposed independent, that is, not necessarily connected with each other.

Hence, it is easy to account, how it happens, that the most plausible political and physical reasonings lead so often to conclusions false in fact.

Mr. de Moivre has solved two problems, tending to establish the degree of assent that ought to be given to experience. He determines from his solutions, that after taking a great number of experiments, it should have been observed, that, if the happenings or failings of an event have been very near in a ratio of equality, it may safely be concluded, that the Probabilities of its happening or failing, at any one time assigned, are very near equal.

And if, after taking a great number of experiments, it should be perceived, that the happenings and failings have been nearly in a certain proportion, such as two to one, it may safely be concluded, that the Probabilities of happening or failing, at any one time assigned, will be very near in that proportion; and, that the greater the number of experiments has been, so much the nearer the truth will the conjectures be, that are derived from them.

Chance very little disturbs the events which, in their natural institution, were designed to happen or fail according to some determined law. For, if in order to help our conception, we imagine a round piece of metal, with two polished opposite faces, differing in nothing but their colour, whereof one may be supposed to be white and the other black; it is plain that this piece may with equal facility exhibit a white or black face; and we may even suppose that it was framed with that particular view of shewing sometimes the one face, sometimes the other; and that consequently, if it be tossed up, chance will decide the appearance.

But, although chance may produce an equality of appearance, and that a greater inequality, according to the length of time in which it may exert itself, still the appearance, either one way or the other, will perpetually tend to a proportion of equality. This is, in like manner, applicable to a ratio of inequality; and thus in all cases it will be found, that, although chance produces irregularities, still the odds will be infinitely great, that in process of time, these irregularities, will bear no proportion to the recurrency of that order which naturally results from original design. *De Moivre's Doctrine of Chances.*

Kepler's PRO'BLEM (*Dict.*) — As to the solution of this Problem, the late excellent mathematician, Mr. Machin, observes, that many attempts have been made, at different times, but never yet with tolerable success, towards the solution of the Problem proposed by Kepler: to divide the area of a semicircle into given parts, by a line from a given point of the diameter, in order to find an universal rule for the motion of a body in an elliptic orbit. For, among the several methods offered, some are only true in speculation, but are really of no service. Others are not different from his own, which he judged improper. And, as to the rest, they are all some way or other so limited and confined to particular conditions and circumstances, as still to leave the Problem in general untouched. To be more particular, it is evident, that all constructions by mechanical

chanical curves are seeming solutions only, but in reality unapplicable; that the roots of infinite serieses are, upon account of their known limitations in all respects, so far from affording an appearance of being sufficient rules, that they cannot well be supposed as offered for any thing more than exercises in a method of calculation. And then, as to the universal method, which proceeds by a continued correction of the errors of a false position, it is, when duly considered, no method of solution at all in itself; because, unless there be some antecedent rule or hypothesis to begin the operation, (as suppose that of an uniform motion about the upper focus, for the orbit of a planet; or that of a motion in a parabola for the perihelion part of the orbit of a comet; or some other such) it would be impossible to proceed one step in it. But, as no general rule has ever yet been laid down to assist this method, so as to make it always operate, it is the same in effect, as if there were no method at all. And accordingly in experience it is found, that there is no rule now subsisting, but what is absolutely useless in the elliptic orbits of comets; for, in such cases, there is no other way to proceed but that which was used by Kepler: to compute a table for some part of the orbit, and therein examine, if the time to which the place is required, will fall out any where in that part. So that, upon the whole, it appears evident, that this Problem (contrary to the received opinion) has never yet been advanced one step towards its true solution.

Mr. Machin afterwards proceeds to give his own solution of this Problem, which is particularly necessary in orbits of a great excentricity; and he illustrates his method by examples, for the orbits of Mercury, of Venus, of the comet of the year 1680. All which shew the universality of that method.

PROBOU'LEUMA, Προβούλευμα, among the Athenians, a decree or vote of the Areopagus, or senate of Athens.

PROCHARISTE'RIA, Προχαριστήρια, in antiquity, a solemn sacrifice which the Athenian magistrates yearly offered to Minerva, when the spring first began to appear. *Potter, Archæol. Græc.*

Marine PRODUC'TIONS.—To investigate the nature of marine Productions, Count Marsigli moistened in sea water some branches of coral, newly taken up, and found that the tubercles so frequent on its branches, after a little time, all opened themselves into regular flowers, each terminated by eight points. These were white, and were sustained by a cup divided into the same number of segments; and, on the taking the branches again out of the water, he found these flowers all immediately close themselves up again, and only make red irregular tubercles; and the vigorous branches of coral retained this property of opening and closing their flowers for seven or eight days after they were taken out of the sea. The tubercles, when wounded, yield a milky juice, in which, doubtless, there is contained the seed of the coral.

When this curious naturalist had found coral to be a true plant in its organisations, it appeared a very desireable thing to enquire whether it would yield vegetable principles, or those of another kind, in a chemical analysis. This experiment he carefully tried, not only on coral, but on many other of the stony plants, and found all of them yielded the same principles with vegetables. All of them yielded on this trial a phlegm, a volatile urinous spirit, with always more or less of a sea-water smell, and a thick reddish black fœtid oil; and the remainder in the retort being calcined, always yielded a fixed alkaline salt like that of plants.

The sea productions all afforded more or less of every one of these principles; but those of which ever kind that had been kept a long time after they were taken out of the sea, afforded always much less fluid matter than those which were fresh. Mr. Geoffroy was very desirous of following the count in these researches; and, as he had no opportunity of procuring any fresh coral from the sea, he put into the retort a pound of the common red coral, sold by the druggists, which is what wants the outer bark, and has usually been a long time out of the sea. This yielded two drachms and six grains of a reddish volatile urinous spirit, and two or three grains of a fœtid oil; and the remainder in the retort, by the common treatment, yielded afterwards near two drachms of a lixivial salt of a saline taste: the matter remaining after the lixiviation appeared a sort of lime.

The spirit appeared to Mr. Geoffroy to be wholly the same with that which the count had himself sent to the academy under the title of the spirit of old coral; and it appeared scarce at all different from spirit of harts-horn. It turned syrup of violets green, and made a white coagulation with a solution of corrosive sublimate. Though this was much the same with the count's spirit, the salts drawn from the caput mortuum were, however, different; that made by Mr. Geoffroy making a white coagulation with a solution of corrosive sublimate, and that of count Marsigli having no such effect; both the salts, however, turned the syrup of violets green, and Mr. Geoffroy judged the difference in the other trial to be only from the count's salt having been less carefully made, and containing some quantity of earth, which weakened its power and prevented this effect from it. It follows from all this, that the corals and all the other sea productions of that class are properly plants, though of the hardness of stones: and, in the internal use of coral, it may be proper to consider it not as a mere absorbent, but as a substance which contains also a volatile spirit and oil, which may well be supposed to possess virtues above those of mere absorbent earth; and that there is great difference between the virtues of such coral as has been long kept, and such as is newly taken up from the sea. The count, after analysing coral in this manner, tried the same process on several parts of the rocks on which the coral grew; but he found this to yield none of these active principles; so that, although the hardness of corals and of stones seems the same, there is great difference between them in their principles, their nature, and effects.

There is yet one question remaining to be determined in this point, which is, what is the nature of this milky juice contained in the tubercles of flowers, and perhaps not less in the other parts of coral. The count has said nothing as to its qualities, but Boccone says it is hot, acrid, and almost caustic; whence perhaps it is the natural sap of the plant, and is analogous to the milky juice of the spurges and some other plants. It were to be wished that this liquor could be tried with acids and alkalies, and in other ways, and its analysis known: this perhaps would make our knowledge of the nature of this stony vegetable perfect. *Mem. Acad. Par.* 1708.

PROGRE'SSION (*Dict.*)—As a right line, or figure, may increase continually, and never amount to a given line or area; so there are Progressions of fractions which may be continued at pleasure, and yet the sum of the terms be always less than a given number. If the difference between their sum and this number decrease in such a manner, that by continuing the Progression, it may become less than any fraction, howsmall soever, that can be assigned, this number is the limit of the sum of the Progression, and is what is understood by the value of the Progression, when it is supposed to be continued infinitely. These limits are analogous to the limits of figures, and they mutually assist each other. The areas of figures can, in many cases, be no otherwise expressed than by such Progressions; and, when the limits of figures are known, they may sometimes be advantageously applied for approximating to the sums of certain Progressions.

PRONG-*hoe*, in husbandry, a term used to express an instrument used to hoe or break the ground near, and among the roots of plants.

The ordinary contrivance of the hoe in England is very bad, it being only made for scraping on the surface; but, the great use of hoeing being to break and open the ground, besides the killing the weeds, which the ancients, and many among us, have thought the only use of the hoe, this dull and blunt instrument is by no means calculated for the purposes it is to serve.

The Prong-hoe consists of two hooked points of six or seven inches long, and, when struck into the ground, will stir and remove it the same depth as the plough does, and thus answer both the ends of cutting up the weeds and opening the land. The ancient Romans had an instrument of this kind, which they called the bidens; but they were afraid of its use in their fields and gardens, and only used it in their vineyards. The Prong-hoe comes into excellent use, even in the horse-hoeing husbandry; in this the hoe-plough can only come within three or four inches of the rows of the corn, turneps, and the like; but this instrument may be used afterwards, and with it the land may be raised and stirred, even to the very stalk of the plant. *Tull's Husbandry.*

PROOF, in the sugar trade, a term used by the refiners of sugar for the proper state of the dissolved sugar when it should be set to harden.

The process in the bringing sugar to this state may be understood by performing the whole work in miniature in this manner: take six pounds of coarse, or unrefined sugar; dissolve it over the fire in six pints of lime-water; add to this the whites of four eggs beat up to a froth, stir the whole together; then boil the liquor to a higher consistence than syrup, or till, when exposed to the cold, it will concrete into grains. This is what the sugar-bakers call proof. Pour this syrup into an earthen mould, with a hole at its bottom; stop the hole, and set the vessel in a moderately warm place.

The sugar in a few days will set and harden; then open the hole at the bottom, and lay over the top of the sugar some tobacco pipe clay, made into a soft pap with water. The clay must be afterwards wetted at times, and the water from among it will gradually be soaked up by the sugar, and, running thro' it, will wash away the treacle, without dissolving the grained part. And thus all the treacle will by degrees be drained out of the mass, and a loaf of white sugar procured. *Shaw's Lectures.*

PROPAGA'TION (*Dict.*) — The number of vegetables that may be propagated from an individual, is very remarkable, especially in the most minute plants.

It has been recorded, that, in so large a plant as the common mallow, the annual product of one seed was no less than 200,000; but it has been since proved, by a strict examination into the more minute parts of the vegetable world, that so despised a plant as the common wall moss produces a much more numerous

merous off-fpring. In one of the little heads of this plant, there have been counted 13824 feeds. Now allotting to a root of this plant eight branches, and to each branch fix heads, which appears to be a very moderate computation, the produce of one feed is $6 \times 13824 = 82944$; and 8×82944 gives 663552 feeds, as the annual produce of one feed, and that fo fmall that 13824 of them are contained in a capfule, whofe length is but one ninth of an inch, its diameter but one twenty-third of an inch, and its weight but the thirteenth part of a grain. *Philofophical Tranfactions*, N°. 478.

PRO'PHECY (*Dict.*— A late author obferves, that the Chriftians have this in common with the Pagans, that they equally build their religions upon Prophecy and divination.

He adds, that divination was an art learned by the Romans in fchools, or under difcipline; as the Jews did prophefying in the fchools and colleges of the prophets.

In thefe fchools, as the learned Dodwell obferves, the candidates for Prophecy were taught the rules of divination practifed by the Heathens, who were in poffeffion of the art long before them. It is added, that the gift of Prophecy was not an occafional thing, but a conftant and ftanding matter of fact; and fome think they have difcovered an eftablifhment of an order of prophets in the Old Teftament, in analogy to the Heathen diviners.

This is certain, from many paffages of fcripture, that there were great numbers of prophets among them, who not only exercifed their talents in matters of government and religion, but even in the difcovery of loft goods, and in telling of fortunes.

One of the greateft difficulties in Chriftianity turns upon the completion of the fcripture Prophecies. In the prophets of the Old Teftament are frequent predictions of the Meffiah; which the writers of the New frequently urge to the Jews and Heathens as fulfilled in Jefus Chrift; and on this principle evince the truth of his miffion: but thefe texts thus urged from the Old, in the New Teftament, are fometimes not to be now found in the Old; and, at other times, not urged in the New in the literal and obvious fenfe which they feem to bear in the Old; whence moft of the Chriftian commentators, divines, and critics, ancient and modern, judge them to be applied in a fecondary, typical, allegorical, or myftical fenfe.

Thus, for inftance, St. Matthew, after an account of the conception of the Virgin, and the birth of Jefus, fays, 'All this was done, that it might be fulfilled which was fpoken by the prophet, faying, Behold a virgin fhall be with child, and fhall bring forth a fon, and they fhall call his name Emanuel.' But the words, as they ftand in Ifaiah, whence they are fuppofed to be taken, do, in their obvious and literal fenfe, relate to a young woman who was to bring forth a child in the days of Ahaz; as appears from the context, and is owned by Grotius, Huetius, Caftalio, Curcellæus, Epifcopius, Hammond, Simon, Le Clerc, Lamy, &c.

This Prophecy then being not fulfilled in Jefus, in the primary, literal, or obvious fenfe of the words, is fuppofed, like the other Prophecies cited by the apoftles, to be fulfilled in a fecondary, typical, or allegorical fenfe; i. e. this Prophecy, which was firft literally fulfilled by the birth of the prophet's fon in the time of Ahaz, was again fulfilled by the birth of Jefus, as being an event of the fame kind, and intended to be fignified either by the prophet, or by God, who directed the prophet's fpeech.

Grotius obferves this to be the cafe in moft, if not all the Prophecies and citations quoted from the Old in the New Teftament; and Dodwell, with Sir John Marfham, refer even the famous Prophecy in Daniel, about the feventy weeks, to the time of Antiochus Epiphanes; fhewing, that the expreffions taken thence by Chrift, and urged by him as predicting the deftruction of Jerufalem by the Romans, have only in a fecondary fenfe a refpect to that deftruction.

And even that famous Prophecy in the Pentateuch, 'A prophet will the Lord God raife up unto thee, like unto me; to him fhall ye hearken;' which St. Luke refers to as fpoken of Jefus Chrift, is, by Simon, Grotius, Stillingfleet, &c. underftood to fignify, in its immediate fenfe, a promife of a fucceffion of prophets.

It is allowed then, the apoftles applied the Prophecies they quote from the Old Teftament, in a typical fenfe: but unhappily the rules whereby they quoted are loft. Dr. Stanhope laments the lofs of the Jewifh traditions or rules for interpreting fcripture received among the rabbins, and followed by the apoftles. But this lofs Surenhufius, Hebrew profeffor at Amfterdam, thinks he has retrieved from the Jewifh talmud, and the ancient Jewifh commentaries; and has accordingly publifhed to the world the rules whereby the apoftle quoted the Old Teftament.

But the truth is, thefe rules are too precarious, ftrained, and unnatural, to gain much credit.

Mr. Whifton condemns all allegorical explanation of the Prophecies of the Old Teftament cited in the New, as weak, enthufiaftic, &c. and adds, that if a double fenfe of the Prophecies be allowed, and there be no other method of fhewing their completion, than by applying them fecondarily and typically to our Lord, after having been in their firft and primary intention long ago fulfilled in the times of the Old Teftament, we lofe all the real advantages of the ancient Prophecies, as to the proofs of Chriftianity.

He therefore fets up a new fcheme in oppofition thereto: he owns, that, taking the prefent text of the Old Teftament for genuine, it is impoffible to expound the apoftles citations of the Prophecies of the Old Teftament, on any other than the allegorical foundation; and therefore, to folve the difficulty, is forced to have recourfe to a fuppofition contrary to the fenfe of all Chriftian writers before him, viz. that the text of the Old Teftament has been greatly corrupted fince the apoftolical age by the Jews.

His hypothefis is, that the apoftles made their quotations out of the Old Teftament rightly and truly from the Septuagint verfion, which in their time was in vulgar ufe, and exactly agreed with the Hebrew original; and that, as they made exact quotations, fo they argued juftly and logically from the obvious and literal fenfe of the faid quotations, as they then ftood in the Old Teftament: but that, fince their times, both the Hebrew and Septuagint copies of the Old Teftament have been fo greatly corrupted, and fo many apparent diforders and diflocations introduced therein, as to occafion many remarkable differences and inconfiftences between the old Old and New Teftament in refpect to the words and fenfe of thofe quotations.

As to the manner wherein thefe corruptions were introduced, he fays, the Jews in the fecond century greatly corrupted and altered both the Hebrew and Septuagint, efpecially in the Prophecies cited by the apoftles, to make their reafoning appear inconclufive: that in the third century, they put into Origen's hand one of thefe corrupted copies of the Septuagint; which Origen, miftaking for genuine, inferted in his Hexapla, and thus brought into the church a corrupted copy of the Septuagint; and that, in the end of the fourth century, the Jews put into the hands of the Chriftians, who till then had been almoft univerfally ignorant of the Hebrew, a corrupted copy of the Hebrew Old Teftament.

The difagreement then between the Old and New teftament, in refpect to the faid quotations, he contends, has no place between the genuine text of the Old Teftament, now no-where exifting, but only between the prefent corrupted text of the Old and New Teftament: and therefore, to juftify the reafonings of the apoftles, he propofes to reftore the text of the Old Teftament, as it ftood before the days of Origen, and as it ftood in the days of the apoftles: from which text thus reftored, he doubts not it will appear, that the apoftles cited exactly, and argued juftly and logically from the Old Teftament.

But this fcheme of accomplifhing Prophecies labours under difficulties at leaft as great as the allegorical fcheme. Its foundation is incredible, and its fuperftructure, from firft to laft, precarious. In effect, it is inconceivable the Old Teftament fhould be fo corrupted; and it may even be made appear, that the Hebrew and Septuagint difagreed in the times of the apoftles: add to this, that the means whereby he propofes to reftore the true text, will never anfwer that end; nor has he himfelf, from all the means he was yet poffeffed of, able to reftore one prophetical citation, fo as to make that feem literally, which before only feemed allegorically applied.

PRO'PHET (*Dict.*)— Among the canonical books are thofe of fixteen Prophets; four of which are denominated the greater Prophets, viz. Ifaiah, Jeremiah, Ezekiel, and Daniel; fo called from the length or extent of their writings, which exceed thofe of the others, viz. Hofea, Joel, Amos, Obadiah, Jonas, Micah, Nahum, Habakkuk, Haggai, Zachariah, and Malachi; who are called the leffer Prophets, from the fhortnefs of their writings.

The Jews only reckon three greater Prophets; Daniel they exclude, as no more to be ranked among the Prophets than David: not but that both the one and the other foretold many important things: but becaufe their manner of life differed from that of the other Prophets, David being a king, and Daniel a peer.

In the Greek church, the leffer Prophets are placed in order before the great ones; apparently becaufe many of the leffer Prophets are more ancient than the greater.

Among the Greeks too, Daniel is ranked among the leffer Prophets.—In the 48th chapter of Ecclefiafticus, Ifaiah is particularly called the great Prophet, both on account of the great things he foretold, and the magnificent manner wherein he did it.

Spinofa fays, the feveral Prophets prophefied according to their refpective humours; Jeremiah, for inftance, melancholy and dejected with the miferies of life, prophefied nothing but misfortunes.

Dacier obferves, that among the ancients the name poet is fometimes given to Prophets; as that of Prophet is at other times given to poets.

PRO'POLIS, a name given by authors to a certain fubftance more glutinous and tenacious than wax, with which the bees ftop up all the holes or cracks in the fides of their hives. Befides the wax and the honey which the bees gather in their daily travels, they have occafion for this third fubftance at times, and that efpecially when they are placed in a new hive. They very well know that it is neceffary to their well-being, that

that they ſhould be kept perfectly warm in their hives, and ſtrongly defended againſt the injuries of weather: to keep out wind and rain they ſtop every little chink in the ſides of their habitations with this matter; nor is this the only reaſon for it, they have other enemies of the inſect tribe, which are on different occaſions eternally ſeeking a way into their habitations; ſome of them feed on their honey, others on the wax, and others on their young offſpring. To be guarded againſt theſe, they as firmly as poſſible block up all the accidental holes or cracks in the hive, and guard the principal opening, which ſerves as the gate of their city, by numbers, which are always placed round about it, ſo that no enemy can come in that way.

The Propolis itſelf is a ſubſtance perfectly different from wax; it is found to be ſoluble in ſpirit of wine, or in oil of turpentine, and is ſoft when laid on by the bees, but grows hard afterwards; it may, however, even in its hardeſt ſtate, be ſoftened by heat. By all theſe obſervations it appears very plainly, that the Propolis is a true genuine vegetable reſin, of the nature of many others which we have in common uſe. The authors who have treated of this ſubſtance, have deſcribed it very differently; George Pictorius, who has written of bees, ſays, that it is of a yellow colour and an agreeable ſmell, like that of ſtorax, and that it would ſpread when warmed properly. Pliny and the old writers deſcribe it as being of a rank and ſtrong ſmell, and being uſed as a ſuccedaneum for galbanum; and at preſent we uſually find it of an aromatic and agreeable ſmell, inſomuch that ſome rank it among the perfumes. The apothecaries, in ſome places, keep it as a medicine in their ſhops; but it is to be obſerved, that it is very various in its nature; for, according to the deſcription of authors, it is ſometimes ſweet and ſometimes ſtinking. The truth is, that the bees who collect it as a thing to be uſed for a cement, not for food, are not over curious of what plants they gather it from; and hence in different hives it is found of very different colours and conſiſtences. In general, the Propolis is of a browniſh red colour on the ſurface; the red ſometimes predominating, ſometimes the brown; but when broken it is yellowiſh, or approaching to the colour of wax. It very readily diſſolves in ſpirit of wine or oil of turpentine, and this ſolution is of a fine gold colour, and will ſerve extremely well as a varniſh to colour ſilvered picture frames, or other the like work, into the appearance of gold. It gives a fine gold-like appearance, indeed, to any white metal of a poliſhed ſurface; all that it wants is a little more brilliancy, which is eaſily given it by mixing a ſmall quantity of maſtich, or of ſandarach, in the ſolution. *Reaumur's Hiſt. Inſ.*

Mr. Reaumur was very deſirous of ſeeing the manner in which the bees collected this tenacious matter, but watched them in vain in the fields and upon the trees: although an accident gave him an opportunity of obſerving them at their work on this occaſion. He had taken off the cover of one of his glaſs hives on ſome occaſion, and as there was much of the Propolis ſticking to its edges, which the bees had uſed to ſtop the crevices when it was fixed in, the bees of a neighbouring hive ſoon found that here was this ſubſtance ready for them in large quantities together, and that they could have it at a very eaſy rate: they therefore immediately detached a party to bring it off; and, in conſequence of this, it was eaſy to obſerve any one of them, during the whole courſe of his work. The manner of ſeparating it from the ſubſtance it lay upon, was by detaching very ſmall pieces at a time with the teeth; theſe, when they had been with great labour looſened from the reſt, were delivered to the foot of one of the fore-legs: they were here moulded into a roundiſh lump, and, after a little working, delivered to the foot of a ſecond leg; and finally, by this to the flat triangular piece which makes the third joint of the hinder legs, the part deſtined in their common labours to receive the lumps of rough wax. It is here preſſed down with ſome violence, and afterwards fixed in its place by three or four ſtrokes from the ſame foot; and then another is ſeparated by the teeth in the ſame manner, and by the ſame means carried to the ſame place, and added to the firſt piece; and ſo on till the whole work is finiſhed. The bees which found this treaſure loaded themſelves to an immenſe degree, carrying off a lump larger than a pea on each leg; and the time to take up theſe large parcels was at leaſt half an hour: after carrying this load to the hive, and being relieved from it by the joint labours of ſeveral others, the bee which has been at all the pains of collecting it, joins a cluſter of others in ſome quiet part of the hive, where it reſts for the remainder of that day.

PROPO'RTIONALS, in geometry, are quantities, either linear or numeral, which bear the ſame ratio or relation to each other.

Thus, if 3, 6, 12, be Proportionals, then will 3 : 6 : : 6 : 12.

To find a fourth PROPORTIONAL *to three given lines*, A B, A C, and BD, *Plate* XXXV. *fig.* 6. draw an angle F A G at pleaſure; from A ſet off the firſt of the lines to B; from A, the ſecond, to C; and, from B to D, the third: draw BC; and in D make an angle equal to A B C: then is C E the fourth Proportional ſought; and A B : A C : : B D : C E.

If a third Proportional be required to two given lines, A B and A C; make B D equal to A C, i. e. let A C be repeated twice: then A B : A C : : A C : C E.

To find a mean PROPORTIONAL *between two given lines* A B and B E, *fig.* 7, join the two given lines into one continued right line, and biſect it in C. From C, with the interval of A C, deſcribe a ſemicircle A D E; and from B erect a perpendicular B D; this is the mean Proportional ſought; and A B : B D : : B D : B E.

The geometricians have been theſe two thouſand years in ſearch of a method for finding two mean Proportionals.

The ancients performed it mechanically, by the meſolabe deſcribed by Eutochius; and many of them attempted to give the demonſtration; ſome by the ſolid loci, as Menechmus; others by the plain loci, as Nicomedes, Diocles, and, in our times, Vieta; and others by implicit motions, as Plato, Archytas, Pappus, and Sporus; others tentatively, by the deſcription of circles, as Hero and Apollonius, &c. but all in vain.

To find a mean PROPORTIONAL *between two numbers*: half the ſum of the two given numbers is an arithmetical mean Proportional, and the ſquare root of their product a geometrical mean Proportional.

PROSLAMBANO'MENOS, in the ancient Greek muſic, was the firſt note of their ſcale, whether aſcending or deſcending. It was uſual among the Greeks to conſider a deſcending as well as an aſcending ſcale; the former proceeding from acute to grave preciſely by the ſame intervals as the latter did from grave to acute. The not diſtinguiſhing theſe two ſcales has led ſeveral learned moderns to ſuppoſe, that the Greeks, in ſome centuries, took the Proſlambanomenos to be the loweſt note in their ſyſtem; and in other centuries to be the higheſt. But the truth of the matter is, that the Proſlambanomenos was the loweſt or higheſt note, according as they conſidered the aſcending or deſcending ſcale. The learned author of this remark thinks this diſtinction of the aſcending or deſcending ſcales conducive to the variety and perfection of melody; but he ſays, he never met with above one piece of muſic, where the compoſer appeared to have any intelligence of that kind: and this piece was above 150 years old.

PRO'STYPA, Πρόστυπα, in the ſculpture of the ancients, images carved in ſuch a manner as to be only half raiſed above the ground, or plain, on which they were formed.

PRUNE'LLA, *ſelf-heal*, in botany, the name of a ſmall plant, uſed in medicine.

The roots of ſelf-heal are ſlender, creeping, and fibrous; the lower leaves grow on long foot-ſtalks, beſet with a few hairs, as is the reſt of the plant; they are broadeſt in the middle, and narrower at both ends, leſs than betony, and not at all indented about the edges. The ſtalks are ſquare, about a foot high, with two leaves ſet oppoſite at a joint, which are not many on a ſtalk; the nearer they grow to the top, the ſhorter are their foot-ſtalks. The flowers are ſet on the top of the branches in thick verticillated ſpikes, of a purple colour, having an hollow galea, and a three lipped labella, ſtanding in brown flattiſh calyces, ſix ſtanding round the ſtalk in a whorle; each flower is ſucceeded by four longiſh brown ſeeds growing in the bottom of the calyx. It grows every-where in meadows and paſture grounds, flowering all the latter part of the ſummer: the leaves and flowers are uſed. Self-heal is reckoned among the vulnerary plants, and is accounted ſerviceable for all ſorts of wounds, and putrid ulcers. It is reſtringent, and good for inward bleedings, and making bloody water; and is much uſed in gargles, for ulcers in the mouth, throat, or gums, either the juice or a ſtrong decoction. *Miller's Bot. Off.* Prunella abſterges and conſolidates: its principal uſe is in wounds, eſpecially of the lungs, and in coagulations of blood. It is alſo frequently employed outwardly in wounds, and in the quinſey, and other affections of the mouth and fauces, hæmorrhages, and dyſenteries, and in ſpitting or piſſing of blood. *Hiſt. Plant. adſcript. Boerhaave.*

PRU'NING (*Dict.*)— There is not any part of gardening, which is of more general uſe than that of Pruning; and, yet, it is very rare to ſee fruit-trees ſkilfully managed: almoſt every gardener will pretend to be a maſter of this buſineſs, though though there are but few who rightly underſtand it; nor is it to be learned by rote, but requires a ſtrict obſervation of the different manners of growth of the ſeveral ſorts of fruit-trees; ſome requiring to be managed one way, and others muſt be treated in a quite different method, which is only to be known from carefully obſerving how each kind is naturally diſpoſed to produce its fruit: for ſome ſorts produce their fruit on the ſame year's wood, as vines; others produce their fruits, for the moſt part, upon the former year's wood, as peaches, nectarines, &c. and others upon curſons or ſpurs, which are produced upon wood of three, four, or five, to fifteen or twenty years old, as pears, plums, cherries, &c. therefore, in order to the right management of fruit-trees, there ſhould always be proviſion made to have a ſufficient quantity of bearing wood in every part of the trees, and, at the ſame time, there ſhould not be a ſuperfluity of uſeleſs branches, which would exhauſt the ſtrength of the trees, and cauſe them to decay in a few years.

The reaſons which have been laid down for Pruning of fruit-trees, are as follow: firſt, to preſerve trees longer in a vigorous bearing ſtate; the ſecond is, to render the trees more beautiful to the eye; and, thirdly, to cauſe the fruit to be larger, and better taſted.

1. It preſerves a tree longer in an healthy bearing ſtate; for by Pruning off all ſuperfluous branches, ſo that there are no more left upon the tree than are neceſſary, or than the roots can nouriſh properly, the root is not exhauſted in ſupplying uſeleſs branches, which muſt afterwards be cut out; whereby much of the ſap will be uſeleſly expended.

2. By ſkilful Pruning of a tree, it is rendered much more pleaſing to the eye: but here I would not be underſtood to be an advocate for a ſort of Pruning which I have ſeen too much practiſed of late; viz. the drawing a regular line againſt the wall, according to the ſhape or figure they would reduce the tree to, and cutting all the branches, ſtrong or weak, exactly to the chalked line; the abſurdity of which practice will ſoon appear to every one who will be at the pains of obſerving the difference of thoſe branches ſhooting the ſucceeding ſpring. All therefore that I mean by rendering a tree beautiful, is, that the branches are all pruned according to their ſeveral ſtrengths, and are nailed at equal diſtances in proportion to the different ſizes of their leaves and fruit; and that no part of the wall, ſo far as the trees are advanced, be left unfurniſhed with bearing wood. A tree well managed, though it does not repreſent any regular figure, yet will appear very beautiful to the ſight, when it is thus dreſſed, and nailed to the wall.

3. It is of great advantage to the fruit; for the cutting away all uſeleſs branches, and ſhortening all the bearing ſhoots, according to the ſtrength of the tree, will render the tree more capable to nouriſh thoſe which are left remaining, ſo that the fruit will be much larger, and better taſted. And this is the advantage which thoſe trees againſt walls of eſpaliers have to ſuch as are ſtandards, and are permitted to grow as they are naturally inclined; for it is not their being trained either to a wall or eſpalier which renders their fruit ſo much better than ſtandards, but becauſe they have a leſs quantity of branches and fruit for their roots to nouriſh; and, conſequently, their fruit will be larger, and better taſted.

There are many perſons who ſuppoſe, that if their fruit-trees are but kept up to the wall or eſpalier, during the ſummer-ſeaſon, ſo as not to hang in very great diſorder, and, in winter, to get a gardener to prune them, it is ſufficient: but this is a very great miſtake; for the greateſt care ought to be employed about them in the ſpring, when the trees are in vigorous growth; which is the only proper ſeaſon to procure a quantity of good wood in the different parts of the tree, and to diſplace all uſeleſs branches, as ſoon as they are produced, whereby the vigour of the tree will be intirely diſtributed to ſuch branches only, as are deſigned to remain; which will render them ſtrong, and more capable to produce good fruit; whereas, if all the branches are permitted to remain, which are produced, ſome of the more vigorous will attract the greateſt ſhare of the ſap from the tree, whereby they will be too luxuriant for producing fruit, and the greateſt part of the other ſhoots will be ſtarved, and rendered ſo weak, as not to be able to produce any thing elſe but bloſſoms and leaves, as hath been before mentioned; ſo that it is impoſſible for a perſon, let him be ever ſo well ſkilled in fruit-trees, to reduce them into any tolerable order by winter Pruning only, if they are wholly neglected in the ſpring.

There are others, who do not intirely neglect their trees during the ſummer ſeaſon, as thoſe before mentioned; but yet do little more good to them by what they call ſummer Pruning; for theſe perſons neglect their trees at the proper ſeaſon, which is in April and May, when their ſhoots are produced, and only about Midſummer go over them, nailing in all their branches, except ſuch as are produced fore-right from the wall, which they cut out; and at the ſame time often ſhorten moſt of the other branches; all which is intirely wrong practice; for thoſe branches which are intended for bearing the ſucceeding year, ſhould not be ſhortened during the time of their growth, which will cauſe them to produce two lateral ſhoots from the eyes, below the place where they were ſtopped, which ſhoots will draw much of the ſtrength from the buds of the firſt ſhoot, whereby they are often flat, and do not produce their bloſſoms; and if thoſe two lateral ſhoots are not intirely cut away at the winter Pruning, they will prove injurious to the tree, as the ſhoots which theſe produce will be what the French call water-ſhoots: and in ſuffering thoſe luxuriant ſhoots to remain upon the tree until Midſummer, before they are diſplaced, they will exhauſt a great ſhare of the nouriſhment from the other branches, as was before obſerved; and by ſhading the fruit all the ſpring-ſeaſon, when they are cut away, and the other branches faſtened to the wall, the fruit, by being ſo ſuddenly expoſed, will receive a very great check, which will cauſe their ſkins to grow tough, and thereby render them leſs delicate. This is to be chiefly underſtood of ſtone-fruit and grapes; but pears and apples, being much hardier, ſuffer not ſo much, though it is a great diſadvantage to thoſe alſo, to be thus managed.

It muſt alſo be remarked, that peaches, nectarines, apricots, cherries, and plums, are always in the greateſt vigour, when they are the leaſt maimed by the knife; for, where theſe trees have large amputations, they are very ſubject to gum and decay; ſo that it is certainly the moſt prudent method carefully to rub off all uſeleſs buds when they are firſt produced, and pinch others, where new ſhoots are wanted to ſupply the vacancies of the wall; by which management trees may be ſo ordered, as to want but little of the knife in winter Pruning, which is the ſureſt way to preſerve theſe trees healthful, and is performed with leſs trouble than the common method.

The management of pears and apples is much the ſame with theſe trees in ſummer; but in winter they muſt be very differently pruned: for, as peaches and nectarines do, for the moſt part, produce their fruit upon the former year's wood; and therefore muſt have their branches ſhortened according to their ſtrength, in order to produce new ſhoots for the ſucceeding year; ſo pears, apples, plums, and cherries, on the contrary producing their fruit upon curſons or ſpurs, which come out of the wood of five, ſix, or ſeven years old, ſhould not be ſhortened, becauſe thereby thoſe buds which were naturally diſpoſed to form theſe curſons or ſpurs, would produce wood-branches, whereby the trees would be filled with wood, but never produce much fruit; and as it often happens, that the bloſſom-buds are firſt produced at the extremity of the laſt year's ſhoot, ſo, by ſhortening the branches, the bloſſoms are cut away, which ſhould always be carefully avoided.

There are ſeveral authors who have written on the ſubject of Pruning in ſuch a prolix manner, that it is impoſſible for a learner to underſtand their meaning: theſe have deſcribed the ſeveral ſorts of branches, which are produced on fruit-trees; as wood-branches, fruit-branches, irregular branches, falſe branches, and luxuriant branches; all which they aſſert, every perſon who pretends to Pruning, ſhould diſtinguiſh well: whereas there is nothing more in all this but a parcel of words to amuſe the reader, without any real meaning; for all theſe are comprehended under the deſcription already given of luxuriant or uſeleſs branches, and ſuch as are termed uſeful for fruit-bearing branches: and, where due care is taken in the ſpring of the year, to diſplace theſe uſeleſs branches, as was before directed, there will be no ſuch thing as irregular, falſe, or luxuriant branches, at the winter Pruning; therefore it is to no purpoſe to amuſe people with a cant of words, which, when fully underſtood, ſignify juſt nothing at all.

The following hints will be of great uſe in Pruning ſtandard trees.

Firſt, you ſhould never ſhorten the branches of theſe trees, unleſs it be where they are very luxuriant, and grow irregular on one ſide of the tree, attracting a great part of the ſap of the tree, whereby the other parts are unfurniſhed with branches, or are rendered very weak; in which caſe the branch ſhould be ſhortened down as low as is neceſſary, in order to obtain more branches, to fill up the hollow of the tree: but this is only to be underſtood of pears and apples, which will produce ſhoots from wood of three, four, or more years old; whereas moſt ſorts of ſtone fruit will gum and decay, after ſuch amputations.

But from hence I would not have it underſtood, that I would direct the reducing of theſe trees into an exact ſpherical figure, ſince there is nothing more deteſtable, than to ſee a tree, which ſhould be permitted to grow as it is naturally diſpoſed, with its branches produced at proportionable diſtances, according to the ſize of the fruit, by endeavouring to make it exactly regular at its head, ſo crouded with ſmall weak branches, as to prevent the air from paſſing between them; which will render it incapable to produce fruit. All that I intend by this ſtopping of luxuriant branches, is only when one or two ſuch happen on a young tree, where they intirely draw all the ſap from their weaker branches, and ſtarve them; and then it is proper to uſe this method, which ſhould be done in time, before they have exhauſted the roots too much.

Whenever this happens to ſtone fruit, which ſuffer much more by cutting than the former ſorts, it ſhould be remedied by ſtopping or pinching thoſe fruits in the ſpring, before they have obtained too much vigour; which will cauſe them to puſh out ſide branches, whereby the ſap will be diverted from aſcending too faſt to the leading branch, as hath been directed for wall trees; but this muſt be done with caution, as before.

You muſt alſo cut out all dead or decaying branches, which cauſe their head to look very ragged; eſpecially at the time when the leaves are upon the tree, theſe being deſtitute of them, have but a deſpicable appearance; beſides, theſe will attract noxious particles from the air, which are injurious to the trees; therefore, the ſooner they are cut out, the better: in doing of this, you ſhould obſerve to cut them cloſe down to the place where they were produced, otherwiſe, that part of the branch left will decay, and prove equally hurtful to the tree; for it ſeldom happens, when a branch begins to decay, that it does not die quite down to the place where it was produced, and, if permitted to remain long uncut, does often infect ſome of the other parts of the tree. If the branches are large which you cut off, it will be very proper, after having ſmoothed the cut part exactly even with a knife, chiſſel, or hatchet, to put on a plaiſter of grafting clay, which will prevent the wet from ſoaking into the tree at the wounded part.

All ſuch branches as run acroſs each other, ſhould alſo be cut out; for theſe not only occaſion a confuſion in the head of the tree, but, by lying over each other, rub off their bark by their motion, and very often occasion them to canker, to the great injury of the tree; and on old trees, especially apples, there are often young vigorous shoots from the old branches near the trunk, which grow upright into the head of the trees: these therefore should carefully be cut out every year, lest, by being permitted to grow, they fill the tree too full of wood; which should always be guarded against, since it is impossible for such trees to produce so much, or so good fruit, as those trees whose branches grow at a farther distance; whereby the sun and air freely pass between them, in every part of the tree. *Miller's Gard. Dict.*

PRU'NUS, *the plum*, in botany, a genus of trees, whose characters are:

The calyx is monophyllous and quinquefid; the flower rosaceous, pentapetalous, and furnished with thirty or more stamina. The ovary in the bottom of the calyx becomes an ovated or globous fruit, containing, under a thin, smooth membrane, or skin, a soft pulp, in the middle of which is inclosed an oblong or oval flattish stone, acuminated at both ends, and containing a single kernel; the pedicle of the fruit is of a good length. See PLUM.

PRU'SSIAN *Blue*. See the article *Prussian* BLUE.

PSE'UDO-*acacia*, *bastard acacia*, in botany, the name of a genus of trees, the characters of which are these: the flower is of the papilionaceous kind, and from its cup there arises a pistil, surrounded by a fimbricated membrane. This finally becomes a flat pod, which bursts into two parts, and contains kidney-shaped seeds. To this it is to be added, that the leaves are placed in series over-against one another, on a middle rib, the end of which is terminated by a pod leaf.

PSEUDO-*pulex arboreus*, in natural history, the name of a genus of insects described by Mr. Reaumur, and somewhat approaching in their form to the pulex arboreus; but having their wings covered with a squammose case, which those creatures have not, and having broader and flatter bodies.

These principally live upon the fig-tree and the box; they pass through a sort of metamorphosis into a hopping fly, supposed by some of the nature of the grasshopper; but erroneously, for that animal has a case for its wings, and the other not.

PSEUDO-*tinea*, in natural history, the name of a very remarkable insect, described by Mr. Reaumur, approaching to the nature of the tinea, or cloaths moth, while in the worm state; but not making themselves coats of the substance of leaves, cloaths, &c. though they form a sort of cases for their defence against a very terrible enemy.

These creatures are truly of the caterpillar kind, and have, in the manner of any of these insects, sixteen legs. They feed on wax, and for food enter the bee-hives; where they boldly engage the bees, and are not to be prevented by them from feeding, though at the expence of their habitations and the cells of their reservoirs of honey: so that it is no uncommon thing for a swarm of bees to be forced to change their place of habitation, and make new combs elsewhere; leaving the old ones to this contemptible victor, whom they know not how to drive out or dispossess.

PSI'TTACUS, *the parrot*, in the Linnæan system of zoology, makes a particular and distinct genus of birds, of the order of the hawks; the distinguishing characters of which are, that the feet have two toes before and two behind.

The parrot is a very well known bird, of which there are several very beautiful species.

Its head is large, and beak and skull extremely hard and strong. It might seem a wonder why nature has destined to this, which is not naturally a bird of prey, but feeds on fruits and vegetable substances, the crooked beak allotted to the hawk and other carnivorous birds; but the reason seems to be, that the parrot being a heavy bird, and its legs not very fit for service, it climbs up and down trees by the help of this sharp and hooked bill, with which it lays hold of any thing, and secures itself, before it stirs a foot; and besides this, it helps itself forward very much, by pulling its body on with this hold.

Of all animals, the parrot and crocodile are the only ones which move the upper jaw; all creatures else moving the under only. As some particular animals besides are fond of particular foods, so the parrot loves nothing so much as the seeds of the carthamus, or bastard saffron; and eats them without any hurt, though they are a purge when given to other creatures.

The parrots are common both in the East and West-Indies: they are a very brisk and lively bird in the warmer countries, but with us lose much of their vigour. They lay two or three eggs in the hollow of a tree.

In all the known parrots the nostrils are round and placed very high upon the beak, and very near one another.

PSY'LLIUM, *fleawort*, in botany, a genus of plants, whose characters are:

It agrees, in all respects, with the plantago and coronopus; only the stalks are leafy and ramous, or divided into a multitude of branches.

Fleawort has round hairy stalks, a foot or more high, beset at the joints with two, and sometimes three, long, narrow, sharp-pointed, somewhat hairy leaves, often lightly cut in about the edges. From the bosom of these, towards the upper part of the stalks, arise pretty long slender foot-stalks, bearing at the ends round short spikes of small stamineous flowers, of four leaves apiece, with a-pices standing out, and somewhat resembling the heads of the long plantain; and are succeeded by round seed-vessels; containing two round shining reddish-brown seeds, that look like fleas, whence it takes its name. The root is stringy and fibrous; it grows in the southern parts of France, from whence we have the seed which only is used.

Some attribute a purgative quality to this seed, but we use it only to extract a mucilage for sore mouths and throats, and to help thrushes and quinseys. It is, likewise, useful to obtund sharp acrimonious humours, which corrode the bowels, and cause dysenteries. Outwardly it is good for sore, inflamed, blood-shot eyes. *Miller's Bot. Off.*

The salt of this plant resembles that of coral, but is mixed with a little of sal ammoniac, a great deal of sulphur, and terrestrial parts.

By the chymical analysis, it yields a great deal of oil and earth, no volatile concrete salt, a little urinous spirit, and several acid liquids.

Psyllium-seed is used in the electuary de psyllio; but its purgative virtue ought to be attributed to the scammony, and the other cathartics. The mucilage of Psyllium is very lenifying, and good to asswage the inflammation of the eyes: it is given in a clyster for the dysentery, and inflammation of the kidnies. *Martyn's Tournefort.*

PTI'LOSIS, πτίλωσις, from πτίλος, a person who has lost his eye-lashes. A baldness of the eye-lashes. Paulus Ægineta, Lib. 3. cap. 23, says, the Ptilosis and madarosis are disorders of the external margins of the eye-lids. The madarosis is only a falling off of their hairs, produced by a defluxion of acrid humours; whereas, in a Ptilosis, the margins of the eye-lids become thick and callous; so that it is a disorder complicated of a madarosis and an hard lippitude: for which reason the remedies proper for the one are, also, conducive to the removal of the other. For procuring the growth of the hairs, and preventing an itching and corrosion of the corners of the eyes, the best medicine is that of Philoxenes, distinguished by the epithet dry. For removing a dimness of sight, the following preparation is excellent:

Take of cadmia, eight drachms; of sal ammoniac, two drachms; of saffron and spikenard, each two drachms; and of white pepper, one drachm: mix all together for use. Antimony, also, answers the same purpose.

For a corrosion of the corners of the eyes and a Ptilosis:

Take of calcined antimony, extinguished in women's milk, thirteen drachms; of aloes, myrrh, and spikenard, each two drachms; and of calcined barley, carefully triturated, four drachms: mix, and use dry.

Another medicine for a Ptilosis, and corrosion of the eye-lids, is thus prepared:

Take of the marrow of an ox, a sufficient quantity; triturate it duly with soot, and use it.

The soot intended for this purpose is to be thus prepared: immerse a sufficient quantity of paper in the oleum sesaminum: put the paper in a lamp, kindle it, and hold above it a smooth shell, or brazen vessel, in order to collect the soot, which, when triturated, with the above-mentioned marrow, is to be used.

The rennet of a calf is, also, excellent for the same purpose.

For a milphosis, an increase of flesh in the corners of the eyes, and other inveterate disorders of them, Sosander directs the following medicine:

Take of cadmia, antimony, crude chalcitis, and crude misy, each eight drachms: bruise these, mix them with honey, and torrefy them, after extinguishing them in wine, and triturating them: add to them, of spikenard, two drachms; of torrefied saffron, two drachms; and of pepper, one drachm; all these, when triturated together, are to be used.

The more simple medicines contributing to the cure of a Ptilosis, and a corrosion of the eye-lids, are boiled amurca, Indian lycium, and Armenian stone, used by the painters; which last, when mixed with water, and used by way of ointment, consumes the peccant humours, and augments the natural hairs; the rust of iron, triturated for many days in the heat of the sun, and reduced to the form of a collyrium, with wine and myrrh; and spodium, mixed with the juice of onions, is all of service.

PU'CERON, the name given by naturalists to a small insect of a peculiar nature, frequently found on the young branches of trees and plants, and that often in such clusters, as wholly to cover them.

The Puceron is a small animal, but very numerous in the several genera and species; insomuch that Reaumur has observed that there is scarce a vegetable to be found, either in the fields or gardens, that has not its peculiar species of Puceron to feed on its juices. M. de la Hire, of the Paris academy, has left many curious particulars in regard to these animals, in the year 1703; and Mr. Lewenhoek, and others since, have given figures and descriptions of several of the species.

Pucerons are all viviparous animals, and that after a very singular manner. It is to be observed, that the name is scarce more expressive of the creature, than some of the others given of late to insects; that of the polype to a creature which has no no legs or feet at all, is very improper; and that of the Puceron hardly less so, as it would naturally lead us to imagine, that the creature thus called was able to hop like a flea, whereas, in reality, it is very slow in its motions, and seldom so much as walks.

These creatures have six legs, which are extremely small and slender; and which, when the animal is at its full growth, are loaded with a weight so large, that they seem scarce able to support it. Some of these species arrive at a tolerable bigness for common observation; but the greater number are too small to be accurately seen, without the assistance of glasses. Among these insects there are great numbers that in their full perfection have wings, and become a sort of little flies: these are distinguished from the others, by the name of luted Pucerons. *Reaumur's Hist. Inf.*

The elder is the tree, on which they are of all others the most plentifully produced, and on which they are observed in their several stages with the greatest accuracy and ease. They often cover the thick green roots of this tree for many inches together, and sometimes for many feet; and they are always placed so close together, that they touch in every part, and sometimes they lie two beds, one over another. These are of a greenish black. If they are observed on the branches undisturbed, they are always found to be perfectly quiet, and seem to pass their whole lives in inaction; but they are all this time doing the most necessary business of life, that is, sucking in the nourishment from the juices of the tree. They do this by means of a fine slender trunk, which easily escapes the naked eye, but is always found by the microscope; and it is by means of this that they pierce the bark of the tender parts of the vegetables, and get at their juices. The trunk is usually of two thirds of the length of the body; but, when they are moving on, it is always applied so closely under the belly, that it is not seen.

Bladder PUCERON, a sort of Puceron that lives in bladders on the leaves of trees.

We often observe, on the leaves of different trees, a sort of roundish bladders, which only adhere to the leaf by a short pedicle: these are a sort of small galls, and their figure varies much in the different kinds; some are less round than others, and many are very rough on the surface; and sometimes they are long, terminating in a point, and being broader at the base than in any other point, and sustained by no pedicle, but fixed immediately to the leaves.

The elm and ash afford us more frequent instances of these than any other trees, and very often, on the first of these, they grow to the bigness of a nut, and sometimes much larger; and, when they are grown to their full size, they often take up the whole surface of the leaf. When these bladders are opened, they are found to contain a large number of Pucerons.

If these bladders are examined at the time when they are newly risen, which usually is in the beginning of June, on opening them there is usually found in them only one Puceron, and that always a female big with young; and, in others more advanced, the parent insect is found surrounded with different numbers of her young ones. These bladders have all of them at first only one female Puceron; but afterwards they have more, as they become larger; and the largest of all are usually found filled with a prodigious number of young ones. The newly risen bladders are always found close and firm in every part, the aperture, at which the female had entered, being usually neatly and closely stopped up. The question is, how this bladder was formed?

We very well know, that winged insects of several kinds prick holes in the leaves and branches of vegetables, and deposit their eggs in them; and that thence arise all the various species of galls, the eggs hatching within these tumors into worms or maggots, and these finally become winged insects like their parents.

Malpighi has given an excellent account of the several species of these galls; but he has not mentioned any of them being produced by a viviparous insect, for the bringing up her numerous family: he has not omitted the bladders on the leaves of trees among the numbers of galls, but he has had no true idea of their origin; nor could this, indeed, have been any way found out, but by the observation that the creatures contained within them were of the same nature and origin with those on the surface of the same or other leaves.

There seems no doubt, but that each of the female Pucerons, found in the bladders of these leaves, has been herself the occasion and the maker of that bladder in which she is found so close shut up.

The female thus finds herself in a secure place, and the elevation she makes in the leaf is scarce perceivable, only appearing as an oblong small species of gall. The mark of the aperture at which she made her way in, is always to be seen at some distance behind her, though usually very neatly closed up: thus the whole continues till the creature produces her young. But, then, the scene is quite altered; the young ones begin to suck as soon as produced, and as they usually seize upon the sides of the small gall, already formed for that purpose, this derives more juices than otherwise would flow into it; and it begins to elevate itself much higher, and forms a tubercle of the shape of a nut or pear.

Its growth in this case is intirely analogous to that of the common galls on the branches of trees, &c. and all the difference, in the shape of the several bladders, is owing to the manner of the young Pucerons sucking: for, if they suck much at its base, that enlarges and becomes the broadest part, as is the case in the conic and pointed ones; but, if they let this alone, and suck only the sides and upper part, they swell while this does not, and consequently this forms a sort of pedicle to the growing bladder. *Reaumur's Hist. Inf.*

PUFF-*ball*, the common English name for the fungus pulverulentus, or lycoperdon.

The dust contained within this body, which, when it is crushed, flies out in an inconceivable fine powder, in form of a cloud of smoak, when examined by the microscope, appears to be a multitude of regular figured, though extremely small bodies. These require the most powerful magnifiers to distinguish them, and are found to be little globules of an orange colour, and somewhat transparent; and so small, that the cube of the diameter of a hair would be equal to an hundred and twenty-five thousand of them. In other species of this mushroom, the globules are evidently seen to be so many Puff-balls, being of a darker colour, and having each a little stalk or tail: by means of these stalks they penetrate into the ground, when shed from the parent plant.

The dust of these mushrooms is very hurtful to the eyes, and we have had instances of persons being blinded for a long time by it, with violent pain, swelling, and inflammation; and this is probably owing to the sharpness of these almost inconceivably minute stalks or tails. *Baker's Microscope.*

PUFFIN, *puffinus*, in zoology, the name of a water-fowl, with its three fore-toes connected by a membrane; but its hinder ones loose, and with a sharp and crooked beak. It is a sea bird, but not generally known.

It is larger than the tame pigeon: its head, neck, and back, are black: its breast and belly white: its beak is two fingers breadth long, and its base covered by a naked membrane, and has on each side a furrow, running from thence to the end of it: its wings are very long, and its tail a hand's breadth long, and black: it is extremely common in the Isle of Man, but is so fat, that its flesh is accounted unwholesome, unless it is salted: it is also common in the islands of Scilly. They breed only in the Calf of Man, an uninhabited part of the first mentioned island, and each female only lays one egg.

They lay in rabbit holes, and, as soon as the young are hatched, they follow their parents all day to sea, returning only in the evening. The people take them early in the morning, about the time of their going out; and, that every man may remember how many he takes, he always cuts off one of the legs, and keeps it in his pocket; hence they vulgarly obtained an opinion, that Puffins have but one leg. *Ray's Ornithol.*

PUGNI'TIUS, in zoology, the name of the common stickleback, or barnsticle, called also from its spines aculeatus, and by some authors spinachea, turonilla, and centiscus.

PULE'GIUM, *pennyroyal*, in botany, a genus of plants, whose characters are:

The flowers, which are very small, are disposed in close thick whorles, and their upper lip is intire: in other respects, this herb resembles the mentha or mint.

Pennyroyal has many creeping fibrous roots; from which spring a great many smooth roundish stalks, hardly able to support themselves, but leaning on the ground, and sending out small fibres, by which it roots itself in the ground: it bears two small, round, but yet pointed leaves, at a joint: the flowers grow towards the upper part of the branches, coming forth just above the leaves, in thick close whorles; they are of a pale purple colour, small and galeated, set in small and somewhat downy calyces, in which grow four small seeds. The whole plant has a very strong smell, and an hot aromatic taste: it grows frequently upon moist commons, and in places where water has stood all winter, and flowers in July. But what we use in the shops is generally cultivated in gardens, where it grows tall and large: the whole herb is used.

It is hot and dry, of very subtile volatile parts, and is peculiarly appropriated to the female sex, being a good uterine, provoking the menses and lochia, expelling the birth and secundines. It likewise warms and comforts the bowels, and helps the cholic and jaundice, and is good against coughs and shortness of breath: the juice, or a strong decoction of the leaves, sweetened with sugar, has been accounted a specific against a whooping cough.

Officinal preparations are only the distilled water and oil. *Miller's Bot. Off.*

This plant, which is very bitter, acrid, and of a very penetrating smell, gives a deep tincture of red to the blue paper; so that it is probable, it contains a volatile, aromatic, and oily salt, loaded with acid; whereas, in the artificial, volatile, and oily salt, this acid is detained by the salt of tartar.

Thus this plant is aperitive, hysteric, and good for the diseases of the stomach and breast; since it evacuates those glutinous sordes, which fill part of the bronchia, and vesicles of the

the lungs; especially if it is boiled with honey and aloes; for then, as Dioscorides observes, it purges, and procures expectoration. Tragus very much commends the decoction of pennyroyal in white-wine, for the suppression of the menses, and fluor albus. The juice of this plant, according to the same author, clears the sight, and removes lippitude. Montanus prescribed the powder of pennyroyal mixed with equal quantities of vinegar, honey, and water, for the diseases of the eyes. The conserve of its flowers and leaves is good for the dropsy and jaundice. Ray affirms, from Mr. Boyle, that a spoonful of the juice of pennyroyal is a good remedy for the chin-cough of children. Chesneau prescribes a glass of its decoction for hoarseness, and advises to take it before going to bed.— For the method of propagating pennyroyal; see the article PENNYROYAL.

PU'LEX, *the flea.*— It is to Signior Redi that we owe the true history of the generation of this common and troublesome animal. The flea lays its eggs, and from each egg is hatched a small worm: this worm spins itself a bag of silk, in the same manner that the silk-worm does, and out of this bag it comes at last in the perfect form of a flea, as the other does in its winged state.

The flea deposits its eggs on the bodies of dogs, cats, and other animals, and on the cloaths of men, or the beds, and other places where they sleep. These eggs, being round and smooth, slip easily down till they come into some fold of the cloaths, or some other place, where they are hatched. In this place each egg produces a small white worm of a silvery appearance; these worms feed on the white scurfy matter which is found in great plenty on the skins of dogs and other animals; and they are also found among the folds of linen in drawers, and other places: they are a fortnight in arriving at the full bigness of the worm state, and will roll themselves close up into a ball, in the manner of the wood-louse, when touched. They, soon after this, spin themselves their web, in which they lie a fortnight, and then come out perfect fleas.

The flea, if examined a day or two before its full growth in the bag, is found to have all its parts and lineaments; but it is soft and white. After this it gradually becomes hard and coloured, is as strong and large as it ever is to be.

PULEX-*eaters*, a name given by naturalists to a sort of worms, frequently found on the leaves of trees, where they devour the animals called pulices arborei.

Of these there are several species, which owe their origin to the eggs of different creatures; for they are none of them in their ultimate state in this their time of feeding. According to the different animals whose eggs they are hatched from, these are of different form and structure; some are hexapodes, or endued with six feet; these belong to the beetle tribe, and finally change into beetles like the parent animal from whose eggs they sprung: others have no legs, and are produced from the eggs of flies of various kinds: and, finally, others are genuine caterpillars, though small; but these are the most rare of all.

The two general kinds are the hexapodes, or beetle-worms, and the apodes, or fly-worms. The fly which gives origin to the last of these, is a four-winged one, and takes care always to deposit her eggs in a place where there are plenty of the pulices, usually on the stalk or young branches of a tree in the midst of large families of them. The worm, as soon as hatched, finds itself in the midst of abundance of food, preying at pleasure on these animals, which are wholly defenceless. The stalk of the elder and wood-bine are frequently found covered over with these Pulices, and among them there may usually be found one or more of these destroyers feeding at will, sucking in the juices from their bodies, and then throwing away the dry skins. Besides the worms of this four-winged fly, there is one of a two-winged wasp-fly, very destructive of these animals. *Reaumur's Hist. Inf.*

PULEX *arboreus*, in natural history, the name given by Mr. Reaumur to a very large genus of small animals. They are a kind of half-winged creature; they have granulated antennæ, and some of them, in their most perfect state, have perfect wings.

PU'LMO *marinus, sea lungs*, in natural history.—This substance floats in the sea; is of a pellucid bluish colour, resembling, in some measure, that of crystal; and is so tender, that it can hardly be taken out of the sea intire. When recently triturated, and used by way of ointment, it cures gouts and chilblains. *Dioscor. Dale.*

PULMONA'RIA, *sage of Jerusalem*, in botany, a genus of plants, whose characters are:

The calyx is like a tube, pentagonal and quinquefid. The flower is monopetalous, cylindrical in its lower part, and shaped like a bason above, with its margin cut into five round segments. From the sides of the internal cylindrical part, which are neatly fimbriated, arise five stamina.

This is accounted a pectoral, balsamic plant, and good for coughs, consumptions, spitting of blood, and the like disorders of the lungs. It is, likewise, put into wound-drinks, and traumatic decoctions; being agglutinating, and good to heal wounds and ulcers, and old sores. *Miller's Bot. Off.*

PU'LVIS *e bolo compositus*, a powder prescribed in the late London Pharmacopœia, and intended to be used in the place of the confectio Fracastorii or diascordium. It being supposed that this medicine was by its author meant as an alexipharmic, and being now principally used as an astringent, it was thought necessary to make this separate medicine. This powder is composed of bole armenic, half a pound; cinnamon, four ounces; and tormentil-root and gum arabic, of each three ounces, made together to a powder. *Pemberton's London Dispensatory.*

PULVIS *bezoarticus*, the name given in the late London Dispensatory to the powder commonly called Gascoign's powder.

This is now ordered to be made only of crab's claws, one pound; prepared pearls and red coral, of each three ounces; and oriental bezoar, an ounce. The amber and hartshorn are left out of the composition, as improper or inefficacious ingredients; and the whole ordered to be kept also without the bezoar, and called by the name of Pulvis e chelis cancrorum compositus, the name the Gascoign's powder used to be known by. *Pemberton's Lond. Disp.*

PU'LVIS *e cerussa*, a medicine prescribed in the late London Pharmacopœia, in the place of the white troches of Rhases or Razi.

The late compositions of that medicine had been much more complex than the original receipt of the author, and the college have therefore retrenched the number of ingredients in them; and, as the medicine is always to be powdered for use, it is now ordered to kept in the form of powder.

It is thus prescribed there: take ceruss, five ounces; sarcocolla, an ounce; gum tragacanth, half an ounce; make the whole into a fine powder. *Pemberton's Lond. Disp.*

PULVIS *contrayervæ compositus*, the name given, in the late London Dispensatory, to the composition usually called lapis contrayervæ.

The preparation is also, there, made much less complex, by leaving out the less powerful absorbent powders, and using the compound powder of crab's claws in the place of all.

This is now ordered to be made only of the compound powder of crab's claws, a pound and an half; and contrayerva-root, five ounces. *Pemberton's Lond. Disp.*

PULVIS *e myrrha*, a form of medicine prescribed in the late London Dispensatory, to supply the place of the troches of myrrh.

The composition is the same, but for the omission of one or two of the ingredients, supposed not of the same virtues with the rest, or very disagreeable to the taste.

It is ordered to be made thus: take of dried leaves of rue, of dittany, of crete, of myrrh, each an ounce and a half; of assa fœtida, sagapenum, Russia castor, and opopanax, each an ounce; beat all together to a fine powder. *Pemberton's Lond. Pharm.*

PULVIS *e scammonio*, a name given, in the late London Dispensatory, to the purging powder commonly called the Earl of Warwick's powder.

It is, however, wholly altered here, the crystals of tartar and diaphoretic antimony being left out, and the medicine ordered to be made only of four ounces of scammony and three ounces of burnt hartshorn reduced together to a fine powder. *Pemberton's Lond. Disp.*

PULVIS *e succino, amber-powder*, a form of medicine prescribed, in the late London Pharmacopœia, to stand in the place of the troches of amber, or trochisci de carbone of former dispensatories.

The composition of the powder is this: take prepared amber and gum arabic, of each ten drachms; juice of hypocistis, balaustines, and Japan earth, of each five drachms; olibanum, half an ounce; strained opium, a drachm; mix all together into a fine powder. *Pemberton's Lond. Disp.*

PULVIS *fœcundans*, in natural history, a name given by late writers to that fine powder which is contained in capsules upon the stamina or threads in the flowers of plants, and is called by some English writers the male dust, and in general the farina of flowers.

Puteolanus PULVIS, in natural history, the name of a fossil substance, found in form of powder, and famous for its consolidating under water. The accounts of it seem, however, to be a little erroneous.

The substance itself is a pale greyish powder, composed of particles so extremely minute, as to escape the distinction even of the best glasses, and appear, when viewed by the microscope, only a loose, very fine, irregular powder. It has among it a few small spangles of talc, and, being shook up in a phial of water, leaves a whitish muddiness in it, which is very long in subsiding. If wetted with salt-water, it immediately dries into a firm solid mass, like stone. It does the same also in common water; but the mass is less firm.

The antients were all acquainted with this substance, and its properties. It is said, indeed, that, on running down into the water, it becomes a hard stone, while it remains under it; but this is probably a mistake, arising from this, that the powder was continually running down the hills into the sea, and lodging on their sides in large quantities in many places; when these masses came wet with the waves, in storms or high tides, and afterwards deserted by them, they naturally hardened into so many masses of a sort of stone; and these were probably what authors have seen and described, for they never,

never, probably, ſearched for theſe maſſes under water. The principal uſe of this powder, among the antients, was in mixing with their cements for buildings ſunk into the ſea. It is at preſent well known in France and Italy, as an ingredient in that ſort of plaiſter they call pozzolane.

The remarkable quality of its coaleſcing, on its being mixed with water, is probably owing to its having in its compoſition a quantity of a certain earth known in almoſt all ages and countries for coaleſcing into a kind of plaiſter without previous burning. The antients knew this earth by the name of gypſum tymphaicum; and we, by that of calx nativa. It is very common on the ſides of hills, in many parts of Italy. *Hill's Hiſt. of Foſſ.*

PU'NCTURE, (*Dict.*)—Among the number of the moſt ſimple wounds are reckoned thoſe which are made by Puncture, or ſtabbing on the external parts, and not penetrating to a very great depth. In theſe wounds, after the blood has been ſtopped at the firſt dreſſing, by the application of dry lint, the common digeſtive, or linimentum Arcæi, is to be ſpread upon a pledget and applied once every day; or, if the diſcharge is but ſmall, every other day, covering the dreſſings with a plaiſter and compreſs, and ſecuring the whole with a proper bandage. At each dreſſing, care muſt be taken to remove every thing that will give way readily; the pus or ſanies is to be gently wiped off with fine rags; and, unleſs a great diſcharge of matter make it neceſſary, too frequent dreſſings do rather harm than good. The firſt dreſſings that have been applied, eſpecially when there has been a flux of blood, ſhould by no means be removed forcibly, but be left till they will fall off of themſelves, which they will do after a ſuppuration is formed: and, by this caution, much pain, and, perhaps, a freſh hæmorrhage, are avoided.

When a Puncture, however, penetrates very deep, the cure is attended with many difficulties; eſpecially if it is made perpendicularly down, and has no depending orifice: for, in this caſe, the blood and matter are eaſily collected at the bottom, and protract the cure, and frequently form fiſtulæ. To prevent theſe conſequences, it will be proper to preſs the wound from the bottom upwards, to apply a compreſs towards the bottom of the wound externally, and to apply a bandage over all, which preſſes much tighter upon the lower than upon the upper parts. If all this precaution, however, prove of no effect, which, indeed, is too often the caſe, it is the moſt proper method to make a large opening at the bottom of the wound, before any fiſtulæ are formed there. In order to make this opening to the greater advantage, it will be proper to get a particular ſort of probe or needle, very blunt at top, and at the other end provided with a large eye, or hole, through which a linen rag may be paſſed. This probe is to be paſſed to the bottom of the wound, and the blunt end of it preſſed outwards toward the ſkin, till you can feel it with a finger: when you can feel it, cut down upon it, if you can ſafely, and make a large opening; ſpread the rag that you have run through the eye of the probe with ſome vulnerary balſam, and draw it through the wound after the manner of a ſeton, and leave it there, dreſſing up both the orifices with the ſame balſam, and covering the whole with compreſſes and the proper bandages. In every ſucceeding dreſſing, that part of the rag that is left out of the wound, is to be ſpread with freſh ointment, and the lower part drawn down till this takes place in the new wound. This method is to be continued till the wound is well cleanſed, the diſcharge greatly diminiſhed, and all in a readineſs to heal: the ſeton is then to be removed, and the wound healed as uſual. *Heiſter's Surg.*

PU'PIL (*Dict.*)—Pupil *contracted.* The diſtemper of the eye called by ſurgeons a contraction of the Pupil, is ſo total or cloſe a contraction of that part as will not let it tranſmit light enough to the bottom of the eye to enable the patient to ſee objects diſtinctly. Sometimes this diſorder is from infancy, and ſometimes it ariſes from an intenſe inflammation of the eye, or other cauſes.

The cure of this is extremely difficult; but Mr. Cheſelden has invented a method by which he has often proved very ſucceſsful in his attempts to relieve it. The method is this: the eye-lids being held open by a ſpeculum oculi, he takes a narrow ſingle-edged ſcalpel, or needle, almoſt like that uſed in couching for a cataract, and paſſing it through the ſclerotica, as in couching, he afterwards thruſts it forward through the uvea or iris, and in extracting it cuts through the iris.

If the diſorder is not accompanied with a cataract, it will be beſt to cut through the iris in the middle; otherwiſe, when there is a cataract, the inciſion ſhould be made a little higher in the uvea, that the cataract may not obſtruct the ingreſs of the rays of light. The cataracts that accompany this diſorder are uſually very ſmall, and ſometimes their adheſion to the iris is ſo firm, as to render it impracticable to couch or ſuppreſs them. *Heiſter's Surg.*

PU'PPETS, in natural hiſtory, the name given by Swammerdam to the nymphæ of animals, which he diſtinguiſhes from the chryſaliſes, by this ſimple name, calling theſe the gilt Puppets, from their golden colour.

PUR *autre vie*, in our law-books, is uſed where lands are held for the life of another.

PU'RCHASE-*book*, among traders, is the name given to a book which is a kind of journal, containing an account of all the purchaſes made, or things bought in the day.

PURCHASE, in the ſea-language, is the ſame as draw in: thus when they ſay, the capſtan Purchaſes apace, they only mean it draws in the cable apace; alſo, when they cannot draw or hale in any thing with the tackle, they ſay, the tackle will not Purchaſe.

PU'RGATIVE (*Dict.*)— Dr. Cheyne accounts for the action of Purgatives in the following manner: — A Purgative medicine being received into the ſtomach by the mouth, its particles do there vellicate or ſtimulate the fibres of the ſtomach, and thereby increaſe the digeſtive faculty, i. e. bring the muſcular fibres of the ſtomach and the muſcles of the abdomen and diaphragma into more frequent contractions than ordinary, till the medicine is admitted into the inteſtines; the fibres and glands whereof being more ſenſible than thoſe of the ſtomach, (whoſe parts, by the frequent rough contacts of one againſt another, and of the groſs bodies often thrown into it, are, as it were, deadened) it eaſily moves and brings them into frequent forcible contractions, whereby theſe glands are ſqueeſed, and ſo emit a fluid matter, which lubricates the paſſages, and which mixing with the feculent matter of the inteſtines, (which is rendered fluid by the ſame active and ſtimulating quality of the purgative medicine) renders it more fluid; by which, and by the uncommon contractions of the inteſtines, it paſſes more eaſily and plentifully into the inteſtinum rectum, and is thence ejected by ſtool.

Thus do gentle purges act, and only cleanſe the inteſtines, few of their particles entering in by the lacteal veins ſo as to affect the blood.—But in violent Purgatives the ſtimulating particles are mixed with the blood, and produce there, many times, very great effects, by occaſioning unnatural fermentations, by ſeparating the natural coheſions of the fluids of the body; and do alſo, by vellicating the ſpiral fibres of the veins and arteries, bringing thoſe into more forcible contractions, and thereby accelerate the motion of the blood:—all which may have ſometimes a good, ſometimes a bad effect.

As to the effects of Purgatives on animal bodies, Dr. Quincy adds, that every irritation of the inteſtines either quickens the periſtaltic motion in its natural direction, or occaſions ſome little inverſions of it.—Now, in both caſes, any matters that but ſlightly adhere to the coats, or inner membranes, will be looſened, and ſhook off, and carried forwards with the other contents; and they will alſo be more agitated, and thus rendered more fluid.

Hence is manifeſt how a purging medicine haſtens and increaſes the diſcharges by ſtool; but the ſame manner of operation alſo carries its effects much farther, in proportion to the force of the ſtimulus: for, where it is great, all the appendices of the bowels, and even all the viſcera in the abdomen, will, by a conſent of parts, be pulled or twitched ſo as to affect their reſpective juices in the ſame manner as the inteſtines themſelves do their contents.—The conſequence of which muſt be, that a great deal will be drained back into the inteſtines, and made a part of what they diſcharge.—And when we conſider the vaſt number of glands in the inteſtines, with the outlets of thoſe viſcera opening thereunto, and particularly of the liver and pancreas, it will be no wonder, that vaſt quantities, eſpecially in full conſtitutions, may be carried off by one purge.

As to thoſe Purgatives diſtinguiſhed by the names of cholagogues, hydragogues, phlegmagogues, on a ſuſpicion of an elective quality therein, they may be accounted for upon more intelligible principles:—for, when the diſcharges by ſtool diſcover an over-proportion of any particular humours, it is to be ſuppoſed there was a redundance of ſuch an humour, whoſe diſcharge any irritation would have occaſioned. Thus, in proportion to the proximity of ſome humours in the inteſtinal tube, and the diſpoſition of the paſſages to convey them that way, do they require greater or leſſer vibrations or ſhakes of the fibres to fetch them out.

For this reaſon, the briſker cathartics, which vellicate the membranes, moſt of all, pump out, as it were, from all the meſenteric glands, and neighbouring parts, their contents, which, becauſe they abound ſo much with lymphatics, and viſcid watery humours, make the diſcharges thin and watery. Thoſe which act in a ſomewhat lower degree, yet irritate enough to deterge and draw out a great deal of mucous and viſcid matter, which ſometimes, by lodgment and want of due motion, changing into various colours, occaſions the different names of phlegm or choler: as the former therefore paſs for hydragogues, ſo do the latter for purgers of phlegm and choler. But there is another principle beſides that of a ſtimulus, whereby a purging medicine is enabled to anſwer its intentions, viz. by fuſing the humours, and rendering them more fluid than before, whereby they are better fitted to paſs off by their proper emunctories.—Thoſe which conſiſt of very ſubtile and active parts are not ſo ſenſible in the larger paſſages, becauſe of the great quantities of matter, which lay too great a load upon them, and make them unheeded; but, when they are got into the blood in any conſiderable number, they divide and fuſe thoſe coheſions which obſtruct or move heavily

vily along the capillaries, and scour the glands; insomuch that every pulsation throws something through the intestinal glands, which goes away by stool, that the refluent blood had washed away and brought back from all parts of the body.

Of this kind are all those cathartics, which are said to purge the joints, and are prescribed in rheumatisms, and arthritic pains, as the radix turpethi, and all the aloetics.—And this is the reason why purging medicines of this sort are so easily changed into the most efficacious alteratives; for an alterative is a cathartic in a lower degree, or of a more remiss operation. Whatsoever brings such particles to a secretory orifice, which is fitted for its passage, oftener, either by accelerating the blood's motion, or breaking it into more particles of that particular size and disposition, will increase the secretion. According, therefore, to the difference of the parts where such secretions are inlarged, as the glands of the intestines, kidneys, or skin, are the medicines, which are the instruments therein, called cathartics, diuretics, or diaphoretics.

In order to explain more fully the operation of Purgatives, it may be convenient to attend to the common way of making a purge operate, more or less, than it otherwise would do.

Substances, then, which are gross and heavy, as those consisting chiefly of saline and earthy particles; such as tartar, manna, and the like; when reduced smaller by triture, or repeated solutions, operate more gently; but when acuated by acids, or any way made to expose their angles more plentifully to the membranes, they become rougher, and sooner take effect.

Resinous medicines, as scammony, gamboge, jalap, and most vegetable productions, are more violent, and operate sooner, when they are more tenacious and adhesive, as in their extracts; but gentler, when divided by hard brittle substances, such as salt of tartar, sugar, &c.

Medicines, which have in their composition sulphur and salt, are more or less rough and speedy in their operation, in proportion to their greater or lesser participation of the saline ingredient, and the asperity of its angles.—Of this kind are most minerals, and their preparations: it may be sufficient to instance in the management of antimony and mercury; the first of these is by chymical analysis known to be a composition of a subtile sulphur and salt; and the more the saline part is set loose by preparation, and opening the sulphur, as it is commonly termed, the speedier, and with the greater vehemence, will it operate; whereas, in its more imperfect preparations, when the salts are closely wrapped up in their native sulphur, it will hardly work at all, till it reaches the farthest stages of circulation.

Mercury per se is little known as a medicine; and its first preparation, which makes it into a sublimate, so loads it with saline spiculæ, that it amounts even to a poison; but the more those spiculæ are broken by triture, sublimation, &c. the milder doth it operate, and, if to the comminution of its points be added a sulphur subtile enough to join it, it may be reduced to so mild a medicine, as not to be felt but in the last stage of operation.

This short view may be sufficient to shew, 1. That it is the too great asperity and motion in a medicine, that will not suffer it to pass the stomach, without irritating it into such convulsions, as will throw it up again by vomit.

2. That a farther comminution, and smoothing its figure, will gain it admittance into the bowels, and cause it to operate, as a proper Purgative, by stool.

3. That a yet farther remission of these properties will convey it into the blood, and allow it there to promote evacuation by urine.

And, lastly, that a still farther comminution will pass it into the minutest canals, where, by the same properties, only in a lower degree, it will cause sweat, or increase perspiration.

Hence it appears, that the more subtle medicines operate in the capillaries, and smallest fibres, by the same mechanism that the more gross ones do in the common stream of the blood, when they go off by urine; or as the grossest of all do in the greater passages, when they promote evacuation by stool.

Hence it is evident, that the skill of preparing and administring of medicines consists in proportioning their manifest and known properties to the capacity and circumstances of the part they are to operate in; and to intend or remit their mechanical affections, as they are sooner or later to take place in the greater or smaller vessels.

Of the first class there are few can be reduced small enough to go beyond the larger passages, and none of them are worth the pains they require, to fit them farther than for diuretics: besides, their natural disposition to attract, and join with the serous part of the blood, whenever they get into that stage of motion, runs them off by the kidneys, before they can undergo comminution enough to get farther: but if by frequent repetitions of such medicines, and an uncommon laxity of the passages, any parts are passed into the habit, their grossness fouls the delicate strainers, which are destined for their expulsion; and they lodge upon the glands and capillaries in such manner, as to induce intermittents; which are observable in many persons, after a long use of cream of tartar, the common cathartic salts, and the purging waters, especially at the latter end of the summer, when the heat of the preceding season has debilitated the solids, and left them under too great a relaxation.

Among the resinous purges, there are many very powerful ones; but where their operation is desired in the viscera, blood, and remoter parts, they must be extremely divided; and this we find spirituous menstruums will do, by taking up the most subtile parts only, and carrying them into the very small passages, where they operate chiefly by fusion; because the softness of such substances cannot enable them, hardly in any degree, to act as stimuli, farther, at least, than ordinary detergents. And thus we find that aloe, the chief of this tribe, goes farthest into the habit, and continues longest before it operates, when managed with a spirituous menstruum, as in the tinctura sacra. The rad. turpethi, and colocynth likewise, with all of the vegetable kind, that will yield to a spirituous liquor, may, by that means, be carried into the farthest scenes of animal action; where they will prove efficacious medicines in cases, which, with other management, they would never be able to reach: and on this account it must undoubtedly have been, that we frequently meet, in practical writers, with many materials of this sort mentioned as alterants; the colocynth particularly by Helmont: for all medicines, which operate in the farthest passages, they commonly include under that general appellation.

But the most efficacious purges, and those which require the most skill, are procured from the mineral kingdom; these abound in solidity beyond any other materials, and therefore, where-ever they are brought into action, necessarily excel in the quantity of impulse; many of these therefore want not only the utmost comminution to carry them into the farther scenes of operation, but also some restraint of their asperities and motions, to fit them for many intentions.—Thus sublimate is not only to be much sweetened, that is, smoothed in its points, to make it a safe purge in the larger vessels; but if it be intended to go farther than the blood, and those glands, which in that circuit it is most apt to be lodged upon when it salivates, it must not only be rendered very fine, but also be covered with such substances as weaken its points, and make it pass into the last subdivisions of the constitution. To this purpose, the common practice wisely contrives in distempers, which, according to the course of circulation, lie most remote, to wrap up the basis of this medicine in sulphurs, and suchlike substances, as follow it into its last division, without giving it any asperities to make it act as a stimulus. Thus, for all cutaneous foulnesses, and habitual taints, the cinnabar, the æthiops, and all of that sortment, are in readiness; and that ordinary sulphurs will cover and deaden the efficacies of mercurial preparations, so that they shall not operate, but in such parts only, and in certain circumstances, is demonstrable in ordinary salivations, which are to be lowered by sulphureous medicines.

Medicines from such minerals where a salt and sulphur are united by nature, as they are in some mercurials by art, as antimony, the native cinnabar, steel, &c. are manageable only upon the same principles; and, the more they are designed to be carried into the habit, the more are they to be restrained by their natural or adventitious sulphurs: steel, when opened by, and joined with, the points of acid liquors, operates the sooner, and will sometimes prove even emetic; but, when it is covered with an additional sulphur, it will go farther, and answer intentions much more remote; as is manifest in the common preparations of steel with tartar or vinegar, and with sulphur.

This way of reasoning on these occasions seems the more just, from considering the texture of those substances, which by a natural preparation are fitted for operation in the minutest part of an animal body; such as those of the aromatic kind, all which, more or less, according to their greater or lesser degree of subtility and smoothness, promote a diaphoresis: for these consist of exquisitely fine salts, covered with a most subtile sulphur, as is demonstrable by chymical analysis; and the common sal volatile oleosum is an admirable contrivance upon the same foundation, where a very volatile animal salt is covered with a most exalted vegetable oil; whereby it is fitted to pass into the minutest fibres, and make, as it were, a part of the animal spirits themselves.

And here it may not be amiss to observe, that all animal salts are very volatile, or easily rendered so; but when bare and naked, just as the fire draws them out, with a mixture also of its own particles in their composition, they are too pungent to be felt without painful sensations; and when softened with a fine portion of somewhat of an opposite texture, which is smooth and yielding, they become most efficacious and safe sudorifics.

On these considerations it likewise ceases to be a wonder, why the subtile salts of cantharides are more sensibly injurious to the bladder than any other parts, and why camphire prevents those injuries; for the exquisite smallness of those spiculæ makes them imperceptible but in the most minute canals, into which the fibres composing the membranes of the bladder are known to be divided; and camphire blunts their irritations, because its extreme subtility enables it to follow them into those meanders, and sheathe their asperities.

To

To this purpoſe is very remarkable what many now commonly practiſe in guarding even mercurials againſt their ſtimulating properties, and ſending them into the fineſt paſſages to operate by fuſion, and the bare force of impulſe: for not only calomel and the mercurius dulcis may be reſtrained from manifeſt operation in the wider paſſages, and the glands about the mouth; but even the mineral turbith, which of itſelf, in a ſmall doſe, will operate powerfully by vomit and ſtool, will not, when mixed with camphor, be ſo much felt in thoſe reſpects, but go into the fartheſt circuit of motion, and promote the cutaneous diſcharge in a more efficacious manner, than any medicine of leſs ſpecific gravity.—In this management, the camphor is to be mixed but a very little while before taking, otherwiſe it has not the effect; which appears to proceed from its great volatility, which makes it in a great meaſure exhale while it ſtands mixed in a medicine.

PURIFICA'TION, in matters of religion, denotes an offering made the prieſts by women riſing out of child-bed, before they be re-admitted into the church.

By the law of Moſes, a woman, after bringing forth a male child, was unclean forty days; after a female, eight days; during which time ſhe was not to touch any thing holy, nor to go near the temple; but to continue within doors, ſeparate from all company and commerce of others.

This term expired, ſhe was to preſent herſelf at the temple, and at the door of the tabernacle to offer a lamb, as a holocauſt, and a pigeon or a turtle, which the prieſt taking, offered to God, and prayed for her, that ſhe might be purified.

This ceremony, which conſiſted of two things, a holocauſt, and a ſacriſice of expiation, was called טהר טהרה purificatio, purgatio.

The holy virgin, though, according to the fathers, exempt from the terms of the law, yet complied therewith; and at the time preſcribed went to the temple, and accompliſhed the law: in commemoration whereof, the church yearly ſolemniſes the feaſt of the Purification of the virgin, on the ſecond of February; called alſo the feaſt of Candlemas.

The feaſt of the PURIFICATION ſeems to be very ancient. It is ordinarily ſaid to have been inſtituted in the time of Juſtinian, in the year 542; and this, on occaſion of a mortality which that year diſpeopled almoſt the whole city of Conſtantinople. Yet there are ſome who imagine it to have been obſerved before, though in another manner, and on a different day, from that fixed by Juſtinian, viz. between the circumciſion and epiphany.—The ſame day is the preſentation of our Saviour in the temple.

PU'RPLE, *purpura* (*Dict.*)—In natural hiſtory, the name of a genus of ſhell-fiſh, the characters of which are theſe: it is a univalve ſhell, jagged and beſet from head to tail with ſpines, tubercles, umbo's, or ſtriæ. The mouth is ſmall and roundiſh: the tail is ſhort, and uſually the baſe runs out into a long beak.

It has been uſual with moſt authors to confound together the genera of the murex and Purpura, and to uſe the words as ſynonymous: but, though there is ſome external reſemblance between many of the ſhells of the two genera, yet they are eaſily diſtinguiſhed by this, and the mouth of the Purpura is leſs long, and is leſs dentated and alated than that of the murex. The body and the head of the ſhells of this genus are not ſo elevated as thoſe of the murex kind, and are not covered with points or buttons at the mouth. If a ſhell is therefore found to have a ſmall, ſmooth, and round mouth, and a body covered with undulated leaves, as it were, like thoſe of ſavory or endive, and ſometimes with long points, and its tail, whether long or ſhort, be hollowed and ſomewhat bent, this may be called a Purpura and not a murex.

The antients diſtinguiſhed three kinds of Purpura, one which had a long and crooked tail, made hollow like a tube or pipe; a ſecond which had either no tail at all, or at the moſt a very ſhort one; and a third which had no ſpiral head, or, as we ſhould expreſs it, no clavicle.

On examining the whole family of the Purpuræ, we may diſtinguiſh four remarkable ſpecific differences among them. The firſt of theſe comprehends thoſe Purpuræ which have the body of the ſhell garniſhed with a ſort of undulated foliage in clouded ridges, and have a ſhort and crooked tail. The ſecond comprehends thoſe which have the body of the ſhell covered with acute points, and have a long tail. The third comprehends thoſe which have as long a tail as the former, but have a ſmooth body, or at the utmoſt have only a few ſlight protuberances and wrinkles on it. And the fourth takes in thoſe which are ſmall, and have an elevated clavicle, a ſhort crooked tail, and the body of which is covered either with ſlender ſpines or hairs. See *Plate* XL. *fig.* 1.

This ſpecies of fiſh, as well as the murex, ſerved among the antients to dye the fine purple colour they were ſo fond of, and ſome of the buccina have been of late found to have the ſame juice. The Purpura and murex are both fiſhed up in great plenty in the gulph of Tarentum; but the ſmall quantity of the coloured juice which each fiſh contains, and the neceſſity of uſing it before the animal dies, makes it impoſſible to bring it to any regular article of traffic. The antients uſed this colour only on cotton and woollen ſtuffs, whereas our cochineal, which was unknown to the antients, ſtrikes equally well on ſilks and ſtuffs.

The Purpura lives on other fiſh. It uſually hides itſelf at a ſmall depth in the ſand, ſometimes even in freſh-water rivers, and as it lies hid, it thruſts up a pointed tongue, which wounds and kills any thing that comes over it. We frequently find ſea-ſhells with round holes bored through them, as regularly as if made with a boring inſtrument: theſe are generally allowed to be made by the tongue of the Purpura, in order to its feeling on the fiſh within.

The Purpura has two horns like that of a ſnail; and Fabius Columna ſays, that they have eyes in theſe, not placed at the ends, as in the ſnail, but in the middle of each horn.

The purple-fiſh is very well known, and has been known alſo in almoſt all times to afford a purple liquor; but, as there has been no method diſcovered of bringing this liquor into uſe in dying, the fiſh has been neglected, and its fluid never attempted to be brought into uſe.

The juice which gives this beautiful purple colour is, while it remains in the body of the animal, and while that is in health, wholly white; but no ſooner is it expoſed to the ſun, than it begins to change colour, and in leſs than five minutes goes through the ſeveral changes of pale green, yellowiſh, and a beautiful emerald green: after this, it becomes of a deeper and duſkier green, then bluiſh, reddiſh, and finally a deep and very beautiful purple. Sometimes the juice is found naturally green in the animal; this is probably from the creature's being in a diſeaſed ſtate: but, when it is naturally thus, it immediately becomes red, and afterwards purple, on being expoſed to the ſun, its ſeveral preceding changes ſeeming to have been made already in the body of the animal.

If a piece of linen be rubbed over with this juice, and part of it expoſed to the ſun, part not, that only will turn red which is ſo expoſed, the other remaining green without any alteration; and it is obſerved, that the ſtronger the ſun ſhines, the quicker the change appears, and probably the colour is in proportion alſo the more beautiful and lively. And it is very remarkable, that if a needle, or any other opake body, be laid upon the linen which is yet green, and is to become red on being expoſed to the ſun; after ſuch an expoſure the whole ſhall be changed red or purple, excepting only that ſmall ſpot which is covered by the needle, which will ſtill remain green.

A plate of glaſs, though it be three inches thick, will not prevent the colour from changing purple by being laid over it; but the thinneſt piece of metal will keep it wholly green. The one being opake, and the other pellucid, are evidently the only reaſons for this difference.

If the coloured linen be ſucceſſively covered by three pieces of paper, the one blacked with ink, the other in its natural ſtate, and the third rubbed over with oil, it will change colour on being expoſed to the ſun in different degrees; and that exactly in proportion to the degree of tranſparence in each of the papers: moſt of all in that which was covered with the oiled paper, ſomething leſs than that covered by the paper in its natural ſtate, and leaſt of all in that which was covered with the blacked paper, as that is leaſt tranſparent.

The common heat of a fire, or that of a red-hot iron, produce no change at all in the colour when green. The vapour of burning ſulphur produces a little; but the green which had not changed to purple by theſe experiments, immediately changed to it on being expoſed to the rays of the ſun.

Theſe experiments were all made in the months of January and February, by Mr. Du Hamel, in Provence; and, the ſun having power to change the colour ſo ſpeedily there in theſe cold months, probably in a warmer climate or ſeaſon the air would have been ſufficient for the purpoſe, without the open ſun; ſince it ſeems, from experiment, that both the ſolar rays, and the light alone in a cloudy day, can act upon this colour. The light and heat of the ſun both act on this colour: light is always ſufficient to produce the effect; but the heat may eaſily be too great, or too little, and, to do the whole in perfection, it muſt be at a certain middle degree.

This beautiful purple, if it can ever be brought into uſe in dying, will have one very great advantage from its viſcoſity. The pieces of cloth that had been ſtained by it retained their colour, in ſpite of ſeveral boilings in different liquors, which Mr. Du Hamel made them paſs through; and the colour, on examination, was found not to be ſuperficial, but penetrated the whole body of the ſtuff which was tinged by it. There are many inconveniencies which muſt naturally attend the uſe of this ſubſtance as a dye, but they may, perhaps, all be got over by care and application. It is very certain, that it is of too viſcid a nature eaſily to penetrate many ſubſtances; but it is alſo certain, that this might be obviated by diſſolving it in ſome proper liquor. It appears very plainly, that the ancients had a method of thus diſſolving their purple; but we neither know what was their purple, nor what was its diſſolvent; nor, which would be of much more conſequence to us at preſent, what is the proper diſſolvent for our own. *Mem. Acad. Scien. Par.* 1736.

PU'RPURA. See PURPLE.

PUS (*Dict.*) — A very ſmall portion of Pus, abſorbed into the blood-veſſels, raiſes a putrid fever as certainly as yeſt does a fermentation in wort. This fever is not owing to its ſtimulating the ſolids to quicker and greater vibrations, but to its increasing the inteſtine motion and accelerating the animal proceſs, haſtening the change of the juices to that ſubtile acrid ſtate which renders them unfit to be retained in the body, and diſpoſes them to run off in colliquative evacuations, ſuch as ſweating and purging, which conſtantly attend theſe putrid or hectic fevers, or riſing to internal ulcers. *Med. Eſſ. Edinb.*

When Pus is laudable and mild, it is one of the moſt powerful digeſters, ſuppurants, and incarners; when it ſtagnates too long, or when the liquors and veſſels are faulty, it may become an acrid, ſtimulating, eroding ſanies; when abſorbed into the blood, it affects all the liquors, ſtimulates the veſſels, and is capable of producing violent diſorders.

PU'SHERS, a name given by thoſe who breed ſinging birds to Canary birds when new flown.

PUSILLA'TUM, a word uſed by ſome medical writers to expreſs a coarſe powder, or any medicinal ſubſtance, beat into ſmall pieces for infuſion, or the like purpoſes.

PU'SU, in botany, the name of a famous plant, growing in China, and greatly eſteemed there. This and the ginſeng theſe people a long time kept to themſelves; but at length it was diſcovered, that the one was eſteemed a certain prolonger of life, and the other a preſervative againſt all diſeaſes.

They, in their manner of ſpeaking, ſay, that the Puſu gives immortality: we have not been ſo happy to obtain any of this famous plant for the trial, but the ginſeng having been brought over, and found not to poſſeſs thoſe great virtues they aſcribe to it, and the people in China, who are poſſeſſed of the Puſu, dying, as well as thoſe who have it not, we find, that the virtues of both are ſo greatly exaggerated by the eaſtern dialect that there is not much to be expected from them. *Reid's Experiments.*

PUTO'RIUS, in zoology, the name by which authors call the pole-cat; a creature of the weaſel kind, but larger than the common weaſel, and of a blackiſh colour; and remarkable for its ſtinking ſmell.

The whole circumference of the face is white; at the extremity of the angles of the mouth there begins a broad line of a yellowiſh hue, which ſurrounds the head, and is white in ſeveral parts. Its long hairs are black, its ſhort ones yellowiſh; and the throat, the feet, and the tail, are blacker than any other part of the body. The upper jaws ſtand out a little beyond the lower. The ears are broad and ſhort, and are fringed, as it were, with white. Its ſtink is occaſioned by an extremely fœtid matter, ſecreted by two glands, which it has in common with all the creatures of this kind, within the anus. It feeds on fleſh, conſequently ſtealing hens and other poultry, and ſometimes contenting itſelf with their eggs. *Ray's Syn. Quad.*

PUTREFA'CTION (*Dict.*)—In Putrefaction, there is a great inteſtine motion; when carried to a height, and, when the putrefying ſubſtance is much compreſſed, it is accompanied with heat and ſmoke, and ſometimes flame. Air is neceſſary to it, and the viſible texture of the putrefying maſs is changed. Putrefaction is the moſt ſubtle of diſſolvents. It effectually diſjoins and ſeparates all the component parts of putrifying bodies, except the ſea-ſalt. In this powerful ſolution, the inteſtine action of the minute particles of bodies creates, collects, or is by ſome way or other the cauſe and means of heat.

The fluids of the human body are much diſpoſed to Putrefaction, and out of the body become highly putrid, even in cool air, and without any ſtirring or agitation; and our blood and ſome of our juices, out of the circulation, but within the body, change to putrid matter.

The changes, wrought in bodies by Putrefaction, are no where more remarkable than in the Putrefaction of vegetable ſubſtances, which by means of this change are brought nearly into the condition and nature of animal ſubſtances.

To prove this by an eaſy experiment, take a large quantity of cabbage-leaves, and preſs them hard down with weights in an open tub, with holes bored in its ſide; ſet them in a warm place, and the leaves will ſoon conceive a heat in the middle, and at length the whole, or nearly the whole, will be converted into a ſoft pappy ſubſtance. This ſubſtance, diſtilled in a glaſs retort, yields the ſame kind of volatile ſalt and oil as animal ſubſtances do: neither is it particular to this plant, but all equally do this; the acid and the alcaline, the ſweet and the bitter, the aſtringent and emollient. Hence, we may learn, how it is that nature, in our bodies, converts vegetable into animal ſubſtances; and it is very remarkable, that not a grain of fixed ſalt can be procured from this putrefied maſs. *Shaw's Lect.*

It is an obſervation of lord Bacon, that an enquiry into the means of preventing or ſtaying Putrefaction is of excellent uſe in phyſic. Dr. Pringle has made a great many curious experiments and remarks on this ſubject, which are publiſhed by way of appendix to his Obſervations on the Diſeaſes of the Army.

Putrefaction is one of the inſtruments of nature, by which many great changes are brought about. With regard to medicine, we know that neither animal nor vegetable ſubſtances can become aliment, without undergoing ſome degree of Putrefaction. The criſis of fevers ſeems to depend upon it; and even animal heat, according to Dr. Stevenſon, does the ſame.

Now, that the concoction of the humours is nothing elſe but Putrefaction, ſeems probable from hence, that, whenever they are in that ſtate, they are always more fluid, and fitter to paſs through the ſmaller veſſels, where they ſtagnated before. Again, the offenſiveneſs of the ſweats, or other excretions conſequent on a criſis, is likewiſe a ſure ſign of a high degree of corruption. The time of reſolution or Putrefaction depends on the degree of the habit of the patient, and on the part obſtructed. Reſolution is the Putrefaction of the impacted humour only, but ſuppuration implies a corruption of the veſſels alſo. This manner of ſpeaking, indeed, has been diſuſed, from the prejudice that nothing was putrid but what was offenſively ſo; whereas, in fact, every fibre becoming more tender, and humour thinner, may be conſidered as putrid in ſome degree, whether the change tends to the better health, or to the deſtruction of the perſon, or whether it becomes grateful or offenſive to the ſenſes. *Pringle, Obſerv. on Diſeaſ. of the Army.*

Mr. Boyle has uſed the words fermentation and Putrefaction of the blood promiſcuouſly, in his treatiſe on the human blood. Stahl, and other celebrated chemiſts, likewiſe uſe the terms putrid ferment.

Putrefaction is always found to generate air. Hence, though fleſh, as well as blood, be ſpecially heavier than water, yet dead bodies are found to float, after lying ſome time at the bottom, from air generated in the bowels by Putrefaction. Now, as it has been found by experiments, that the blood and other animal ſubſtances begin to emit air, before they are ſo far corrupted, as the ſame frequently are in putrid diſeaſes, it is probable that ſeveral of the ſymptoms in deep ſurfeits may be owing to the action of the confined air.

As all the humours of the animal bodies become thinner by Putrefaction, ſo the ſolid or fibrous parts are thereby relaxed, or rendered more tender. And hence the extraordinary bulk of the heart, liver, and ſpleen, incident to perſons labouring under putrid diſeaſes, may be accounted for. It is remarkable, that in diſſections of people who die of the plague, the heart is always found of an uncommon bigneſs; and, as to the ſcurvy, the liver and ſpleen are ſometimes inlarged to ſuch a degree that the tumor may be ſeen outwardly. *Id. ibid.*

It being a received opinion, that bodies become highly alkaline by Putrefaction, the doctor made the following experiments, in order to diſcover how far this might be true.

The ſerum of human blood putrefied, made, with a ſolution of ſublimate, firſt, a turbid mixture, and afterwards a precipitation; which is indeed one of the teſts of an alkali, but not to be admitted here, ſince the ſame thing was done with the recent urine of a perſon in perfect health, which is never accounted alkaline. The ſame ſerum did not tinge the ſyrup of violets green, and made no efferveſcence when the ſpirit of vitriol was poured upon it. The experiment was twice made upon portions of different ſerums, both highly putrid; and once on water, in which corrupted fleſh had been ſome time infuſed; and the moſt that could be found was, that, a reddiſh caſt having been previouſly given to the ſyrup with an acid, this colour was rendered fainter, but not deſtroyed by the putrid humours. And, as to efferveſcence, the ſpirit of vitriol being dropped into thoſe liquors unmixed, and alſo diluted with water, the mixture was quiet, and only a few air-bubbles appeared on ſhaking the glaſſes.

Upon the whole, though there were ſome marks of a latent alkali in the putrid ſerum, they were ſo very faint, that a quantity of water, equal to that of the putrid liquors, mixed with only one drop of ſpirit of hartſhorn, being put to the ſame trial, ſhewed more of an alkaline nature, than any of the other.

It has alſo been a maxim, that all animal ſubſtances, after Putrefaction, being diſtilled, ſend forth a great quantity of volatile ſalt in the firſt water; but Mr. Boyle found, that this held good only in urine; and that, in the diſtillation of the ſerum of human blood putrefied, the liquor which came over firſt had little ſtrength, either as to its ſmell or taſte, and did not at firſt efferveſce with an acid. And here it may be obſerved, that the chemiſts have generally applied theſe particles, which they diſcovered in urine, to all the humours indifferently; whereas, in fact, there is a great diverſity: for ſome animal ſubſtances, ſuch as urine, the bile, and the craſſamentum of the blood, ſoon putrefy; the ſerum, the ſaliva, and the white of an egg, ſlowly. Yet, thoſe that ſooneſt corrupt, do not always arrive at the higheſt degree of Putrefaction: thus, the bile is ſooneſt corrupted, but the rankneſs of it is not to be compared to that of fleſh; and the white of an egg is not only much leſs diſpoſed to putrefy than the yolk, but, when corrupted, yields a different and leſs offenſive ſmell.

Doctor Pringle farther obſerves, that it ſeems peculiar to ſtale urine to contain an alkaline ſalt, which, without diſtillation, makes a ſtrong efferveſcence with acids. Whereas moſt other animal humours putrefied, though of a moſt intolerable fetor, yet contain leſs volatile ſalt, leſs extricable, and then not efferveſcing with acids. But what makes the difference between ſtale urine and other putrid ſubſtances ſtill more ſpecific, is its inoffenſiveneſs with regard to health; whilſt the ſteams of moſt other corrupted bodies are often the cauſe of putrid and malignant diſeaſes. So far then from dreading the volatile alcali as the deleterious part of corrupted bodies, it ſhould rather ſeem to be a corrector of Putrefaction. *Pringle's Obſerv. on the Diſ. of the Army.*

But

But ſtill there remains a prejudice, as if theſe ſalts, being the produce of corruption, ſhould therefore haſten Putrefaction; and not only in diſtempers where they are unwarily taken, but alſo in experiments out of the body. As to the effects ariſing from the internal uſe of them, little can be ſaid, unleſs the kind of diſeaſe were preciſely ſtated: for ſuppoſing theſe ſalts were by nature diſpoſed to promote Putrefaction; yet, if that is already begun, from a languor of circulation, and obſtruction, then may the volatiles, by their ſtimulating and aperient qualities, be the means of ſtopping its progreſs; and, on the other hand, though they were really antiſeptic, yet, if the humours are diſpoſed to corrupt, from exceſs of heat or motion, theſe very ſalts, by adding to the cauſe, may augment the diſeaſe. So that, upon the whole, it ſeems to be the faireſt criterion of the true nature of theſe volatiles, to enquire whether they accelerate or retard Putrefaction out of the body?

In order to decide this queſtion, repeated experiments were made, by joining both the ſpirit and the ſalt of hartſhorn to various animal ſubſtances; and it was conſtantly found, that, ſo far from promoting Putrefaction, they evidently hindered it, even more powerfully than common ſea-ſalt. Hence, the doctor thinks it probable, that the ſame, taken by way of medicine, will likewiſe prove antiſeptic; or, at leaſt, that we cannot juſtly ſuppoſe them corrupters of the humours, more than fermented ſpirits or ſea-ſalt.

With regard to the Putrefaction of dead bodies, it is found that ſome parts corrupt much ſooner than others. Thus, as the abdominal viſcera and muſcles corrupt the ſooneſt, it is a rule with anatomiſts, to begin their diſſections and demonſtrations with thoſe parts, the quick Putrefaction of which may be aſcribed to the putrid ſteams of the fæces. Next to the abdominal viſcera and adjacent parts, the lungs are commonly ſooneſt tainted, either from the air ſtagnating in the veſiculæ bronchiales, or from ſome remains of perſpirable matter, that, by acting as a ferment, may haſten the Putrefaction. *Pringle's Obſerv. on Diſeaſes of the Army.*

It is obſervable, that the Putrefaction of meat, and other ſubſtances, advances quicker in a confined than free air; for, as the moſt putrid parts are alſo the moſt fugitive, they inceſſantly iſſue from a corruptible ſubſtance, and diſperſe with the wind; but, in a ſtagnation of air, they remain about the body, and, in the nature of a ferment, excite its corruption.

Putrefaction is one cauſe of bilious and intermitting fevers, the dyſentery, malignant or peſtilential fevers, the ſcurvy, lepra Arabum, &c.

PUTREFACTION *of water*. It is ſaid to be the peculiar quality of the Thames water, that it will ſtink, and yet be wholeſome; and, after this, will recover itſelf again. Many ſailors have been obliged to drink it ſtinking, ſo that they held their noſes while they poured it down their throats, yet no ſickneſs enſued from it. It generates a ſort of ſpirit alſo in this ſtinking ſtate, which will take fire at the approach of a lighted candle, as if ſpirit of wine were touched by the ſame.

PU'TTOCKS, or PUTTOCK-*ſhrouds*, in a ſhip, are ſmall ſhrouds which go from the ſhrouds of the main-maſt, fore-maſt, and mizen-maſt, to the top-maſt ſhrouds; and, if there be any top-gallant maſts, there are Puttocks to go from the top-maſt ſhrouds into theſe. Theſe Puttocks are at the bottom ſeized to a ſtaff, or to ſome rope which is ſeized to a plate of iron, or to a dead-man's eye, to which the lanniards of the fore-maſt ſhrouds do come.

PY'CNI, [illegible], in the ancient muſic, was uſed for ſuch ſounds or chords of a tetrachord as might enter the ſpiſſum, or [illegible].

PYGA'RGUS, in natural hiſtory, a ſpecies of eagle, called alſo by ſome authors albicilla and iliannularia.

It is a large and fierce bird, of the ſize of a common turkey. Its beak is yellow, and covered with a yellow membrane at its baſe. It has large hazel-coloured eyes. Its feet are yellow, and its claws extremely ſtrong and ſharp. The head is white, and there are no feathers, but ſome fine hairs between the eyes and noſtrils. The upper part of the neck is of a reddiſh brown, and the rump black; all the body beſides this is of an obſcure ruſt colour, and its wings are partly black, partly grey. Its tail is long, and the upper part of it is white, and the reſt black. It is from this white part that it has its name albicilla.

Authors who have written on this ſubject, ſeem not all agreed to call the ſame bird by this name. The Pygargus of Aldrovand ſeems different from this, and the Pygargus prior of Bellonius ſeems no other than the male of that kind of hawk called in Engliſh the hen-harrier. *Willughby's Ornithol.*

PY'KER, or *Pycar*, in our law books, a ſmall ſhip or herring-boat.

PY'RAMID (*Dict.*)—Under this article we have obſerved that every Pyramid is a third part of a priſm, which hath the ſame baſe and height.

That is, the ſolid content of the Pyramid A B D (*plate* XLIV. *fig.* 21, in the Dictionary) is one third part of its circumſcribing priſm A B E F.

For every Pyramid which has a ſquare baſe (ſuch as A *a* B in the figure) is conſtituted of an infinite ſeries of ſquares, whoſe ſides or roots are continually increaſing in arithmetical progreſſion, beginning at the vertex or point D, its baſe A *a* B being the greateſt term, and its perpendicular height C D is the number of all the terms; but, the laſt term multiplied into the number of terms, the product will be triple the ſum of all the ſeries.

From hence it will be eaſy to conceive, that every Pyramid is a third of its circumſcribing Priſm, that is, of a priſm of equal baſe and altitude, of what form ſoever its baſe is of, viz. whether it be ſquare, triangular, pentangular, &c.

You may very eaſily prove a triangular Pyramid to be a third part of a priſm of equal baſe and altitude, by cutting a triangular priſm of cork, and then cut that priſm into three Pyramids, by cutting it diagonally.

PYRE'THRUM, in the materia medica, a root of which the druggiſts ſell us indiſcriminately two kinds; the one the root of a corymbiferous plant, called by authors Pyrethrum flore bellidis, or the daiſy-flowered pellitory of Spain; the other, the Pyrethrum cumbelliferum, or umbelliferous pellitory: and it is a diſpute among the learned, which of the two is the genuine and proper kind; the deſcription left us of it by Dioſcorides, as it is differently written, ſerving as well to prove the one ſo as the other.

The roots of the daiſy-flowered pellitory are what we moſt frequently meet with. They are of three or four inches long, of the thickneſs of one's little finger, greyiſh and wrinkled without, and whitiſh within, and of an acid and burning taſte. Thoſe of the umbelliferous pellitory are of the ſame length, but ſomewhat thinner, of a browniſh grey without, and white within, and are furniſhed with a ſort of beard at top, ſomewhat like the roots of the meum. It is of an acrid taſte, and much reſembles the other in its virtues. They are both uſed in the tooth-ach, and preſcribed by ſome in diſeaſes of the head and nerves, and are found to be diuretic and violently ſudorific; but they are very ſeldom given.

PY'RGUS, among the Romans, a dice-box of the ſhape of a modius, open above, and having a great many ſhelves or partitions within; ſo that, when the dice were thrown into it out of the fritillum, they were thereby overturned many times before they could reach the bottom, in which there was an opening for them to fall through upon the table. *Pitiſc. in voc.*

PYRICU'BIUM, in natural hiſtory, the name of a genus of foſſil bodies, uſually comprehended, with many others of a very different figure and ſtructure, under the general name pyrites. See *plate* XL. *fig.* 2.

The diſtinguiſhing characters of the Pyricubia are theſe: they are compound, inflammable, metallic bodies, of a cubic figure, or reſembling a die, being compoſed of ſix ſides.

Of this genus there are only two known ſpecies: Firſt, the great Pyricubium, of a foliaceous ſtructure; and, ſecondly, the ſmaller ſolid Pyricubium.

The firſt of theſe is a very elegant foſſil, and is ſo regularly ſhaped, and ſo highly poliſhed by nature, that it has been often ſuppoſed to be wrought by art. It is but moderately hard, but is very heavy, and is of a foliaceous ſtructure. It is exactly of the figure of a die, being compoſed of ſix regular ſides, placed at right angles; but, though ever thus regular in ſhape, it is not at all ſo in ſize: the moſt common ſpecimens of it are about a third of an inch in diameter; but it is found much larger, even to three inches, and ſo ſmall as to the tenth of an inch. It is perfectly poliſhed and ſmooth on all its ſurfaces, and is of a very beautiful whitiſh green, with a faint admixture of yellow. It is found in the German and Hungarian mines, and in the Eaſt-Indies.

The ſecond ſort, or the ſmall ſolid Pyricubium, is a foſſil of much leſs beauty, though equally regular in its ſhape and appearance. It is very heavy, and extremely firm and hard, and is not of a foliaceous or flaky ſtructure, but of one regular and uniform maſs, and, when broken, appears very bright and gloſſy. It is ever found in the regular form of a cube, or regular ſolid body, made up of ſix flat ſides placed at right angles. Its uſual ſize is about the eighth of an inch diameter, but it is found ſmaller than a pin's head, and ſometimes ſo large as to be near an inch. It is perfectly ſmooth on all its ſurfaces, and is naturally of a pale yellowiſh green, and as bright on the outſide as within; but very often it is found in a ferrugineous or duſky ſurface, owing to a ſort of ruſting, which is an accident to which the ſeveral ſpecies of naturally bright pyritæ are moſt of them alſo ſubject.

It is very common in Germany and Italy, and in ſome parts of America, as alſo in our own country. With us it is commonly found immerſed in ſlate, ſuch as we cover houſes with; but, in Germany and other places, it is uſually found looſe among the earth of mountains. With us it is uſually of a bright ſurface, in Germany it is more frequently duſky. *Hill's Hiſt. of Foſſ.*

PYRI'PLACIS, in natural hiſtory, the name of a genus of pyritæ, the characters of which are theſe: they are compound, inflammable, metallic bodies, found in looſe detached maſſes of a ſimple and uniform, not ſtriated, internal ſtructure, and are covered with an inveſtient coat or cruſt.

PYRIPOLYGO'NIUM, in natural hiſtory, the name of a genus of foſſils, the characters of which are, that they are compound metallic bodies, of a regular figure, conſiſting of twelve plants.

There is only one known ſpecies of this genus, though ſubject to great varieties in its appearance; and this has been by authors hitherto confounded, with many other bodies of a very different

different nature and figure, under the general name pyrites. The Pyripolygonium, when perfect, is an extremely elegant and beautiful fossil; but this is a state it is very rarely found in. It is moderately firm, of a compact texture, and very heavy; though its natural figure be a regular body, composed of twelve planes, yet it is subject to great imperfections and irregularities. It often seemsto want one or more of its sides, and not unfrequently, from the accident of breaking of some of its angles, to have more than its number; and very often has a great many other smaller and less perfect bodies of its own kind, growing to its larger and less perfect specimens. It is found, from the twentieth part of an inch, to four inches in diameter; but its most common size is about a third of an inch. It is naturally of a polished and shining surface, and of a pale whitish yellow; but sometimes it is brownish, or of an iron colour.

PYRITES (*Dict.*) — The principal contents of Pyritæ may be in general guessed at from their colour. The white Pyrites usually contains arsenic, the yellowish contains sulphur and iron, and the fully yellow sulphur and copper. The colours, therefore, make a very essential mark for the distinction of the several kinds of this fossil. The yellowish Pyrites, that is, such as contains iron and sulphur, is found in the strata of several kinds of stone, in clay, and in the earth lying over the mines of several metals. The white or arsenic Pyrites, and the fully yellow, are less common, but are usually met with about mines. *Agricola de Metall.*

It is a matter of great difficulty to ascertain the time of the formation of fossils. Many of them seem to have remained in their present state, unaltered, from the beginning of the world; but many have also been formed in later times, and continue to be formed to this day. Of the number of these last the stalactitæ, or stony icicles, hanging down from the roofs of grotto's, are known to be; and it is equally certain, that the pyritæ also are so formed, for many of the stalactitæ, in the caves dug by the German miners, are found to be coated over in several parts with Pyritæ; and, even in our own kingdom, pieces of wood buried in clay that contains Pyrites, such as is commonly dug to make tiles, if taken up again after a number of years, are always found impregnated with this substance, forming veins in it, and sometimes nodules on its surface. *Act. Erudit. Ann.* 1726.

The Pyritæ affixed to stalactitæ are finer than the other kinds, and it appears very evident to such as have thoroughly considered the process of nature in them, that they are not formed of particles brought together by water, in the manner of the Pyrites, in wood buried under clay, or in the manner of these stalactitæ themselves; but are composed of infinitely minute particles, brought together by their mutual attractions on a proper basis, and which had been before floating in the air.

The ancients in general supposed that copper was contained in the Pyrites; but they had no opinion that iron was a part of it, though it is certain that iron is the basis of almost all of them, and copper has a part only in a very few: but this was the effect of judging from appearances, instead of having recourse to experiments. Our own Lister has the honour of being the first author who has treated properly of them, and found out their true and general basis to be iron; but he carries it too far when he supposes them to be all properly iron ores: for this is not the case, many of them, which contain no other metal besides iron, yet, holding it in small quantities, and in such a combination of other principles, that it is scarce extricable from them, and some kinds contain no iron at all. *Lister de Font. Medic. Angliæ.*

Berger, who has written on the Caroline baths, has taken up the subject, and, improving upon Lister's plan, has given a much more just account of them. He allows that iron seems the basis of great numbers of the Pyritæ, and that this is evident from the observation, that the remaining matter of many of them, after burning away the sulphur, is found to be attracted by the magnet; but he observes also, that in many copper is mixed with the iron, and that, though iron is in general found in even those kinds which give the most obvious proofs of copper, yet there are some in which there can no iron be found.

This author observes also, that, besides the metalline particles, whether iron or copper, there is also contained in the pyritæ an unmetallic earth, which is in the composition of this stone most equally mixed and perfectly blended with the particles of these metals, and with those of the salts and sulphurs contained also in the mass. Sulphur also he acknowledges to make a great part of the Pyritæ, particularly of all the yellowish and full yellow kinds. The white or silvery Pyrites contains less sulphur than any of the others, and yet the yellow or venereal Pyrites, though it contains much arsenic, yet does not fail to contain sulphur also in considerable quantities. *Berger de Font. Carolin.*

The mention of gold and silver in the Pyrites is very common among authors, but the colour of these stones seems principally to have given ground for that opinion. In reality these metals are very seldom found naturally making parts of the Pyrites, and, when they are, it is only in a very inconsiderable quantity. But, in those specimens found about the mines of gold and silver, the particles of those metals assembled into visible masses are sometimes found unbedded in lumps of the Pyrites; and such pieces of this stone may well then be said to contain those precious metals. The occasion of this accident, however, is no more than this, that the Pyrites is formed in mines and other places at this day, which is plain from its being in some places found adhering to the sides of the stalactitæ, as has already been mentioned; and in like manner it might adhere to particles of gold and silver, and thereby give ground to the supposition of their being parts of it.

The common Pyritæ of our clay-pits and sea-coasts are used in the making of copperas and vitriol; but among these there is found a very great difference, some of them turning themselves very easily to vitriol, when only exposed to moist air; others doing it with more difficulty; and some not at all, though exposed many years. Some also yield all their vitriol at once, on pouring warm water on them; while others must lie exposed to the air at several different times, and roasted in the mean while, in order to obtain it. The settled observations on this subject, as collected from experiments, are these: No Pyrites which contains any copper, or any arsenic, will of itself turn into vitriol, but requires a previous roasting.

The sulphureous iron Pyrites, void of copper or arsenic, all turn to vitriol on being only exposed to the air; and that the sooner or later, as they are more or less of a compact substance. The fibrous or radiated Pyritæ are usually of this kind; but this is no general rule, for there are some radiated ones which remain whole years unaltered in the air.

Copper and arsenic always resist the shooting of the salts of the Pyrites, or its turning to vitriol; but these are not the only agents that resist this change, for in some merely ferreous and sulphureous Pyritæ the change is not made but with much time and difficulty. *Henkell, Pyritol.*

It is remarkable also, that vitriol is found in some Pyritæ, if water be poured upon them immediately after the roasting; while others will not yield any till they have been afterwards exposed to the air. It even seems, that we are to look into the air for the cause of the appearance of vitriol in the copperas stones. This it may greatly assist in effecting, as it carries a quantity of moist vapours in it: for it is well known, that the acid of sulphur has not the power to resolve iron into the form of a salt without the addition of water; nay, oil of vitriol, or of sulphur, being moderately concentrated, though it be then diluted with much more water than it is united with, while yet in sulphur, does not even dissolve filings of iron, unless there be four times or six times as much water poured to it. Water alone, however, though a great and necessary agent, cannot be supposed to effect the whole change; for, though there are some of the Pyritæ that yield their vitriol by means of it, yet there are others that do not; and some Pyritæ are presently turned into vitriol, when exposed to the air, which had before remained for many years under water unaltered. Of this kind there are many on the shores of the sea in most parts of Europe. In England particularly we have them in great plenty in Sheppey island in Kent. These Pyritæ will long resist the change into vitriol, when in the air, and yet they evidently contain no copper nor arsenic.

There is also a kind very common on the shores, which resembles wood in texture and appearance; and has probably once been wood, but has now its pores filled with the Pyrites: of these many lie buried a foot or more deep in the sand under the sea water; and in that state they never shoot into vitriol, but are of a firm texture and considerable hardness, and, when broken, look very bright within, and have no taste of vitriol, nor give any mark that they contain any: yet these, if they are taken up and exposed to the air for a fortnight, lose all their brightness and their hardness, and, mouldering to pieces, become so rich in vitriol, that it forms itself into regular crystals on their surfaces. Now, if moisture alone was sufficient to produce this effect, there is no reason why they should not have been resolved into vitriol under a very moist sand. The great cause we are able to assign, appears to be the vague acid, so common in the fossil world, and filling also the region of air; but an ingenious reasoner will still own, that, though this may do much, yet there must be some other cause, yet undiscovered, for the production of vitriol in these fossils; since this, as well as the moisture of the air, ought to act more equally than we find by experience it does on these stones, if all were owing to it. *Henkell, Pyritol.*

In the exposing these copperas stones to the air, if it be a moist season, no farther care need be taken of them than the piling them up in a heap; but moistening them now and then is a necessary circumstance in dry seasons, and in this case the water should be sprinkled on them in small quantities at a time, and the heaps now and then turned and new made. Much depends on this management, the same quantity of stones yielding twice as much copperas, with proper care, as they would without it.

When the matter of the Pyrites is mixed with the lead ores, the method of separating the metal by assaying is this: roast two centners of the ore, as in the usual method, and keep a stronger fire than when the ore is pure. The Pyrites, especially when it is merely iron, hinders an ore from easily growing clammy, or turning into large lumps, or entirely melting. When the ore is sufficiently washed, let it cool, beat it to powder,

der, and repeat the roasting to a third fire, till, when it is red-hot in the fire, there is no smell of sulphur: then mix the ore with six centners of black flux, and two of sandiver, and finish the work in the common way, only making the fire greater, and continuing it longer, towards the end of the operation. *Cramer's Art.*

PYRITRICHIPHY'LLUM, in natural history, the name of a genus of fossils of the class of the Pyritæ, the characters of which are these: they are compound, inflammable, metallic bodies, found in loose masses not of any regularly angular figure, and of a striated texture, with foliaceous ends to the striæ, appearing on the surface or within the mass. They are common in several parts of England.

PYRITRI'CHUM, in natural history, the name of a genus of pyritæ, the characters of which are these: they are compound, inflammable, metallic fossils, always found in detached masses of no regularly angular figure, and of a simply striated internal structure.

PY'RMONT-*waters.* — The country, all about where these springs are, abounds with materials which give virtue to the waters; and the quarries of stone, wherever they are dug, send up spirituous and martial exhalations as well as the springs that run from them, and the water among them has in general a vitriolic taste. Iron is found all about the place also, under the appearance of a yellowish earth or ochre, which contains so much of that metal, that it may be worked as an ore of it to great advantage. Ferruginous stones are also found in great abundance in the neighbourhood of the place; these may be also worked as iron ores, and the selenites is found in the strata of earth that make up the hills thereabouts, in great abundance, and in beautiful perfection.

The waters themselves, though they shew evident marks of an alcali, yet, have also an acid principle in them, of the nature of the common acid of sulphur, except in this, that in these waters the acid carries with it a subtile mineral oil or fattiness; and, mixing with the common alcali salt, which is found in all mineral waters, these together form a neutral salt: but, as in the composition of this salt there is much more alcali than acid, it is necessary that the water should shew alcaline rather than acid qualities. The analysis shews also, that the waters contain a stony matter embodied in them, which is pure, insipid, colourless, tasteless, and seems to be in nothing different from common crystal. The earth about the springs contains also a great number of lumps of a clayey matter, of the size of a walnut, and of a yellowish colour; in all of which, when broken, there is found pure crystal in small shoots, sometimes in its own regular figure, and sometimes irregular and mutilated.

A water, containing these principles thus combined, cannot but possess those virtues we find so eminent in this; these are the opening obstructions, correcting the sharpness of the humours, and restoring the solids to their due state. *Seipp. Nova Descrip. Font. Pyrm.*

The history of these waters is accurately given by Hoffman in his Observations on them, both in their natural state and in mixture with other bodies.

He first observes, that they contain a volatile and subtile principle, greatly more penetrating and strong, as well as in larger quantities, than any other mineral water, but that this is not to be expected in them any where but upon the spot, for those who transport them to other places are constrained to let a part of this fly off to preserve the rest. If either glass or earthen vessels be filled at the spring, and immediately corked and fastened down, the consequence is, that they will burst on the first motion or heat of the weather. They are, therefore, forced to fill them only in part at first, and let them stand a while for this subtile spirit to exhale, and then, a while after the filling them up, to cork and fit them for carriage.

Secondly, if they are drank upon the spot in a morning on an empty stomach, they affect the nose with a pungent tingling, and disturb the head for many hours afterwards.

Thirdly, if they are taken at the spring, they purge but very little, but, if taken in another place, after transportation, they purge considerably more, and render the stools black. It is observable also, that, if they are left in an open vessel a few days, their virtue exhales, and they no longer purge or render the stools black.

Fourthly, if tea leaves, balaustine flowers, or galls, are put into this water, they first change it to a blue, from that to a purple, and finally to a black. This is a ready proof, that black is only a deep purple, and purple only a deep blue: a little spirit of vitriol added to this liquor destroys all the colour, and renders it limpid as before.

Fifthly, if any acid be mixed with Pyrmont-water, there is raised an effervescence, and bubbles of air are carried up in great quantities; and this whether the stronger acids, such as spirit of vitriol, or aqua-fortis, be used; or the weaker, as vinegar, lemon juice, or Rhenish wine.

Sixthly, if an alcaline liquor be added, whether it be volatile, as the spirit of sal armoniac, or fixed, as the oil of tartar, there is no ebullition raised, but the liquor becomes turbid and milky. If spirit of vitriol be afterwards added to this, to saturate the additional alcali, the liquor becomes limpid again.

Seventhly, cow's milk mixed in equal quantity with Pyrmont-water does not coagulate, but, on the contrary, becomes thinner than before, and is preserved from turning sowre so soon as it otherwise would in hot weather. This is a proof that there is no predominating acid in these waters.

Eighthly, if syrup of violets be added to this water, it turns it to a beautiful green. This is a proof of the alcaline nature of these waters; and it is farther proved by adding spirit of vitriol, or any other acid, to this green liquor, which on that becomes limpid again.

Ninthly, four pints of this water, evaporated over a gentle fire, yield no more than two scruples of a dry residuum. Oil of vitriol being poured on this, an effervescence arises, and with it an acrid and pungent vapour, like that produced by mixing oil of vitriol and common salt. If spirit of vitriol be used instead of the oil, the effervescence is in a less degree, and the salt is in part changed to a bitter saline mass, the remainder separated from which proves to be a calcarious earth no longer fermenting with the spirit of vitriol.

Tenthly, if a quantity of Pyrmont-water be exposed twenty-four hours to the open air in a bason, it will at the end be found to have lost all its virtues, tasting wholly insipid, and being turbid instead of the fine clearness it had before, and a yellow ochreous earth is precipitated to the bottom; after this, the liquor will no longer shew any of those qualities which were before its distinguishing characters; it will no longer ferment with acids, nor turn black with galls, nor green with syrup of violets.

It appears from the whole, that the Pyrmont-waters possess a pure, extremely penetrating, and elastic mineral spirit, and that in a very large proportion, and to this their virtues are principally to be attributed. This mineral spirit, while it remains engaged in a calcarious earth, imitates the properties of an alcaline substance; and, when joined with a subtile martial earth, it emulates the properties of vitriol, giving the stools a black colour, and turning a tincture of galls into ink: and, while this remains in the water in those forms of an alcaline or vitriolic principle of so great subtility, it cannot but give them very great virtues in strengthening the tone of the viscera, opening obstructions, and stimulating in a proper manner the excretory ducts, so as to make them duly perform their office; but as soon as by the standing of the water open, or by any other accident, this subtile element is evaporated, all the virtues of the water must be gone with it.

The great quantity of this powerful spirit, contained in the waters, makes them more fit for the robust and strong constitutions, when depraved by illness, than for the weak and tender ones; but even the tenderest people may take them, only observing to take but a small dose, or to dilute them with an equal quantity of common water immediately before the taking them.

Hoffman also recommends the Pyrmont-water mixed with equal quantities of milk, on his own experience, in scorbutic and gouty cases. *Hoffm. Opera.*

Near the famous well at Pyrmont, is a stone quarry under ground, from some parts of which a sulphureous steam comes out, which commonly rises to a small height. Animals held in this steam are soon suffocated, but recover, if quickly taken out. When a man stands in this steam, but with his head over it, it proves an excellent sudorific. Dr. Seip proposes to perform cures in several diseases with it.

Imitation of PYRMONT-*water.* — This medicinal water may be imitated very nicely by art in the following manner: take a quart of the purest and lightest water, add to it thirty drops of a strong solution of iron made in spirit of salt, a drachm of oil of tartar per deliquium, and thirty drops of spirit of vitriol, or a little more or less, as is found necessary, not to let the alcali of the oil of tartar prevail too strongly, though it must prevail a little. Shake all briskly together, and on tasting it will be found extremely to resemble the true Pyrmont-water.

The basis on which this is founded, is the analysis and trial of the true Pyrmont-water, by which it is found to contain a subtile aqueous fluid, a volatile iron, and a predominant alcali, all joined together into one brisk pungent spirituous water. The artificial Pyrmont thus made, if the proportions are carefully minded, will extremely resemble the natural, and will have the same effects as a medicine. *Shaw's Lectures.*

PYRO'BOLUS, in natural history, the name given by many authors to the stone more generally called pyrites; others have called it siderites, pyrobalanus, pyropus, and othonua, and the Greeks mylias.

PYROCTOGO'NIUM, in natural history, the name given by Dr. Hill to a genus of fossils, usually comprehended by authors, with many other bodies of a different figure and structure, under the general name pyrites.

The characters of the Pyroctogonium are these: it is a compound, inflammable, metallic body, of a regular octohedral figure, or composed of eight planes.

There is only one known species of this genus, which is a very singular and elegant fossil, being composed of eight triangular planes; these being the sides of two quadrilateral pyramids, with broad bases, which, being joined base to base, constitute the Pyroctogonium.

This figure is very regular and determinate in the perfect specimens

cimens of the body, but there is ſcarce any foſſil which is more ſubject to imperfections and accidental variations. Its moſt perfect ſtate is when the two pyramids of which it is compoſed are placed evenly one over-againſt the other; but this is rarely the caſe, they are often placed unevenly, or ſlanting; their planes are frequently of very irregular lengths and breadths, and not unfrequently the ſpecimens are found mutilated and imperfect, and very often a number of them cohering in a cluſter one with another, and very much mutilating or injuring one another's figure. They are found of all the ſizes between that of a pin's head and an inch in diameter; but the large ones are ſcarce, and the moſt uſual ſtandard is a third of an inch. They are naturally of ſmooth and poliſhed ſurface, and of the colour of wrought iron; when broken, they are bright and ſparkling, and of a paler colour than without. When nicely examined as to their internal ſtructure, they are found to be compoſed, like the marcaſites, of a number irregularly arranged foliaceous flakes or plates.

It is found very frequently in Cornwall, Devonſhire, and moſt other of our countries where there are mines. It is ſometimes met with looſe in the earth, ſometimes lodged in the bodies of marcaſites, or in the ſolid foſſils, and varies ſometimes from its iron colour to a duſky yellow. It is ſometimes alſo found with many ſpecimens connected into a maſs; theſe are ſeldom uniform in ſize, and cohere in various directions, often injuring one another's figure. Sometimes alſo, as in the caſe of the cryſtals, they form a large maſs, of which the outer ſurface only is concreted into or covered with regular figures, the whole inner part being a confuſed ſubſtance.

Maſſes of this kind are not unfrequently found of a regularly orbicular figure, and beſet all over with regularly figured Pyroctogonia of various ſizes. *Hill's Hiſt. of Foſſ.*

PYRO'LA, *winter-green*, in botany, a genus of plants, whoſe characters are:

The leaves are alternate; the flower is roſaceous, pentapetalous, ſhaped like a hat, with a recurvated piſtil, and diſpoſed in a ſpike; the fruit is roundiſh, ſtriated, umbilicated, quinquecapſular, and full of ſmall ſeeds.

The leaves, which are the only part uſed, and that not often, are cooling and drying, and a good vulnerary, both for inward and outward wounds and hæmorrhages, ulcers in the kidnies or bladder, as, alſo, againſt making bloody water, and the exceſs of the catamenia. *Miller's Bot. Off.*

PYROLA'MPIS, *the glow-worm*, a ſmall inſect, remarkable for its ſhining in the night.

The male and female differ greatly in this ſpecies of inſect.

The male has wings, and is a ſmall fly; the female has no wings, but is a large crawling worm. The body of the male is oblong, and ſomewhat flatted; the wings are ſhorter than the body; the head is broad, dun, and flat; the eyes are large and black. This has no light iſſuing from it, and is not commonly ſuppoſed to be at all of kin to the glow-worm; but a very different inſect.

The female is what we expreſly call by this name. This is a very ſlow-paced animal, without wings, and ſomewhat reſembling a caterpillar; the head is ſmall, flat, hard, and black, and ſharp towards the mouth; it has ſhort antennæ, and ſix moderately long legs: the body is flat, and compoſed of twelve rings, whereas the body of the male conſiſts only of five; it is of a duſky colour, with a ſtreak of white down the back. It is often ſeen in the day-time, but is not known till in the dark; at which time it is eaſily diſtinguiſhed by the glowing light, or lambent flame, that is ſeen near the tail, iſſuing from the under part of the body.

PYRO'METER *, in mechanics, a machine for meaſuring the degree of expanſion of metals by heat.

* The word is derived from the Greek πῦρ, fire, and *μετρέω*, to meaſure.

The following Pyrometer is that of the ingenious Mr. John Ellicot.

A A (*plate* XXXV. *fig.* 12.) is a flat piece of braſs, which, for farther ſtrength, is ſcrewed down to a thick piece of mahogany: upon this plate are ſcrewed three pieces of braſs, two of which, marked B B, ſerve as ſupports for the flat iron bar C; and which, on account of its uſe, I ſhall call the ſtandard bar. The upper part of the third piece of braſs is a circle about three inches diameter, divided into 360 equal parts or degrees: within the circle is a moveable plate, divided likewiſe into 360 parts, and a ſmall ſteel index. The braſs circle in the fig. is marked D, and the moveable plate *d*. Upon the ſtandard bar the bar of metal is laid, on which the experiment is to be made, as E.

F is a lever two inches and a half in length, faſtened to an axis, which turns in two pieces of braſs ſcrewed to one of the ſupports marked B: to the end of this lever is faſtened a chain, or ſilk line, which after being wound round a ſmall cylinder; to which the index in the braſs circle D is faſtened, paſſes over a pulley, and has a weight hung to the end of it: upon the axis, to which the lever is fixed, is a pulley, $\frac{1}{4}$ of an inch in diameter, to which a piece of watch-chain is faſtened; the other end of this chain is hooked to a ſtrong ſpring, marked G, which ſpring bears againſt one end of the metal E.

H is a lever exactly of the ſame form and dimenſions with the former; but the chain faſtened to the pulley on its axis is hooked to the ſtandard bar. The line faſtened to the end of this lever, after being wound round a cylinder, to which the moveable plate is fixed, paſſes over a ſmall pulley, and has a weight hung to the end of it; or rather the ſame line paſſing under a pulley, to which the weight is hung, has its other end faſtened to the lever F: thus one weight ſerves for both levers, as in the figure.

From this deſcription it is plain, that, whenever the bar E is lengthened, it gives liberty to the weight to draw the lever F upwards by its action on the ſpring G; and the index will, at the ſame time, by means of the ſilk line, be carried forward in the circle; and as the bar ſhortens, it will return back again; the ſame motion will be communicated to the ſtandard bar.

The lengthening the bar the $\frac{1}{20}$ of an inch will carry the index once round the braſs circle, which is divided into 360 degrees; therefore, if the metal lengthens the 7200th part of an inch, the index will move one degree.

To make an experiment with this inſtrument, lay a bar of any kind of metal, as E, on the ſtandard bar; then heat the ſtandard bar to any degree of heat with a lamp, and mark the degree of its expanſion, as marked by the moveable plate: obſerve alſo the degree of expanſion of the metal E, by the heat communicated to it from the ſtandard bar, as marked on the braſs circle by the index: let the inſtrument ſtand, till the whole is thoroughly cold; then removing the bar E, lay a bar of any other metal in its place, and heat the ſtandard bar to the ſame degree of heat as before, which is ſeen by the moveable plates marking the ſame degree of expanſion. Then the index will ſhew the degree of expanſion of the ſecond metal, as it did of the firſt; and, by this means, the degrees of expanſion of different metals, by the ſame degree of heat, may be exactly eſtimated.

PYRO'PHORUS, the name uſually given to that ſubſtance called by ſome black phoſphorus.

It is made in this manner: take four or five parts of alum, and one part of wheat-flower, calcine this together to a brown or blackiſh maſs; powder this, and put it into a phial, ſtop it looſly with a paper, and ſet in a ſand heat, ſo as to make it continue glowing hot for ſome time; after this, remove the whole from the fire, ſuffer it to cool gradually, and finally ſtop the bottle very cloſe down.

A little of this powder being poured out of the bottle, and expoſed to the open air, immediately takes fire, and appears like a glowing coal; but the powder muſt be freſh made to have a good effect, for the ſun's rays, or the moiſture of the air being admitted to it, gradually take away its virtue.

Almoſt any animal or vegetable ſubſtance may be ſubſtituted inſtead of wheat-flower in this proceſs, and it will ſucceed equally well; but no other ſalt will do in the place of alum. *Shaw's Lectures.*

PY'RUS, *the pear-tree*, in botany, a genus of trees, whoſe characters are:

The flower conſiſts of ſeveral leaves, which are placed in a circular order, and expand in form of a roſe; whoſe flower cup afterwards becomes a fleſhy fruit, which is more produced towards the foot-ſtalks than the apple, but is hollowed like a navel at the extreme part: the cells in which the ſeeds are lodged, are ſeparated by ſoft membranes, and the ſeeds are oblong. See PEAR.

Q.

QUADRANGULA'RIS *piscis*, the *square-fish*, in zoology, the name of a fish, which, in its most usual size, is about fifteen inches long, four inches in the middle, and three inches and an half over. The forehead is square, a little hollow, and, by the eminency of the eyebrows, two inches and an half over. The nose blunt, and not very steep, with two holes in the place of nostrils, and the mouth very small. The back is a little convex toward the tail, and on the sides a little obtusely angled; as is also the belly, which is plain and flat, and a little rising towards the tail. It has five fins, two near the gills, two near the tail, and the tail-fin, which is considerably long. Part of the head and tail are covered with a soft skin, the rest of the body with a kind of crust, adorned all over with little round knots, reduced for the most part into hexagonal figures, and subdivided into equilateral triangles. *Grew. Muf. Reg. Soc.*

QUA'DRANS, a word used by some authors to express a fourth part of a pound, that is, three ounces troy weight, or four of the avoirdupois.

Hadley's QUA'DRANT (*Dict.*)— Though the late Mr. Hadley was undoubtedly the inventor of it, yet the principle upon which his invention turns, had not escaped the sagacity of Sir Isaac Newton, long before, as appears from a paper in his hand-writing found among the papers of the late Dr. Halley. But this was totally unknown to Mr. Hadley, and seemed to have been forgot by Dr. Halley himself. The account of Sir Isaac's invention is inserted in the *Philosophical Transf.* N°. 465, and is as follows.

P Q R S, *Plate* XXXV. *fig.* 8, denotes a plate of brass accurately divided, in the limb D Q, into ½ degrees, ½ minutes, and $\frac{1}{12}$ minutes, by a diagonal scale; and the ½ degrees, ½ minutes, and $\frac{1}{12}$ minutes, counted for degrees, minutes, and ½ minutes. A B is a telescope, three or four feet long, fixed on the edge of the brass plate. G is a speculum, fixed on the said brass plate perpendicularly, as near as may be to the object glass of the telescope, so as to be inclined 45 degrees to the axis of the telescope, and intercept half the light which would otherwise come through the telescope to the eye. C D is a moveable index, turning about the center C, and, with its fiducial edge, shewing the degrees, minutes, and ½ minutes, on the limb of the brass plate P Q; the center C must be over-against the middle of the speculum G. H is another speculum, parallel to the former, when the fiducial edge of the index falls on 00° 00′ 00″; so that the same star may then appear through the telescope, in one and the same place, both by the direct rays and by the reflected ones; but, if the index be turned, the star will appear in two places, whose distance is shewed, on the brass limb, by the index.

By this instrument the distance of the moon from any fixed star is thus observed: view the star through the perspicil by the direct light, and the moon by the reflected, or, on the contrary, and turn the index till the star touch the limb of the moon, and the index shall shew, upon the brass limb of the instrument, the distance of the star from the limb of the moon; and, though the instrument shake, by the motion of your ship at sea, yet the moon and star will move together, as if they did really touch one another in the heavens; so that an observation may be made as exactly at sea as at land. And by the same instrument may be observed, exactly, the altitudes of the moon and stars, by bringing them to the horizon; and thereby the latitude, and times of observations, may be determined more exactly than by ways formerly practised. In the time of observation, if the instrument move angularly about the axis of the telescope, the star will move in a tangent of the moon's limb, or of the horizon; but the observation may notwithstanding be made exactly, by noting when the line, described by the star, is a tangent to the moon's limb, or to the horizon. To make this instrument useful, the telescope ought to take in a large angle: and, to make the observation true, let the star touch the moon's limb, not on the outside of the limb, but on the inside.

Mural QUADRANT. Mr. Gersten has lately given us a description of a new astronomical mural Quadrant, which he says is free from many of the usual inconveniencies attending the use of such instruments. See *Phil. Transf.* N°. 483.

QUADRA'TO, or QUADRO, in the Italian music, is a name given to the note B, when it comes in the natural or diatonic order, and is thus marked ♮. It is a semitone minor higher than the B mol, or ♭, and in respect of that may be called sharp.

QUA'DRATURE *of the ellipsis.*—The ellipsis, is a curve whose precise Quadrature in definite terms is not yet effected. We have here therefore, as in the circle recourse, to a series.

Let A C (*Plate* XXXV. *fig.* 9.) $= a$, G C $= c$, P C $= x$. Then will

$$y^2 = c^2 = (a^2 - x^2) : a^2$$
$$y = c\sqrt{(a^2 - x^2)} : a$$

But $\sqrt{[a^2 - x^2]} = a - \frac{x^2}{2a} - \frac{x^4}{8a^3} - \frac{x^6}{16a^5} - \frac{5x^8}{128a^7} - \frac{7x^{10}}{256a^9}$, &c. in infinitum. Therefore, $ydx = cdx \frac{cx^2dx}{2a^2} - \frac{cx^4dx}{8a^4} - \frac{cx^6dx}{16a^6} - \frac{5cx^8dx}{128a^8} - \frac{7cx^{10}dx}{256a^{10}}$, &c. in infinitum.

if then for x be put a, the quadrant of the ellipsis will be $ac - \frac{1}{6}ac - \frac{1}{40}ac - \frac{1}{112}ac - \frac{5}{1152}ac - \frac{7}{2816}ac$, &c. in infinitum. Which same series exhibits the intire area of the ellipsis, if a denote the intire axis.

Hence, 1. If $\sqrt{ac} = 1$, the area of the ellipsis $= 1 - \frac{1}{6} - \frac{1}{40} - \frac{1}{112} - \frac{5}{1152} - \frac{7}{2816}$, &c. in infinitum: whence it is evident that an ellipsis is equal to a circle whose diameter is a mean proportional between the conjugate axis of the ellipsis. 2. Hence, also, an ellipsis is to a circle whose diameter is equal to the greater axis, as ac to a^2; that is, as c to a, or as the less axis to the greater. Hence, lastly, having the Quadrature of the circle, we shall likewise have that of the ellipsis, and on the contrary.

QUADRATURE *of the parabola.*—For the parabola we have a quadratrix or transcendent curve, which gives its squares. But it may be likewise had thus:

$$ax = y^2$$
$$a^{1:2}x^{1:2} = y$$
$$ydx = a^{1:2}x^{1:2}dx$$
$$\int ydx = a^{1:2}x^{3:2} = \tfrac{2}{3}\sqrt{ax^3} = \tfrac{2}{3}\sqrt{x^2y^2} = \tfrac{2}{3}xy.$$

Hence, the parabolic space is to the rectangle of the semiordinate into the abscisse, as $\frac{2}{3}xy$ to xy; that is, as 2 to 3.

Note, If a curve be not supposed described, but only an equation to it given, so as it does not appear, for instance, where the origin of x is to be fixed, we are to put $x = o$ in the integral, and, expunging what are multiplied by x, add to it the remainder, if there be any, under the contrary sign; to have the Quadrature sought.

QUADRATURE *of the hyperbola.*—For this, too, we have a quadratrix, invented by Mr. Perks.

The analytical Quadrature was first given by N. Mercator, of Holstein, the first inventor of infinite series's. But, Mercator finding his series by division, Sir Isaac Newton and Mr. Leibnitz improved upon his method; the one seeking them by the extraction of roots, the other by a series presupposed.

Mercator's QUADRATURE *of the hyperbola between its asymptotes.*—Since, in an hyperbola within the asymptotes, $a^2 = by + xy$; or if $a = b = 1$, which may be supposed, since the determination of b is arbitrary.)

Then will
$$1 = y + xy$$
$$1:(1 + x) = y$$

That is, the division being actually performed,

$$y = 1 - x + x^2 - x^3 + x^4 - x^5 + x^6, \text{ \&c.}$$
$$ydx = dx - xdx + x^2dx - x^3dx + x^4dx - x^5dx + x^6dx, \text{ \&c.}$$
$$\int ydx = x - \tfrac{1}{2}x^2 + \tfrac{1}{3}x^3 - \tfrac{1}{4}x^4 + \tfrac{1}{5}x^5 - \tfrac{1}{6}x^6 + \tfrac{1}{7}x^7, \text{ \&c.}$$

in infinitum.

QUADRATURE *of the cycloid.*—Since T P (*Plate* XXXV. *fig.* 10.) = P M; in the triangle P M T, the angles M and T will be equal; and consequently, T P Q = 2 M. But the measure of the angle A P Q is the half arch A P; which likewise measures the angle T P A. Therefore A P Q = T M P = M *m* S, by reason M Q and *m q* are parallel. Wherefore, since the angles at S and Q are right-angles, we have

$$AQ : QP :: MS : mS.$$

Let, then, A Q $= x$, A B $= 1$; then will P Q $= \sqrt{(x - xx)}$ and mS $= dx\sqrt{(x - xx)} : x$. But it is shewn, that $\sqrt{(x - xx)} = x^{1:2} - \frac{1}{2}x^{3:2} - \frac{1}{8}x^{5:2} - \frac{1}{16}x^{7:2}$, &c. in infinitum. Therefore, $dx\sqrt{(x - xx)} : x =$ (the numerators of of the exponents being diminifhed by two units in the divifion by x) $x^{-1:2}dx - \frac{1}{2}: x^{1:2}dx - \frac{1}{8}x^{3:2}dx - \frac{1}{16}x^{5:2}dx$, &c. in infinitum. Whofe fum $2x^{1:2} - \frac{1}{3}x^{3:2} - \frac{1}{20}x^{5:2} - \frac{1}{56}x^{7:2}$, &c. in infinitum, is the femiordinate of the cycloid Q M referred to the axis A P. Hence, Q M dx, or the element Q M S q of the cycloidal fpace A M Q $= 2x^{1:2}dx - \frac{1}{3}x^{3:2}dx - \frac{1}{20}x^{5:2}dx - \frac{1}{56}x^{7:2}dx$, &c. in infinitum. Whofe fum $= \frac{4}{3}x^{3:2} - \frac{2}{15}x^{5:2} - \frac{1}{70}x^{7:2} - \frac{1}{252}x^{9:2}$, &c. in infinitum, expreffes the fegment of the cycloid A M Q.

If, then, $mS = gG = dx\sqrt{(x - xx)} : x$ be multiplied into G M $=$ A Q $= x$; we fhall find the element G M H G of the area A M G $= dx\sqrt{(x - xx.)}$ Which being the fame with the element of the fegment of the circle A P Q, the fpace A M G will be equal to the fegment of the circle A P Q; and, confequently, the area A D C equal to the femicircle A P B.

Hence, fince C B is equal to the femiperiphery of the circle, if that $= p$ and A B $= a$; the rectangle B C D A $= ap$; and the femicircle A P B; and confequently, the external cycloidical fpace A D C $= \frac{3}{4}ap$. Therefore the area of the femicycloid A C B $= \frac{1}{4}ap$, and A M C B P A $= \frac{3}{4}ap$. Confequently, the area of the cycloid is triple of the generating circle.

Quadrature *of the logiftic, or logarithmic curve.*— Let the fubtangent P T, *Plate* XXXV. *fig.* 11, $= a$, P M $= x$— P $p = dx$; then will

$$y\,dx : dy = a$$
$$y\,dx = a\,dy$$
$$\int y\,dx = ay$$

Wherefore the indeterminate fpace H P M I is equal to the rectangle of P M into P T.

Hence, 1. Let Q S $= z$; then will the indeterminate fpace I S Q H $= az$; and, confequently, S M P Q $= ay - az = a(y - z)$; that is, the fpace intercepted between the two logiftic femiordinates is equal to the rectangle of the fubtangent into the difference of the femiordinates.

2. Therefore the fpace B A P M, is to the fpace P M S Q as the difference of the femiordinates A B and P M to the difference of the femiordinates P M and S Q.

Quadrature *of Des Cartes's curve*, which is defined by the equation, $b^2 : x^2 :: b - x : y$.

Since, $b^2 y = bx^2 - x^3$

$$y = (bx^2 - x^3) : b^2$$
$$y\,dx = (bx^2\,dx - x^3\,dx) : b^2$$
$$\int y\,dx = x^3 : 3b - x^4 : 4b^2$$

Quadrature *of all curves comprehended under the general equation*, $y = x\sqrt[m]{(x + a)}$

Since $y = (x + a)^{1:m}$

$$y\,dx = dx(x + a)^{1:m}$$

To render the element integrable, fuppofe,

$$(x + a)^{1:m} = v$$

Then will $x + a = v^m$

$$dx = mv^{m-1}\,dv$$
$$y\,dx = mv^m\,dv$$

$\int ydx = \frac{mv^m}{m+1} + 1 = \frac{m}{m+1}(x+a)\sqrt[m]{(x+a.)}$ Let $x = o$:

The remainder $\frac{m}{m+1}a\sqrt[m]{a}$. Whence, the area of the curve $\frac{m}{m+1}(x + a)\sqrt[m]{(x + a)} - ma\sqrt[m]{a}$.

Quadrature, in aftronomy (*Dict.*)— When the moon is in her Quadrature, fhe exhibits that phafis which we call the half-moon, i. e. fhe fhines with juft half her face; and is faid to be bifected, or dichotomifed. See PHASIS and DICHOTOMY, in the Dictionary.

In the moon's progrefs from the fyzygies to her Quadrature, her gravity towards the earth is continually increafing by the action of the fun; and her motion retarded for the fame reafon.— Her motion, then, in her orbit is floweft as her gravity to the earth is greateft when in the Quadratures.

In her recefs from the Quadratures to the fyzygies, the gravity continually decreafes, and the velocity increafes.

The ratio is thus: as radius is to the fum, or difference of one and an half the co-fine of double the diftance of the moon from the fyzygy, and half the radius; fo is the addition of gravity in the Quadratures to the diminution or increafe thereof in any other fituation.

Hence, the moon's orbit is more convex in the Quadratures, than in the fyzygies; and hence the circular figure of the moon's orbit is changed into an oval, whofe greater axis goes through the Quadratures; and hence, alfo, the moon is lefs diftant from the earth at the fyzygies, and more at the Quadratures.

It is no wonder, therefore, that the moon approaches nearer the earth when her gravity is diminifhed; that excefs not being the immediate effect of this diminution, but of the inflexion of the orbit towards the Quadratures.

QUADRI'GA, in furgery, otherwife called Cataphracta, is a ftrong bandage made ufe of in fractures of the fternum. It is compofed of a double-headed roller about fix Paris ells long and three or four fingers broad.

QUADRI'GÆ, among the Romans, chariots drawn by four horfes, which were harneffed all a-breaft, and not two and two.

QUADRI'LLE, a well known game at cards; and which has been, in feveral cafes, the object of mathematical computations. *De Moivre's Doctrine of Chances, 2d. edit.*

QUADRI'SETÆ, *the four-haired fly*, a term ufed by the writers, in natural hiftory, to exprefs thofe flies of the feticaude or hair-tailed kind, which have four hairs or briftles growing from the tail, as the others have three, two, or one.

QUA'DRULA, in natural hiftory, a word fometimes ufed in the fame fenfe as teffela, and fpoken of the cubic pyrites. Sometimes it is ufed alfo as the name of thofe light fpangles of fhining matter that are mixed among fand. Thefe are generally fragments of talc, and are of various colours, white, yellow, and blackifh.

Solinus has ufed the word Quadrula to exprefs the fragments of yellow talc that are found in that fand called ammochryfos, or golden fand. He miftakes thefe fhining particles for maffes of real gold, and makes the fand itfelf a kind of precious fubftance ranked among the gems, and brought from Perfia; but in this he does not agree with the reft of the ancients.

QUA'DRUPED (*Dict.*)— Quadrupeds are divided by Mr. Ray into thofe which are hoofed, ungulata, and clawed or digitate, unguiculata.

Hoofed Quadrupeds are either,

1. Whole-hoofed, folidipeda, μονώνυχα, μώνυχα, folidungula: as the horfe, afs, the onager or wild afs; the mule and the zebra of Africa, or the fine ftriped Indian or African afs, almoft like a mule in form and ftature.

Of the whole-hoofed kind, Ariftotle has obferved, that no one hath two horns—(he might have faid any horns) no one hath the talus or aftragalus, nor have the males any appearance of breafts.

2. Cloven-footed, and that either, 1, into two divifions only; as the δίχηλα, or bifulcate kind, which are again fubdivided into fuch as are, firft,

Ruminant, μηρυκάζοντα, that is, fuch as chew the cud; and thefe either have hollow and perpetual horns, as the bull, fheep, and goat-kind; or deciduous horns, as the hart and deer-kind, which ufually fhed their horns annually. See RUMIMANT, in the Dictionary.

Of the bull-kind are reckoned thefe: the common bos or bullock, of which the male is taurus, the female vacca: the German urus, urochs, or aurochs: the bifon, the bonafus, the bubalus, or bufalo: the bos Africanus of Bellonius, Obf. l. ii. c. 50, which he takes to be the bubalus of the ancients.

Of the fheep-kind, befides the common fort, are reckoned the Arabian ovis laticauda, whofe tail is fometimes of thirty pounds weight; the ovis ftrepficeros Cretica Bellonii; the ovis Africana, with fhort hair inftead of wool; the ovis Guineenfis, or Angolenfis of Marcgrave, *Hift. Brafil.*

Of the goat-kind, are, befides the common capra domeftica, the ibex, or German fteinbock, found in the tops of the Alps; the rupicapra, French chamois, or German goms; the gazella Africana or antelope; the gazella Indica; the capra fylveftris Africana Grimmii; the capra mambrina, or Syriaca of Gefner; the bufelaphus, or mofchelaphus Caii in Gefner; the tragelaphus Caii in Gefner, &c.

Of the hart or deer-kind, are reckoned, the cervus ἔλαφος, or red deer; the cervus platyceros or palmatus, the fallow deer; alce or the elk; rangifer, the rain-deer; the axis Plinii, according to Bellonius; the caprea Plinii, the cuguacu-etc, and cuguacu-zapara of Marcgrave; the caprea Groenlandica.

Secondly, of cloven-footed animals into two parts only, and which do not chew the cud, there is only the hog and fwinekind: under this head, befides the common fwine, are reckoned the wild boar, or fwine; the porcus Guineenfis Marcgravii; the porcus Indicus, called babyrouffa; the tajaca or aper Mexicanus mofchiferus of Dr. Tyfon, called by Marcgrave tajaca cunagoara, by others quauhtla coymalt, and quapizotl, and by Acofta, and fome others, zaino.

2. There are fome Quadrupeds, whofe hoof is cloven into four divifions; and thefe feem to be not ruminant: as the rhinoceros, the hippopotamus, the tapijerete of Brafil, the capy-bara of Brafil, and the animal mofchiferum.

Clawed or digitate Quadrupeds.— Of this kind, there are, firft, a fort whofe claws are not divided or feparated, but adhering to one another, covered with one common fkin, but with obtufe nails, fticking out round the margin of the foot; as the elephant, which is anomalous, and not clearly referable to this kind, or to that of cloven-footed Quadrupeds.

A fecond fpecies of this digitate-kind of Quadrupeds, which has only two claws, is that of camels; and, though thefe have no horns, they both ruminate, and have alfo the four ftomachs of horned ruminant animals.

Of the camel or dromedary there are two forts; one having but one bunch on the back, the other two.

To this kind alfo belong the Peruvian glama, which fome have reckoned among the fheep-kind; as alfo the pacos, the oris Indica, or Peruviana vulgo, much leſs than the glama.

A third ſpecies of this unguiculate kind includes ſuch animals as the Greeks called πλατυώνυχα, and ἀνθρωπόμορφα, which have the foot divided into many claws, with broad nails on them; as the ape and monkey kind.

Of theſe, ſome have no tails, and are called ſimiæ, or apes: others have tails, and are called monkeys, cercopitheci; and ſuch as have either long or ſhort tails, if they are of a larger ſize, are called papiones or baboons.— There are great numbers and varieties or this ſpecies of Quadrupeds; of which naturaliſts have deſcribed theſe: viz. the orang outang or homo ſylveſtris of Dr. Tyſon, deſcribed by him in a particular diſcourſe: the guarita of Braſil, Marcgravii; the cagui of Braſil, greater and leſſer; the cay of the ſame region, deſcribed by Lerius; the caitaia of the ſame country; the cercopithecus barbatus Guineenſis, two or three ſorts of it; the cercopithecus Angolenſis major; the cercopithecus non barbatus Cluſii; the cercopithecus Cluſ. called ſagouin: laſtly, if apes and monkeys have their ſnouts very prominent like dogs, they are called cynocephali.

A fourth ſpecies of this unguiculate kind, is when, though the claws are many, yet they are not covered at the end with broad flat nails, like the monkeys or apes; but are rather like the talons of hawks, &c. crooked and ſharp-pointed.

Theſe, in reſpect of their teeth, may be divided into ſuch as have many dentes primores, or inciſores, that is, cutting teeth, in each jaw, of which there are two ſorts; a greater, which either have a ſhort, round head, as the cat-kind; or a leſſer ſort, having a long ſlender body, with very ſhort legs, as the weaſel or vermin-kind.— There are alſo ſome of this ſpecies of Quadrupeds, which have only two large remarkable teeth in each jaw: theſe are the hare-kind, and live only upon herbs, graſs, &c.

Of the cat-kind of Quadrupeds are reckoned to be the lion, the tyger, the pardalis, which male is pardus, and female panthera, the leopard; the lupus cervarius, or lynx; the catus pardus, or cat-a-mountain; the common cat, and the bear.

Of the dog-kind are reckoned the wolf; the lupus aureus or jackall; beſides the common dog, of which kind they enumerate, the maſtiff; the canis Venaticus graius, Græcus, or Scoticus, the greyhound; graius Hibernicus, or the Iriſh greyhound; the canis Venaticus ſagax, indagator, ſpectator ferarum, &c. the hound; canis Venaticus Hiſpanicus or Aviarius, the ſpaniel for land or water; vertagus or tumbler; canis οἰκουρός, or domeſticus, the houſe-dog; canis melitæus, or the lap-dog; canis Getulus or Iſlandicus, the ſhock: and of all theſe ſorts there are many varieties of mongrels, and hybridous breeds.

Another ſort of the dog-kind is the fox; the animal zibethicum, or civet-cat, as it is corruptly called, but, by it's teeth and ſnout, is plainly of the dog-tribe; the American coati, rackoon, or rattoon; the yzquiepate; the carigueya, marituxaca, carigoy, ropoza, or poſſum; the taxus or meles; the badger, grey, or pate; the lutra or otter; the phoca, ſea-calf, or ſeale; the equus marinus, morſe, or ſea-horſe, miſtaken by ſome for the hippopotamus; the Dutch call him walras, the Danes and Iſlanders roſmarus; laſtly, the manati or vacca marina, the ſea-cow.

Of the vermin, or weaſel-kind of Quadrupeds, is firſt, the muſtela vulgaris, the common weaſel, in Yorkſhire called foumart or fitcher, γαλῆ; the viverra Indica, called quel and quirpele; and another ſort called mungo and mungathia, of a reddiſh grey: the muſtela, ermin, or ſtoat, if white: and muſtela ſylveſtris, the ferret; putorius, the pole-cat; martes or foyna, the martin or martlet; muſtela zibellina, the ſable; laſtly, the genetta, and the ichneumon Bellonii.

Of the hare kind of Quadrupeds, are firſt, lepus, or the common hare: cuniculus, the rabbet or coney: tapeti, or Braſil coney, and the aperea of Braſil; the hyſtrix, or porcupine, and the hyſtrix Americanus, or cuanda of Braſil; caſtor, fiber, or the beaver; ſciurus vulg. or ſquirrel: the Virginian, Zeylandic, Barbary, and American flying ſquirrel; mus domeſticus, major and minor, the common rat and mouſe: to theſe alſo may be referred mus major aquaticus, the water-rat; the muſk-rat, mus avellanarum, major and minor; the dormouſe or ſleeper, mus noricus, Cricetus, Alpinus ſeu Marmotta; the cavia cobaya, or cuniculus Americanus, the Guinea-pig; the agati and paca of Brazil; the mus Norwegicus, or leming; the glis Geſneri, or the rell; the mus Indicus, &c.

Anomalous QUADRUPEDS.— To theſe ſeveral kinds the following anomalous ones muſt alſo be added.

1. Such four-footed viviparous animals as have a longiſh ſnout, with their feet divided into many claws and toes, and having teeth; as the echinus terreſtris, or common urchin, or hedge-hog; erinaceus Indicus albus; tatu or armadillo prima of Marcgrave; tatuete of Braſil, or the ſecond ſpecies of the armadillo, according to Marcgrave; tatu apara, his third ſpecies of armadillo; tatu Muſtelinus, Soc. Reg. Muſ. the weaſel-headed armadillo; talpa, the mole, warp, or mold-warp; mus araneus, ſhrew, hardyſhrew, ſhrew-mouſe.

2. Quadrupedous and viviparous animals with a longiſh ſnout, having their feet divided into many claws or toes, but without teeth; as the tamandua-guacu of Braſil, Marcgravii; urſus formicarius Cardani, the great ant-bear; the tamanduais of Braſil, or Marcgrave's leſſer ant-bear.

3. Anomalous flying Quadrupeds, with a ſhorter ſnout, and their feet divided as above; being of the bat-kind, or flitter-mice; of which there are ſeveral ſizes and different forms.

4. There is one very anomalous animal which has but three claws on each foot; and that is the aſs, or ignavus of Marcgrave, the ſloth or ſluggard.

5. Viviparous and ſanguineous Quadrupeds, breathing with lungs, but having only one ventricle in the heart; as the rana aquatica, the frog or froſh; rana arborea, ſeu ranunculus viridis, the ſmall tree or green frog; bufo, ſive rubeta, the toad; teſtudo, the tortoiſe, in Greek, χελώνη; of theſe there are land and water ones, and many different ſpecies in foreign parts.

6. Oviparous Quadrupeds, with a long tail ſtretched out horizontally, are the lizard kind; as lacertus omnium maximus, the crocodile; cordylus, ſive caudiverbera, uramaſtix Græcis, larger than the green lizard; tapayaxin Novæ Hiſpaniæ; lacertus orbicularis of Hernandez; lacertus vulgaris, the common eſt, ſwiſt, or newt; lacertus viridis, the green lizard; lacertus fucetanus Adrovandi, at Rome and Naples called the tarantula: lacertus Indicus, called ſenembi and inguana; lacertus Braſilienſis, called tejuguacu, and temapara by Marcgrave; the taraguira, ameira, taraguico, Acuraba Americima, Carapopepa, Teiunham, &c. of Marcgrave; the lacertus Indicus; the ſcincus, or crocodilus terreſtris; the ſeps, or lacerta chocidica, a kind of footed ſerpent; ſtellio, the ſwiſt, or ſpotted lizard; ſalamandra terreſtris; ſalamandra aquatica, the water eſt; lacerta volans Indica; and the chamælion, or camelion.

Alated QUADRUPEDS. Among the many fabulous things with which natural hiſtory has been loaded, ſtories of flying Quadrupeds ſeem to claim a very high rank; the gryphon, the Quadruped dragon, and a great many other imaginary animals, having been introduced ſo ſeriouſly among the deſcriptions of real animals, that too many have been taught to believe them. Scheuchzer, in his Phyſica ſacra Jobi, has done much towards diſcountenancing ſuch relations, and Hyacinthus Gemma, who has written expreſly de fabuloſis animalibus, has added much on the ſame occaſion: yet all is not done. The world have late hiſtories of lemmas and baſiliſks, which never exiſted but in the imagination of the relator, or in the ſubtle contrivances of the fabricator; as is evidently the caſe in the baſiliſks, which we find in the muſæums of the curious, and which are all made out of the wray-fiſh. And the generality of readers are ſo fond of any thing that is marvellous, that theſe things are ſure to be remembered, while perhaps all the truths in the book are forgotten.

Though moſt of the ſtories of alated or flying Quadrupeds are falſe, yet, there are evidently ſome animals which ſhew, that this property is not denied to all Quadrupeds. We have bats in every part of this kingdom, and the Eaſt and Weſt-Indies are not without them; and whoever accurately examines this creature, will find that it has nothing of a bird but that one property of flying; and that what are called its wings, and ſerve it in the office of wings, are, in reality, only its fore-feet extended, and webbed with a peculiar kind of membrane.

There is a ſpecies of flying lizard very common in Java, and called by many the flying dragon. Bellonius had led the world into a great error in regard to this animal, having miſtaken it for a two-legged creature, and deſcribed and figured it as ſuch; but Bontius, and others ſince his time, have ſet us right about it from their own obſervation, and Piſo, as well as many others, have deſcribed it truly as a Quadruped.

Theſe creatures are properly enough called flying animals, as they can ſuſpend themſelves a long time in the air, and move about in it at pleaſure; but leſs accurate writers have added to the numbers of flying Quadrupeds the common ſquirrel, and ſeveral other creatures which live in woods, and being very light in their bodies, and very ſtrong in their legs, can leap or throw themſelves forward to a great diſtance, and by this means paſs from one tree to another. Of this kind the moſt eminent is that ſpecies called the flying ſquirrel, which has a ſort of membrane which it expands on each ſide to catch the air, and ſupport it from falling in its leaps; which by this means it makes very long, and ſeems to fly, eſpecially when it throws itſelf from the top of a very high tree to a low ſhrub.

Upon the whole, the ſtandard of the flying or alated Quadrupeds ſeems to be properly enough reducible to this: that the words flying and alated are not ſynonymous terms, and that there are three kinds of flying among the Quadruped claſs. The firſt abſolute and ſwift, flying as perfect as in birds; this peculiarly belongs to the bat, which is the only alated or winged Quadruped, properly ſpeaking. 2. An imperfect flying by means of certain membranes ſerving as wings, but imperfectly, and not turning quick, or enduring long flights; ſuch is the flying of the lizard, which is not properly an alated animal. And, laſtly, the imperfect flying of the ſquirrel kind, which even in that ſpecies called, by way of eminence, the flying ſquirrel, is not properly flying, but only long leaping; the

the creature being able to turn but very little out of a right-line, and only to suspend itself during a short time in a leap from a high place to a lower. *Phil. Transf.* Nº. 427.

QUADRUPLATO'RES, among the Romans, were informers, who had the fourth part of the confiscated goods for their pains. *Pitisc. in voc.*

QUÆ'RENS *non invenit plegium*, a return made by the sheriff upon a writ directed to him with this clause, viz. Si A. fecerit B. securum de clamore suo prosequendo, &c. F. N. B. 38. *Blount. Cowel.*

QUAIL, in ornithology, the name of a well known bird of passage, frequenting the corn fields, and sometimes the meadows. They begin to sing in the month of April, and make their nests in May, building on the ground.

Quails are to be taken by means of the call, during their whole wooing time, which lasts from April to August. The proper times for using the call are at sun-rising, at nine o'clock in the morning, at three in the afternoon, and at sun-set; for these are the natural times of the Quail's calling. The notes of the cock and hen Quail are very different, and the sportsman who expects to succeed in the taking them, must be expert in both; for, when the cock calls, the answer is to be made in the hen's note; and when the hen calls, the answer is to be made in the cock's. By this means, they will come up to the person, so that he may, with a great ease, throw the net over them and take them. If a cock Quail be single, on hearing the hen's note he will immediately come; but, if he have a hen already with him, he will not forsake her. Sometimes, though only one Quail answers to the call, there will three or four come up; and then it is best to have patience, and not run to take up the first, but stay till they are all entangled, as they will soon be.

The Quail is a neat cleanly bird, and will not run much into dirty or wet places: in dewy mornings they will often fly instead of running to the call; and in this case, it is best to let them go over the net, if it so happens that they fly higher than its top, and the sportsman then changing sides, and calling again, the bird will come back, and then will probably be taken in the net.

The calls are to be made of a small leather purse, about two fingers wide, and four fingers long, and made in the shape of a pear; this is to be stuffed half full of horse-hair, and at the end of it is to be placed a small whistle, made of the bone of a rabbit's leg, or some other such bone: this is to be about two inches long, and the end formed like a flageolet, with a little soft wax. This is to be the end fastened into the purse, the other is to be closed up with the same wax, only that a hole is to be opened with a pin, to make it give a distinct and clear sound. To make this sound, it is to be held full in the palm of the hand, with one of the fingers placed over the top of the wax; then the purse is to be pressed, and the finger is to shake over the middle of it, to modulate the sound it gives into a sort of shake. This is the most useful call, for it imitates the note of the hen Quail, and seldom fails to bring a cock to the net, if there be one near the place.

The call that imitates the note of the cock, and is used to bring the hen to him, is to be about four inches long, and above an inch thick; it is to be made of a piece of wire turned round and curled, and covered with leather; and one end of it must be closed up with a piece of flat wood, about the middle of which there must be a small thread or strap of leather, and at the other end is to be placed the same sort of pipe, made of bone, as is used in the other call. The noise is made by opening and closing the spiral, and gives the same sound that the cock does when he gives the hen a signal that he is near her.

QUA'KERS, a religious sect, who made their appearance in England, during the time of the interregnum.

They took their origin from George Fox, an illiterate person, born at Draiton in Leicestershire; and by profession a shoe-maker.

The accounts of those times tell us, that as he wrought at his trade, he used to meditate much on the scriptures; which, with his solitary course of life, improving his natural melancholy, he began at length to have visions; and, in consequence thereof, set up for a preacher.

The new prophet proposed but few articles of faith; dwelt mostly on morality; preached mutual charity, the love of God, and a deep attention to the inner motions and secret workings of the spirit.—He would have a simple worship, and religion without any ceremonies; making it a principal point to wait, in profound silence, the motion and direction of the holy spirit.

The genius of the times, the novelty of the doctrine, and the great appearance of devotion in the man, soon gained him disciples; and some unusual shakings and convulsions which they were seized withal, at their first meetings, procured them the appellation Quakers.

They profess a great austerity of behaviour; a singular probity and uprightness in their dealings; a demureness and gravity of countenance; a coldness and sparingness of discourse, to have time to weigh what they say; a great deal of frugality in their tables, and of plainness in their dress.

They declaim much against the interested views of the English ministers; blame all war, and set aside all use of oaths, as prohibited under the gospel.

According to the genius of rising sects, an eager zeal at first led them to some extravagancies: they would run about the streets naked, and were frequently in prison for interrupting the ministers in service time.

One of their company, Naylor, is said to have had the impiety to allow his followers to call him son of God, son of justice, and king of Israel; to strew garments before him, and hale him at his entry into Bristol, with Hosanna son of David. He had his trial for the same, was whipped for blasphemy, and excommunicated by the rest.

Besides other penalties inflicted on them, they were laughed at, and rallied in writing, and exposed on the theatre: but they despised alike both the press and the prison, and formed their sect, maugre all opposition of both; and under the direction of Fox, Dewsbury, and others, grew, from a loose, undisciplined multitude, into a regular body, with stated laws and polity; which they retain with great œconomy to this day.

The modern Quakers retain nothing of the extravagancies charged on their leaders; having approved themselves a sober, quiet people, of exemplary morals, and remarkably charitable and friendly to each other.

Their doctrines are not easily collected; at least, not easily represented out of their own terms, which appear somewhat ambiguous.

They hold Christ to be a light which hath lighted every man; and that whoever will soberly and seriously turn into himself with a sincere desire to know and practise his duty, will not fail to find there a sufficient director; a ray from the fountain of light illuminating the understanding, and assisting to distinguish good from evil.

They add, that such as follow the directions and convictions of this light, shall be holy and acceptable to God; and that this was the end of Christ's coming into the world.— That, so far as they follow this light, they shall be infallible; and that it is not opinions, speculations, or notions of what is true, or subscription of articles or formula's of faith, how soundly soever worded, that make a man a true believer or christian; but a conformity of mind and practice to the will of God, according to the manifestation and dictates of this divine principle of light within them.

Our Saviour's injunction about baptism they understand, in a figurative sense, of a conversion and change of the heart; and wholly neglect the outward sign.— Water-baptism, they hold, was only John's; that it was no more than a type or figure, fitted for the infant-state of the gospel; and therefore now useless, in a dispensation, which is spiritual and inward.

The same they hold of the supper; alledging, that both allude to old Jewish practices, and were used as types or significations of a near and accomplishing work.—They add, that the communion of saints consists only in a participation of the same divine principle, shewing itself in an unity of spirit.

As to ministry and ordinances, they deny that any are to be used of man's wit, or will, or carnal invention, or imitation; or other than what the inward principle directs them to.— Accordingly, they have no persons set apart for the ministry; but without distinction of quality or sex, every one who is of a sober life, and approved conversation, and believes him or herself called or moved thereto, is permitted to speak and prophesy in their assemblies.

They own the scriptures to be given by divine inspiration, and allow them the appellation of the form of sound words; but refuse to call them the word of God, as being a denomination properly attributed to Christ alone.— They add, that what makes them more scrupulous in this respect, is, that people are apt to be hereby led to think that, if they have the scriptures, they have all; and so look for no farther word or light.

They acknowledge the holy three that bear record in heaven, father, word, and spirit; but reject the school-terms, trinity, distinct, persons, hypostases, &c. as not scriptural, and as apt to convey too gross ideas.

They have been even charged with denying the incarnation, our Saviour's humanity, divinity, plenary satisfaction, and the resurrection of the dead: but this is injurious to them; and all that can be justly said, is, that they do not allow of them in the same sense, or speak of them in the same terms, as is commonly done among others.— They allow the incarnation, and that the Godhead dwelt bodily in Jesus; and yet many of them say, there is no Christ but what is within them: whence it should seem their notion of the incarnation only implied this, that the light, which they call the Christ within, dwelt in the man Jesus Christ fully.— Their reasoning, here, is, that, Christ, as God, not being divisible, the measure or manifestation of the spirit of Christ in us is a manifestation of the same Christ which dwelt bodily and fully in the man Jesus Christ.

They are silent as to the hypostatical union; and some of them are charged with allegorising away the whole history of the crucifixion, the resurrection, and ascension; though their best and most approved writers have been very explicit in their acknowledgment of the reality of the history.

They

They decline the uſe of modes or forms of civility; expreſſing their reſpect to their ſuperiors no other way but by obeying all juſt laws under their government.

The ſyſtem of quakeriſm is laid down in fifteen theſes, by Robert Barclay, in a well writ Apology addreſſed to king Charles II. Their hiſtory, writ in low Dutch by William Sewel, and ſince tranſlated into Engliſh, traces them from the beginning to the year 1717.—A hiſtory of this people was alſo publiſhed, anno 1695, by Gerard Croeſe; but that author is by them accuſed as having miſrepreſented facts, and in many reſpects done them injuſtice.

As to diſcipline and polity; the affairs of the communion are all managed under a democratical government, by rules eſtabliſhed by common conſent; and this principally at their meetings, whereof they have many kinds; viz. monthly, quarterly, yearly, ſecond day's meetings, meetings of ſufferings, &c.

Their monthly and quarterly meetings are held in their reſpective counties.— To theſe deputies are ſent from the ſeveral particular meetings.— Here inquiry is made into the ſtate of each meeting; who ſtand faſt to the rules and orders, and who backſlide; who pay tithes, and church rates, and who ſuffer for non-payment of either; who are married by prieſts, &c. and accordingly they proceed to cenſure, or incourage. —Here, too, they excommunicate, and here receive again into communion; of all which things exact regiſters are kept.

From theſe meetings appeals lie to their yearly ones, which are always held in London, and conſiſt of three orders or claſſes; viz. repreſentatives ſent from the quarterly meetings; correſpondents for the ſeveral counties and foreign countries; and miniſters, or preachers. —Hither are tranſmitted accounts of what has been tranſacted in all the monthly and quarterly meetings over all the world.— Here are meaſures concerted, and directions given as to behaviour about tithes and rates, providing for the poor, compoſing differences, &c.— Here public accounts are audited, and proper inſtructions given to the deputies to be obſerved at their return, and a yearly epiſtle of admonitions diſpatched to be read in all the monthly and quarterly meetings throughout the world.

The ſecond day's meeting, is a ſtanding committee conſiſting of the principal preachers in and about the city, who meet every Monday, to concert particular caſes and exigencies relating to the body, happening between the yearly meetings; particularly to examine, approve, licenſe, &c. all books printed in their behalf.

The meeting of ſufferings is held every week, and conſiſts of the correſpondents for each county.—Its buſineſs is to receive complaints from ſuch as have ſuffered for non-payment of tithes and rates, and to procure them relief, either by ſending them money, for which they have a ſettled fund, or by ſolliciting their cauſes above, or both.

QUALIFICA'TIONS *of members of parliament.* A knight, baronet, or any other under the degree of a baron, may be elected knight, citizen, or burgeſs.

An alien, though made a denizen, cannot ſit in parliament; even perſons naturaliſed by act of parliament are uſually reſtrained from ſitting as members. Perſons under the age of twenty-one years are not capable of being elected members of parliament. The election is void, and minors, though choſen, preſuming to ſit and vote, are under the ſame penalties as if they had ſat and voted without being choſen.

None of the judges of the King's-bench, Common-pleas, or barons of the Exchequer, that have judicial places, can be choſen knights, citizens, or burgeſſes of parliament. 4 Inſt. 47.

None of the clergy can be elected knight, citizen, or burgeſs of parliament; becauſe they are of another body, the convocation.

A perſon attainted of treaſon or felony is not eligible; for he ought, according to the writ, to be idoneus, diſcretus, & ſufficiens.

The king cannot grant a charter of exemption to any man, to be freed from election of knight, citizen, or burgeſs of the parliament.

For the incapacities of ſheriffs, mayors of towns, and the reaſons why they may or may not be elected knights, citizens, or burgeſſes, *vid.* 4 *Inſt.* 48. *Bro. Abr. Tit. Parliament. Cromp. Juriſd.* 3. 16. *Ruſhw. Collect. Townſh. Coll.*

QUA'LITY *of curvature,* in geometry, is uſed to ſignify its form, as it is more or leſs inequable, or as it is varied more or leſs in its progreſs through different parts of the curve.

QUA'NTITY (*Dict.*)— Mr. Machin, in the poſtſcript to the ſolution of Kepler's problem, inſerted in the *Phil Tranſ.* N°. 474, ſays, That he takes a mathematical Quantity, and that for which any ſymbol is put, to be nothing elſe but number with regard to ſome meaſure which is conſidered as one. For we cannot know preciſely and determinately, that is, mathematically, how much any thing is but by means of number. The notion of continued Quantity, without regard to any meaſure, is indiſtinct and confuſed; and although ſome ſpecies of ſuch Quantity, conſidered phyſically, may be deſcried by motion, as lines by points, and ſurfaces by lines, and ſo on; yet the magnitudes or mathematical Quantities are not made by that motion, but by numbering according to a meaſure.

Accordingly, all the ſeveral notations that are found neceſſary to expreſs the formations of Quantities, do refer to ſome office or property of number or meaſure; but none can be interpreted to ſignify continued Quantity as ſuch.

Thus ſome notations are found requiſite to expreſs number in its ordinal capacity, or the numerus numerans, as when one follows or precedes another, in the firſt, ſecond, or third place from that upon which it depends; as the Quantities x', x'', x, x', x'', referring to the principal one x.

So, in many caſes, a notation is found neceſſary to be given to a meaſure as a meaſure; as, for inſtance, Sir Iſaac Newton's ſymbol for a fluxion $\dot{x}$; for this ſtands for a meaſure of ſome kind, and accordingly he uſually puts an unit for it, if it be the principal one upon which the reſt depend.

So ſome notations are expreſly to ſhew a number in the form of its compoſition, as the index to the geometrical power x^n, denoting the number of equal factors which go to the compoſition of it, or what is analogous to ſuch.

But that there is no ſymbol or notation but what refers to diſcreet Quantity, is manifeſt from the operations, which are all arithmetical.

And hence it is, there are ſo many ſpecies of mathematical Quantity as there are forms of compoſite numbers, or ways in the compoſition of them; among which there are two more eminent for their ſimplicity and univerſality than the reſt; one is the geometrical power, formed from a conſtant root; and the other, though well known, yet wanting a name, as well as a notation, may be called the arithmetical power, or the power of a root uniformly increaſing or diminiſhing.

QUA'RRY, (*Dict.*)— For Quarries of free-ſtone, they firſt open a hole in manner of a well, twelve or fourteen feet in diameter; and the rubbiſh, drawn out with a windlaſs in large oſier baſkets, they heap up all around; placing their wheel, which is to draw up the ſtones, thereupon.

As the hole advances, and their common ladder becomes too ſhort, they apply a particular ladder for the purpoſe—When they have got through the earth, and are arrived at the firſt bank, or ſtratum; they begin to apply their wheel and baſkets to diſcharge the ſtones as faſt as they dig through them.

They uſually find ſeven of theſe different ſtrata, or beds of ſtones, of different heights, and ſerving for different purpoſes; though the number, as well as order wherein they follow, is various.

As to the drawing of the ſtone, i. e. the freeing it from the bed, they find that common ſtones, at leaſt the ſofter kinds, as they lie, have two grains; a cleaving grain running parallel with the horizon, and a breaking grain perpendicular thereto.—After uncoping, i. e. clearing the earth from off it, they obſerve by the grain where the ſtone will cleave, and there drive in a good number of wedges till they have thus cleft it from the reſt of the rock.

This done, they proceed to break it: in order to which, applying the ruler to it at both ends, (ten, e. gr. or twelve inches apart, according to the uſes the ſtone is intended for) they ſtrike a line, and by this cut a little channel with their ſtone-ax; and in the channel ſet five or ſix wedges (ſuppoſing the ſtone three or four feet) driving them in very carefully, with gentle blows, and ſtill keeping them equally forward.

Having thus broke the ſtone in length, (which they are able to do to half an inch of any ſize) applying a ſquare to the ſtraight ſide, they ſtrike a line, and proceed as before to break it in breadth.

This method of drawing is found vaſtly preferable to that where the ſtones are broken at random.—One load of the former is found to do the buſineſs of a load and an half of the latter.

But it may be obſerved, that, this cleaving grain being generally wanting in the harder ſtones, to break up theſe in the Quarries, they have great heavy ſtone-axes wherewith they work down a deep channel into the ſtone, and into this channel, a-top, lay two iron bars, driving their iron wedges between theſe bars.

Some in drawing of ſtone, eſpecially the very hard kind, make uſe of gun-powder, and with very good effect.—In order to which, making a ſmall perforation pretty deep into the body of the rock, ſo as to have that thickneſs of rock over it judged proper to be blown up at once; at the farther end of the perforation they diſpoſe a convenient quantity of gun-powpowder, filling up all the reſt with ſtones and rubbiſh ſtrongly rammed in, except a little ſpace for the train. — By this means is the rock blown in ſeveral pieces, moſt of them not too unweildy for a workman to manage.

In ſeveral parts of England we find ſea-ſhells buried in hard ſtone, and under great beds of earth.

Near Broughton, in Lincolnſhire, all the Quarries abound with them. At the eaſt end of the town there is a Quarry of a ſoft ſtone, which they dig through to get at a bed of clay, which is of peculiar glutinous quality, and hardens like mortar in drying; this is uſed for cementing other ſtones together, and in this are innumerable fragments of ſhells of cockles, ſcallops, ſea-echini, and corals; and among theſe fragments there are found ſome whole ſhells of their natural colours, and often wholly unhurt; though ſome of them are bruiſed and preſſed quite flat by the great weight of earth that lies upon them. On the ſouth ſide of the town there is a Quarry of a blue ſtone, which was doubtleſs in the times before the deluge a blue clay, of the ſame nature with that juſt mentioned. This contains in its body vaſt numbers of the ſame ſorts of ſhells, and of many other kinds; but they are all ſo firmly bedded in the ſtone, that it is not eaſy to get them out whole: but there is this very remarkable, that they only lie in the ſuperficial part of the ſtone, the ſtratum being very thick, but not one ſhell found in it beyond the depth of two feet from the ſurface.

The ſurface of this ſtratum of ſtone is not even and ſmooth, but is waved and ridged irregularly, like a bed of ſnow, or like the waves of the ſea in the time of a ſmall wind. This has juſt the appearance that the ſurface of a maſs of half hardened matter muſt have, if the wind blew fiercely upon it from one quarter; and, by the direction of theſe undulations, it is eaſy to ſee from what quarter the wind blew at that time. In that part of the ſtone which forms this undulated roughneſs, there are as many ſhells as any where elſe; and theſe lie partly buried and partly ſtanding out of the ſtone, juſt as we ſee the freſh-water ſhell-fiſh lie half in and half out of the mud of the bottom of a pond or river that is dried up in ſummer.

It is very obſervable, that, in this caſe, as much of the ſhell as is within the ſtone is perfectly well preſerved, and as hard as ſtone; whereas that part which ſtands out is either wholly decayed, or at the beſt of the nature of a rotten ſhell, which falls to pieces on being touched with the hands. The part of the ſhell within the ſtone is uſually converted into a maſs different from the ſhell in all things but figure; but that which ſtands out always preſerves the true texture of the natural ſhell, and is made up of many flakes and cruſts as the natural ſhells of the kind to which it belongs are.

Among the ſhells buried in the ſubſtance of the ſtone, ſome have their ſhell perfect on them, others have only a thin cruſt of a whitiſh ſtony matter in the place of it, and others are wholly naked, and have no ſhell nor any covering at all: theſe are properly only caſts of ſtone in the places where ſhells once were, all the matter of the ſhells themſelves having been diſſolved and waſhed away. In ſome of theſe there is a thick white ſubſtance in the place of the ſhell, between the caſt and the bed of ſtone: theſe come out the moſt eaſy and perfect of any, and the matter which ſupplied the place of the ſhell remains faſtened to the bed of the ſtone; others ſeparate themſelves very perfect after froſty nights.

Some of the cockles and other bivalves are found cloſed, others are found half open, as ſhell-fiſh naturally open their ſhells when deſerted by the water. In theſe the cavity is always filled with the matter of the ſtratum, and both petrified together. In ſome places they lie in heaps together in the ſtone, and there they uſually enter into and injure one another. Some are found ſhut ſo cloſely, that the matter of the ſtone-bed could not get into their cavity; and, of theſe, ſome are at this time wholly empty, others are filled, or partly filled, with cryſtals and ſpars: theſe bodies muſt have been in them only from the cryſtalline and ſparry matter riſing through the earth in vapour, and penetrating the very ſubſtance of the ſhells after their being lodged in the ſtone.

In this Quarry there is alſo found a very remarkable ſhell, reſembling a ram's horn, bent in the ſame manner, and with the ſame lineations. This is wholly different from the common cornu ammonis claſs, and has an operculum to cloſe its mouth with, in the manner of the wilks and other ſuch ſhells. This operculum is often found entire with the ſhell, or near it, in the ſame bed of ſtone.

This ſpecies of foſſil ſhell is found in prodigious numbers together, and uſually lies near the ſurface of the bed of ſtone, a part being buried in the ſtone, and a part ſtanding out of it; many of them ſtand more than half-way out, and the ſhell of theſe is ſo much more durable than that of the common kinds, that it is uſually very firm and ſtrong, even in ſuch places where the other kinds moulder all away. Theſe are uſually found entire, but in ſome places they are cruſhed flat, and otherwiſe bruiſed and injured.

From theſe and the like obſervations made on the whole ſurface of the earth, and to great depths in its bowels, wherever men have dug on any occaſion, ariſe plain proofs of the univerſality of the deluge; and from many of theſe obſervations it ſeems very plain, that in the time of the deluge the earth ſuffered great violence in many parts, that the bottoms of ſeas were in ſome places raiſed into mountains, and in others the tops of mountains ſunk into ſeas, and the beds of ſhells ſtill preſerved in the foſſil world were very often cruſhed and bruiſed by large maſſes of earth and pieces of rock thrown upon them.

Some think that it appears from the conſideration of the Quarries and ſtrata of earth, &c. in the preſent world, that the antediluvian earth had ſeas and ſhores, mountains and plains, rivers and vallies, as ours has; and that waters from within the earth were let out upon its ſurface, and the whole cruſt of the then world ſubſided under theſe; that the contents of the ſeas, ſuch as ſhells, corals, and the like, were after this toſſed variouſly about over the ſurface of this drowned world, and left in different parts of it; and that this preſent earth afterwards partly aroſe out of the common flood, as iſlands are now formed in ſome ſeas, and partly was deſerted by the waters, when called off again by the ſame almighty hand that brought it on: and, as the ſtrata of the earth were at that time ſoft, it is no wonder that matter then ſoft enough to let in the ſhells, &c. afterwards hardened, together with the ſhells it had received, into ſtone; and that in proceſs of time the ſtony particles, eternally floating in the air and waters that pervade all the ſtrata, depoſited their ſmall parts in the interſtices of theſe ſhells, and finally the whole became ſtone.

It is no wonder that all ſorts of marine productions, ſhells, parts of ſea-fiſhes, corals, and the like, are found at this time in beds and Quarries, in hills and mountains, and alſo in the bowels of the earth; for it is certain that they were produced in the antediluvian ſea, and were either elevated with the hills and mountains in the time of the deluge, or they fell into holes, clifts, and chaſms in the earth, which muſt be formed in vaſt numbers during the time of that terrible cataſtrophe, and in theſe they remain buried to this time; while others, lodged on what was then the ſurface, became afterwards covered with more ſtrata, depoſited from what was ſtill ſuſpended in the waters, and ſo were buried at great depths from the preſent ſurface; when others rolling about among the laſt ſediments of the ſame waters, while yet ſo unfixed as to be carried away with their violence, were finally left on or near the ſurface.

The Quarries about Broughton ſeem to have been but little diſturbed, and to have been originally the mud which formed the bottom of ſome large freſh-water lake; for the ſhells, found in greateſt plenty of all there, are freſh-water ſhells. Theſe ſeem to have remained in their original mud while turned to ſtone; and the other ſhells, natives of the ſea, which are buried there among them, ſeem to have been ſome of that immenſe number and variety that muſt have rolled along the bottom of that bed of waters; and the viſcid nature of the clay detained many of theſe among its own proper inhabitants, and preſerved them together in its ſtrong ſtate.

Beſides the parts of animals, theſe Quarries have vegetable matters alſo in them: the leaves and branches of whortles are not uncommon, and pieces of wood turned black and reſembling charcoal are alſo found there. Theſe have been preſerved in the ſame manner with the leaves of fern on the ſlate of our coal-pits, and the plants and fiſhes found in hard ſtone in many of the German mines. Many of theſe vegetable remains are alſo found in looſe nodules of ſtone reſembling pebbles: theſe are not leſs eaſily accounted for than the reſt; for it is not ſtrange to conceive, that leaves and pieces of plants might be, in that general confuſion, received into lumps of clay, which might afterwards be rolled into roundneſs by the motion of the water, and finally received into chaſms of the earth, and there petrified. *Phil. Tranſ.* N°. 266.

QUA'RTAN (*Dict.*)—*Continual* QUARTANS, in medicine, the name given to a ſpecies of compound fever, which has the paroxyſms of a common Quartan; but in which the heat never goes wholly off, but continues till the time of the ſucceeding fit. In all reſpects, except the regular returns of the paroxyſms, this diſeaſe greatly reſembles a hectic.

Signs of it. Every fourth day there is a regular paroxyſm, which begins with a coldneſs and ſhivering: this, however, does not return exactly to an hour, as the ſimple Quartan does in its fits; but uſually the ſucceeding fit anticipates the time of the former. When the cold fit is over, there comes on a violent day burning; the heat is much greater the firſt day than the ſucceeding ones, but continues in ſome degree till the fourth day, when the cold fit returns again, and the patient is ſeldom able to keep long together out of bed in the whole time. There is a continual thirſt, and dryneſs of the mouth, and the ſaliva is very little in quantity and very frothy; the appetite is bad, and the patient has uſually more inclination to ſalted and cold foods than any other; the head is diſordered rather than aking, and there is a continual deſire to ſleep, but what ſleep the patient has, is troubled and unſound, and gives very little refreſhment; the urine, during the whole courſe of the diſeaſe, reſembles, that of hectical patients, and is reddiſh and turbid, depoſiting, after a time, a roſe-coloured ſediment.

Perſons ſubject to it. This diſeaſe is frequently brought upon perſons who have had a common Quartan, by the injudicious treatment of that diſtemper, and particularly by the taking hot medicines in it before the approach of the fit; the too free uſe of aſtringents has alſo in many caſes changed that diſeaſe into this. People of a middle or more advanced age are more ſubject to it than youth; and, of theſe, ſuch are principally ſeen to be afflicted with it, as are of a melancholic habit and ſedentary life.

Prognoſtics in it. This diſeaſe, though in itſelf leſs dangerous than many others, yet very eaſily changes, under improper management, into a hectic, and ſometimes into a dropſy. This is the caſe not unfrequently, when it is treated with large repeated doſes of aſtringents; on the other hand, when it is treated with vomits and a hot regimen, it eaſily paſſes into an acute and dangerous inflammatory fever.

Method

Method of cure. Towards the time of the fit there should be given powders composed of the digestive salts, such as vitriolated tartar, with crabs-eyes, saturated with lemon juice. So long as the heat continues violent, the person is to be kept quiet, and to drink plentifully of warm and weak liquors; and in the following days, when the heat is observed to be decreased, gentle purges are to be given, with gentle aperitives and resolvents, such as the decoctions of dandelion and succory roots; and, towards evening, a gentle dose of some anodyne, as the storax pill and the like. The common violent methods by vomits, bleeding, stimulating purges, and hot alexipharmics, have no place in the cure of this disease; but, on the contrary, violently disturb nature, and add to the complaints. Absorbents in large quantities are also to be avoided, lest the viscid matter which is the cause of the disease should be increased by their effects: and, when the patient is happily cured, he is not immediately to abstain from medicines, since relapses are very frequent. Digestives and stomachics, taken for some weeks after, is the way to prevent them. *Junker's Consp. Med.*

QUARTA'RIUS, a measure among the antients, being the fourth part of a sextary, and nearly equal to a quarter of a pint of our wine-measure.

QUA'RTER-*chord*, in mining, is seven yards and a quarter, which the miner hath cross-ways of his vein on either side, for liberty to lay his earth, stones, and rubbish on, and to wash and dress up his ore. *Houghton's Compl. Miner in the Explan. of the Terms.*

QUARTER *of a ship*, is that part of the ship's hull which lies from the steerage room to the transom.

Close-QUARTERS, in a ship, those places where the seamen quarter themselves, in case of boarding, for their own defence and clearing the decks.

QUA'RTERING *the men*, in the sea language, the disposing of the ship's company at the time of an engagement in such a manner, that each may know where his station is, and what he is to do: as, some to the master, for the management of the sails; some to assist the gunners, to traverse the ordnance; some for plying the enemy with small shot; some to fill powder in the powder-room; others to carry it from thence to the gunners in cartridges, &c.

QUEEN-*bee*, a name given by late writers to what used to be called the king-bee, or king of the bees; a large and long-bodied bee, of which kind there is only one found in every swarm, and which is always treated with the greatest respect by the rest.

This is, indeed, the parent of the swarm, and from the fecundity of this one female, a whole hive is easily and soon re-peopled.

It is to be observed, that the autumn and winter seasons destroy a great number of the bees; so that a hive, which was full in the summer, is often found so thinly peopled before the end of winter, that the bees seem only a few inhabitants in a very large city: by Midsummer again this same hive shall, however, be found so well filled with inhabitants, that there shall be a necessity of sending out a colony in the name of a new swarm, and yet the hive will remain as full as it can well hold. This increase might well appear very amazing, if all the remaining bees of the hive were supposed to be females, and to join in it; but how much more so when it must be acknowledged, that it is all owing to one female, and that this Queen-bee, or bee-mother, alone, has given origin to such an immense progeny?

The form of this bee, and there being only one such in a hive, naturally led all who saw it into an opinion of something singular in its nature, and the antients determined that it must be the king over the rest: they made it an absolute monarch, and have supposed that all the business of the hive was done by its immediate orders; and that the several parties of bees allotted to work in the making the combs, in the filling their cells, in the stopping the crevices of the hives, and in carrying away the filth, &c. had all their several stations allotted them by this wise and provident monarch. This was giving great talents to the monarch-bee; but this was mere fancy, and it is plain, that, if this creature rules, it is over a people who all perfectly well know their several business: but it rather appears, that there is no sovereignty at all, but that this creature is respected in a very high degree by the rest as the common parent of the whole nation.

There were not wanting among the antients, however, some who believed this large bee to be a female, and these pretend that she brought forth only females like herself, which succeeded her in her reign. They had a very different opinion as to the origin of the common bees, not supposing them generated of animal parents like themselves, but produced out of corruption, and born of the flesh of a bull or cow. Among the later writers this opinion, notwithstanding the sanction of the poet Virgil, has been laughed out of the world; yet it was long before the true origin of bees, even after this, was known. The author of the female monarchy, though well apprized of this great bee being of the female sex, yet supposed that she only produced young ones like herself; and pretended that the common bees copulated together for the production of other bees like themselves: this, however, has been since found to be wholly erroneous, the female, or Queen-bee, giving birth to all, and these common bees being of no sex at all. Many of the authors who have not given into the idle opinion of the bees being bred of putrid flesh, have yet given them an origin not less idle and ridiculous. They pretend that the bees are exempted from the pain of producing either eggs or young; and that their offspring are formed of the juices of flowers, the different kinds, as the drones, females, &c. owing their rise to juices of different kinds. These, and a number of other false notions, have been propagated in regard to bees; but their true origin could not well be found till we were in a condition to see what passes at certain times within the recesses of the hive, which is done by the use of that excellent invention the glass hive. By this, and by the help of dissections, we may easily inform ourselves perfectly of the true state of the case. The parts of generation are the subjects of our enquiry for this purpose, and, though the bodies of these animals are so small, these are usually sufficiently large to be distinguished, often taking up more room in the abdomen than all the other parts together. Thus, if the large long-bodied bee be opened, the abdomen will be found to contain vast numbers of oblong bodies, which any one acquainted with insects will easily distinguish to be eggs: vast numbers of these are large enough to be observable by the naked eye, but, when the assistance of glasses is called in, there are discerned a vast number of other smaller eggs, which exceed all computation. It is easy to determine from this, that this creature, so long esteemed a male, is in reality a female, and is in condition to give birth to a very numerous posterity.

In order to distinguish this, however, a proper time must be chosen for the dissection, and the most proper of all is when the creature is just ready to deposit her eggs. This is in the months of April and May, and the most certain time of all is when she is in a hive where a new swarm have been received about ten days before: if she be dissected at other times, the eggs are less visible; and, particularly in winter, there requires a good glass to shew the rudiments of them. This is a disagreeable experiment, indeed, because it is always the destruction of a future swarm; all the eggs we see in the dissected female being what would have produced bees to labour for our benefit.

When the body of one of the drones is opened, there is found, instead of these vast numbers of eggs, a part seeming proper for a male organ of generation; and in the abdomen a number of vessels running in several windings and contortions, and filled with a milky humour. These seem destined for the important use of impregnating the eggs in the belly of the female, and it is very natural to determine from this that these are the males.

The common bees, when dissected, at whatever time of the year, never shew the least marks of any sex at all. The intestines of these bees are found at times to be more or less distended with honey, and with rough wax; but there are never discovered any eggs, nor any of the winding seminal vessels, so that it is plain they have no share in propagating the species: and the observation of the swarms from time to time, with the assistance of glass hives, gives proof to what the dissections seem to make sufficiently certain without this evidence.

The female bee resides within the center of the hive, always living in one of the spaces between the combs; if she occasionally comes out to the surface, and is seen walking over the edge of a comb, she is to be well observed at those times; for her only business is the laying her eggs in some of the empty cells of that part of the comb, which done, she always retires again.

In order to see the female, or mother bee, employed in this operation, we are to observe in the morning hours, between seven and ten, what passes in a glass-hive into which a swarm have been received a few days before. The speed with which the common bees labour in making their combs on this occasion is almost incredible, and they seem not only to labour to have cells to deposit their honey in, but to know that the parent bee is at this time loaded with eggs for the production of a numerous progeny, and that she has an immediate necessity of cells for the depositing them in. This necessity is so urgent, that she is often forced to deposit them in cells not yet finished; though the bees labour so vigorously, that they often will erect a whole large comb in one day. If the hive be narrowly watched at these times in the morning hours, the female bee will be soon found employed in her work, and will be seen dropping her tail by turns into several cells every day. If the combs be examined a day or two after this, they will also be found to contain the eggs; one of these is placed in each cell, and appears in form of an oblong white body, fixed either to the solid angle of the base, or to one of the angles composed by the rhombs which form the triangular base of the cell, and is always attached in such a manner, that it lies nearly in an horizontal position.

The flat glass hives are the most favourable for the making these observations, since in those the combs are so narrow and so numerous, that the whole is taken in view at a time, from one side or the other; and there are always several combs to be made choice of for the operation; in the morning hours of April and May, the female mother-bee will be usually seen walking

walking very foberly over one or other of thefe combs, attended by a guard of about twenty of the common bees, all placing themfelves in fuch a manner, that their faces are turned towards her, and all paying her the greateft marks of homage and adoration. As fhe walks along in this ftate, fhe examines every cell as fhe paffes over, and fuch as fhe finds yet empty, and fit for her purpofe, fhe refts at: and, introducing the hinder part of her body at the top, plunges it fo deep in that her tail touches the bottom. Then fhe depofits one egg and no more, and this is at that time covered with a glutinous matter, which faftens it to the place where it is laid: from this cell the female paffes to feveral others, where fhe depofits her eggs in the fame manner.

Some authors who have written of the polity of bees, have reprefented the time of the female bee's laying her eggs as a feafon of feftivity and rejoicing in the hive; but this does not at all appear to be the cafe; the few bees which attend her on this occafion feem the only ones that know any thing of the matter, and their behaviour favours more of homage and refpect than of joy: they are continually ftroking and brufhing her clean with their legs and with their trunks, and offer her from their own mouths the fineft honey, when fhe has occafion for food. The reft are all employed in their proper offices, and the work of the hive goes on as ufual; and, indeed, it is well that it does fo, for this time of rejoicing would be of very bad confequence to the affairs of the hive, if carried on as fuppofed, fince the female bee is thus employed, more or lefs, during the whole fummer months.

When the female bee has laid fix or feven eggs, fhe always takes a time of refpite or repofe; and, during this time, the bees which form her levee are doubly bufy in their careffes, fome brufhing her head and breaft with their trunk, but feveral being always employed together to cleanfe the hinder rings of the body, which have been fouled by being thruft into the cells. When this is done, fhe begins again; but Mr. Reaumur obferves, that he never could fee a female lay more than ten or twelve eggs at one time: he fuppofes that his prefence difturbed the creature, and finally drove her into the inner parts of the hive, where fhe might continue her works in cells lefs expofed. It is not difficult to compute the number of eggs which the female lays every day, from the fwarm which is ready to leave the hive at the end of May: this fwarm ufually amounts to at leaft twelve thoufand, and, as the hive out of which thefe depart is not the lefs peopled by their lofs, it is evident that they were all the produce of the eggs depofited by the female in the preceding months of April, with a part of March, and a few of the firft days of May. On a moderate computation on thefe principles it will appear, that the female bee cannot lay lefs than two hundred eggs every day, for a long fpace of time together; and this, though feemingly a monftrous increafe, is yet much lefs than that of fome other of the winged infects, in one of which, a two-winged fly, that author counted no lefs than twenty thoufand living worms, all ready to be depofited by the parent, and to become flies of the fame kind.

It has been ftrongly objected againft this fyftem, that, though the female bee lays eggs, fhe is not the only one that lays; and many will not give up the opinion of the common bees alfo laying fome eggs, though but a few in number; obferving, that, if each of thefe lay only four or five eggs, it would be enough to give birth to a whole fwarm, without fuppofing that this prodigious fœcundity belonged to the female bee alone: but this is running into the old error of the female producing only females like herfelf; whereas, if we obferve the cells in which we fee the female depofit her eggs, we fhall in the fequel find the common bees produced from thefe eggs, and iffuing out of thefe cells: this is a fufficient proof to any fair reafoner, fince it appears very plain, that, if the female produces them, they do not produce one another. It is alfo evident, that not only thefe common or working bees, but alfo the drones, or male bees, are produced from the eggs of this fame female; and there is this remarkable forecaft in the female, that fhe always depofits the eggs which are to give origin to thefe, in peculiar cells, proper for the reception of the worms which are to be hatched from them. It is obferved, in examining a hive, that there are always fome combs, or fome parts at leaft of combs, the cells of which are much larger than thofe of the other parts or combs: thefe large cells are deftined for the refidence of the larger worms, which are to produce the drones or male bees. It has been obferved as a miraculous fingularity by fome, that the female bee always knows before-hand, whether the egg fhe is going to lay will produce a male or a common bee; and that, according to this knowledge, fhe never depofits the eggs for a male in a fmaller cell, nor that of a common bee in a large one; but there is, in reality, lefs wonder in this than is fuppofed, for the eggs of which the drones are to be hatched are much larger while in the body of the female than thofe of which the common bees are to be produced, and the whole occafion of this choice in regard to the placing of them is, that, when the creature finds a large egg coming forth, fhe feeks one of the large cells to depofit it in; and, when the common fmall eggs are coming, fhe contents herfelf with the common cells.

It is very natural to believe, that the female bee lays a third kind of eggs; and that, befides producing many thoufand common, or working bees, and many hundreds of the males or drones, fhe ought to lay one egg at leaft capable of producing a female like herfelf, which is to be the mother of a future progeny, and the Queen of the prefent race; fince, without fuch a one for their leader, the young brood would never leave the hive in the nature of a colony, and fettle themfelves elfewhere. What we thus perceive ought to be the cafe, is alfo found in reality to be fo, and the female, befides the other kinds of eggs, is found by a ftrict obfervation to lay alfo eggs of this kind. We might perhaps only expect one female bee to be produced for each fwarm, but, as nature has feemed everywhere prodigal in the manner of the increafe of her works, fo it is in this cafe alfo. What millions of feeds are produced on a common elm-tree, for one that ftrikes and fucceeds fo well as to grow up to be a tree? And, of the number of young produced from the fpawn of a carp, how few live to the fize of a parent? Thus it alfo is in regard to the female bees: nature, though it has allotted only one of this kind, as abfolutely neceffary to the new fwarm, yet has given abundance of chances for that one to fucceed, by the female's ufually laying at leaft ten eggs for the production of the female offspring, and often not lefs than twenty: there are, indeed, fome feafons when not one female is produced; but in thefe feafons there is no fwarm going out from the old hive, the creatures being informed by nature, that they have no bufinefs for combs and cells when they can have no offspring to rear in them.

The working bees are not only very obedient to, and very careful of their Queen, or female parent; but they are alfo very follicitous about her progeny. This is very evident in the ftructure of the cells, which they prepare for the reception of thofe eggs which are to be hatched into females. It has been before obferved, that they prepare larger cells for the eggs which are to become drones, or male bees, than for thofe which are to produce workers like themfelves. The large cells deftined for the drones are, however, of the fame fhape and figure with the others, differing only in fize; but this is not the cafe with thofe deftined for the female offspring: thefe are not only very large, but very clumfily contrived, for the fake of ftrength; their fides being much thicker than thofe of the reft, and their figure oval. The bees are extremely fparing of their wax on all other occafions, but for the conftruction of thefe royal cells, as they may not improperly be called, they are as remarkably profufe: one of the royal cells will weigh more than an hundred and fifty of the common kind. The bees are no more fparing of the room than of the materials in the conftruction of thefe royal habitations: they are often placed near the center of a comb, and a vaft number of other cells are deftroyed for their bafe; often alfo they hang down from the reft of the comb, in form of ftalactitæ from the roofs of fubterraneous caverns.

A cell of this kind, when firft formed, reprefents an acorn cup; but it is foon lengthened beyond the poffibility of retaining that figure, and it remains thus till the creature is hatched from the chryfalis or nymph ftate, and comes out of it; after which the bees, to lofe no room in the hive, form other common cells upon it, and the only remaining mark of the female cell, is the appearance of a knot in the place where it once ftood.

The number of cells deftined to receive the eggs which are to produce female bees are fo few, and they are commonly placed in fuch clofe parts of the hive, that there is no great probability of the feeing the female employed in laying her eggs in them: there is no reafon to doubt the fact, however, fince, when we know that fhe lays eggs for the production of the male and the working bees, there is no wonder that fhe fhould alfo lay fome for the production of females like herfelf.

It might feem much harder to conceive how fo vaft a number of bees fhould be produced from this one, as we know are produced from her; but, when one of the females is opened, the vaft number of eggs difcovered in each of her ovaries makes the prodigious increafe no way wonderful.

Swammerdam obferved, that the number of veficles in the ovary of the female bee was aftonifhingly great; he eafily counted an hundred and fifty in each ovary, and could count about feventeen eggs in each veficle large enough to be diftinctly vifible; each ovary contains, therefore, two thoufand five hundred and fifty eggs, and both ovaries five thoufand one hundred. When we find fo many eggs at once diftinguifhable by their fize, it will be eafy to conceive, according to the common courfe of nature in the propagation of infects, that there may be more than as many too fmall to be yet diftinguifhable; and, at that rate, the number of twelve thoufand bees, which is the quantity that compofes a moderate fwarm, is not wonderful for the product of the eggs of one female for one feafon. *Reaumur's Hift. Inf.*

QUE'RCUS, *the oak*; fee the article OAK.

QUERCUS *marina*, *the fea oak*, in botany, the name of one of the broad-leaved dichotomous fea-fucufes.

It is not agreed among the late botanifts what was the fea-oak of Theophraftus; and the moft ancient botanifts, Clufius and Cæfalpinus, fuppofe it to have been a fpecies of the fhrubby coralline; but that feems by no means to have been the cafe, fince Theophraftus fays his fea-oak had a long, thick, and flefhy fleshy leaf, when we may more naturally conclude it to have been of the fucus class. *Park. Herb.* 294. *Gen.* 1378, *&c. Dale, Pharmac.*

QUERQUE'DULA, in zoology, the name by which authors call the teal.

This is the smallest of all the duck kind. Its beak is black, and its head and the upper part of its neck of a reddish brown; but there runs on each side of the head a green streak from behind the eyes quite to the back park, and between these there is a black spot under the eyes; there is a white line which separates the reddish colour from the green. The lower part of the neck, the shoulders, and the sides are very beautifully variegated with black and white streaks. The breast and belly are of a dusky greyish white. The wings have some white in them, and the legs are of a pale brown. There is a black spot on the rump in the male, which is wanting in the female. The head also in that sex is less beautifully coloured. *Ray's Ornithol.*

QUERQUEDULA *cristata*, the crested teal, given by Bellonius and some others to a species of duck, remarkable for a tuft of feathers of an inch and a half long, hanging down from the back part of its head, and thence called the tufted duck, but more known among authors by the name capo negro. *Bellonius de Avib.*

QUICK.—By the word Quick are generally understood all live hedges, of whatever sort of plants they are composed, to distinguish them from dead hedges: but, in the more strict sense of this word, it is applied to the hawthorn, or mespilus sylvestris; under which name the young plants, or sets, are commonly sold by the nursery gardeners, who raise them for sale.

In the choice of these sets, those which are raised in the nursery, are to be preferred to such as are drawn out of the woods; because the latter have seldom good roots; though, as they are larger plants than are commonly to be had in the nursery, many people prefer them on that account: but from long experience I have found, that those hedges which have been planted with young plants from the nursery, have always made the best hedges. Indeed, if persons would have patience to wait for these from seed, and to sow the haws in the place where the hedge is designed, these unremoved plants will make a much stronger and more durable fence, than those which are transplanted: but I am aware that most people will be for condemning this practice, as being tedious in raising; but, if the haws are buried one year in the ground, to prepare them for vegetation; before they are sown, it will not be so long before this will become a good fence, as is generally imagined. Nay, from some trials of this kind, which I have made, I have found, that those plants which have remained where they came up from seed, have made such progress as to overtake, in six years, plants of two years growth, which were transplanted at the time when these seeds were sown.

And, if the hedges are raised from seed, it will not be amiss to mix holly berries with the haws, and, if so, these berries should also be buried one year, to prepare them, so that then both will come up together the following spring; and this mixture of holly with the Quick will not only have a beautiful appearance in the winter, but will also thicken the hedge at the bottom, and make it a better fence.

But, where the hedge is to be planted, the sets should not be more than three years old from the haws; for, when they are older, their roots will be hard and woody; and, as these are commonly trimmed off before the sets are planted, so they very often miscarry; and such of them as do live, will not make so good progress as younger plants, nor are they so durable; for these plants will not bear transplanting so well as many others, especially when they have stood long in the seed-bed unremoved. *Miller's Gard. Dict.*

QUI'ETISM, the sentiments of the Quietists, a religious sect which made a great noise towards the close of the last century.

Molinos, a Spanish priest, who died at Rome in the prison of the inquisition, passes for the author of Quietism; and yet the Illuminati in Spain had taught something like it before.

The name is taken from a sort of absolute rest, and inaction, which the soul is supposed to be in, when arrived at the state of perfection, which in their language is called the unitive life.—To arrive at this, a man is first to pass through the purgative way; that is, through a course of obedience, inspired by the fear of hell: hence, he is to proceed into the illuminative way, before he arrive at perfection; to go through cruel combats, and violent pains; i. e. not only the usual drinesses of the soul, and the common privations of grace, but infernal pains: he believes himself damned; and the persuasion that he is so, continues upon him very strongly several years: St. Francis des Sailes, says the Quietists, was so fully convinced thereof, that he would not allow any body to contradict him therein. — But the man is, at length, sufficiently paid for all this, by the embraces of God, and his own deification.

These sentiments of the Quietists, with regard to God, are wonderfully pure and disinterested.— They love him for himself, on account of his own perfections, independently of any rewards or punishments: the soul acquiesces in the will of God, even at the time when he precipitates it into hell; insomuch that, instead of stopping him on this occasion, B. Angelo de Foligny cried out, 'Haste, Lord, to cast me into hell: do not delay, if thou hast abandoned me, but finish my destruction, and plunge me into the abyss.'

At length, the soul, after long travail, enters into rest, into a perfect quietude.—Here it is wholly employed in contemplating its God; it acts no more, thinks no more, desires no more; but lies perfectly open, and at large, to receive the grace of God, who by means thereof drives it where it will, and as he will.

In this state, it no longer needs prayers or hymns, or vows; prayers where the spirit labours, and the mouth opens, are the lot of the weak and the imperfect: the soul of the saint is, as it were, laid in the bosom, and between the arms of its God, where, without making any motion, or exerting any action, it waits, and receives the divine graces. — It, then, becomes happy: quitting the existence it before had, it is now changed, it is transformed, and, as it were, sunk and swallowed up in the divine being, insomuch as not to know or perceive its being distinguished from God himself. *Fenel Max. des Saints.*

QUINQUEFO'LIUM, *cinquefoil*, in botany, a genus of plants, whose characters are:

The root is fibrous and perennial: the leaves grow by more than threes, at the top of the pedicle, round one center: the calyx is monophyllous, not caduceous, and, as it were octophyllous, or decaphyllous, expanded like a star, and furnished with very numerous stamina, proceeding from the compass of the base of the ovary: the flower is rosaceous, pentepetalous, and more rarely tetrapetalous, the petals standing round the base of the ovary: the ovary is a feminal head, involved in a calyx, hemispherical, and has several eggs, furnished with a long erected tube. The common cinquefoil, or five-leaved grass, has a large spreading, thick, woody root, covered with a dark-brown bark, and full of small fibres, sending forth many slender creeping stalks, which lie on the ground, emitting small fibrous roots from the joints, by which it easily propagates itself; at every joint grows the leaves, five set together upon one long foot-stalk, which are narrow, veiny, serrated about the edges, the two outermost being the shortest: amongst these come forth the flowers, consisting of five round yellow leaves, with several stamina in the middle, set, also, on long foot-stalks; and, after them, small, brown, naked seed: it grows everywhere by hedges and way-sides, flowering all summer. The leaves and root are used.

They are restringent and drying, and serviceable against all kinds of fluxes and hæmorrhages: the powder of the root, given to the quantity of a drachm, two or three times a day, is said to cure agues. The same is, also, accounted good against malignant distempers, and is an ingredient in Venice-treacle: it is frequently used in gargles for sore mouths and ulcerated gums, and to fasten loose teeth. *Miller's Bot. Off.*

QUINQUERTIO'NES, among the Romans, an appellation given to those who had gained the victory in the quinquertium or pentathlion.

QUINQUER'TIUM, among the Romans, was the same with the Grecian pentathlon, comprehending the five exercises of running, leaping, throwing, darting, and wrestling.

QUI'NTAIN, QUINTENA, in ancient customs, a post driven into the ground, with a buckler fixed to it, for the performance of military exercises on horseback, throwing of darts, breaking of lances, &c.

Math. Paris describes the Quintain as a kind of mark, formed like a man from the navel upwards, holding a shield in his left hand, and in his right a sword or stick; the whole so fitted as turn round on its foot, and so as that, a cavalier running a-tilt against it with a lance, if he hit it in the breast, it whisked round, and, unless he were very dexterous, struck him with the sword held in the other hand.

In other places, a-top of a post, was erected a slender beam fitted to turn round a spindle; at one of whose ends was a slope or flat board, and at the other a bag of sand, or dirt. — The sport was, with a long staff, or wooden lance, to ride a-tilt at the board, and to be either so skilful or lucky to escape the blow of the sand-bag.

This some take to be the same with the arietum levatio, frequently prohibited in our synods and episcopal constitutions.

The custom is still retained in Shropshire, and some other counties, among the nuptial solemnities.—He that breaks the most poles against the Quintain has the prize, which was anciently a peacock, now a garland.

Some derive the word from an ancient game called quintus; others from a man of the name Quintus.

The Vallus and Passus, mentioned in Cæsar, are taken, by Vigenere, for a kind of Quintain, or wooden man fixed up as an adversary, or man of straw, to prove one's dexterity against.

Mention is made of this exercise in the code, de aleatoribus, and in the paratitles of Cujas on the same — Juvenal speaks of women engaging therein:

Aut quis non vidit vulnera Pali?

QUINTAIN was also a right which the lord had to oblige all the millers, watermen, and other young people unmarried, to come

come before his caſtle every three years, and break ſeveral lances, or poles, againſt a poſt, or wooden man, for his diverſion.

QUINTE'SSENCE (*Dict.*)—QUINTESSENCE *of wine*, a term uſed by Glauber, to expreſs an eſſential oil of wine, which he directs to be made by a careful diſtillation, and which he is very fond of, as having a power to meliorate, improve, and even to ſpecificate the poorer wines into the nature of thoſe from which it was obtained.

This is one of the ſchemes of Glauber, generally eſteemed an impracticable one, though very plauſible in theory; but though, in general, there is a diſagreeable flavour in the Quinteſſence drawn after this method, which is different from the true flavour of the wine, and ſpoils the liquor it is added to; yet, by proper care, there is a poſſibility of ſucceeding ſo far as to render this extraneous flavour almoſt imperceptible, and produce an oil that will mend poor wines extremely, and give a truly vinous flavour to ſuch as are in themſelves taſteleſs; but whatever may be done by this method, may alſo be done with much more certainty, and much leſs trouble, by the concentration of wines by freezing. This may be eaſily practiſed in the wine countries; and by this means Burgundy, Champaign, and other the moſt valuable wines, may be reduced into thick extracts and robs, by the means of which wines may be made in England; a very ſmall quantity of theſe concentrated wines being ſufficient to convert the whole of any of the poor taſteleſs and inſipid wines, which are of themſelves of little or no value, into the very wine from which the rob was made, and that in ſuch perfection, that the niceſt judge cannot find out the difference.

Theſe robs of wine, made and preſerved upon the ſpot, would alſo be of infinite uſe, in the wine countries, as they might be kept to improve the wine of bad years. *Stahl, de Concentr. Vin.*

QUOD (*Dict.*)—QUOD *ei deforceat*, in law, a writ for tenant in tail, tenant in dower, by courteſy, or for term of life, having loſt their lands by default againſt him that recovers or his heir.

QUOD *permittat*, in law, a writ that lies where a man is diſſeized of his common of paſture, and the diſſeizor aliens, or dies ſeized, and his heir enters; then, if the diſſeizee die, his heir ſhall have this writ.

R.

R.

RA'BBIT, *cuniculus*, in zoology, a well known animal of the hare kind.

The female or doe Rabbit goes with young thirty days, and then ſhe kindles; and, if ſhe take not buck preſently, ſhe loſes her month, or at leaſt a fortnight, and often kills her young and eats them.

In England they begin to breed at a year old, but in ſome places much ſooner; and they continue breeding very faſt from the time when they begin, four, five, ſix, or ſeven times a year being common with them. They have uſually from four to ſeven in a litter, and hence it is that a ſmall number at firſt will ſoon ſtock a whole warren, if left to breed a little while undiſturbed. The does cannot ſuckle their young till they have been at buck again; this therefore is to be done preſently, elſe there is a fortnight loſt of the time for the next brood, and the preſent brood alſo probably loſt. When the buck goes to the doe, he always firſt beats and ſtamps very hard with his feet, and, when he has copulated with her, he falls backwards, and lies as it were in a trance; in this ſtate it is eaſy to take him, but he ſoon recovers from it.

The buck Rabbits, like our boar cats, will kill the young ones, if they can get at them; and the does in the warrens prevent this, by covering their ſtocks, or neſts, with gravel or earth, which they cloſe ſo artificially up with the hinder part of their bodies, that it is hard to find them out. They never ſuckle the young ones at any other time than early in the morning, and late at night, and always, for eight or ten days, cloſe up the hole at the mouth of the neſt, in this careful manner, when they go out. After this, they begin to leave a ſmall opening, which they increaſe by degrees, till at length, when they are about three weeks old, the mouth of the hole is left wholly open, that they may go out: for they are at that time grown big enough to take care of themſelves, and to feed on graſs.

People who keep Rabbits tame for profit, breed them in hutches, but theſe muſt be kept very neat and clean, elſe they will be always ſubject to diſeaſes. Care muſt be taken alſo to keep the bucks and does apart till the latter have juſt kindled, then they are to be turned to the bucks again, and to remain with them till they ſhun and run from them.

The general direction for the chuſing of tame Rabbits is, to pick the largeſt and faireſt; but the breeder ſhould remember that the ſkins of the ſilver-haired ones ſell better than any other.

The food of the tame Rabbits may be colewort and cabbage leaves, carrots, parſneps, apple rinds, green corn, and vetches, in the time of the year; alſo vine leaves, graſs, fruits, oats, and oatmeal, milk-thiſtles, ſow-thiſtles, and the like; but with theſe moiſt foods they muſt always have a proportionable quantity of the dry foods, as hay, bread, oats, bran, and the like, otherwiſe they will grow pot-bellied, and die. Bran and grains mixed together have been alſo found to be very good food. In winter they will eat hay, oats, and chaff, and theſe may be given them three times a day; but when they eat green things, it muſt be obſerved that they are not to drink at all, for it throws them into a dropſy. At all other times a very little drink ſerves their turn, but that muſt always be freſh. When any green herbs, or graſs, are cut for their food, care muſt be taken that there is no hemlock among it, for, though they will eat this greedily among other things, when offered to them, yet it is ſudden poiſon to them.

Rabbits are ſubject to two principal infirmities. Firſt, the rot, which is cauſed by the giving them too large a quantity of greens, or from the giving them freſh gathered with the dew or rain hanging in drops upon them. It is over moiſture that always cauſes this diſeaſe; the greens therefore are always to be given dry, and a ſufficient quantity of hay, or other dry food, intermixed with them, to take up the abundant moiſture of their juices. On this account the very beſt food that can be given them, is the ſhorteſt and ſweeteſt hay that can be got, of which one load will ſerve two hundred couples a year; and out of this ſtock of two hundred, two hundred more may be eat in the family, two hundred ſold to the markets, and a ſufficient number kept in caſe of accidents.

The other general diſeaſe of theſe creatures is a ſort of madneſs: this may be known by their wallowing and tumbling about with their heels upwards, and hopping in an odd manner into their boxes. This diſtemper is ſuppoſed to be owing to the rankneſs of their feeding; and the general cure is the keeping them low, and giving them the prickly herb, called tare-thiſtle, to eat.

The general computation of males and females is that one buck Rabbit will ſerve for nine does; ſome allow ten to one buck, but thoſe who go beyond this always ſuffer for it in their breed.

The wild Rabbits are to be taken either by ſmall cur dogs, or by ſpaniels bred up to the ſport; and the place of hunting thoſe who ſtraggle from their burrows is under cloſe hedges, or buſhes, or among corn-fields and freſh paſtures. The owners uſe to courſe them with ſmall greyhounds, and, though they are ſeldom killed this way, yet they are driven back to their burrows, and are prevented from being a prey to others. The common method is by nets, called purſe nets, and ferrets. The ferret is ſent into the hole to force them out, and the purſe net, being ſpread over the hole, takes them, as they come out. The ferrets mouths muſt be muffled, and then the Rabbit gets no harm. For the more certain taking of them, it may not be be improper to pitch up a hay net or two, at a ſmall diſtance from the burrows that are intended to be hunted: thus very few of the number that are attempted will eſcape.

Some who have not ferrets ſmoak the Rabbits out of their holes with burning brimſtone and orpiment. This certainly brings them out into the nets, but then it is a very troubleſome and offenſive method, and is very detrimental to the place, as no Rabbit will, of a long time, afterwards come near the burrows which have been fumed with theſe ſtinking ingredients.

RA'CA, or RACHA, a Syriac term, found in the goſpel of St. Matthew, ch. v. 22. and preſerved in moſt tranſlations.

Father Simon obſerves that the Greek tranſlator of St. Matthew's goſpel retained the Syriac Raca which he found in the original, by reaſon it was very common among the Jews. And St. Jerom, Luther, the Engliſh tranſlators, thoſe of Geneva, Louvain, Port-Royal, &c. ſtill preſerve it in their reſpective languages.

F. Bouhours chuſes rather to expreſs the ſenſe thereof in a ſort of paraphraſe, thus: he that ſays to his brother 'homme de peu de ſene, man of little underſtanding,' ſhall deſerve to be condemned by the tribunal of the council, &c.

Moſt tranſlators, except the Engliſh, and F. Simon, for Raca write Racha: but the former orthography ſeems the beſt founded; all the copies having Raca, and all the Greek ones ῥακά, or, with Heſychius, ῥακκά, which is the ſame: all we mean, but St. Irenæus, and Beza's copy, now at Cambridge, which have ῥαχά — In effect, the origin of the word ſhews it ſhould be Raca; as coming from the Syriac ריקא, Raca, of the Hebrew רק rek, empty, ſhallow.

RACHI'TIS, in medicine, a diſeaſe generally called the rickets. See RICKETS, Dictionary and Supplement.

RA'CING, the riding heats for a plate or other premium.

The firſt thing to be conſidered in this ſort of gaming is the chuſing a rider; for it is not only neceſſary that he ſhould be very expert and able, but he muſt be alſo very honeſt. He muſt have a very cloſe ſeat, his knees being turned cloſe to the ſaddle ſkirts, and held firmly there, and toes turned inwards, ſo that the ſpurs may be turned outwards to the horſe's belly; his left hand governing the horſe's mouth, and his right the whip. During the whole time of the race he muſt take care to ſit firm in the ſaddle, without waving or ſtanding up in the ſtirrups. Some jockies fancy this is a becoming ſeat; but it is certain, that all motions of this kind do really incommode the horſe. In ſpurring the horſe, it is not to be done by ſtriking the calves of the legs cloſe to the horſe's ſides, as if it were intended to preſs the wind out of his body; but, on the contrary, the toes are to be turned a little outwards, that, the heels being brought in, the ſpurs may juſt be brought to touch the ſides. A ſharp touch of this kind will be of more ſervice towards the quickening a horſe's pace, and will ſooner draw blood, than one of the common coarſe kicks. The expert jockey will never ſpur his horſe until there is great occaſion, and then he will avoid ſtriking him under the fore-bowels between the ſhoulders and girth; this is the tendereſt part of a horſe, and a touch there is to be reſerved for the greateſt extremity.

As to whipping the horſe, it ought always to be done over the ſhoulder on the near ſide, except in very hard running, and on the point of victory; then the horſe is to be ſtruck on the flank with a ſtrong jerk; for the ſkin is moſt tender of all there, and moſt ſenſible of the laſh.

When a horse is whipped and spurred, and is at the top of his speed; if he claps his ears in his pole, or whisks his tail, it is a proof that the jockey heats him hard, and then he ought to give him as much comfort as he can, by sawing the snaffle backwards and forwards in his mouth; and by that means forcing him to open his mouth, which will give him wind, and be of great service. If there be any high wind stirring in the time of riding, the artful jockey will let his adversary lead, holding hard behind him, till he sees an opportunity of giving a loose; yet, in this case, he must keep so close behind, that the other horse may keep the wind from him; and that he, sitting low, may at once shelter himself under him, and assist the strength of the horse. If the wind happen to be in their back, a just contrary method is to be taken with it; the expert jockey is to keep directly behind the adversary, that he may have have all the advantage of the wind to blow his horse along, as it were, and at the same time intercept it in regard to his adversary.

When running on level carpet ground, the jockey is to bear his horse as much as the adversary will give him leave, because the horse is naturally more inclined to spend himself on this ground: on the contrary, on deep earths, he may have more liberty, as he will there spare himself.

In riding up hill the horse is always to be favoured, by bearing him hard, for fear of running him out of wind; but, in running down hill, if the horse's feet and shoulders will bear it, and the rider dare venture his neck, he may have a full loose. If the horse have the heels of the rest, the jockey must always spare him a little, that he may have a reserve of strength, to make a push at the last post.

A great deal depends on the jockey's knowing the nature of the horse that is to run against him, for, by managing accordingly, great advantages are to be obtained; thus, if the opposite horse is of a hot and fiery disposition, the jockey is either to run just behind him, or cheek by joul with him, making a noise with his whip, and by that means forcing him on faster than his rider would have him, and consequently spending him so much the sooner; or else keep just before him, in such a slow gallop, that he may either over-reach, or by treading on the heels of the fore horse, endanger tumbling over.

Whatever be the ground that the adversary's horse runs worst on, the cunning jockey is to ride the most violently over; and, by this means, it will often happen that, in following, he either stumbles or claps on the back sinews.

The several corrections of the hand, the whip, and the spur, are also to be observed in the adversary, and in what manner he makes use of them; and when it is perceived by any of the symptoms, of holding down the ears, or whisking the tail, or stretching out the nose like a pig, that the horse is almost blown, the business is to keep him on to this speed, and he will be soon thrown out or distanced. If the horse of the opponent looks dull, it is a sign his strength fails him; and, if his flanks beat much, it is a sign that his wind begins to fail him, and his strength will soon do so too.

After every heat for a plate, there must be dry straw, and dry cloths, both linen and woollen, ready to rub him down all over, after taking off the sweat with what is called a sweat knife; that is, a piece of an old sword-blade, or some such thing. Some advise the steeping the cloths in urine and saltpetre the day before, and letting them be dried in the sun for this occasion. After the horse has been well rubbed with these, he should be chafed all over with cloths wetted in common water till the time of starting again. When it is certainly known that the horse is good at the bottom, and will stick at the mark, he should be rid every heat, to the best of his performance; and the jockey is, as much as possible, to avoid riding at any particular horse, or staying for any, but to ride out the whole heat with the best speed he can. If, on the contrary, he has a fiery horse to ride, and one that is hard to manage, hard-mouthed and difficult to be held, he is to be started behind the rest of the horses with all imaginable coolness and gentleness; and, when he begins to ride at some command, then the jockey is to put up to the other horses; and, if they ride at their ease, and are hard held, they are to be drawn on faster; and, if it be perceived, that their wind begins to rake hot, and they want a sob, the business is to keep them up to that speed: and, when they are come within three quarters of a mile of the post, then is the time to push for it, and use the utmost speed in the creature's power. When the race is over, the horse is immediately to be cloathed up, and rode home, and immediately on his coming into the stable the following drink is to be given him: beat up the yolks of three eggs, and put them into a pint and half of new milk made warm; let there be added to this three-penny worth of saffron, and three spoonfuls of sallad oil, and let the whole be given with a horn. After this, he is to be rubbed well down, and the saddle-place rubbed over with warm sack, and the places where the spurs touched, with a mixture of urine and salt, and afterwards with a mixture of powder of jet and Venice turpentine; after this, he should have a feed of rye bread, then a good mash, and, at some time after these, as much hay and oats as he will eat. His legs after this should be bathed sometimes with a mixture of urine and salt-petre.

RA'DISH, *raphanus*, in botany, a genus of plants, whose characters are:

The flower consists of four leaves, which are placed in form of a cross: out of the flower cup rises the pointal, which afterwards turns to a pod in form of an horn, that is thick, spongy, and furnished with a double row of roundish seeds, which are separated by a thin membrane.

There are several species of Radish, but we shall only mention that which is commonly cultivated in kitchen-gardens for its root; of which there are several varieties, as the small-topped, the deep-red, and the long-topped striped Radish; all which are varieties arising from culture. The small-topped sort is most commonly preferred by the gardeners near London, because they require much less room than those with large tops, and may be left much closer together; and, as the forward Radishes are what produce the greatest profit to the gardener, so these being commonly sown upon borders near hedges, walls, or pales, if they are of the large-topped sort, they will be apt to grow mostly at top, and not swell so much in the root as the other, especially if they are left pretty close.

The seasons for sowing this seed are various, according to the time when they are desired for use; but the earliest season is commonly towards the latter-end of October, that the gardeners near London sow them to supply the market; and these, if they do not miscarry, will be fit for use in March following, which is full as soon as most people care to eat them. These (as I said before) are commonly sown on warm borders, near walls, pales, or hedges, where they may be defended from the cold winds.

The second sowing is commonly about Christmas, provided the season be mild, and the ground in a fit condition to work: these are also sowed near shelter, but not so near pales and hedges as the first sowing. These, if they are not destroyed by frost, will be fit for use the beginning of April: but, in order to have a succession of these roots for the table through the season, you should repeat sowing of their seeds once a fortnight, from the middle of January till the beginning of April; always observing to sow the latter crops upon a moist soil and an open situation, otherwise they will run up, and grow sickly, before they are fit for use.

Many of the gardeners near London sow carrot-seed with their early Radishes; so that many times, when their Radishes are killed, the carrots will remain: for the seeds of carrots commonly lie in the ground five or six weeks before they come up, and the Radishes seldom lie above a fortnight under-ground: so that these are often up, and killed, when the carrot seed remains safe in the ground: but, when both crops succeed, the Radishes must be drawn off very young, otherwise the carrots will be drawn up so weak, as not to be able to support themselves, when the Radishes are gone.

It is also a constant practice, with the gardeners, to mix spinach-seed with their latter crop of Radishes; so that, when the Radishes are drawn off, and the ground cleaned between the spinach, it will grow prodigiously, and in a fortnight's time will as completely cover the ground, as though there had been no other crop. And this spinach, if it be of the broad-leaved kind, will be larger and fairer than it commonly is, when sown by itself; because, where people have no other crop mixed with it, they commonly sow it too thick, whereby it is drawn up weak; but here the roots stand pretty far apart, so that, after the Radishes are gone, they will have full room to spread; and, if the soil be good, it is a prodigious size this spinach will grow to, before it runs up for seed: but this husbandry is chiefly practised by such gardeners as pay very dear for their land, and are obliged to have as many crops in a year as possible, otherwise they could not afford to pay such large rents.

When the Radishes are come up, and have got five or six leaves, they must be pulled up where they are too close, otherwise they will draw up to top, but the roots will not increase their bulk. In doing of this, some only draw them out by hand: but the best method is to hoe them with a small hoe, which will stir the ground and destroy the young weeds, and also promote the growth of the plants. The distance which they should be left, if for drawing up small, may be three inches; but, if they are to stand until they are pretty large, six inches are full near enough, and a small spot of ground will afford as many Radishes at each sowing, as can be spent in a family, while they are good.

Horse RADISH, a well known plant, belonging to the genus cochlearia.

Horse Radish is propagated by cuttings or buds from the sides of the old roots. The best season for this work is in October or February; the former for dry lands, and the latter for moist. The manner of doing it is as follows: provide yourself with a good quantity of off-sets, which should have a bud upon their crowns; but it matters not how short they are: therefore, the upper part of the roots which are taken up for use, should be cut off about two inches long with the bud to it, which is esteemed the best for planting. Then make a trench ten inches deep, in which you should place the off-sets at about four or five inches distance each way, with the bud upward, covering them up with the mould that was taken out of the trench: then proceed to a second trench in like manner, and continue the same until the whole spot of ground is planted. After this, level the surface of the ground even, observing to keep it clear from weeds, until the plants are so far advanced, as to be ftrong enough to over-bear and keep them down. With this management, the roots of the horfe Radifh will be long and ftraight, and free from fmall lateral roots; and the fecond year after planting will be fit for ufe. It is true, they may be taken up the firft year, but then the roots will be but flender; therefore it is the better way to let them remain until the fecond year. The ground in which this is planted ought to be very rich, otherwife the roots will make but a fmall progrefs.

Radifhes have the virtues of the fcurvy grafs; the root is efculent, expels phlegm from the inteftines, and is a carminative. The flowers, leaves, feeds, and roots are antifcorbutic; for which reafon they are much in requeft, and are proper for phlegmatic conftitutions: the expreffed juice of the roots and feeds, taken in a morning with honey, is a very wholefome medicine, efpecially if a draught of whey be taken afterwards; for it cleanfes the ftomach, kidnies, and lungs, and is good againft an inveterate cough and hoarfenefs, proceeding from phlegm; but it is not proper in a cough proceeding from an inflammation, nor for thofe who fpit blood. The leaves are ufed among other greens. The root contains much of an aqueous and acrimonious fubftance; and, the drier it is, the more acrid it becomes; but its acrimony is loft in boiling. Its aquofity renders it flatulent, on which account it is faid not to be good in hypochondriacal diforders: the daily ufe of the root, however, is of fufficient efficacy to cure a great dropfy in the beginning; and it is of excellent fervice in the fcurvy. It is alfo aperitive, inciding, and good for the ftone, the nephritic cholic, a retention of urine, and the menfes, and in the jaundice. The feeds are opening; but, taken inwardly by themfelves, they excite a naufea. *Hift. Plant. afcript. Boerhaave*.

RAGS.—In fome counties of England, particularly in Oxfordfhire, it is a common thing to ufe old woollen Rags by way of manure upon land. Taylor's fhreads anfwer this purpofe, in fome degree; but the old Rags of cloaths which have been worn by men and women, are much better, which is owing to the falts they have imbibed from the perfpiration of the body they ufed to cover. *Plot's Oxfordfhire*.

RAG-*bolts*, in a fhip, are fuch as have jags or barbs on each fide, to keep them from flying out of the hole wherein they are driven.

RAG-*ftone*, a name given by our artificers to a kind of ftone, which they ufe for fetting an edge upon knives, chiffels, and other tools. It is a greyifh-coloured ftone, containing a large quantity of talcky particles, and fplits eafily into thin flakes. It is a foft ftone, and is ufed only to finifh the fetting an inftrument after the edge has been prepared by grinding or rubbing the tool upon fome other ftone of a coarfer texture. We have this from Newcaftle and many other parts of the north of England, where there are very large rocks of it in the hills.

RAG-*wort*. — There are two or three fpecies of this plant cultivated in the gardens of the curious; and one very common in moft places, which is the maritime kind, remarkable for its white leaves. This had been long ufed to be nurfed up, with great care, in our green-houfes: but of late, fome ftraggling feeds of it having propagated themfelves on a wall, and there ftood the winter's cold without hurt, we were taught that the plant did not require the care it had been ufed to be treated with. All the kinds may be propagated by fowing their feeds in March, on a bed of light earth, watering it frequently in dry weather. In May the plants may be taken up, and planted in pots, and fet in a warm fituation till October, when the tenderer kinds are to be taken into a green-houfe.

Thefe require much pruning in fummer to keep them in fhape, for they grow very faft, and in winter will die, if they are not often watered. *Miller's Gard. Dict.*

RAIN (*Dict.*) — As to the quantity of Rain that falls, its proportion in feveral places at the fame time, and in the fame place at feveral times, we have ftore of obfervations, journals, &c. in the Memoirs of the French academy, the Philofophical Tranfactions, &c. an idea whereof will not be unacceptable. Upon meafuring, then, the Rain falling yearly, its depth, at a medium, is found as in the following table:

Depth of RAIN *falling yearly, and its proportion in feveral places.*

Preternatural RAINS (*Dict.*)— We have numerous accounts in in the hiftorians of our own, as well as other countries, of preternatural Rains, fuch as the raining of ftones, of duft, of blood, nay, and of living animals, as young frogs, and the like. We are not to doubt the truth of what thofe who are authors of veracity and credit relate to us of this kind, fo far as to fuppofe that the falling of ftones and duft never happened; the whole miftake is, the fuppofing them to have fallen from the clouds; but, as to the blood and frogs, it is very certain that they never fell at all, but the opinion has been a mere deception of the eyes. Men are extremely fond of the marvellous in their relations; but the judicious reader is to examine ftrictly whatever is reported of this kind, and is not to fuffer himfelf to be deceived.

There are two natural methods, by which quantities of ftones and duft may fall in certain places, without their having been generated in the clouds, or fallen as rain. The one is by means of hurricanes; the wind which we frequently fee tearing off the tiles of houfes, and carrying them to confiderable diftances, being equally able to take up a quantity of ftones, and drop them again at fome other place. But the other, which is much the more powerful, and probably the moft ufual way, is for the eruptions of volcano's, and burning mountains, to tofs up, as they frequently do, a vaft quantity of ftones, afhes, and cinders, to an immenfe height in the air; and thefe being hurried away by the hurricanes, and impetuous winds, which ufually accompany thofe eruptions, and being in themfelves much lighter than common ftones, as being half calcined, may eafily be thus carried to vaft diftances, and there falling in places where the inhabitants know nothing of the occafion, they cannot but be fuppofed by the vulgar to fall on them from the clouds. It is well known, that, in the great eruptions of Ætna and Vefuvius, fhowers of afhes, duft, and fmall cinders, have been feen to obfcure the air, and overfpread the furface of the fea for a great way, and cover the decks of fhips; and this at fuch a diftance, as it fhould appear fcarce conceivable that they fhould have been carried to; and probably, if the accounts of all the fhowers of thefe fubftances mentioned by authors be collected, they will all be found to have fallen within fuch diftances of volcano's; and, if compared as to the time of their falling, will be found to correfpond in that alfo with the eruptions of thofe mountains. We have known inftances of the afhes from Vefuvius having been carried thirty, nay, forty leagues, and peculiar accidents may have carried them yet farther. It is not to be fuppofed that thefe fhowers of ftones and duft fall, for a continuance, in manner of fhowers of Rain, or that the fragments are as frequent as drops of water; it is fufficient that a number of ftones, or a quantity of duft, fall at once on a place where the inhabitants can have no knowledge of the part from whence they come, and the vulgar will not doubt their dropping from the clouds. Nay, in the canton of Berne in Swifferland, the inhabitants counted it a miracle that it rained earth and fulphur upon them, at a time that a fmall volcano terrified them; and, even when the wind was fo boifterous, and hurricanes fo frequent, that they faw almoft every moment the duft, fand, and little ftones, torn up from the furface of the earth in whirlwinds, and carried to a confiderable height in the air, they never confidered, that both the fulphur thrown up by the volcano, and the duft, &c. carried from their feet, muft fall foon after fomewhere. It is very certain that in fome of the terrible ftorms of large hail, where the hail-ftones have been of many inches round, that, on breaking them, there have been found what people have called ftones in their middle; but thefe obfervers needed only to have waited the diffolving of one of thefe hail-ftones, to have feen the ftone in its center difunite alfo, it being only formed of particles of loofe earthy matter, which the water, exhaled by the fun's heat, had taken up in extremely fmall moleculæ with it; and this only having ferved to give an opake hue to the inner part of the congelation, to which the freezing of the water alone gave the apparent hardnefs of ftone.

The raining of blood has been ever accounted a more terrible fight, and a more fatal omen, than the other preternatural Rains, already mentioned. It is very certain, that nature forms blood no where but in the veffels of animals, and therefore fhowers of it from the clouds are by no means to be credited. Thofe who fuppofe that what has been taken for blood, has been actually feen falling through the air, have had recourfe to flying infects for its origin, and fuppofe it the eggs or dungs of certain butter-flies difcharged from them, as they were high up in the air. But this feems a very wild conjecture, as we know of no butter-fly whose excrements, or eggs, are of such a colour, or whose abode is so high, or their flocks so numerous as to be the occasion of this.

It is most probable that these bloody waters were never seen falling, but that people, seeing the standing waters blood-coloured, were assured, from their not knowing how it should else happen, that it had rained blood into them. A very memorable instance there was of this at the Hague, in the year 1670. Swammerdam, who relates it, tells us, that one morning the whole town was in an uproar on finding their lakes and ditches full of blood, as they thought, and having been certainly full of water the night before, they agreed it must have rained blood in the night; but a certain physician went down to one of the canals, and taking home a quantity of this blood-coloured water, he examined it by the microscope, and found that the water was water still, and had not at all changed its colour, but that it was full of prodigious swarms of small red animals, all alive, and very nimble in their motions, whose colour, and prodigious number, gave a red tinge to the whole body of the water they lived in, on a less accurate inspection. The certainty that this was the case did not however persuade the Hollanders to part with the miracle; they prudently concluded, that the sudden appearance of such a number of animals was as great a prodigy, as the raining of blood would have been; and are assured to this day, that this portent foretold the scene of war and destruction which Lewis the XIVth afterward brought into that country, which had before enjoyed forty years uninterrupted peace.

The animals which thus colour the water of lakes and ponds are the pulices arborescentes of Swammerdam, or the water-fleas with branched horns. These creatures are of a reddish yellow, or flame colour; they live about the sides of ditches, under weeds, and among the mud, and are therefore the less visible, except at a certain time, which is in the end of May or beginning of June; it is at this time that these little animals leave their recesses to float loose about the water, to meet for the propagation of their species, and by that means become visible in the colour they give the water. This is visible, more or less, in one part or other of almost all standing waters at this season; and it is always at this season that the bloody waters have alarmed the ignorant.

Artificial RAI'NBOW, a phænomenon produced by continually throwing water up into the air, as from a fountain, which breaking into small drops, exhibits the appearance of the Rainbow.

RAI'SIN-*brandy*, a name given by our distillers to a very clear and pure spirit, procured from Raisins fermented only with water. Thus treated, they yield a spirit scarce at all distinguishable from some of the wine spirits; for there are as many kinds of wine spirits as there are of grapes. The coarser the operation of distilling is performed in this case, the nearer will be the resemblance of the wine spirit; that is, there will be most of this flavour in the spirit, when as much as can be of the oil is thrown up with a galloping heat.

The distillers are very fond of the wine spirit, with which they hide and disguise the taste of their nauseous malt, and other spirits; and in defect of that spirit, this of Raisins, made in this coarse manner, will go almost as far. It is indeed surprising how extensive the use of these flavouring spirits is, ten gallons of Raisin spirit, or somewhat less of the wine spirit, being often sufficient for a whole piece of malt-spirit, to take off its native flavour, and give it an agreeable vinosity. It is no wonder, therefore, that the distillers, and ordinary rectifiers, are so fond of this, as it is a good cloak for their defects, and the imperfection of their processes. When Raisin brandy is intended for common use, the fire should be kept slower and more regular in the distillation, and the spirit, though it hath less of the high flavour of the grape, will be more pleasant and more pure. *Shaw's Essay on Distillery.*

RA'NA, *the frog*, in zoology, a very well known animal of the amphibious kind; the characters of it are, that the body of it, in one part of its life, is furnished with a tail.

The feet of the frog are webbed, for the better swimming, and it has very strong muscles in the hinder part of its body, to assist it in leaping. The lungs of the frog are different from those of all other animals; they are only a sort of membranaceous bladders, with several tubercles, by means of which they resemble the fruit of the firs or pines; these, when once inflated, do not immediately become flaccid, as in other animals, but remain in that state as long as the creature pleases. The creature can remain a long time under water, and has been kept so for several days by tying it down, and received no hurt from it. It is a very long-lived animal; and even if its belly be opened, and the intestines, and all the viscera, taken out, it will continue its leaping, and all its other motions, as if nothing had happened to it, for a considerable time; but, if the nerve of one of the hinder legs be cut, it loses all power of using that limb on the instant.

The frog differs from all creatures in the manner of its generation. It no way resembles any of the quadrupeds in this particular, and though, in some sort, it approaches to the nature of fishes, yet it differs from them also in many things. The egg of the frog is a small black spot, inveloped in a mucilaginous substance; in this egg is contained the embryo frog, which, on breaking of the egg in hatching, comes forth in form of a tadpole. This young animal is for some time nourished by the gelatinous matter which invelopes the egg, but it does not consume the whole of it; for the particles of water, making way by degrees into it, divide its parts, and it soon becomes expanded, frees itself from the living animal, and floats on the surface of the water, or at a small depth in it, in form of a thin cloud: this, though it now no longer serves for food to the young creature, is however of some service to it, serving it as an asylum, or place of rest and safety, when tired with swimming.

The egg of the frog therefore is, in some degree, analogous to that of an insect of the winged kind, which is to go through a metamorphosis before it arrives at its perfect state; for it hatches into the tadpole, as the egg of a butterfly into a caterpillar, and arrives at that its ultimate state, after a determinate time spent in the other. In this it differs from the generation of fishes, the eggs of whose spawn hatch into perfect fishes, which go through no change; and it differs from all in the gelatinous substance, which invelopes the egg, and serves as the first food to the fœtus.

The eggs are indeed, when nicely examined, found to be inclosed in a double liquor, a more pellucid and thin one within the gelatinous one, which serves as the general covering to the whole series of eggs; and it is this thin one which it principally feeds on, when first hatched, and which serves to the same purposes as the white of an egg in the fowl kind.

There is also an opinion that the male sperm of the frog is deposited on the spawn of the female after it is laid. *Ray's Syn. Quad.*

RANU'NCULUS, *crowfoot*, in botany, a genus of plants, whose characters are:

The flower consists of several leaves, which are placed in a circular order, and expanded in form of a rose; having, for the most part, a many-leaved empalement or flower cup: out of the middle of the flower rises the pointal, which afterwards becomes a fruit, either round, cylindrical, or spiked; to the axis of which, as a placenta, adhere many seeds, for the most part naked.

There are a great variety of species of Ranunculus; but that called the Persian Ranunculus, being universally admired, we shall only give the method of cultivating that beautiful flower.

The beds in which the Persian Ranunculus roots are planted, should be made with fresh light sandy earth, at least three feet deep: the best soil for them may be composed in this manner, viz. take a quantity of fresh earth from a rich up-land pasture, about six inches deep, together with the green sward: this should be laid in an heap to rot, for twelve months before it is mixed, observing to turn it over very often, to sweeten it, and break the clods: to this you should add a fourth part of very rotten neat's dung, and a proportionable quantity of sea or drift sand, according as the earth is lighter or stiffer; if it be light, and inclining to a sand, there should be no sand added; but, if it be an hazel loam, one load of sand will be sufficient for eight loads of earth: but if the earth is strong and heavy, the sand should be added in a greater proportion: this should be mixed six or eight months before it is used; and you should often turn it over, in order to unite their parts well together, before it is put into the beds.

The depth which this should be laid in the beds, must be about three feet; this should be below the surface, in proportion to the dryness or moisture of the place where they are situated; which, in dry ground, should be two feet eight inches below the surface, and the beds raised four inches above; but in a moist place they should be two feet four inches below, and eight above the ground; and, in this case, it will be very proper to lay some rubbish and stones at the bottom of each bed, to drain off the moisture; and, if, upon this, at the bottom of the beds, some very rotten neat's dung is laid two or three inches thick, the roots will reach this in the spring, and the flowers will be the fairer. This earth I would by no means advise to be screened very fine; only, in turning it over each time, you should be careful to break the clods, and throw out all large stones, which will be sufficient; for if it is made very fine, when the great rains in winter come on, it will cause the earth to bind into one solid lump, whereby the moisture will be detained, and the roots, not being able to extend their tender fibres, will rot.

The beds, being thus prepared, should lie a fortnight to settle, before the roots are planted, that there may be no danger of the earth settling unequally after they are planted; which would prejudice the roots, by having hollow places in some parts of the bed, to which the water would run and lodge, and so rot the roots in such places. Then having levelled the earth, laying the surface a little rounding, you should mark out the rows by a line, at about six inches distance each way, so that roots may be planted every way in straight lines; then you should open the earth with your fingers at each cross, where the roots are to be planted, about two inches deep; placing the roots exactly in the middle, with their crowns upright; then, with the head of a rake, you should draw the earth upon the surface of the bed level, whereby the top of the roots will be about an inch covered with earth, which will be be sufficient at first. This work should be done in dry weather, because the earth will then work better than if it were wet; but the sooner after planting there happens to be rain, the better it will be for the roots, for if it should prove dry weather long after, and the earth of the beds be very dry, the roots will be subject to mould and decay; therefore, in such a case, it will be proper to give a little water to the beds, if there should no rain happen in a fortnight's time, which is very rare at that season of the year; so that they will seldom be in danger of suffering that way.

When the roots are thus planted, there will no more be required until towards the end of November; by which time they will begin to heave the ground, and their buds appear; when you should lay a little of the same fresh earth, of which the beds were composed, about half an inch thick all over the beds, which will greatly defend the crown of the root from frost: and when you perceive the buds to break through this second covering, if it should prove very hard frost, it will be very proper to arch the beds over with hoops, and cover them with mats, especially in the spring, when the flower buds will begin to appear; for if they are exposed to too much frost, or blighting winds, at that season, their flowers seldom open fairly, and many times their roots are destroyed: but this happens more frequently to the Persian kinds, which are tenderer, than to those sorts which are pretty hardy; for which reason they are commonly planted in open borders, intermixed with other flowers, though in very hard winters these are apt to suffer, where care is not taken to guard off the frost.

In the beginning of March the flower stems will begin to rise; at which time you should carefully clear the beds from weeds, and stir the earth with your fingers between the roots, being very careful not to injure them; this will not only make the beds appear handsome, but also greatly strengthen their flowers. When the flowers are past, and the leaves are withered, you should take up the roots, and carefully clear them from the earth; then spread them upon a mat to dry, in a shady place; after which they may be put up in bags or boxes, in a dry room, until the October following, which is the season for planting them again.

RA'PA, *the turnep*; see TURNEP.

RAPU'NTIUM, *rampions or cardinal's flower*, in botany, a genus of plants, whose characters are:

The flower consists of one leaf, which is of an anomalous figure, hollowed like a pipe, and furrowed or channelled; divided, as it were, into many parts, in the shape of a tongue, defended by a vagina or covering, which infolds the pointal: when the flowers decay, the flower-cup turns to a fruit divided into three cells, full of small seeds, which adhere to a placenta, which is divided into three parts.

The crimson Rapuntium is greatly prized by the curious, for the beauty of its rich crimson flowers, which exceed all the flowers I have yet seen, in the deepness of its colour: and these commonly, when their roots are strong, produce large spikes of these flowers, which continue a long time in beauty, and make a most magnificent shew amongst other flowers. The time of their flowering is commonly in July and August; and if the autumn prove very favourable, they will sometimes produce good seeds in England. These plants are natives of Virginia and Carolina, where they grow by the sides of rivulets, and make a most beautiful appearance; from whence the seeds are often sent into England. These seeds commonly arrive here in the spring; at which time they should be sown in pots filled with light earth, and but just covered over; for, if the seeds are buried deep, they will not grow. These pots should be placed under a frame, to defend them from cold, until the season is a little advanced; but they should not be placed on an hot-bed, which will also destroy the seeds.

When the weather is warm, towards the middle of April, these pots should be placed in the open air, in a situation where they may have the morning sun till twelve o'clock, observing to water them constantly in dry weather; and, when the plants are come up, and are grown pretty strong, they should be transplanted each into a small pot filled with fresh light earth, and placed in the same situation, observing to water them in dry weather; and, in winter, they should be placed under an hot-bed-frame, where they may be sheltered from severe frosts; but, in mild weather, they should be as much exposed to the open air as possible.

The March following these plants should be put into larger pots filled with the same fresh earth, and placed, as before, to the morning sun; observing to water them in dry weather, which will cause them to flower strong the autumn following.

These plants are also propagated by parting of their roots: the best season for which is, either soon after they are past flower, or in March; observing to water and manage them, as hath been directed for the seedling plants, both in winter and summer. *Miller's Gard. Dict.*

RATAFI'A, a fine spirituous liquor, prepared from the kernels, &c. of several kinds of fruits, particularly cherries and apricocks.

Ratafia of cherries is prepared by bruising the cherries, and putting them into a vessel wherein brandy has been kept; then adding to them the kernels of cherries, with strawberries, sugar, cinnamon, white pepper, nutmegs, cloves; and to 20 pounds of cherries 10 quarts of brandy.—The vessel must be left open 10 or 12 days, then stopped close, for two months before it be tapped.

Ratafia of apricocks is prepared two ways; viz. either by boiling the apricocks in white wine, adding to the liquor an equal quantity of brandy, with sugar, cinnamon, mace, and the kernels of apricocks; infusing the whole for 8 or 10 days; then straining the liquor, and putting it up for use: or by infusing the apricocks, cut in pieces, in brandy, for a day or two; passing it through a straining bag, and putting in the usual ingredients.

RA'TTLE-*Snake*, in natural history, a very dreadful species of serpents, whose bite is fatal, if not timely remedied, and which is distinguished from all other serpents by the rattle in its tail. This is composed of several scaly substances, and is said to increase by the creature's age, every year adding one scale to it. It moves over the rocks and mountains with prodigious swiftness; but is less nimble on even ground, than many other snakes.

It grows to four or five feet long, and sometimes, though rarely, to more: one, of more than four feet long, having been dissected, and accurately described by Dr. Tyson, the account that gentleman gives of it may not be unacceptable to the reader: the body where largest, which was near the middle, measured six inches and an half round. Its neck only three inches. Its head was flat, as that of the viper; and, as the jaws are very broad and protuberant, and the nose sharp, it somewhat resembles the head of an arrow. At the end of the nose are placed the nostrils; and between these and the eyes there are two other holes, which may be mistaken for ears; but they only go into a hollow of the bones of the skull, without any perforation into the brain. The viper has nothing of these holes. The eyes are round, and wholly resemble those of the viper. The whole body of the creature greatly also resembles the viper, but for the singularity of the Rattle; and over the eyes there are two large scales looking like eyebrows.

The scales which cover the head are very small; thence they become gradually larger, as they reach towards the middle of the body, and from the middle to the tail they grow less and less again; and all, in shape, much resemble the broad and flat seeds of the common garden parsnip. There is some variety in the colours of this creature, whether according to the difference of age or sex, or from lesser accidents. The most usual colours are these: the scales are of a dusky greenish, like the feathers of the back of the green-finch, and are variegated with small black spots in great numbers; there are also four large ones of the same colour.

The back is of a mixed colour, of a dead yellowish brown, variegated with blotches of black and yellow, and with a number of small dots of the same colours; the larger blotches being laid in great regularity, and making a very beautiful tessellated figure. The scales become darker, as they approach the tail, where they are almost black; and those on the ridge of the back, all along, are raised into a sort of sharp prominence in their middle, like the scales of a crocodile; those on the sides are plain and flat. The belly is all along covered with oblong parallelogram scales laid transversely; these are very bright and glossy, and yellow, spotted with black.

The head is small, in proportion to the body, but the mouth is capable of opening to a prodigious width. The tongue is wholly like that of the viper, composed of two oblong portions, joined towards the bases, but separate as they approach the end. The teeth are of two kinds, the smaller ones designed for its eating with, the larger and longer for biting and poisoning what it seizes. These are only placed in the upper jaw; but all the teeth of the mouth are of the canine kind, as the creature, never chewing its prey, has no use for dentes molares, or grinders.

The poisonous teeth are situated on the outside of the jaw, in the anterior part of the mouth, not fixed in the sockets of the jaws, as the others, but fixed to two bones. These, in their natural state, are not visible, even when the creature's mouth is opened, unless it be with an intent to wound; for they lie back under a membranaceous covering, and the creature has a power of erecting and wounding with them at pleasure, as the lion and cat kind can retract or thrust out their claws. The teeth are crooked, and have a hollow at their bottom; and, at their point, a very plain and evident slit, looking like the nib of a writing-pen. The teeth are hollow all the way, from this slit to their bottom; and, on pressing the gums in a dead Rattle-snake, the poisonous juice may be seen to ascend, by degrees, up the teeth, and, at length, to be discharged out of the slit at the point. This makes it very plain in what manner the poison is conveyed into the flesh, when the creature bites.

The rattle is affixed to the last vertebra of the tail, and is composed of a series of small bones; that next the tail is usually of a bluish-grey colour, the rest of a pale brown. These bones are hollow, very thin, hard and dry, and of a brittle texture, and very sonorous. They are all of the same figure, representing, in some degree, the os sacrum in the human skeleton, and all are nearly of the same size. The last of these is is ſeen to have a rigid extremity, in manner of a tail; and all the others have the ſame, though it is not diſtinguiſhable in them, as, in the joining, it runs under two others; and, by means of this ſtructure, they are all moveable with the ſmalleſt force, and the ſound is the more vigorous, as each of theſe tails ſtrikes on two of the hollow joints, when put into motion. The age of the creature is known by the number of joints of this rattle, which are found to be from one to twenty, or more. The uſe of this ſeems not to be to the creature itſelf, but to other animals, that they may be alarmed at the approach of ſo terrible an enemy, and get out of its way in time. Piſo and ſome others affirm, that this rattle, put up a man's fundament, is as fatal a thing as the creature's bite. The power of doing miſchief, which nature has allotted to this animal, ſeems not only by its bite; but, according to the joint accounts of almoſt all authors, it appears to have a power of deſtroying, even by a look.

The charming or faſcination of the Rattle-ſnake, as this is uſually called, has exerciſed the wits of many naturaliſts in vain, and many have diſbelieved the fact. Sir Hans Sloane mitigates the matter, by ſuppoſing the creature firſt to ſeize or bite its prey, which it then ſuffers to eſcape, as far as the poiſon will let it, watching its death, that it may devour it without trouble: and that it is in this poiſoned ſtate that people have ſeen the ſquirrels, &c. dancing about before the Rattle-ſnake, and dying convulſed; all which they have attributed to the power of charming in the eye of the ſnake, not conceiving that it was the effect of the creature's having before bitten them. This, though a very plauſible account, yet, however, wants experience to confirm it, and the general teſtimony of people, who have ſeen the facts, makes againſt it.

The ſame author gives us, however, from Colonel Beverley, the whole proceſs of the charm. The Colonel acquaints us, that ſome company he was with once ſaw a hare, about half-grown, ſitting quietly in an orchard, and, ſtriking at her, ſhe only removed a few yards; when, wondering at the cauſe, they ſaw a Rattle-ſnake, at about ten feet diſtance, eyeing the hare as his deſtined prey. The poor creature was, by this time, in agonies and convulſions, often getting up on her legs, as if intending to run away, but always immediately falling down again; and, growing worſe and worſe, ſoon loſt the uſe of its hinder legs, and, panting vehemently, fell on its ſide. In about half an hour more, the hare ſeemed to have done with all ſtruggles, and to be dead; on which the ſnake uncoiled itſelf, and moved gently towards it, but, the poor hare ſtarting again, he ſtopped; but, when all was again quiet, he moved up to it, and, raiſing his head, looked all over his prey, his colours looking at that inſtant more beautiful than before, and his eyes ſparkling. The hinder part of the hare had been towards the ſnake all this time, and it had periſhed without much looking at its enemy. The ſnake wetted the body all over with his ſlaver; and then, with great difficulty, taking firſt the head into his mouth, ſwallowed that, and afterwards the whole body, ſucking it gently down, but not getting in the ſhoulders without much difficulty.

It is certain, upon the whole, that there is much in this account to favour Sir Hans Sloane's opinion of the hare's having been bitten, though that was not ſeen, ſince the convulſions, and loſs of the uſe of the hinder legs, ſeem a very natural effect of poiſon; but we are aſſured, by perſons who have been eye-witneſſes to the fact, that a bird, hopping about in all this agony and terror, has, on the frightening the Rattle-ſnake away, flown off without any difficulty: ſo that the whole ſeems not yet underſtood.

Rattle-*ſnake root.* See POLYGALA.

RAVELIN (*Dict.*)—*Plate* XXXI, *fig.* 14, exhibits a plan of a ſquare work, with four Ravelins before the curtins.

RAY (*Dict.*)—It is from the circumſtances of Rays, that the ſeveral kinds of bodies are diſtinguiſhed in optics. A body, for inſtance, that diffuſes its own lights, or emits Rays of its own, is called a lucid, or luminous body.

If it only reflect Rays which it receives from another, it is called an illuminated body.

If it only tranſmit Rays, it is called a tranſparent body.

If it intercept the rays, or refuſe them paſſage, it is called an opake body.

Hence no body radiates, i. e. emits rays, unleſs it be either luminous or illuminated.

It is by means of Rays reflected from the ſeveral points of illumined objects to the eye, that they become viſible, and that viſion is performed; whence ſuch rays are called viſual Rays.

In effect we find that any point of an object is ſeen in all places to which a right line may be drawn from that point: but it is allowed, nothing can be ſeen without light, therefore every point of an object diffuſes innumerable Rays every way. Again, from other experiments it appears that the images of all objects, whence right lines may be drawn to the eye, are painted in the eye, behind the cryſtalline, very ſmall, but very diſtinct.

And laſtly, from other experiments, that each Ray carries with it the ſpecies, or image of the radiating point: and that the ſeveral Rays emitted from the ſame point are again united in one point, by the cryſtalline, and thus thrown on the retina.

It is the ſpiſſitude, or cloſeneſs of the Rays emitted from a luminous body, that conſtitutes the intenſeneſs of the light. Yet the direction wherein the Rays ſtrike the eye, has a good ſway. In effect, a perpendicular Ray, ſtriking with more force than an oblique one, in the ratio of the whole ſine to the ſine of the angle of obliquity, as follows from the laws of percuſſion, a perpendicular Ray will affect the eye more vividly than an oblique one in that ratio.

If then the ſpiſſitude of the Rays be equal, the intenſity will be as the direction; if the direction be the ſame, the intenſeneſs will be as the ſpiſſitude. If both differ, the intenſeneſs will be in a ratio compounded of the direction and the ſpiſſitude.

Hence, firſt, If light be propagated in parallel Rays through an unreſiſting medium, its intenſity will not be varied by diſtance.

Secondly, If light be propagated in diverging rays through an unreſiſting medium, its intenſity will decreaſe in a duplicate ratio of the diſtances from the radiant point, reciprocally.

Thirdly, If light be propagated in converging Rays through an unreſiſting medium, its intenſity will increaſe in a duplicate ratio of the diſtances from the point of concourſe, reciprocally.

Fourthly, If the breadth of an illuminated plane be to the diſtance of the radiant point, as 1 to 2000000, it is the ſame thing as if the Rays ſtruck upon it parallel: and hence, ſince the diameter of the pupil of the eye, when largeſt, ſcarce exceeds half an inch; the Rays will fall upon it parallel, as to ſenſe, at the diſtance of 3860 Engliſh feet, which is nearly 6 furlongs.

The effect of concave lenſes, and convex mirrours, is to make parallel Rays diverge; converging Rays become parallel, and diverging Rays to become more divergent.

The effect of convex lenſes, and concave mirrours, is to make diverging Rays become parallel; parallel Rays become convergent, and converging Rays to converge the more.

The Rays of light are not homogeneous or ſimilar, but differ in all the properties we know of, viz. refrangibility, reflexibility, and colour.

It is probably from the different refrangibility, that the other differences have their riſe; at leaſt it appears, that thoſe Rays which agree or differ in this, do ſo in all the reſt.

Thus from the different ſenſations the differently diſpoſed Rays excite in us, we call them, red Rays, yellow Rays, &c.

RE, in grammar, &c. an inſeparable particle, or prepoſition, added at the beginning of words, to vary, double, or otherwiſe modify their meaning.

The modificative Re was firſt introduced by the Latins, from whom it is borrowed, into moſt of the modern tongues: Priſcian derives it from retro, backwards; others rather derive retro from Re; others derive Re from the Greek ῥᾳ, eaſy, or from ῥέω, I flow.

The effect of the Re is various: uſually it ſignifies again, rurſum, ἀνὰ; as in Re-join, Re-ſign, Re-ſume, Re-courſe, Re-bound, Re-cite, Re-hear, Re-cogniſe, Re-compare, Re-double, Re-linquiſh, &c.

Sometimes it ſtands for contra, ἀντὶ, againſt, as in Re-luctance, Re-cumbent, Re-cline, &c.

Sometimes for ὑπὲρ, ſuper, over, as in Re-dundant; ſometimes for πόῤῥω, longe, far, as in Re-moving, &c.

REA'LGAR (*Dict.*)—Realgar is of two kinds, native and factitious: the native Realgar is dug out of the ſame mines with orpiment, reſembling cinnabar in colour, and ſmelling like ſulphur and garlic when burnt, and made up in ſolid brittle glebes. The factitious kind is made of orpiment melted and boiled for ſome time in ſubliming veſſels, by which the yellow flowers are raiſed to the upper part of the veſſels, and the maſs remaining at the bottom, being condenſed by cold, becomes of a red colour, like cinnabar, and is called Realgar; which, if it be expoſed to the free air for a long time, becomes covered with a ſaline efloreſcence. This Realgar is not to be confounded with the factitious red arſenic.

Realgar is brought from China, in different figures; ſome of which reſemble the figures of little men called pagods; and I am of opinion that it is not cut into theſe figures, but caſt in moulds.

The correction of Realgar, firſt propoſed by Helmont, and afterwards publiſhed by Dallicot, firſt phyſician to the duke of Lorrain, which has been found ſucceſsful in many caſes, is this: put any quantity of Realgar, finely powdered, into a glaſs matraſs, and pour upon it as much of a ſtrong lixivium of tartar and nitre, as will ſwim four fingers breadth above the Realgar. Digeſt them in a ſand-heat for twenty-four hours, ſhaking the matraſs very often. Then pouring off, and preſerving the tincture, pour new lixivium upon the powder, and repeat the whole operation, till almoſt all the Realgar is diſſolved, ſome indiſſoluble metallic parts only remaining. Afterwards mix all the tinctures together, paſs them through cap-paper, and pour, at ſeveral times, as much vinegar of lead to the ſtrained liquor, as will precipitate all that can be ſeparated from it. Then pouring off the clear liquor from the precipitate by inclination, let the powder be waſhed with warm water till it becomes almoſt inſipid; and, when it is well dried, burn a sufficient quantity of rectified spirit of wine upon it; and they calcine it with the tincture of opium extracted with spirit of wine. The powder, so prepared, is a gentle escharotic, of great service in cancerous swellings. *Geoffroy.*

REA'LISTS, Realistæ, a sect of school philosophers, formed in opposition to the Nominalists.

Under the Realists are included the Scotists, Thomists, and all excepting the followers of Ocham.

Their distinguishing tenet is, that universals are realities, and have an actual existence, out of an idea and imagination; or, as they express it in the school language, a parte rei: whereas the Nominalists contend that they exist only in the mind; and are only ideas, or manners of conceiving things.

Doctor Odo, or Oudart, a native of Orleans, afterwards abbot of St. Martin de Tournay, was the chief of the sect of the Realists; he wrote three books of dialects; where, on the principles of Boethius and the ancients, he maintained that the object of that art is things, not words: whence the sect took its rise and name.

REA'SONING (*Dict.*)—The agreement or disagreement of two ideas does not appear from the bare consideration of the ideas themselves, unless some third be called in, and compared either separately or conjointly therewith: the act, then, whereby from ideas thus disposed and compared, we judge this or that to be so or not so, is called Reasoning.

Rohault defines Reasoning to be a judgment depending on some antecedent judgment: thus, having judged that no even number can be composed of five uneven numbers; and that ten is an even number; to conclude that ten cannot be divided into five uneven parts, is a ratiocination, or Reasoning.

This agrees with father Malebranche's doctrine, one of the great points whereof is, that Reasoning, on the part of the understanding, is only a mere perceiving.

That ingenious author endeavours to shew, that as to the understanding, there is no difference between a simple perception, a judgment, and a Reasoning, except in this, that the understanding perceives a simple thing without any relation to any thing else, by a simple perception.—That it perceives the relations between two or more things in a judgment.—And lastly, that it perceives the relations that are between the relations of things in a Reasoning. So that all the operations of the understanding are no more than mere perceptions.

Thus, for instance, when we conclude, that 4 being less than 6, twice 2, being equal to 4, are of consequence less than 6; we do no more than perceive the relation of the inequality between the relation of twice two and four, and the relation of 4 and 6.

The manner of proceeding justly in Reasoning, so as to arrive with the greater safety at the knowledge of truth, makes what we call method.

RECEI'VER (*Dict.*)—It is to be observed, that a very small crack in the Receiver, used in pneumatical experiments, does not render them useless; for, upon evacuating the internal air, the external, pressing the glass on all sides, brings the edges of the glass closer together. But, in case of considerable flaws, a plaster may be applied, made of quick-lime finely powdered and nimbly ground, with a proper quantity of the scrapings of cheese, and water enough to bring the mixture to a soft paste, which, when the ingredients are well incorporated, will have a strong and fetid scent; and then it must be immediately spread upon a linen cloth, and applied, lest it begin to harden. *Boyle's Works.*

RECLU'SE (*Dict.*)—The word is chiefly used for such as thus imprison themselves out of devotion, to do penance.—It is sometimes also applied to incontinent wives, whom their husbands procure to be thus kept in a perpetual prison in some convent.

Recluses were anciently very numerous: they were then a kind of solitaries who shut themselves up in some little cell, with a vow never to stir out of it.

None were admitted to this oath until they had given sufficient proofs of their abstinence, and had leave from the bishop, or the abbot of the monastery where they were shut up: for the cells of the Recluses were always to join to some monastery.

The prelate's permission being obtained, they were tried for a year in the monastery; out of which, during that time, they never stirred.

They were then admitted to their vow of stability in the church before the bishop; which being done, and the Recluse entered his little cell, the bishop set his seal on the door.

The cell was to be very small, and very exactly closed.—The Recluse was to have every thing within it necessary to life; and, even, if he were a priest, an oratory consecrated by the bishop, with a window which looked into the church, through which he might make his offerings at the mass, hear the singing, sing himself with the community, and answer those who talked to him. But this window was to have curtains before it, both within-side and without; so that the Recluse might neither see nor be seen.

Indeed he was allowed a little garden in his reclusion, to plant a few herbs and take fresh air: adjoining to his cell was that of his disciples, which he was very rarely without; with a window, through which they served him with necessaries, and received his instructions.

When it was judged proper to have two or three Recluses together, their cells were made contiguous to each other, with windows of communication: if any woman would consult them, or confess to them, it was to be in the church, and in the face of all the world.

Where there were two or three Recluses together, they were never to hold any conference, but on spiritual matters; and to confess to each other: where there was but one, he was to confess and examine himself.

If the Recluse fell sick, his door was opened for people to come in and assist him; but he was not allowed to stir out on any pretence whatever.

These articles are extracted from the rule, compiled for the Recluses, by Grimlaic, a priest in the IXth century.

There were also women Recluses, who led the same life, in proportion. St. Viborade lived a Recluse at St. Gall, and was there martyred by the Hungarians in 825.

RECH *interni minores*, in anatomy the name of a muscle which arises from the fore-part of the first vertebra of the neck, and is inserted into the anterior appendix of the os occipitis.

RECTIFICA'TION (*Dict.*)—That the Rectification of spirits may, in all cases, proceed with the greatest exactness, a due regard to it must be had even from the first fermenting the substances from which they are to be made, and continued through all the stages of distillation, the low wines, proof spirit, and alcohol. The management of the fermented liquor, to this purpose, is principally the letting it stand to subside after the fermentation is over, and the drawing it off clear and thin, not too rich for the still. The still is not to be over-filled with this. Great care must be taken to prevent its burning; and the faints that run last must be kept separate, not mixed with the rest of the liquor distilled, which is now called the low wines. In the rectifying these into proof spirit, great caution must be used that the fire be kept regular, not raised by sudden starts, which always throw up the oil in large quantities, which is to be left behind. In the succeeding Rectification of the proof spirit into alcohol, the same cautious management of the fire is necessary; and in both this, and the last, the faints are not to be suffered to run in among the spirit, but to be saved separate. They may be all mixed together at last, and reduced to a spirit fit for burning in lamps; but the keeping them out of the rectified liquor will keep away the coarsest and most stinking part of the oil of the ingredients. By these easy means, without any additional trouble or charge, we might be furnished with a spirit greatly exceeding what we commonly meet with. And, in general, the art and mystery of our sellers of the several sorts of English brandies seem to consist in this prudent management, and in the adding a little of the oleum vini, or oil of wine lees, to the spirits thus procured pure: this gives the flavour of foreign brandies, and is so extensive in its use, that half an ounce of it is sufficient for a hogshead of pure spirits.

Malt spirit is that which principally requires all this care in the Rectification, because its oil is more nauseous and offensive than that of any other spirit; but all others will be greatly the better for being treated in the same manner; and it is indeed necessary that they should for some particular uses. It is remarkable, that no one method of combinatory Rectification, that is, of the Rectification performed by the means of salts, and other additions, is suited to all the several kinds of spirits; scarce indeed will any one way serve for any two spirits; but this method, by simple and careful distillation, is equally suited to all. Melasses spirit, cyder spirit, wine spirit, or brandy, rum, and arrac, are all improved by it, and all of them are then known to be perfectly rectified. When in the state of alcohol, they not only prove totally inflammable in a little vessel floating upon cold water, but, when poured into the purest spring water, they have not the least power of making any change in it, nor leave any marks of oiliness, or that unctuosity, which, on the mixture of the less pure spirits, floats on the top, and in certain lights gives the rainbow colours. *Shaw's Essay on Distillery.*

RE'CTIFIER, in the distillery, the person whose employment it is to take the coarse malt-spirit of the malt-stiller, and re-distil it to a finer and better liquor. The art of the Rectifier might be intirely set aside, if the malt-stiller could make his spirit perfect at second operation; which seems very practicable, if the malt-stillers could be got to forsake their old track. The great things to be recommended for the improvement of their art, would be first the brewing in perfection, and secondly the keeping their wash after the manner of stale beer, till it has entirely lost its malt flavour, and required a pungent acid vinosity; and then thirdly leaving out the lees to distil with a well regulated fire. It is scarce to be thought how pure a spirit is to be obtained from malt this way; but the great art would be, the finding a way to make malt liquors artificially stale, bright, and of a fine flavour, though otherwise vinous. *Shaw's Lectures.*

RED, (*Dict.*)—To make a deep Red in glass, the following method is that most practised by the glass-men: take crystal frit twenty pounds, broken pieces of white glass one pound, calcined tin two pounds; mix these well together and put them into a pot to melt and purify; when these are melted, take steel calcined, scales of iron from the smith's anvil, both

both powdered very fine, of each an equal quantity; put leiſurely an ounce of this mixed powder to the beforementioned metal, mix all well together, and let them ſtand ſix or eight hours in fuſion, to incorporate; take out a proof after this, and, if there be too little of the powder, it will appear of a duſky yellow; then more of the powder muſt be added, and then add three quarters of an ounce of calcined braſs ground to a fine powder; mix them thoroughly together, and the maſs will be of a blood Red; continue ſtirring the whole together, and frequently taking out proofs of the colour; when it is right, work it immediately, otherwiſe it will loſe its colour and become black. The mouth of the pot muſt in this proceſs be left open, elſe the colour will be loſt. *Neri's Art of Glaſs.*

Blown Red, in the porcelain manufacture, a name given to a particularly coloured China ware of a ſpangled red, or to the colour alone that ſpangles it. It is an ornament eaſily introduced into uſe in our own manufactories of porcelain ware, and is done in the following manner: the colour is to be prepared of common copperas, calcined to a Red colour in a charcoal fire, in a crucible, with another luted on the top of it inverted, and with a hole in its bottom. The ſignal of the calcination being finiſhed, is, when the black clouds ceaſe to come up through the hole, and a fine white thin vapour ariſes in their place. The veſſels are to be then ſuffered to cool, and the Red matter in them is to be reduced to a fine powder. While the veſſels to be coloured with this are yet wet, the operator is to provide a glaſs pipe, and, covering one end of it with a piece of fine gawſe, he is to dip this into the powder, and taking it carefully out, with what little is ſticking to it, he is to blow againſt the veſſel at ſome diſtance from it: thus the fineſt part of the powder only will reach the veſſel, and will be laid on in form of glittering ſpangles, very ſmall, but all diſtinct. This is a ſort of colouring much eſteemed by the Chineſe themſelves, and they have a way of uſing the common blue in the ſame manner, but few of the veſſels, thus painted, come over to us. *Obſerv. de la Coutum. de l'Aſie.*

Red-*game*, an Engliſh name of a bird, common in the mountainous parts of Yorkſhire, and ſome other of our northern counties. It is of the ſhape of a partridge, but much larger, and of a mixed colour of red and black, and is feathered down to the ends of the toes.

Indian Red, a name uſed by the colourmen and painters, for a kind of purple ochre, brought from the iſland of Ormus, in the Perſian gulph, and uſed as a Red colour. It is called, among the authors on theſe ſubjects, terra Perſica. *Hill's Hiſt. of Foſſ.*

Red-*land*, in agriculture, a term much uſed by huſbandmen to expreſs a ſandy ſoil of a reddiſh hue, interſperſed for the moſt part with pieces of ſand ſtone of the ſame colour, or ſomewhat deeper.

There are ſeveral varieties of this ſoil, one of which is almoſt entirely made up of ſand; another with an admixture of clay with the ſand, the whole making a looſe loamy earth; and a third, full of fragments, of a poor ſandy iron ore, and often containing ſhining ſpecks of ſelenitæ. *Moreton's Northamp.*

Red-*ſhank*, in zoology, the name of a water bird, called by authors gallinula erythropus, and callidrys. It is about the ſize of the common plover. The back is of a greyiſh or browniſh green, uſually ſpotted with black; its neck grey, and its throat variegated with black and white; the breaſt is white, with a few looſe ſtreaks of black. The wing-feathers are variegated with black, brown, and white; the beak is two fingers breadth long, ſlender, and ſhaped like the beak of the woodcock; reddiſh at the baſe, and blackiſh lower down. Its legs are of a fine beautiful red, and the hinder toe is very ſhort and ſmall. *Ray's Ornithol.*

Red-*ſtart*, in zoology, the Engliſh name of the ruticilla, a very beautiful bird, with a white ſpot on his head and a very fine red tail.

Red-*weed*, in botany, a name given to a plant common in Bermudas, and ſome other places; and called by our firſt travellers to that part of the world the ſummer iſland Red-weed. Its berry is of a fine red colour, and affords a tincture little inferior to that of cochineal, and poſſeſſing all its virtues in medicine; the only misfortune of this, and ſome other very fine vegetable colours, is, that they fade ſoon. The juice of the fruit of the opuntia, or prickly pear, is as fine a dye as can be procured from the cochineal, but it will not ſtand; the inſect feeding on this, however, we find affords a colour of the ſame nature, that will ſtand. The fruit of the Red-weed is in the ſame manner liable to be eaten by inſects as that of the prickly pear, and it is worthy a trial, whether its colour, obtained at ſecond hand from thoſe inſects, will not ſtand as well as the cochineal does, and whether the inſects may not be propagated in a ſufficient abundance to ſerve the markets in the ſame manner. *Phil. Tranſ.* N°. 40.

Red-*wing*, in zoology, the name of a bird of the turdus, or thruſh kind, called alſo in ſome places the wind-thruſh, or ſwine pipe, and by authors the turdus iliacus, or tylas. It is a little ſmaller than the common thruſh, and is leſs ſpotted. Its back, neck, and head are of the ſame colour with thoſe of the common thruſh; but its ſides, under the wings, and the feathers which line the wings, are of an orange colour, or duſky red; its belly and breaſt are whitiſh, and its throat yellowiſh, with brown ſpots; the wings are of a ſort of cheſnut colour, a little variegated. It feeds on inſects, as worms, and the like; and is a bird of paſſage, coming to us at the ſame time with the fieldfare, and leaving us alſo, when that bird does. It is not well known where they breed, though ſome have gueſſed it to be in the mountains of Germany and Bohemia. They have a bitteriſh taſte, and are leſs valued than the fieldfare. *Ray's Ornithol.*

RE'DDLE, the common Engliſh name for the ſubſtance called, in Latin, rubrica, and uſed in painting and for marking ſheep, &c. *Hill's Hiſt. of Foſſ.*

REDUCTION *of a figure* (*Dict.*)—The great uſe of the proportional compaſſes is in the Reduction of figures, &c. whence they are alſo called compaſſes of Reduction.

There are various methods of reducing figures, &c. the moſt eaſy is by means of the pentagraph or parallelogram; but this has its defects. The beſt and moſt uſual methods of Reduction are as follow:

To Reduce *a figure:* As ABCDE, (*Plate* XLII. *fig.* 1.) into a leſs compaſs: about the middle of the figure, as *z*, pitch on a point: and from this point draw lines to its ſeveral angles, A, B, C, &c. then drawing the line *a b*, parallel to A B, *b c* parallel to B C, &c. you will have the figure *a b c d e* ſimilar to A B C D E.

If the figure *a b c d e* had been required to be enlarged, there needed nothing but to produce the lines from the point beyond the angles, as *z* D, *z* C, &c. and to draw lines, viz. D C, D B, &c. parallel to the ſides *d c*, *d b*, &c.

To Reduce *a figure by the angle of proportion.* — Suppoſe the figure A B C D E (*fig.* 2.) required to be diminiſhed in the proportion of the line A B to *a b* (*fig.* 3.) Draw the indefinite line G H (*fig.* 4.) and from G to H ſet off the line A B: on G deſcribe the arch H I. Set off the line *a b* as a chord on H I, and draw G I. Then with the angle I G H you have all the meaſures of the figure to be drawn. Thus, to lay down the point *c*, take the interval B C, and upon the point G deſcribe the arch K L; alſo, on the point G deſcribe M N; and upon A with the diſtance M N deſcribe an arch cutting the preceding one in *c*, which will determine the ſide *b c*. And after the ſame manner are all the other ſides and angles to be deſcribed.—The ſame proceſs will alſo ſerve to enlarge the figure.

To Reduce *a figure by a ſcale.* — Meaſure all the ſides of the figure, e. gr. A B C D E (*fig.* 2.) by a ſcale, and lay down the ſame meaſures, reſpectively, from a ſmaller ſcale in the proportion required.

To Reduce *a map, deſign, or figure, by ſquares.*—Divide the original into little ſquares, and divide a freſh paper of the dimenſions required, into the ſame number of ſquares; which will be larger or leſs than the former, as the map is to be inlarged or diminiſhed.

This done, in every ſquare of the ſecond figure, draw what you find in its correſpondent one in the firſt.

Reduction *to the ecliptic*, in aſtronomy, is the difference between the argument of latitude, as N P (*Plate* XLII. *fig.* 5.) and an arch of the ecliptic N R, intercepted between the plane of a planet, and the node N.

To find the Reduction: the angle of inclination P N R, and the argument of latitude N P being given; find, by the doctrine of ſpherics, the arch N R: ſubtract N R and N P from each other, the remainder is the Reduction.

Reduction, in metallurgy, is the bringing back metalline ſubſtances, which have been changed into ſcoriæ or aſhes, or otherwiſe diveſted of their metallic form, into their natural and original ſtate of metals again. *Cramer's Art of Aſſaying.*

All metals and ſemi-metals may be reduced by proper management, whatever have been their changes, except only zink, which, having been burnt to aſhes, admits of no Reduction. But the mixture of gold and ſilver was never yet radically diſſolved by any experiment, whatever ſome may have imagined. Even ſome earths will turn into metal by the admixture and intimate union of a phlogiſton, or inflammable principle; but theſe metals never need any ſuch principle to aſſiſt their Reduction.

REFI'NERS.—This is a very curious as well as uſeful trade, by which, they not only purify gold and ſilver themſelves, but ſeparate the filings made by the ſeveral operators thereon, from all manner of filth, without which art a great deal would be loſt.

The work is none of the eaſieſt nor cleanlieſt, but there is good pay to the journeymen, who can get three or four ſhillings a day, and no want of ſufficient profit to the maſters, who are not many in number, and will not take an apprentice under ten pounds, (I mean to the bare labouring part) whoſe hours for working muſt be from ſix to eight.

Some of the maſter Refiners deal alſo largely in gold and ſilver, which they ſell out in ſmall parcels for the worker's uſe, by which trade many good eſtates have been obtained; but thoſe in this way ſhould have five hundred or a thouſand pounds to turn about, and ſome extend it to eight thouſand pounds, yet a ſet of utenſils, fit for a bare working Refiner, will not coſt above fifty pounds.

REFI'NING (*Dict.*) — Refining of copper is only performed by giving the mineral matter ſeveral lotions before the melting it, and then giving it ſeveral repeated fuſions.

Refining of tin is performed much after the ſame manner as that of copper.

Though we may diſtinguiſh two kinds of fineneſs of this metal: the one ariſing from its fuſion; that tin, taken firſt out of the furnace wherein it is melted, being always purer than that towards the bottom.

The other kind of fineneſs is that given the tin by adding ſome other metal or mineral to it, to render it more ſonorous, as well as brighter: ſuch is tin of antimony, pewter, &c.

Refining of iron, begins likewiſe by the melting it.

The greater degree of fuſion the mineral has, the more the metal is purified: but this firſt fuſion is not ſufficient.—To render the iron malleable, and fit to endure the file, it muſt be melted a ſecond time; then forged or beaten a long time with huge heavy hammers, wrought by water; then heated in the fire, and at laſt reduced, on the anvil, into bars of ſeveral thickneſſes.

The more the iron is heated in the fire, and the more it is beaten, whether hot or cold, the finer it becomes.

Steel is only iron refined to a great degree by heating it, with ſome other ingredients which cloſe up the pores, and ſoften the grain thereof.

Refining of lead, is performed, like that of moſt other imperfect metals, by frequent meltings, ſtill ſcumming it before it be cold, and caſting in tallow, and other kinds of fat.

They alſo make eſſays of lead; not to refine it, but to ſee if it be pure, and without mixture of any other metal.

Subterranean RE'GION.—The earth is not only divided on its ſurface into Regions and countries, but philoſophers, who have had occaſion to diſcourſe of its inner parts, have alſo divided them into three diſtinct Regions, according to their different depths from the ſurface. The temperature of the ſubterranean parts of the globe is diſtinguiſhed according to the diviſion of theſe Regions, but is not ſo regular and preciſe as ſome have ſuppoſed. The firſt Region of earth is very variable both as to bounds and temperature. The ſecond Region ſeems for the moſt part cold in compariſon of the other two; but in ſeveral places, which, by reaſon of their diſtance from the ſurface of the earth, it would be natural to call the middle Region, the temperature of the air is very different at the ſame ſeaſons of the year, which ſhews that it depends on ſomething more than bare depth from the ſurface. The third Region of the earth is univerſally obſerved to be warm, but by no means regularly, or uniformly: the ſame depth in ſome places giving only a moderate warmth, while in others it gives a very conſiderable heat. Borrichius tells us of a certain abbé fond of chemiſtry, and particularly curious in the matter of long digeſtions by regular heat, who found a way of making a furnace pepetually warm, by piercing the earth to a certain depth, and uſing the heat of this third Region of it. His method, we are told, was to bore a hole with a pike twenty feet deep, and pour into it ten or twelve pounds of quickſilver; this made its way into the ſtrata, and through them in a body into the chambers of heat in this third Region, where the heat, having a vent upwards made by this opening, never failed to aſcend in a perpetual and regular ſtream, and gave that regular digeſting heat that no artificial fire could equal. But this is an alchemical ſtory. *Boyle of Coſmical Qualities. Borrich. de Ortu Chem.*

REGLETS, *or riglets*, in printing, are thin rulers, or ſlips of wood of different dimenſions, placed in the chaſe, between the pages, and at the extremes thereof, to keep them aſunder and hold them tight.

The Reglets make the chief part of what they call the furniture of the chaſe.

They are particularly denominated from the place they hold in reſpect of the pages, head-ſticks, foot-ſticks, gutter-ſticks, &c.

The term Reglet is alſo uſed abroad for a ruler of metal, three quarters of an inch long, but which may be lengthened out by joining ſeveral together; uſed to ſeparate the columns, in books that have ſeveral in the ſame page; as alſo for lines to place the notes on in printing of muſic.

Reglet, is alſo uſed for a little thin ſlip of wood uſed by ſome compoſitors to take off the lines from the compoſing-ſtick, and place them on the galley, as faſt as compoſed.

RE'GULUS (*Dict.*)—To procure the Regulus, that is, the mercurial parts of metals, &c. flux powders are commonly uſed; as nitre, tartar, &c. which purge the ſulphurous part adhering to the metal, by attracting and abſorbing it to themſelves.

Regulus is principally uſed for that of antimony, which is a ponderous metallic powder, that, upon fuſing ſome of the mineral in its crude ſtate, ſinks to the bottom, leaving the ſcoria or impurities a-top.

The alchymiſts will have this matter called Regulus, i. e. little king, as being the firſt born of the royal metallic blood; which is really a ſon, but not a perfect man, i. e. not yet a perfect metal for want of time and proper nouriſhment.

Antimony, purified by ſimple fuſion, is called Regulus of antimony, or Regulus antimonii philoſophorum.—But the more common way of reducing it into a Regulus, is with the addition of flux powders, as tartar and nitre.

The ſcoria found at the top of this Regulus is violently emetic, as well as the Regulus itſelf, whereof if cups or drinking veſſels be caſt, the wine put into them will become vomitive.

Of this Regulus caſt in moulds are made thoſe commonly called the antimonial pills, weighing about eight or ten grains each, one of which, being ſwallowed, will operate conſiderably by vomit and ſtool.

Theſe pills having thus performed their office, and been diſcharged the body, will ſerve the ſame purpoſe again and again; whence they have obtained the name of perpetual pills.—The virtue of this Regulus is not however inexhauſtible, as has been imagined; for by repeated infuſions in wine, though the liquor be made violently emetic at firſt, yet by degrees it loſes its force, and at length ceaſes to be vomitive.
